Indian Journal of Forensic Medicine & Toxicology

EDITOR in Chief
Prof. R K Sharma

Formerly at All India Institute of Medical Sciences, New Delhi, E-mail: editor.ijfmt@gmail.com

EDITOR
Prof. Dr. Adarsh Kumar
Forensic Medicine & Toxicology, AIIMS, New Delhi

INTERNATIONAL EDITORIAL ADVISORY BOARD

1. Prof Mete Gulmen Cukurova University, TURKEY
2. Prof. Leandro Duarte De Carvalho, Minas Gerais, Belo Horizonte, Brazil
3. Prof. Donata Favretto (Full Professor) Forensic Toxicology at University of Padova, Italy
4. Prof. Babak Mostafazadeh Department of Forensic Medicine & Toxicology, Shahid Beheshti University of Medical Sciences, Tehran-Iran
5. Prof Halis Dokgoz, Mersin University, TURKEY
6. Prof Jozef Sidlo, Comenius University, Bratislava, SLOVAKIA
7. Dr. Rahul Pathak (Lecturer) Forensic Science, Dept of Life Sciences Anglia Ruskin University, Cambridge, United Kingdom
8. Dr. Hareesh (Professor & Head) Forensic Medicine, Ayder Referral Hospital, College of Health Sciences, Mekelle University, Mekele Ethiopia East Africa
9. Dr. Mokhtar Ahmed Alhrami (Specialist) Forensic Medicine & Clinical Toxicology, Director of Forensic Medicine Unit, Attorney General’s Office, Sana’a, Yemen
10. Dr. Sarathchandra Kodikara (Senior Lecturer) Forensic Medicine, Department of Forensic Medicine, Faculty of Medicine, University of Peradeniya, Sri Lanka
11. Dr Noha A. Magdie El Rafie, Forensic Toxicology, Ain Shams University, Cairo, EGYPT

SCIENTIFIC COMMITTEE

1. Prof Udai Pratap Singh, Department of Anthropology Lucknow University Lucknow
2. Dr Anil Rahule (Associate Professor) Dept of Anatomy, Govt Medical College Nagpur
3. Dr Shankar Bakkanwar (Associate Professor) Forensic Medicine, Kasturba Medical College, Manipal, Karnataka
4. Dr P K. Ravikumar Raksha Shakti University, Ahmedabad, Gujrat.
5. Dr. Pragnesh Parmar (Associate Professor) Forensic Medicine, Valsad, Gujrat
6. Dr Vandana Mudda (Awati) (Associate Prof) Dept of FMT, M.R. Medical College, Gulbarga, Karnataka,
7. Dr. Asha Srivastava (Senior Scientific Officer) Forensic Psychology, Central Forensic Science Laboratory, CBI, Delhi
8. Dr. Lav Keshawani (Asst.Prof.) School of Forensic Science, Sam Higginbottom Institute of Agriculture Technology & Sciences, Allahabad U.P.
9. Dr. Anu Sharma (Associate Prof) Dept of Anatomy, DMCH, Ludhiana (PB)
10. Dr. Shalini Gupta (Prof ) Oral Pathology and Microbiology, Dental Sciences King George Medical University, Lucknow, UP
11. Dr Rituja Sharma, Associate Prof, Law Banasthali Vidyapeeth Jaipur

NATIONAL EDITORIAL ADVISORY BOARD

Chairman
Prof Sudhir K Gupta - Head, Department of Forensic Medicine
All India Institute of Medical Sciences, New Delhi

Members
1. Prof. SK Dhattarwal, Forensic Medicine, PGIMS, Rohtak, Haryana
2. Prof. N K Aggrawal Forensic Medicine, UCMS, Delhi
3. Prof Ajay Ghangale Forensic Medicine Dr DY Patil Medical College, Pune, Maharashta
4. Dr. Amar Jyoti Patwory Professor, Forensic Medicine NEIGRIHMS, Shillong
5. Dr. S. Venkata Raghava Professor, Forensic Medicine, Banglore Medical College, Bengaluru
6. Prof Praveen Arora, Professor Department of Forensic Medicine & Toxicology, SAIMS, Indore
7. Dr. Pankaj Datta (Principal & Head) Department of Prosthodontics, Indraprastha Dental College & Hospital, Ghaziabad
8. Dr. Mahindra Nagar (Head) Department of Anatomy, UCMS & GTB Hospital, Delhi
9. Dr. Virender Kumar Chhoker Professor Forensic Medicine and Toxicology, Santosh Medical College, Ghaziabad, UP
10. Dr. Dayanand G Gannur (Professor) Department of Forensic Medicine & Toxicology, Shri BM Patil Medical College, Hospital & Research centre, Bijapur, Karnataka
11. Dr. Alok Kumar Professor Department of Forensic Medicine & Toxicology, UP Rural Institute of Medical Sciences and Research, Saffai, Etawah, U.P.

Institute of Medico-Legal Publications
Logix Office Tower, Unit No. 1704, Logix City Centre Mall, Sector-32, Noida - 201 301 (Uttar Pradesh)
Volume 14, Number 2  April-June 2020

2. Analysis of Hospital Deaths at Tertiary Care Teaching Hospital Jeeveswararao Bagadi, Srinivasulu Pothireddy Sujan Kumar Mohanty

3. Study of Fingerprints in Relation to Dental Caries Maitrayee Dutta Swargiary, Bhanukul Barman

4. Trends & Pattern in Unnatural Female Death Cases Due to Burn: A One Year Retrospective Study Manjit Nayak, Saumil Merchant, Kalpesh Shah

5. Effectiveness of Structured Exercise Programme Versus Elastic Band Exercise on Individuals with Rounded Shoulder Geetan Manoj Pathak, Khushboo Chotai, Smita Patil, Amrutkuvar Rayjade

7. Effect of Meditative Movement Exercises with Breath Control on Depression in Nulliparous Women Mrunmayi Sandip Gadre, T Poovishnu Devi

8. To Assess Dentist Knowledge About Lipid Treatment of Local Anesthetic Systemic Toxicity Nitin Bhagat, Rohit Sharma, Siddharth Rawat, Sheikh Abrar, Singh Priyanka Jaiprakash

10. Pattern of Cranio-Cerebral Injuries at a Tertiary Care Centre – A Retrospective Study Anand Patil, Tasgaonkar V N, Rakesh M Marigoudar

14. Flibanserin: A Miracle Drug in Management of Hypoactive Sexual Desire Disorder in Female Jeetendra Kumar Gupta, Ahsas Goyal, Kajal Thareja, Bhavini Saraf

44. The Effect of Structured Physiotherapy Exercise Programme on Lung Function in Industrial Workers. Patil Poonam, Kanase Suraj B

47. Effect of Step Aerobics Applied Early in Phase 2 Cabg Subjects on Functional Capacity and Exercise Tolerance. Kaustubh G. Jadhav, T. Poovishnu Devi

50. A Study on Bio-Medical waste Segregation Monitoring in a Tertiary Care Hospital at Telangana. Sachin Suresh Shinde, Kishore Babu Marivina, Shalini

51. Effectiveness of Open Kinematic Chain Exercises and Closed Kinematic Chain Exercises in Adductor Groin Pain in Recreational Football Players. Raghavendra Sunilkumar Pandey, Trupti Yadav, Amrutkuvar Rayjade, Radhika Chintamani, Apoorva Kolhatkar

52. Self Care Practices among Hypertensive Patients with the View to Develop Informational Pamphlet. Priyanka Mohan Mali, Mahesh B. Chendake, Samir K. Choudhari

54. Comparative Evaluation of MTA and Biodentine as a Restorative Material In Deciduous Teeth. Sravani Uppala

55. Effects of Circuit Training Program on Quality of Life of Children with Hemophilia. Mandar Malawade Amrutkuvar Rayjade, G. Varadharajulu

56. Assessment of Serum Levels of Salusin α and Salusin β in Cardiovascular Disease Patients Undergoing Transcatheter Therapy. Ayat Saeed Awad*, Hanaa Addai Ali , Mohauman Mohammad AL-Rufaie

58. Evaluation of CEA, CA19-9, and CA242 Tumor Markers in Patients with Colorectal Cancer by ELISA Technique. Ahlam Shakir Hammood AL- Rubaaiawi Mukhtar Khamis Haba, Laith Raouf Ahmed AL- Hadad
59. Knowledge about Emergency Contraception Pills among Primary Health Care Doctors in Baghdad Al-Karkh Sector.......................................................... 321
  Waleed Arif Tawfeeq, Amer Aboas, Zaid Abulateef Abdulkareem

60. Relationship of Vitamin D with Some Electrolytes in the Serum of People with Rheumatoid Arthritis in the City of Samarra............................................ 327
  Adeeb Mahfooth Farag Al-Samaria, Kader Abdullah Shanak Al-Esawi, Esraa Ali Abdul Kareem Al-Samaria, Dhamer Ismael Madab AL-Khazraji

61. Study of Thyroid Hormones for Vitiligo Patients in AL-Anbar Governorate ........................................... 332
  Yasser Q. Hussein Wajeeh Y. Mohammed Abdulla S. Al-Hasan, Sabri M. Al-marsomi

62. Detection of Quorum Sensing Signal Molecules and Identification of \esp B and Crt4 genes among Biofilm Forming of Citrobacter freundii ........................................... 336
  Wathiq Abbas Hatite Al-Daraghi, Mautham Khazaal Kadhim AL-Behadili

63. The effect of Beta-amino Butyric Acid in Levels of Interleukin4 & Interleukin 10, Complement Proteins C3 & C4 and Immunoglobulin IgM in Males Rats Sprague Dawley Infected with Pseudomonas aeruginosa.......................................................... 342
  Zainab Makki Sagheer Mohammad Abas Jasim

64. The Toxic Effect of Cadmium Chloride on Lung Function and Tissue and the Protective Role of Pomegranate Seed Oil in Female Rabbits ........................................ 348
  Noor Ibrahem Hasan AL-Kraie, Israa Salman Dalas; Qasim Azeez Razooqi

65. A Biometric Assessment of a Combined Topical Levofloxacin, Retinol, Cloxacillin and Ascorbic acid Against Facial Acne.......................................................... 355
  Naser A Naser, Hussein Abdulkadhim A, Sahar A. Alhar, Karrar K. Alhaidary, Rana Talib Al-Nafakh

66. Assessment the Efficacy of Arthrocentesis with Corticosteroid and Arthrocentesis with Sodium Hyaluronate in Treatment Temporomandibular Joint Disorders: A Comparative Study.......................... 361
  Samer Majeed Mohammed, Muntathar Muhsen Hassan Abusanna, Zina Ali Daily

67. Aqueous Extract of Date Palm Fruit (Phoenix dactylifera) Protect Liver Against Cyproterone Acetate Toxicity in Male Mice ........................................................... 367
  Nuha Yaarub Al-Harbi, Eman Fadhel Abbas Awadh, Wasan Najim Abdul-Sada

68. Molecular Detection of Pseudomonas aeruginosa and its Relationship with Multidrug Resistance and Transposons .......................................................... 373
  Wathiq Abbas Hatite Al-Daraghi, Mohammed Sattar Abdulkadim Al-Badrwi, Haider Rida Jassim

69. Antifungal Activity of Silver Nanoparticles Using Penicillium Chrysogenum Extract Against The Formation of Biofilm for Candida Glabrata ........................................ 379
  Nada S. Salah, Thamer A.A. Muhsen, Mohssten H. Risan

70. Study of Epidemiological Factors According to the Positive Response of Igg of Patients Infected with Blastocystis hominis in Diyala province, Iraq............................................... 385
  Muna Hameed Ahmed Alazzawi, Nabaa Ali Jasim, Masar H.Ismail

71. Epidemiological and Histopathological Study of Appendicitis in Karbala Province.............................. 390
  Khetam L.Hussain, Aiyat hazem al-shugary, Eman Jabbar Rahim, Ameer Ali Aenad, Sajida Jawad Mahdi, Abdullah ali Kate
72. Molecular investigation of virulence factors genes in *streptococcus pyogenes* by PCR ........................................ 395
Russell Issam AL-Daher, Maysa S. AL-Shukri, Hayam K. AL-Masoodi

73. Iron Deficiency among Patients with Febrile Seizures in Al Ramadi Maternity and Children teaching Hospital, Western Iraq ................................................................. 400
Sahar j. AL-Hiali

74. Antibiotic Susceptibility of Bacteria Isolated From Under Nails................................................................. 406
Zahraa AL-Tae, Sura Ihsan Abed Jabuk, Raftaa S.H. Hussian, Zainab H. Kareem, Yasis H. AL-Mawlah

75. Removal of Tetracycline from Aqueous Solutions using Pomegranate Peels Residues Accessing to ZRL.. 410
Rajaa S. Abass Suad Turkly Ali, Tamara Sami Naji

76. Complications of Laparoscopic Cholecystectomy in a Sample of Patients Admitted to Al-Ramadi Teaching Hospital, Anbar-Iraq ........................................................................ 415
Tarek Mahdi Salih

77. Physiological Study Comprising the Sequelae of Magnetic Radiation on Human........................................ 421
Wissam Sajid Hashim, Azal Hamoody Jumaa, Noor Thamer Alsaadi, Ayad Gaber Arean

78. Assessment of Transdermal Vasodilatatory Effect of a Combined Panthenol, Amlodipine, Isosorbide Dinitrate and Betahistine HCl on Peripheral Vessels ....................................................... 426
Hussein Abdulkadhim A, Naser A Naser, Fadhaa A. Ghafil, Rana Talib Al-Nafakh, Karrar K. Alhaider

79. Evaluation of Using Titanium Mesh in the Reconstruction of Traumatic Orbital Floor Fracture ...................... 433
Mukhalled Salim Alasady, Ihsan Abdullah Kumail, Alyaa Turkly Alsultany, Ali B. Roomi

80. Association of Epstein- Barr Virus (EBV) with the Development of Nasopharyngeal Carcinoma (NPC) in Western Region of Iraq: Unmatched Molecular Case-Control Study ........................................ 439
Mothana Ali Khalil, Arkan Obaid Jasim Al-Essawi, Mohammed Tafash Dagash

81. Molecular Detection of Toxogenic Cyanobacteria Isolated from Tigris River in Baghdad City –Iraq........... 446
Zainulabdeen H. A. AL-Khafaji, Ahmed S.Dwaish

82. Flame Atomic Absorption Spectrophotometry Analysis of Heavy Metals in Some Food Additives Available in Baghdad Markets, Iraq ................................................................. 451
Wasan Abdulwahid Jasim, Jasim Dawood Salman, Jasim Mohammed Shamar Jamur

83. Detection Malta Fever by Interferon-gamma and Steroid Hormone S Level .............................................. 457
Ali Anok njum, Layla Saleh Abdul-Hassan Ihasan A. Hashem

84. Hepatic Toxicity in Patients with Rheumatoid Arthritis and Psoriasis Taking Methotrexate Therapy .......... 463
Haider Hamza Omran, Basim Mohammed Mothlum

85. Scolicidal Activity of Zirconium Oxide (ZrO2) nanoparticles Against Protoscolices of Hydatid Cysts ...... 469
Amenah Abdul-Jabbar Ibrahim

86. Molecular Study of Fimh Gene in Klebisella Pneumoniae Isolated From Urinary Catheter Patients ......... 473
Israa Abdul Ameer Al-Kraety, Zahraa Hameed Oda Alquraishi, Aqeel A Alsadawi

87. Chemerin Level as a Marker in Preeclampsia and its Relation to the Disease Severity and Neonatal Outcome ........................................................................................................................................ 478
Ali Mohammed Murad, Marwa Jaafar Sadac Hanan Hazim Mohammed Noori
88. Production, Analysis and Optimization of Inulin Produced from Pseudomonas fluorescens.......................... 485
    Alyaa Razooqi Hussein, Alaa Raheem Kadhim

89. Epidemiology of Hepatitis B and C in Al-Muthanna Province.................................................................. 492
    Adian Abd Alrazak Dakl, Wafaa Ayad Alnuaimy

90. The Impact of Congenital Heart Diseases on Growth Parameters in Children and Their Correlations
    with Leptin Levels.................................................................................................................. 495
    Fouad Shareef, Amal Salih Mahdi Bayee

91. Hormonal and Mineral Imbalance Effect on Bone Resorption in Predialysis Iraqi Patients with Chronic
    Kidney Disease......................................................................................................................... 501
    Inaam Ahmed Ameen, Sarah Hashim Mhaibes, Shahad Wisam Ahmed, Kaled Nather Taha And Dhiakra
    Abdul Hameed Dawood

92. Robust Controller Electromyogram Prosthetic Hand with Artificial Neural Network Control and Position
    508
    Saygin Ahmed, Aydin S. Ahmed, Bülent Yilmaz, Nuran Dogru

93. Study the Genotoxicity of Aqueous and Alcoholic Extracts of Adhatoda Vasica on the Roots of Allium
    cepa L. by RAPD-PCR Technique ........................................................................................... 514
    Adnan Owayez Jasim, Mohammed Mahdi Jawad

94. Histological Study of the Effect of Isoxicam on Ovary of Albino Mice Mus Musculus ......................... 520
    Ali Khudheyer Obayes, Wurood Mohamed Mutar, Rasha Hamid Ayub, Sahar Abdullah Mohammed

95. Genotyping of Tumor Necrosis Factor-α in Inflammatory Bowel Iraqi Patients .................................... 526
    Inas Fadhe, Wafaa Sabri Mahood

96. Antibacterial activity of Eruca Sativa Seeds Aqueous Extract Against Human Pathogenic Bacteria....... 533
    Madeha H. Hussain, Aml Hendi Salih, Rajaa Hendi Salih, Ali S. Hassoon

97. Possible Role of Toxoplasmosis on Gene Sequence Alteration in Patients with Cardiovascular Diseases.. 537
    Nazar Sh. Mohammed, Ammer Abd. Mohammed, Salwa S. Muhsin

98. Article Deleted.................................................................................................................................. 541

99. Study the Cytochrome P450 Gene Expression Changes in Iraqi Patients with Chronic Liver Disease...... 546
    Areej GH Al-Charak, Hamza H Kzar

100. The Reliability of Orthodontic Treatment, According to the Needs of Patients Using the Dental
    Aesthetic Index......................................................................................................................... 551
    Esraa Salman Jasim, Noor F. K. Al-Khawaja

101. Study the Protective Role of Arabic Gum Extract on Some Physiological and Histological Criteria for
    Liver of Male Rabbit Treated with Atrazine.................................................................................. 558
    Noor Rahi AL-Shimmari, Rasha Abdulameer Jawad

102. Relation between Working in Petrol Station and Blood Hemoglobin Levels for the Filling Workers in
    Al-Najaf City/ Iraq....................................................................................................................... 565
    Fulath Abdul-Redah Muhsin

103. Effect of Preoperative Breathing Exercise on Postoperative Patients’ Lung Functions....................... 570
    Dhiaa A. Al-Reda, Rajfa A. H.

275. Association of Diffusion Weighted Magnetic Resonance Imaging Profile and Apparent Diffusion Coefficient Value with Brain Tumor’s Histopathology .......................................................... 1586
   Hartati Rusni Tri Wulijeng, Anggraini Dwi Sensusiati, M. Yamin Sunaryo Suwandi

276. Mitochondrial 16S rRNA gene-dependent Blood typing as a Forensic Tool ........................................ 1594
   Hayder J.H. Al-Nayili, Hussein O.M. Al-Dahmoshi

277. Curcumin Improves the Regulation of Ovarian Folliculogenesis in Culture Media with Peritoneal Fluid from Infertile Women with Endometriosis ................................................................. 1603
   Hendy Hendarto, M Yohannes Ardianta Widyanugraha, Widjati, Soehartono Darmosoekarto

278. Correlation of Fugl-Meyer Assesment Score with Barthel Index and Functional Independence Measure in Patients with Stroke .......................................................... 1609
   Husnul Mubarak, Noor Idha, Bayu Santoso

279. Determination of Priority Elements of Vigilance in the Use of Pesticides based on Difficulty and Usefulness (A Supporting Study for Law and Policy in Health) ............................................. 1615
   Ilyas Ibrahim, I Ketut Sudiana, H J Mukono, Suhartono, Heru Santoso Wahito Nugroho

280. The Association Between Myoglobin, Troponin I, Hfabp and Nt-ProBnp Levels with Acute Myocardial Infarction in Patients with Acute Coronary Syndrome .......................................................... 1620
   Ime Fransiska Adidharma, Jusak Nugraha, Muhammad Aminuddin

281. Time Recommendation and Alternative Parameters for Severe Maxillofacial Trauma Reconstruction..... 1638
   Indri Lakhsmi Putri, Magda Rosalina Hutagalung, Ida Bagus Narmada, David Sontani Perdanakusuma

282. Decrease of Sensorineural Hearing Frequency and Cochlear Hair Cell Function in Malignant Head and Neck Tumor Post Cisplatin Chemotherapy Series II .............................................. 1655
   Irawati. Bakti Surarso, Haris M. Ekorini
287. Thiophene-Cyclic and Sulfazane Derivatives (Preparation, Spectral Analysis, the Behavior in Organic Solvents, Microbial Testing)........................................................................................................................ 1662
   Jalal Hasan Mohammed, Alaa Jawad Kadhim, Nagham Mahmood Aljamali

288. Diagnostic test of Brief Peripheral Neuropathy Screen as Distal Sensory Polyneuropathy-HIV Diagnostic Tool........................................................................................................................ 1670
   Joko Rudyono, Mudjiani Basuki, Erwin Astha Triyono

289. Relation of Homocysteine With Malondialdehyde and Dyslipidemia in Type 2 Diabetic Patients with Coronary Artery Diseases........................................................................................................................ 1676
   Khalid Shaalan Sahab, Ali S. Mahmoud Al-Saadi

290. Determination of Some Biomarkers that affect in Behaviors of Autism Spectrum Disorder Individuals in Iraq........................................................................................................................................................... 1681
   L. Basim M. Ali, Iqbal Jasim Badr Alasadi, Sameerah Ahmed Zearah

291. Detection of VT1 and VT2 genes in *Escherichia coli* isolated from Diarrhea Patients in AL-Anbar, Iraq using PCR Sequencing........................................................................................................................ 1687
   Laheeb Rajab Hamad, Muthanna Hamid Hassan, Abdalwahab Bdewi Hussain

292. Correlation between the Duration of Ethambutol Therapy and the Toxic Optic Neuropathy Occurrence in Patients with Multidrug-Resistance Tuberculosis........................................................................................................................ 1694
   Muhammad Hamdan, Eko Wahono R., Kurnia Kusumastuti, Laily Irfana

293. Macrophage Activity and Histopathological Differences of Lung Tissue on Sequential Co-infections of Heligmosomoides Polygyrus Nematode on Mycobacterium Tuberculosis Infection........................................................................................................................ 1699
   Laksmi Wulandari., Muhammad Amin, Soedarto, Gatot Soegiarto., Kenji Ishiwata

294. Nurses’ Knowledge Regarding Pneumonia in Children Under Five Years of Age at Pediatric Wards in Kirkuk Teaching Hospitals ......................................................................................................................................................... 1705
   Luay Amjed Mahmood Al-Waly, Mohammed Ahmed Sultan Al-Wily, Radhwan Hussein Ibrahim

295. The Effectiveness Comparison of Desloratadine and Loratadine in Reducing Total Nasal Symptom Score and the Level of Interleukin 4 in the Nasal Secretions of Allergic Rhinitis Patients ............................................................................... 1711
   Luh Putu Dhena Purwaningsih, Dwi Reno Pawarti, Bakti Surarso

296. Prevalence of Dermatophytes Fungal Infection among Different Gender........................................................................................................................ 1717
   Luma T. Ahmed, Zahraa A. Darweesh, Wathiq M. Hussain

297. Risk Factors of the Elderly Falling in Public Hospitals: A Systematic Review Study.......................................................................................................................................................................... 1723
   Masoumeh Otaghi, Zahra Mohammad-Niakan, Sanaz Aazami, Ali Khorshidi

298. Effect of Web-Based Early Diagnosis of Dental and Oral Diseases with Validity Level of Dentist Final Diagnosis in Public Health Center, Makassar, Indonesia ........................................................................................................................ 1728
   Masriadi, Dolly Indra, Harlinda

299. Association between Intelligence Level and Handicap Degree in Epilepsy Patients................................................. 1736
   Meity Meiliyanny Beslar, J. Eko Wahono, Istri Suharjanti, Paulus Sugianto, Riani Wisnujono

300. Effect of Glutamine Before Gets Cisplatin on Aif and Bcl-2 in the Evidence of Apoptosis Cell Tubulus Proximal in Rats Kidney of Rattus Norvegicus Strain Wistar........................................................................................................................ 1742
   Michael Lumintang, Endang Joewarini, Sunarni Zakaria, Gunawan Widodo, Imam Susilo
301. Association between Soluble Contents CD40 Ligand (sCD40L) and Acute Coronary Syndrome (ACS) . 1747
Mirza Elita, Muhammad Aminuddin, Jusak Nugraha

302. The Potential Role of Radiology in Diagnosis of Traumatic Versus Non-Traumatic Cerebral Hemorrhages for Medicolegal Application ................................................................. 1753
Mohamed Khairy, Dina A. Shokry, Ehab Abdelhaleem, Reham Nafad Elbendary

303. Comparison of Saffron versus Fluoxetine in Treatment of Women with Premenstrual Syndrome: A Randomized Clinical Trial Study .......................................................................................................................... 1760
Mohammad Nemat-Shahi, Atefeh Asadi, Mahbobeh Nemati-Shahi, Davood Soroosh, Shakiba Mozari, Hamidreza Bahrami-Taghanaki, Mahsa Mehrpour

304. Comparison of the Effects of Passiflora Incarnata and Piroxicam in opioids withdrawal-Induced Myalgia and Anxiety: A randomized Clinical Trial .................................................................................................................. 1766
Mohammad Nemat-Shahi, Seyyed Mehdi Mir Moahmadi, Davood Soroosh, Atefeh Asadi, Samaneh Nakhaee, Mahsa Mehrpour

305. Hematological Changes in Blood of Smokers of Cigarettes and Nargyle ................................................. 1771
Mohammed S. Hussain, Nuhad Mohammed Hamid, Mohammed Qais Al-Ani, Belal K. Muden, Mustafa J. Hamad-Allah, Omer H. Sweed, Suror S. Sabbar

306. Correlation between Hyperglycemia Stress and Short-Term Memory Function in Thrombotic Stroke Patients .................................................................................................................................................................. 1777
Muhammad Hamdan, Riani Wisnujono, Yudha Haryono, Abdulloh Machin, Dian Puspitarini

307. The Difference between hs-CRP and Serum IL-6 Levels in Patients with Glaucoma and Non Glaucoma 1782
Muhammad Riduan, Endang Retnowati Kusumowidagdo, Nurwasis

308. The Risk Factors Effect of Knee Osteoarthritic Towards Postural Lateral Sway ........................................ 1787
Muhammad Siddik, Ratna Darjanti Haryadi

309. Microbial Risk Assessment (MRA) As a Method of Assessment for Drinking Water Refill in Pattinggalangoang District of Makassar City ...................................................................................................................... 1793
Alfina Baharuddin, Muhammad Ichsan

310. Association of Early Nutritional Status with the Clinical Severity in Patients with Acute Stroke .......... 1799
Myrna Ika Purnama, M. Hasan Machfoed, J. Eko Wahono R

311. The Legal Protection of Well-Known Service Trademark (The Case of Inter-Continental Vs The Intercontinental) ................................................................................................................................................ 1804
Nanda Riwanto, Agung Sujatmiko

312. Determining the Quality of Services Provided in Delivery Room at Ayatollah Kashani Hospital (Jiroft, Iran) from the Perspective of Clients Using Service Quality Model (SQM) During Spring 2019 . 1809
Narges Mahyapour Lori, Hourie Taheri Sarvetomin, Mahdiyeh Ahmadi, Sareh Mehni, Neda Dastyar

313. Correlation between Serum & Urinary Placental Protein (Pp13) in Pre-eclamptic Women at their Third Trimester ................................................................................................................................................ 1814
Nesreen Ahmed Nasser, Rayah Sulaiman Baban, May Fadhil Al- Habib, Risala A. Ali Jameel

376. A Histological and Histochemical Study on Olfactory Bulbs to Detection Amyloid Protein Depositions
by Congo-Red and Routine Staining Techniques .................................................................................. 2209
Rajaa Ali Moheiseen Al- Tae, Muna Hussain Al-Aameli, Yarub Modhar Al-Qazwini

377. The Intraperitoneal-Ketoprofen-Histopathological Induced Alterations in the Wistar Rat Kidneys .......... 2215
Samer Riyadh fadhil, Hakim Bahlok Jebur

378. Association between IL12A Gene of G/A genotype Polymorphism and Pulmonary Tuberculosis Risk
in Baghdad Population .............................................................................................................................. 2220
Anwar Abed Nasser Dhabaan, Mayes Abdul-Hadi Mahdi

379. The Effect of Allogenic Bone Marrow on Integration  Dev-Mesenchymal Stem Cell And Vascular
Endothelial Growth Factor ....................................................................................................................... 2226
Ferdiansis

380. Influence of BRACA Usage on Self Improvement of Breast Cancer Patient by Post Mastectomy......... 2233
Dewi Maryam, Iskandar Ali

381. Correlation of Quadriceps and Hamstring Muscles Strength with Knee Osteoarthritis Stages and Pain
Levels in Elderly Female Subjects ................................................. 2237
Mohammad Fathul Qorib , Hening Laswati

382. Effect of Dates (Phoenix dactylifera L.) on Liver of Broiler Chicks Infected with Infectious Bursal
Disease Virus. Biochemical and Histological Study ............................................................................. 2243
Balqees Hassan Ali, Ziad Khalaf Jalob, Zaid Yaseen Ibrahim, Ahmed Sami Jarad, Mustafa Salah Hasan

383. Identifying the Correlation between the Incidence of Breast Cancer and Hepatitis B Virus of Iraqi
Women....................................................................................................................................................... 2250
Minen Al-Kafajy

384. Cyclic Fatigue Resistance of Wave One Gold, F6 SkyTaper, One Curve, and AF Blue R3 NiTi Rotary
Instrumentation Systems............................................................................................................................. 2256
Zainab M. Abdul- Ameer, Samar Abdul Hamed, Rasha H. Jehad, Jacob Al-Hashemi
385. Relation between Cardiorespiratory Fitness Measured with Six-Minute Walk Test and Walking Speed Measured with 1—Meter Walk Test in Patients of Post-Subacute and Chronic Ischemic Stroke .......................... 2265
   Hening Laswati, Cut Jaswanita Eka Putri, Patricia Maria Kurniawati

386. Comparison Study of Urinary Retention Incidence in Assisted Vaginal Delivery Case with and without 24-Hour Catheterization .................................................................................................................. 2271
   Eighty Mardiyan Kurniawati, Hari Parathon, Suskhan Djasad, Fernandy Moegni, Junizaf, Budi Iman Santoso

387. Effectiveness of Additional Intranasal Phototherapy through Decrease Score of Nose Symptom and Eosinophil Mucosa on Persistent Allergic Rhinitis ................................................................. 2277
   Hamna Fitriah, Roestiniadi Djoko Soemantri

388. Hydration Status and Degree of Clinical Severity Patients with Thrombotic Infarction Stroke ........... 2283
   Agung Nugroho, Hendro Susilo

389. Prevalence of Benign Vocal Cord Disorder at Dr. Soetomo General Hospital Surabaya Indonesia in June 2015-June 2016 .................................................................................................................................... 2289
   Lucia Miranti Hardianingwati, Diar Mia Ardani

390. Utilization of Deconcentration Health Funds in Planning, Budgeting, and Implementation in Indonesia . 2294
   Gurendro Putro, Ristrini, Tumaji

391. The Influence of Slow Stroke Back Massage, Cold-compress and Warm-compress to the Level of Prostaglandin F2α (PGF2α) in Primary Dysmenorrhea ......................................................................................... 2301
   Mukhoirotin, Kurniawati, Diah Ayu Fatmawati

392. The Effect of Dexterity and Perturbation Exercise on Knee Osteoarthritis through Functional Balance and Power Improvement of Quadriceps and Hamstring ........................................................................... 2307
   Rini Lestari Ansanay, Damayanti Tinduh

393. Biocompatibility Test of Decellularized Cartilage Bovine Scaffold in Vitro and In Vivo ......................... 2313
   Achmad Fachrizal, Dwikora Novembri Utomo

394. Predictors of Hospital Utilization Among Papuans in Indonesia .......................................................... 2319
   Agung Dwi Laksono, Ratna Dwi Wulandari

395. Hydration Status and Degree of Clinical Severity Patients with THRoMBotic Infarction Stroke ......... 2325
   Agung Nugroho, Hendro Susilo

396. The Effect of Allogenic Bone Marrow Mesenchymal Stem Cell - Platelet Rich Plasma (Bmses - Prp) Intra-Articular Injection Effect on the Regeneration of Full-Thickness Joint Cartilage Defect on Rabbit. 2331
   Ahmad Taufik.S, Dwikora Novembri Utomo, Hari Basuki Notobroto

397. Health Wisdom in the Traditional Healing of the Panaragan Java Subethnicity: The Case Study of Warok Ponorogo ........................................................................................................................................ 2337

Morphology of Palatal Rugae in Various Sagittal Skeletal Malocclusions in Kerala Population- A Retrospective Study

Crystal Runa Soans1, Azhar Mohammed2, Murali PS1, Mcqueen Mendonca3, Prajwal Shetty3, VartikaKumari4

1Senior lecturer, 3Reader, 4Ex-Post Graduate, Department of Orthodontics and Dentofacial Orthopaedics, A.B Shetty Memorial Institute of Dental Sciences, NITTE (deemed to be) University, Mangalore, India.

Abstract

The present study was designed evaluate the structural morphology of palatal rugae in Kerala orthodontic subjects with varying Sagittal Skeletal Malocclusions. Pretreatment maxillary casts of 105 patients were analyzed for rugae patterns qualitatively and quantitatively using modified Thomas and Kotze classification. The data were statistically analyzed. According to the Fishers exact test, the most common type of rugae pattern in all the groups (Class I, Class II, and Class III) were observed to be wavy followed by curved. Skeletal Class III had the highest number of straight rugae 71.4% among the three groups which was statistically significant. Direction of rugal alignment was horizontal and droplet-shaped incisive papilla was identified among different skeletal dysplasia groups.Palatal ruage may serve as valuable indicators for population identification and help in facial reconstructions through their association with varying skeletal malocclusions.

Keywords: Palatal Rugae Pattern, Skeletal Malocclusion, Dental Casts, Forensic Dentistry

Introduction

The irregular asymmetrical palatine folds on the anterior third of the palate are called as palatal rugae. They possess unique individualistic morphologic characteristics that are helpful in population identification and are stable over time.1, 2

In a county like India where usable dental anthropological data is sparse palatal rugae could be valuable for forensic identification due to racial specificity, facilitating population identification and post-mortem identification.

Rugae are classified based on their length, shape, direction of alignment, unification or branching number distributed on either side of the median palatal raphae. The plica palatinae are thus assessed qualitatively and quantitatively based on these parameters.

Studies have shown the uniqueness of the rugae when assessed in various populations and may be helpful in individual identification and population identification.3- 7

Stability of palatal rugae, pre and post orthodontic treatment have made them reliable markers of identification. Studies have also attempted to establish the relation of palatal rugae pattern and various dental malocclusions, thereby allowing for early intervention and prevention of dento-skeletal issues.8, 9 A study was conducted to investigate morphological structure of palatal rugae in Turkish orthodontic subjects with various sagittal skeletal malocclusions, concluded the uniqueness of rugae morphology in relation to skeletal dysplasia.10

No study has been conducted on individuals with various sagittal skeletal malocclusions in Indian population with varying ethnicities. The purpose of this study was to evaluate the morphological structure...
of palatal rugae in Kerala orthodontic subjects with different sagittal skeletal malocclusions.

The objective of the present study was to evaluate and compare the structural morphology (number, pattern, direction of alignment) of palatal rugae and shape of the incisive papilla in Kerala orthodontic subjects with varying sagittal skeletal malocclusions i.e. Skeletal Class I, Skeletal Class II and Skeletal Class III.

**Material and Method**

The study was designed to be a retrospective study. Pretreatment records i.e lateral cephalograms and maxillary casts of 105 subjects age ranging 18-25 years, were procured from the archives of the department. Records of patients with any congenital deformity or history of palatal surgery and previous history of orthodontic treatment were excluded. The maxillary models whose palatal rugae were clearly visible were selected.

**Methodology**

The subjects were grouped into Class I, Class II, Class III (n=35 each) according to the ANB angle measured on lateral cephalometric radiographs. (Class I ANB angle 0º to 4º, Class II ANB angle >4º and Class III ANB angle <0º).

The maxillary casts were numbered. A midline was drawn coinciding with that of the mid palatine raphae extending from the incisive papillae to the posterior most extent of the rugae dividing the palate into right and left halves. The outlines of the rugae were traced using graphite pencil under adequate illumination. The rugae were then measured and categorized as primary, secondary and tertiary rugae and assessed for different patterns. Modified Thomas and Kotze\(^{11}\) method was used for quantitative and quantitative assessment. The number, pattern, direction of rugae alignment and shape of the incisive papilla were assessed among all the groups.

**Statistical Analysis**

All data were analysed using IBM SPSS software VERSION 22.0. The Kruskal–Wallis test was used to compare the number of primary palatal rugae (PPR) among the groups. Fishers exact test was used to compare the pattern of rugae between the various skeletal malocclusions on both sides of the palate and the direction of rugae among the groups. Chi square test was used to compare the shape of the incisive papilla among the groups. P values of less than 0.05 were considered statistically significant.

**Results**

Kruskal- Wallis test analyzed the primary palatal rugae (PPR) quantitatively and compared among the groups on the right and left side of the palate. As regards to the number of PPR on the left and right sides, there was maximum number of primary palatal rugae on the right side of subjects with Skeletal Class II (mean 3.86right and 3.80 left) and Skeletal Class III (mean 4.17 right and 3.97 left) in comparison with Skeletal I (mean 3.54 right and 3.60 left) with the highest number of primary rugae in Skeletal Class III on the right side among the groups, which was statistically significant (p value 0.003) (Table 1).

N=Samples In Each Group*p<0.05 statistically significant,
Wavy and curved types were the most common types of rugae pattern in all skeletal dysplasia groups. On the right side (Class I, 93% wavy and 31.4% curved, Class II, 91% wavy and 51.4% curved, Class III, 80% wavy and 65.7% curved). Followed by straight and unification pattern. Skeletal Class III had the highest number of straight rugae 71.4% among the three groups which was statistically significant (p value 0.00) (Figure 1). On the left side of the palate Wavy pattern was the most common pattern in all malocclusion groups (Class I, 94.3% wavy, Class II 94.3% wavy, Class III, 77.1%), but this was not statistically significant. Followed by curved, straight and unification pattern. Skeletal Class III had the highest number of straight rugae 62.9% among the three groups which was statistically significant (p value 0.003). (Figure 2)

**Figure 1:** Graph showing the pattern of rugae on right side among the groups.

**Figure 2:** Graph showing the pattern of rugae on left side between the groups.

Fischer’s exact test compared the direction of rugae among the groups. Direction in all groups was horizontal (54.3% Class I, 85.7% Class II, 68.6% Class III). Irregularly directed rugae were seen highest in Skeletal Class I group (40.0%) as compared to the other groups and this was statistically significant (p value 0.003). (Figure 3).
Figure 3: Fisher’s Exact Test showing the direction of rugae alignment in different skeletal malocclusions among the groups

Droplet-shaped incisive papilla was identified to be predominant among different skeletal malocclusion groups. (Table 2).

Discussion

Palatal rugae with their individual uniqueness have aided in forensic identification and population identification and have imposed their importance in cases where digit biometrics are unavailable. The shape of the palatal rugae seems to remain constant throughout life.\(^\text{12}\) Palatal rugae facilitate population identification as they possess identical characteristics amongst certain racial groups.\(^\text{13}\) Like fingerprints the palatal rugae do not alter during the course of life with only increase in length due to normal growth.\(^\text{14}\)

Even though examination of the palatal rugae is relatively a subjective process, it can be easily recorded sans any complex armamentarium. Palatal rugae are unique in each individual similarly, in this present study, each subject’s palatal rugae were found to be unique.\(^\text{15-18}\)

Some authors suggest that palatal rugae remain unchanged as of 12\(^\text{th}\) weeks of intrauterine life; whereas other authors suggest that palatal rugae may change quantitatively with increasing age but retain their general configuration.\(^\text{19, 20}\)
In the present study we only assessed the number and shape of the palatal rugae among different skeletal malocclusion groups and no time related evaluation of the rugae was undertaken.

The number of PPR ranged from 2-6 and SPR ranged from 0-5 in the subjects examined in the present study. Study done by Surekha et al\(^5\) showed more number of PPR in Kerala population as compared with Manipuri population. In addition, there was significant difference among different Sagittal Skeletal Malocclusion groups in terms of the overall number of PPR on either sides of the palate. Primary rugae were distributed more on the right side of the palate among the groups, especially in Skeletal Class II and Skeletal Class III. These results concur with those of Kallianpur et al\(^21\) who compared rugae patterns of Indian and Nepalese population. Rugae were higher in number on the right side of the palate in Indians as compared to Nepalese population but the results were not statistically significant. Dhoke and Osato\(^22\) and Kapali et al\(^13\), explained the phenomenon of regressive evolution that dominates the right side of the palate mainly pertaining to secondary rugae. Our results may thus vary due to the exclusion of secondary rugae and based on the population chosen.

According to Thomas 1983, palatal rugae do not undergo any changes except in length, throughout a person’s life probably due to underlying growth.\(^11\) Comparative studies performed amongst geographically diverse populations belonging to Indian regions such as Karnataka and Kerala\(^23\) and Manipur and Kerala\(^5\), have demonstrated important differences in rugae pattern. A study comparing two groups of Indian population (southern Indians and western Indians) predominantly showed the prevalence of wavy and curved rugae forms followed by straight rugae pattern.\(^24\) Studies conducted by Nayak et al\(^25\), Kotrashetti el al\(^26\), Kumar el al\(^27\), Surekha et al\(^8\), Shanmugam et al\(^7\), Bajracharya et al\(^28\) and Kapali et al\(^13\) showed the predominance of curved and wavy pattern of rugae in most populations. The Present study was aimed more towards assessing the characteristics of rugae in various skeletal malocclusions in Kerala population. Wavy pattern was seen most predominantly on both sides in Class I followed by Class II and Class III skeletal malocclusion. These are in accordance with the results published by Surekha et al\(^8\) and M Selvamani et al\(^29\) and SwethaS\(^30\). This was followed by curved, straight and unification pattern of rugae. Study by J K Savitha et al\(^23\) has seen similar results where curved rugae were more prominent in Kerala population as compared to Karnataka population. Horizontal rugae alignment and droplet-shaped incisive papilla was identified among all three skeletal dysplasia groups. The study by Ekrem Oral et al\(^10\) also reported droplet-shaped incisive papilla to be the most common type in Turkish population. M Selvamani et al\(^29\) concluded that females of Kerala origin had more number of primary rugae as compared to males. In our study we have not compared for sexual dimorphism among the various skeletal malocclusion. This leaves room for future scope of the study.

Further studies on a large number of subjects of varying Indian ethnicities are required in order to confirm the relationship between the pattern of palatal rugae and sagittal skeletal malocclusion.

**Conclusions**

- Primary rugae were significantly distributed more on the right side in comparison to the left side on the palate, especially in skeletal Class II and Class III.
- Wavy and curved pattern of the rugae were seen on both right and left side of all the skeletal malocclusion groups and skeletal Class III had more number of straight rugae.
- Direction of rugae alignment was horizontal and droplet-shaped incisive papilla was identified among different skeletal dysplasia groups.
- Palatal ruage may serve as valuable indicators for population identification and help in facial reconstructions through their association with varying skeletal malocclusions.

Analysis of Hospital Deaths at Tertiary Care Teaching Hospital

Jeeveswararao Bagadi
Srinivasulu Pothireddy
Sujan Kumar Mohanthy

1Assistant Professor, 2Professor & Head, Department of Forensic Medicine & Toxicology, Great Eastern Medical College, Srikakulam, Andhra Pradesh, 3Associate Professor, Fakhir Mohan Medical College and Hospital, Balasore, Odisha

Abstract

Recording of Death and its causes constitute an important component of health information system. The study was conducted on 90 hospital deaths during the period of six months from July-December of 2017, at Great Eastern Medical School and Hospital. Males more than 60 years of age group were the major victims in our study. Improving primary health care facilities in rural areas may reduce the Mortality and Morbidity.

Key words:- Sudden Death, Mortality, Morbidity.

Introduction

Thanatology is a branch of science that deals with the study of death. A good death is not a single event; it is a series of events. Death analysis gives the circumstances and cause of death of patient and steps to be taken for prevention of same.

India is undergoing rapid transition as a consequence of economical and social reforms. Life expectancy at birth in India shows a continuous increasing trend from 23.63 years for male and 23.96 years for female in 1901 to 66.9 years for males and 70.0 years for females in 2011. The pattern of diseases in developing countries is different than developed ones. In India about 40% of deaths are from infectious, parasitic and respiratory diseases as compared with 8% in developed countries.

Death analysis determines the causes of major illness, quality of medical care provided to patients from analyzing the clinical records and hospital services. The pattern of mortality is a key indicator of the consequent health scenario.

Hospital based death records provide information regarding the causes of deaths, case fatality rates, age and sex distribution, which are of great importance in planning health care services. Mortality pattern is poorly documented in rural areas lacking retention of up-to-date medical records. In 19th and early 20th century communicable diseases dominated the health problems, in recent years non communicable diseases account for half of all deaths in developing countries. The main 4 killers of non communicable diseases are Cardio vascular diseases, Cancer, Diabetes and Chronic Lung Diseases.

Material and Method

A retrospective study was conducted at Great Eastern Medical School and hospital Srikakulam, a referral, tertiary care teaching hospital. All deaths that occurred during 6 months period from July to December of the year 2017 were considered for this study. Total 9,436 cases were admitted and 90 deaths were recorded. Age, Gender, Place of residence, Date of admission, Date of death, Survival period, Socio economic status, Family history, Past history, Chronic diseases, Proper basic patient care like CPR,ECG, were done or not, Consent taken or not, MCCD form properly filled or not and cause of death were recorded in this study. Approval of institution ethics committee was obtained prior to the study.

Observations & Discussion

Deaths were more common in the age group > 60 years (37.77%) followed by 41-60 years (31.11%). This study correlates with M M kauser et al, V M holamble. Lowest percentage of hospital deaths were recorded in the age group 11-20 years (3.33%). More deaths after 60 yrs can be explained by the pathological basis of disease, and decreased immunity in old age to infections.

More number of male deaths were recorded (61.11%) than female deaths (38.88%). This study correlates with M M kauser et al. This can be explained by more attention towards the health of male by family members. Deaths in Hindu religion (94.44%) can be explained by the more people belonging to Hindu religion in this area.

The highest numbers of Hospital deaths were in people belonging to rural area (88.88%) than urban area (11.11%). This may be because of location of the hospital is in rural area and serving more rural population. People from rural area are poor and referred from all types of medical centers like PHC, CHC, to medical college hospital in terminal stages of illness. People from urban area may have medical care from private sector. This study correlates with M M kauser et al, V M holamble.

More deaths were recorded in uneducated people (72.22%) than in educated people. This may be due to lack of knowledge on health in uneducated people in rural areas. In people with low socioeconomic status (84.44%) highest number of deaths was recorded followed by middle class people (11.11%). This may be due to poverty, poor people may be neglecting health and don't visit the hospital for screening and awareness programs. The highest number of deaths (n=62) were in married people than unmarried (n=28). More number of married people deaths can be explained by lower marriage age in rural areas.

People admitted with one of the chronic diseases (42.22%) were suffering from Hypertension, Diabetes, Thyroid, Carcinoma, which are prone to develop complications and early death. Past history of suffering from similar disease or other chronic disease was found in (27.77%) patients. In 5.55% of patients, family history of same disease was present. The patients who have not gone through any previous treatment or any screening procedures died more (62.22%), when compared with patients taking treatment (37.77%). The patients who are under treatment may take care of their health, there by prolonging the life. A positive history of alcohol and smoking was present in 22.22% of patients.

Highest numbers of deaths were recorded during day time (68.88%) than night time (31.11%). More number of deaths were recorded in people admitted in day time (72.21%) than night time (27.77%).

Deaths with in 24 hrs of hospital admission were more (n=34) in this study, implying the importance of screening procedures in rural villages of this district to prevent sudden deaths. Death is said to be sudden or unexpected when a person not known to have been suffering from any dangerous disease, injury or poisoning is found dead or dies within 24 hours after the onset of terminal illness. The incidence is approximately 10 percent of all deaths, which contrasts with our study (37.77%).

Diseases of Respiratory System killed more number of patients (n=26) followed by Cardio Vascular System (n=21), Central Nervous System (n=14), Gastro Intestinal System (n=8), Renal System (n=7), Hematology (n=3), Endocrine (n=2), and Multiple Systems (n=9). This study correlates with c.palaivel et al. contrasts with yogeshwar V. kalkonde et.al where stroke is the leading cause of death in rural people.

Myocardial Infarction and acute respiratory distress syndrome were the major immediate causes of death. This study correlates with c.palaivel et al. contrasts with yogeshwar V. kalkonde et.al where stroke is the leading cause of death in rural people.

In 75.55% of cases CPR was done and flat ECG was obtained in 81.11% cases and detailed consent was taken in 65.55% cases. MCCD forms were filled in 100% of cases.

Manner of death in 96.66 % of cases was natural and in 3.33% accidental.

Cadaveric organ donation was not done in this part of state even though 28 patients died below 40 yrs of age group in this study, due to lack of awareness.

In 18 cases, in MCCD forms immediate cause of death was written as cardio respiratory arrest. It shows the doctors are not well trained in MCCD form filling.

Conclusions

1. Deaths were more common in males aged more than 60 years.
2. Most of deaths occurred in rural, uneducated, low socio economic group people.

3. Respiratory diseases followed by Cardio vascular diseases accounted for highest number of deaths.

4. Acute respiratory distress syndrome and Myocardial infarction are the major immediate cause of deaths in respiratory and cardio vascular diseases respectively.

5. Diabetes and Hypertension were the common co morbid conditions observed in this study.

6. Significant number of deaths in young (n=15) people indicates importance of preventive measures like vaccines, screening methods etc.

7. Medical services were not available /used by most of the people before reaching this hospital.

8. More than one third of deaths (n=34) were sudden deaths i.e. <24 hrs of survival period after starting of the symptoms.

9. Most of deaths were natural deaths.

Suggestions and Recommendations

1. Higher mortality among males in rural areas will retard economic growth rates. So there should be strong health policy for preventive as well as curative health services.

2. Government should initiate better health awareness campaigns for healthy life styles, environment modifications, and safety measures in rural people.

3. Airway management, fluid resuscitation along with screening procedures for respiratory and cardiovascular diseases are the early contributors to prevent sudden deaths in hospitals.

4. Continuous evaluation in hospital records provides stimulation for improvement of clinical services, professional education, hospital administration and better patient care.

5. First three days after admission is better period which needs proper medical attention to avoid preventable deaths.

6. As hypertension and diabetes are the risk factor for Myocardial Infarction, screening and treatment of patients with hypertension and diabetes in rural areas reduces Myocardial Infarction mortality.

7. Delay in diagnosis and immediate treatment, and decision to transfer to higher centre may be the factors for deaths in rural area. Government should provide proper transport and should improve health facilities in rural area.

8. Late admissions, poor maintenance of health due to poor socioeconomic status may come under contributory negligence. Government should provide health workers in rural area to screen the people and avoid the late admissions.

9. Organ donation awareness programs should be conducted to improve organ donations in rural areas.

Study of Fingerprints in Relation to Dental Caries

Maitrayee Dutta Swargiary¹, Bhanukul Barman²

¹Assistant Professor, Assam Don Bosco University, Tapesia Gardens, Sonapur; ²B.Sc ⁴th Semester, Science College, Kokrajhar

Abstract

Fingerprints of 40 individuals of age group 4-18 years were sampled from Agyaram Kherbari L.P. School, D. L. P School and J.N. M. E school (Dhubri District) to study the pattern of fingerprints and their relation with dental caries as they may be associated with the disease and serve as a predictor for early detection of it. Analysis was carried out in the affected individuals and it was found that the percentage of ulnar loop is highest (23.75%) in females and also in males (19.7%) and percentage of lateral loop is lowest (1.25% and 1.24%), whereas the control had more percentage of ulnar loop in both males and females. The study shows an association of dermatoglyphic pattern of fingerprints and prevalence of dental caries.

Key Words: Fingerprint patterns, Dental caries

Introduction

Fingerprints are impressions of skin ridges which are formed in the early embryonic life and remain permanent in each and every person including twins throughout life except changes during serious accidents. The physical attributes and its functions serve to identify a person and serve as a visible marker to predict different diseases. Fingerprints can be acquired from the fingers, toes, palm of hands and soles of feet and deployed in forensic as well as non forensic applications including identification and association of different diseases such as Diabetes mellitus, hypertension, congenital heart disease etc., from the authentication based on individual peculiarities and their unique individual specificity [¹²,⁷,⁸]. They are heritable and noted to play a significant role in human biology, research, medical field to study leukemia, breast cancer, in the field of dentistry, etc. Fingerprints can be a diagnostic tool in various pathologies of oral cavity and serve as a useful tool for preliminary investigations as it is heritable. Dactylography is a powerful diagnostic tool for fingerprint analysis to study psychological, medical and genetic conditions of individual. Since it is heritable it can be considered as a window for congenital abnormalities and an indicator of future diseases and one of the best available diagnostic tools to study genetic disorders. Due to their macrofeatures they can be classified variously and the important ones are arch, whorl, loops and composite types because the ridges are differentiated in their definitive form during third to fourth month of the fetal life which remains permanent throughout the whole life. The development of fingerprints is under genetic control and dermatoglyphics shows clear resemblance among related persons. Since dermatoglyphic features are genetically determined it can be now used as a tool to diagnose genetic disorders and to evaluate the relationship between different diseases whose relation may probably help us to identify an individual with high risk of developing a disease. As every part of the body is unique and synchronous with different parts, the distinctive fingerprint pattern can be a potential diagnostic tool for preliminary investigations for studying various diseases. It can be used as a screening tool for identifying patients who are likely to develop disease. Since different genes influence the enamel by its chemistry or morphology, fingerprints can be considered as an indicator of dental abnormalities [¹⁰, ¹³]. So the present study was carried out for studying the dermatoglyphic patterns of fingerprints of different age groups and to find the association of dermatoglyphic patterns with dental caries.

Material & Method

A total number of 40 school students in the age group of 4-18 years were selected from Agyaram Kherbari L.P. School, D. L. P School and J.N.M. E School (Dhubri District). A tabular chart was prepared before taking the fingerprint and clean finger imprints was taken for both hands on an A4 size paper by using a stamp pad for the Ink Method \[3\]. Sample fingerprints was then dried and studied with a magnifying lens with prior reference to identify the fingerprints. The fingerprint patterns were then classified according to the topological method \[5, 3\] for fingerprint identification.

Results

Among the 40 students, 20 students suffered from dental carries, out of which 10 were control girls and 8 were affected girls, and 7 were control males and 12 were affected males.

Fingerprints in control students

**Table 1.** establishes that in all control students, the highest per centage of fingerprint pattern in both hands was observed for radial loops (30.5%), followed by ulnar loop (28.5%), plain whorl (8%), double cored, plain whorl (7.5%), double loop (5.5%), spiral whorl (5%), tented arch (4.5%), plain arch (3.5%), central pocket loop whorl (2.5%), elliptical whorl (1.5%), lateral pocket loop (1%) and accidental whorl (1%). The left hand shows a higher per centage (30.5 %) radial loop count in control and the ulnar loop count is 28.5% for right hand.

Fingerprints in affected students

The highest per centage of fingerprint pattern as shown in **Table 1.** for both hands was observed for ulnar loop (21%), followed by radial loop (20%), spiral whorl (18.5%), double cored whorl (9%), elliptical whorl (8%), plain arch (7.5%), plain whorl (7%), double loop (4.5%), tented arch (2%), central pocket loop whorl (2%) and lateral pocket loop (0.5%) in affected students. The left hand shows a less per centage of radial loop count in affected individuals results with no occurrence of radial loop. The right hand shows highest ulnar loop count (28.5%) and in affected the count is 21 %.

The fingerprint patterns of affected female and male students are graphically represented in **Fig.1** and **Fig. 2.** **Table 1.** also shows the fingerprint per centage of control female and affected female.

Fingerprints in control female students

The fingerprints of control female in **Table 2.** shows radial and ulnar loop (28%), plain whorl (11%), double cored whorl and tented arch (7%), spiral whorl (5.4%), double loop (3.9%), central pocket loop whorl and plain arch (3%), accidental whorl (1.54%) and lateral pocket loop (1.54%), elliptical whorl (0.8%).

Fingerprints in affected female students

The fingerprints of affected female shows ulnar loop (23.75%), radial loop (22.5%), spiral whorl (17.5%), plain arch (10%), double cored whorl (8.75%), plain whorl (6.5%), tented arch (3.75%), double loop (2.5%), central pocket loop whorl (1.25%), lateral pocket loop (1.25%). However accidental whorl is not observed in affected female (**Table 2**).

Fingerprints in control male students

As observed in **Table 2** in control male the highest per centage of fingerprint is found in radial loop (35.72%), followed by ulnar loop (30%), double cored whorl (8.57%), double loop (8.6%), spiral whorl (4.2%) and plain arch (4.2%), plain whorl (2.85%) and elliptical whorl (2.85 %), central pocket loop whorl (1.43%). However, accidental whorl and tented arch is not observed in control male.

Fingerprints in affected male students

In affected male ulnar loop is found to be highest (19.17%), followed by radial loop (18.33%), spiral whorl (19%), elliptical whorl (13%), double cored whorl (9%), plain whorl (6.67%), double loop (5.9%), plain arch (5.9%), central pocket loop whorl (2.5%), tented arch (0.84%). Accidental whorl is not observed (**Table 2**).

Fig. 1. Study of fingerprints of control and affected females.

Fig. 2. Study of fingerprints of control and affected males.
Discussion

Our study reveals, the fingerprint patterns varied among the students affected with dental caries. The loop pattern of fingerprint was found to be the highest and more prevalent in students having dental caries \[9, 11\] compared to fingerprint patterns in normal unaffected students. This study also clarifies that among the loops, ulnar loop (21\%) was the most prevalent.

As per our findings per centage of loops are followed by whorls in affected individuals and our study is in contrast to the other observations \[6, 4\] wherein, prevalence of dental carries was highest among students with whorl pattern compared to other fingerprints.

In this study the left hand of individuals showed a higher per centage (30.5\%) radial loop count in control compared to affected individuals (20\%) with no occurrence of radial loop in the left hand. The results are in accordance with workers \[11\] who also found radial loops among the control and the results are also at par with some similar works \[2\] as more number of radial loops is considered as a negative indicator for dental caries. The right hand however, shows highest ulnar loop count (28.5\%) in control individuals and lowest in affected (21 \%) individuals, which may indicate that the radial loops are more abundant in left hand compared to right hand. Our study also reveals higher percentage of ulnar loops (21 \%) compared to radial (20\%) when both hands are compared and ulnar loop fingerprint pattern can be a predictor for dental carries which however contradicts certain results \[2\] where it was found that whorl pattern shows positivity for dental caries prediction.

Comparative study between normal female and affected female also shows more number of ulnar loops (23.75\%) in students affected with dental caries compared to normal females who had equal per centages of radial loop (28\%) and ulnar loop (28\%). The results of this study also shows similarity with the affected males with the highest per centage of ulnar loop (19.17\%) followed by radial loop (18.33\%) compared to control males with radial loop (35.72\%).Thus ulnar loops may be an indicator to assess the susceptibility of an individual to dental carries.

Comparative studies also show a difference in the per centage of whorl fingerprint pattern. Spiral whorl pattern has a difference in which the per centage of affected is more (37\%) and in case of normal it is very less (5\%). Similarly, elliptical whorl for affected is 8\% and for normal it is 3\%, accidental whorl is present in unaffected individuals but is absent in affected individuals. Our result corroborates the results \[2\] which established the prevalence of dental caries with whorl pattern.

Conclusions

It is hereby concluded from our research that

1. Frequency distribution of fingerprint patterns among normal students differs from affected students.

2. Frequency of ulnar loop pattern is more prevalent followed by radial loop pattern in individuals with dental carries, with no occurrence of accidental whorls. This may serve as a predictor between fingerprint patterns and dental caries. The frequency of ulnar loop is more in right hand compared to left hand followed by the radial loop pattern. More radial loops are a negative indicator for dental caries. Spiral whorls can also be a predictor for dental carries as it is followed by the ulnar loop in affected individuals.

3. Out of the 40 individuals, 10 males and 10 females were affected which may indicate equal occurrence in both and this might be genetical or oral hygiene in the age groups of 6-14 years students which however, require further study.

4. Thus dermatoglyphics gives a hope in the prediction of dental caries much before its initiation giving a sufficient time to implement preventive measures. So further studies is required to be carried out in the field of medicine with their related genetical studies and more comparative studies with large samples

Trends & Pattern in Unnatural Female Death Cases Due to Burn: A One Year Retrospective Study

Manjit Nayak¹, Saumil Merchant², Kalpesh Shah³

¹Tutor, (PhD Scholar-Gujarat University) Department of Forensic Medicine & Toxicology, B.J Medical College, Ahmedabad, ²Professor & Head, (PhD Scholar-Gujarat University) Department of Forensic Medicine & Toxicology, AMC MET Medical College, Ahmedabad, ³Professor & Head, (PhD Guide-Gujarat University) Department of Forensic Medicine & Toxicology, B.J Medical college, Ahmedabad

Abstract

Burns are the injuries that are produced by application of dry heat such as flame, radiant heat or some heated soiled substance like metal or glass from the surface of the body resulting in tissue destruction. According to WHO estimates about 2,65,000 deaths occur each year from fires alone globally, with more deaths from scalds, electrical burns, and other forms of burns for which data are not available. The majority of these deaths occur in low- and middle-income countries, with almost half occur in the WHO South-East Asia Region. In India around 7 million people suffer from burn injuries each year with 1.4 lakh deaths and 2.4 lakh people suffer with disability. Burn death rates have been decreasing in high income countries. Burn injury are higher in females than males. The higher risk for females is associated with open fire cooking, or unsafe cook stoves, loose clothing. Self-directed or interpersonal violence is also a factor for burn injuries. The present study is retrospective study which was carried out in the Department of Forensic Medicine and Toxicology at B. J. Medical College and Civil Hospital, Ahmedabad during the period from January 2018 to December 2018 to determine trends & pattern in unnatural female death due to burns cases and their practical approach to shrinkage the incidence of female burns cases as much as possible. In study we come across some particularized factor which exaggerated the recent condition in the society. The various facets are investigated and conferred in specifics.

Keyword: Unnatural female death, thermal injury, Septicemia

Introduction

Burns are a critical public health problem, causing deaths, disability and disfigurement. Globally, there are about 300,000 deaths due to burns every year. Of these, 95% take place in developing countries with Southeast Asia recording nearly 57% of deaths due to burns.¹ World Health Organization (WHO). A who plan for burn prevention and Care. 2008; WHO: Geneva.² Extrapolation of data from major hospitals indicates an estimation of 7 million burn incidents in India each year, making burn injuries the second largest group of injuries after road accidents. In 1998, India was the only country in the world where fire was among the 15 leading causes of death, according to WHO.³ However, the Government of India has not put in place a national injury surveillance system, hence the exact incidence of burn-related morbidity and mortality is not known. In 2010, the Government of India announced the National Programme for Prevention of Burn Injuries (NPPBI) which aims at prevention, burns injury management and establishment of a central burn registry, but its impact is not yet noticeable.⁴ A study of women’s health priorities based on the 2004 mortality estimates and disease burden of the WHO Global Burden of Diseases Study found that burns in young women were common in Southeast Asia, with it being the third cause of death for women aged 15–44, followed by self-inflicted injuries.⁵ Burn-related injuries and deaths amongst women in India are likely to be caused by: kitchen accidents related to use of kerosene and flammability of garments; self-immolation or suicides; and homicides related to domestic violence. Evidence suggests that domestic violence (physical, sexual and emotional), which is widespread in India, could have an important role in these burn injuries.⁶
The NCRB records show 122,877 cases of violence by husband or relatives, 8,455 dowry deaths and 2,233 suicides among women due to dowry harassment in 2014. The NCRB data is based on cases registered with the police and these numbers are therefore grossly underreported and may not provide accurate data on burn injuries. A burn injuries death is very excruciating but what compels or in what surroundings women commits suicide or homicide or those accidentally burned but most heinous is burning of newly married women i.e. homicidal burning. In this respect it is very difficult to find out the manner (Suicidal, Accidental and Homicidal) of burn injuries that in what circumstances the burn injuries took place, it can only be possible by meticulous investigation of scene of crime and interrogation of person concerned.

Aims & Objective

To find out burn affect in respect to sex, religion, season, time of incidence, marital status, total body surface area distribution (TBSA), Duration of survival, alleged history, manner & cause of death wise distribution and Its medico-legal consequence.

Materials & Method

This study was carried out in the Department of Forensic Medicine and Toxicology at B. J. Medical College and Civil Hospital, Ahmedabad during the period from January 2018 to December 2018. The Proforma of the study was prepared and numerous information and conclusions were collected & analysed from Post-Mortem report records & hospital data records. Data has been analysed in respect to sex, religion, season, time of incidence, marital status, total body surface area distribution (TBSA), Duration of survival, alleged history, manner & cause of death wise distribution. The details were accumulated, tabulated, discussed & concluded.

Observations & Result

Total 3930 Autopsy were conducted in B.J Medical college, Ahmedabad during during the period from January 2018 to December 2018 among them 816 (20.76%) cases are unnatural female death cases. Unnatural Female death cases due to burn(Thermal injury)(64.25%) are near to double than the unnatural death cases due to burn male death (35.75%) cases. It shows the definite crucial factor in gender-biased in the society. Religion wise distribution of burn female cases shows more incident in Hindu Female(48.81%), and Muslim Female(39.89%) than others. Hence highest in the Hindu religion among all. Unnatural burn(Thermal) injury cases are more predominant in winter(Nov-Feb) (46%) & Summer(March-June)(40%) than in rainy season(July-Oct)(14%) Incidence of unnatural female death due to burn cases are more prone in Morning(6am-12 pm)(37%) & Evening(6pm-12am) (39%), as they are more active in cooking related activities where incidence of accidental burns are more prominent. Triple times of incidence of unnatural female death due to burn in female in married female (64%) than unmarried(23%) is noted as dowry and other social factors are responsible in married female.

Averagely 30-40% of Total body surface area (TBSA)(21%) & 40-50% of TBSA(20%) involved in unnatural female death cases and lesser in 10-20% (1%) & >80%(5%).

Discussion

The present retro-spective study which was carried out in the Department of Forensic Medicine and Toxicology at B. J. Medical College and Civil Hospital, Ahmedabad during the period from January 2018 to December 2018 to determine trends & pattern in unnatural female death due to burns cases and their practical approach to shrinkage the incidence of female burns cases as much as possible. In study we come across some particularized factor which exaggerated the recent condition in the society.

In a total of 381 cases of burns, females formed the majority with 64.25% which is in harmony with the
studies of Chawla et al.17, Mazumdar et al.8, Aggarwal9 and Chandra, Doshi10, Ganguly11, Sinha et al.12, Haralkar and Rayate13, Naralwar and Meshram14. The reason may be accredited to the fact that women in India are accountable for the domestic duties including cooking where due to cultural and religious motives they wear dangerously long and loose fitted clothing. This together with lack of safe installation of cooking appliances that involves chullah, kerosene stove burst and gas leakage, making them the more vulnerable gender.

Majority of the burn victims were Hindus (48.81%) of the total burn Female victims) which is similar to the findings of D. Nath15 P.Singh16. The reason being Hinduism is the largest religion practised in India where the previous dowry system and “sati pratha” still existed in rural area.

Seasonal variations in our study showed that burn deaths occurred mostly in winter(46%) followed by summer(40%).17 This might be due to the fact that, in winter, there is more need for hot water for bathing. The traditional kerosene stove; which is extensively used in the slum areas city for cooking and providing the necessary boiling water for bathing; lacks any safety measures more in Morning (37%) & evening(39%).

Thus, it is condemned to be responsible for much of the flame and scald burns in our country. This fact has been previously highlighted by the work of reporters from low income countries.18

The domestic violence can be further reinforced by the marital status of the genders in this study in which, the majority of the female death due to burn victims were married (64%) than unmarried(23%).19 Average 30-40% of TBSA(21%) & 40-50% of TBSA(20%) involved in unnatural female death cases.

Though the majority of the incidents are accidental in nature, suicidal and homicidal cases were also observed. As noted with other studies, accidental burning was the commonest manner of deaths due to burning followed by suicidal and homicidal burning.20-23 More incident noted in Previous suicidal attempt(27%) than Psychiatric illness(10%),chronic illness(13%),addiction(15%) and more in accidental(41%) than suicidal(24%)

Shock is found to be the most common cause of death in most of the victims, which is similar to the findings of Chawla R, Chanana A, Rai H, Aggarwal A.D et al7, Singh P, Sharma16 and D. Nath.15 Shock (neurogenic[25%], hypovolemic[14%]) is more common in 1-2 day period after burn injury. Any kind of injury including burn injury was the common source of infection, which resulted in septicaemia,pneumonia,renal failure and septicaemic death. Lack of care on the part of the doctor was the main reasons for the septicaemic deaths in the burn victims.

### Conclusion

Female(64.25%) are more prone to death due to Burn (Thermal) injury than male(35.75%) in this retrospective study almost near double. Hindu Female(48.81%) & Muslim female (39.89%) are more indulge to death due to Burn(Thermal) injury than others. There is increased incidence of death due to burn injury in summer(March-june) (40%) & winter (Nov-feb) (46%) than in rainy season. There is increased incidence of death due to burn in Morning(37%) & evening(39%) as Female are more active in cooking during this time period. Married woman(64%) are more prone to thermal injury than unmarried & widow. Averagely 30-40% of TBSA(21%) & 40-50% of TBSA(20%) involved in unnatural female death cases. Duration of survival after incidence is least in more than one month. Alleged history of previously attempted suicidal attempt (27%) are more prone to burn(Thermal) injury for unnatural female death. Accidental burn (41%) cases are more predisposed than others. Death due to burn are more (28%) in septicaemia,pneumonia ,acute renal injury & Neurogenic shock (25%).

Effectiveness of Structured Exercise Programme Versus Elastic Band Exercice on Individuals with Rounded Shoulder

Geetan Manoj Pathak1, Khushboo Chotai2, Smita Patil3, Amrutkuvar Rayjade4
1Internee, 2Associate Professor, Department of Sports physiotherapy, 3Assistant Professor, Department of Musculoskeletal sciences, Krishna College of Physiotherapy, 4Associate Professor, Department of Orthopaedics and Manual therapy, Krishna College of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra

Abstract

Background: Rounded shoulder is a common postural abnormality in young adults due to abnormal posture adaptation while working. It may lead to decrease in thoracic mobility and increase in intradiscal pressure. In severe cases breathing problem may occur due to changes in the anterio-posterior diameter. Few studies have shown the effect of elastic band exercise on rounded shoulder to improve the postural alignment. Shoulder stabilization exercises and pectoralis minor stretching is also effective in rounded shoulder. In these study structured exercise were use to correct the rounded shoulder posture and to prevent the further complication.

Objective: To find out the effectiveness of structured exercise programme on subjects with rounded shoulder.

Material and method: In this pre-post intervention study 32 individuals with rounded shoulders were included. They were randomly divided into 2 groups with 16 individuals in each group. Group A were treated with structured exercises and Group B were treated with elastic band exercises for 4 weeks. After pre-post assessment, data was analysed with the help of appropriate statistical methods.

Results: According to the statistical analysis there is significant decrease in measurement of rounded shoulder in both Group A and Group B with p value <0.0010 and <0.0001 respectively.

Conclusion: Structured exercise and elastic band exercises both are equally effective in improving the rounded shoulders.

Keywords: Rounded shoulders, vernier calliper, structured exercises and elastic band exercises.

Introduction

Rounded shoulder posture is the commonest abnormal structural anomalies of the shoulder complex. Incidence of rounded shoulder posture is increasing in young adults due to repetitive work and bad posture while working.[1] It is a posture in which scapulae are elevated and the acromion processes are protruded forward to compromise the centre of gravity. It involves anterior tilt of the cervical vertebra and the posterior tilt upper thoracic vertebra which leads to shoulder protraction, turn downwards and anterior tilting.[1,4]

Any changes in the skeletal alignment can indicate changes in antagonist and agonist muscles, imbalance in stretching and shortening of muscles. Inappropriate posture may aggravate the pain and soft tissue damage. Rounded shoulder increases the thoracic kyphosis which abdominal muscles may shorten and the anterior part of vertebral bodies is compressed it leads to increase in the intradiscal pressure.[1,11]

Stretching of trapezius muscle is also seen in this individual due to scapular protraction. In individuals with this condition there is shortening of pectoralis
minor due to adaptation and through the restriction of the scapular motion.[1,12,13,14]

In this study to assess the rounded shoulder vernier calliper was used. Patient position is supine and examine the distance between plinth and the acromion process with vernier caliper. If the distance is > 2.5 cm then the individuals are included in this study.[2,19]

Posture correction programs can correct the postural alignment and help in decreasing the pain. In this study elastic band exercise and structured exercise programme was used to correct the rounded shoulders. Velocity and intensity of elastic band can be varied. It is used to improve the muscular strength, flexibility and balance control. Elastic band exercise programme consists of the following exercises – lateral pull down, shoulder external rotation, shoulder horizontal abduction exercise, a seated bend row, shoulder abduction exercise, shoulder flexion exercise, shoulder extension exercise. 1) For lateral pull down subjects held both the ends of elastic band and stretch the band in sideway direction and pull it down to their chest, abdominal muscles should be contracted while performing this exercise. 2) To perform shoulder external rotation subjects should be in standing position and their elbow in 90 degree, palm towards the ceiling. Elastic band should be stretch in outward direction while performing this, elbow should be in stable position. 3) Shoulder horizontal abduction – subjects extend their arm in front of their body at 90° and place the shoulder width apart. Their palm should face down and held the elastic band and slowly stretch the elastic band horizontally keep elbow straight while performing it. 4) In seated bend row, the subjects place the elastic band in such a way that their leg should be in middle of the band and stretch the band towards body. 5) Shoulder abduction exercise – subjects should keep one feet on the elastic band and another end of elastic band should be hold on one hand after that stretch it out in outward direction or away from the body. 6) For the shoulder flexion exercise kept one end of elastic band under feet and another end hold in hand, perform shoulder flexion with elbow straight. 7) Shoulder extension exercise, the examiner hold one end of elastic band and other end hold by the patients and ask them to extend the arm backward with elbow straight as much as possible.[3]

In structured exercise programme exercises consists of- chin tucks, reverse plank, cat and camel, Bhujangasana ( cobra pose), wall push ups, shoulder blades squeeze. Chin tucks is exercise to improve the neck strength, flexibility and neck function. To perform it subjects should sit upright, place a finger on chin then pull the chin until the stretch is felt. Hold it for 10 seconds and repeat for 10 times, per session. Reverse plank is done in supine position subject should be in supine position place a palm on floor slightly behind hips. Press the palm and lift the hips towards ceiling, squeeze the core muscle and hold it for 5-10 seconds. To perform cat and camel subjects should be in quadrupod position, slowly alternate between arching and rounding your back so that spine extend and flex alternately. In cobra position subjects should patients should be in prone lying gently lift the forehead, elbow should be straight while performing it and hold the position for 10 seconds and it will be done for 10 times. Wall push ups- patient should stand in front of wall keep one arm distance between wall and patients then palm should be rest on wall after that gently try to push the wall and come forward towards wall. Shoulder blade squeeze- in standing position patient should keep arm at sides then squeeze the shoulder blade together.[5,6,7,8]

Rounded shoulder may cause complications like increase in intradiscal pressure, decrease in thoracic mobility and in severe cases there may be breathing problems. Rounded shoulder should be corrected with the help of stretching and strengthening exercise of the scapular muscles to prevent the further complications.

**Methodology**

An experimental study was carried out using pre and post study design. The place of the study was Krishna institute of medical sciences, Physiotherapy department, Karad. There were 32 participants in the study with rounded shoulders. The samples were chosen using the simple random sampling method. Participants was included as per inclusion and exclusion criteria.

**Procedure**

Subjects were selected for the study according to the selection criteria. Demographic data and consent form was taken from them. Included participants was divided into two groups by random sampling method. Pre and post assessment was taken before and after 4 weeks of the treatment respectively with the help of outcome measures. Group A received structured exercise programme, 15 repetitions of 3sets, 3 times per week for 4weeks. Structured exercises consist of chin tucks, reverse plank, cat and camel, Bhujangasana ( cobra pose), wall push ups, shoulder blades squeeze,
shoulder shrug.

Group B received elastic band exercise consists of lateral pull down, shoulder external rotation, shoulder horizontal abduction exercise, a seated bend row, shoulder abduction exercise, shoulder flexion exercise, shoulder extension exercise. Each exercise are for 15 repetitions of 3 sets per session, 3 session per week. The effect of each treatment were assess after 4 weeks using outcome measures.

The effect of exercises of the group was noted with the help of outcome measures. The experimental results was statistically analysed. The significant difference between the two groups was investigated with the unpaired t test and within the group with paired t test.

### Findings

Pre and post data was analysed according to the result within group A of both right and left side and it considered extremely significant with p value <0.0010. The mean ± SD of pre assessment of left and right side is 6.36 ± 1.17. Mean ± SD of post assessment of left and right side is 5.80 ± 1.06 (fig. no. 1).

The pre and post data was also analysed according to the result within group B of both right and left side and it considered extremely significant with p value <0.0001. The mean ± SD of pre assessment of left and right side is 5.90 ± 0.95. Mean ± SD of post assessment of left and right side is 5.73 ± 0.91 (fig. no. 2).

The mean ± SD of post intervention of group A is 5.80 ± 1.06 and of group B is 5.73 ± 0.91 (fig. no. 3).

### Discussion

This study aimed to investigate the effectiveness of structured exercise programme versus elastic band exercise on individuals with rounded shoulder with an objective of finding the benefits of each exercise and comparing its effects to fulfil the aim of the study.

The individuals with rounded shoulders are assessed with the help of vernier caliper. There were 32 participants which were selected according to the inclusion and exclusion criteria and they were randomly divided into 2 groups (group A and group B) with 16 in each group. Group A was asked to perform structured exercises and group B was asked to perform elastic band exercises. Pre and post assessment were taken prior to treatment with the help of vernier calliper. In structured exercise programme exercises included are chin tucks, reverse plank, cat and camel, Bhujangasana (cobra pose), wall push ups, shoulder blades squeeze. Elastic band exercises are lateral pull down, shoulder external rotation, shoulder horizontal abduction exercise, a seated bend row, shoulder abduction exercise, shoulder flexion exercise, shoulder extension exercise. The study was carried out for 4 weeks 5 times in a week. After the pre
and post assessment the data was statistically analysed.

The result indicated that both the exercise groups appeared to be equally effective in improving the rounded shoulder posture. Various study showed that stabilization exercises and stretching exercises are helpful in improving rounded shoulder posture\(^1\). According to the study by author Kim TW, An DI, Lee HY, Jeong HY, Kim DH, Sung YH\(^2\) which was on effects of elastic band exercise on subjects with rounded shoulder posture and forward head posture suggest that elastic band exercises are effective in improving the rounded shoulder posture.

**Conclusion**

On the basis of the result it is concluded that the structured exercises and elastic band exercises are equally effective in improving the posture in individuals with rounded shoulders. The impact of these exercises on the rounded shoulders needs to be taken into consideration.

**Acknowledgement:** I sincerely thank the management of KIMSDU for allowing me to conduct this study by providing me the necessary requirements. I thank dean Dr Varadharajulu sir for his support and guidance. My sincere thanks to guide Dr Khushboo Chotai for helping me in my research. Effectiveness of Cognitive Therapy in Post-Menopausal Women

Mrunal V Ghangrekar¹, Trupti Yadav², Amrutkuvar Jadhav³, Smita Patil⁴

¹Intern, ²Assistant Professor, ³Associate Professor, ⁴Assistant Professor Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed to Be University, Karad, Maharashtra, India.

Abstract

Objective: To find the effectiveness of cognitive therapy in post-menopausal women.

Method: The study group consisted of 50 post-menopausal women, aged between 45-65 years, screening of 100 women was done and 50 women having cognitive changes and fulfilling the inclusion and exclusion criteria were selected. They were given exercises for 4 weeks, 4 times per week and pre-post result were calculated on the basis of attention, memory, anxiety and depression. The scores were measured by using mini mental scale, mood scale and Hamilton depression rating scale.

Conclusion: The results demonstrated that there is statistically extremely significant difference in cognitive changes in post menopausal women. (p >0.0001)

Key Words: post-menopausal, women, cognitive changes.

Introduction

Menopause is defined as time of cessation of ovarian function resulting in permanent amenorrhea. The climacteric is the phase of weaning ovarian activity, and may begin 2-3 years before menopause and 3-4 years after menopause, it also involves physical, sexual and psychological adjustments. Menopause in India generally occur at the age of 45-50 years (mean age 47 years). During this phase ovarian activity declines, no corpus luteum is formed and no progesterone is formed. Later graafian follicles fail to develop and estrogenic activity is reduced¹.

Due to these changes’ women suffer from various symptoms initially such as hot flushes, sweating, insomnia, headache, osteoporosis etc. Ovarian estrogen begins to decline 1 or 2 years before menopause and becomes stable 2 years after menopause. Direct effects of estrogen influences brain function through effects on vasculature and immune system. Estrogen actions are potentially relevant to cognitive changes occurring after menopause. Estrogen enhances neurite growth, neurogenesis, long term potentiation and episodic memory and has influence on neurotransmitter. Functional brain imaging studies demonstrate that estrogen modulates neural activity during performance of cognitive task. Around the time of menopausal transition, many women report problem with memory (episodic memory), attention n, sleep problems, poor concentration, difficulty recalling an acquaintances name, leading to anxiety and depression. Factors such as mood, stress, physical heath may also contribute to memory symptoms.²

Cognitive therapy states that thoughts, feelings and behavior are all connected and that individual can move towards overcoming difficulties and meeting their goals by identifying and changing unhelpful or inaccurate thinking, problematic behavior and distressing emotional responses. This also involves the individual testing and modifying beliefs, identifying distorted thinking, relating to others, relaxation and many techniques to improves your overall performance.

Cognitive therapy is a systematic process utilizing leisure activities and other interesting activities as interventions to address the needs of individuals with cognitive impairments as a means of recovery and well-being.

Study regarding the effects of cognitive therapy on memory, attention, anxiety and depression has not been conducted. We wanted to study its effect in postmenopausal women in whom attention and memory is reduced and signs of depression and anxiety are present.

Materials and Methodology

An approval for the study was obtained from the Protocol committee and the Institutional Ethical Committee of KIMSDU. A study was conducted for a duration of 6 months which was conducted in and around Karad. Individuals were approached and those fulfilling the inclusive criteria were selected.

Subjects

All participants were selected by Convenient sampling method. Each of them was selected according to the inclusion criteria. Female participants were included. Individuals having cognitive changes and willing to participate, between age group 45-65 years were included. Women having any other neurological deficit, any hormonal therapy, suffering from depression and women who had surgical menopause were excluded from the study. 100 participants were screened for the study, 50 individuals who fulfilled the inclusion and exclusion criteria was selected. The procedure was explained and written informed consent were taken from those willing to participate. A session was held in Karad, where data collection was done and exercises were performed for 4 days per week for 4 weeks. Demographic information of the subjects was collected. Primary outcome measure used was Mini mental scale, Mood scale, Hamilton depression rating scale. All the score was taken before and after the treatment.

If the individuals were explained about the purpose of the study. They were informed about the procedure. Each participant was assessed and the scores were calculated and the Data was recorded for the individual participant.

Statistical Analysis

Statistical analysis was done using unpaired t test. The analysis was performed using the software Instat. Arithmetic means & standard deviation was calculated for each outcome measure and Arithmetic mean was derived from adding all the values together and dividing the total number of values. MS Excel was used for drawing various graphs with given frequencies and the various percentages that were calculated with the software.

Standard deviation (SD) was calculated according to the following formula:

\[
SD = \sqrt{\frac{1}{N} \sum (X - \mu)^2}
\]

Results

The results showed that there is extremely significant difference in cognitive changes in postmenopausal women. (p value >0.0001)

Discussion

The current study was aimed to find the effect of cognitive therapy in postmenopausal women with memory, attention, anxiety and depression difficulty when given for 4 weeks. Total 100 post-menopausal women were screened and 50 individuals having cognitive changes and fulfilling the inclusion and exclusion criteria were selected. Objectives of this study was to find whether there is any effect of cognitive therapy on postmenopausal women with memory, attention, anxiety and depression difficulty; and if yes, how did it affect the daily activities.

A study by Henderson VW compared various age groups with cognitive changes due to estrogen activity. He reported the changes that occur in midlife and later in lifetime. There was significant decline in cognitive changes after 80-85 years and drug therapy showed no improvement in the cognitive changes. In this article we have selected the age group between 45-65 years as cognitive changes are seen more in this age group.

A recently reported randomized trial of selective estrogen receptor modulator reported on cognition in postmenopausal women revealed no significant difference, although the women who received raloxifene tended to have a slightly lower risk of decline in cognitive therapy as measured by testes of verbal memory and attention. Raloxifene and estrogen may not affect overall cognition but may protect against the development of
cognitive impairment.  

Previously conducted research on estrogen activity on the structure and function of brain areas was known to be involved in memory and attention. Controlled study of administration of estrogen to postmenopausal women have found that estrogen enhances verbal memory and maintain the ability to learn new material.  

Previously conducted research on HRT activity concluded that there is good evidence that both HRT and ERT do not prevent cognitive decline in older postmenopausal women when given as short term or long-term therapy. It remains to be determined whether factors such as younger age, type of menopause, type of treatment, mode of delivery, and dosage have any positive effects at clinically relevant level. The main cause of change in cognitive function is associated by the activity of estrogen to protect and maintain brain structures. Thus, it is biologically plausible that maintaining high levels of estrogen in postmenopausal women could be protective against cognitive decline.  

Previously conducted study on cognitive therapy in depression reviewed that cognitive therapy is more effective than behavior therapy or any other forms of psychotherapy addition, it appears that cognitive therapy is independent of the length of the therapy, because the average length of therapy in this study was only 14.9 weeks. It is not clear, however, to what extent the process of cognitive therapy achieves changes in depressive types or to what extent cognitive therapy achieves its therapeutic outcomes through the specific modification of cognitive distortions or depressogenic assumptions.  

A study conducted on cognitive rehabilitation for attention deficits following stroke stated that cognitive therapy can improve alertness and sustained attention but there is no evidence that it helps people to do daily activities without help after stroke. Attention problems can occur following stroke, although there is spontaneous recovery with cognitive therapy. The exact mechanism is still unknown and more study needs to be done.  

There are cognitive changes seen even after HRT, ERT drug treatment and patients with stroke who are not under medications have showed significantly improved results by cognitive therapy. Hence, cognitive therapy may also effective in post-menopausal women. From the above-mentioned effects of cognitive therapy on memory, attention, anxiety and depression. It may significantly improve cognitive functions in postmenopausal women.  

**Conclusion**

The present study provided evidence to support the use of cognitive therapy in reducing the depression and anxiety and increasing the memory and attention in post-menopausal women. Thus, the Alternate hypothesis is proved.

Effect of Meditative Movement Exercises with Breath Control on Depression in Nulliparous Women

Mrunmayi Sandip Gadre1, T Poovishnu Devi2

1Intern, 2Associate Professor Department of Cardio - Pulmonary Sciences, Krishna college of physiotherapy, KIMS “Deemed to be” University, Karad, Maharashtra, India

Abstract

Background: The prevalence of nulliparous women in India is 66% out of 8 million married women. In nulliparous women depression is the most common factor due to various other factors as single mother, or are not able to conceive, low income earners and those in unsupportive social situations. So as to reduce the depressive symptoms or thoughts we can teach them a set of meditative movement exercises specially in women who are nulliparous.

Objective: To study the effect of meditative movement exercises with breath control on depression in nulliparous women.

Methodology: The study was conducted in and around Karad, Maharashtra, and was carried over a period of 12 weeks. Study was conducted using sample size of 22 nulliparous women with minimal to moderately severe depression. The inclusion criteria was age group of 25 – 35 years females with exclusion criteria as history of high blood pressure, chronic medical illness and major psychiatric problem.

Results: Statistical analysis for effect of meditative movement exercise on depression in nulliparous women was extremely significant (P value=0.0001). It was extremely significant during pre-test as well as post-test. So there is improvement in the depression score after teaching the exercises to the individuals.

Conclusion: From this study, it can be concluded that the individuals showed improvement in depression levels after teaching them the meditative movement exercises.

Key words: depression, nulliparous women, breath control, age group 25-35 years, meditative movement exercises.

Introduction

Nulliparous means a women who has never given birth either by choice or for any other reason. This term is also used in case of women who give birth to a still born baby, or a baby who is not able to survive outside the mother’s womb. Globally 75% of women are nulliparous and have problems in conceiving. In India, 66% of 8 million married women are nulliparous. Among married young women aged from 20 to 24 years about 9.1 million are nulliparous. The main causes which lead to nulliparity in women can be ovulation problems caused due to polycystic ovarian syndrome, due to older age as in this period the female may face various problems as high blood pressure or gestational diabetes, nulliparity can also be caused due to endometriosis as they block the fallopian tube cause disrupt implantation and impact the egg quality, the other cause can be overweight due to inactive lifestyle or due to any eating disorder as anorexia or bulimia, due to tubal issues caused mainly due to STD and due to uterine abnormalities i.e. due to fibroids which develop within the wall of uterus.

Women who can’t conceive often experience distressing emotions as shock, depression, anger and frustration as well as loss of self-esteem, self-confidence. They may also avoid social interaction with family and friends. Depressive disorders have become a widespread health concern throughout the world. The worldwide prevalence of depression and anxiety has been estimated at 10.4%. Some of the reasons nulliparous women struggle with depression include stress due to pressure on the women to get pregnant,
medical conditions such as PCOS may also increase the risk of depression, the emotional and physical challenges of treatment for infertility. It is not unusual to feel depressed occasionally. However, when these feelings persist over time and affect a person’s quality of life, they may be experiencing depression. Some symptoms of depression are loss of interest in most activities, sleeping too much or too little, having low energy, feeling worthless, trouble in concentrating or thinking. There are no studies being conducted on whether depression can cause infertility in women though some studies have just found a correlation between depression and increased rates of infertility. Also, depression may lead to lifestyle habits that can negatively impact fertility. For example, depression often causes overeating, being overweight or underweight which can cause infertility in women. Another factor is women who are depressed may often smoke or drink which can also cause problems to conceive. For measuring the depression level of the subject PHQ-9 questionnaire was used, which is basically used in multipurpose screening, diagnosing, and measuring the severity of depression.

To reduce the nulliparity and depression there are various exercises. Studies show that physical activity reduces depression and anxiety. Exercise also helps to reduce the risk for physical comorbidities that occur with depression. Studies show that moderate regular exercise can improve fertility and the chance of conceiving increases. Studies has shown that vigorous exercise reduces the risk of ovulation and that moderate exercise decrease the risk of miscarriage and increase the chance of conceiving. While some studies show that low intensity exercises are helpful in reducing nulliparity as meditation, yoga etc. whereas high intensity exercises should be avoided as it may reduce the fertility. So, teaching low intensity exercises is helpful in women who can’t conceive. There are various ways as relaxation, meditative movement exercises as well as yoga.

Payne and Godreau (2013) used the term Meditative Movement for forms of physical exercise which concentrates towards the bodily sensations, including proprioceptive, interoceptive, and kinesthetic sensations. The general overall purpose of meditative movement exercise is to increase vitality, balance circulation and to harmonize body-mind relationship. Meditative movement exercises has shown a positive effect on depression. These cause change in levels of cytokines and growth hormone. As this exercise increases the body temperature and at the same time the temperature of brain increases which results in feeling of general relaxation. It also prevents various disorders and improve the functioning of the body which helps in reducing the depression in these women. It also increases the appetite and quality of sleep.

**Material and Methodology**

An approval for the study was obtained from the Protocol committee and the Institutional Ethical Committee of KIMSDU. An Experimental study was conducted for duration of 6 months at Physiotherapy department of Krishna college of Physiotherapy. Individuals were approached and those fulfilling the inclusive criteria were selected. This study included 22 individuals with depression according to inclusion and exclusion criteria. These individuals were given a PHQ-9 questionnaire prior to check the level of depression they had on minimal to moderately severe depression scale. Then according to the level of depression and the inclusion criteria individuals were selected and were taught all the meditative movement exercises. These exercises are performed in sets lasting about 20min per day. These are followed in following ways-

**Outcome Measures:**

The outcome measure used for this study was PHQ-9 Questionnaire.

This questionnaire aims at evaluating the degree of depression severity. It is a multipurpose questionnaire used for screening, diagnosing, monitoring and measuring the severity of depression.

**Statistical Analysis**

Statistical analysis of the recorded data was done by using the software SPSS version20.

22 subjects were successfully completed by giving them the questionnaire prior and after teaching them exercises. The result showed that mean of the pre-test score of depression is 13.22 and SD is 1.744. The mean value of post test score of depression is 7.318 and SD is 1.524.
### Result

The statistical analysis for the pre-test depression score shows significance and after the exercises given to the subjects the post-test depression score is extremely significant. There was improvement in the depression score after giving the meditative movement exercises.

### Discussion

Depression has been a major widespread health concern. The worldwide prevalence of depression has been estimated at 10.4% (Andrews et al 2000). During pregnancy, depression affects 10-50% of women with the incidence being higher in low socioeconomic status. Many studies have been conducted on effect of aerobic exercise training on depression in nulliparous women but there are very few studies on this category of exercises. The present clinical trial was conducted to compare the effectiveness of meditative movement exercises with breath control on depression in nulliparous women. Results of this study were focused on improving or reducing the depression in nulliparous women by advising them set of meditative movement exercises.

In this study, 22 nulliparous women suffering from minimal to moderate depression were selected between the age group of 25-35 years. They were selected based on the inclusion criterion. They were given a PHQ-9 questionnaire prior, to check the level of depression before advising them the meditative movement exercises. After filling the questionnaire from the subjects they were checked on the basis of having minimal or moderately severe depression according to that they were given a set of meditative movement exercises. They were advised to do these exercises daily for 15 to 20 minutes. After giving them the exercises, the subjects were assessed again after 3 months to check the effect of those exercises on depression level. The percentage of depression before the test is 59% moderate depression, 35% moderately severe depression, 5%mild depression and 1% minimal depression and after teaching them the exercises the percentage of depression is 71% minimal depression, 23% mild depression, 5% moderate and 1% moderately severe depression.

Our study showed that there were considerable changes with significant difference seen in the level of
depression in the nulliparous women, as we analyzed that the changes in the PHQ-9 questionnaire for screening the depression level, before and after incorporating meditative movement exercises.

In a study done by Angelo Fernando Robledo-Colonia, they showed effect of aerobic exercise training on depression in nulliparous women where they had an experimental group to perform 60-min exercise classes per week, starting from week 16 and 20 of gestation and continuing for 3 months. Sessions consisted of walking, stretching, aerobic exercises with relaxation.

In another study done by Eun Sun Ji, RN, they showed effect of Qi exercises on maternal/fetal interaction and maternal well-being during pregnancy where they selected 18 weeks pregnant women and gave them Qi exercises to perform twice a week for 90 minutes for 12 weeks. The results showed that Qi exercises lowered maternal depressive symptoms and improved the physical health of the mother.

This study showed has a positive influence among the nulliparous women with depression. And results were found to be statistically significant by the use of PHQ-9 questionnaire.

**Conclusion**

After analyzing the data, it was found that there is a significant effect of meditative movement exercises with breath control on depression in nulliparous women.

**Abbreviations:**

PHQ-9: Patient Health Questionnaire

MME: Meditative movement exercises

**Conflict of Interest:** There is no conflict of interest concerning the interest of study.

**Source of Funding:** This study is self-funded.

**Ethical Clearance:** The study was approved by institutional ethical committee of KIMSDU.

To Assess Dentist Knowledge About Lipid Treatment of Local Anesthetic Systemic Toxicity

Nitin Bhagat¹, Rohit Sharma², Siddharth Rawat², Sheikh Abrar³, Singh Priyanka Jaiprakash³
¹Associate Professor, ²Lecturer, ³2nd year Post Graduate Student, Dept of Oral and Maxillofacial Surgery, School of Dental Sciences, Sharda University

Abstract

Background: The present study was conducted to assess dentist knowledge about lipid treatment of local anesthetic systemic toxicity.

Materials & Method: This study was conducted on 260 dentists of both genders. All were provided with a questionnaire. Information regarding LAST, signs of LAST they encountered and treatments for LAST, the length of professional experience, training on local anesthesia, LAs used most often, side effects seen most often were recorded.

Results: Out of 260 dentists, 140 were male and 120 were female. 0-5 years experience was seen in 20, 5-10 in 70, 10-15 years in 50 and >15 years in 120 dentists. The difference was significant (P< 0.05). 62% had no idea of lipid treatment, 23% had heard but did not have enough knowledge of it, 13% had read an article about lipid treatment and 2% knew how to use lipid treatment. The difference was significant (P< 0.05). 85% had never seen LA toxicity, 12% had not use lipid treatment in local anesthesia toxicity and 3% had use lipid treatment in local anesthesia toxicity. The difference was significant (P< 0.05).

Conclusion: Authors suggested that dentists must be aware of LA toxicity and knowledge of how to treat it.

Key words: Knowledge, LAST, local anesthetic

Introduction

An ideal local anesthetics should be potent, reversible, low cost, stable, and easy to metabolize and emit. Furthermore, it should have rapid onset action, suitable duration of effect, and good tissue penetration. Another one of the important qualifications is that there should be no adverse effect, neither local nor systemic.¹ Complications due to local anesthesia can be divided into three major areas; complications associated with vasoconstrictor, needle, and absorption of local anesthetics. Complications associated with the added vasoconstrictor include elevated blood pressure and increased heart rate. Another complications associated with the needle include syncope, hematoma, pain, edema, infection, paresthesia, nerve paralysis, and breakdown of needle or cartridge. Absorption of the local anesthetics includes local reaction, idiosyncrasy, toxicity, and allergy or anaphylactic reaction.² All amidetype LAs can cause local anesthetic systemic toxicity (LAST), and in addition, risk of cardiovascular system (CVS) and central nervous system (CNS) toxicity is still a major problem. LAST is a very serious condition that can cause death.³ In LAST, blood levels of LAs exceed the maximum dose, usually as a result of multiple injections of the anesthetic or accidental injection into a vein. If the level of LA in the blood reaches an individual’s maximum dose, LAST may occur. LAs are the drugs most often used by dentists, and although dentists may encounter few adverse events, this does not change the fact that LAST can occur. Overdose, anatomy, and other patientspecific factors can contribute to LAST. Intravascular injection

has been reported in 15.3% of cases when the inferior alveolar nerve block is targeted. The present study was conducted to assess dentist knowledge about lipid treatment of local anesthetic systemic toxicity.

**Material & Method**

This study was conducted in the department of Oral Surgery. It comprised of 260 dentists of both genders. All were informed regarding the study and written consent was obtained. Ethical clearance was obtained prior to the study.

Data such as name, age, gender etc. was recorded. All were provided with a questionnaire. Information regarding LAST, signs of LAST they encountered and treatments for LAST, the length of professional experience, training on local anesthesia, LAs used most often, side effects seen most often were recorded. Results were subjected to statistics. P value less than 0.05 was considered significant.

**Table I Distribution of patients**

Table III shows that 62% had no idea of lipid treatment, 23% had heard but did not have enough knowledge of it, 13% had read an article about lipid treatment and 2% knew how to use lipid treatment. The difference was significant (P< 0.05).
Graph I: Have you ever use lipid treatment in local anesthesia toxicity?

Graph I shows that 85% had never seen LA toxicity, 12% had not use lipid treatment in local anesthesia toxicity and 3% had use lipid treatment in local anesthesia toxicity. The difference was significant (P< 0.05).

Discussion

LAST refers to the complication particularly affecting the central nervous system (CNS) and cardiovascular system (CVS) due to the overdose of local anesthetics. LAST is a life-threatening complication and reportedly occurs in 0.03% people.5 To elaborate, the order of incidence of complications from highest to lowest based on the type of block is penile, local infiltration, neuraxial, upper extremity, paravertebral, lower extremity, head and neck, topical, transversus abdominis plane, and intravenous block. Penile blocks are most commonly associated with complications, because of the large distribution of blood vessels. This is followed by local infiltration, which is commonly used in dentistry.6 The order of incidence of complications from highest to lowest according to the local anesthetics used is bupivacaine, lidocaine, ropivacaine, mixture local anesthetics, levobupivacaine, chloroprocaine, and articaine. Lidocaine, the most commonly used anesthetic in dentistry, accounted for approximately 25% of complications reported. The high incidence of complications of lidocaine, which is comparatively safe, could be due to its high frequency of use.7 The present study was conducted to assess dentist knowledge about lipid treatment of local anesthetic systemic toxicity.

In this study, out of 260 dentists, 140 were male and 120 were female. 0-5 years experience was seen in 20, 5-10 years in 70, 10-15 years in 50 and >15 years in 120 dentists. Vijayalakshmi et al8 have described the toxicity caused by overdose of local anesthetics during dental treatments and the pharmacokinetic progression, and reported the importance of drug selection and safety levels of the drugs.

We found that 62% had no idea of lipid treatment, 23% had heard but did not have enough knowledge of it, 13% had read an article about lipid treatment and 2% knew how to use lipid treatment. 85% had never seen LA toxicity, 12% had not use lipid treatment in local anesthesia toxicity and 3% had use lipid treatment in local anesthesia toxicity.

Basaranoglu et al9 administered 600 questionnaires that asked about the frequency with which dentists encountered LAST and the symptoms of LAST and its treatment, especially with lipids. The results showed that 520 (86.66%) respondents had never seen LAST, and 404 (67.3%) had no idea about lipid treatment. In addition, 128 (21.3%) had heard about lipid treatment but had inadequate knowledge of it and 59 (9.8%) had read an article about lipid treatment, but only 9 (1.5%) knew how to use lipid treatment. Finally, 80 (13.33%)
participants had seen LAST but had used a treatment other than lipids.

Guzmán et al.\textsuperscript{10} in their study interviewed anesthetists at hospitals about their knowledge and use of lipid therapy for LAST. Results showed that 50% of the anesthetists knew about lipid therapy and had adequate information to use it correctly. However, it also found that they did not know how to obtain lipids and that lipid solutions were not kept in locations where local anesthesia was administered.

**Conclusion**

Authors suggested that dentists must be aware of LA toxicity and knowledge of how to treat it.

Assessment of Medico- Legal Awareness of Practicing Obstetricians and Gynecologists

Ajay V Patil¹, Rajendra Bangal²

¹Professor and Head of the department, Dept. Of Forensic Medicine and Toxicology, KIMS, karad, ²Prof and HOD, Dept. Of Forensic Medicine and Toxicology, SKNMC &GH, Narhe, Pune

Abstract

**Background:** In the care of suffering the medical professionals need scientific knowledge, technical skill, moral understanding of profession and awareness about the relevant laws of the land. The present study was conducted to assess medico- legal awareness of practicing obstetricians and gynecologists.

**Materials & Method:** The present study was conducted on 156 gynecologist. All were provided with standard questionnaire consisting of ten questions was given to them and their response was collected.

**Results:** Age group 30-45 years had 30, 35-40 years had 45, 40-45 years had 50 and >45 years had 31 subjects. The difference was significant (P< 0.05). Questionnaire used was promptness in examination of victim of sexual assault, procedure related to Death Certification in MLCs, evidence Preservation in rape cases, awareness of Laws related to Obst.& Gynac Practice, real Causes of the Negligence Complaints, Awareness Regarding the provisions of PCPNDT Act and awareness about need of examining genuine MLCs. Most of the subjects was aware. The difference was significant (P< 0.05).

**Conclusion:** Most of the gynecologist had sufficient awareness regarding medico- legal issues.

**Key words:** Gynecology, Medicolegal, victims.

**Introduction**

No greater opportunity, no greater responsibility, no greater obligation can fall to any other human being than to become a medical professional. In the care of suffering the medical professionals need scientific knowledge, technical skill, moral understanding of profession and awareness about the relevant laws of the land. Primarily doctors but also on other ancillary and administrative staff of the hospital have several ethical and legal obligations in the performance of their duties.

It is important therefore, that every concerned person of the hospital, related with treatment and care of the patients must understand the nature of obligations and thus fulfills these obligations to the best of their ability, to maintain nobility of medical profession.

The obstetricians and gynecologists are one of the important specialties of medical faculty. Increase in life expectancy, decreasing number of female births and reduction in family size cast a significant quantum of accountability on these “doctors. They are working day and night for the benefit of patients. They are also very helpful with the Mother and Child Health Programme, Family Planning Mission, etc. of Government of India. The obstetricians and gynecologists are also helpful to society at large for their work for crime against woman, in the form of examination of victim of sexual abuse, the PC & PNDT act, Maternal Mortality. The present study was conducted to assess medico- legal awareness of practicing obstetricians and gynecologists.

Table II shows that questionnaire used was promptness in examination of victim of sexual assault, procedure related to Death Certification in MLCs, evidence Preservation in rape cases, awareness of Laws related to Obst.& Gynac Practice, real Causes of the Negligence Complaints, Awareness Regarding the provisions of PCPNDT Act and awareness about need of examining genuine MLCs. Most of the subjects was aware. The difference was significant (P< 0.05).

**Discussion**

There is increased use of internet, electronic and print media there is an increase in awareness among public on the subject of ethical conduct of medical practitioners. Hence there are more cases against doctors, which is an issue of immediate concern to the medical fraternity. To keep away from this, doctors need to make acquainted themselves with laws and regulations that concern their
It is a known fact that adverse outcomes to the patients in the course of healthcare management are frequent day by day and this is not without the danger of professional risk to this group of practitioners. These risks range, from failure to attend patient, examination and diagnosis at one end to specific investigative procedures and complicated operations and other. Same is the story in relation to the medicolegal management of cases of violence against woman. It is interesting to note that the social, medical and legal requirements in both these situations are qualitatively almost similar. The medical science is advancing and law is encroaching in almost every area of medical practice. It also cannot be ignored that society deserves the right to nourish great expectations from the advances in modern medicine and legal provisions aimed at their welfare. The present study was conducted to assess medico-legal awareness of practicing obstetricians and gynecologists.

In this study, age group 30-45 years had 30, 35-40 years had 45, 40-45 years had 50 and >45 years had 31 subjects. Kachare et al conducted a study to assess medico legal knowledge and awareness in interns and post graduate students. Total 200 students were included in our study. We found that 84 (70%) interns and 32 (40%) post graduate students had no proper knowledge in handling medico legal cases independently. 55 (45.83%) interns and 63 (78.75%) post graduate students were of opinion that the present UG teaching is not sufficient for them to tackle medico legal cases. Only 36 (30%) interns and 33 (41.25%) post graduate students were aware about the preservatives that are generally used for chemicals analysis of organs and 25 (20.83%) interns and 65 (81.25%) post graduate students were aware of Consumer Protection Act.

In present study, questionnaire used was promptness in examination of victim of sexual assault, procedure related to Death Certification in MLCs, evidence Preservation in rape cases, awareness of Laws related to Obst.& Gynac Practice, real Causes of the Negligence Complaints, Awareness Regarding the provisions of PCPNDT Act and awareness about need of examining genuine MLCs. Most of the subjects was aware.

Giri et al found that awareness status regarding different medico-legal case management like medico-legal cases, Promptness in examination of victim of sexual assaults, Death certification in MLC, Evidence Preservation in MLC, Medico-legal severity of injury, Importance of Identity in MLC, Criminal Abortion Cases, Awareness of Law related to medical Practice, Real causes of Negligence complaints, Awareness regarding the provisions of PCPNDT Act, Importance of good medical record and Rights of the patients etc. 33.69% were aware, 31.02% were partly aware and 24.93% were not aware and 10.36% has given no response in related subject matter or issues.

### Conclusion

Most of the gynecologist had sufficient awareness regarding medico-legal issues.

Abstract

Head injuries are accounting for most serious injuries in terms of morbidity and mortality1. The present study was carried out at a tertiary care hospital, Maharashtra for duration of three years. This study was conducted on 173 cases, which were directly brought to mortuary for postmortem examination from the site of incidence. The objective of this study is to find out the pattern of skull fractures irrespective of cause of injury. Linear fracture was found to be more common among the total no of cases. In the present study it was observed that skull fractures are more commonly seen in assault cases. In this study it is observed that extradural hemorrhage is most commonly associated with motor cycle riders. It has been also noticed that younger age group (21-30 years) are most commonly effected age group. In this present study it is noticed that abrasions are the most common type of injuries associated with skull fractures.

Key words: Cranio-cerebral injuries, Skull fractures, Hemorrhages and autopsy.

Introduction

Cranio-cerebral injuries accounts for the most serious injuries in terms of morbidity and mortality.1 Cause of cranio-cerebral injuries may be assault, RTA, fall from height and even fall on ground.1 Head is the most common part injured in road traffic accident as it is the most prominent and vulnerable part of human body by virtue of its situation and to sustain serious and fatal injuries owing to the great risk of striking the head.2 Depending upon the severity of violence involved, cranio-cerebral injuries can be associated with injury to the scalp, skull, intracranial hemorrhages and injury to brain tissue.2 Cranio-cerebral injuries are a major public health problem and have already attained epidemic proportion in India. As a result cranio-cerebral trauma places a huge financial and psychological burden upon the society.3

Material and Method

The present study was carried out at CPR hospital of RCSM GMC Kolhapur, for period of three years. This study was done on 173 cases, which were directly brought to mortuary for postmortem examination from site, irrespective of cause of injury. Hospitalized and operated cases were excluded from the present study.

The present study has been carried out after obtaining the ethical clearance and consent from the relatives to collect the relevant information.

Meticulous postmortem examination was done, skull and brain was specifically studied for the presence of fracture, hematoma, hemorrhage and injury to the brain tissue. To study the fractures and other injuries, magnifying lenses and measuring tape were used. Detailed study of police inquest and police record was done.

All data was collected and analyzed.

Results

The results of the present study which was carried on 173 cases at CPR hospital of RCSM GMC Kolhapur, for period of three years, which were directly brought to mortuary for postmortem examination from site,

irrespective of cause of injury are as follows.

In the present study we found that skull fractures are more commonly seen in motorcycle riders cases i.e. 56 cases (32.36%) followed by assault i.e. 52 cases (30.05%), least commonly seen in fall from height i.e. 7 cases (4%).

Table 1: Pattern of skull fractures according to the type of case.

Most common type of fracture seen is linear fracture i.e. 72 cases (38.92%) followed by depressed fracture i.e. 59 cases (31.89%), and least common type of fracture seen is ring fracture i.e. 1 case (0.54%). Sutural fracture, gutter fracture and ponds fracture are not seen in any cases of this study.

Discussion

The present study was carried out at CPR hospital of RCSM GMC Kolhapur, for period of three years. This study was done on 173 cases, which were directly brought to mortuary for postmortem examination from site, irrespective of cause of injury. This study shows that the skull fractures are more common in motorcycle riders cases i.e. 56 cases (32.36%) followed by assault i.e. 52 cases (30.05%). Similar findings were observed by Kirti jaiswal et al.4 The most common type of fracture seen is linear (41%) followed by depressed fracture. similar findings are observed by Sreekanth S Nair et al.5 The most common intracranial hemorrhage seen is extradural hemorrhage (69%), followed by Subdural hemorrhage (58%), similar findings were observed by Rahman MA et al.6 The most commonly seen type of injury associated with skull fractures is abrasion (90%), followed by contused lacerated wound (76%). similar findings were observed by soni SK, et al.7 The majority of the victims in this study are of 21-30 years age group (30%), followed by 31-40 years age group. similar findings were observed by S Gowda H et al.7 and Dhakankar S et al.8

Conclusion

The conclusion of the the present study, which was carried out at CPR hospital of RCSM GMC Kolhapur, for a period of three years. This study was done on 173 cases, which were directly brought to mortuary for postmortem examination from site, irrespective of cause of injury is as follows.

From the present study we observed that, the skull fractures are most commonly seen in motor cycle accidents, followed by assault. Majority of the victims in this study are of 21-30 years i.e. nothing but the younger age group. Most common type of fracture is linear fracture, followed by depressed fracture. Most common type intracranial hemorrhage was extradural hemorrhage. The most common injury seen along with the skull fracture was abrasion.

Prevention

So road traffic accident and assault is an unfortunate economical burden for a developing country like India. Cranio-cerebral injuries due to Road traffic accidents are recognized as a major health problem causing death and disabilities among the population of this country. Mortality and morbidity due to vehicular accidents cannot be stopped completely but it can be definitely reduced by implementing strict road traffic rules as well as by improving road conditions by concerned authorities, at the same time users of the road and vehicles also realize their responsibility in following traffic rules. Awareness programmed regarding proper protective measures and effect of intoxicating substances on ones driving ability, help in preventing their injuries by accidents. Last but
not the least; better health care facilities are required for effective emergency transportation and treatment of victims of vehicular accidents.

Abstract

Poisoning is an important health problem in every country of the world and it is a known fact that the incidence of poisoning in India is highest and it is estimated that more than 50,000 people die every year from poisoning¹. Poisoning affects all age groups from infants to seniors, but poisoning in teens and adults are more serious and it contributes to morbidity and mortality. Due to easy accessibility of poisons and lack of awareness, self-poisoning deaths are more common. In most of the poisoning deaths, the poison consumed was unknown at the time of autopsy but Forensic Science Laboratory plays a vital role in detection of poison. With this background, the present study has been carried out to determine the profile of poisoning cases, autopsied at SSIMS&RC, DAVANGERE, KARNATAKA. The study revealed that more number of poisoning is seen in males (62.3%) as compare to females (37.7%). Common age group affected is 21 to 30 years, followed by 31 to 40 years and least in 41 to 50 years. Agriculture group is commonly affected, followed by unemployed and least in government employees. Majority of victims belongs to lower socioeconomic group (84%). The suicidal deaths by poisoning (97%) being highest followed by homicidal and accidental.

Key words: Autopsy, FSL Report and Poisoning.

Introduction

Till today poisoning remains one of the commonest causes of unnatural death. Annually it has been estimated that the health hazards are directly or in directly due to poisons is for more than 1 million illnesses worldwide, and this could be just the tip of the iceberg as most of the cases of poisoning actually go unreported and untreated, especially in developing and underdeveloped countries.¹

Poisoning being invariably medico legal in nature among fatal cases, postmortem examination is done to establish the exact cause and manner of death. Manner of death in these cases is predominately suicidal because of the general belief that it terminates life with minimal sufferings. Even accidental or homicidal cases are also reported and alleged which was more prevalent in the past as there were no well established means of detecting poison from the viscera, etc. and it was believed that if dead body was black, blue, or spotted in places or smelled bad, the cause of death was a poison. With the advent of modern techniques of chemical analysis, this method of committing homicide has lost its grounds.¹

The commonest cause of poisoning in India and other developing countries is pesticides, the reasons being agriculture based economics, poverty, unsafe practices, illiteracy, ignorance and lack of protective measures and easy availability of highly toxic compounds. ² The attempt has been made in the present study to know the commonest group or type of pesticide involved, commonest age group affected, socio-economic status, gender and occupation affected in poisoning and to know the manner of poisoning.

Materials and Method

The present study has been carried out after obtaining the ethical clearance and consent from the relatives to take the relevant information. All the cases brought to the department of Forensic Medicine and Toxicology, SSIMS and RC, Davangere, for medico legal autopsy with history of poisoning and cases that were diagnosed as poisoning after post mortem examination during the period of one and half year, from November 2013 to March 2015. Total 61 cases were selected for this prospective study.

In all cases of poisoning the detailed history and information were collected from the police and the relatives of the deceased questionnaire, and post mortem findings were analyzed with the chemical analysis reports. In case of hospital admitted and treated cases the information’s were collected by the perusal of hospital records. In cases of allegations, information was supplemented by either visit to the scene of crime or from the photographs of the scene of crime. The cases of food poisoning, snake bite and any other insect bite envenomation and deaths due to idiosyncratic reaction to the drugs were excluded from the study group.

Meticulous autopsy was done in all cases and the routine viscera and body fluids were collected and sent to Forensic Science Laboratory for Chemical analysis and report. After obtaining the report from the Forensic Science Laboratory, the results of the report and information acquired from the relatives and the investigating officer were entered into the standard proforma for further study.

Results

Total 61 cases were selected for the present study and the following observations were made. It has been observed that maximum number of poisoning in the study population are seen in males (62.3%) as compared to females (37.7%). Out of total 61 cases males were 38 in number and females were 23 in number (Table No 1).

**Discussion**

The objectives of the present study are to ascertain the commonest gender and age group involved, occupation, socio-economic status, manner of poisoning, and the commonest type of poison involved in the study population.

Our study has showed the highest correlation with all the parameters when compared with other similar studies done in the past.

Mrinal Haloi and others had studied the cases of suspected poisoning brought to Gauhati Medical college and Hospital during the period of one year, a total sum of 96 cases of suspected poisoning deaths were analyzed. Male victims (62.50%) outnumbered Females (37.50%) and maximum number of cases was in the age group of 20-29 years. Economic status was found to be lower in 66.66% cases and maximum cases (73.95%) are from rural habitat. Organophosphorus compounds were the most common agents responsible for poisoning with 22.91% cases. Our study has shown the similar findings which were in correlation with the study mentioned above.
A study done by B.D Gupta and others for a period of one year among the poisoning cases admitted in the department of Medicine of G G Hospital, Jamnagar during the period of 1-1-2005 to 31-12-2005. A total of 268 cases were registered. A total of 124 cases were due to poisoning and 144 cases due to various bites. Of 124 cases, 89 (71.77%) were males. Majority of the victims fell in the age group of 20-29 (42.74%). Commonest poison was Organophosphorus. Majority of cases were of suicidal cause. The findings of our study were in similar and are in agreement with the above study.

A prospective study done by a Tejus Prajapati and others on poisoning cases (excluding animal bites) which were brought to the Civil Hospital Ahmadabad, from 1st October 2006 to 30th September 2007. Total 366 cases of acute poisoning were recorded over a period of one year. Of these 70.8% were males and 29.2% female. The majority (45.08%) cases were from age group of 21-30 years. 71.6% cases were from rural area. Commonest type of poison was pesticide in 33.9% cases, followed by household chemicals (26.8%), and in 74.6% of cases poisoning was suicidal. The findings of this study are in agreement with our study except the second most commonest poison, in the above study it is household chemicals, but in our study it is Aluminum phoshide, so it is in disagreement with above study.

Vishwajeet Pawar and others did a study at Mahatma Gandhi Institute of Medical Sciences, Sewagram during the period May 2007 to April 2009. During this study cases of poisoning were observed more in males than females. Male to female ratio was 1.4:1. Maximum poisoning cases were seen in the age group of 20-29 years in both sexes. Maximum poisoning cases belong to low socioeconomic group. Insecticides poisoning was the most common and among them Organophosphorus was the commonest. Incidence of suicidal poisoning cases was more than the accidental poisoning. Agriculture was the most common occupation of the victims of poisoning. These findings were in agreement with our study.

Vikram Palimar, & Prateek Rastogi did a retrospective post mortem study at Kasturba Medical College, Manipal, India, during the period of 1992-2004. Of the total 1917 autopsies conducted, 372 cases were due to poisoning, of which 287 cases were due to insecticides with a predominance of organophosphates. More than 90% of poisoning deaths were suicidal. Majority of the victims were males in their third decade of life. These findings were in consistent with our study.

A study was done by Sinha US, Kapoor AK, Agnihotri and Srivastava PC on 285 poisoning cases at SRN Hospital, Allahabad. It was see that males (69.47%) outnumbered the females. Young age group (15-30 years) was predominantly affected. Aluminium phoshide (42.1%) was the poison of choice with mortality being highest, followed by Organophosphorus (17.17%). Manner of poisoning was suicidal (87%) followed by accidental (7.37%). The findings are in agreement with the present study. But the commonest compound detected in our study is Organophosphorus (50.8%) followed by Aluminium phoshide (26.2%), so this finding is in disagreement with the above study.

In a retrospective study carried out at Department of Forensic Medicine, B.M. Patil Medical College. Bijapur, Karnataka. Total 210 fatal pesticide poisoning cases were selected for the study out of 980 medico legal autopsies conducted from 1st January 2003 to 31st December 2009. The study revealed that the age group 21-30 constitutes the majority (38.12%) of victims followed by 31-40 (25.56%). Males outnumbered the females, the male female ratio being 2.6:1. 192 (91.42%) cases were of suicidal in nature. Organophosphorus compounds were prevalent (64.3%), followed by organo-chloro compounds (25.2%) and carbamates (11.5%). The lower socio-economic status (78%) group is commonly affected. These findings were in agreement with our study except the second most prevalent poison, in the study mentioned above, Organochloro was second common compound but in our study it is Aluminium phoshide.

**Conclusion**

Following were the conclusions drawn after a detailed study of 61 cases of poisoning, autopsied at SSIMS and RC, Davangere.
1. Most of the victims are males (62.3%), where the females were of 37.3%.

2. The most common age group involved is 21 to 30 years (34.4%).

3. Most common occupation involved is Agriculture (42.6%).

4. Victims belongs to lower Socio-economic group are most commonly affected (84%).

5. Suicidal deaths were more common (96.7%) when compared to Homicidal and Accidental deaths.

6. Organophosphorus compound was the most commonly found pesticide followed by Aluminium Phosphide in the chemical analysis at Forensic Science Laboratory (50.8%).

In India, prevention of poisoning deaths poses a difficult task, as the cause of poisoning is multifaceted. The agricultural group being frequently exposed to pesticides, chances of suicide is more prevalent of various reasons like, poverty, loss of crops, unemployment and other socio-economic problem. Divorce, dowry, love affairs, illegitimate pregnancy, extra-marital affairs and such conflicts relating to the issue of marriage, play an important role, particularly in the suicide of women in India. In order to minimize the deaths due to poisoning, awareness need to be created among the public about the seriousness of poisoning, implementing the measure to uplift the socio-economic status and to solve unemployment and last but not the least, the law has to be strengthened towards the sale and distribution of pesticides. Establishing the poison control center in every treating hospital may decrease the deaths due to poisoning.

Scope of Periodontium in Forensic Science

Gayathri S¹, Gomathi M², Nandhini V³, Sumathi H R⁴, Geetha T⁵, Dona Samm²
¹Reader, ²Crri, ³Reader, ⁴Professor, ⁵Tutor, Sathyabama Dental College and Hospital

Abstract

Forensic odontology is the application of dental knowledge in forensic science in identification of victims during criminal justice. This article highlights the important role of gingiva and the surrounding periodontal structures in forensic field. Evidence can be collected only with proper documentation of the dental records. The importance of dental records plays a key role not only in identification but also in terms of dental malpractice or in insurance claim. Recent studies have established ante mortem and postmortem changes in gingival and periodontal tissues. Thus periodontitics has a scope in forensic odontology.

Key-words: Forensic odontology, Periodontitium, Age estimation, Dental records

Introduction

Forensic dentistry is a branch of forensic medicine dealing with evidences and marks left by teeth (as in identifying criminal suspects or the remains of a dead person). It is performed by a comparatives evaluation of the ante mortem (missing person) and postmortem (dead person).

Periodontics is a branch; which deals with clinical science of disease in periodontium. It is utilized for identifying individuals through morphology and pathology of periodontal structures and age estimation studies. Periodontal disease factors are most important for periodontics. Case documentation and photographs are proved to be the most important evidence for forensic odontology. Dentistry plays a significant role in this process. To identify the victims of crime and disaster through dental records, dentists assist those officials involved in criminal investigation. Recently, the periodontitis identified the features of ante mortem and postmortem changes in gingival tissues. In future, periodontal structures would play a crucial role in forensic odontology. This article gives an update on the assessment of periodontal structures and its uses in forensic science.

Gingiva

Cell death occurs by apoptosis, necrosis, or autolysis.¹ Time lapsed after death is important in crime cases. Cellular change that takes place in gingival tissues helps to estimate changes after death. These changes vary in individuals at cellular level. Histological examination of gingival tissue when observed at different time intervals within 10 hours after death cellular changes occurs, in both postmortem and ante-mortem reports.² Gingival cells analysis by quantitative cytomorphometric method, involves scraping of attached gingiva to assess age and gender related alterations in the nucleus and cytoplasm. Chromatin clumping, nuclear karyopyknosis, widened intercellular junction and loss of epithelium are some of the changes at microscopic level seen at different intervals of time after death. Oral premalignant and malignant lesions, pathologic smears have cytoplasmic ratio values which showed that attached gingiva can be used for human identification.¹

COLOUR

Normal color of gingiva is pink and in some cases with pigmentation. Pigmentation is most commonly seen on labial aspect of gingiva and highest at the incisors. Pathologic pigmentations could be in various conditions like peutz jehgers syndrome, Addison’s disease, oral melanoma and melanotic macule.

CONTOUR

In healthy individuals, the gingival margin has
scalloped margin. This scalloping contour depends on location of teeth, size of proximal contact, gingival embrasures and alignment of teeth. Contour can be altered in case of improperly constructed restorations, gingival pathologies, and improper prosthetic abutments. Stillmans cleft and McCall’s festoons are changes in contour seen on canine premolar region and are usually associated with occlusal trauma.

**Position**

Gingival margin is located 1 mm above the level of cemento enamel junction (CEJ) or at the level of CEJ. Apical migration of marginal gingiva below CEJ which leads to exposure of root surface due to periodontal diseases is called gingival recession. The main etiology of recession is gingival inflammation and faulty tooth brushing. Secondary factors include anatomic, habits, iatrogenic and physiologic. Studies have proven that gingival recession varies in different races.

**Periodontal Ligament**

Morphology of periodontal ligament as age advances. Average width of ligament space is documented as 0.2mm. Considerable variation occurs in various individuals. This space is decreased around teeth that are nonfunctional and increased in hyper functional teeth.

**Thickness**

The thickness of PDL will be exactly connected to age and mesiocclusal drifting of teeth. PDL ranges in width from 0.15 to 0.38mm and progressively decreases with age. Periodontal ligament thickness is directly proportional to root dimensions.

**Widening**

Periodontal ligament widening is seen in Bisphosphate associated osteonecrosis of the jaws, progressive systemic sclerosis primary hyperparathyroidism.

**Lamina Dura And Alveolar Process**

Height, contour, density of crestal bone, tori, exospores, bone loss (horizontal/vertical) are the clinical parameters alveolar bone for establishing identity of the individuals. Height and density of crestal bone are important factors of periodontitis. Alveolar crest height loss in mandibular. The thickness and alveolar process width increase between the first premolar.

**Cementum**

Cementum is a dynamic structure that gets deposited throughout life. Cementum annulations play a role in age estimation in males and females. During the formation of cementum the alternate light and dark bands are formed from alternate deposition of hyper mineralized extracellular matrix with less mineralized layers. These light and dark bands correspond to one year of an individual. These are counted on a pictomicrograph under microscopes.

Number of Incremental lines (n) = X/Y

Where,

X=Total width of dentinocementum junction surfaces

Y=Width of two adjacent incremental lines in cementum.

Dental cementum has opaque and translucent bands in winter (dormant) and summer (growth) seasons. Dental cementum increment analysis (DCIA) is used to specify the season of death.

**Significance of Implants in Forensic Odontology**

Dental implants have a high melting point. when teeth is exposed to extreme heat, vaporization of pulp tissues occurs, leading to separation and disintegration of the tooth crown and root. Dental amalgam, composite resin and gold are the conventional restorative materials which may melt or distort in high temperature. Dental implants have a melting point above 1650 degree centigrade. Implants can sustain thermal insults which is an added advantage in identification of victims. Pre and post incineration of the laser etched batch number is also visible which depends on the depth of etching and presence of the oxidation layer on the implant surface.

Software database is also available which stores information related to implant designs, Implant systems, clinical and radiographic images which aids in crime cases.

**Dental Radiographs**

Dental radiographs are easily available and serve as a vital clue for identification. Shape of the teeth and roots, teeth present, missing teeth, residual roots, supernumerary teeth, attrition abrasion, fractures, bone
resorption due to periodontal disease, bone pathology, dental caries, endodontic treatment, intraradicular post, intracoronal post and dental prostheses treatment, are the parameters used in dental radiographs.\textsuperscript{15}

**Conclusion**

Forensic odontology having a great effect or influence in the field of dentistry, which is practiced worldwide. This article aims to enlighten the importance of forensic odontology and its relationship with periodontium. Forensic odontology plays a significant role in identifying the deceased by determining sex and age, using various techniques, including that of the gingiva and periodontium.

**Clinical implications**

This article gives an overview of structures of periodontium and its application in forensic science which implies maintaining a dental record will further aid in the process of legal issues. A dental record should contain all related information of the patient, his medical history, teeth with restorations, or pathologies, missing teeth, soft tissue changes in gingiva, alveolar bone loss, treatment planned and done and prognosis. Preoperative and postoperative photographs and radiographs all should be maintained. It would not only help in forensic odontology but also in cases of medico legal issues, insurance and consumerism. Computer generated dental records earn more benefit because it can be easily networked and for routine professional consultation forensic in cases.\textsuperscript{16}

Touch Dna as Forensic Aid: A Review

Indresh Kumar Mishra1, Bhoopendra Singh2, Amarnath Mishra3, Braja Kishore Mohapatra4, Ruchika Kaushik5, C Behera6

1Assistant Director, Biology, 2Scientific Assistant, Regional Forensic Science laboratory, Chanakyapuri, GOVT of NCT of Delhi, India, 3Assistant Professor, Forensic Sciences, Amity Institute of Forensic Sciences, Amity University, Noida, Uttar Pradesh, India, 4Principal Scientific Officer, Biology, Central Forensic Science Laboratory (CBI), CGO Complex, New Delhi, India, 5PhD Scholar, 6Associate Professor, Dept. of Forensic Medicine & Toxicology, AIIMS, New Delhi

Abstract

Touch DNA technique which is being used in many advanced countries as a modern tool in criminal justice system. It is basically meant for acquiring genetic information from biological substances (cells released from epidermal surfaces) left on touched samples to establish it’s relatedness. It refers to recovery of traces of DNA from the biological cells released during the contact which is in a very low quantity, for further analysis and generation of a DNA profile of a person. Released dead cells are not visible to naked eyes and hence it is difficult to locate and recover successfully. DNA profiling from touched samples is difficult and hence require sensitive approach in recovery, extraction and amplification. Success of Touch DNA analysis, therefore, depends upon various factors like collection, sampling and preservation, removal of contaminations, quantification, amplification, analysis and interpretations. Various methods have been developed for the collection of Touch DNA over the time. Sophisticated kits and instrument and well equipped forensic laboratories help to provide concrete DNA profiles thus helping to the Criminal Justice System.

Keywords: Touch DNA, Contact DNA, Trace DNA, DNA fingerprinting, criminal investigation, forensic science, Real Time PCR, PCR

Introduction

High profile cases including exoneration of Timothy Masters and the Jon Benet Ramsey homicide investigation has increased interest in Touch DNA1. The ability to recover DNA sample from epithelial cells was reported for the first time in 1997 by Van Oorschot and Jones. Touch DNA can be very useful in different cases, including sexual assault, rape, and murder2. Millions of skin cells are shed each day by humans and these cells may be transferred to any object coming in our skin’s contact. It is possible to deposit sufficient number of skin cells to any object at the scene of crime. The DNA from the cells of the perpetrator/ deppositor can be lifted and utilized as a potential source of physical evidence to link him with the scene of crime. DNA profiles can be obtained from the clothing that have been worn by the perpetrator act as potential physical obtained from the transferred skin cells. DNA profile from inside of the shoe can link a wearer of the shoe thus increasing the evidential value of the forensic evidence. Castella and Mangin conducted a touch DNA study on 1739 case samples and found only 26% suitable DNA profiles3. Raymond et al conducted a touch DNA study on 252 case samples and found only 44% suitable DNA profiles4.

In keeping the view of challenges various sensitive DNA typing kits have been evolved to develop DNA profiles from just a few cells having trace DNA from objects such as postage stamps, documents, bullets, knives, door handles1. Touch DNA can be recovered from a variety of items like bottles, cans, handled items, personal items, forehead marks, cutlery, food,
envelopes, letters, postage stamps, etc. Chew gums, cigarette butts, hats, upper garments, gloves, socks, shoes, underwear, etc. have been used as the potential source of the touch DNA.

This review article throws some light on the conventional to the latest sampling methods, benefits, evidential value and limitations of Touch DNA. Touch DNA Analysis requires trained laboratory personnel/investigating officers/Police personnel to lift, handle and transport exhibit from scene of crime to the forensic laboratories. Several factors affect the quality of STR profile of Touch DNA i.e. pressure, area, time and personnel’s state of mind. More the touch pressure, touch area and touch time, more is the chances of obtaining good quality STR profiles. The rough substrate has greater chances of having Touch DNA. Various methods have been developed for the collection of Touch DNA over the time. Sophisticated kits and instrument and well equipped forensic laboratories help to provide concrete DNA profiles thus helping to the Criminal Justice System.

Methods of Lifting Touch DNA Sample

Swabbing Techniques: Traditionally, dry sterile cotton wool swabs are used to lift touch DNA samples from the scene of crime called dry swabbing which are being replaced by wet sterile cotton wool swabbing. Swabbing techniques recovered less DNA, therefore, it is further advanced with tape lifting technique. Cotton wool swabs are still being used to collect Touch DNA from the handled objects. Cotton wool swabs are useful to plain substrates but results in the huge loss of DNA from the rough and porous substrate. Indianapolis implemented the use of prepackaged touch DNA swab kits (TriggerPro) for collecting touch DNA samples from a seized firearm during 2008-09. TriggerPro contained three moistened swabs with antimicrobial fluid to be used by police officers. Sterile distilled water is replaced with non-polar surfactants as wetting agents for the sterile cotton wool swabs to collect the Touch DNA from the suspected articles might be used at crime scene. As swabbing techniques recover very little amount of sample, the extracted amount of the DNA from the swab of touched area is very less.

Tape Lifting: Collection of Touch DNA via tape lifting from fabrics in many jurisdictions done routinely. Now water soluble tape lifts are available increasing the amount of touch DNA e.g. SceneSafe Fast™ minitapes.

Cutting/Scraping: The best method to obtain Touch DNA is cutting/scraping the suspected touch area but being destructive in nature generally nondestructive techniques like swabbing and tape lifting techniques are used to lift touch DNA from the scene of crime.

FTA Card: FTA Cards, MicroFLOQ swabs have been devised for direct PCR amplification reducing the chances of loss of touch DNA during DNA extraction and quantification.

Touch DNA Extraction

Bright and Petricevic conducted organic (phenol:CHCl3) and Chelex 100 resin method for the recovery of DNA on swabs collected from the hands and feet of volunteers showed that organic extraction gave increased yield. A study has shown organic DNA extraction method is most effective method for extracting trace DNA from crime scene samples in DNA laboratory. DNA extraction from saliva samples by using SceneSafe Fast™ minitapes is most efficient with conventional organic Phenol-chloroform-isooamylalcohol method on the other hand “iPrep Forensic Kit” and “PrepFiler Express BTA™ Kit” (Thermofisher) proved to be safe and fast as compared to conventional organic solvent extraction method.

Silica based magnetic automated DNA extraction systems viz. EZ1/XL BioRobot (Qiagen), Maxwell® FSC (Promega) etc.; provide a good quality genomic DNA and reduces chances of contamination during manual handling as well as rapid.

A Low DNA Content BioChipSet (LDC BCS) designed to function in the fully automated Accelerated Nuclear DNA Equipment (ANDE) performs efficient DNA purification followed by microfluidic ultrafiltration of DNA, maximizing the quantity of DNA for subsequent amplification, electrophoretic separation, and detection of amplified fragments. Recently a 96-well centrifugal filtration plate has been designed and used in an automated DNA extraction method of touched objects. 92 Samples can be processed for extraction and purification automatically on a robotic workstation in 90 minutes.

Quantification

The quantification step plays an important role in determining how a sample will be processed downstream. Advantage of DNA quantification includes
results in fewer off-scale, over & under amplified samples, gives normalized profiles, resulting in reliable data interpretation, designed to reduce the need for downstream reanalysis which enables long-term cost savings. DNA quantification can be done using various instruments i.e. UV – spectrophotometry, Micro drop / Nano drop (based on UV spectrophotometry) or Real Time PCR which provide variable data quantity of DNA from isolated samples. Real time PCR is considered above spectrophotometry as it gives actual initial concentration of human DNA being amplified whereas absorbance may vary due to contaminants.

**Amplification And Detection**

Amplification of extracted DNA is a crucial step as the whole profiling is read on the basis of those amplified loci. Multiplexing is used for STR profiling, for which various sophisticated kits are available from different manufacturers for example: AmpF/STR SGM Plus™, AmpF/STR Identifiler Plus, Globel filer™ PCR Amplification Kit system (Applied Biosystems) Investigator 24Ples QS kit (Qiagen), PowerPlex® 21/18D System (Promega) etc. by following the recommended protocols. In many cases where partial profiles are found, another approach for generating profile can be done using Mini STR kit. As initial sample concentration in such cases is too low an increase in the number of PCR cycles can result in successful STR profiling. Separation of DNA fragments is done using capillary electrophoresis by using any of the Genetic Analyzer (3100, 3130, 3500, 3500XL) and the software for data analyses is Gene Mapper ID-X software (Applied Biosystems).

**Automation in DNA Profiling**

Bio Chip Set based fully automated Accelerated Nuclear DNA Equipment (ANDE), RapidHIT ID System for Human Identification systems enables direct processing of samples right after collection. The automated process does right from cell lysis, amplification, and capillary electrophoresis to generation of STR profiling in less than 2 hours. Self-contained sample cartridges transform a multi-component protocol into a single instrument and single user-initiated task.

**Results Interpretation**

The profiles obtained from the samples are classified as either full DNA profile, partial DNA profiles, mixed DNA profiles (for profiles containing DNA from 2 or more people) or no result depending on the number of alleles detected. Touch DNA interpretation can be done after STR profiling. When two DNA profile match to each other is considered as ‘Inclusion’ and two profile not matches to each other is considered as ‘Exclusion’.

**Problems in Analysis**

**Sampling and handling problems**—Various methods i.e. swabbing, tape lifting, cutting, scraping, etc. have been utilized to obtain Touch DNA from the scene of crime. Special care should be taken while lifting Touch DNA as there are chances of DNA contamination from the person himself lifting the DNA and from the other sources at the crime scene. The method of recovering the DNA should be chosen depending on the nature of the substrate. Though swabbing techniques are simple and nondestructive, recovers less Touch DNA and have higher chances of contaminations. Only the trained-laboratory personnel/police personnel should be allowed to lift touch DNA from exhibits.

**Contamination problems**—Touch DNA analysis faces a various variety of contamination due to improper handling, sampling and preservation inhibition by bacteria or any other type of chemical such as EDTA, sodium fluoride, saline solution, microbial development and environmental effects. Contamination problems in DNA Samples increase with high demand of DNA analysis in forensic laboratories. Despite the consciousness, the risk of contamination arises from the first handler police staff, during transportation and even in forensic laboratories. Special care should be taken while lifting the touch DNA samples. High recommendations should be made for the use of aprons, face masks, head masks, gloves, sterile forceps, scissors, etc.

**Preservation and transportation problems**—Biological samples are preserved by drying using any of processes of viz. desiccation, refrigeration and freezing. Transportation of these samples requires special handling procedures without which there is chances of degradation/decomposition of biological samples rendering it unsuitable for DNA fingerprinting analysis. Delay in sample freezing and temperature fluctuation during transportation from one place to from another place makes biological samples unfit for DNA fingerprinting analysis. An emphasis is being made on the development of storage devices at room temperature, thus reducing the cost of freezing or refrigeration.
Benefits of Touch DNA

Touch DNA reflects an implicit decision that the marginal benefits of DNA collection are greater than that of additional patrol resources made available if touch DNA is not used by officers. Benefits of Touch DNA lies in its specificity. Even minute quantity of DNA from just a few cells from the scene of crime can provide complete DNA profiles of perpetrator. Touch DNA is very fast, it can be applied on a variety of surfaces, and it can be used on a very small sample. Latest more sensitive kits, sophisticated equipments have proved boon to touch DNA technology.

Limitations of Touch DNA

The amount of deposition of Touch DNA is variable due to different factors for examples on rough and porous surface as compare to smooth surfaces, and some persons are known to leave more Touch DNA while some others are known to leave less DNA, person during stress or during sweating leave more Touch DNA as compare to normal persons. Touch DNA being a biological material is prone to environmental and biological degradation by fungal bacterial contaminations.

Touch DNA samples being very small in quantity can be easily destroyed and can’t be recreated. DNA material in aerosols can contaminate the laboratory environment by making other DNA material unfit for further profiling. Touch DNA technology depends on well trained personnel. Any error during processing technique may result in incorrect or incomplete DNA profiles. False/erroneous interpretation of results can lead to wrongful conclusions which in turn mislead the case.

Conclusions

The success of Touch DNA use as a forensic tool lies in the optimization of techniques starting with collection of biological samples, preservation, extraction, amplification and genotyping. Many newer methods have been developed, sophisticated kits, instruments along with well-equipped established laboratories which will help right from recovery of biological samples at crime scene to handling to profile generation. However, a careful and meticulous planning is required success for individual cases. The limitations of Touch DNA technique should be also kept under consideration while interpreting the results.

Flibanserin: A Miracle Drug in Management of Hypoactive Sexual Desire Disorder in Female

Jeetendra Kumar Gupta1, Ahsas Goyal1, Kajal Thareja2, Bhavini Saraf2
1Assistant Professor, Pharmacology Division, 2Scholar, Institute of Pharmaceutical Research, GLA University Mathura, Uttar Pradesh, India

Abstract

Female sensuality encircles wide range of behaviours and activities, including female sexual identity and etiquette. Many dimensions of female sexuality have been addressed by various societies and religions of the world, pertaining to biological sex, orientations and attitudes. A sufficient sexual appetite and libido in adults are essential for continuation of race. It also nurtures psychological health and immune functions. In case of hypoactive sexual desire, there will be recurrent deficiency or absence of interest and receptivity to sexual activities which causes distress and many interpersonal difficulties in fledged adult life. Flibanserin is the latest approved drug for the treatment of hypoactive sexual desire disorder in female. It generally functions on the activity and the role of neurotransmitters affecting mood and drives. Flibanserin has affinity with serotonin autoreceptor (5-HT1A) and dopamine receptor (D4). It is a full-fledged agonist of 5-HT1A in prefrontal cortex region and partial agonist in the CA3 region of hippocampus. It also acts as partial agonist of dopamine receptor (D4) but it has poor antagonist property with 5-HT2A, 5-HT2B and 5-HT2C receptors. Flibanserin declines neuronal firing rate generally in the cells of hippocampus, dorsal raphe and cortex region of brain. Hence, it can assist to improve the brain activation pattern and drives of hypoactive women.

Keywords: Flibanserin, Hypoactive women, Autoreceptor agonist, Libido, Drive disorder.

Introduction

Issues related to women’s health are widening day-by-day. According to World Health Organization (WHO), women are more prone to hormonal imbalance, while males have a great tendency to resist the change1. The physiology of female is quite dependent on her cyclic menstrual and shows severe fluctuations in case of any interference with exogenous factors such as environmental toxins, poor-diet and impaired lifestyle2. It can also be impeded during chemotheraphy, hysterectomy and after prolonged use of xenoestrogens. Xenoestrogens are the chemicals that are found in everyday usable items, such as certain food products, cosmetics and preservatives. Excessive use of those items has dreadful tendency to imbalance many hormones, such as estrogens and progesterone3.

Women’s well-being and their unique health issues are usually related to the hormonal essence in their body. Such issues include pregnancy, menopause and ambiance of female organs. Due to the sociocultural factors, discrimination among sex is also a major cause that affects women’s health and well-being. Depression, anxiety as well as hormonal misbalancing diseases are more likely to affect the women health as well as their libido4. Libido generally regarded as a person’s drive for sexual activity. It is the force that is responsible for the intimate contact between a man and a woman but if the person loses the drive then this condition may lead to hyposexuality which is also referred as hypoactive sexual desire disorder (HSDD). Many systems of the human body are involved in sexual drive such as nervous system, vascular system, endocrine system and other structures that are auxiliary in intercourse5. For the modulation of women’s sexual craving steroids are implicated such as testosterone and estradiol. Chief neurotransmitters

responsible for the regulation of libido in humans are dopamine as well as oxytocin. Stress, illness, pregnancy and many other factors collectively affect the human sex desires. Women’s sexual problems are due to the mental and physiological reasons. In present scenario, women are gradually loosing their drives because of their disturbed life style and ill food-drink habits. Many other factors have also been seen. Libido could also be affected due to social issues, such as work and family. It could also be disturbed due to certain medical conditions and puberty. Non-sexual diseases such as diabetes, blood pressure, neurological diseases could also affect the sex desire. Hormonal alterations are the main and leading cause of loss of libido. Stunted libido can also lead to disquiets, such as dyspareunia, vaginal dryness, failure of orgasm, vaginismus and awful sex.

Material and Method

Flibanserin is a new drug approved by US FDA for the treatment of hypoactive sexual desire disorder in premenopausal women. Interpretation of the importance of the drug has been accomplished on the basis of existing literatures and researches. The concerned articles have been assessed through various electronic searches such as Pubmed, Scopus, Medline and Google scholar using different key words. Various inclusion and exclusion criteria such as age, gender and disease-stage have also been followed while assessing the literatures through the electronic databases.

Female Sex Hormone And Behaviour

The two major hormones which are responsible for the sexual activity in females are estrogen and progesterone but testosterone is also produced in small amount in women although it is a male sex hormone. Placenta also produces the estrogen amid the gestation period. When the stimuli reaches the brain and strikes the hypothalamic region it generates gonadotropin-releasing hormone (GnRH) at puberty and arouse the pituitary to produce Follicle stimulating hormone (FSH) and Luteinizing hormone (LH). FSH and LH are the two hormones indirectly responsible for the synthesis of estrogen (mainly estradiol) as well as androgens. The main hormone that is responsible for the maturation of follicles is FSH. When the level of estrogen gets elevated it stimulate the endometrial proliferation and leads to the deluge of LH. The LH rush is responsible for ovulation.

Puberty, menstruation, pregnancy as well as menopause are generally governed through estradiol. Progesterone is responsible for the preparation of uterus lining for the fertilized egg and it also supports pregnancy. Testosterone is generally produced in very small amount in females from the adrenal glands and ovaries and it is also responsible for the sexual desire, regulation of menstrual cycle as well as muscle and bone strength. An elevated levels of different sex hormones in female result in the growth of pubic and armpit hairs, breast budding, increase in stout of thighs and hips as well as maturation generally of uterus, vaginal and ovaries that may lead to the onset of menstruation. If there is hormonal imbalance in the female body it may cause certain critical conditions such as polycystic ovarian syndrome (PCOS), hot flashes and many behavioural changes. Hence, hormones do influence behaviour of women, especially desire and drives are copiously affected. The commonest categories of woman’s sexual dysfunctions are impaired desire and orgasmic dysfunction.

Sexual fragility in women

There are several factors that are responsible for women’s sexual response that includes contextual, personal psychological and biological factors. According to the American Psychiatric Association’s Diagnostic and Statistical Manual (DSM-IV-TR) women’s sexual dysfunction is usually due to the absenteeism of sexual convictions or fantasies before the sexual activity. Sexual difficulties are more prevalent in women. About 40% of premenopausal women lack engrossment in sexual drives because of certain physiological, psychotic or drug induced factors. The main focus of sexual dysfunctioning lies on the genital staging and lubrication to the fulfilment and resolution. Women’s sexual stimulation or desire is more complicated as their fantasies and emotional contact towards this feeling is complex. A woman requires increased level of emotional intimacy while stimulating for sexual adventure and amusement. Women’s sexual dysfunction may be a result of sexual response that is due to the impaired perceptions, fantasies and desires contextual, personal psychological and biological factors has led to recently published recommendations for revision of definitions of women’s sexual disorders found in the American Psychiatric Association’s Diagnostic and Statistical Manual (DSM-IV-TR). There are many factors that affect women’s sensualities and drive.
Impairment in the drive is also due to the elevated level of prolactin as it is seen in case of polycystic ovarian syndrome. The symptoms of enhanced prolactin in premenopausal women may lead to amenorrhea and galactorrhea. Prolactin generally inhibits the Gonadotropin releasing hormone. The stimulatory effect of prolactin is on the mammary cells that results in lactation. Ingurgitation of alcohol elevates the women’s sexual arousal transiently but shows negative effect after persistent use. Encephalonic arousal in the pre-frontal limbic system and amygdala elevate the feeling of love and enhances the responsiveness to ecstasy with female orgasm solely from sexual intercourse often regarded as a unique feature of human sexuality. However, orgasm from sexual intercourse occurs more reliably in men than in women, likely reflecting the different types of physical stimulation men and women require for orgasm. In men, orgasms are under strong selective pressure as orgasms are coupled with ejaculation and thus contribute to male reproductive success. By contrast, women’s orgasms in intercourse are highly variable and are under little selective pressure as they are not a reproductive necessity. The proximal mechanisms producing variability in women’s orgasms are little understood. In 1924 Marie Bonaparte proposed that a shorter distance between a woman’s clitoris and her urethral meatus (CUMD. Amygdala has dual role i.e. in sexual behaviour as well as in maternal care and extensively involved in building emotional competence, but in postpartum women amygdala is greatly responsible for maternal behaviour. Impairment in oxytocin release is also a noteworthy factor. It is an orgasmic hormone well-known by many names, such as ‘trust hormone’ or ‘lust hormone’. Oxytocin is also responsible for inhibition of fear in amygdala. Sexual dysfunction is the common issue in the perimenopausal women. The chief reason for the sexual dysfunctioning is hormonal imbalance.

Factors Responsible For Impaired Libido

Sexual drive disorders: Disorders of sex drive are basically classified in two types namely Hypoactive sexual drive disorder (HSDD) and Sexual aversion disorder (SAD). The induction of HSDD is caused by persistently deficient sexual reveries and desires for long time due to certain emotional factors, such as persistent anxiety and depression that may cause marked interpersonal difficulty also. It is also caused by certain...
physical factors like diabetes and extreme tiredness. SAD is developed as a result of persistent avoidance of all genital sexual contacts with a sexual partner due to some specific phobia.  

Effect of medicines: Decreased level of sexual desires have been seen in case of long term medications, such as anti-hypertensive medications, anti-psychotic medications, anticoagulants, monoamine-oxidase (MAO) inhibitors, sedatives and also in case of fat lowering medicines.  

Interpersonal and contextual factors: It includes the emotional intimacy of the women with her partner during sexual as well as the general activities. Deepening of emotional concerns are essential for intimate relationship. In case of fable relationship, boredom may happen between the partners.  

Psychogenic factor: Psychogenic distractions affect the sexual arousal in women. Anxiety and life-style have also indubitable impact on women’s drive. Psychological factors may include certain stress, guilt, worry, negative thoughts and memories of past.  

Depression: It is the major cause of declined sexual functioning. Change in sex drive has association with depression. A study in psychosomatic medicine revealed that females who had depression are more prone to hypoactive sexual desire disorder and about one-third of premenopausal females with hypoactive sexual desire disorder are firmly associated with depression.  

Chronic illness: Serious health issues and chronic illnesses have enormous adverse effects on biological drives. Physical and mental well-being play a significant role in libido expression and execution. Chronic diseases such as diabetes, arthritis and cardiovascular diseases have negative influence on drives and functioning.  

Hormonal factor: As women become older the levels of hormones such as estrogen, testosterone and progesterone decrepitude especially after menopause. Low levels of these hormones generally reflect negative impact on sex life. Reduced level indicates female sexual fragility and dysfunctions. Estradiol enhances the sexual desires, but testosterone is also responsible for the alterations in sexual desire of a woman. Low levels of estrogen leans the uterine lining and leads to decrease in sexual desire. Vaginal dryness, painful intercourse, mood swings and unstable sleep patterns are the symptoms of low estrogen. Therefore, hormonal imbalance is considered as a leading cause in reduction of sexual arousal and response.  

Flibanserin-A Wonder Drug  

Flibanserin is a N-alkylpiperazine compound chemically known as 1-(2-(4-(3-trifluoromethylphenyl)piperazin-1-yl)ethyl)benzimidazol(1H)-2-one as a P-Glycoprotein inhibitor. It works as a 5-hydroxytryptamine 1A (5-HT1A) agonist and 5-hydroxytryptamine 2A (5-HT2A) antagonist. Flibanserin behaves as all-inclusive agonist for 5-HT1A receptor in the frontal cortex as well as in the raphe dorsalis, however it acts as partial agonist in the subfield of hippocampus, especially in the CA3 region. Despite much affinity with serotonergic receptors, flibanserin has weak agonistic activity on dopamine receptor (D4) also. The upshots of flibanserin on intermediate biomolecule adenylyl cyclase are non-identical to that of buspirone which is also a well-known 5-HT1A receptor agonist. Flibanserin has also been found to increase the level of norepinephrine in the prefrontal cortex region (Figure 2).
Both dopamine and norepinephrine manifest significant role in sexual excitement. The norepinephrine shows exciting role in sexual arousal while dopamine has important contribution in boosting desires. Flibanserin has very weak blocking activity on 5-HT\textsubscript{2C} as well as 5-HT\textsubscript{2B} receptors. It has also been reported to decrease the level of serotonin in the prefrontal cortex with long time administrations. The receptor 5-HT\textsubscript{1A} acts primarily as an autoreceptor in brain and inhibits firing of 5-HT neurons from the nerve endings\textsuperscript{28}.

Flibanserin shows an absolute bioavailability of 33\% from oral route. It exhibits linear pharmacokinetics from dose 100mg to 250 mg in adult healthy women and achieves maximum concentration after 45 minutes of administration. Flibanserin shows high protein binding property and extensively undergoes first-pass metabolism through hepatic isoenzymes. The endorsed dose of flibanserin is 100 mg at bed time and maximum course of medication is up to eight weeks\textsuperscript{29}. The drug is now defined as a key drug in the treatment of female sexual interest / arousal disorder (FSAID) in premenopausal women.

**Conclusion**

Flibanserin is a new drug used to treat hypoactive sexual desire disorder in female and has wide link with 5-HT\textsubscript{1A} autoreceptor. It has also antagonistic relations with 5HT\textsubscript{2A}, but preferentially stimulates 5HT\textsubscript{1A} receptor and has also been found to increase the levels of dopamine and norepinephrine in the prefrontal cortex. It is generally used in the treatment of premenopausal women. Flibanserin is the first US-FDA approved drug for stimulating the female sexual desire. The drug is benzimidazole compound and generally enhances the sexual performance as well as number of satisfactory events of a month in premenopausal women. Flibanserin is available as 100mg tablet which should be taken orally once at bedtime. Bioavailability of Flibanserin is 33\% and 98\% of the drug shows high bound to protein mostly albumin while the half-life is of 11 hours and this drug is generally metabolized by liver enzymes. The woman who receives flibanserin experiences significant increase as compared to placebo in the frequency of sexual events. Female sexual disorder is also known by a term ‘female sexual interest/arousal disorders (FSIAD)’. It includes the changes in orgasm, reduced genital and non-genital sensations. Low libido is mostly recorded sexual problem with pervasiveness of 38.7\% as compared to 10\% prevalence when patient feels low desire along with distress. Many agents have been discovered to treat the patient suffering from female sexual desire generally low libido. But Flibanserin is the first FDA approved drug for the treatment of low libido.

Canine Width as a Means for Stature & Sex Prediction

Jyoti Barwa¹, Rattan Singh², Shipra Agarwal³

¹ Assistant Professor, Department of Forensic Medicine & Toxicology, Shri Guru Ram Rai Institute of Medical & Health Sciences, Patel Nagar, Dehradun, Uttarakhand, ² Assistant Professor, Department of Forensic Medicine & Toxicology, Himalayan Institute of Medical & Health Sciences, SRHU, Jolly Grant, Dehradun, Uttarakhand, ³ MDS, 1st yr student, Department of Periodontics, Vokkaligari Sangha Dental College & Hospital, KR road, Visvesvarapuram, Bengaluru, Karnataka

Abstract

Background: Estimation of stature, along with sex, age and race, is one of the four pillars of forensic anthropology and is considered a preliminary screening in identification of skeletal remains. Teeth, particularly the canines form an excellent material for such forensic investigations as they resist decay due to caries or other diseases of tooth as well as remain highly stable during natural calamities.

Materials & Method: Study was conducted in SSSMC, Dehradun among 100 healthy subjects (>17 years), comprising 66 males and 34 females. Mean mesio-distal width of mandibular canine tooth was measured on both side on dental casts and mean stature measured by anthropometer. The collected data was subjected to statistical analysis; correlation and sexual dimorphism was calculated for both sexes and a linear regression formula obtained for estimating stature.

Observations & Result: Mean canine width on both right and left side as well as height was more in males as compared to females. Sexual dimorphism was more involving right canine width. The findings were found to be statistically significant for right canine width (RCW) and for height, between male and females. Accuracy for sex prediction was high in females (F= 64.7%, M=59.1%). Using the values of RCW and LCW, regression equations were obtained for estimating height.

Conclusion: Width of mandibular canine is reliable for stature estimation but for sex prediction it is not much reliable on the left side. However these parameters can be used as an adjuvant in situations when only single tooth is available for identification.

Keywords: canine width, stature, identification, sexual dimorphism

Introduction

In mass disasters, identification of an unknown person from fragmentary remains is the utmost requirement in order to aid the legal authorities in further investigation. Significant parameters for establishing the identity include age, sex and stature because as only these criteria needs to be considered and rest all can be excluded in the missing persons¹. A definite biologic relationship exists proportionately with every part of the human body including head, face, trunk, long bones, foot length as well as shoe print.² ³ Forensic dentistry too plays an important role in human identification, especially when conventional methods cannot be applied, usually due to advanced decomposition, carbonization or fragmentation of the body.⁴ ⁵

The method of using teeth has several advantages as it is easy to locate & measure. Also, they are relatively resistant to damage and most of the odonto-metric parameters remain constant over time⁶ ⁷. Amongst all the teeth in human dentition, canines are the most stable because of the labio-lingual thickness of the crown and root anchorage in the alveolar process of jaws. They are the least frequently extracted tooth or affected by periodontal diseases, less exposed to plaque, calculus and abrasion from brushing. In fact, they are

DOI Number: 10.37506/ijfmt.v14i2.2717
reported to withstand extreme conditions and have been recovered from human remains even after hurricanes and air disasters\textsuperscript{13-16} Though, most of studies have been conducted to correlate combined mesio-distal width of maxillary or mandibular anterior teeth with stature and sex prediction due using various indices; this study aims to study the relationship of only mandibular canine with stature and sex which could prove to be useful when disarticulated tooth from the socket is recovered in above mentioned situations.

**Materials & Method**

The study was conducted in Shridev Suman Subharti Medical College, Dehradun among 100 (66 males & 34 females) healthy students of the Institute having age > 17 years. Those having broken/ damaged or caries involving canine, spinal deformity (kyphosis, scoliosis etc.) or any history of orthodontic/ orthognathic treatment were excluded from the study. A written informed consent was duly obtained from all the willing participants; procedure and purpose of study was explained in detail. Stature was measured as the vertical distance from the vertex to the floor using a standard anthropometer. Measurements were taken by making the barefooted subject stand erect on a horizontal resting plane. Anthropometer was placed in straight vertical position behind the subject with the head oriented in the Frankfurt Horizontal Plane & shoulders & hips touching the vertical limb of the instrument. The movable rod of the anthropometer was brought in contact with the vertex in the mid-sagittal plane. A dental cast of lower jaw was prepared for all the subjects using alginate paste and dental stone. Maximum mesio-distal width of mandibular canines was measured directly on these casts using a digital vernier calliper. It was noted by a single observer on both sides to minimise subjective errors; all these measurements were taken twice and an average was duly noted. Subsequently, using statistical software SPSS version 20, sexual dimorphism, Pearson’s correlation and simple linear regression equations formulated for determining stature.

**Observation & Results**

Among the subjects in the study, mean canine width on both right and left side was more in males as compared to females. Similarly, height was found to be more in males. In all the parameters, t value expressed a very slight difference between male and females, in a positive direction. These findings were found to be statistically significant for right canine width and for height between male and females since p value (0.032) is less than 0.05. However, they were found to be insignificant for left canine width. Sexual dimorphism is highest when height is being considered, but among canine width it is more on the right side. (Table 1)

NOTE: RCW-Right canine width, LCW-Left canine width, H-Height, N-Number, SD-Standard deviation

Paired t test showed that in females LCW > RCW as the t value obtained is –0. 596 while in males RCW > LCW as t value is 0.170. However, there is statistically non-significant difference between right and left canine width in both the sexes as p value is more than 0.05. (Table 2)
The percentage of accuracy in predicting sex was found to be 64.7% for females and 59.1% for males by using Discriminant function analysis.

In females, the Pearson’s correlation value between height and canine width on both sides is found to be positive and very weak having statistically non-significant correlation as p value is more than 0.05. Similarly, in males, correlation value between height and RCW is positive and very weak; statistically non-significant correlation. However, on left side (LCW) there is statistically significant correlation. Also, in total subjects, correlation value is positive, very weak and found to be statistically significant. Using the values of RCW and LCW as independent variable, regression equations were obtained for predicting height in both the

Discussion

Since no two dentitions are alike, this dental identification can be applied for differentiating the size, stature and appearance between male and females. Various studies have been conducted in the past to predict sex from tooth measurements and to determine sexual dimorphism. It has been found that highest sexual dimorphism is observed with canines as compared with other teeth.

Most of the authors failed to obtain a significant difference in canine widths between the right and left sides, which is consistent with our study. Also, statistically significant differences were obtained by some authors in mesiodistal widths of mandibular canines between males and females, which is inconsistent with our study. This significant sexual dimorphism in the tooth can be attributed to the presence of relatively more dentine in males when compared with females.

Similar to our study, some of the authors found a higher sexual dimorphism in right canines as compared to the left canines except in the study by Kaushal et al who found a higher sexual dimorphism on the left side.

Numerous studies have been conducted considering various odontometric parameters either individually or collectively, having some degrees of positive correlations with stature with or without significance between them.

Yadav AB et al conducted a study involving individual tooth dimensions of maxillary canines which revealed that that all odontometric parameters showed positive correlation with stature independent of gender; among them maxillary canine width showed highest correlation. Few studies involving only crown dimensions of teeth failed to provide accuracy of estimation of stature due to significant but low to moderate correlations. This is in concordance with our study to some extent as we did observe statistically significant correlation when all the subjects were considered together and among the male on left side. These relatively non-significant findings could possibly be attributed to early completion of growth of tooth crowns as compared to other parameters such as long bones which on the other hand mature much later and have a higher stature-correlation.

Conclusion

From the present study, it can be concluded that regression equations generated from meso-distal width of mandibular canine can be used as a supplementary
approach for predicting stature when limbs/extremities are not available or are fragmented. Since, there is statistically significant difference between male and female only for RCW and sexual dimorphism is more on the right side, sex prediction is not much reliable using measurement of left canine. Also, accuracy for sex prediction using canine width as a parameter is more in females (64.7%). However, these parameters are population specific and anthropometric difference varies between races. It is also invariably influenced by national, social and economic conditions. Hence, the findings need to be used with caution and the study requires to be extended further to involve different population groups.

Introducing Micro-hardness Test in Forensic Odontology as an Aid in Solving Crimes: Multidisciplinary Approach

Kuldeep Singh Shekhawat1, Arunima Chauhan2, Manoj Varma3

1Associate Professor Department of Public Health Dentistry, Century International Institute of Dental Sciences, Kasaragod, Kerala University of Health Sciences, India, 2 Professor, Department Of Oral Biology, Faculty of Dentistry, Melaka Manipal Medical College (Manipal Campus), Manipal Academy of Higher Education, Manipal Karnataka- 576104, India, 3Professor and Dean, Department of Prosthodontics, Srinivas Institute of Dental Sciences, Mukka, Karnataka, India

Abstract

Background: Many studies have used dental radiography, light microscopy and electron microscopy to study the incinerated tooth for a possible estimation of temperature. However, no study so far has focused on measuring the change in hardness of dental hard tissue owing to higher temperatures.

Objective: To introduce a novel method which may indicate the approximate temperature to which dental hard tissues (teeth) might have been exposed.

Methods: We utilized Vickers hardness testing machine on a set of unrestored, non-carious extracted human teeth which were grouped and exposed to particular temperature of 200, 400, 600 and 800 degree Celsius respectively. Vickers Hardness Number (VHN) was obtained by measuring the diagonals formed after indentation at specific weight and time (constant) for all specimens in every group. Optical Photomicrography was used to view the enhanced images of indentation. The value was computed for all specimens in every group.

Results: We observed overall reduction in VHN values with increase in specified temperature. VHN of enamel was limited to 200 and 400 degrees Celsius, whereas VHN for dentin greatly reduced at 600 and 800 degree Celsius by 10 times. Surprisingly, VHN values for enamel were higher for incinerated tooth (at 200 and 400 degrees Celsius) than VHN reported in literature for non-incinerated tooth.

Conclusion: We suggest that micro-hardness test in forensic odontology is feasible and can be added in the list of already existing techniques for temperature estimation however, further experiments are recommended for its reproducibility.

Introduction

Dental structures are the hardest and well protected structures in the body. These structures resist decomposition and high temperatures and are among the last ones to disintegrate after death.1 Incinerated human remains often require dental comparison to establish ones’ identity. These remains are often fragile and vulnerable to damage teeth and facial bones on minor forces, disrupting anatomical relationships, and impairing the ability to compare with ante mortem records.2

A systematic, conservative approach prevents the loss of valuable dental information before a thorough picture of the individual’s dental remains has been
adequately documented. The presenting conditions of fire victims are often explained and illustrated with photographs, with a series of illustrations and text describing the damage seen in the dentition of the fire victims. Studying the effect of heat on teeth and the restorations would help ascertain the temperature reached by the fire, which would be highly crucial in cases where skeletal remains are recovered. This general estimation of burning temperature could provide important information to reconstruct a criminal act.

Various studies have been done to examine physical changes such as change in colour, texture, or morphology that occurs after exposure of teeth to high temperatures in an incremental pattern. Microscopic, radiographic and ultra-structural examination using scanning electron microscope have also been documented. In the present study we propose a novel method which may provide reliable range of temperature at which a dental hard tissues (teeth) could have been exposed.

**Materials and Method**

Permission to conduct the study was obtained from concerned authorities of the institute. Since the present study did not involve any human participants, the procedure followed were in accordance with the standards from Declaration of Helsinki and its amendments. Sixteen unrestored, non-carious extracted human teeth stored in 10% formalin were conveniently collected and categorized into 4 groups [Group A, Group B, Group C and Group D]. Each group consisted of one central/lateral incisor, one canine, one premolar and one molar [no distinction was made with respect to maxillary or mandibular teeth and the sequence of teeth]. All the teeth specimen were then removed of any soft tissue using a hand surface scaler.

The teeth specimen were then vertically mounted on a tray that could withstand high temperature (Figure 1) and each group was subjected to particular temperature of 200 C, 400 C, 600 C and 800 C [C – Degree Celsius] respectively in an electric muffle furnace (figure 2). The increase in temperature was gradual, starting at 18 C, with an increment of 26 C/min, till the desired temperature was obtained. The teeth specimen were then carefully placed inside the muffle furnace for 15 minutes and then carefully removed at the same temperature. This ensured that the same temperature was maintained when the specimen were removed. The teeth specimen were not observed for any morphological changes.

These specimen were then semi/half-embedded in self-cure resin blocks of uniform dimensions. The specimen were embedded in such a way that the labial surface of the crown and root were almost parallel to the upper surface of the resin block. Each block had teeth specimen which were exposed to particular temperature. These blocks were labelled as Block 1, Block 2, Block 3 and Block 4. Due care was taken to minimize the damage during handling of the specimens.

The resin blocks were filed to reduce the thickness if required to permit ease of procedure. The teeth specimen was not filed to prevent any intentional damage. The embedded teeth specimen were then subjected to micro hardness testing using a micro hardness tester (Shimadzu HJV – G20ST) [figure 3] with square based diamond indenter of 1360 with a constant load of 500 gm for 15 seconds. The minimum spacing between indents was 40µm. Each test condition with the same load and time was conducted on every specimen of the block. Indents having well-formed sharp edges were considered for every specimen in all resin blocks. A total of three reading per specimen was included in calculation. This was followed by calculating average Vickers Hardness Number (VHN) for each resin block irrespective of individual specimen. The VHN values for every indent was automatically calculated and displayed on the screen installed on the micro hardness testing machine. The accuracy of the indentation was determined using optical photomicroscope with 100X resolution. [Figure 4] The procedure was limited to coronal part only since, in-vivo the radicular part of tooth is embedded within the alveolar bone.

**Results**

The VHN for each group exposed to a particular temperature is shown in table 1. The VHN for Group C and Group D was calculated for dentin. The VHN for un-supported enamel could not be estimated. A decrease in VHN was observed from group A to group B. The VHN for dentin also decreased from group C to group D. The magnified images of indentation for each group (specific temperature) is shown in figure 5. The VHN number could not be obtained for few teeth specimens since the optical microscope could not establish accurate indentations.

Discussion

There is no standard condition for enamel and/or dentin micro-hardness testing for normal teeth and perhaps neither for incinerated teeth. In the present study, we propose micro-hardness test as a novel method for incinerated dental hard tissues (teeth) for estimation of higher temperatures. Given the paucity of literature on the concept that was experimented in the present study, we took the liberty to select the testing conditions of incinerated dental hard tissue (teeth).

There is literature to support that fragmentation is an important complication when human remains are exposed to higher temperature. This also decreases the hardness of teeth structure and makes it more brittle. We have made an attempt to overcome the above mentioned characteristic using a multidisciplinary approach. To our knowledge, there is no other study reported in literature which have implemented the concept of micro-hardness testing for estimating temperatures in forensic odontology.

Micro-hardness tests are commonly used to study the physical properties of materials, and they are widely used to measure the hardness of teeth. In the present study, we chose Vickers Hardness over Knoop Hardness since, the test indentation is very small in Vickers and hence it is more useful in testing very thin materials, surface of a part or small areas. Gutiérrez-Salazar and Reyes-Gasga also proposed that in tooth hardness studies the Vickers indenter is more useful than the Knoop because a square shape indent is always conserved, and because the indentation produced on a non-flat surface, or by the difference in hardness of enamel and dentin, is easily detected.

In the present study, it was interesting to find that VHN values for enamel were slightly higher at 200 C and 400 C respectively than the VHN values of non-incinerated teeth reported in literature. Lupi-Pegurier et al reported micro-hardness of enamel in the range of 322 to 353 VHN, Chuenarrom et al reported in the range of 316 to 328.4 kg/mm² with the exception of 418 ± 60 VHN reported by Colly et al. We would also like to highlight that the above VHN values mentioned are irrespective of different loads and time duration. In the present study we set our load at 500gm for 15 seconds and the corresponding mean VHN values obtained were slightly higher. The underlying reasons for this interesting observation needs to be further explored. VHN values for enamel at higher temperatures could not be determined since at temperature above 600 C enamel if present was very brittle and limited to few surfaces and at 800 C enamel got chipped off from DEJ and its remnants were in small pieces which often go unnoticed in fire debris. However, these unsupported enamel were also tested for micro hardness testing but could not sustain the force of indenter at 500 gm. Such unsupported enamel needs to be further tested at lower loads and time.

VHN values for dentin were limited to 600 C and 800 C, since enamel was either present in bits and pieces or completely fragmented thereby exposing the dentin. VHN values could not be obtained at 200 and 400 C. This is because we had no baseline values for dentin prior to incineration, which requires slicing of specimens at the beginning of experiment (which we did not) prior to incineration. Hence VHN values obtained after slicing the specimens post incineration would not have helped us to a large extent. However, this shortcoming needs to be rectified in further experiments for more detailed information. We have compared the values with findings previously reported in literature and found that VHN values for dentin, post incineration were slightly lower than for non-incinerated dentin. This difference in temperature and its associated reduction in VHN values at higher temperatures might prove beneficial in forensic dental sciences.

It is evident from the present study that micro-hardness tests can be applied to estimate the temperature range to which the dental hard tissues (teeth) might have been exposed. These temperature ranges vary according to site involved, the oxidant involved, duration of exposure to fire and burning atmosphere. For example, cremation occurs at temperatures ranging from 871 C to 982 C and combustion of petrol occurs at a temperature of 800 – 1100 C. With increase in temperature we believe the values of micro-hardness tests will also vary. Another added point is that the values are provided as an automated output from the micro-hardness tester which eliminates the possibility of any subjective bias. It also provides a feasible method to store teeth specimens/samples (embedded in resin blocks) for further evaluation if required. The values in the present study provides average VHN for a group of teeth exposed to particular temperatures. We have not made any attempt to provide individual VHN values for incisors, canines, premolars and molars. This was not included due to insufficient time and funds. Further studies are recommended to overcome the shortcomings
of the present study.

With not much literature to help us with the concept, we highlight the limitations of this experiment. They are a) Small sample size b) The VHN values were not recorded before the samples were exposed to higher temperatures: Had we recorded the values, it would have helped us to statistically analyze the results for more scientific validity. However, we have referred to VHN values from the literature to compare the findings. c) The VHN was not determined for dentin at lower temperatures: This would have involved slicing the mounted samples. Teeth become brittle at higher temperatures, the slicing was avoided since we weren’t sure if the resultant samples would be ideal for micro-hardness testing at load as high as 500 gm which was used in the present study. d) The VHN values are obtained only from the indentations on buccal surface of the samples: There are variations in the thickness of enamel on occlusion, middle third and cervical third near the Cemento Enamel Junction (CEJ) on buccal and lingual/palatal surfaces. Any information of VHN at various anatomical regions of enamel (tooth) will improve its sensitivity. e) The load and time duration was constant in the present study; though there is no set value [load and time] for either dentin and/or enamel, variation in time and load across different areas of incinerated teeth might provide more reliable results.

**Conclusion**

The present study provides a rough outline to map the changes associated with higher temperatures using micro-hardness test. It can be concluded from the present study that VHN values of enamel slightly increase than the normal at 200 C and 400 C, whereas, VHN values for dentin decrease at higher temperatures of 600 C and 800 C, for a set load and time duration. We again reinforce that further experiments are recommended to obtain more reliable results which may aid in providing estimated temperatures to which dental hard tissue might have been exposed.

Abstract

Background: Plyometric training is effective to improve the performance of the athletes by increasing the speed power and ability to do the activity. Most of the recreational athletes have no idea about the proper training in the field and they are very prone to get injury. This study was designed to provide the proper training and prevent further injuries in the athletes.

Objectives: To find out the effect of plyometric training on vertical jump height and horizontal jump height in recreational athletes indulging in jumping activities according to age, gender, body mass index and years of playing.

Methodology: 61 subjects participated in this study according inclusion and exclusion criteria. Prior consent was taken. Pre and post assessment of the vertical and horizontal jump height was taken. The protocol was for 3 days per week for 6 weeks. Later evaluation and interpretation of data was done.

Result: There is significant comparison between the pre and post treatment ($p<0.0001$) of horizontal and vertical jump height. Even there is positive correlation of years of playing in week 6 ($p=0.58$) for horizontal jump height and in week 6 ($p=0.43$) for vertical jump height. There is negative correlation of age in week 6 ($p=0.002$) of horizontal jump height in week 6 ($p=0.31$) of vertical jump height.

Conclusion: This study concluded that the effect of plyometric training was seen in recreational athletes indulging in jumping activities.

Keywords: Athletes, plyometric training, vertical jump height, horizontal jump height.

Introduction

Athletes involved in jumping activities are greater risk for sustaining non-contact injuries when compared with other counter-parts[1]. During the maximum running speed phase, forward propulsion of the body is determined mainly by the action of the hip extensors and ankle extensors[2]. There are various type of jumps that athletes do during their practices which can use the muscle power of the leg mostly, so the clinician use better prognostic or diagnostic value[3].

Recently, weighted-vest jumping has shown to enhance jump performance in athletic populations[4]. Recent findings from training studies of kinematic and kinetic data suggest that lower extremity malalignment is related to inefficient neuromuscular control strategies[1].

The application of the strength and power occur under condition by the type of posture, contraction type and movement pattern during the activity[3].

Vertical jump is the act of raising one’s centre of gravity higher in the vertical plane solely with the use of one’s own muscle[5]. It is divided into two types:

a) Standing vertical jump: It refers to vertical jump done from a stand still with no steps involved.

b) Running vertical jump: It refers to vertical jump after an approach or run to help add energy to the jump in an effort to improve on the standing vertical jump[5].

Sometimes seem that horizontal assessment, which involved both vertical and horizontal propulsive forces
which predict those activities that involve horizontal linear motion. In training the players, there are many factors which can be used to improve their performances in the challenging phase. The most challenging for them is the physical fitness and capacities of the player to adapt the exercises. Thus it is important to evaluate the current training and practices to provide sport-specific temporal and kinetic parameters.

Plyometric exercises are defined as eccentric loading immediately followed by a concentric contraction. Plyometric exercises involved stretching the muscle immediately before making a rapid concentric contraction. The combined action is called as stretch-shortening cycle. The rapid eccentric loading phase is called stretch phase and concentric phase is called shortening phase and the period between the stretch and shortening is called amortization phase. During this phase the muscle reverses its action, switching from deceleration to acceleration of the load. In power-related sports, plyometric training is an important component of athletic preparation to increase muscle power.

Plyometric training is thought to utilize the series-elastic properties of connective tissues and the stretch reflex of the neuromuscular unit. During the initial stretch phase the muscle contracts eccentrically and lengthens under tension. The eccentric contraction is thought to prepare the contractile elements of the muscle for the concentric contraction by stimulation and activation of the monosynaptic stretch reflex. Then the receptors send the information to the central nervous system through afferent pathways. From the efferent pathways the signal return and the reflex facilitated the activation of the shortening contraction.

Plyometric training increases performances and decreases the risk of injury in players. There are very rare studies done on the horizontal jump in player indulging in jumping activities. Tobin and Delahunt said that plyometric exercises were able to elicit a potential response in professional rugby players. Complex training is considered by strength and conditioning coaches to be a superior way to develop athletic strength, speed, and power. Plyometric should not be given in presence of inflammation, pain or significant joint instability.

Plyometric training has been proposed for the development of explosive-power performance and specifically for the improvement of vertical jump ability. As the lower extremity is subjected to high joint loads and velocities during plyometric activities, so these exercises are ideal for encouraging the reflexive pathways of feedback motor control. Plyometric training is an established technique for enhancing athletic performance but may also facilitate beneficial adaptation in sensorimotor system that enhance dynamic restraint mechanisms and correct faulty jumping mechanisms. Researches have suggested that plyometric exercises were initially utilized to enhanced sports performance and more recently used in the rehabilitation of the injured athletes to help in participation for a return to sports.

Researches have investigated the relationship between leg power and functional performance have mostly used bilateral vertical jump assessment to predict the activities. Basically there are various component are used to assess the body fat in context to the physical fitness, which are commonly used to determine health related physical fitness.

Wilt suggested that muscular performance gains after plyometric training are attributed to these neural adaptation and it may enhances neuromuscular function. Plyometric training program had positive effect in improving power and agility, and players use this training method during competitive phase.

Gambetta even suggested that using plyometric exercise in athletics training is essential, as it has become an important part in physical preparation programs utilized to developed leg explosive power especially for long and high jump which require the combination of speed and strength. In general, plyometric training is commonly thought to be more effective training exercise than training including countermovement jumps due to an increased stress for the lower leg muscle.

Loturco et al. compared the effect of unloaded vertical vs. horizontal plyometrics on sprint performance in soccer players and found out that horizontal jump group gave greater improvement in speed capacity over short duration, where as vertical jump showed superior improvement over long distances. Luebbers et al. showed that short-term plyometric training result in significant in vertical jump performance in physically active college-aged men.

Rosas et al. analyzed the effect of jumping with or without haltere type handheld loading on vertical and horizontal jump performance in youth soccer player and
the found out that they improved jump performance after 6 week, however loaded jump group showed greater improvement in jump capacities\cite{20}.

**Methodology**

61 subject were taken for the study according to inclusion and exclusion criteria. Inclusion criteria were age group was between 15-30 years and recreational athletes indulging in jumping activities like hurdle jump, long jump. Exclusion criteria were Players have previous injuries in lower extremity or have gone through previous surgeries or having ankle instability. Prior consent was taken. Pre and post assessment of vertical and horizontal jump height was taken. The protocol was for 3 days per week for 6 weeks. Each session was of 60 min.

**Exercise protocol** was started with warm-up exercise that is jogging, stretching, shoulder exercise, skipping. Then Landing drills, take off drills,full speed 30-50 meter, squat jumps, depth jumps, box jumps, lateral jumps, ankle hops, double leg jump forward and backward, double leg zig-zag hops, cone jumps. Cool down period was 15 minute.

**Statistical Analysis**

Statistical analysis of the recorded data was done by using the software SPSS version 2.0. mean+standard deviation and paired t-test were used for analysis of data. Correlation of the result with age, body mass index and years of playing were determined by using Spearmen’s correlation coefficient.

**Findings**

---

**Discussion**

Vertical jump height and horizontal jump height are used to measure the athletes performances\(^5\). The distance achieved during the jump are dependent on the athletes ability to transfer the linear momentum force directly from the ground to athletes body’s center of mass which is critical to break the inertia and attain high velocities over short-distances. Plyometric training is helpful in increases performances and decreases injury in players\(^1\). During the maximum running speed phase, forward propulsion of the body is determined mainly by the action of the hip extensors and ankle extensors\(^2\).

The jump height is recorded as distance score. It can be affected by the angle of knee bending, effective use of hands, coordination etc.\(^5\). To achieve the maximum height during jump the athletes center of mass need to be as high as possible in relation to the ground to attain the highest velocity at the take-off. At these moment the subject follow the sequence pattern of the lower limb rotation result in increase in amount of external force.
which applied to overcome the inertia and accelerate the body vertically. As the ground force increases the jump height increases\(^{[13]}\). In previous study they found out that sprint training produces similar or greater training effects than does plyometric training\(^{[2]}\).

Several studies showed that muscle power and overall muscle strength correlate negatively with the obesity in children and positively in adults with functional status and bone health. Even they suggest that there are many factor which can contribute to the decrease in the performance in relation to the horizontal jump like changes in the body and lifestyle which can be improved. Further studies should include the invasive technique that dependent on the individual’s subjectivity and cultural factors for proper use\(^{[9]}\).

In present study we find out that the maximum age group is around 21-25 years where they have achieved the maximum level of maturity. Even there is negative correlation of the age with both result of vertical and horizontal jump height. In previous study they stated that during and following the puberty there has been seen marked difference and unable to explain the absence of significant improvement \(^{[5]}\).

The result of the present study showed that there is significant effect of the training in recreational athletes indulging in jumping activities which increases both vertical and horizontal jump height of the players \((p=0.0001)\). Loturco et al. observe a meaningful increase in vertical and horizontal performances of elite U-20 players who executed short-term program for 3-week composed of vertical or horizontal. The reason behind this is the player’s both horizontal and vertical jump height being fully related to the body’s vertical as well as horizontal acceleration; and the acceleration is equal to force divided by mass. Sprint training increased the body’s vertical as well as horizontal acceleration thus increasing the capacity to accelerate the player’s own body weight. \(^{[13]}\)

Even in this study we found out the positive result of the athletes years of playing in relation with both vertical jump height week 1 \((p=0.86)\) and week 6 \((p=0.43)\) and horizontal jump height week 1 \((p=0.23)\) and week 6 \((p=0.05)\) which shows that have increased their performances for competitive level. This study has some limitation but majorly due to small sample size. Further studies can be done on larger sample size and also on the horizontal jump height as there are very rare studies done.

**Result**

There is significant comparison between the pre and post treatment \((p=0.0001)\) of horizontal and vertical jump height. Even there is positive correlation of years of playing in week 1 \((p=0.31)\) and week 6 \((p=0.58)\) for horizontal jump height and in week 1 \((p=0.86)\) and week 6 \((p=0.43)\) for vertical jump height but we found out that there is negative correlation of age in week 1 \((p=0.326)\) and week 6 \((p=0.002)\) of horizontal jump height and week 1 \((p=0.64)\) and week 6 \((p=0.31)\) of vertical jump height.

**Conculsion**

This study concluded that the effect of plyometric training was seen in recreational atheletes indulging in jumping activities.

Risk factors in Implant Placement: A Retrospective Analysis

Thilak Shetty1, Shobha Rodrigues2, Sharon Saldanha3, Umesh Pai3, Mahesh M3, Puneeth Hegde3, Manawar Ahmad4

1Professor, 2Professor& Head, 3Associate Professor, Department of Prosthodontics, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, 4Assistant Professor, Department of Prosthetic Dental Sciences, Jazan University, Jazan, Saudi Arabia.

Abstract

Purpose: The aim of this retrospective study was to determine the prevalence of implant failure and its associated risk factors using a single implant system in our clinical setting.

Method: Patients who received implant treatment with a single implant system (MIS, Confident India) at Manipal College of Dental Sciences, Mangalore from 2010 to 2016 were enrolled. The following data were collected for analysis: patient details, field of expertise to which the surgeon belonged, diameter and length of the implant, The outcomes assessed were early or delayed failure on the basis of operator, implant, anatomy and patient related factors.

Results: This study analyzed 363 implants in 327 patients, who comprised 136 females and 191 males and were followed up until failure was reported after implant placement. 22 implants failed prior to final prosthesis delivery (early implant failure), and 5 implants were lost after prosthesis delivery. Out of 363 implants 206 (57%) implants were placed by the Department of Prosthodontics, 77 (21%) by the Department of Periodontics and 69 (19%) by the Department of Oral surgery and remaining were placed by a single Endodontist (3%) specialized in Implantology. (9/206=4%) failures were reported from Prosthodontics and 18 (18/69=26%) failures from Oral Surgery No failures were reported from Periodontics and Endodontics.

Conclusions: Prospective studies are warranted to further elucidate the factors contributing to implant failure. In the meantime, surgeons should receive appropriate training and carefully select the bone bed in order to minimize the risk of implant failure.

Key words: Early implant failure, overload, risk factors

Introduction

Dental implants have been considered to be a highly predictable treatment modality for replacing lost teeth in both partially and completely edentulous patients. Buser et al. retrospectively evaluated 511 implants with a sandblasted, large-grit, and acid-etched (SLA) surface, and reported a high 10-year success rate of 97%. However, not all implants are expected to show successful results, and adverse results that lead to implant removal are inevitable in routine practice due to the potential presence of many contributing factors.

Implant failure has been categorized as early and late in retrospective studies according to the time of prosthesis connection and time of loading. Recent studies have found that the prevalence of implant failure is higher in the early phase than in the late phase regardless of the loading time. This might be largely attributed to the vulnerability of the early phase, during which the primary stability decreases while the secondary stability gradually increases. Therefore, considerable interest has emerged in investigating the mechanism of early implant failure and the management interventions that are required to minimize the rate of implant failure.

DOI Number: 10.37506/ijfmt.v14i2.2753
Early failure arises from a lack of osseointegration and that the clinically discernible mobility of an implant is a clear sign of early failure.5

Considering that dental implants are placed in a complex biological environment, multiple factors could contribute to implant failure. Numerous retrospective studies have shown that several patient-related, surgeon-related, and biomaterial-related factors can contribute to implant failure.6 However, many of these studies used diverse implant systems with different designs, which could have greatly affected the results.

Therefore, the aim of this retrospective study was to identify the factors influencing early implant failure at a single center using a single implant system.

Materials and Method

Inclusion of participants

This study recruited patients who received an implant-supported prosthesis using a single bone-level implant system (MIS, Confident India) with internal hex design and an SLA surface from 2010 to 2016 at this Institution. Patients with systemic disease were included if their condition was not a contraindication for implant surgery. Patients who were lost to follow-up and contact after implant placement were excluded from the study.

Clinical procedures

All implant placement procedures were mainly carried out by 18 residents supervised by 4 faculty members except those performed by the Endodontist. Sinus-floor elevation (SFE) and/or guided bone regeneration (GBR) was performed in patients with insufficient vertical bone height and/or width of the ridge crest either prior to or combined with the implant placement procedure. Either a 1-stage or 2-stage protocol of implant placement was selected according to the primary stability of the implant or the necessity for a bone augmentation procedure. In the 2-stage protocol, the second-stage surgery for implant exposure was performed after 3–4 months of healing.

All surgical procedures were performed under local anesthesia induced by 2% lignocaine hydrochloride with 1:200,000 epinephrine (Lox, Neon Laboratories, Mumbai, India). Sutures were generally removed at 7 days after surgery. The patients were recalled after 4–6 months, and the stability of implants checked clinically and then referred to the Department of Prosthodontics.

This study defined early implant failure as an implant showing clinical mobility before placement of a final prosthesis and late failure as clinical mobility after placement of final prosthesis with loading. Failed implants were removed after receiving consent from the patient, and the sites were restored using new implants or another prosthesis according to the modified treatment plan. Implants were categorized according to their size, the jaw in which they were placed (maxilla or mandible) and their position in the dental arch (anterior or posterior). The surgeons were dichotomized into faculty members and residents.

Discussion

This retrospective assessment of the factors contributing to early implant failure found that the early failure rate of a single implant system was 6% and late failure rate was1% with the total implant failure rate being 7.4%.with significant number of failures associated with residents of Oral Sirgery.

Highly predictable long-term results of oral rehabilitation using dental implants have been documented in efficacy studies performed over the past 50 years. Literature has assessed the effectiveness of implant therapy and analyzed risk factors for implant failure with the aim of further improving treatment outcomes. The current study also focused on the latter aspects, but only included patients who received implant treatment using a single implant system at a single center in order to minimize the possible confounding effects of the surface or system of the implant and other differences between implant brands. In addition, the present study focused on implant failure occurring between different specialties of dentistry and the incidence of early failure.

The prevalence of early failure in the present study was within the previously reported range at the implant level (1.3%–6.36%). Rates can vary with the cutoff time point used to divide the early and late phases. Setting the cutoff time as the time of abutment connection has the advantage of minimizing heterogeneity resulting from differences in the timing of loading and the loading methods. Meanwhile, setting the cutoff time as 1-year after final prosthesis delivery can reflect delayed failures suspected to have been initiated during implant surgery and the tendency for radiographic evaluations to be performed for evaluating marginal bone loss.

Implants placed in the anterior maxilla were found to have a higher risk of failure in this study 4 of which were on account of road traffic accidents and defeciency in premaxillary region requiring bone grafting and one was on account of immediate implant placement in an infected socket. Therefore, the higher risk of implant failure in the anterior maxilla should be interpreted in the context of the characteristics of patients as demonstrated in the present study.

This study found that the implant failure was higher for shorter 8-mm implants with most of these implants failing in the posterior maxilla( 75%). It is well known that the length of an implant has less effect than its
diameter on dispersing occlusal loads. In addition, it has been reported that the outcomes for short implants (less than 8 mm) appear to be as predictable as those for standard-length implants placed in augmented bone. Placing a short implant will reduce the degree of invasion into surrounding anatomical structures and the need for regenerative procedures. Most of these short implants were placed by residents in order to avoid invasive procedures of Direct as well as in some instances indirect sinus lift. A retrospective study found that the survival rate of implants did not appear to be associated with the experience of the 80 included surgeons. Meanwhile, another study found that a learning curve was present for implant placement, in that the early failure rate was 2-fold higher for surgeons who had previously placed fewer than 50 implants than for surgeons who had placed more than 50 implants. Experience or competence of the surgeon influences the failure rate of dental implants. Therefore, the results should be interpreted in context of the characteristics of competency-based surgical skill of residents and experience necessary for successful implant placement.

Jemt et al., who suggested that the individual personality or attitude of the surgeon can affect the implant outcome, based on the rate of implant failure being significantly lower for 1 surgeon who preferred a 2-stage protocol and delayed implantation after tooth extraction. This could be a possible explanation as to why most implants failed when speciality of Oral Surgery and Prosthodontics placed implants.

The main limitation of this study is that the medical histories of patients were not fully scrutinized. However, recent studies did not identify any medical conditions that significantly increased the risk of implant failure. Furthermore, eliciting and recording the medical history only based on the verbal statements of patients might provide incomplete or inaccurate information. Another limitation is that parameters regarding bone quality and quantity were not analyzed objectively. The effect of alveolar ridge atrophy on early implant failure can vary considerably according to the implant position and dimension. Therefore, it might be helpful for avoiding bias to use postoperative parameters such as peri-implant bone wall thickness, dehiscence, or fenestration size when analyzing bone quantity.

Recently developed implants have macro-level designs and surfaces that improve the primary stability and facilitate osseointegration. Nevertheless, implant failure is still observed in routine practice.

**Conclusion**

The present study found that speciality and experience of the surgeon, position of the bone bed of patients and height of the implant affected the likelihood of implant failure using a single-implant system. Considering that the characteristics of the surgeon strongly influenced early implant failure, educational programs should be developed for increasing surgical competency and performance, and further prospective studies are warranted.

Effect of Upper Body Strength Training in Spatiotemporal Parameters of Gait In Individual with Thoracic Kyphosis

Vinayak Sawant¹, Poonam Patil ²
¹Internee, Krishna College of Physiotherapy, ²Assistant Professor, Department of Cardiopulmonary Physiotherapy, Krishna College of Physiotherapy, Krishna Institute of Medical Sciences Deemed To Be University, Karad, Maharashtra

Abstract

Background: The human spine is an integral part of the human body. Its function includes mobilizing the torso, controlling postural stability, transferring, loads from upper body to lower body, all of which is essential for the activity of daily living. Spine deformity affects spinal mobility and trunk balance, thus altering locomotion pattern during each step. Spinal deformity also alters the center of body mass (com) during gait which leads to gait abnormality. Exaggerated thoracic kyphosis is common in the elderly as there is age related increase in thoracic spine curvature. Generally, patients with thoracic kyphosis mostly have gait impairment with reduced movement in upper limb strength and muscle mass gets altered in upper limb.

Objective: The objective of the study is to study the effect of upper body strength training on spatiotemporal parameters of gait in individuals with thoracic kyphosis and to find out the effect of upper body strength program on gait parameters after thoracic kyphosis.

Material and Method: In this interventional study a total of 25 individuals with in the age group of 20 to 50 years, were selected. Pre-test and post-test assessment was done using the outcome measures of flexi curve ruler to assess kyphosis index and spatiotemporal measurement. Exercises were administered for 6 weeks. Later, post-test assessment and statistical analysis was done to determine its significance.

Results: According to the result, there was a considerable change in the stride length(p-value<0.0001) step length(p-value<0.0001) and cadence (p-value<0.0001). There was also a marked change in the kyphosis index. (p-value<0.0001).

Conclusion: As per the result of this study, we conclude that the effect of upper body strength training on spatiotemporal parameters of gait in individuals with thoracic kyphosis was extremely significant.

Keywords: Kyphosis, strength, thoracic, spatiotemporal, gait, parameters, upper body, stride length, step length, cadence.

Introduction

Thoracic kyphosis refers to forward curvature of the thoracic spine. Exaggerated thoracic kyphosis is common in the elderly as there is age related increase in the curvature of the thoracic spine¹.

There are three main types of abnormal kyphosis. Postural kyphosis is more common in girls than in boys and typically appears during adolescence. Poor posture and weakening of the muscles and ligaments in the back causes postural kyphosis². This patient can have symptoms of pain and muscle fatigue. Scheuermann’s kyphosis is the result of structural deformity of the vertebrae. It is more common to develop kyphoscoliosis with Scheuermann’s kyphosis than with any other type of kyphosis. Congenital kyphosis is the least common

Corresponding author:
Dr. Poonam Patil
Assistant Professor, Department of Cardiopulmonary Physiotherapy, Krishna college of Physiotherapy, Karad, Contact no: 7719028515

vinayaksawant402@gmail.com
type of abnormal kyphosis and occurs due to abnormal development of vertebrae.

The most common symptom for patients with abnormal kyphosis are appearance of poor posture with a hump at the back or round back. Symptoms may also include back pain, muscle weakness and stiffness in the back. Physical and social outcomes of spinal kyphosis include in high, protuberant abdomen, downward gaze, digestive problems, impairments of respiratory function and decreased quality of life. Therefore, basic activates of daily living, leisure, and emotional are negatively affected by spinal deformity. The functional consequence of this postural deformity and the overall decline in quality of life often overlook. Generally, patients with thoracic kyphosis have gait impairment with reduced movement in upper limb. Reduction in strength and muscle mass in upper limb also occurs.

Gait is the most common human movement involved in daily activity. Gait is the series of alternating movement of the lower extremities in a rhythmic motion that results in forward propagation of body. Gait parameters like cadence, step length and stride length generally tend to be reduced due to thoracic kyphosis. Basically cadence is the number of steps taken per unit time. Step length is the distance between corresponding successive points of heal contact of opposite feet. Stride length is the distance between successive points of heal contact of the same foot.

Normally in patients with altered gait, free movement of upper limb is necessary to improve gait and its parameters. Upper limb strengthening also helps in free motion of upper limb.

The human spine is the integral part of the human body. Its function includes mobilizing the torso, controlling postural stability, transferring, loads from upper body to lower body, all of which is essential for the activity of daily living. Spine deformity affects spinal mobility and trunk balance, thus altering locomotion pattern during each step. Spinal deformity changes the center of body mass (COM) during gait which leads to gait abnormality.

Measurement should be taken on the same population for which the measure is intended. For assessment of severity of kyphosis, normally radiographic method is used. However, it is a relatively expensive method as well as exposes the individual to radiation. Hence, flexi curve ruler is used here. It is a flexible ruler that molds according to the curvature of the spine and thus the angle can be measured. It reliability had a intra class correlation coefficient of 0.906 which is highly reliable.

Therefore, the purpose of this study was to assess the pre-test and post-test reliability of the measurement of thoracic kyphosis using the flexi curve ruler with spatiotemporal parameters measurement.

Methodology

The ethical clearance was taken from ethical committee of Krishna institute of medical sciences, Karad. There were 25 participants in the study. The study took place in the Physiotherapy department, Krishna institute of medical sciences. The study was effect of upper body strength training in spatiotemporal parameters of gait in individual with thoracic kyphosis. The treatment protocol was of 8 weeks. The subjects were assessed for severity of kyphosis and spatiotemporal parameters as well. The type of study was experimental study. The study design was pre and post. The samples were chosen using the simple random sampling method. Participants were included as per inclusion criteria, i.e. age group of 20-50 years, individuals with acquired thoracic kyphosis and with Secondary kyphosis.

Procedure

All the subjects were selected for the study according to the selection criteria. Demographic data and consent form was provided. Pre and post assessment were taken before the treatment began and after completion of treatment i.e. at 6 weeks respectively with the help of outcome measures.

In 1st and 2nd week, mirror image thoracic extension exercises for a hold time of 30sec and for a total of 5 repetitions was given. Along with this, head retraction for a hold time of 15sec and for a total of 5 repetitions was given as well as superman exercise for a hold time of 3sec and for a total of 10 repetitions was given.

In 3rd and 4th week, mirror image thoracic extension exercises for a hold time of 30sec and for a total of 7 repetitions was given. Along with this, head retraction for a hold time of 15sec and for a total of 5 repetitions was given as well as superman exercise for a hold time of 3sec and for a total of 10 repetitions was given.

In 3rd and 4th week, mirror image thoracic extension exercises for a hold time of 30sec and for a total of 7 repetitions was given. Along with this, head retraction for a hold time of 15sec and for a total of 7 repetitions was given as well as superman exercise for a hold time of 3sec and for a total of 15 repetitions was given. Raise up thoracic extension for a hold time of 15sec and for a total of 10 repetitions was given.
In 5th and 6th week, mirror image thoracic extension exercises for a hold time of 30sec and for a total of 10 repetitions was given. Along with this, head retraction for a hold time of 15sec and for a total of 10 repetitions was given as well as superman exercise for a hold time of 3sec and for a total of 15 repetitions was given. Raise up thoracic extension for a hold time of 15sec and for a total of 15 repetitions was given along with thoracic spine foam rolling for a hold time of 30sec and for a total of 10 repetitions was given.

**Discussion**

The human spine is the integral part of the human body. Its function includes mobilizing the torso, controlling postural stability, transferring loads from upper body to lower body, all of which is essential for the activity of daily living. Spine deformity affects spinal mobility and trunk balance, thus altering locomotion pattern during each step. Spinal deformity changes the center of body mass (com) during gait which leads to gait abnormality. Exaggerated thoracic kyphosis is common in the elderly this age related increase in thoracic spine. Generally patient with thoracic kyphosis mostly have gait impairment with reduced movement in upper limb strength and muscle mass gets altered in upper limb. Thus kyphotic individuals need appropriate treatment and awareness of such therapeutic techniques
like upper body strengthening necessary for preventing further complications as well as improving the quality of life of the individual.

In this study, 25 individuals who had kyphosis were taken. Individuals in the age group of 21-50 years were included in this study, out of which 13 (52.0%) individuals were in the (21-30) age group, 8 (32.0%) individuals were in the (31-40) age group, 4 (16.0%) individuals were in the (41-50) age group.

Also, out of the total 25 individuals participating in this study, 16 (64%) were male and 9 were female (36%).

Score according to Kyphosis index (KI) and spatiotemporal parameters of subjects were taken before the treatment/intervention was given. The mean Kyphosis Index score prior to the intervention was 35.92 and post intervention was 33.44.

Statistical analysis of Kyphosis index score of pre and post intervention was done to confirm that the difference between the pre and post measurements is significant. The comparison for pre and post Kyphosis index scores was found to have a p-value of (<0.0001) which was extremely significant.

To analyze the impact of kyphosis on gait in terms of spatiotemporal parameters like stride length, step length and cadence was done. Same as Kyphosis index score, measures of stride length, step length and cadence were taken before and after the treatment. The mean scores of stride length pre and post intervention was 68.48 and 75.56 respectively, for step length the pre and post intervention score was 34.32 and 37.76 respectively and for cadence the pre and post intervention score was 76.32 and 80.88 respectively. Here, stride length was altered the most among all the parameters.

Statistical analysis was done to compare the mean pre and post intervention scores of spatiotemporal parameters to confirm whether they were significant or not and it was found that stride length had a p-value of (<0.0001) which was extremely significant, step length had a p-value of (<0.0001) which was extremely significant and cadence also had a p-value of (<0.0001) which was extremely significant. Thus there was a significant improvement in the spatiotemporal parameters post intervention.

The reason behind this may be due to the fact that the exercises administered by us also utilized the lower limb muscles in some instances. Moreover, these exercises are known to strengthen the scapular muscles as well as the back muscles that link the trunk to the lower extremities. The trunk is the central key point of the body, and the control of movement proceeds from proximal to distal body regions. Motor control literature also suggests that an improvement in the levels of proximal trunk control might lead to a better distal limb control. Hence, strengthening the trunk plays a significant role in improving gait.

Thus the results obtained by studying both the pre and post intervention scores in this study suggest that in treatment of kyphosis, upper body strengthening is extremely effective.

Acknowledgement: I sincerely thank the management of KIMSDU for allowing me to conduct this study by providing me the necessary requirements. I thank my Dean Dr. G. Varadharajulu sir for his support and guidance. I convey sincere thanks to my guides Dr. Poonam Patil for helping me in my research. I take this opportunity to thank all those who have been directly or indirectly involved for smooth conduction of my study.

Conclusion

On the basis of the result of the study it is concluded that in treatment of kyphosis, upper body strengthening is extremely effective.

Abstract

The Tau protein is a microtubule-associated protein that acts as a three-dimensional “railroad tie” for the microtubule. Accumulation and Aggregation of the Tau is the pathogenesis of Alzheimer’s disease. Risk factors like ApoE risk alleles, changes in the endoplasmic reticulum, and Kinases and phosphatases dysregulation have identified as the most critical factors. In Tau pathology, the abnormal hyperphosphorylation of tau appears as its accumulation in the affected neurons in Alzheimer’s disease.

Neurofibrillary Tangles has shown truncated tau in both Glu-391 and Asp-421. Truncated tau associated with apoptosis in cultured cells. All six molecules of tau are the hyperphosphorylated state in PHF. In AD, hyperphosphorylated tau is present as a cytosolic protein and PHF. Treatments related to tau pathology are under research. Tau phosphorylation inhibitors and Tau aggregation inhibitors tested in people with AD. In tau phosphorylation inhibitors, Lithium has multiple targets and inhibits GSK-3b, and in tau aggregation inhibitors, many drugs block aggregation of tau in cell-free conditions. Methylene blue has multiple targets; it slows disease progression. Tau pathology appears to be a primary cause of neurodegeneration in AD. Risk factors showed a relation between AD and Tau pathology clearly. Abnormal hyperphosphorylation of tau leads to AD, and truncated tau is the main finding in tau pathology. Tau phosphorylation inhibitors and Tau aggregation inhibitors are emerging treatments.

Keywords: Alzheimer’s disease, Paired Helical Filaments, Neurofibrillary tangles, Tau pathology, Abnormal Hyperphosphorylation, Truncation, Conformation and Isoforms, Toxicity, Tau Phosphorylation Inhibitors and Tau Aggregation Inhibitors.

Introduction

Tau is the essential Microtubule-Associated proteins (MAP) in the neurons and acts as a three-dimensional “railroad tie” for the microtubule. Accumulation and Aggregation of the Tau is the pathogenesis of Alzheimer’s disease. Phosphorylation of tau binds it to the microtubules and helps in maintaining the structure, stability of neurons¹. Accumulation of phosphate (Hyperphosphorylation) on the tau proteins cause “paired helical filaments” (PHFs) that accumulate and lead to the neurofibrillary tangles (NFTs)². PHFs are the main component in NFTs. Abnormally hyperphosphorylated, insoluble, and filamentous tau was the main component of Neurofibrillary Tangles³⁴⁵. NFTs are neurological hallmark of AD⁶. It expressed in the central and peripheral nervous system and less amount observed in the kidney, lungs, and testis⁷. Abundantly seen in neuronal axons⁸. The human tau gene is located over 100 kb on the long arm of chromosome 17 at band position 17q21 and has 16 exons⁹. Tau divided into four regions: N-terminal Projection Region, a Proline-Rich Domain, a Microtubule-Binding Domain (MBD), a C-terminal region¹⁰. Tau can bind to outside and inside of microtubules by N- and C-terminal regions projecting outwards¹¹¹².
Factors related to Alzheimer’s disease

ApoE Risk alleles

ApoE is a risk factor related to AD in relation to tau pathology. ApoE, as a vital component of chylomicrons and IDLs involved in the catabolism of lipoproteins. It has a crucial role in the metabolism of fats in the body. ApoE is a cholesterol carrier in the brain. ApoE transfers lipoproteins, fat-soluble vitamins, cholesterol to the lymph vessels, and into the blood. ApoE is abundant in CNS but synthesized in the liver.

Accumulated cholesterol in the neurons converted into 24OHC (24S-hydroxycholesterol) in neurodegeneration. The CSF tau levels related to neurodegeneration in AD. The association between ApoE, 24S-hydroxycholesterol, and tau shows its direct involvement in the generation of NFTs.

Damage in Endoplasmic reticulum

Damage in Endoplasmic reticulum is a significant risk factor related to AD in relation to tau pathology. The Endoplasmic reticulum functions are energy production, folding, and trafficking of proteins and apoptosis. Role of ER in the development and progression of neurodegenerative diseases. Inositol-Requiring kinase 1 (IRE1) starts the ER stress pathway by triggering Apoptosis signal-regulating Kinase 1 (ASK 1), activates c-Jun N-terminal Kinase (JNK) signaling route. This cascade has the strength to trigger AD pathology through hyperphosphorylation of tau and aggregation of neurofibrillary tangles. ER stress causes deposition of misfolded like tau, and long-time existence of these toxic misfolded proteins triggers intrinsic apoptosis pathways. Overexpression increase the intracellular concentration of tau may inhibit the plus-end-directed transport of vesicles along microtubules by kinesin, and the minus-end-directed transport by dynein becomes dominant.

Tau degradation decreased by 20% in ER stress due to a decrease in the tau binding to CHIP (carboxyl-terminus of Hsc70-interacting protein), which delayed the tau degradation through the ubiquitin-proteasome pathway.

Kinases and phosphatases dysregulation

Dysregulation of kinases and phosphatases is a critical risk factor related to AD in relation to tau pathology. Several protein kinases like cyclic AMP-dependent Protein Kinase A (PKA), Glycogen Synthase Kinase-3 (GSK-3), cyclin-dependent protein kinase-5 (cdk5), Calcium/Calmodulin-dependent Protein Kinase-II (CaMKII), Mitogen-Activated Protein (MAP) kinase, Extracellular signal-regulated kinase (ERK 1/2), Stress-activated protein kinases are involved in abnormal hyperphosphorylation of tau. Some kinases like Protein Kinase A (PKA), Protein Phosphatases 2A (PP2A), Glycogen Synthase Kinase-3 (GSK-3), Calcium/Calmodulin-dependent Protein Kinase-II (CaMKII) plays a role in Tau phosphorylation and dephosphorylation. Abnormally hyperphosphorylated sites in tau are proline-directed, serine, and threonine, followed by proline are official sites of proline-directed protein kinases (PDPKs). GSK-3, cdk5, PDPKs, and ERK 1/2 are subjected to phosphorylate tau the sites in AD.

The preparation of tau by PKA or CAMKII is enough to initiate the abnormal hyperphosphorylation of tau. Dysregulation of Tau kinase CAMKII effects AD progression, and CAMKII inhibits tau-microtubule interaction by tau phosphorylation. When GSK-3 overexpressed and it results in hyperphosphorylation of tau. GSK-3 activation results in brain aging and AD initiates detrimental events like NFT formation and neuronal death pathways. PP-2A and PP-1 do 90% of serine/threonine protein phosphatase activity. Phosphorylation of ERK inhibits activity in response to neuronal stimuli.

Tau pathology

In AD, the regular role of tau impaired because this protein loses its capacity to bind to microtubules. Tau pathology starts from the entorhinal cortex and continues to the hippocampus, neocortex, frontal, temporal cortices, and all isocortex areas. Tau pathology observed in the form of abnormal Hyperphosphorylated protein. There is a very robust correlation between tau pathology and clinical measures of dementia. In AD, tau pathology also plays a significant role because this has the potential to trigger AD in humans.

Abnormal hyperphosphorylation of tau

The main characteristic feature of tau pathology is the abnormal phosphorylation of tau. The abnormal hyperphosphorylation of tau and significant protein subunit of PHF, which results in neurodegeneration by sequestration of MAPs, self-assembles bundles of
PHF and forms NFTs. In Tau pathology, accumulation of abnormal Hyperphosphorylated tau associated with neurofibrillary degeneration and dementia. The abnormal hyperphosphorylation of tau observed in both NFTs and the cytosol of AD brains. Mutations in the tau gene and their cosegregation linked to chromosome-17 (FTDP-17) have abnormalities in tau as a leading, and the first event leads to neurodegeneration and dementia. The study of mAb Tau1 revealed deposits of abnormally hyperphosphorylated tau in neurons without tangles (stage “0” tangles) in AD. In tau, Ghost tangles are ubiquitinated, and in abnormally hyperphosphorylated tau, cytosome has no ubiquitin reactivity. Abnormal hyperphosphorylation of tau might be due to a conformational change in tau, and tau conformationally altered in AD. On hyperphosphorylation, murine tau self assembles into tangles of filaments (PHF/ SF)\(^4\). Abnormal hyperphosphorylation of tau comes before its accumulation into NFT’s. In our research, tau hyperphosphorylation seen at many sites and even HMW-tau hyperphosphorylated at many locations. An essential finding of the study is overexpressing p25 initiates and promotes hyperphosphorylation. This abnormal hyperphosphorylation leads to filaments self-assembly.

**Truncated tau**

Presence of truncation connected to neurofibrillary pathology in the brain of AD patients. Neurofibrillary Tangles has shown truncated tau in both Glu-391 and Asp-421. Truncated Tau associated with apoptosis in cultured cells. There is no report on what percentage of tau truncated at affected sites in different stages of AD. Neurodegeneration in AD seen for a long time from months to years, and there is a fair chance to view truncation in tau. Truncation is seen in both affected neurons and ghost tangles (extracellular space) when NFTs exposed to hydrolases. Truncation of tau was observed by immunolabeling with the monoclonal antibody Tau-C3. Tau-C3 recognizes Asp-421. Asp-421 was associated with the neurofibrillary pathology in the AD brain. In vitro studies described that truncated tau at ASP-421 showed elevated rates of polymerization over full-length tau. Cells transfected with truncated tau protein, it has demonstrated that both soluble and insoluble forms can induce toxicity. In COS7 cells that Asp-421 is highly phosphorylated and abnormally redistributed. In HEK-293T cells that Glu-391 has a problem in binding with microtubule, and there is toxicity resulted in cell death. In the progression of the disease, Early event truncation of Asp-421 and preceded by truncation of C-terminal of Glu-391, further occurring from intermediate to advanced stages of NFTs evolution. In truncation, this research specially confined to truncated tau in Glu-391 and Asp-421. In our findings, COS7 cells highly phosphorylated in Asp-421 and HEK cells have a binding problem with microtubule.

**Isoforms of tau**

Six isoforms of tau differ by contents of three (3R) or four (4R) tubulin-binding domains of 31 or 32 amino acids in C-terminal and one (1R), two (2R) or inserts of 29 amino acids each in N-terminal of tau. All six molecules of tau are the hyperphosphorylated state in PHF 3,4,54. 441-residue tau is the longest tau isoform seen in the human CNS. In AD, hyperphosphorylated tau is present as a cytosolic protein and PHF 3,4,54. Cytosolic hyperphosphorylated tau (P tau) has 5-9 mol of phosphate per mole of the protein (contains 2-3 phosphate groups). Tau self-assembles by intermolecular hydrophobic interaction and microtubule-binding repeat R3 (3R taus), and R2 and R3 (4R taus), when the rest of the molecule neutralized. Inhibitory amino-terminal and carboxyl-terminal regions neutralized by abnormal hyperphosphorylation in AD. Cytosolic and PHF are abnormally hyperphosphorylated taus are readily dephosphorylated by phosphatases in vitro. Tau molecule changing its conformation to form a paperclip-like conformation by folding the N- and C-terminal portions back on the microtubule-binding repeats. FTDP-17 mutations alter the conformation of the protein, and it becomes a more favorable substrate to brain protein kinases. Mutated taus are soon hyperphosphorylated and self-assemble at a lower level of hyperphosphorylation. In tau, Dephosphorylation inhibits self-assembly, and hyperphosphorylation promotes self-assembly, but Deglycosylation of AD promotes self-assembly. This study found that all six tau
isoforms self-assembled into PHF/SF. This result clearly explains that hyperphosphorylation is enough to initiate self-assembly of tau into filaments. The 3R isoforms are more toxic than 4R.

**Possible treatments for tau pathology**

Treatments targeting different aspects of tau pathology are under research. Tau phosphorylation Inhibitors and Tau Aggregation Inhibitors are in clinical trials for people with AD, while tau reduction strategies are still in preclinical trials.

**Tau Phosphorylation Inhibitors**

In tau phosphorylation inhibitors, Lithium has multiple targets and inhibits GSK-3β69. Lithium has a narrow safety margin60. Studies in geriatric patients taking chronic Lithium for BPAD showed a reduced risk of developing AD. Lithium inhibits chemical changes in tau that lead to the formation of NFT’s. Studies on Lithium shown benefit with low doses in mild cognitive impairment, Reduction of GSK-3β impairs NMDAR-mediated long-term depression61 and memory consolidation62, raising concerns about potential side effects of GSK-3β inhibitors. CDK5 is essential for multiple cell signaling pathways and adult neurogenesis, limiting its appeal as a tau-targeting approach in AD. However, CDK5 and p25, a truncated form of the CDK5 subunit p35, promote neurodegeneration through mechanisms that are independent of tau phosphorylation63.

**Tau Aggregation Inhibitors**

Filamentous tau aggregates are damaging forms of tau and Filamentous tau is toxic. Tau enters dendritic spines, and adverse effects of tau aggregates are seen only in intracellular compartments64. Many of the drugs that block the aggregation of tau also prevent the pathological aggregation of other proteins under cell-free conditions265. Some tau aggregation inhibitors are effective in Neuro2A cell lines overexpressing a 4R tau microtubule repeat domain fragment with a K280 deletion and promotes its aggregation66. In AD patients, the Methylthioninium Chloride (methylene blue) showed slowing disease progression67. Methylene blue is the first drug targeting tau. The drug derived from the dye used to stain NFT’s in neuropathological studies. Primarily inhibits tau aggregation and showed cognitive benefits. Methylene blue inhibits tau-tau interactions68 and reduces soluble tau by mechanisms69. Inhibition of tau aggregation mediated by direct binding of tau to the FK506 binding protein 5270. It is unknown that tau assembly is responsible for tau-dependent neuronal dysfunction and degeneration71.

**Other treatments**

Hyperacetylation increases half-life72 and due to this microtubule-binding impairs and initiates aggregation73. Lysosomal pathway degrades proteasome, removes aggregated tau74, and inhibition of this pathway produces NFT-like tau deposition75. Lysosomal pathway of tau degradation involved in Niemann-Pick type C disease (NPC), seen with neurological symptoms and NFT formation76. NPC caused by loss of function of NPC1 (Lysosomal trafficking protein)77. We found that that degradation of tau occurs in Lysosomal and ubiquitin-proteasome pathways. Destabilization of microtubules and problem binding to microtubules are two main problems related to overexpression of tau. Microtubule stabilizers have shown excellent results in preclinical and clinical trials of AD. Epothilone D has better BBB permeability, improved microtubule density, and cognition78. Peptide NAP stabilizes microtubules79 and reduces tau phosphorylation80. In our study, Microtubule stabilizers have shown more than one mechanism of action.

**Conclusion**

Tau pathology is the leading and primary cause of neurodegeneration in AD. In the brain of AD, the level tau expression has no change concerning healthy aging, and toxicity depends on the contribution of many factors, like loss of normal function, the impermanent aggregation, and state of tau processing. Abnormal posttranslational modifications, like hyperphosphorylation and truncation, are responsible for altered tau structure in AD. Abnormal hyperphosphorylation and truncation are supported by *in vitro* experiments explain modifications elevate fibrillization of tau and induce cell toxicity81. Conformational changes of tau promoted by posttranslational modifications and the role of fibrillization important for checking the potential of tau-directed therapies81. Inhibition of the abnormal Hyperphosphorylation of tau and sequestration of MAPs by the hyperphosphorylated tau41 is the most critical therapeutic targets for AD. The pathogenic tau slowed or prevented by treatments that reduce levels of extracellular tau, so neurons cannot internalize it82. Identification and characterization of mechanisms of tau release and uptake
are essential for therapeutic interventions that may slow or prevent neurodegeneration in AD. Drugs are needed to develop more effectively to slow or prevent tau pathology. Methods to be prepared to restrict or inhibit the hyperphosphorylation of tau because inhibiting abnormal hyperphosphorylation does not self-assemble tau, and there will be no formation of PHF/SF.

Association between Running Activity and Pronated Foot Posture in East Java Puslatda Athletes

Yani Christina¹, Indrayuni Lukitra Wardhani¹, Bayu Santoso¹

¹Department of Physical and Rehabilitation Medicine, Dr. Soetomo Teaching Hospital, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia

Abstract

Background: Athlete begins intense exercise at a young age when the musculoskeletal system is still immature, thus it has the potential to cause specific changes in body. A more pronated foot have a greater mobility in both lateral medial plane and vertical plane. Hyperpronated foot allegedly can increase injury risk because it will cause a great moment of force and instability. The research aimed to determine correlation between running activity and pronated foot posture, and to obtain foot posture description of East Java puslatda athletes during running activity in their exercise.

Methods: The research employed cross sectional design using 75 athletes, consisting of 43 athletes who run more than 20 km per week and 32 athletes who run less than 20 km per week. The research variables were running activity obtained from questionnaire and foot posture obtained from the Foot Posture Index examination. The study protocol was approved by the ethics committees of Dr. Soetomo Teaching Hospital (Surabaya, Indonesia).

Results: The subjects’ demographic data characteristics based on age and exercise duration showed no difference between the two sample groups. On the other hand, the research found a significant difference between age (p = 0.001) and body mass index (p = 0.049). There was no significant correlation between running activity and pronated foot posture, with p = 0.293.

Conclusion: The study found that running activity more than 20 km per week had no correlation with pronated foot percentage. Pronated foot posture was commonly found in the sample group with running activity more than 20 km per week, but it was not statistically significant.

Keywords: athlete, foot postur index, pronated foot posture, running.

Introduction

Athlete begins intense exercise at a young age when the musculoskeletal system is still immature, thus it has the potential to cause specific changes in body. Athlete’s foot morphology may be associated with a variety of sports. Some data suggest that specific exercise and repetitive movements in certain sports can affect foot arch index ¹. In his study in 1323 professional athletes, found an increased risk of flat foot and splay foot occurrences in the endurance runner group ².

A research conducted in General Practice Department of Groningen University and Rehabilitation Department of Utrechts University, Netherland, from September 2007-April 2009 found 23.7% of sport injury incidence per 1000 patients, with 27.8 prevalence per 1000 patients ³. Running-related injuries comes second after soccer injuries, and lower extremity injury occurs three times more often than upper extremity ³. Moreover, a study conducted in 2010 by Indonesia Ministry of Youth and Sports found 78 of 84 athletes had injuries.
92% of injuries occurred during exercise and most of them were lower extremity.

Researchers and clinicians must pay attention to sport injury prevention and intervention. One of proactive efforts in injury prevention is by performing screening process to detect athlete's injury risk. Lower extremity injury could be affected by a huge biomechanical stress while running and a varied foot posture. Foot morphology is an important factor that determines correlation between ground reaction force and lower extremity rotation axis. A more pronated foot have a bigger mobility, both in lateral medial and vertical planes. A hyperpronated foot allegedly can increase injury risk because it has the potential to cause a great moment of force and instability. Various techniques have been used to assess foot posture, including visual observation, footprint evaluation, foot arch index, to measure heel position in frontal plane and navicular tuberosity position. Foot Posture Index is a quick and convenient visual measurement method to determine normal or abnormal foot posture classification (pronation, supination or normal), based on visually-observed six foot posture criteria.

The research aimed to determine correlation between running activity and pronated foot posture, and to obtain foot posture description of East Java puslatda athletes during running exercise. Foot posture description is one of the information to estimate injury risk, therefore it could increase athletes, coaches and doctors caution against possible injury threats.

Method

The research was conducted at Sport Clinic of Dr. Soetomo General Hospital, Surabaya, Indonesia, using East Java puslatda athletes who followed screening process from April to September 2013. The subjects met inclusion criteria (subjects who practiced a lot of running activities and less running activities) and exclusion criteria (aged less than 18, foot deformities such as syndactyly, polydactyly, terminal phocomelia, sport injuries, subject cannot stand relax and stack weight on both legs e.g. in pain condition), and signed informed consent. The study protocol was approved by the ethics committees of Dr. Soetomo Teaching Hospital (Surabaya, Indonesia).

The research is an observational analytic with cross sectional study design using 75 subjects, consisting of 43 subjects in the group that did a lot of running activity and 32 subjects in the group that did less running activity. The physical examinations included anthropometric and foot examinations, including inspection, palpation, examination of ankle and toe range motion, joint laxity and Foot Posture Index measurement. The process of data analysis was conducted using SPSS 13 software (SPSS, Inc., Chicago, IL). The obtained data were then statistically analyzed using logistic regression.

R² was obtained from Nagelkerke.

The study had a sample of 75 subjects, consisting of 43 subjects in the sample group that did a lot of running activity and 32 subjects in the group that did less running activity. The average subjects’ age in the group that did a lot of running activity was 22.8 with age range between 18.0-33.9, while the average subjects’ age in the group that did less running activity was 23.5 with age range between 18.0-31.2.

The measurement of left foot posture obtained 47 normal postures (62.7%), 27 pronated postures (36%) and 1 hyperpronated posture (1.3%). In the squash group, there were 3 normal postures (37.5%) and 5 pronated postures (62.5%). 5 normal postures (55.6%) and 4
pronated postures (44.4%) were found in the martial arts group, while there were 12 normal postures (60%), 7 pronated postures (35%) and 1 hyperpronated posture (5.0%) in the sepaktakraw group. In the karate group, there were 3 normal postures (100%). Moreover, there were 7 normal postures (100%) in the athletic group, 8 normal (61.5%) and 5 pronated postures (38.5%) in the softball group, 4 normal (40%) and 6 pronated postures (60%) in the baseball group and 5 normal postures (100%) in the table tennis group (Table 5.4). There were differences between left and right foot postures in the group that did a lot of running activity, while there was no difference between left and right foot postures in the group that did less running activity. The differences were found in 8 subjects, consisting of 2 squash subjects, 1 martial arts subject, 3 sepaktakraw subjects and 2 karate subjects.

Moreover, the study found 1 normal posture (2.3%) and 1 pronated posture (3.2%) in the group with less BMI, 39 normal postures (88.6%) and 27 pronated postures (87.1%) in the group with normal BMI, as well as 7 normal postures (9.3%) and 3 pronated postures (9.7%) in the group with excess BMI.

Correlation between Running Activity and Pronated Foot Posture

The results of multivariate logistic regression analysis found that running activity, age, body mass index and exercise duration variables did not show significant results. Meanwhile, sex variable showed significant results with \( p < 0.05 \) (0.032) (Table 5.9 and 5.10).

The results of multivariate logistic regression analysis in the male sample group showed that age and exercise duration variables had significant results (*), while BMI and running variables did not show significant results (Table 5.11).

Moreover, the results of multivariate logistic regression analysis in the female sample group showed that BMI, running, age and exercise duration variables did not have significant results (Table 5.12).

Discussion

The research found no significant difference between sex and exercise duration in both sample groups. On the other hand, there was a significant difference between sex \( (p = 0.001) \) and body mass index \( (p = 0.049) \). The number of subjects mainly affected these findings since there were 28 males and 4 females in the group that run less than 20 km per week, while there were 20 males and 23 females in the group that run more than 20 km per week. Moreover, there were 5 subjects with excess BMI in the group that run less than 20 km week, while there were 2 subjects with excess BMI in the group that run more than 20 km week.

Running Activity

Running provides external and internal forces in the run musculoskeletal system. External forces include resistance of air, gravitation and GFR, while internal forces are given by muscles and tendons in the joints. Bone and ligament structures should hold the GFR three to four times the normal weight while running. The present study found two running distances performed by the athletes of different sports. The running distance data were classified into group with running distance more than 20 km per week and group with distance less than 20 km per week. The group with a lot of running activity consisted of squash, martial arts, sepaktakraw, karate and athletics with an average exercise duration of 9 years. Meanwhile, the group with less running activity consisted of softball, baseball and table tennis with an average exercise duration of 8.5 years. The body forces during running activity correlated with foot pronation’s magnitude and speed. Foot pronation is a protective mechanism during running activity that could spread the force for a longer time compared to the condition without pronation. The use of shoes and orthosis during exercise could maximize performance and minimize trauma risk. All subjects in the present study used running shoes during running exercise.

Foot Posture Measurement Results

Foot posture was measured using Foot Posture Index with 6 measurement criteria, including talar head palpation, supra and infra lateral malleolar curvature, calcaneal frontal plane position, prominence in the region of the talonavicular joint, congruence of the medial longitudinal arch and abduction/adduction of the forefoot and the rearfoot.

Running activity

The pronated foot posture measurement results showed a higher percentage in the group with running activity more than 20 km per week. There were differences between right and left foot postures in the
group with a lot of running activity. These findings allegedly correlated with extremity dominance.

**Age**

Degenerative process, incomplete trauma healing and large mechanical loads allegedly become the cause of tendon rupture. The flat foot deformity is often associated with posterior tibial tendon dysfunction. Posterior tibial tendon dysfunction does not always occur due to trauma, but it commonly occurs due to degenerative process. The condition is more prevalent in females aged 50-60. The present study found no correlation between pronated foot posture and age. This finding was allegedly affected by the subject’s age range (18-33.9 years old).

**Sports**

The study found that pronated foot posture was more prevalent in squash, karate and baseball. This might be due to a correlation between athlete’s foot morphology and sports. Some data suggest that specific exercise and repetitive movements in certain sports can affect foot arch index 1. Further studies are necessary in order to determine correlation between pronated foot posture and sports.

**Sex**

The study found that pronated foot posture was commonly found in the male subjects (23;74.2%) compared to females (8;25.8%). The statistical results showed no significant correlation between sex and foot posture in bivariate logistic regression test, with p=0.126. These findings were consistent with a study conducted by Rodriguez et al. (2013) that found no difference between male and female foot posture index. Multivariate logistic regression test found a significant correlation between sex and foot posture, with p=0.032. This finding indicated that age variable was a confounding factor.

**Body Mass Index**

Body weight is transmitted into foot through ankle. When standing and silent, about half the weight rests on the heel. In this condition, talar head will shift to medial as much as 2-6 mm, while lateral turbecle from calcaneus will shift to media as much as 2-4 mm. Rearfoot will be more adductive-pronation, while forefoot will be more flexyabductive-supination 9. Increased mass with an addition of 20% body mass will result in static and dynamic plantar pressure, but it is not significantly change foot structure. Increased long-term body mass index associated with obesity can be seen in the horizontal medial longitudinal arch on the legs, confirmed by increased foot contact areas on the floor. This change is unclear whether permanent or reversible 10. The present study found no significant correlation between body mass index and foot posture, with p=0.931. This might be due to no subject classified as obesity.

**Correlation between Running Activity and Foot Posture**

In his study conducted in 1323 professional athletes, found an increased flat foot and splay foot risks in the endurance runner group 2. After a 20-kilometer run, the force distributed on the legs increased on the forefoot, middle foot and medial heel, while decreased force occurs in the lateral toe. The foot posture study which was measured immediately after runners run at a speed of 3.3 m/s for 60 minutes showed foot posture change. 10 of 30 participants showed a more pronated posture after running, and there was an increased pressure in the plantar. This finding showed an excess force in the medial heel.

The present study found no significant correlation between running distance and pronated foot posture, with p = 0.293. The research hypothesis was not proven. This might be due to a distant foot posture measurement after the subjects performed running activity. This finding was consistent with a study conducted by Karagounis et al. that examined correlation between increased plantar pressures after running. They found that this increment would return again as before after 24 hours. Bisiaux and Moretto in their study found increased plantar pressures at 30 minutes after exercise did not return at 30 minutes after break. This plantar pressure change is allegedly correlated with muscle fatigue.

**Conclusion**

The research found no correlation between running activity more than 20 km per week and pronated foot posture. A higher percentage of pronated foot posture was found in the group that run more than 20 km per week, but it was not statistically significant.

Morphometry Study on Thoracic Vertebrae Pedicle withComputed Tomography Scan in Population of Surabaya,Indonesia

Yoki Surya¹, I Ketut Martiana¹
¹Department of Orthopedics and Traumatology, Faculty of Medicine Universitas Airlangga, Dr. Soetomo Teaching Hospital, Surabaya 60285, Indonesia

Abstract
The fixation technique with pedicle screw is widely used for stabilization as well as deformity correction. However, data on vertebral morphometry have not been obtained. Most previous studies were conducted on the Caucasian race and slightly in the Asian race considering that there was a significant difference in pedicle morphometry of vertebrae between races and age. The objective to examine the morphometry of the thoracic vertebral pedicle in young adult population of Surabaya, comparing with the pedicle morphometry in the overseas population. The method we collected patients’ data of thorax CT Scan in Dr. Soetomo Teaching Hospital and Airlangga Hospital Surabaya. Patients with spinal deformities including congenital abnormalities, trauma, infection, and tumors were excluded. The variables to be measured were pedicle diameter (Pedicle width), pedicle depth to anterior cortex corpus vertebrae (Cord Length), and transverse pedicle angle. The result CT scan data collected was 123 consisting of 56 males and 67 females with an average age of 18.1 years old. The average pedicle width, cord length, and transverse pedicle angle in Surabaya population differed significantly from the Caucasian population of the previous study. Conclusion there were no significant differences in transverse pedicle angle between males and females. There was no significant difference in morphometric data compared to the Asian population.

Keywords: Thoracic Vertebrae, Pedicle Screw, Pedicle Morphometry, Surabaya Population

Introduction
The use of pedicle screw as a fixation tool on spine surgery has become popular all over the world. This procedure is the only system that can provide fixation on three vertebral columns and restrain movement in all dimensions¹. Accurate and comprehensive antopometric data for the spine (vertebrae) is not available at this time. Information about the dimensions of the vertebrae is essential for the development and design of rational spinal implants such as pedicle screw. Previous studies have measured this with X-ray modalities, and computed tomography (CT) scan². Several studies also performed analysis on cadaveric specimens³.

The thoracic vertebrae have unique characteristics and these characteristics are associated with potential complications of injury to the neural structure. The magnitude of this potential complication that causes the use of pedicle screw on the thoracic vertebrae is very limited. The pedicle diameter of the thoracic vertebrae is sometimes smaller than the available pedicle screw diameter⁴. The lateral aspect of the dural sac is directly adjacent and attached to the medial wall of the pedicle. Therefore, misalignment of screw mounting in the medial direction may cause injury to the dural sac and spinal cord⁵, and lateral errors can cause injury to the blood vessels⁶.
A study in Asian populations and using CT scans showed that the data is not applicable for the Caucasian population. Recently, the development of digital imaging and computer usage has led us to a new generation of X-ray imaging that enables the manipulation and improvement of the resulting image quality, and allows precision measurements in different areas of the vertebrae. These data can produce basic anthropometric models for the study of spinal implant design.

Most of the anatomical studies of vertebrae pedicle morphology were conducted in the Caucasian population, and a small percentage in the Asian population. Several studies reported no statistically significant difference between the data examined on CT scans and on cadavers. Previous studies have also shown significant differences in pedicle size between human races. Therefore, we aimed to examine the morphometry of the thoracic vertebral pedicle in young adult population of Surabaya, comparing with the pedicle morphometry in the overseas population.

Method

The subjects of this study were patients of Dr. Soetomo Teaching Hospital and Universitas Airlangga Hospital Surabaya, Indonesia that fulfilled the criteria of inclusion and exclusion. The inclusion criteria of the subjects included patients aged 16-25 years old and patients underwent thoracic CT scan with all indications. The exclusion criteria included patients with spinal deformities including congenital abnormalities, trauma, infections, and tumors. Subjects who were willing to participate to the research filled out the informed consent sheet.

This study used cross-sectional observational design that described the average morphometry of young adult vertebrae pedicle in population of Surabaya, Indonesia and compared morphometry of vertebrae pedicle among young adult population in Surabaya, Indonesia and overseas population whose data obtained from previous study. The process of determining the number of subjects included identification according to the inclusion and exclusion criteria in which the subjects obtained 123 patients consisting of 56 male patients and 67 female patients. The number of thoracic vertebrae examined was 1476 pieces consisting of 672 pieces of male vertebrae and 804 pieces of female vertebrae.

The research procedure was performed based on the results of 16 slices of thorax CT Scans (Siemens Ltd, Berlin and Munich, Germany) on the subjects. The CT-Scan data was a opened with the application of Osirix version 6.5. Furthermore, by using the application, the file of CT-Scan can be opened, re-formatted, and measured the variables needed. Measurements were performed on the vertebral pedicle T1 to T12. The variables to be measured were pedicle diameter (mm), pedicle to anterior cortex corpus vertebrae (mm), and pedicle transversal angle(°). The pedicle width was determined by measuring the shortest distance between the pedicle walls. The transverse angle pedicle was determined by measuring the angle formed between the central axis of the pedicle and the perpendicular line from the pedicle width line passing through the pedicle. Chord length was measured from the posterior and anterior cortical ends of a line perpendicular to the pedicle width used in the transverse pedicle angle measurement. All measurements used axial piece of CT scan.

Measurable structures in the vertebrae included (1) chord length of the pedicle, measured from the posterior cortex (entry point) pedicle to the anterior cortex of the vertebrae in line with the pedicle axis, (2) length of the pedicle, measured from the pedicle posterior cortex to the posterior longitudinal ligament along the pedicle axis, (3) transverse pedicle diameter, measured at isthmus horizontal orientation, (4) the pedicle insertion angle, measured from the midline towards the pedicle mid-axis, (5) the height of the pedicle, measured in the vertical orientation isthmus, (6) the length or width of the vertebral corpus, measured from the posterior to the anterior longitudinal ligaments on the mid-sagittal pieces (measurements were made on both end plates, and the average value was calculated), (7) the pedicle offset, calculated from the spinous processus to the medial and lateral walls of the pedicle, and from the inferior facet to the superior extent of the outer wall of the pedicle, and (8) the pedicle’s entry point (central axis), measured at the confluence between the transversus processus and the nearest facet joint.

After all variables were obtained, the mean and standard deviation measurements were performed on each variable. The measurement were differentiated between males and females at each vertebral level to look for significant differences. Due to the absence of gender discrimination in previous studies defined as comparative studies, measurements of mean and standard deviations of all samples were divided regardless of
gender. Furthermore, these data were compared with previous research.

**Results**

In both males and females, the average pedicle width was highest at T12 level with a magnitude of 9.05 mm and 7.63 mm respectively. The diameter of the pedicle gradually decreased from T1 until it reached the smallest diameter in T4, and gradually enlarged again. The narrowest diameter was at T4 (male: 4.75 mm; female: 3.98 mm). The diameter of the vertebra pedicle was significantly larger in males compared with females at all levels.

Pedicle chord length was significantly shorter in females than in males at all vertebral levels. The pedicle chord length ranged from 27.28 mm to 50.98 mm in males and from 25.88 mm to 43.84 mm in females. The longest pedicle chord length was at 50.98 mm and the shortest was at 25.88 mm in males and females. The length of the pedicle chord increased from T1 to T9, and shortened from T10 to T12. Compared with previous research data, the trend was found similar.

The level with the widest transverse pedicle angle was T1 (36.29°) in males and also T1 (35.71°) in females. The transversal pedicle angle gradually narrowed to its level from T1 to T12, and the narrowest at T12 (male: -4.08°; female: -6.26°). No significant difference was found between the transverse pedicle angle of male and female subjects. Compared with other studies, no significant difference was found in the transverse pedicle angle, but had similar trends in the pattern.

Discussion

In the caucasian population, previous research examined the morphometry of the thoracic vertebrae pedicle using a CT scan by measuring several parameters. When compared with the results the morphometric size of previous the thoracic vertebral pedicle in the Surabaya population is proved to be significantly smaller. These size differences may be associated with a smaller body size in Asians. Asians have a smaller body mass index, but have a greater percentage of body fat when compared to Caucasians. Therefore, height and body mass index size may provide good predictive value for pedicle size of the vertebrae. Measurement of pedicle size of the vertebrae using a pre-operative CT scan may also provide precision vertical pedicle dimension precision data, and improves the accuracy of pedicle screw mounting on the thoracic vertebrae; thus, the complications can be avoided.

The comparison of mean pedicle width between Kai et al’s study(19) study and some previous studies in Table. It appears that the large pedicle width in the Surabaya population is smaller when compared with the Caucasian population and has similarities with the Asian population. Comparison between Kim et al’s study(5) and the current study chord length pedicle of Surabaya population with other research. It appears that the chord length pedicle in Surabaya population is smaller than the Caucasian population and similar to other Asian populations. The Comparison between Panjabi et al’s study(6) and the current study appears that the large mean transverse pedicle angle in Surabaya population is also smaller than the Caucasian population and similar to other Asian populations.

Researcher performed a comparison between pedicle morphometry in Surabaya population and pedicle morphometry in the Asian population. From these comparisons, it is evident that pedicle morphometry in Surabaya populations does not differ significantly with other Asian populations. There was a comparison of pedicle morphometry between Surabaya population and Caucasian population. From the comparison, the morphometry of pedicle of Caucasian population is significantly greater than Surabaya population.

The Malaysian population compared with our study on the population of Surabaya using two sample T-tests, it was found that both the comparison of pedicle width, cord length, and transverse pedicle angle showed no significant difference. Kai et al. conducted a cross-sectional study of pedicle morphometry in 180 patients of Malaysian Malay race with ages ranging from 18 to 80 years. Kai’s research concludes that the existing pedicle screw system is incompatible with the majority of the Malay population, especially at the midthoracic level. Kai also stated that the smaller pedicle size of the Malay race examined may be related to the Malay race body that is shorter than Caucasian races.

Conclusion

CT scan evaluation of the thoracic vertebrae can provide morphometric data which is very useful in determining the length and length of the pedicle screw, and determining the direction of the pedicle screw on transpedicle spinal surgery. The size of the pedicle’s morphometry in humans varies from one to another. In this study, it appears that the morphometry of the human pedicle differs from one population to another. Smaller thoracic vertebrae pedicle dimensions in Surabaya population compared with Caucasian population can be associated with smaller body size in Asian populations. Many factors that cause this difference are: race, weight, height, and body mass index. Therefore, in carrying out the transpedicle instrumentation action, it is necessary to consider these factors and, if possible, CT scan can be performed before the surgery to estimate the pedicle dimensions of patients.

Awareness about Whole Slide Imaging and Digital Pathology among Pathologists - Cross Sectional Survey

Sandhya Sundar¹, Pratibha Ramani², Herald J Sherlin³, Gheena Ranjith³, Abilasha Ramasubramani⁴, Gifrina Jayaraj⁴
¹Postgraduate, ²Professor and Head of the department, ³Professor, ⁴Reader, ⁵Senior Lecturer, Dept. of Oral Pathology, Saveetha Dental College & Hospitals, Saveetha University

Abstract

Aim: To assess awareness of pathologists on whole slide imaging and digital pathology

Method: An online, structured questionnaire was sent to pathologists of various dental and medical colleges in Chennai. The data was collected using Microsoft excel version 2011 and statistically analyzed using SPSS software.

Results: 28.6% of pathologists were only aware of the fact that whole slide imaging can perform a live scanning of digital images. 81% said the magnification produced by WSI were greater than conventional microscopy. 52.4% agreed on the time taken to perform the whole slide scanning to be one minute. 85.7% were convinced that diagnostic difficulties could be best consulted through the digital slides. 52.4% agreed integrated automated image analysis increased the diagnostic efficacy of WSI in routine histopathology. 62.5% of them felt that the high cost of the equipment and infrastructure was the major impeding factor in usage of WSI.

Conclusion: Whole slide imaging and digital pathology is a promising future of pathology as it can significantly reduce the workload and enhance the diagnostic efficiency in various aspects. There was a reasonable awareness among the pathologists. Until hospitals collaborate and take initiative to bring whole slide imaging into practice, it’s difficult to make the best of its advantages.

Key words: Pathologists, Digital pathology, virtual slides, whole slide imaging

Introduction

As digitalization embracing through any and every known field, Pathology is no exception. Time and again, many digital technologies have been introduced into pathology starting from digital photomicrographs (1900s) to Telepathology (1980s) to Digital pathology involving whole slide imaging (2000s). Whole slide imaging refers to scanning and storage of entire histopathological glass slide into set of high-resolution digital files that can be interpreted using image viewers on computer workstations.

The complete digitalization of slides has the potential to transform practice of diagnostic pathology – safety, quality and efficiency of histopathological diagnosis. Despite the promise of digital pathology to offer huge benefits, its uptake in clinical practice has been slow. One of the main reasons was considered to be the unfamiliarity with the viewing software and perceived inefficiency of digital diagnosis. Clearly cannot change instantaneously.

The present study forms the first step in bridging the gap between the pathologists and digitalization. It aims to assess the awareness level of Pathologists on whole slide imaging and its advantages as future of pathology.

Materials and Method

The study was designed to be a cross-sectional survey since it aimed to evaluate the awareness of pathologist on given point of time. An online questionnaire was designed to assess the knowledge, attitude of pathologists towards the whole slide imaging technique and digital pathology and its future perspectives.
The questionnaire was prepared using Google forms and distributed online to general pathologists and oral pathologists of various dental and medical colleges in Chennai. The pathology postgraduates and lectures of pathology department were randomly selected and invited to participate in the study. The questionnaire had sections, which gave a brief introduction about scope of the study, email address was collected and the questions with multiple choices had been provided. Explanations were given if the any of the participants could not understand the items.

The data was collected and analyzed through the Google forms using Microsoft excel version 2011.

Results

Forty-two completed responses were collected online. Four out of ten questions evaluated the awareness on the technical aspects of WSI and DP. Three questions were on the applications of WSI and DP. Three were questioned to assess the knowledge on practical aspects of WSI and DP.

66.7% pathologists were aware Whole slide imaging utilizes the advantages of digital images and live cameras. 81% said the magnification produced by WSI were greater than conventional microscopy. 52.4% felt the whole slide scanning can be done with one minute. 47.6% pathologists opined that high speed scanners are major indispensible need to put DP and WSI to daily use while 35.4%f elt the need to be high resolution display monitors. The major hindrance in adopting widespread practice of WSI and DP were felt to be the High cost involved by 62.5% pathologists and technical factors by 27.5% pathologists. 85.7% pathologists were convinced that digital slides achieved faster consultations at its best. The promising role of DP and WSI in forming next-generation education were felt to be the scalable nature of digital file & availability to numerous students at a time by 33.3% pathologists, due to the incorporated annotations, videos, sound clips by 33.3 % and due to whole 3D picture of the specimen provided by DP by 33.3% pathologists. 59.5% felt that integration o WSI to pathology reports while 36.6% felt it was accessibility of WSI on iPads and PDA.

Discussion

Our study was based on data from online questionnaire and rate of return of these questionnaire reflect maximum amount of interest in whole slide imaging and digital pathology. Research into whole slide imaging ad digital pathology has been in progress for a decade. [1,2] All have inherent problems yet interest continues to increase worldwide with a growing consensus regarding acceptable applications, [3,4] particularly those related to teaching and quality assurance.

The practical experience of Whole slide imaging and Digital pathology are uncommon among histopathologists in India. Consequently there is an understandable skepticism with regard to technology and its ability to enhance conventional method of practice. Capital costs of installing DP and WSI are really high (particularly the image scanners). [5]

Many of the fears regarding DP and WSI have arisen through unfamiliarity with technology and can be overcome by onsite technical assistance combined with protocol driven referral pathways. [5] 66.7% of the pathologists perceived the virtual pathology to be a set of digital images only, although it involves recording digital images of the pathology slides with live scanning. This predicts the bird’s view, not a detailed understanding of the technology.

Although several reports of enhanced teaching experiences had been witnessed through digitalization in western countries, [6,7,8] less cumbersome software along with adequate training of teaching faculties in them, and more easier identification of structures with clarity can help increase the level of acceptance in India. 85.7% of pathologists felt the unanimous solution on difficult diagnostic cases would be through digital consultations with their distant colleagues. Rapid remote initial diagnosis is possible as is consensus diagnosis for problematic cases. [9] The human resources can be maximized by remote participation.

52.5% felt the automated analysis of histopathology slides could help reduce their work burden give an accurate diagnosis in a quick time interval especially when it comes quantitative measurement of increased mitosis and other prognostic factors in cancers. [1,10] 52.5% of the pathologists the scanning speed to be under 1 minute. The latest technology scanners offer to complete the whole slide scanning in just <50 seconds. Al-Janabi et al has documented a success rate of 82% for primary reporting with digital slides. [11] Snead et al had
reported 97.7% complete concordance between glass and digital slide diagnosis. [12]

47.6% of the pathologists believed the high speed “slide scanners” are the major requirement to keep digital pathology in day-to-day diagnosis. These scanners provide the high-resolution images of the entire tissue section but at an outrageous cost. This can hinder its application in practice particularly in developing countries with limited resources. Attempts at developing substitutes for these scanners at negligible cost have been showing promising results with their own disadvantages. [13] However the technical advances would help overcome these problems in the future.

**Conclusion**

There is a reasonable level of awareness among pathologists on whole slide imaging and digital pathology. The practical hindrances in adoption of this technique should be overcome to achieve the huge advantage it holds. Innovations on production of low cost, efficient slide scanners are the need of the hour. Government should take initiative in collaboration with private organizations to install Digital set up for whole Slide Images.

Alteration in Physicochemical Parameters of Soil Beneath Rabbit Carcass: Consequence of Carcass Decomposition

Sarabjit Singh¹, Madhu Bala²
¹Scholar, Department of Zoology and Environmental Sciences Punjabi University Patiala, Punjab (India), ²Assistant Professor, Department of Zoology and Environmental Sciences Punjabi University Patiala, Punjab (India)

Abstract

Forensic taphonomy involves the use of decomposition to estimate post-mortem interval (PMI) or locate cadaveric grave. The process associated with carcass decomposition in outdoor setting. Some other methods are available to determine the accurate post mortem interval (PMI). Instead of these methods, a soil-based approach one of the best methods to determine post mortem interval. As a consequence, we investigated the physical characteristics of the carcass, soil pH, soil moisture content, electrical conductivity and the concentration of total carbon, total nitrogen and soil-extractable phosphorus in soil beneath rabbit (Oryctolagus cuniculus L.) carcass which was placed on soil surface up to skeletal stage of decomposition. The significant increases were observed in concentration of soil pH, moisture content, soil-extractable phosphorus and total carbon.

Keywords: Decomposition stages, Forensic taphonomy, rabbit carcass, physicochemical.

Introduction

Forensic taphonomy is an applied science with clear aims: Use the processes associated with cadaver decomposition to estimate post mortem or post burial interval, determine the manner of death, locate graves and identify the deceased[1,2]. Forensic taphonomy derives these aims from taphonomy, a branch of palaeontology[3]. The majority of these studies have focused on the activity of above ground insects[4,5] and scavengers[6] whereas less attention has been given to the processes that occur in soils associated with cadaver breakdown[7].

The estimation of soil in a demise examination is frequently taken as cooperative proof. This mirrors the customary perspective of criminological science: Soil is a medium that can be characterized by natural substance, and physical properties[8]. Soil has evidential values, it contains mineral, vegetation (both vegetative and as pollen), and animal material (living and dead). The components like fossils, bone and glass are also found in soil, these all are rare and helpful for characterization. Now a day stereomicroscopic observation, scanning electron microscope, x-ray spectrometer, detection of soil colour (before and after heating soil samples) and macroscopic observation are being used for the soil studies. These attributes are generally performed to investigate a serious crime.

Decomposition is a process that commences immediately after death and, depending on environmental conditions, will proceed until skeletonization has occurred[9,10]. The chemistry associated with decomposition and the destruction of soft tissue is complex[11]. During decomposition chemical components are released from body through autolysis and putrefaction[12]. Carcasses are mainly decomposed by microbes and invertebrates[13]. Decomposition results the degradation of carbohydrates, lipids and protein, which will yield carbon-based, phosphorous-based and nitrogen-based products which may be retained in the soil from the body of carcass, therefore, Grave soils were found to have higher levels of total C and total N after burial.

Research model: - A rabbit (Oryctolagus cuniculus L.) carcass weighing about 2.5 kg was used as a research model to study alteration in physico-chemical parameters of soil beneath them. The rabbit carcass was procured
Experimental site: - The course of decomposition of carcass and its impact of soil was studied during March, 2016 at village Miani of District Hoshiarpur, Punjab. The site of experiment was located north side of Dasuya (31°42´15ʺN, 75°35´5ʺE). The climatic condition of experimental site during research period is; the normal annual rainfall of experimental site is 991 mm and average temperature is varying from 24°C to 42°C during experimental period. The soil of experimental site is loamy with pH vary from 7.4 to 8.2. The unwanted vegetation of experimental site was removed. The heavy iron cage was used to cover the carcass to protect them from animal scavengers.

The soil samples were collected with the help of rustproof stainless steel spatula which has no chemical interference with soil. During sampling, approximately 40 g of soil was collected below carcasses and placed into zip lock bags. The collected samples were sieved, placed in sterile vials and transferred to deep freezer (-20°C) for pending analysis[14].

Analysis of Physico-Chemical Characteristics of Soil

Soil pH was calculated with the help of pH meter. One part of soil and five parts of water (1:5) were taken for the analysis[14]. Before the analysis the instrument was calibrated with solutions of different pH i.e. 4.0, 7.0 and 10.0. Electrical conductivity of soil was calculated with the help of digital conductivity meter. Soil and water were taken in 1:5 ratios. Calibration was done with KOH solution[15]. Moisture content of the soil was estimated by heating methods. 5 grams of soil were taken and heated at temperature of 105°C for 24 hours in oven. Weight of pre heated and post heated soil was recorded with the help of weighing balance. Difference between initial and final weight of soil is moisture content of soil.

The extraction of phosphorus from soil has been done according to[16] soil extraction method. The acid-soluble forms of phosphorus were extracted by using combination of Hydrochloric acid and Ammonium fluoride. 1 g of oven dried soil was extracted with diluted of ammonium fluoride (NH₄F) and concentrated hydrochloric acid (HCl). The soil samples were centrifuged at 6000 rpm for 5 minutes. Dispense 0.50 mL of the supernatant plus 2.0 mL colourimetric reagent was added and mix into a test tube to stand for 30 minutes. Soil-extractable phosphorus absorbance was measured with the help of Spectrophotometer at wavelength of 880 nm.

A colourimetric reagent was prepared to dissolved 17.14 g ammonium molybdate [(NH₄)₆MO₇O₂₄.4H₂O] in 200 mL of warm deionised water, 0.392 g potassium antimonyl tartrate (KSB₉C₂H₄O₆) separately in 150 mL deionised water. Place 500 mL deionised water in a 2 L volumetric flask and slowly add 200 mL concentrated sulphuric acid with mixing.

Total carbon and total nitrogen content in soil was analysed by combustion with helium gas and estimated by using Vario EL Cube Elementar CHNS analyser. The temperature of combustion tube was maintained at 1150°C and 850°C for reduction tube. The analysis was conducted at Punjab Agriculture University, Ludhiana (Punjab).

Statistical analysis: - The statistical analysis was conducted by using software SPSS Version 15 to compare variation among parameters in experimental soil and control soil. The variance in parameters was tested by using Levene’s test.

Results

Rabbit carcass took 9 days for complete decomposition. The decomposition was divided into different stages viz. fresh, bloated, active decay, dry decay and skeletal. The soil beneath carcass were taken from three different depths i.e. 0-5 cm top, 6-10 cm middle and 11-15 cm in order to check pH, electrical conductivity and moisture content, but in case of total nitrogen, total carbon, soil-extractable phosphorus upper layer (0-5 cm) of soil were taken into account because most significant changes were occur in top most layer of soil only. This experiment was conducted in the month of March, 2016. The average temperature during experiment was 38±1° C and humidity was 27±1%.

Soil pH

A significant difference (P < 0.05) in pH of control soil and soil beneath carcass was observed (Fig. 1). Soil is become slightly acidic during active decay stage as compare to control soil due to seepage of fluid into the soil.

Electrical conductivity

There was no significant difference (P > 0.05) in electrical conductivity of control soil and experimental soil was observed (Fig. 2). Increase was seen during
active decay stage of decomposition at depth of 5 cm and 10 cm of soil samples as compare to control soil.

**Moisture content**

A significant difference ($P < 0.05$) in moisture content of control soil and experimental soil was observed (Fig. 3). The moisture content of experimental soil was high during bloated, active decay and dry decay stages of decomposition due to seepage of body fluid.

**Soil-extractable phosphorus**

There was a significant difference ($P < 0.05$) in soil-extractable phosphorus of control soil and experimental soil was observed (Fig. 4). This is due to the large number of components like enzymes, phospholipids, proteins; nucleic acids which were store in the form of phosphorus in the body and a decomposing carcass can release high amount of phosphorus in the soil beneath carcass.

**Total carbon**

A significant difference ($P < 0.05$) observed in concentration of total carbon in experimental soil and control soil (Fig. 5). The increase in total carbon concentration of soil was observed during dry decay stage of decomposition. This is due to release of CO$_2$ gas during decomposition.

**Total nitrogen**

There was no significant difference ($P > 0.05$) was observed in total nitrogen content of soil beneath rabbit carcass and control soil (Fig. 6). The increase in total nitrogen concentration observed during dry decay stage of decomposition. However, the nitrogen concentration level returns to basal level by skeletal stage of decomposition.
Fig. 2 Electrical conductivity of control soil and soil beneath rabbit carcass

Fig. 3. Moisture content (%) of control soil and soil beneath rabbit carcass
Fig. 4. Extractable Phosphorus of control soil and soil beneath decomposed rabbit carcass

Fig. 5. Total Carbon (%) content of control soil and soil beneath rabbit carcass
**Discussion**

The present study has significance from forensic point of view and has implication in PMI estimation. In the entire study the biochemical attributes were considered, the alteration in these attributes support the forensic investigation in estimation of time since death as well as place of death by comparing the contents of control soil and soil beneath corpse. The significant increase in concentration of nutrients occurs during bloated stage, active decay stage and dry decay stage of decomposition. Currently forensic entomology is considered as most accurate means to estimate PMI. However, forensic entomology will not able to answer all the questions after emergence of adult blow flies. If proper experimentation occurs then nutrient cycle in soil could be an important tool in cases where bodies remain undiscovered for extended period of time. In current study rabbit carcass was used as research model. Five decomposition stages were observed during whole course of study. Previous decomposition studies provided conflicting results. pH is almost remain same in control soil as well as in experimental soil during fresh stage of decomposition due to negligible seepage of nutrient into the soil. In previous study the increase in pH values was observed during decomposition of carcass\[^{14}\]. In some other decomposition studies by also provide variation in pH level of soil beneath carcasses\[^{17,18}\]. Soil pH may decrease during early stages of decomposition as a result of the fermentative processes carried out by anaerobic bacteria in the gastrointestinal (GI) tract as well as in soil\[^{19}\] and subsequently increase due to carcass proteolysis\[^{18}\]. The reduced level of pH did not increase over time as compare to control soil. The significant changes in soil was seen only in upper layer (0-5 cm) of soil as compare to middle and bottom layers of soil and this is due to the rapid conversion of the Nitrate to Ammonium ion by the microbes. Variations in pH level not able to demonstrate consistent correlation with process of decomposition.

The concentration of soil-extractable phosphorus was significantly increases during the decomposition of carcass. The significant increase detected in soil-extractable phosphorus concentrations beneath a decomposing carcass of pig (*Sus scrofa*) during 100 days of decomposition study of grave soil\[^{14}\]. A significant increase in Phosphorus concentration beneath a decomposing ungulate (*Bos bison*) carcass and given the results that there was a increase in Phosphorus level of soil at carcass site as compare to control soil, upto 3 years post-mortem\[^{20}\]. In addition the large number of components likes enzymes, phospholipids, proteins; nucleic acids are store in the form of phosphorus in the body. After death these all components flow out from the body in form of fluid and mix up with soil. Therefore
a decomposing carcass can release high amount of phosphorus in the soil beneath carcasses.

In present study the total carbon content would increase during bloated and active decay stages of decomposition. Otherwise there was no significant difference between total carbon content of control soil and experimental soil occurred during other stages of decomposition. There was no significant difference of total carbon concentration between control and grave soil was observed beneath decomposed carcass\textsuperscript{[14]}. The total carbon concentration in soil was due to carbon dioxide gas could release from the body of carcass and mixed in soil or lost in environment.

A significant increase in total nitrogen content has been reported in present study which was similar with the previous study which was conducted on gravesoil\textsuperscript{[14]}. The significant increase was observed in total nitrogen concentration of soil beneath decomposing carcass\textsuperscript{[21]}. There is an either organic or inorganic form, i.e. NO\textsubscript{3}\textsuperscript{-N} and NH\textsubscript{4}\textsuperscript{+N} of nitrogen which helps to increase the level of nitrogen. A decomposing carcass is a rich source of nitrogen.

**Conclusion**

The present study satisfactorily demonstrated that decomposition of carcass influxes a significant amount of nutrients into the soil beneath carcass. There is a significant variation in some physico-chemical parameters of soil beneath carcass as compare to control soil viz. Soil pH, moisture content, soil-extractable phosphorus and total carbon due to influx of nutrients into the soil. There is also variation among parameters according to stages of decomposition, which assists in PMI estimation in case where decomposed remains scavenged or displaced from its original position.

The results of this study are only applicable to the local soil environment, region and area from where soil samples were taken and cannot be extrapolated to other soil types or conditions. Hence, future studies will also investigate the nutrient influx from decomposing remains in a range of soil types to determine whether those patterns observed in this study are reproducible in different soil conditions.

We conclude that the effect of a rabbit carcass on the nutrient concentrations of soil is evident in this part of world. We believe that the decomposition of human remains in this environment would also increase nutrients level into the soil. This information has the potential to assist investigations in confirming the presence of decomposed remains where remains have been scavenged or dragged from their original site, or in shallow grave sites where relocation of the remains has occurred post-mortem. In spite not include in the present study there is a suggestion of utilizing soil microorganisms to estimate the PMI. Soil microbiology along with carcass microbiology plays important role in flawless evaluation of PMI.

**Source of Funding:** This research did not receive any specific grant from funding agencies. This research is self funded.

Knowledge and Awareness of Medical Students about Injuries in Forensic Perspective

Sulekha Naresh
II MBBS, Saveetha Medical College, Thandalam, Chennai, India

Abstract

Introduction: Injury is any harm caused illegally to a person, which may be caused by any mechanical force which results in a break in natural continuity of any tissue. Each and every injury as its own medico-legal importance which is the key in interpretation of specific injury. Thus every medical student must be clear about this, which helps in concluding different injuries as every medical practitioner has to deal with injuries throughout their life. This can be dealt only when there is proper knowledge and awareness about different injuries in medical field.

Objective: This study was done to study knowledge and awareness of medical students about injuries in forensic perspective.

Materials and Method: It is a cross-sectional study done at Saveetha Medical College, Chennai, Tamil Nadu. Students of 2nd, 3rd, and 4th year M.B.B.S participated after giving informed consent. 115 students participated in the study. Questionnaire containing 20 questions were distributed and responses were obtained and analyzed.

Results: Out of 115 students, 95% of the students had basic knowledge on injuries. Though awareness was present, there was minimal lack in certain areas such as knowledge on contusions, grievous hurt and differentiating cut and chop wounds.

Conclusion: The knowledge and awareness on various injuries is very important for every medical student and practitioner for recognizing and differentiating it. So students should gain more knowledge and awareness on injuries.

Key Words: Injury, Medical students, Knowledge and awareness, Forensic perspective.

Introduction

Legal definition of injury: Section 44 IPC defines injury as “any harm what so ever illegally caused to any person in body, mind, reputation or property.” Medically, a wound or injury is a break of natural continuity of any of the tissues of living body. Injuries can be classified medically, legally and medico legally.

An injury is always caused by some mechanical force, in which there may be a counterforce given by the body or rigid stationary object when there is movement of person or combination of both. Thus the energy produced is transferred into a person’s tissue. A tissue is a complex structure thus the energy is not transferred uniformly which causes compression or traction or combination of both. Rigid structures such as bones, resist deformation, but if the limit exceeds fracture occurs. Mechanical force to soft tissues alters their shape, which results in cohesion between the tissue cells, connective and vascular tissue frameworks and capsules of organs. Soft tissues rupture when they are stretched beyond the limits of their tensile strength. [8]

Mainly, injuries are due to mechanical or thermal or electrical or chemical etc. Each and every form of injury as its own medico-legal importance. Injuries have acquired least importance among doctors, despite of being one of the leading causes for complications and death. Many things can be done to gain understanding on specific injuries and examine. Any injury can give clues for its occurrence by proper examination, for example,
bite marks, nail tissue scrapings. So any medical person can be effective in this, but can be successful only by gaining knowledge and getting more exposure. This is the duty of every medical practitioner. This can be done only when there is good understanding on injuries and their medico-legal importance during the course of study. Many aspects like, cause of injury, time since it happened, manner of injury, site of impact, direction of force applied, position of the victim and assailant, place of injury, motive of the offence and many factors can be concluded only with proper knowledge on injuries. Even ante mortem and postmortem injuries can be differentiated. Every doctor should know that irrespective of their speciality, they are going to deal with medico-legal aspects of injuries comes throughout their life. Thus the key part of any medical practitioner is to assess appropriately, document clearly and interpret the injuries which were occurred. Medical practitioners are constantly exposed to examination of victims and handle medico-legal aspects of injuries. They are often subjected to court of law, so if they lack knowledge it will lead to negative conclusions. The interpretation and assessment of different injuries can be done only when there is good awareness and knowledge about injuries among medical practitioners. Mechanical injuries have great part in interpretation and assessment and also important in medico-legal aspects, so they were included mainly in this study were knowledge and awareness of different types of injuries among medical students was checked.

**Materials and Method**

This cross-sectional retrospective study was conducted in Saveetha medical college and hospital, Chennai. Undergraduate medical students underwent this study. 115 students participated in the study. Students of 2nd year, 3rd year and 4th year MBBS were included in this study Students of 1st year was excluded as they lacked knowledge on forensic medicine. Study period was from 21st January 2019 to 30th March 2019. This study was done with the help of specially prepared questionnaires for which the validity was checked. It had about 20 questions and they were asked to tick their choice of option. The questionnaire consisted of knowledge on various injuries regarding forensic science such as abrasions, lacerations, contusions, chop and cut wounds, hesitational cuts, grievous hurt and their importance medico legally. The participants were assured that participation was voluntary and confidentiality would be maintained. The Approval of the ethical committee was done before starting. The questionnaires were given to students after explaining the importance of the study. Informed consent was obtained from students who participated and the responses were collected. 120 questionnaires were distributed out of which 5 students didn’t sign the informed consent; so, it was excluded. The data was then entered in MS Excel and was analyzed and percentages were obtained using SPSS software.

**Results**

Total 115 students participated in the study. In general 95% of the medical students had basic knowledge and awareness about various types of injuries and its forensic perspectives, as they were able to classify forensic injuries medically, legally and medico legally. Other 5% were lacking on this basic knowledge.

Knowledge and awareness on abrasions:

(Figure 1)- Abrasions are due to blunt force
Out of 115 students, 69% of students had knowledge on abrasions [refer figure 1]. Other 28% disagreed that abrasions are due to blunt force and 3% had no knowledge on abrasions. Most of them had awareness on abrasions common during road traffic accidents. Nearly half of the students were aware that abrasions do not affect both superficial and deep layers of skin. Whereas others lacked this information. 87.8% of the students had knowledge on pattern of abrasions and also agreed that time since abrasion can be identified by colour of scab. Only few disagreed that pattern of abrasion helps in identifying type of weapon and, that time since abrasions can be known with colour of scab. Other percentage of students didn’t have knowledge.

Knowledge and awareness on contusions:

(Figure 2)- Contusions causes bleeding

Knowledge and awareness on contusions were present only among of 49 students and 50% said contusions does not cause bleeding [refer figure 2]. Three by forth of students approximately had knowledge on ectopic contusions and minimal number of students lacked knowledge. Only 17.3% of students knew that bridging of tissue is not seen in bruise. Other 47.8% believed it and 26% didn’t know that it is only seen in laceration.

Knowledge and awareness on lacerations:

(Figure 3)- Lacerations involve all the layers of skin
Knowledge about lacerations was present among 75.6% of students [refer figure 3]. Others disagreed and few didn’t know that lacerations involve all layers of skin. Only 69.5% of students were able to differentiate between lacerations and incised wounds and believed that lacerations can lead to produce scar. Other few students were not able to differentiate between lacerations and incised wounds and 20% had no awareness and 20% disagreed the fact that lacerations will produce scar.

Knowledge and awareness on hesitational cuts:

(Figure 4)- Hesitational cuts are suicidal in nature

91% of students had good understanding on hesitational cuts [refer figure 4]. Only 5 out of 115 students disagreed that hesitational cuts indicates the suicidal nature of injury and believed that it’s homicidal. 6 students didn’t know what hesitational cuts are.

Knowledge and awareness on grievous hurt:
Only 70% of students gave correct responses on grievous hurt, [refer figure 5] where, few disagreed that emasculation comes under grievous hurt and some lacked knowledge on grievous hurt. And only 35.6% were known that abrasions do not come under grievous hurt while other students accepted it.

Knowledge and awareness on other types of mechanical injuries:

</tbody>
</table>

(Table 1)- Other types of mechanical injuries

71.3% students gave correct response as incised wounds are not due to sharp force whereas few gave incorrect responses and somewhere not aware.

Cut in genitalia are usually suicidal was disagreed by 80% of students and were correct about it.

Perpendicular strike due to heavy cutting weapon indicates chop wounds was disagreed by only by less percentage of students and nearly three forth students agreed it and gave incorrect responses and so was not able to differentiate between chop and cut wounds.
Penetrating and perforating wounds are caused by pointed weapons was known by many of students, minimal population disagreed and few lacked knowledge and awareness [refer table 1]

**Discussion**

The definition of physical injury in the forensic medicine is “damage to any part of the body due to the deliberate or accidental application of mechanical or other traumatic agent” [1]. The purpose of this assessment and documentation is establishing how injury is caused. As mistakes happen often, it is every doctor’s work to acquire knowledge on different injuries and their interpretation. Wounds are generally classified according to the method of caution and appearance. Each and every wound has different characteristics. These characteristics indicate the type of weapon. It is important for every medical practitioner as they often deal with medico-legal aspects of injuries throughout their practice.

A study done by, Barek A, Haque ST. [2] concluded that, the term hurt, injury and wound have almost the same meaning and some differences as well. They usually mean any damage to any part of the body or bodily harm caused by application of violence. Injury also includes any harm to the mind, reputation and property, and hurt includes bodily pain, disease or infirmity. Clinically a wound is produced when there is breach of anatomical continuity of the skin or mucous membrane with or without damage of the underlying tissues.

According to this study, knowledge and awareness on injuries were good among medical students. 115 medical students from Saveetha Medical College, Chennai, Tamil Nadu underwent this study. Out of which 95% of students had basic knowledge on injuries. There was a minimal lack of knowledge on contusions and grievous hurt and differentiating cut and chop wounds. This study mainly included mechanical injuries like abrasions, contusions, lacerations and other injuries like incised, cut, and chop wounds. Knowledge on medico-legal importance of each injury, hesitational cuts and grievous hurts was also present. In a similar study done by Rajeshree Rajendra Gaware et al., [3] 128 medical students participated, where knowledge and awareness on various injuries and its forensic perspectives were fairly good among medical students. Knowledge on its importance was present among 87.5% of the students. Knowledge on different types of injuries were present among 84.37% of students. But the knowledge on history taking were lacking among students. Thus understanding these injuries plays vital role among healthcare workers.

This study also shows that, students are having some knowledge and awareness about injuries but it should be improvised among them to make them fully aware about injuries. Similarly, Giannakopoulos GF et al., [4] done study to assess the knowledge of inflicted injuries of domestic violence and found that it should be improved among healthcare providers.

It is every medical professional’s duty to develop skills to assess and interpret different injuries. Another study done by Payne-James JJ, Hinchcliffe J. [5] says that, assessment and documentation about different injuries establishes the cause for the injury. They are rarely done correctly, so these skills should be within the remit of any medical professional. As there are many factors involved in interpretation of injury, it can be successfully done by forensic expertise. It can be undertaken by referring different documents like chart mapping, written descriptions or photographs.

The most common reason why medical evidence on injuries given in court is disagreeable is, confusing about the terms used by doctors and the inappropriate or inaccurate description of a wound, for example, documenting that the wound is laceration to describe cut wound caused by some sharp force such as a knife, when the wound is in fact, an incised wound [7], thus concludes that for proper differentiating and understanding various injuries, knowledge and awareness about it must be included among medical students which will surely help in future for better documenting of evidence. A comparative study done by, Reijnders UJ, Giannakopoulos GF, de Bruin KH.[6] concluded that, the injury assessment scores varied from good to blank in various participant groups such as forensic physician, emergency room physicians and nurses and medical students. So training in this field of medicine remains compulsory in all fields.

**Conflict of Interest:** Nil

**Source of Funding:** Self

**Conclusion**

The knowledge and awareness on various injuries is very important for every medical student and practitioner for recognizing and differentiating it. All types of
injuries have their own medico-legal importance which helps to clearly depict and for documenting them. Such reports certified by medical professionals only will help in judgment in the courts of law. The medical students were having good knowledge of the forensic perspectives of the injury, but certain areas shows lack of awareness. Thus it needs to be improved and the students should gain more understanding of injuries and their medico-legal importance because as a medical professional they are constantly exposed to plenty of injury cases.

A Cross Sectional Study on the Awareness and Practice of Road Safety Measures among the Medical Students in Chennai

Sushil Chakravarthy1, A, Magendran J2

12nd MBBS, 2Associate Professor, Department of Forensic Medicine, Saveetha Medical College, Thandalam, Chennai, India.

Abstract

Background: The global epidemic of road traffic accidents is still increasing. The present study was aimed to assess the level of awareness regarding road safety among the study participants and to study the behaviour patterns while using motorised vehicles among the study participants.

Methods: The present cross-sectional study was conducted in Saveetha medical college and hospital, Chennai. A total of 125 students were studied. The study period was from 21st January 2019 to 30th March 2019.

Results: In total, 125 medical students were studied, ranging from 1st to final year M.B.B.S. of age 19-24 years; the mean age being 21.4. Only 65(52%) participants wear helmet and only 22(17.6%) participants interpreted Gap-In-Median correctly.

Conclusions: The awareness regarding road safety measures among the study group was satisfactory but interpretation of the road signs was not satisfactory -only 17.6% interpreted them correctly. The behavioural patterns among medical students are not satisfactory-only 52% of students wear helmet while riding, only 49.6% wear seat belts always while 41.6% wear seatbelts sometimes and 24% don’t follow lane rules while driving.

Keywords: Road safety measures, Undergraduate students, Awareness, Behavioural patterns.

Introduction

A road traffic accident (RTA) is any injury due to crashes originating from, terminating with or involving a vehicle partially or fully on a public road. It is projected that road traffic injuries will move up to the third position by the year 2020 among leading causes of the global disease burden [1]. In India, motor vehicle population is growing at a faster rate than the economic and population growth [2].

It has been estimated that unless immediate action is taken, road deaths in India will rise to the fifth leading cause of deaths by 2020 [3]. It may result in an estimated 2.4 million fatalities per year. Developing countries like India face the double burden of already existing communicable diseases and increasing burden of non-communicable diseases including RTAs [4]. Moreover, since it is affecting the younger generation of India, the future assets of the country are turning into a liability which is not ideal for the progression of our developing country to a developed one.

Road traffic accidents cost most countries more than 3% of their gross domestic product. Injuries sustained during RTAs cause considerable economic losses to individuals, their families, and to nations as a whole. The losses incurred are from the cost of treatment as well as lost productivity of those killed or disabled by their injuries, and for family members who need to take time off work or school to take care of the affected family member. An increase in average speed is directly related both to the likelihood of a crash and to the severity of the aftermath. Road traffic injuries can be prevented.
The 2030 Agenda for the Sustainable Development has set a lucrative target of halving the global number of fatalities and injury from road traffic accidents. This requires a hand from multiple modalities such as police, transport, education, medical, and actions that address the safety of vehicles, roads, and road users. Major interventions such as safer infrastructure and stressing the importance of road safety features in the transport planning, improving the safety of vehicles by enhancing the protective features, improving post-accident medical care for victims of crashes, making and enforcing laws relating to important risk aspects, and more importantly improving the awareness among the public. Simple measures such as following the road safety measures properly and also having the basic awareness about road safety can effectively reduce the impact of RTAs. On top of this another survey stated that in the last decade alone, India lost 1.3 million people to preventable road crashes and another 5.3 million have been left disabled for life [5].

The present study is aimed to assess the level of awareness regarding road safety among the study participants and to study the behaviour patterns while using motorised vehicles among the study participants. It is a questionnaire based retrospective study.

Methods

The present cross-sectional retrospective study was conducted in Saveetha medical college and hospital, Chennai with the aim to study the awareness of students on road safety and the road traffic accidents associated with them. Undergraduate MBBS students were included in the study, both male and females took part in this study. Students without driving licenses were included in the study as violation of the road traffic rules were incorporated in the questionnaire. Students belonging to the age group of 19 to 24 years were targeted in this study and a total of 125 students were studied. Mean age of the study group was 21.4. The study period was from 21st January 2019 to 30th March 2019.

A pretested semi-structured Questionnaire including general information and specific questions regarding awareness and behavioural patterns about road safety measures was given to the study participants and were instructed to fill them, the questionnaire validation had been accounted for by esteemed professionals and filled Questionnaire were obtained from the participants. A total of 27 multiple choice questions were included and the participants were asked to answer every question. Every possible measure was taken so as to uphold the confidentiality that was promised to the participants in the first place. No personal information regarding the participants was let out and the participants were also provided with the contact number and address of the principal investigator in the information sheet which the participants were given the liberty to take it with them if they wish.

Any queries regarding the study was well appreciated and addressed to in the best manner possible. The participants were also given the liberty to pull out of the study whenever they wanted if they felt unsafe or uncomfortable with the study. After obtaining the data, it was entered in excel spreadsheet and was analysed using SPSS software and frequencies and percentages were obtained.

Results

In total, 125 medical students were studied, ranging from 1st year to 4th year MBBS of age 17-25 years. 72(57.6%) participants were 19 years old, 30(24%) participants were 20, 7(5.6%) participants were 21, 2(1.6%) participants were 23 and 14(11.2%) participants were 24 years old. 62(49.6%) participants were male and 63(50.4%) participants were female (Refer Fig 1).

(Fig 1) Gender of Participants

Out of 125 participants, 64(80%) participants did not attend any programs regarding road safety measures and 36(45%) participants had attended. The response to the question whether the participants always wear their helmets was equally split among yes and no. To the question “From which side are you supposed to overtake vehicles” almost 63% participants gave the correct answer which is from the right side.
From the data collected, 31 (24.8%) participants said they use mobile phone while driving, 94 (75.2%) participants said they don’t. Majority of the participants told they do not always drive below the speed limit mentioned on the signboard. Another alarming result was the number of people who drive vehicles without obtaining their driving license, 74 (59.2%) participants answered that they had driving license and 51 (40.8%) participants answered no. When asked the question regarding the importance and necessity of wearing seatbelt’s or helmet more than 90% participants answered yes which is satisfactory. 110 (88%) participants answered no to the question “Have you ever driven a vehicle under the influence of alcohol?” and 15 (12%) participants answered yes.

Among the participants, 58 (46.4%) participants answered 0.03% to the question “What is the permissible blood alcohol content for drivers in India” which is the correct value and the rest 67 (53.6%) participants answered wrongly. The results obtained regarding getting apprehended by the police for flouting road rules were meagre. 97 (77.6%) participants answered that they always follow the lane rules while driving whereas the rest 28 (22.4%) participants answered in the contrary. 95 (76%) participants kept track of their vehicles condition and service records whereas the rest 30 (24%) participants did not. A good chunk of the study group had violated the traffic signals at least once in their lifetime. (Refer table 1).

<table>
<thead>
<tr>
<th>Questions</th>
<th>Yes</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Have you ever been caught by the police for drunk and drive</td>
<td>6 (4.8%)</td>
<td>119 (95.2%)</td>
</tr>
<tr>
<td>Do you always follow lane rules</td>
<td>97 (77.6%)</td>
<td>28 (22.4%)</td>

<td>74 (59.2%)</td>
</tr>
<tr>
<td>Do you keep track of your vehicles condition and service records</td>
<td>95 (76%)</td>
<td>30 (24%)</td>
</tr>
</tbody>
</table>

Identification of road signs was poor only a handful answered correctly. 95(76%) participants felt that drinking and driving was more dangerous than texting and driving. When asked who was the most influential person for a teen driver, mixed results were obtained (Refer fig 2).

(Fig 2) Impact of Social Circle on Driving

92 (73.6%) participants answered that they always stop their vehicles within the stop line at the signal whereas the
rest 33(26.4%) participants answered they don’t always stop before the line. When asked to give a response on the maximum number of people who could travel safely on a two wheeler 106(84.8%) participants answered 2, 12(9.6%) participants felt it was 3, 6(4.8%) participants felt it was 4 and only 1(0.8%) participant felt it was 1. 92(73.6%) participants were aware of the stipulated hand signals to indicate slowing down, stopping, turning or overtaking and 33(26.4%) participants weren’t aware of the hand signals. 50(40%) participants felt the police had the right of way over other vehicles on the road, 42(33.6%) participants felt it was the pedestrians, 22(17.6%) participants felt it was the driver themselves and the rest 11(8.8%) participants felt it was animals. On giving the description about a road sign and asking to identify what modality it belonged to this was the response (Refer table 2).

**Discussion**

Road traffic accidents (RTA’s) are the result of many factors related to bike, car, driver and the nature of the road. Though the bike, car and road contribute to some extent, driver errors remain the most significant factor in increasing or decreasing the rate of RTAs [6].

While India contributes only a meagre 1% of the world’s vehicles, it accounts for more than 10% of global RTAs associated fatalities – the most in the world. According to the 2015 report on ‘Road accidents in India’, by the Transport Research Wing (TRW) of Ministry of Road Transport and Highways (MoRTH), 1,46,133 fatalities occurred in RTAs in 2015 which included a count of 12,589 children. This count is not only the highest that India has ever recorded in history, but it represents a 53.9% increase over the last decade, and nearly a ten-fold increase since 1970 [5].

The present study was conducted to assess the awareness and behaviour patterns regarding road safety measures among under graduate dental students. The mean age of the study participants was 21.4 and there was almost equal representation for both males and females. A study previously conducted reported that 67.3% were males and 32.7% were females [7,8]. Awareness of road safety measures among the participants was good. This may be due to the increase in campaigning through mass media. But only 79(63.2%) know that overtaking must be from right side only. This may be due less addressing of this issue in comparison to the other measures.

In the interpretation of traffic signs, the knowledge of the participants was not satisfactory. Only 22(17.6%) interpreted all the road signs correctly. Similar finding was observed by Gharaibeh et al in a study conducted in Saudi Arabia [9]. Regarding the behavioural patterns, nearly 40.8% of the participants were not having a driving license. 48% of the study participants don’t wear helmet always and 12% were involved in drunken driving.

Our findings were similar to the observation in the study conducted by Swamy et al in Chandigarh [10]. Use of seat-belts was one of the most cost effective way to prevent RTA related morbidity and mortality [11]. Thirty one (24.8%) participants admitted that they used mobile phones without hands free devices while driving. Furthermore, nearly seventy one (56.8%) participants agreed to having exceeded speed limits while driving. Almost similar findings were reported by Kulkarni et al from South India [12]. Janlert et al also reported 14% of
the riders who met with an accident had drunken driving [13]. 28 (22.4%) participants answered they do not follow lane rules while driving, which was similar to the results obtained in a previous study [14].

An alarming 41% participants answered that they blow the red light when they are in a hurry which is a significant rise in percentage when compared to a previous study which stated that only 28% people believe in breaking the signals if they are in a hurry.

Almost 41% participants said they maintained their vehicles in prime condition and were happy with that while a previous study stated that 57% participants were willing to pay more to improve the condition of their vehicles in order to make it more foolproof on the roads [5]. The behaviours concerning mobile usage and over-speeding while driving are highly dangerous to the driver and to the public. Hence, these behaviour patterns need to be addressed through proper legislative and educative measures.

From the results of the current study it is evident that the road safety rules aren’t followed up to the mark yet. Still there is a high incidence of young people driving vehicles without passing their driving tests, people using mobile phones on the road and high speeding on roads just for the fun of it. The current study has also cemented the fact that usage of helmets and seat-belts are still below par. One more alarming fact is that majority of the study group didn’t know what the basic sign boards meant which seems to be the most worrying aspect.

Practices relating to road safety should be encouraged to reduce the morbidity and mortality related to road traffic accidents. For young drivers to have a change and practice safe driving is by educating them the importance of having goals to drive and not to drive for sheer fun [15].

Conclusion
From the study it is pretty evident that the awareness on road safety measures among the study group satisfactory but interpretation of road signs was not up to the mark -only 17.6% interpreted the road signs correctly which is very poor. The behaviour patterns among medical students are not satisfactory-only 65% of students wear helmet while riding, only 49.6% wear seat belts always while 41.6% participants answered sometimes and 22.4% participants don’t follow lane rules while driving. The efforts for increasing road safety measures through signboards, posters and mass media should be strengthened to reduce the morbidity and mortality in relation to road traffic accidents. Further research needs to be conducted regarding this topic to assess the current situation regarding road safety measures across the various modalities and aspects of populations. Awareness generation and orientation towards road safety issues among the students should be done through periodic trainings. Strict enforcement of laws and periodic organization of traffic awareness campaigns are essential for checking out risky practices in driving and thereby can result in decreasing the burden of road traffic accidents.

A Study on Awareness of Breast Cancer among Nursing Students

Tansushree. B1, Magendran.J2
1II MBBS, Saveetha Medical College, Thandalam, Chennai, India, 2Associate Professor, Department of Forensic Medicine, Saveetha Medical College, Thandalam, Chennai, India

Abstract

Background: Breast cancer is the most common type of cancer in women worldwide and its incidence is increasing in many countries. Breast cancer could happen to any woman irrespective of her education, social or cultural background. The lack of knowledge and incorrect perception about breast cancer prevention among females are responsible for the negative perception of the curability of cancer detected early and of the efficacy of the screening tests. It is, therefore, important to assess the level of awareness of risk factors in our communities. Therefore the present study is aimed to assess the awareness of breast cancer among nursing students.

Methods: The present cross-sectional study was conducted among nursing students of SAVEETHA MEDICAL COLLEGE AND HOSPITAL, CHENNAI. A total of 150 nursing students were included in the study with their prior consent. The study period was from 21st January 2019 to 30th March 2019.

Results: Our results showed insufficient knowledge of breast cancer among nursing students even though majority of them have heard of it. The results indicated the need for increased breast cancer awareness among university students.

Conclusions: Our study participants did not have adequate knowledge on risk factors and symptoms of breast cancer. The implications of this study are to emphasize the need to teach nursing students breast cancer awareness and detection of breast cancer in the early stage their undergraduate courses.

Keywords: Breast cancer awareness, Nursing students, knowledge, Consequences, Attitude.

Introduction

Cancer is becoming a leading cause of death worldwide [1]. Breast cancer is the most common type of cancer in women worldwide and its incidence is increasing in many countries [2]. It is also the second leading cause of cancer death in women after lung cancer. Breast cancer could happen to any woman irrespective of her education, social or cultural background [3]. Breast cancer occurs when there is abnormal breast cell growth. Most common breast cancers include invasive ductal carcinoma and invasive lobular carcinoma or in other cells or tissue within the breast. Breast cancer signs may include a lump in the breast, a change in breast shape, dimpling of the skin, fluid coming from the nipple, a newly inverted nipple, or a red or scaly patch of skin.

According to the World Health Organization report in the year 2011, it is estimated that worldwide over 508,000 women died in 2011 due to breast cancer [4]. Almost 70% of women with breast cancer are aged over 50 years, and only 5% are younger than 40 years old [5]. There is marked geographical variation in incidence rates, being highest in the developed world and lowest in the developing countries in Asia, Middle East, and Africa. The global incidence of breast cancer is rising, particularly in developing countries that formerly had a low incidence [6]. The incidence of breast cancer is
increasing due to increase life expectancy, increase urbanization and adoption of western lifestyles in the developing world.

Therefore, it is important that emphasis on prevention and early diagnosis of breast cancer are employed everywhere. One of the major difficulties regarding breast cancer relates to the lack of patients’ awareness about the disease. The negative perception of the curability of cancer detected early and of the efficacy of the screening tests are due to the lack of knowledge and incorrectly held beliefs about breast cancer prevention among females. It is, therefore, important to assess the level of awareness of risk factors in our communities. The survival rates of breast cancer have increased, and the number of deaths associated with this disease is steadily declining, largely due to factors such as earlier detection, a better approach to treatment and a better understanding of the disease. Breast cancer can be detected at an early stage through a combination of monthly breast self-examination (BSE), regular clinical breast examinations and annual mammography beginning at the age of 40 years, are the best ways to limit morbidity and mortality associated with breast cancer [6]. Early detection of breast abnormality is an essential factor. This is a challenge for health care professionals, especially nurses; contribute a crucial role in providing breast cancer awareness to women. Nursing students are the future nurses who will have the opportunity to encourage and influence women to be breast aware [3]. Therefore this study is aimed to assess the awareness of breast cancer among nursing students.

**Materials and Method**

This study was conducted among nursing students of SAVEETHA MEDICAL COLLEGE AND HOSPITAL, CHENNAI. A total of 150 nursing students were included in the study with their prior consent. The study period was from 21st January 2019 to 30th March 2019. Institutional Ethics Committee (IEC) clearance was applied for and obtained. All the participants who took part in the study were briefed on the study’s purpose, and requested to participate in it. The questionnaires were distributed after describing the purpose of the study. The participants were assured that participation was voluntary, and confidentiality would be maintained. The study was done by using a cross sectional and a semi-structured questionnaire which included questions related to

1. Awareness regarding breast cancer
2. Knowledge regarding breast cancer.
3. Attitude towards risk factors for breast cancer.

Informed consent was obtained from the study participants. After collecting data, the data was edited and tabulated on Microsoft excel sheet before data analysis. The data was then analyzed and the percentage were obtained and chi square test was applied.

**Results**

In total, 150 nursing students were studied, ranging from 1st year to final year nursing of age 17-22 years; the mean age being 18.73. Out of 150 participants, 127(84.7%) belong to < 20 years and 23(15.3%) belong to > 20 years. 32(21.3%) belong to 1st year, 102(68%) belong to 2nd year, 7(4.6%) belong to 3rd year and 9 (6%) belong to final year.

Out of 150 participants, 148 (98.6%) have heard of breast cancer and 2 (1.4%). Out of which 78 (52%) have heard of breast cancer through books, 43 (28.6%) through media, 22 (14.6%) through hospital, 5(3.3%) through conferences and remaining through friends and other sources. (Refer fig 1 & table 1)

Out of 150 participants, 19(12.6%) have family members suffering from breast cancer and 131(87.4%) do not have family members suffering from breast cancer. (Refer fig 2)

FAMILY MEMBER OF NURSING STUDENT HAVING BREAST CANCER

Out of 150 participants, major cause of death in women diagnosed with breast cancer was thought to be due to lack of awareness by 99(66%), due to low socio economic status by 23(15.3%), due to poor access to health care by 20(13.3%), due to hesitation by 8 (5.3%).(Refer fig 3)
Out of 150 participants, 22(14.7%) have attended breast cancer awareness programme and 128(85.3%) have not attended breast cancer awareness programme. 98(65.4%) were aware and 52(34.6%) were not aware of consequences of breast cancer if left untreated. (Refer fig 4 & 5)

STUDENTS WHO HAVE ATTENDED BREAST CANCER AWARENESS PROGRAM
Discussion

Breast Cancer is the most common cancer in women in India [7]. Breast cancer is overlooked by many till a near and dear one suffers from it. So this results in most people presenting only when symptomatic, and on an average, most ‘symptomatic’ cancers are stage 2B and beyond (significant numbers in stages 3 and 4). So the breast cancer patients tend to survive for shorter time than their western counterparts. In the Western countries, most of the breast cancers (read more than 75%) present in stages 1 and 2, resulting in good survival; and there is an ever increasing numbers of patients presenting with mammography detected cancer, with no symptoms. India has to reach this achievement, and it is only with aggressive promotion of screening and awareness and proper treatment that India will achieve this; and will take at least a few decades to reproduce similar results [8]. The main focus of the study was to assess breast cancer awareness and knowledge among university students.

The evaluation of public awareness, attitudes and practice of BSE is of important for the successful implementation of breast cancer control activities. There are no known proven means to prevent breast cancer, which increases our reliance on the methods for early detection in order to improve patient outcomes. The main motive of breast cancer awareness program is to promote and develop awareness about the importance of its early detection. Our overall results, projected a general lack of breast cancer awareness and knowledge among university students irrespective of their gender, marital status, years in university and nature of high school attended even though 148(99%) have heard of it. In the current study, of the 148 participants who have heard of breast cancer, 52% obtained their information through books and only less than 1% obtained their information from friends which is in contrast to the study conducted among female Jordanian students in which 51.8% obtained their information from friends [6]. This may be due to hesitation among the students.

In contrast to a study done by Mafuvadze et al who reported 72% of university students reporting knowledge of someone with breast cancer in the USA, in our study, less than 15% of participants reported knowledge of someone with breast cancer [9]. Our study similar to study among female Jordanian students showed that more than 80% participants were aware that BSE might help in early detection of breast cancer [6]. Our study showed
that only 14.7% has attended breast cancer awareness program and more than 85% have not attended any such programs. This might also be the reason for increased incidence of breast cancer. Therefore, more breast cancer awareness programs should be developed in universities including lectures, seminars, workshops and on hands training.

**Conclusion**

Our study participants did not have adequate knowledge on risk factors and symptoms of BC. However, the knowledge about prevention and early detection was observed among majority with a healthy attitude among nurses towards BC.

Our study participants did not have adequate knowledge on risk factors and symptoms of BC. However, the knowledge about prevention and early detection was observed among majority with a healthy attitude among nurses towards BC.

Our study participants did not have adequate knowledge on risk factors and symptoms of BC. However, the knowledge about prevention and early detection was observed among majority with a healthy attitude among nurses towards BC.

Our study participants did not have adequate knowledge on risk factors and symptoms of BC. However, the knowledge about prevention and early detection was observed among majority with a healthy attitude among nurses towards BC.

Our study participants did not have adequate knowledge on risk factors and symptoms of breast cancer. This study shows the need to teach nursing students about the breast cancer awareness and early detection of breast cancer in their undergraduate courses. In addition, the provision of regular programs are necessary to increase and build up the confidence and skills of nursing students in BSE. This is the primary step toward increasing awareness about breast cancer and encourages early adoption of breast screening initiatives. Such workshops are recommended for the nurses working in primary health care settings. The nurses would be the advocates to promote breast awareness and BSE among people and it is important that they should be aware.

Assessment of the Feedback Questionnaire from Students for a Weekend Lecture

Vishal Marwaha¹, Anu Sasidharan², Greeshma C.R³

¹Principal & Chairman, Department of Medical Education, Amrita School of Medicine, Amrita Vishwa Vidyapeetham, Kochi, Kerala, India, ²Associate Professor, Department of Forensic Medicine & Toxicology, AIMS, Kochi, ³Tutor, Department of Biostatistics, Amrita School of Medicine, Amrita Vishwa Vidyapeetham, Kochi, Kerala, India

Abstract

Competency Based Medical Education (CBME) and Curriculum Implementation Support Program (CISP) are gaining a lot of momentum in India. Lecture still remains as a very important large group teaching method. Attendance of the students was seen to be reduced in weekend lectures. The primary objective of this research work was to estimate the understanding of learning objectives of the previous weekend lecture; and to get the students’ feedback on ‘status of attendance’, ‘relevance of weekend lectures’, ‘acceptance as adult learners’ and ‘marking proxy attendance in lectures’. The secondary objective was to find the association of the answers with that of ‘status of attendance’. The tertiary objective was to check if any association existed between students’ responses of ‘relevance of weekend lectures’, ‘marking of proxy attendance in lectures’ and ‘acceptance as adult learners’. A feedback questionnaire tool post validation was conducted unannounced following the weekend lecture and students voluntarily participated in the same – sample size was 82.

The students who had attended the lecture had given the maximum number of correct responses. The largest group of responses were ‘not answered’ and they belong to those who had not attended the lecture. All these interpretations of associations were found to be highly significant statistically - p < 0.001. There was an association between responses of ‘acceptance as adult learners’ with that of ‘marking proxy attendance in lectures (as bad attitude)’ - p < 0.049.

Key words: Adult Learner, Attendance, CBME, Feedback, Interactive Lecture, Pedagogy

Introduction

Competency Based Medical Education (CBME) is right now booming in India, and the doctors are mandatorily being teacher trained for the same. The Board of Governors (BOGs) through the Academic Cell are now focussing on Curriculum Implementation Support Program (CISP) very seriously for all the colleges in India; i.e. practical real time implementation of the new CBME curriculum. Nodal Centres and Medical Education Departments are responsible for carrying forward this vision of the BOGs.¹ In light of these recent developments in our country, while taking a look into the new curriculum; it was understood that CBME is actually a blend of traditional teaching methods along with the newer training methodologies. Under the section of Teaching-Learning (TL) Methods, in the new curriculum ‘Lecture’ was very much a part of the large group teaching methods. It is impossible to conflict the statement that Lecture has been the most common form of knowledge delivery TL method.²³ Small group teaching which is being now over-emphasized will be replacing most of the lecture hours; but even then there are earmarked lecture hours for each subject in the new CBME curriculum.
MCI expects medical colleges to take advantage of newer TL methods because one single approach is unlikely to suit for all learners, in terms of learning styles and preferences. However when it comes to scrutiny of attendance for lectures, a work was done abroad by Mattick and associates regarding attendance of students for non-compulsory lectures. They found the reason for diminishing attendance of students; as and when they progress through academic years, is their increasing confidence in the subjects or because of their increasing confidence as a result of learning through other TL methods. The researchers also saw a higher attendance percentage in lectures scheduled at lunch time because the students are having either morning or afternoon classes, and hence are more likely to be there in the teaching campus.4

The education system cannot be reformed and polished unless the feedback from the stakeholders are utilised for the same. A learner’s feedback can be reliable, valid and used genuinely in enhancing the quality of student learning and experience. Feedbacks can be questionnaires (which can be judgemental) or reflections (open ended). Even student diaries can be taken as one of the confidential reflections of a teaching learning environment.5 More than for the system, feedback can influence (improve or worsen) the learning behaviour of students and the skill development. It is perhaps understood that action without feedback is completely unproductive for any learner and this is even more apparent when feedback happens without any subsequent changes in actions.6,7

The data collected from feedback of learners is often considered very divisive, political and sensitive in an education system; and there exists a ‘tension’ between stakeholders (administrators, teachers and students) and the very purposes of collecting the feedback. This is because the demands of improvement and accountability are in conflict. Hence a perfect system/method of collecting feedback would maintain peace among the stakeholders.8

In the current research work, the following objectives were considered: The primary objective of this research work was to estimate in students the understanding of learning objectives of the previous weekend lecture (as answers); and to get the students’ responses/feedback on ‘status of attendance’, ‘relevance of weekend lectures’, ‘acceptance as adult learners’ and ‘marking proxy attendance in lectures’. The secondary objective was to find the association of the answers with that of ‘status of attendance’. The tertiary objective was to check if any association existed between students’ responses of ‘relevance of weekend lectures’, ‘marking of proxy attendance in lectures’ and ‘acceptance as adult learners’.

Materials & Method

It was decided to take an unannounced feedback of an interactive lecture that was conducted on a Saturday. Usually the attendance on such weekend lectures were found to be dropping low and there were few incidents of marking proxies too for the same. Following the Saturday 3-4pm lecture the same topic was further continued on Monday 1-2pm. The Monday session began for the same batch of students with a structured closed end feedback questionnaire that was completed in 10 minutes. The questionnaire was validated by the faculty members of the same subject and was modified accordingly post validation. The feedback questionnaire contained 15 points. Anonymity was ensured and students were given the freedom to opt out of the questionnaire completely. In the questionnaire six aspects were pertaining to the topic that was covered in the previous Saturday session and three were focussing on their attitudes and opinions (responses) of ‘relevance of weekend lectures’, ‘marking of proxy attendance in lectures’ and ‘acceptance as adult learners’. The other pointers were for recording their attendance of the Saturday session-with reason for absence, feedback of the feedback questionnaire, sex, age and signature.

The class had an attendance of 82 students. This batch of students was chosen since they had attended the Saturday lecture. Hence it was purposive sampling as far as the batch was considered. The study was prospective in nature. All the students who had attended the Monday interactive lecture had taken part in the study; there were no exclusions/omissions. The sample size was all the 82 students. The study was a pilot work since there was no exactly similar research work in the existing literature. The statistical analysis was done using IBM SPSS 20.0. For all the continuous variables, the results are given in Mean ± SD and for categorical variables as percentage. To find out the association between two categorical variables, chi-square test was applied. A P-value < 0.05 was considered as statistically significant.

Results

In total, 64.6% of the students were having an
age above 20 years (mean was 19.82 ± 0.818) and 53 (64.6%) students were females. The name of the topic that was taken on Saturday was correctly answered by 33 (40.2%) students. The mnemonic (for muscarinic effects of A/C poisoning with organophosphates) was answered correctly by 30 (36.6%) students. The antidote/s was correctly listed by 25 (30.5%) students. The requisite of an end-point in antidote administration was answered rightly by 33 (40.2%) students, and as to how this end-point needs to be clinically confirmed was correctly written by 15 (18.3%) students. As the last pointer, 18 (22%) students wrote the correct expansion of High Performance Liquid Chromatography (HPLC).

It was seen that 46 (56.1%) students had attended the lecture session on Saturday. The reasons for ‘not attending’ as given by the remaining students were grouped into three categories – Went home, Unwell and Other appointments. Of these three, ‘Unwell’ category constituted the highest percentage. The response from students for ‘relevance of Saturday (weekend 3-4pm) lectures’ were grouped into three categories: Lectures are - Boring, Not Sure and Essential. The highest number of responses was for the group ‘Essential’ (38 students - 46.3%). The students were asked as to whether they were adult learners and 36.6% (30 students) of them said that they believe in same (andragogy). The next pointer was as to the reasons they feel they are adult learners or not; and the highest group of responses supporting andragogy was the fact that these students believe in concept of self-learning. At the same time, the maximum number of reasons supporting pedagogy was the fact that they ‘require teacher input’. The students were asked for their opinion in giving proxy attendance during such lecture hours and their responses were grouped into three categories – Bad attitude, Neutral and Good attitude. The highest response was in support for ‘proxy attendance being a bad attitude’ – 69.5% (57 students). A feedback of the feedback questionnaire was taken and 38 (46.3%) students had chosen the response – ‘interesting feedback questionnaire’. Miscellaneous comments were sought from the students as to in-general how they are finding the lectures and 27 (32.9%) students gave their comments. Out of these nine students - 11% (highest category of response) said that the interactive lectures are ‘interesting and good’.

Table one and two - the ‘answers from students’ were compared to their ‘status of attendance’; those who had attended the Saturday session had given the maximum number of right responses. The largest group of responses are ‘not answered’ and for all the six questions they are coming under the category of students who had not attended the lecture on Saturday. All these interpretations of associations were found to be highly significant statistically.

Responses of the ‘relevance of weekend lectures (boring/not sure/essential)’ were compared with that of ‘marking of proxy attendance in lectures (bad attitude/neutral/good attitude)’ and it was seen that responses of marking proxy as being a bad attitude was associated with that of weekend lectures being considered as essential; but this was not statistically significant. Similar an association was seen in the ‘not sure’ and ‘neutral’ categories respectively (statistically not significant).

The responses of ‘acceptance as adult learners’ was also compared with that of ‘marking proxy attendance in lectures’. There was a good association between being considering them self as an adult learner with that of considering marking proxy attendance in classes as a bad attitude (24 students – 80%); and it was significant statistically (p < 0.049). The non adult learners were similarly associated with the ‘neutral’ attitude to marking proxy attendance, with same statistical significance (Fig 1).

Fig 1: Association of ‘adult learners’ with ‘marking proxy attendance’ (AL – Adult Learner, NAL – Non-Adult learner)
Last but not the least; ‘acceptance as adult learners’ responses was compared with responses of ‘relevance of weekend lectures’. There was no obvious or strong association, and there was no statistical significance also for the same.

**Discussion & Conclusion**

The students have taken part with an open mind set and genuine interest to improve the system. So the teachers have their own share of responsibility by being transparent to identify the actions that need to be taken. In other words the educators are meant to take an active role rather than a passive receiver of feedback. When comparing the different methods in literature, this study was that of a rapid feedback method, and hence is less stressful and not too demanding from the students.5 It was also a closed end type of feedback session, thereby convenient for statistical summation, but on the other hand being a quantitative study and not a qualitative one (without focussed group discussions); the educator often will struggle to make sound reforms in the TL process.

The ‘name of the topic’ and the ‘importance of end-point’ were answered as higher percentages because the teacher had stressed on these two points in the previous class. But the ‘clinical confirmation of end-point’ was remembered the least among the take home messages, which could be because the students had not understood the relevance of the same; and this needs to be taken care in subsequent lectures. Out of the reasons that were sought for not attending the lecture, since ‘unwell’ was top scoring, the educators have to seriously take into consideration as to why the students are falling ill – whether it is to do with the poor food habits or unhealthy lifestyle prevailing at their residence/hostel.

It is to be taken with a positive stroke that the majority of them are considering themselves as ‘adult learners’, since this is the crux of the SPICES9 model of modern education system. Even the majority have opined that marking proxy attendance is a matter of shame and bad attitude. This category of students was also supporting the concept of self-learning. The importance of self-learning was already studied by the author in another research work involving only faculty members10, and now when the results of that work is read together with the students’ response in this work, everything is pointing in the direction of andragogy through self directed learning. The non-adult learners need to be encouraged by the educators to slowly start taking responsibilities on their own for their own benefits. The modus operandi of taking the attendance will be tightened up in the future lecture sessions.

Statistically all the answers for the six subject/lecture pointers were compared to the presence and absence status of the Saturday lecture. The largest category of the ‘unattended/not answered’ was coinciding with their absence in the previous lecture. Similarly the right answers were highest in students who had taken part in the Saturday Lecture. Being statistically significant this shows beyond any reasonable doubts that the students who had attended got definitely benefitted from the interactive lecture session on this particular topic. This also strengthens the fact that we cannot do away with lectures permanently. The responses for ‘relevance of weekend lectures’ with that of ‘marking of proxy attendance’ in class though had an association, cannot be affirmed for its veracity because of non-significant statistical interpretation. However the association of the responses of ‘acceptance as adult learners’ with that of ‘marking of proxy attendance’ was statistically significant and this shows the importance of adult learners being responsible for shouldering their learning responsibilities and also having the right attitude in a lecture session; including to not to mark proxy attendance.

**Acknowledgment:** We would like to thank the Professor and HOD of Forensic Medicine and Toxicology Department in AIMS, Dr. VV Pillay for his kind support in conducting this feedback questionnaire session in one of the interactive lectures of the subject. We would also like to thank the other faculty members in the same department for validation of the questionnaire tool.

**Conflict of Interest:** There are no conflicts of interest in this research work

**Source of Funding:** Nil

**Ethical Clearance** Ethical Clearance was not required, (as per the guidelines in ICMR) for any research work into medical education or curricula/teaching activities modification.

Assessment and Examination of Female Rape Victims and Their Genital Injuries

Yamini Patil¹, Sanjay Kumar Patil²
¹Associate Professor, Department of Obs & Gynaecology, KIMS, Karad,
²Professor, Department of Obs & Gynaecology, KIMS, Karad

Abstract

**Background:** The prevalence of genital injury resulting from sexual assault has been an area of interest to the scientific and health care community. The present study was conducted to assess female rape victims and their genital injuries.

**Materials & methods:** The present retrospective study was conducted in the department of Gynaecology. It consisted of 28 female patients of rape victims. All suspected victims were examined in gynecology and forensic medicine department. A through vaginal examination was performed by gynecologist.

**Results:** Age group 20-25 years had 16 females and age group 25-30 years had 7 females and 30-35 years had 5 females. The difference was significant (P< 0.05). Tanner staging- hair stage II was seen in 8, hair stage III in 20, V-shaped notches were single in 4, multiple in 24. Notches were at 6 o clock position in 5, 9 o clock position in 6 and at both positions in 17. The difference was significant (P< 0.05).

**Conclusion:** The number of rapes is increasing day by day. A through gynecological examination is required to confirm the crime.

**Key words:** Rape, Gynecology, genital injuries, sexual assault.

Introduction

An estimated 876,064 rapes are perpetrated against women each year in the United States. Among injured female victims of sexual assault, one half of those in which the violence was reported received some type of treatment from a health care provider. The prevalence of genital injury resulting from sexual assault has been an area of interest to the scientific and health care community since the 1970s.¹ Investigators have, over the years, typically reported the prevalence and location of injuries that occur most commonly; however, less is known about other more subtle aspects of injury, such as the type, severity, and extent of the wounds. Sexual violence occurs throughout the world.²

Although in most countries there has been little research conducted on the problem, available data suggest that in some countries nearly one in four women may experience sexual violence by an intimate partner, and up to one-third of adolescent girls report their first sexual experience as being forced.³ Sexual violence has a profound impact on physical and mental health. As well as causing physical injury, it is associated with an increased risk of a range of sexual and reproductive health problems, with both immediate and long-term consequences. Its impact on mental health can be as serious as its physical impact, and may be equally long lasting. Deaths following sexual violence may be as a result of suicide, HIV infection or murder – the latter occurring either during a sexual assault or subsequently, as a murder of “honour”. Sexual violence can also profoundly affect the social wellbeing of victims; individuals may be stigmatized and ostracized by their families and others as a consequence.⁴ The present study was conducted to assess female rape victims and their genital injuries.
Materials & Method

The present retrospective study was conducted in the department of Gynaecology. It consisted of 28 female patients of rape victims. All subjects were informed about the study and written consent was taken. Ethical clearance was obtained prior to the study.

Data such as name, age, sex etc was recorded in performa. All suspected victims were examined in gynecology and forensic medicine department. A through vaginal examination was performed by gynecologist. Results thus obtained were studied. P value < 0.05 was considered significant.

Discussion

Sexual violence is defined as: any sexual act, attempt to obtain a sexual act, unwanted sexual comments or advances, or acts to traffic, or otherwise directed, against a person’s sexuality using coercion, by any person regardless of their relationship to the victim, in any setting, including but not limited to home and work. Coercion can cover a whole spectrum of degrees of force. Apart from physical force, it may involve psychological intimidation, blackmail or other threats – for instance, the threat of physical harm, of being dismissed from a job or of not obtaining a job that is sought. It may also occur when the person aggressed is unable to give consent – for instance, while drunk, drugged, asleep or mentally incapable of understanding the situation. Sexual violence includes rape, defined as physically forced or otherwise coerced penetration– even if slight – of the vulva or anus, using a penis, other body parts or an object. The attempt to do so is known as attempted rape. Rape of a person by two or more perpetrators is known as gang rape. Sexual violence can include other forms of assault involving a sexual organ, including coerced contact between the mouth and penis, vulva or anus. The present study was conducted to assess female rape victims and their genital injuries.

In this study, age group 20-25 years had 16 females and age group 25-30 years had 7 females and 30-35
years had 5 females. Typically, acute injuries of the external genitalia observed in child rape victims include lacerations, bruise, abrasion, redness, and edema of the posterior fourchette, labia majora, labia minora, hymen, or vulva. The hymen of a child is easily torn by the insertion of an adult penis, as the pre-pubertal physical structure of the hymen is relatively smaller than that of adults.\(^8\)

In a study conducted by Plichta et al\(^9\), the genital scars of pre-adolescent sexual abused victims were monitored for 10 years. Of 24 child victims who were raped, transection was observed in 12 victims. The transection of the hymen did not naturally heal unless they were surgically reconstructed.

We found that Tanner staging- hair stage II was seen in 8, hair stage III in 20, V- shaped notches were single in 4, multiple in 24. Notches were at 6 o clock position in 5, 9 o clock position in 6 and at both positions in 17. Campbell et al\(^10\) conducted a study on scar patterns in the genital organs of sexually assaulted female victims. Hymenal laceration occurred more frequently in adolescents than in adults, and the difference was statistically significant. Hymenal injury is more frequent in adolescents than in adults because of the lack of sexual and childbirth experience. Therefore, when a child is raped, hymenal injury is more likely to occur, or the severity of the injury is more serious in adolescents than in adults. Severe hymenal scars, such as deep notches of over 50% or transections, may remain permanently even after several years. Most child rape cases have a delayed disclosure of sexual abuse. Therefore, by the time medical professionals examine child victims, the injuries are most likely healed to a certain degree.

**Conclusion**

The number of rapes is increasing day by day. A thorough gynecological examination is required to confirm the crime.

Visum Et Repertum in the Evidencing Process of Rape in Indonesia

Arief Budiono1, Wilma Silalahi2, Ayesha Hendriana Ngstiningrum3, Wafda Vivid Izziyana1, Suparji4, Sofyan Wimbo Agung Pradnyawan5, I Nyoman Putu Budiartha6

1Lecturer, Universitas Muhammadiyah Ponorogo, 2Researcher, Mahkamah Konstitusi Republik Indonesia, 3Lecturer, Poltekkes Kemenkes Surabaya, 4Associate Professor, Poltekkes Kemenkes Surabaya, 5Lecturer, Universitas PGRI Madiun, 6Professor, Faculty of Law, Universitas

Abstract

Rape is part of sexual crime in which its evidencing process is rather complicated if the victims do not directly report the case, or if the law-enforcing apparatus are not quick in handling it. *Visum et repertum* is a medical-aspect report from the doctor after a written demand from the law-enforcing apparatus of authority for the sake of the case investigation and examination in court. Thus, from this definition, *visum et repertum* can only be proposed by the law enforcers or the authorities such as the police department, the lawyers, or the judges in court to the special doctors who are in charge of that field. The lawyers and the judges may ask for the *visum* through the police department. This research uses a normative doctrinal method. The research results show that the evidencing process of rape as a criminal act of sexual crime has some different difficulties compared to other general criminal acts. This is because there needs to be *visum et repertum* which will uncover the perpetrator and the time of occurrence, which will ease the process of searching for and finding the perpetrator. The obstacle of *visum et repertum* is that its evidencing process is the same as a letter of evidence in the aspect of power.

**Keywords:** visum et repertum; evidencing; rape; Indonesia

Introduction

In obtaining adequate evidences of a criminal case, the law enforcers are often faced with complicated cases, which require special skills. They might not even have the skills as they are not in their expertise. Thus, there needs to be other elements in the law enforcement to make a criminal case clear. This is the importance of the experts’ role to find a complete material truth to complete the evidencing process of a case file, so that it may be judged and decided upon by the judge, as said by Soesilo.\(^{(1)}\)

Rape is a criminal action which is very different from other crimes. This is because the evidencing process require a special aspect, which is only understood by medical forensic experts. Rape is an action of violence and a crime of decency which attacks someone’s dignity. It is done by coercing someone to undergo sexual intercourse using violence or threat of violence. Because this intercourse must be proven on when it happened, and who did it, there needs to be information from experts of medical forensics to be expert witnesses in that case. They also need to make a report called *visum et repertum*. The expert witnesses will also be present in court if the case is under trial.

The aim of the expert information’s presence is to assist the law enforcers in the levels of investigation, lawsuit, and trial to give valid evidences and medical information which can be trusted regarding the victim’s condition, especially regarding evidences of sexual violence which comes with intercourse, both physical violence on the victim’s body and the threats of violence which preceed it.

DOI Number: 10.37506/ijfmt.v14i2.3476
Visum et repertum is used to uncover rape cases as criminal cases with the aim to achieve truth. This will bring justice to the victims, as the visum et repertum is crucial in the medical forensics for evidence. This is the importance of visum et repertum for obtaining evidences.

The function of criminal law procedures according to JM. Van Bemmelen in Soedjono(2) are as follows:

1. To find truth of the accusation in the criminal code violation through the state instruments;
2. The effort to find the perpetrators who violated those regulations/to find the perpetrators of the action;
3. The effort so that the perpetrator of that action is caught, and if needed, they should be imprisoned;
4. The collection of evidences or bewijsmateriaal which have been obtained to uncover the truth, to be given to the judges, and to bring the defendant to the face of the judges;

The view of the criminal law procedures is carried out to obtain a material truth, which is according to the aim of the criminal law, which is to find the material truth of a case. This is different from the civil law, which only looks for a formal truth. In the other hand, the evidences are taken from the body of the victim, such as traces of saliva, sperm in the victim’s vagina, and evidences of violence such as wounds, bruises, etc. Such things are usually invisible to the eye. Only medical forensics can translate those evidences as well as to find them as carefully as possible, as opined by Idris and Tjiptomartono.(3)

There is a tendency in the Indonesian culture that the rape victims are considered as unclean and polluted creatures. This makes the victim, the family, the friends, and the acquaintances hesitate from reporting as they are ashamed. They are scared that the society will view them negatively. Thus, the report which is supposedly done as soon as possible is postponed. They may not even report until months or years. Thus, the evidences of rape are gone. This will make the evidencing process of that case difficult.

**Finding and Discussion**

The science of medical forensics calls visum et repertum only as visum. Visum is the latin word for visa, which means to see. Terminologically, visum means a sign from an evidence from anything found, agreed upon and validated. Meanwhile, repertum means to report. Thus, terminologically, it means whatever is found from the doctor’s examination to the victim or what has been validated by that doctor, as opined by Ranoemihardja.(4)

The report of that doctor, which is called visum, must be in the form of a written report from a forensics doctor who have done a medical swear, so that it may become a valid evidence in the court trials while judging the perpetrator, as explained by Ranoemihardja.(4) Visum et repertum, which is part of medicolegal has three kinds, in which according to Soeparmono(5) are explained as follows:

1. **Visum et repertum** for living people

   There are three kinds of this visum, which are:
   a. **Visum et repertum** for wounds/direct visum et repertum/ definitive visum et repertum

   The qualification of the wound written by the doctor on the conclusion of the visum et repertum is wounds of the first degree and group C wounds. The doctor is not allowed to write light violence wound as this is a legal term.
   b. **Temporary visum et repertum**.

   This visum needs further care and treatment, thus it may become an obstacle for the victim’s work.
   c. **Continued visum et repertum**.

   This visum is done when the victim’s wound is considered as healed. Another reason is when the victim is moved to another hospital, of if he/she is treated by a different doctor, or he/she goes home before the assigned time.

2. **Visum et repertum** for dead bodies.

   This visum is done if the victim is dead. Thus, the doctors undergo visum et repertum for dead bodies. The doctor writes the wound qualification in the conclusion of the visum et repertum.

3. **Expertise**

   This visum et repertum is specially done to check the condition of an item or the victim’s body part. For instance, this may be blood, sperm, saliva, body tissues, hair, bone, etc. There are parties who say that expertise is not part of visum et repertum.
In asking for a *visum et repertum* report to the doctors, especially if the victim is still alive, the authorities or the apparatus must take note of these things regarding the rape victim, as described by Soeparmono:(5)

1. The demand for *visum* must be done in a written form, as opposed to the oral form;
2. The demand for the *visum* must be done directly to the doctor, without any mediators, including the media of postal service, and/or through the victim or the family;
3. It is not a past phenomenon, as it is included in the confidential information of the doctor’s position;
4. The reason of why there must be the *visum*, and why he/she must be taken to the doctor;
5. The victim’s identity and the identity of the apparatus who asked for the *visum* and date of visum.
6. The victim must be directly accompanied by the police or the lawyer.

The main aim of investigation is to collect as much data as possible, regarding the matter, evidences, and correct facts regarding the phenomenon. Based on these facts, the investigators will try to reexplain and describe what had happened. The incomplete facts will be looked for to complete the imagery of the occurrence, so that it will be complete.

The process of a criminal case investigation by the investigators is then informed to the general plaintiff with the giving of the Notification Letter regarding the Start of an Investigation (SPDP) based on Article 109 paragraph (1) of the Criminal Code. After the evidences are collected, and the alleged perpetrator is found, then the investigator will assess the defendant carefully. The investigator will see if the evidences are enough, to be bestowed to the general plaintiff or maybe it is not a criminal act. If the investigators think that the occurrence is not a criminal action, thus the investigation is stopped for the sake of law.

Then, in Article 8 paragraph (3), if the investigation is finished, then the investigator will give the case files to the general plaintiff. The handover is carried out through two stages. *First*, in the first stage, the investigator will only handover the case files. *Second*, in the second stage, if the investigation is considered to be complete, the investigator will bestow the responsibility for the defendant and the evidences to the general plaintiff.

Then, in Article 110 paragraph (4) of the Criminal Code, the investigation is regarded as finished if within a 14 (fourteen)-day period, the general plaintiff does not return the investigation result files. Or, if before the determined period has ended, there has been a notification regarding that case from the general plaintiff to the investigators. After the investigation is regarded as finished, thus the investigator will bestow the responsibility regarding the defendant and the evidences to the general plaintiff, as explained by Prodjodikoro.(6)

The aim of an investigation is to obtain a decision from the general plaintiff, whether there is enough evidence to sue the alleged perpetrator. The criminal case process is a part of an integrated action of the law enforcement implementation. Between the investigation and the prosecution there is a strong relation. Even, the success of the prosecution in court trials cannot be separated from the results of the investigation.

The crime of rape means trying to coerce through violence, forcing with violence or overpowering. The definition of the criminal action of rape is wider than merely sexual intercourse. Yet, it may also happen in different forms, including the violation of another person’s human rights, according to Van de Tas.(7)

According to Soetanjo, what is meant by rape is an effort to force a man’s sexual desire to a woman, which violates the morals and law which apply. According to this definition, what is meant by rape on one side may be seen as an action of coercion to release one’s sexual desire. And, on the other side, it can be seen as an action of violation towards the norms and the social order, said Soebroto.(8)

The definition of rape above shows that rape is a form of an action in which a man forces his sexual desires towards a woman. Bothe morally and legally, this action violates the norms of morality and decency in the society. Thus, it is clear and it is even an obligation to categorize rape as a type of criminal action.

The provisions which regulate the forms of action and imprisonment of rape is called *verkrachting*, which is regulated in Article 285 of the Criminal Code. It is written in that article that, “Whoever, with violence or threat of violence, forces a woman to undergo sexual intercourse with him outside of marital relations, is deemed to have underwent rape, with the sanction
of imprisonment for a maximum of twelve years,” as written by Moeljatno.\(^{(9)}\)

In the material regarding the criminal act of rape in Article 285 of the Criminal Code, its elements, according to Chazawi\(^{(10)}\), may be described as follows:

1. The action: coercion
2. The manner, may be done through as follows:

With violence, with the threat of violence, with a woman who is not his wife, there is the action of intercourse

The action of coercion (dwingen) is an action which is done to another person by pressing the willingness of that person. This is so that the other person accepts the willingness of the enforcer. The point of coercion’s definition is doing something outside of another person’s willingness, which is against that person’s desire.

Satochid Kartanegara states that this action of coercion should be interpreted as an action which creates fear withing another person. The action which makes a woman “coerced” to undergo a sexual relation, must be categorized into the definition of “coercing” a woman to undergo sexual relations, even if that person undresses her own clothes, according to Marpaung.\(^{(11)}\)

According to Soesilo, the definition of violence is “using big power and physical strength illegally”. Meanwhile, according to Kartanegara, violence is “every action which uses physical strength which is not light yet rather hard,” according to Marpaung.\(^{(11)}\)

The understanding through the definition of violence in Article 285 is as follows. Violence is a manner or an effort to undergo (something abstract) which is targeted to another person to create an action using physical strength, which makes another person physically powerless. As said by Chazawi\(^{(10)}\) it may be done using wood, hitting, stabbing, etc.

Tirtamidjaja opines that sexual relations or sexual intercourse is the internal contact of the man’s and the woman’s genitals which usually causes pregnancy, there is no need for the excretion of sperm in the woman’s vagina, as said by Mapaung.\(^{(11)}\) Then, Anwar\(^{(12)}\) defines intercourse as the action of a penis’ penetration to the vagina. This penetration may be complete or incomplete, with or without ejaculation. Then, even though the action of intercourse happened in the past, it can still be seen by the science of medical forensics, through careful \textit{visum et repertum} according to Harahap.\(^{(13)}\)

The evidencing of the \textit{visum et repertum} results have the same power as the evidence of letters. The judge has the authority to determine the strength of each. If the judge believes that the \textit{visum} is truthful, thus the judge may give the verdict that the defendant is guilty. Thus, in the criminal case of rape, the accuracy of the doctor’s analysis in producing the evidence of \textit{visum et repertum} is crucial. This is the main point of the evidencing process, to ease the judge’s belief so that he/she believes in that evidence.

\section*{Conclusion}

Sexual violence in the form of rape is a criminal act. It does not only happen in developing countries, but it is also a disturbing problem in developed countries. It can be said that the evidencing process of this crime is rather different and more complicated compared to other crimes. Thus, there needs to be the involvement of different parties to handle this sexual violence case of rape. Usually, the law-enforcing apparatus involves the medicolegal element or medical forensics which has the special skills in uncovering the evidences of the rape case. Such evidences may then be used in the court trials. The police usually have trouble finding strong evidences. Another obstacle is the fact that the rape victims are usually reluctant to report their case. This is because in the local culture, such cases cause shame to the victim. That’s why, there needs to be special skills from the medicolegal, through \textit{visum et repertum} to obtain such evidences. The evidencing strength of the \textit{visum et repertum} depends on the judge’s belief. Thus, a weak \textit{visum} may be a strong evidence if the judge believes that it is truthful.

Effectiveness of Conventional Physiotherapy Exercises Versus Kinesiotaping in Recreational Football Players with Plantar Fasciitis

Pratiksha Rahane1, Khushboo Chotai2, Amrutkuvar Rayjade3, Smita Patil4
1Internee, 2Assistant Professor, Department of Sports Physiotherapy, 3Assistant professor, Department of Orthopaedic and Manual Therapy, 4Assistant professor, Department of Musculoskeletal Sciences, Krishna College of Physiotherapy, Krishna Institute of medical sciences deemed to be university, Karad, Maharashtra, 415110

Abstract

Background: Plantar fasciitis is a disorder in which there is non-inflammatory structural breakdown of the plantar fascia. It is more common in sports that involve running and long-distance walking. Many of the literature suggest that there is 21.7% of prevalence rate of plantar fasciitis in individuals who play sports, especially in football players who uses studs/cleats shoes. Attachment of the cleats place the foot in a dorsiflexed position throughout the stance phase of running which produces and increases pressure upon the calcaneus. This creates a pull from soft tissue attachments such as plantar fascia which further leads to disorders like plantar fasciitis which needs to be treated early and by more advanced techniques to prevent further overuse injuries.

Objective: To find the effect of conventional physiotherapy exercises versus kinesiotaping in football players with plantar fasciitis.

Material and Method: In this pre-post intervention study 40 football players having plantar fasciitis were included. They were randomly divided into 2 groups with 20 individuals each. Group A was treated with conventional exercises and Group B with kinesiotaping along with conventional exercises for two weeks. After pre-post assessment, data was analysed with help of appropriate statistical methods.

Results: According to the result, in Group A and Group B there is significant difference in pain and measures of foot function index with p value < 0.0001.

Conclusion: The results obtained by studying both the groups in this study suggests that in treatment of plantar fasciitis, Conventional Therapy along with Kinesiotaping is more effective than Conventional Therapy alone.

Keywords: Plantar Fasciitis, Conventional physiotherapy exercises, Kinesiotaping, Pain assessment, Foot Function Index.

Introduction

Heel pain or pain in the sole of the foot is the most common site of pain in general population.1 It can occur due to tendinitis, disease of calcaneum, bursitis or inflammation of fat pad.1 It also commonly occurs due to plantar fasciitis.

Plantar fascia is a dense, fibrous connective tissue structure originating from the medial tuberosity of the calcaneus.1 There are 3 portions – medial, lateral and central bands of the fascia of which the central band is the largest portion. The fascia extends through the medial longitudinal arch into individual bundles and...
Plantar fascia is an important static support for the longitudinal arch of the foot. It acts as a shock absorber as it has an ability to elongate with increased loads.

Plantar fasciitis is a disorder in which there is non-inflammatory structural breakdown of the plantar fascia. In this disorder, there is classic presentation of gradual, insidious onset of inferomedial heel pain at the insertion of the plantar fascia. Typically, this pain is described as “burning”, “aching” and occasionally, “lancinating”. Pain and stiffness are worse with rising in the morning or after prolonged ambulation. Pain and tenderness are sometimes extended into the medial arch. Pain related to this condition may cause substantial disabilities and poor health-related quality of life.

It occurs due to obesity, direct repetitive microtrauma with heel strike, excessive running, standing on hard surfaces for prolonged periods of time, high arches of the feet, presence of limb length discrepancy or flat feet. It is more common in sports that involve running and long-distance walking. It is also common in non-athletic individuals who are overweight and obese.

There is 21.7% of prevalence rate of plantar fasciitis in individuals who play sports, especially in football players who use studs/cleats shoes.

Studs or cleats are protrusions on the sole or an external attachment to a shoe, that provide additional traction on a soft or slippery surface. They can be conical or blade-like in shape and made of plastic, rubber or metal.

There are three main types of football boots: round, hard ground and bladed. These cleats are often permanently attached to the shoe surface and sometimes they can be removed. The studs/cleats are mostly attached on the forefoot and heel surface of the sole leaving the midfoot area.

Attachments of these studs/cleats can create a negative effect on the sole of the foot. Attachment of the cleats place the foot in a dorsiflexed position throughout the stance phase of running which produces and increases pressure upon the calcaneus. This creates a pull from soft tissue attachments such as Tendo-achillies and plantar fascia which further leads to disorders like plantar fasciitis.

Considering that such a large number of professional football players are suffering from this condition it can be safe to assume that greater number of recreational players will be suffering from this condition as well. The fact that they do not have much knowledge about various types of shoes and how to wear them correctly will add to this problem. Plantar fasciitis has worse effects on the foot function, gait pattern, walking speed and even normal stance. There are several ways to assess foot pain and foot function and Foot Function Index respectively.

In this study foot function was assessed by using Foot Function Index. It is a simple yet reliable test. Test-retest reliability of the Foot Function Index total and subscale scores range from 0.87 to 0.69, while internal consistency ranged from 0.96 to 0.73. It is reported that the FFI is a reliable instrument for use in foot orthopedic intervention trials.

The Foot Function Index has been validated and determined to be a reliable instrument for patients with non-traumatic foot or ankle problems.

Also, recreational players are more prone to get plantar fasciitis as they do not have that much access as professionals does for such facilities. Often players ignore such heel pain thinking it will subside with time but then it leads to various other problems related to foot.

As we know that there is a conventional therapy used widely and for a long time to treat plantar fasciitis. But now there is need for more advanced therapeutic techniques to treat plantar fasciitis which will help in reducing the recovery period and can give more better results than the conventional therapy. And the advanced therapeutic technique for treating plantar fasciitis is Kinesiotaping.

Kinesiology taping or kinesiotaping is a curative tool and has been showing great results when used in treating variety of conditions. Taping has been used for a long time for the prevention and treatment of sporting injuries. It is a Japanese technique used with the intention to alleviate pain and improve the healing in soft tissues.

There are also other benefits of taping such as proprioceptive facilitation, reduced muscle fatigue, muscle facilitation, reduced delayed onset muscle soreness, pain inhibition, enhanced healing, such as reducing edema and improvement of lymphatic drainage
and blood flow.7

It can be applied in various shapes and sizes according to the needs of the condition.7 The shape selection depends upon the size of the affected muscle and the results to be achieved. Here, for plantar fasciitis “I” or “Fan” strip method can be used in the treatment which has a supportive or inhibitory effect on the plantar fascia.

Thus, recreational players need treatment and awareness of such therapeutic techniques for conditions which can lead to many disorders.

Methodology

The ethical clearance was taken from ethical committee of Krishna institute of medical sciences, Karad. There were 40 participants in the study. The study was taken place in the Physiotherapy department, Krishna Hospital. Treatment protocol was of 2 weeks. The subjects were assessed for foot function and foot pain at first. The type of study was experimental study. The study design was pre and post.

Procedure:

All the subjects were selected for the study according to the selection criteria. Demographic data and consent were taken from them. Included participants were divided in 2 groups by simple random sampling method. Pre and post assessment were taken before and after 2 weeks of the treatment respectively with the help of outcome measures.

Group A: In first week, Ultrasound therapy with pulsed mode and intensity of 0.8W/cm² for 7 minutes, for 5 days/week.

Contrast bath with hot water for 3 minutes and cold water for 1 minute for 5 times/session/day.

Active stretching of soleus and gastrocnemius muscles and plantar facia, 30 seconds hold for 5 times/day session.

In second week, Contrast bath with hot water for 3 minutes and cold water for 1 minute for 5 times/session/day. Active stretching of soleus and gastrocnemius muscles and plantar facia, 30 seconds hold each one, for 5 times/day session.

Strengthening exercises like toe curls with towel, 15 repetitions for 3 times.

Heel raise with towel, 15 repetitions for 3 times.

Marble pick-ups, 10 pick-ups for 2 times. All exercises were performed for 1 session/day.

Group B: In first week, Taping for 2 times/week. Patient position- prone lying. Fan method. Ultrasound therapy with pulsed mode and intensity of 0.8W/cm² for 7 minutes and for 5 days/week.

Contrast bath with hot water for 3 minutes and cold water for 1 minute for 5 times/session/day.

Active stretching of soleus and gastrocnemius muscles and plantar facia, 30 seconds hold each one, for 5 times/day session.

In second week, Contrast bath with hot water for 3 minutes and cold water for 1 minute for 5 times/session/day. Active stretching of soleus and gastrocnemius muscles and plantar facia, 30 seconds hold each one, for 5 times/day session.

Strengthening exercises like toe curls with towel, 15 repetitions for 3 times. Heel raise with towel, 15 repetitions for 3 times. Marble pick-ups, 10 pick-ups for 2 times. All exercises were performed for 1 session/day.

Discussion

A study reported that there is 21.7% of prevalence rate of plantar fasciitis in individuals who play sports, especially in football players who use studs/cleats shoes.

Thus recreational players need appropriate treatment and awareness of such therapeutic techniques like Kinesiotaping and proper strengthening exercises are necessary for preventing further complications.

In this study, 40 individuals who played football for recreation (all male) were taken. They were equally divided into two groups i.e. Group A and Group B. Individuals in the age group of 18-30 years were included in this study, out of which 18 (90%) individuals were in the (18-24) age group and 2 (10%) individuals were in the (25-30) age group, in both the groups. This age group consisted of those who played recreational football and did not have any training or experience in professional football.

In Group A, the subjects were given only conventional therapy for plantar fasciitis for two weeks and in Group B, the subjects were given conventional therapy along with Kinesiotaping. Pain score according to Visual Analogue Scale and Foot Function Index score of subjects of both the groups were taken before the treatment/intervention was given. The mean pain score measurements for Group A prior to the intervention was 6.4 and post intervention was 5.15 and for Group B, mean score pre-intervention was 6.65 and post-intervention was 2.70.

Statistical analysis of the pain score of pre and post intervention of both the groups was done to confirm that the difference between the pre and post measurements is significant. The comparison for pre and post pain scores was found to have a p-value of (<0.0001) which was very significant.

To analyze the impact of foot pathology on function in terms of pain, disability and activity restriction of foot was done by using the Foot Function Index (FFI). It is divided into 3 subscales viz; Foot Pain subscale (FPS), Foot Disability subscale (FDS) and Activity Limitation subscale (ALS) which consists of 23 items. Same as Pain score, measures of FFI were taken before and after the treatment. The mean score of FFI for Group A according to the FPS was 16.80, FDS was 28.20 and ALS was 5.10, and for Group B, FPS was 14.20, FDS was 25.20 and ALS was 5.00. Here, the scores of FDS was found to be more among the three subscales.

The mean scores of pre and post intervention of FFI for Group A were 53.53 and 31.49 and Group B were 29.47 and 17.34. Statistical analysis was done to compare the mean post intervention scores of Foot Function Index to confirm whether they were significant or not and it was found that the p-value for Group A was (<0.0001) which was extremely significant and for Group B the p-value was (<0.0001) which was extremely significant.

Analysis was done to compare the total scores of Foot Function Index post intervention of both the groups which were found to have a p-value of (<0.0001) which was extremely significant for both the groups.

Thus the results obtained by studying both the groups in this study suggests that in treatment of plantar fasciitis, Conventional Therapy along with Kinesiotaping is more effective than Conventional Therapy alone.

Acknowledgement: I sincerely thank the management of KIMSDU for allowing me to conduct this study by providing me the necessary requirements. I thank my Dean Dr. G. Varadharajulu sir for his support and guidance. I convey sincere thanks to my guides Dr. Khushboo Chotai and Dr. Amrutkuvar Rayjade for helping me in my research. I take this opportunity to thank all those who have been directly or indirectly involved for smooth conduction of my study.

Conclusion

On the basis of the result of the study it is concluded that in treatment of plantar fasciitis, Conventional Therapy along with Kinesiotaping is more effective than Conventional Therapy alone.

Metanalysis of Qualitative and Quantitative improvement in Active Rehabilitation of Post ACL Repair or Reconstruction

Radhika Chintamani

Assistant Professor, Faculty of Physiotherapy, Department of Musculoskeletal Sciences, Krishna Institute of medical sciences deemed to be University-Malkapur, Karad-Maharashtra

Abstract

Background: Physiotherapy regimen is important in both Pre-Surgery and Post-Surgery phases. However, despite its widespread knowledge of importance of physiotherapy in both pre and post operation phases and during conventional therapy, the efficacy of early active intervention of physiotherapy in post-operative ACL repair/reconstruction is limited on the basis of quantitative and qualitative analysis.

Purpose: The aim of this meta-analysis was to analyze the randomized controlled trials having quantitative and qualitative improvement in parameters after active rehabilitation in subjects with post-repair/reconstruction of Anterior Cruciate Ligament.

Methods: The authors searched Google Scholar and PubMed from 2014 to 2019. Only downloadable randomized controlled trials were included in the study.

Main results: Twelve trials were included in the study with. The schedule of treatments varied greatly from certain days to 6 weeks or even follow up of 12 weeks. Subgroup analysis performed on Qualitative and quantitative assessment of pre-operative and post-operative active physiotherapy regimen showed significant statistical difference.

Conclusion: The result of the present study shows strong evidence to support the active physiotherapeutic treatment pre-operative as well as post-operative in subjects with ACL repair/reconstruction, which helps in improving both qualitative and quantitative parameters.

Key words: Meta-analysis, Qualitative, Quantitative parameters, Active rehabilitation, ACL repair, reconstruction

Introduction

Anterior Cruciate Ligament injury is common in knee joint injuries. Maximum injury of ACL occurs at sudden twisting and turning of flexed knee at the range 30 degrees. According to grading system given by Hopkin’s Usually grade III: is opted for surgical reconstruction and grade I and II: for repair/conservative management.

Most of the musculoskeletal operations require both pre- and post- Physiotherapy regimen. Pre-operative physiotherapy regimen helps in easy future rehabilitation of the subject as the surgery causes definite reduction of the strength within the local muscles. Post-operative physiotherapy regimen helps in increasing the strength as well as range of motion, reducing pain, early recouping of the daily activities, and functionally improving the subject. Various recent therapies used during Physiotherapy pre-operative and post-operative regimen which are known to be significant are: Whole body vibration, cross education, eccentric cycling, Delaware-Oslo, MOON, FES, Jump training with Body weight support.

There are very few randomised controlled trials defining both the qualitative and quantitative improvement in post-operative ACL. Further, information about qualitative and quantitative assessment of the change in parameters with active rehabilitation of ACL post-repair/reconstruction is limited. Hence it is necessary to know the improvement both qualitatively and quantitatively in cases with post-ACL repair/reconstruction after active rehabilitation. Hence this meta analysis is undertaken.
Method

Literature Search:

The reviewer searched the following computerized bibliographic English language databases: Google Scholar and PubMed from 2014 to 2019. The highly sensitive Cochrane collaboration strategy was used which targeted only randomized controlled trails.

Literature selection:

Studies were included if they met inclusion criteria and excluded if they didn’t. Inclusion criteria: 1) Randomised Controlled trial of Physiotherapy following post-ACL reconstruction/repair, 2) RCT’s having Immediate physiotherapy referral, 3) RCT’s having Active physiotherapy intervention, 4) RCT’s having EMG analysis of quadriceps, hamstring, gastrocnemius (any or all of the muscles) or any other qualitative analysis, 5) RCT’s having any one of the disability scales as quantitative analysis relating to knee and 6) RCT’s which can be downloaded 7) RCT’s published after 2014 Exclusion Criteria: 1) Inclusion of any other trauma except ACL injury, 2) Irregular physiotherapeutic regimen, 3) Passive physiotherapeutic regimen, 4) Bilateral ACL injury.

Quality assessment:

Quality of the studies recruited in this study was assessed by quality list from Cochrane Back Review Group18. Data were extracted Independently and checked for accuracy for the purpose of methodological quality.

Ethical Clearance: Ethical clearance obtained from institutional ethical committee Krishna Institute of Medical Sciences Deemed to Be University Karad.

Statistical Analysis

Randomized controlled trials in this study are classified by the year of publication, type of active rehabilitation, follow up time, outcome measure and improvement seen or not. Effect size was calculated of the changes in outcome measure between the control group and active rehabilitation part of the experimental group of various studies. Also, comparison was done between active therapy of each study to analyze the most effective therapeutic approach improving both qualitative and quantitative parameters post ACL repair/ reconstruction using SPSS version 16.0.

Results

Search strategy identified 1250 potential abstracts among which 150 randomized controlled trials were extracted out of which only 12 fit into the criteria of the study- Appendix 1. Table 2 depicts the key clinical and methodological characteristics of each included study.

Evidences:

1. Whole body vibration exercise protocol versus a standard exercise protocol after ACL Reconstruction: A clinical Randomized Controlled Trial with Short Term Follow-up by Berschin G. et al; 2014; quality score=5.1.1. Sample size was 20 in each group with outcome measure: Isometric and isokinetic muscle strength measurements, Lysholm score, neuromuscular functions. Improvement was seen in group with whole body vibration.6

2. Effects of early whole body vibration treatment on knee neuromuscular function and postural control after anterior Cruciate ligament reconstruction: a randomized controlled trial by Pistone et al;2016; Quality score=4.2.2. Sample size was 17 in each group. Pre physiotherapy intervention included whole body vibration therapy. Outcome measure were Maximum voluntary isometric strength during knee flexion and extension and Balance on force platform. Improvement was seen in whole body vibration technique at one month itself.7

3. Effect of targeted exercise on knee-muscle function in patients with persistent hamstring deficiency following ACL reconstruction- study protocol for a randomized controlled trial by Bregenhof; 2018; quality score= 6.2.2. 25 sample was included in each group with Maximal isometric knee flexor-extensor strength, KOOS, IKDC, Tegner activity score Rate of force development for knee flexion and extension, tendon regeneration and potential muscle hypertrophy evaluated by MRI, Postural control, kinetic/kinematic gait characteristics and knee related functional capacity. None of the result were mentioned.8

4. Cross education does not accelerate the rehabilitation of neuromuscular functions after ACL reconstruction: a randomized controlled trial by Zult et al; 2018; quality score=7.3.4. 22 sample was included in each group, with outcome measure: Isometric quadriceps maximal voluntary contraction, Voluntary quadriceps activation, quadriceps force accuracy and variability,
knee joint proprioception and single leg balance and improvement was seen in standard treatment protocol and cross education didn’t show any improvement.9

5. A comparison between Modified Robert Jones Bandage and Intermittent Cold Pack in Arthroscopic Anterior Cruciate Ligament Reconstruction: A Prospective Randomized Controlled Trial by Kijkunasathian et al; 2017; quality score=3.2.2. sample size was 19 in each group with outcome measures were Functional outcomes: positive quadriceps set, active straight leg raise, active knee flexion and limited knee extension, Knee swelling and Overall patient satisfaction. Improvement was seen in intermittent cold packages.10

6. Eccentric cycling rehabilitation in anterior cruciate ligament reconstruction: a randomised controlled trial of strength and biomechanical outcomes by Milandri G. et al; 2017; quality score=1.1.1. outcome measure were: Maximal load rate, Initial load rate, Average load rate, Impact force, Hip-knee angle during gait and hip- knee moments and Frontal knee valgus angle. Improvement in all qualitative parameters except average loading rate and impact force.11

7. Comparison of ACL-SPORTS Randomized Controlled Trial With Delaware-Oslo and MOON Cohorts by Capin et al; 2019 with quality score= 5.2.4. sample size was 20 per group. Outcome measures were Quadriiceps strength, Hop test, Functional outcomes (IKDC, KOOS pain, KOOS symptoms, KOOS ADL, KOOS Sports, KOOS QoL) Return to sport rates. Addition of perturbation did not add any benefit to the therapy.12

8. Pain experience and functional outcome of inpatient versus outpatient anterior Cruciate ligament reconstruction, an equivalence randomized controlled trial with 12 months follow up by Valkering et al;2015; quality score=6.2.2. Sample size was 23 per group with outcome measure: Functional outcomes: Lysholm, Tegner and IKDC Other: Pain experience and readmission rate. No significant difference were found between groups.13

9. Functional electrical stimulation following anterior cruciate ligament reconstruction: a randomized controlled pilot study by moran et al; 2019; quality score= 3.2.2. Sample size was 10 per group with outcome measures were Gait speed, single limb stance gait symmetry, Quadriceps isometric peak strength ration, peak strength inter-limb symmetry. FES was more better option to improve outcome measure.14

10. Kinesiotaping as a treatment method in the acute phase of ACL reconstruction: A double-blind, placebo-controlled study by Balki et al; 2016; quality score= 7.3.4. Sample size was 15 in each group with outcome measure: Lysholm, modified Cincinatti and Tegner scores on first and third post-operative months. KT therapy showed better improvement in all the outcome measures.15

11. A Randomized Control Trial of Acute Post Operative Care Following Anterior Cruciate Ligament Reconstruction: A Comparison of Two Protocols by Hallworth W. et al; 2014; quality score= 3.2.2. sample size were different in both groups i.e. 20 in one group and 17 in another. Outcome measures were: International Knee Documentation Committee (IKDC) Subject Knee Evaluation Form, Numeric Rating Scale for Pain (NRSP), Circumferential measure, Range Of Motion and improvement was shown significant in group given with DVD for performance of exercise.16

12. Clinical Efficacy of Jump Training Augmented With Body Weight Support After ACL Reconstruction: A randomized controlled trial by Elias et al; 2016; quality score= 6.3.3. Sample size was 15 in each group with outcome measure= International Knee Documentation Committee (IKDC) questionnaire, leg landing mechanics via motion analysis, knee joint effusion using a stroke test, surface electromyography–generated co-contraction index during a single-legged landing. Jump training with augmented body weight showed good improvement than without.17

The studies included 2458 patients; study sample size ranged from 10 to 409. Quality varied but tended to be higher in recent studies.

Active physiotherapeutic regimen versus improvement in outcome measure

Forest plots for qualitative measures and quantitative measures:

Effectiveness of various Active Physical therapy on Quantitative measure:
Compared with sham therapy, patients receiving treatment that included various Active Physical therapy intervention were definitely better except for one study which showed no better improvement than control group. On analyzing all the studies the maximum improvement was seen in disability index which one of the inclusion criteria of the study with 95% CI. Most significant effect was seen in study by Capin et al\textsuperscript{12} and Hallworth et al\textsuperscript{16} who used therapies like ACL SPORT- Protocol and A standardized protocol with DVD given to subjects respectively. Kinetic gait parameter was significant in the study by Elias et al including vertical ground reaction force as well by Moran U et al. Present showed significant effectiveness in quantitative parameters like kinematic gait parameters and maximum activation of quadriceps and hamstring by Zult et al\textsuperscript{9} and Elias et al\textsuperscript{17} and with p value 0.015 and 0.001 respectively.

Effectiveness of various Active Physical therapy on Qualitative measure:

Most significant effect was seen in study by Zult et al\textsuperscript{9} and Elias et al\textsuperscript{17} who used therapies like standardized treatment regimen and Jump training with body weight support respectively. Isometric maximal voluntary muscle contraction balance control and muscle strength of hamstring and quadriceps were also highly significant. The present study showed significant effectiveness in quantitative parameters like kinematic gait parameters and maximum activation of quadriceps and hamstring by Zult et al\textsuperscript{9} and Elias et al\textsuperscript{17} and with p value 0.015 and 0.001 respectively.

**Discussion**

All the therapies provided maximum benefit in improvement of both qualitative and quantitative parameters in subjects with post-ACL repair or reconstruction after Active physiotherapy regimen. Our comparison of various active physiotherapy regimen with control group stated that various physiotherapy protocols act differently on different parameters, which are both qualitative as well as quantitative. Most significant protocols were given in the studies by Capin
et al\textsuperscript{12}, Elias et al\textsuperscript{17} and Zult et al\textsuperscript{9}. Capin et al; the study compared three different protocol with one control group that is pure training of strength, agility, plyometric and secondary prevention, when compared to SAPP + perturbation training showed no statistical significance, but on comparison of this control group to MOON and Delaware-Oslo cohort study; ACL-SPORT [ACL-Return to SPORT protocol] group that is the control group showed more significant changes.\textsuperscript{12}

Elias et al; jump training is very important part of rehabilitation of subjects with ACL repair or reconstruction, because it activates the muscle in sudden weight bearing position, and also during landing on uneven surfaces. But, jump training done directly would harm the operative procedure done on the fresh graft of ACL. The graft of ACL is fixed with screws which on sudden landing me cause damage. Also, ACL operated subjects are more prone to early development of osteoarthritis, hence usage of body weight support system will definitely help the rehabilitation process. Initially weight bearing exercises and walking are very painful to the subjects who have undergone ACL repair or reconstruction. Body weight support system, grades the amount of weight borne by the individual while performing weight bearing exercises and also during walking. Hence in this study both qualitative as well as quantitative parameters were seen to improve. Vertical jump training is specifically given to improve the co-contraction of musculature along the knee; both quadriceps as well as hamstrings. But as the loading is painful in knee disorders and vertical jump being dynamic loading if done in ACL injured cases which is therapy followed for attaining dynamic stability in the knee between 6-48 months.\textsuperscript{17}

Zult et al; the study stipulated that the usage of cross education is not beneficial in the regimen of ACL repair/reconstruction. The study compared two groups, one with cross education and one without. At the end both of them were equally significant hence, between group significance was not seen. Though, it is known that training the good leg in any of the operated cases, in lower extremity was helpful in early weight bearing activities like walking and transfer, this study had a negative impact on that and remarkably it had a negative effect of central activation ratio of quadriceps which was calculated and also decreased limb symmetry index of quadriceps muscle strength by the end of the session. Hence, cross education wouldn’t be beneficial in treatment regimen followed for treating subjects who have undergone ACL reconstruction or repair.\textsuperscript{9}

**Conclusion**

Every active therapy deals with improvement of various outcome measures. This meta analysis have gathered twelve such randomised controlled trials passing the quality test by Cochrane. On statistical analysis the significant improvement among all the studies with respect to disability scale, strength training and muscle performance was ACL- Return to SPORT Protocol along with closed kinetic training by jump training along with augmented body weight support system.

**Summary**

This study will used randomized controlled design to investigate the effect active physiotherapy rehabilitation on qualitative and quantitative parameters in subjects with ACL repair or reconstruction compared with controls, on knee-joint function in. The trial results helped to determine which active protocol or active physiotherapy regimen helped in improving both qualitative as well as quantitative parameters.

Effectiveness of Lifestyle Modification in Late Adolescent Females with Normal BMI Polycystic Ovarian Syndrome

Snehal Walmik Hukire¹, T. Poovishnu Devi²

¹Intern, Faculty of physiotherapy, Krishna institute of medical sciences, Deemed to be university, Karad, Maharashtra, ²Associate Professor, Department of cardio-pulmonary, Faculty of physiotherapy, Krishna institute of medical sciences, Deemed to be university, Karad, Maharashtra

Abstract

Background and Objectives: The prevalence of PCOS varies from 2.2% to 26% in different countries. Between 20-50% of women with PCOS are normal weight or lean and the pathophysiology of the disorder in these women may differ from that of obese women; It has been suggested that PCOS develops in non obese women because of a hypothalamic pituitary defect that results in increase release of LH. To determine the effectiveness of life style modification in late adolescent with normal BMI polycystic ovarian syndrome.

Material and Methodology: 28 Normal BMI women with polycystic ovary syndrome were selected for the study. They received the life style modification including diet plan exercise plan. Pre –assessment of body weight is measured by body mass index (BMI),waist-hip ratio(W-H Ratio) and quality of life was scored as per polycystic ovarian syndrome questionnaire(PCOSQ) and post-interventional assessment was taken for the same after 3 months. The exclusion criteria included Type II diabetes, Cardio vascular problems, any concurrent hormone therapy within 6 weeks, pregnant women’s or who are willing to conceive.

Result: Statistical analysis for PCOSQ was extremely significant (P value=0.0001).Statistical analysis for BMI revealed not significant in post intervention .Statistical analysis for W-H Ratio revealed not significant in post intervention.

Conclusion: Lifestyle modification helped in maintaining weight and showed increased quality of life in women with polycystic ovarian syndrome (PCOS).

Key Words: Life style modification, normal body mass index, walking, Polycystic ovarian syndrome.

Introduction

Polycystic ovarian syndrome (PCOS) has been defined by the national institute of health and Rotterdam criteria as a hormonal disorder characterized by the presence of at least one polycystic ovary (presence of multiple cysts) accompanied by ovulatory dysfunction and excessive secretion of androgens.[15] PCOS is a fairly common condition in women of reproductive age[1].Polycystic ovarian syndrome is heterogeneous. [1] and nowadays it is recognized as most common endocrinopathy in reproductive aged women having key features like menstrual irregularity, elevated androgens and polycystic appearing ovaries.[2]

The prevalence of PCOS varies from 2.2% to 26% in different countries.[4] women with PCOS either have normal weight or are found lean in 20-50% women and the pathophysiology in these women may differ from that of obese women; it has been suggested that PCOS develops in non obese women because of a hypothalamic pituitary defect that results in increase release of LH.[4]
The prevalence of normal weight and underweight patients with polycystic ovarian syndrome been reported 1.5-6.6%.[7] The prevalence of PCOS is 9.13% in Indian adolescents.[15] The prevalence rate 6% in South India discover that the probability of urban women vulnerable to acquiring PCOS are 0.1 times higher than women in rural India.[16]

In previous study the subjects taken between the age of 18 to 24 years.[16]

Even in lean women with polycystic ovarian syndrome, we can see the higher waist-hip ratio, greater intra peritoneal and visceral fat.[7] By definition women with BMI< 25 are non-obese and with BMI >25 considered obese.[7]

Polycystic ovarian syndrome is associated so strongly with obesity therefore the women with normal weight often go undiagnosed.[10] Polycystic ovarian syndrome requires at least two of the following characteristics for the diagnosis; clinical or biochemical hyperandrogenism, anovulatory menstrual dysfunction and polycystic ovarian on ultrasound.[9]

Young adolescent girls experiences symptoms from irregular menses, amenorrhea, ovarian cyst, menorrhagia, hirsutism , acne, skin pigmentation. Symptoms like anxiety, depression, thyroid problem also may include.[5]

Obesity, type 2 diabetes, dyslipidemia, hypertension and cardiovascular disease has been linked with PCOS.[11] PCOS is an emerging health problem during adolescence therefore promotion of healthy lifestyle and early intervention are required to prevent future morbidities.[6]

In normal BMI women the polycystic ovarian syndrome seen because the connection between the pituitary gland and the ovaries broken down.

**Importance of Lifestyle Modification**

Life style modification commonly used as the first line treatment for PCOS women.[8] Life style modification contains dietary modification, physical activity and behavioral changes.[8] Exercise is important component of life style intervention by improving several benefits on cardio vascular, metabolic, reproductive and psychological health of women with PCOS.[3] For physical activity, participation and compliance feeling of pleasure during exercise is an important factor.[10] In respect of new randomized controlled trail, arranged and regular physical exercise can improve insulin sensitivity and menstrual regularity in PCOS women.[3]

Maintaining weight can help reduce diabetes risk.[10]

**METHODOLOGY**

Ethical clearance was obtained from the Institutional Ethical Committee, KIMS DHU, Karad. It is an experimental study was carried using cross sectional study design. The study was conducted in and around Karad, Maharashtra and was carried over a period of 12 week. This study include 28 women diagnosed with PCOS. The study protocol was approved by Regional Ethical Committee. Exclusion criteria included Type II diabetes, Cardiovascular problems, any concurrent hormone therapy within 6 weeks, pregnant women’s or who are willing to conceive. After baseline assessment, which include demographic data, body mass index (BMI), W-H ratio, questionnaire PCOS (PCOSQ) using random sampling method.

The hip and waist circumferences were determined using a tape measure, the widest circumference of buttocks and the smallest circumference of the hip.

The participant receive lifestyle modification which include diet, exercise, behavioral therapy

**Exercise**

Warm up exercise and cool down exercise for 10 minutes. The pcos exercise recommended atleast for 3 times per week. Aerobic exercise such as walking and jogging performed for 50-60 minutes per session.[13]

**Diet**

High protein diet include egg white, beans, pulses. Fruits like apple, guava, pear, grapes, oranges etc should be include. Tomatoes, sweet potato, pumpkin, almonds etc. High fiber and leafy vegetables are included. Avoid food with high glycemic index such as bakery and dairy products. Pulses plays an important role in weight control[12]

**Behavioural Management**

Motivation and cognitive behavioural therapy to avoid negative thoughts and to improve state of mind.
Statistical Analysis and Results

Statistical analysis of the recorded data was done by using the software SPSS version 2.0. Study design is cross sectional. Arithmetic mean and standard deviation was calculated for each outcome measure. Paired t test was done.

Discussion

Polycystic ovarian syndrome is associated so strongly with obesity therefore the women with normal weight often go undiagnosed. Even in lean women with polycystic ovarian syndrome, we can see the higher waist-hip ratio, greater intra peritoneal and visceral fat.

Exercises and accepting healthy lifestyle created a good body and mental image in the patient that drastically improved which directly showed impact on higher quality of life according to PCOSQ and also there is no marked significance in other outcome measures.

Visceral fat which is seen in normal BMI women’s, the visceral fat itself secretes adipokines which impair insulin sensitivity in tissue such as liver and skeletal muscle, insulin resistance is manifested as decrease in glucose transport and decline in muscle glycogen synthesis in response to circulating insulin. In normal BMI women the polycystic ovarian syndrome seen because the connection between the pituitary gland and the ovaries broken down.

Because of the lifestyle modification which include exercise, diet the connection between the pituitary gland and the ovaries reestablished which is helpful for to regulate the menstrual cycle.

In the previous study in polycystic ovary syndrome and weight management the conclusion was prevention from weight gain in normal BMI was crucial component.

And in benefits of short-term structured exercise in non-overweight women with polycystic ovary syndrome: a prospective randomized controlled study the result was after 8 weeks of exercise the gap between the menstrual cycle became shorter and the p value <0.05 which considered as significant.

The participant was given lifestyle modification which included exercise with diet and behavioral management which added plus point in keeping them motivated towards their body image and keep holding their diet by setting different goals and target.

The PCOSQ score is the important outcome measure the p value(<0.0001) which was extremely significant and the paired t test performed the t value was(35.24). BMI was slightly change in the some women’s.

Women felt challenging to continue diet and exercises in their routine, which is further challenge to keep going with gained weight. Hence, continuing with lifestyle modification is a challenge and should be kept as long term follow-up, to have good effect.

Conclusion

This study concluded that lifestyle modification for normal BMI PCOS women was effective in maintaining weight and quality of life. The quality of life was improved according to PCOSQ. There by we conclude that lifestyle modification should be the first line treatment for PCOS women.

Conflict of Interest: The authors declare that there is no conflict of interest.

Acknowledement: The authors would like to express their special gratitude towards all the women’s that participated in the study. We would also like to thank our families and institution for their everlasting support which enabled us to continue our research activities.

Ethical Clearance: This study has undergone ethical clearance through the university level ethical committee of Krishna Institute of Medical sciences, Deemed to be University, Karad.

Abstract

Sexual crimes against women are on the rise. It has been well documented that sexual assault cases are under reported. The study was conducted in the Department of Forensic Medicine, M.S. Ramaiah Medical College, Bangalore during the period from September 2008 to February 2010, a period of 18 months where in 52 cases were due to sexually related deaths.

Keywords: Unnatural Deaths, Sexual assault, Autopsy.

Introduction

Sex is a natural phenomenon and is necessary for the continuity of human race on this planet of earth and sexual exploitation is the worst form of degradation of those who indulge in it. The rising trend in the sexual offence cases is a reflection of the western influence in our society. Chastity is very important in the life of an Indian woman. Virginity is considered as an essential prerequisite for a girls to become a bride. The violation of virginity subjects a woman to considerable shame and humiliation. A study reveals, only about 10-50% of the female victims reported about their assaults. Incidence of sexual abuse and death particularly among young and adolescent girl is reported almost daily. It not only humiliates and makes a woman powerless, but for many, the effects are long lasting. The present study was conducted with the objectives to know the age, sex, marital status and socioeconomic status of the victim.

Materials and Method

The study was conducted in the Department of Forensic Medicine, M.S. Ramaiah Medical College, Bangalore during the period from September 2008 to February 2010, a period of 18 months. Out of 1062 unnatural deaths during the study period 52 cases were due to sexually related deaths. All the cases subjected for medico legal autopsy with alleged history of death being sexually related, when there is evidence or acknowledgments of sexual activity in the causation of death were studied. Detailed information regarding the circumstances of death was sought from the police, victim’s relatives, friends, and visit to the scene of occurrence or by the photographs of the scene of occurrence. Unnatural deaths due to sexual harassment, sexual offence, premarital affairs /sexual relationship based on circumstantial evidence and deaths due to sexual asphyxia are included in the study. Deaths due to sexually transmitted disease, natural disease and due to dowry related were excluded.

Results and Observation

In present study out of 1062 unnatural deaths, 52 cases were due to sexually related. Among them 43 cases were female (82.7%) and 09 cases were male (17.3%).

The most vulnerable age group is between 20-29 years (50%) of the total deaths followed by those in 10-19 years (21.17%). Least number of deaths in the age
group of ≥ 50 years (1.92%) followed by age group of 0-9 years (3.84%). The maximum number of victims (57.69%) were from the middle socioeconomic status followed by lower socioeconomic status (34.62%).

The maximum number of deaths were observed in married victims (50%), more so during the early period of their marriage and followed by unmarried victims (46.16%).

The maximum number of victims (57.69%) were from the middle socioeconomic status followed by lower socioeconomic status (34.62%).

Discussion

The present study was conducted with the objectives to know the age, sex, marital status and socioeconomic status of the victim. Out of 52 unnatural sexually related deaths, 43 cases were female (82.7%) and 09 cases were male (17.3%). Females outnumbered the males which is quite understandable as in most of the cases the females are vulnerable on account of their guilable age, physical built as against the strong physique and androgenic behaviour of the dominant male. Similar findings were observed by J Mc Namara\(^3\) where most of them are females and were aged between 11 to 45 years.

The most vulnerable age group is between 20-29 years (50%) of the total deaths followed by those in 10-19 years (21.17%). As these age groups are sexually more active and hence are vulnerable. Least number of deaths in the age group of ≥ 50 years (1.92%) followed by age group of 0-9 years (3.84%). Similar findings were observed by Mc Cook A\(^4\) on African-American women, most of them were in the age group between 15 to 34 years.

The maximum number of victims (57.69%) were from the middle socioeconomic status followed by lower socioeconomic status (34.62%), as India is a developing country and much of the people fall in this group, also the changing social trends of nuclear families, unemployment, illiteracy, financial problems etc. Similar findings were observed by AK Srivastava\(^5\), where the most of the victims were belonged to middle or lower socioeconomic status.

The maximum number of deaths were observed in married victims (50%), more so during the early period of their marriage – extramarital affair was the main reason and followed by unmarried victims (46.16%). Similar findings were observed by AK Srivastava\(^5\), where more deaths were seen in newly married victims (86%).

Conclusion

Sexually related deaths constituted 4.8% of autopsies conducted. Maximum number of sexually related deaths occurred in the age group 20-29 years (50%) followed by 10-19 years (21.17%). Females constituted 82.70% of the victims. Most of the victims were married and were from middle socio economic status. The findings of this study may only be the tip of the iceberg as many sexually related deaths might never be detected, due to various reasons like cover up by the victims own family, improper investigation or because of false history furnished. An awareness must be created in the community to motivate the victims to report and more reporting centers must be opened to overcome the fear of victims.

Knowledge and Awareness about Medical Ethics among Medical Practitioners in a Teaching Medical College and Hospital, Chennai

Subhashree Bangaru¹, Magendran. J²

¹II MBBS, ²Associate Professor, Department of Forensic Medicine, Saveetha Medical College, Thandalam, Chennai, India

Abstract

Objective: The purpose of this study is to assess the knowledge and awareness towards medical ethics among medical practitioners. The results of this study may be used to guide the tutors of medical students, curricula designers and to bring change in attitude among the doctors towards the patient.

Methods: This descriptive, cross-sectional analytic study was conducted to assess the knowledge and awareness towards medical ethics among medical practitioners. A pretested semi-structured questionnaire was given and collected from the participants. After obtaining the data, it was entered in excel spreadsheet and was analysed using SPSS software and frequencies and percentages were obtained.

Results: Most of the participants have gained their knowledge on medical ethics from seminar and workshops (40%) and clinical training (36%) followed by other sources such as journal, lectures, ethical books etc., 71% of the participated medical practitioners agreed that “During treatment, the patient’s wishes must always be adhered to”. 66% of the participants disagreed that “Privacy of one patient may be ignored for the benefit of the larger group”.

Conclusion: This study highlights the lack of improvement in ethics awareness corresponding to increasing exposure to medical education in the last few years. Thus, with the help of the results obtained from this study, it can be used to devise means to sensitize them to these issues and appropriately training them.

Keywords: Ethics, Medical practitioners, Knowledge and awareness, Medical ethics.

Introduction

The moral principles which should guide the members of the medical profession in their dealings with each other, their patients and towards the state are dealt in medical ethics. These moral principles include respect for autonomy, non-maleficence, beneficence, and justice. Ethics reflects the conduct, character, and attitude of a doctor. There are several codes of conduct. The basic principles for medical professionals are discussed in hippocratic oath. At the time of registration of a medical graduate, he/she has to sign a declaration which is the modern version of hippocratic oath and is called as the Declaration of Geneva (1948).

Challenges of an ethical nature are abound in modern-day medicine. Patients, their families, those who provide medical care and institutions, where this care is conducted face difficult choices almost as a routine¹². Ethics is always an integral part of healthcare. Nowadays, modern technologies have blurred the line between medical ethics and quality care.

Ethical dilemmas are usually seen in areas such as abortion, contraception, treatment of patient with a terminal illness, professional misconduct, maintaining a patient’s confidentiality, the doctor’s professional relationship with patient’s relatives, religion, traditional medicine, and conflict of interests. Ethical violation
is professional misconduct and state medical council takes action. A physician shall report to appropriate authorities those physicians who practice unethically or incompetently or who engage in fraud or deception. It is very important to train the students about medical ethics, so that they are capable of solving any kind of ethical issues and to prevent themselves from ethical dilemmas during their practice. Every hospital must have an ethics committee to ensure that appropriate ethical values are being applied within hospitals.

There are varied views on strategizing the teaching of bioethics. The teaching of bioethics should also be holistic. Students could be taught about the value of the “heart” over the “mind” of the system of values and beliefs in a community, and of the need to understand the lived experiences of patients; while also incorporating various ethical approaches\(^9\).

In recent days, medical profession has been commercialized. Ethics teaching has a significant influence on the professionalism and moral qualities of medical professionals. In India, due to the cultural mosaic\(^10\), the teaching of bioethics needs to encompass the various perceptions of morality and ethics unique to people from different cultural, socioeconomic and geographical backgrounds\(^11\). The training in this subject should be integrated with the local social and cultural values.

Training in medical ethics has been made mandatory in the undergraduate curriculum by the regulatory body of medical education, Medical Council of India\(^7\). There are medical colleges in India with a standardized ethics curriculum, and with provisions for evaluation\(^8\). The first step in formulating an ethics curriculum may be to determine the level of the basic knowledge and attitudes among the medical practitioners. Few standard yardsticks have been designed to measure what is known and practiced so as to ensure that educational efforts are better targeted\(^13\).

Various methodologies have been tried to stimulate better ethical conduct in health professionals such as lectures, seminars, workshops etc. Against this background, this study is aimed to assess the level of awareness and knowledge regarding medical ethics among the study participants. It is a questionnaire based retrospective study.

**Methods and Materials**

The present cross-sectional retrospective study was conducted in Saveetha Medical College and Hospital, Chennai. Medical Practitioners were included in the study. A total of 100 medical practitioners were studied. Both male and female took part in this study. Most of the approached doctors were from both clinical and non-clinical departments of Saveetha Medical College and Hospital, Chennai. Even the postgraduates were included in this study. In this study, 126 doctors were approached, out of which 110 of them were willing to take part in this study. They were given the liberty to pull out of the study whenever they wanted if they felt unsafe or uncomfortable with the study. Out of 110 questionnaires, the 10 questionnaires which were partially filled or incomplete were excluded from the study. Only the questionnaires in which the consent form was filled properly were included in the study. The study period was from 21st January 2019 to 30th March 2019. Institutional ethics committee\(^\text{IEC}\) clearance was applied for and obtained. All the medical practitioners who took part in the study were briefed on the study’s purpose, and requested to participate in it. The questionnaires were distributed after describing the purpose of the study. The participants were assured that participation was voluntary, and confidentiality would be maintained. A pretested semi-structured questionnaire was devised, based on the previous research studies and in consultation with faculty members of the department of forensic and state medicine. Some questions were also derived from the code of medical ethics as laid down by the Medical Council of India. The filled questionnaire were obtained from the participants. The first part of the questionnaire contained the information sheet for the participants regarding medical ethics and the present study and also how important it was to create an awareness among the medical practitioners. The second part of the questionnaire covered the demographic details and the consent form which was mandatory to be filled by the participants. The third part of the questionnaire contained questions about their awareness, their knowledge of the existence of the ethics committee and its role; their attitudes on various issues such as consent and confidentiality, privacy, euthanasia, intimate examination and their knowledge of the code of medical ethics of the Medical Council of India. After obtaining the data, it was entered in excel spreadsheet and was analysed using SPSS software and frequencies and percentages were obtained.
Result

Among 100 participants whose responses were analysed, 37% were male and 73% were female.

The graph (figure 1) given below describes the students’ attitude to medical ethics. 94% were positive about the importance of ethics. Out of them, 13% thought that ethics was “extremely important”. However, four medical practitioners, thought that such knowledge was “not important”.

![Graph: Student’s attitude towards medical ethics]

Figure 1 – Student’s attitude towards medical ethics

Seminar and workshop (40%) and clinical training (36%) were considered the predominant sources of knowledge on ethics. 30% from journals, 21% from ethical books, 15% from lectures, 15% from newspaper and 15% from television gained their knowledge about ethics.

The graph (figure 2) given below describes that only 28% agreed and 6% were uncertain as to whether “Ethical conduct is important only to avoid legal action”.

![Graph: Importance of ethical conduct]

FIGURE 2 – Importance of ethical conduct

The graph (figure 3) given below describes that 71% of the participated medical practitioners agreed that the patient’s wishes must always be adhered to during the course of treatment. On the other hand, 44% of the participants had a opinion that “The doctor should do what is best irrespective of the patient’s opinion”. 89% agreed that children should never be treated without the consent of their parents or guardian except in case of emergency. 90% of the participants agreed that the doctor should get an informed written consent from the patient, if he/she refuses to take the treatment offered by the doctor. 83% of the participated medical practitioners disagreed that a doctor should not attend seriously injured and accidental cases before the arrival of the police or registering the cases and completing other formalities.

![Graph: Importance of consent]

FIGURE 3 – Importance of consent

56% of the participants agreed that the patient has a right to refuse life saving medical treatment (passive voluntary euthanasia) while 37% disagreed with it. 55% agreed that they will refer the patient to another doctor for religious conflict situations. 30% agreed that for the benefit of the larger group, privacy of one patient can be ignored while 66% disagreed and 4% were uncertain.

The chart (figure 4) given below describes that 25% of the participants opined that the information about the patient can be revealed to more than one person”, while the other 65% of the participants disagreed and the other 10% were uncertain.

![Graph: Information about the patient]

FIGURE 4 – Information about the patient
The table 1 given below describes the medical practitioner’s knowledge of the code of conduct of the Medical Council of India, to be followed once they graduate. The chart shows that 58% disagreed that it was appropriate for doctors to print their photograph on their signboard, while 32% agreed and 10% were uncertain about it. 72% disagreed that doctors can run an open shop for dispensing drugs and appliances prescribed by other doctors. 84% of the participants thought that it was necessary for a doctor to maintain medical records of his/her patients for 3 years from the date of commencement of treatment.

### Discussion

Ethical conflicts are common during the initial years of a medical professional’s career. Thus, teaching and training about medical ethics is very important among the medical professionals. The findings of the present study shows the knowledge and awareness about medical ethics among the medical practitioners in Saveetha Medical College, Chennai. The participants of this study included both doctors working in clinical and non-clinical departments of the college.

Most of the participants had knowledge and awareness about medical ethics. The responses are reflective of categories such as different subspecialties, i.e. medical, surgical, postgraduates and gender. The respondents had obtained their knowledge of ethics from various sources. It appeared that their clinical training and seminars & workshops was the key source of knowledge.
The questionnaire contained questions about their awareness of ethics and its importance, and the source of this awareness; their attitudes on various issues such as consent and confidentiality, privacy, euthanasia, intimate examination and their knowledge of the code of medical ethics of the Medical Council of India.

The knowledge of ethics and law was obtained from same source by most of the respondents. It is also interesting to note that the source of knowledge of medical ethics amongst the physicians during training and seminars & workshops appeared to be important than the experience at work and one’s own reading. While in the previous study, the source of knowledge from clinical training was less important than the experience at work, lectures and seminars and one’s own reading. Around 70% of the respondents knew about the code of conduct of the Medical Council of India.

The fact that many physicians did not feel that the patient’s wishes should be adhered to at all times, shows the lack of knowledge of the basic principles of medical ethics. On the other hand, many of the participants felt that “A doctor should do what is best irrespective of the patient’s opinion”. The lack of knowledge of basic principles of medical ethics in the present study is similar to another study regarding the healthcare ethics and law among doctors and nurses in Barbados. Around 1/3rd of the participants felt that the patient does not have a right to refuse life-saving medical treatment (Passive voluntary euthanasia) in India, which is contraindicated with the law.

Most of the physicians who took part in the present study, took informed consent and maintained confidentiality during clinical teaching. In another study, a lack of taking informed consent from the patient was seen. On the other hand, several reports suggest that surgical residents often do not proceed with an optimal consent process because of time constraints. These studies highlight the need to better educate surgical residents in the operative procedures in a way that enables them to obtain meaningful consent. Breach of confidence by a doctor is a highly unethical practice, especially on issues of confidentiality vs. law, communicable disease confidentiality vs. spouse knowledge of the disease. The majority of the ethics committees focus on the ethical protection of human beings in research settings. The existence of clinical ethics committees in hospitals is very important for moral deliberation on clinical cases. 

We could assess the basic knowledge and attitudes of medical practitioners regarding medical ethics in order to obtain basic information for better training and improvising the knowledge about ethics in the medical curriculum. This study has the limitation that it does not cover a wider range of medical practitioners.

**Conclusion**

Overall, this study reflects the current situation of knowledge, attitudes and practice of ethics by clinicians in Saveetha Medical College, Chennai, where ethics is taught as a part of a subject at the undergraduate level. Many steps have been taken to bring more awareness among the physicians by introducing Hospital Ethics Committees in many institutes, ethics awareness programmes etc., This study highlights the lack of improvement in ethics awareness corresponding to increasing exposure to medical education in the last few years. It is important to gather basic information on ethics awareness to know if the medical practitioners have better knowledge. To strengthen ethical reasoning and judgment in decision making, clinically oriented measures like case studies, seminars, interactive workshops, is needed. Thus, these can help us to bring more awareness about medical ethics among the physicians.

Effectiveness of Bosu Ball Exercises Versus Thera Band Exercises on Core Stabilization and Balance Performance

Rasika A. Sawant1, Khushboo Chotai2, Smita Patil3, Amrutkuvar Rayjade4

1Internee, Krishna College of Physiotherapy, Krishna institute of medical sciences deemed to be university, Karad, Maharashtra, 2Assistant professor, Department of Sports Physiotherapy, Krishna college of Physiotherapy, KIMSDU, Karad, 3Assistant professor, Department of Musculoskeletal Sciences, Krishna college of Physiotherapy, KIMSDU, Karad, 4Assistant professor, Department of Orthopaedic and Manual Therapy, Krishna college of Physiotherapy, KIMSDU, Karad

Abstract

Background: Greater core stability provides a foundation for greater force production in the upper and lower extremities. When the core muscles are functioning optimally, the person will be able to safely perform specific athletic or other functional activities. Core muscle imbalances are the cause of core instability and reduced balance performance. Few studies have shown the effect of swiss ball exercises on core stabilization and balance performance as well as few studies also shown the comparison between core exercise on stable and unstable surfaces for core stabilization and balance performance. The core stability and balance performance needs to be treated by strengthening core muscles.

Objectives: To find the effect of 2 different types of strengthening exercises on core stability and dynamic balance in collegiate athletes.

Material and Method: In this pre-post intervention study 26 athletes were included. They were randomly divided into 2 groups with 13 individuals in each group. Group A was instructed to perform BOSU ball exercises and group B was instructed to perform thera band exercises for 6 weeks. After pre-post assessment, data was analysed with the help of appropriate statistical methods.

Results: According to the results there is significant increase in both right and left anterior, posteromedial and posterolateral directions with p value <0.0001 as well as in core stability with p value <0.0001

Conclusion: Both BOSU Ball exercises and thera band exercises are found to be equally effective in improving core stability and balance performance in collegiate athletes.

Keywords: BOSU ball exercises, thera band exercises, Y balance test, flexor and extensor endurance test, side bridge test, single leg stance test.

Abbreviations: BOSU ball: Both Sides Up ball

Introduction

The core is a muscular corset, which includes deep and muscles of the trunk1,2. It consists of abdominal muscles in the front, gluteals and paraspinal muscles in the back, the diaphragm at the top, and the pelvic floor and hip muscles at the base3. The core is also referred as the lumbo-pelvic region4. They used to stabilize the spinal column, enhance performance when the extremities move and for align the body1. Core stability is defined as the level of strength or endurance in particular muscle groups of lumbo-pelvic complex5. Increased stability in core is produced by contraction of superficial and deep muscles, made up of both slow and fast twitch muscles. The local (deeper) muscle group are

E-mail id: bathiakhushboo@gmail.com
transverse abdominis, multifidus, and pelvic floor. They composed of type 1 (slow twitch) muscle fibers. They help to improve trunk endurance. The global (superficial) muscle group are rectus abdominis, obliques, latissimus dorsi, and erector spine. They composed of type 2 (fast twitch) muscle fibers. They control flexion and extension of trunk. The core muscle weakness causes reduced proprioception, reduced balance, reduced strength, muscle imbalance, reduced endurance, reduced flexibility, etc.

Core strengthening is the provision of muscular control around the lumbar spine to maintain functional stability. Strengthening of core muscles has strong central effect in the body, as well as in increasing stability of the trunk to extend during reach and functional activities. Core exercises are the exercises to train the muscles that stabilize and control the movements of abdomen, waist, and hip. There are different exercises to strengthen core muscles includes the crunch exercise, the bridge exercise, and the plank exercise. There are many treatment options for core strengthening such as pilates, tai chi, yoga, graded abdominal exercises, and resistance training. Use of thera band improves flexibility, mobility, daily activities, metabolic rate, and for improving athletic performance. Elastic resistance band is a unique type of resistance training. It is used in sports and rehabilitation medicine for improving muscular strength and endurance. The resistance of elastic band depends upon the amount of band is stretched. Elastic bands are available in different colours according to assortment of grades. This colour coding denotes the thickness of product and grade of resistance. These colour coding denotes the resistance levels. It includes following colours: yellow (thin), red (medium), green (heavy), blue (extra heavy), silver (super heavy), golden (max). Use of thera band improves flexibility, mobility, daily activities, metabolic parameters, etc. The exercises performed with thera band are curl up, bridging, side bridging, quadruped stabilization, push ups, etc.

Core stability is important for injury prevention and for improving athletic performance. There are
different tests to check core stability. It includes trunk stability test, plank test, sahrmann core stability test, unilateral hip bridge endurance test, flexor endurance test, extensor endurance test, side bridge test, etc\textsuperscript{14}. The reliability of flexor endurance test (0.93), extensor endurance test (0.97), side bridge test (0.91) is more as compared to others\textsuperscript{17,19,20}.

Balance ability has correlation with athletic performance and sports injury risk\textsuperscript{16}. Static balance can be assessed by single leg stance test, tandem stance test, functional reach test, flamingo test, but the reliability of single leg stance test (0.61-0.81) is more as compared to other tests\textsuperscript{15}. Dynamic balance can be assessed by timed up and go test, star excursion balance test, y balance test, dynamic leap and balance test, modified bass test, single leg squat test, single leg hop test, but the reliability of Y balance test (0.80-0.85) is more as compared to others\textsuperscript{15,20}.

**Methodology**

The ethical clearance was taken from ethical committee of Krishna institute of medical sciences, Karad. There were 26 participants in the study. The study was taken place in the Physiotherapy department, Krishna institute of medical sciences. The study was effectiveness of BOSU ball exercises versus thera band exercises on core stability and balance performance. The treatment protocol was of 6 weeks. The subjects were assessed for core stability and balance at first. The type of study was experimental study. The study design was pre and post. The samples were chosen using the simple random sampling method. Participants were included as per inclusion criteria.

**Procedure**

All the subjects were selected for the study according to the selection criteria. Demographic data and consent from was taken from them. Included participants divided in 2 groups by simple random sampling method. Pre and post assessment were taken after 6 weeks of the treatment respectively with the help of outcome measures.

Group A received BOSU ball exercises. Participants were instructed to perform Seated crunches, Plank, Bridging, Hip extension and knee flexion prone ball hold with knee drive. This exercises were performed for 6 weeks, 3 sets of 15 repetitions in the 1\textsuperscript{st} week; 4 sets of 15 repetitions in the 2\textsuperscript{nd} week; 4 sets of 20 repetitions in the 3\textsuperscript{rd} and 4\textsuperscript{th} weeks; and 4 sets of 25 repetitions in the 5\textsuperscript{th} and 6\textsuperscript{th} weeks.

Group B received thera band exercises. Participants were instructed to perform Curl up, Bridging, Side bridging, Push ups, Lower abdominal crunches.

Session will consist of: 3 sets of 15 repetitions in the 1\textsuperscript{st} week; 4 sets of 15 repetitions in the 2\textsuperscript{nd} week; 4 sets of 20 repetitions in the 3\textsuperscript{rd} and 4\textsuperscript{th} weeks; and 4 sets of 25 repetitions in the 5\textsuperscript{th} and 6\textsuperscript{th} weeks

The effect of the treatment given to each group was noted immediately using the outcome measures. The experimental results were statistically analysed. The significant difference between the two groups was investigated with the un-paired t test and within the group with paired t test.

**Results**

Pre and post data was analysed, according to the result the within the Group A the flexor endurance test, extensor endurance test, side bridge test, single leg stance test, and Y balance test are considered extremely significant with p value <0.0001.

**Discussion**

The aim of this study was to study the effect of BOSU ball exercises versus theraband exercises on core stabilization and balance performance in athletes with an objective of finding the benefits of each exercise and comparing its effects to fulfil the aim of the study.

The individuals included in this study were collegiate athletes which were assessed and scored according to the outcome measure were included in the study.
The study was taken place in Physiotherapy department, Krishna institute of medical sciences. There were 26 participants selected according to the criteria and they were randomly divided into 2 groups (group A and group B) with each containing 13 participants. Group A was asked to perform BOSU ball exercises according to given procedure and group B was asked to perform thera band exercises. This study was carried out for 6 weeks and 3 times per week and pre and post assessment was taken using outcome measures after 6 weeks. After the pre and post assessment the data was statistically analysed.

According to this both the exercise groups appeared to be equally effective in improving the core stabilization and balance performance in the participants and were considered extremely significant with p value <0.0001.

According to a literature variety of exercises must have been used in improving balance and core stability. Some literature suggests that the swiss ball exercises were helpful in improving the core stability and balance performance\(^3,4\). Some studies also proved that BOSU ball trainer is useful for ankle muscle activation and for improving balance\(^10\).

**Acknowledgement:** I sincerely thank the management of KIMSDU for allowing me to conduct this study by providing me the necessary requirements. I thank dean Dr Varadharajulu sir for his support and guidance. I convey sincere thanks to my guides Dr Khushboo Chotai ,Dr Smita Patil and Dr Amrutkuvar Rayjade for helping me in my research. I take this opportunity to thank all those who have been directly or indirectly involved for smooth conduction of my study.

**Conclusion**

On the basis of the result of the study it is concluded that the BOSU ball exercises and thera band exercises appears to be equally effective for core stabilization and balance performance in athletes.

**Source of Funding**

Source Of Funding: Krishna Institute Of Medical Sciences Deemed to be University, Karad.

**Conflict of Interest:** There were no conflicts of interest in my study.

**Ethical Clearance:** The Institutional Ethics committee has hereby given permission to initiate the research project titled, “Effect of BOSU ball exercises versus thera band exercises on core stabilization and balance performance”

A Novel Method of Establishing the Identity of an Individual by Analyzing the Pattern & Volume of the Frontal Sinus Using Computerized Tomogram – A Retrospective Cross Sectional Study

R. Harshada¹, Nalini Aswath²

¹PG Student, ²Prof & Head, Department of Oral Medicine & Radiology, Sree Balaji Dental College & Hospital, Chennai

Abstract

Background: The paranasal sinuses develop early in fetal life. Among the 4 major sinuses present in human skull, Frontal sinus helps in identification of an individual because of its uniqueness and so has the potential to be used as an aid for personal identification in disasters, accidents and natural calamities.

Aim and Objective: To determine the volume & shape of frontal sinus in individuals using CT scan and to establish the uniqueness of frontal sinus in the identification of individuals in forensic science.

Methodology: CT images showing the axial and coronal sections of frontal sinus of patients above the age of 20 years were considered as inclusion criteria and patients below the age of 20 years, previous injury, surgery or pathology in the frontal bone and frontal sinus were excluded. The length, breadth and height of right & left frontal sinus were measured and volume of the frontal sinus was calculated. The pattern of the frontal sinus was analysed in the axial & coronal sections of CT scan by taking screen shots of the slice. The pattern of the frontal sinus was drawn and copied to Microsoft Power Point Software for superimposing over other patterns.

Results: Among the 270 scans collected, the total length, breadth, height and volume of left and right side of male and females were compared by using Independent samples t-test and it showed that the frontal sinus was unique in nature.

Conclusion: The observations showed that no two individuals had the same sinus morphology based on division, volume, position and symmetry of frontal sinus.

Key words: CT scan, Frontal sinus, Volume, Pattern, Unique.

Introduction

The term “Forensic” is derived from Latin word ‘forum’ where legal matters are discussed. Odontology refers to the study of teeth or dentistry¹. Federation Dentaire Internationale[ FDI] defined forensic dentistry as ‘The branch of dentistry in the interest of justice that deals with proper handling and examination of dental evidence with the proper evaluation and presentation of dental findings’ ².

Forensic odontology plays a major role in the identification of an individual by using traditional methods such as bite marks, rugae pattern, dental profiling, assessment of DNA. When these traditional methods are unfeasible, the para nasal sinuses that develop early in fetal life might serve as a reliable guide for identification.
Among the four major sinuses, frontal sinus plays a greater role in the identification of an individual. These sinuses are pneumatic cavities that become radiologically evident at the age of five or six years and develop fully by the age of 20 years. Like fingerprints, frontal sinus patterns are unique for a person. Several authors have reported the uniqueness and its importance in human identification.

Though there are many ways in visualizing the frontal sinus, a single CT image gives a three-dimensional view of the sinus. The aim of the present study is to determine the volume & shape of frontal sinus in individuals using CT scan and to establish the uniqueness of frontal sinus in the identification of individuals in forensic science.

**Material and Method**

After obtaining the ethical clearance from the Institutional Ethical Committee, a retrospective study was performed using 270 Head and Neck CT images of patients that were previously taken for some therapeutic purpose. CT images of patients of age above 20 years were used and CT images of patients below the age of 20 years and the images with evidence of previous injury, surgery or pathology in the frontal bone and frontal sinus were excluded. Informed consent was also obtained.

The slice containing the axial and coronal sections of CT’s of individuals were selected in such a way that complete radiolucency is seen in the region of frontal sinus and the pattern and volume were analysed.

The following measurements were taken in the axial & coronal sections for measuring the volume of frontal sinus:

- Height of right & left frontal sinus
- Length & breadth of right & left frontal sinus
- Volume of the frontal sinus

For analysing the pattern of frontal sinus the outline of the pattern was drawn by taking screen shots (Fig 1, 2). The pattern of sinus was compared to one another by using Microsoft PowerPoint software by:

1. Copping, pasting the cropped image on a PowerPoint presentation slide.
2. The background of the image removed by formatting the image. (This will make the image radiopaque in the sinus region.)

The pattern was compared by superimposing each image.

**Results**

A total of two hundred and seventy PNS Head and Neck CT images (axial and coronal slices) were selected following the selection criteria out of which 155 (57.41%) were males and 115 (45.59%) were females. Out of the 270 images examined the frontal sinuses were present in 266 (98.52%) people and absent bilaterally among 4 (1.48%). Among the 266 subjects, the frontal sinus was unilateral in 14 (5.27%) and bilateral in 252 (94.7%) (Tab 1). The unilateral frontal sinus was more common on the right side (4.81%) than the left side (0.37%). (Tab 1). Division of the sinus was seen in 246 (92.48%) and absence of division was observed in 20 (7.52%) (Tab 1). The symmetry of the sinuses were compared in 232 subjects who had bilateral presence of frontal sinus, by analysing the pattern and simultaneously the volume and was found to be symmetrical in 18 and asymmetrical in 214. While comparing the pattern of the sinuses it was found to be unique in 98.89% (i.e. among all the subjects with presence of sinus). The commonest shape of the front sinus seen in the coronal section was club shaped.

The total length, breadth, height and volume of left and right side of male and females were compared. Independent samples t-test was performed by calculating the mean, SD and SEM. While comparing the volume of right and left side of sinus, volume of the right frontal sinus was more in males whereas it was vice versa in females. The mean total volume of males was greater than that of females, which implies that the sinuses are larger in size in males (Tab 2).

The uniqueness of frontal sinus was analysed by comparing the pattern of the sinus among 266 subjects by superimposing the images in Microsoft paint software.

The following observations showed that no two individuals had the same sinus morphology.

1. The patterns were unique between each individual.
2. Divisions within the sinus varied.
3. Measurements such as length, breadth, height or volume were different between each individual.
4. Positions of the sinus (unilateral/ bilateral) varied.
5. Symmetry of the sinus varied.

Discussion

Every individual is unique. The main aim of forensic science is identification of unknown human being in crime and disasters by using numerous technologies. Forensic odontology is a branch of forensic science which has established itself as an important and often indispensable science in medicolegal matters and identification of the dead. Methods like rugoscopy, bite marks, palatal rugae, photographs, lip prints, etc. are used for identifying the individuals.

Finger prints are more useful in identifying a person as they are unique. But there are situations where the other unique features of an individual must be used in identification. The one among the most interesting part
in the head and neck region of a human is Paranasal sinuses. The frontal sinus does not change in its shape after the age of 20 years\(^6\) except during trauma or due to pathology.

The aim of the present study was to prove that frontal sinus is unique to each individual based on their pattern and volume, three dimensionally. Similar studies have been done previously using two dimensional radiographs where the length and breadth of the frontal sinus were measured. Schuller\(^7\), Culbert and Law\(^8\) were the first to propose the possibility of utilizing radiological images of frontal sinus in identification of an individual by studying its morphology, followed by Asherson\(^9\) and Gerald Quatrehomme\(^10\) who examined monozygotic and dizygotic twins and found that the pattern of frontal sinus was different in each of them.

In this study a total of 270 CT scans were analysed and it showed that 98.5\% participants had frontal sinus which was in accordance with Ertugrul Tatlisumak\(^11\) and the bilateral absence of sinus was seen in 1.4\% i.e. bilateral absence of frontal sinus.

The pattern of the sinus was compared with one another by superimposing the outline of the sinus, on Microsoft paint software. None of them matched each other which showed that the pattern of frontal sinus was unique. This was in accordance to other studies done by Schller\(^7\), Culbert\(^8\), Asherson\(^9\), Gerald Quatrehomme\(^10\), Neha Patil\(^12\) where they have compared the shape of frontal sinus and proved that frontal sinus is unique for each individual in a two dimensional radiographic view. Chetan Belaldavar\(^13\) studied the frontal sinus in a three dimensional way and concluded saying that it has a unique pattern for each individual.

In this study bilateral presence of sinus was seen in 94.74\%, unilateral presence on right side was seen in 4.89\%, unilateral presence on left side in 0.38\%, division of sinus was seen in 92.48\% and no division in 7.52\% which was in accordance to the study by Neha Patil\(^12\) who showed 1\% bilateral aplasia and 3\% unilateral aplasia of frontal sinus. A study by Nateghian Z\(^14\) showed that right and left frontal sinus was found in 67.7\% of the individuals. Right frontal sinus was observed in 4.6\% and left frontal sinus was seen in 9.2\% of the individuals. Studies by Saraswathi Gopal\(^15\), Vidya CS\(^16\) showed bilateral absence of frontal sinus is 5\%, unilateral aplasia in 2.5\%. In Roberto Camerier\(^1\) study out of 99 individuals he found that, there was bilateral aplasia in 10\%, unilateral aplasia in 2\%. A study by MP David\(^18\) showed that there was 6\% unilateral and 4\% bilateral aplasia. The division of the sinus was not compared in other studies.

On comparing the bilateral symmetry of frontal sinus in our study, symmetry was seen in 7.76\% and asymmetry in 92.2\% which was in dispute to Vidya CS\(^16\) who observed that 68\% had symmetry and asymmetry was seen in 30\% in her study.

This study showed that sinus was larger in males than females which were in accordance with Chetan Belaldavar\(^13\) and Hemant Mathur\(^19\). In our study the volume of left and right sinus was compared and it was found that volume of the right sinus was greater in males and vice versa in females.

In the present study out of 270 scans viewed, only 4 showed bilateral aplasia which was present in males. The unilateral presence of frontal sinus was present in 5.18\%, out of which it was more common in right side for males like in other studies. The symmetry of sinus in each individual was compared, where 232 frontal sinuses out of 270 sinuses were compared because bilateral aplasia of sinus was seen in 4 subjects and 14 subjects had unilateral sinus (where the symmetry cannot be assessed). In the present study it is shown that only 7.76\% of subjects had symmetrical sinus. But a study done by MP David\(^18\) and Saxen\(^20\) showed symmetry in 58\% of frontal sinus.

From the present study it is clear that frontal sinus is unique for each individual (Fig 3) and using the antimortem and post-mortem records of frontal sinus, individuals can be identified. Further gender can also be determined, as the frontal sinuses are larger in males.

Limitations of this study : The frontal sinus cannot be used in identification of an individual when they are completely absent or due to any pathologies affecting the sinus. The frontal sinuses are not present during the early stages of life and cannot be seen radiographically till the age of seven years.

**Conclusion**

To identify is to determine the individuality, or it is to prove by means of technical or scientific means that a person is that one & not the another. Human identification is not a difficult task, when it is about a live individual or a cadaver chronologically recent and
After the advent of Computerized Tomographic scan, it is possible to measure the linear and volumetric measurements accurately. In this study an attempt was made to establish the uniqueness of frontal sinus in the identification of an individual using CT scan and it was found that frontal sinus was unique in each individual and it can be used as fingerprint when they are not altered.

Study of Adverse Drug Reactions (ADRs) Occurring with the Drug Use in a Tertiary Hospital

R. Selvaraj1, Abhay P.Betala2

1Associate Professor, Department of Pharmacology, Kerala Medical College Hospital, Mangode, Cherpullassery, PalaKKad Dt, Kerala, 2Assistant Professor, Department of Forensic Medicine, Vinayaka Mission Medical College, Karaikal

Abstract

Aim: To study the adverse drug reactions (ADRs) occurring with the drug use in a tertiary care hospital.

Materials and Method: This observational study conducted over a period of four months (01-Nov-2015 to 29—Feb-2016). The Central Drug Standard Control Organization (CDSCO) suspect ADR forms (15) were distributed to all clinical departments personally in Kerala medical college hospital and research center, Mangode, Cherpullaserry. Regular visits were carried out twice a week for collecting data reports. They were then analyzed, compared with state data, national data, and international data. Results A total of 25 suspected Adverse Drug Reactions forms were reported during the period of four months of the study of the out patients and in patients departments of the hospital. Among all drugs NSAIDS, followed by Antimicrobials, Antipsychotics, Bronchodilators, Antihypertensive and oral hypoglycemic agent etc. were reported to have adverse drug reactions. Most common route of adverse drug reactions was oral, followed by IV, IM, S/C, Topical and Inhalational routes. Reactions mostly seen affecting Skin, Gastrointestinal systems, Central nervous system, and Hematological system Most patients recovered from adverse events taking suitable measures like complete stopping the offending agent, or were prescribed antihistamines, steroids in addition Conclusion: Awareness about ADR reporting is still poor amongst healthcare professionals in India. The incidence and severity of Adverse Drug Reactions documented in our study are lower than those reported in other studies. NSAIDS comprise the major drug family associated with adverse drug reactions so should be rationally prescribed. Improved communication between the physicians and nurses with the pharmacovigilance centre in the hospital is suggested.

Key words: Adverse drug reactions, CDSCO, Pharmacovigillance

Introduction

According to WHO definition an Adverse Drug Reaction (ADR) is a response to a drug that is noxious and unintended, and occurs at doses normally used in human for the prophylaxis, diagnosis, and treatment of disease or modification of physiological function.1

Ultimately pharmacovigilance is concerned with identifying the hazards associated with pharmaceutical products and with minimizing the risk of any harm that may come to the patient.

The safety of prescription drugs represents a major public health concern. Adverse drug reactions are considered to be one of the leading causes of death among hospitalized patients.2 Previous studies suggest that approximately 0.5% of all emergency department visits and tertiary care visits result from adverse drug reactions.

However, low- to middle income countries, which represents more than two thirds of the world population account for a tiny fraction of all the adverse drug reaction data. Among the reasons for this under-reporting are the difficulty that the patients and the providers may have...
liking a particular symptom or condition to a specific drug particularly for individuals who have chronic illness and are taking several medications, a common clinical scenario in tertiary care. Thus, there is a need to capture safety data for drugs in a country like India.

**Documentation of Adverse Drug Reactions:**

The significant adverse reaction of any drug should be notified within seven days. The other facts related to adverse events should be informed within eight days. The drug reaction form can be collected at pharmacovigilance center.

The filled adverse drug reaction form can be submitted to the peripheral pharmacovigilance center. After reviewing the form, the center forwards it to the regional center and after that it is propelled to zonal center.5,6,7

This program is overseen by the central drugs standard control organization. (CDSCO).8,9

Patient reporting has been incorporated into pharmacovigilance systems in several countries including U.S.A, Canada, Australia, Newzeland Denmark, Sweden, and the Netherlands. Until very recently, however, patients in the U.K. were not able to report directly suspected Adverse Drug Reactions to Medicine and Health Care Regulatory Agency (MHRA), although some organizations has been proposing this for several years. In 2001, the UK Consumer Association called for patient reporting to be introduced after highlighting the fact that doctors were often failing to pass on information about suspected adverse reactions to drugs to MHRA. 10

**Aim of the study**

To study the Adverse Drug Reactions occurring with the drug use in tertiary care hospital

**Objective of the study**

1. Critically evaluate the Adverse Drug Reactions occurring with the use of drugs in a tertiary care hospital over a period of 4 months (2015-16)

2. To establish the causality of Adverse Drug Reactions occurring with the use of drugs in the tertiary care hospital using the WHO causality assessment scale and the Naranjo causality assessment scale.

3. To compare the incidences of Adverse Drug Reactions occurring in tertiary hospital, with state data, and international (global) data.

**Methodology**

This observational study is to be conducted over a period of 4 months (01-Nov-2015 to 29—Feb-2016). Permission obtained from the Review and approval by the Institutional Ethics Committee, to conduct the study. An introductory lecture is organized in the academic society of the institute to orient the clinicians towards pharmacovigilance and spontaneous reporting system. The Central Drug Standard Control Organization (CDSCO) suspect Adverse Drug Reactions forms (downloaded from CDSCO website) was distributed to all the clinical departments personally in Kerala medical college hospital and research center, Mangode, Cherpullassery. The forms contains the patient details, The description of the reactions, concomitant medication, coexisting illness, any rechallenge, dechallange etc.

On receiving information from the clinical departments, visit to the hospital and interact with the doctors to gather complete information on the Adverse Drug Reactions. The suspected Adverse Drug Reactions will be carefully analyzed and documented. Apart from this, regular visits will be carried out in respective departments and forms were collected twice in a week for analyzing the data and comparing the incidences of Adverse Drug Reactions occurring in a tertiary care hospital, with State data, national data and international (global) data

**Results**

Out of 25 cases reported with Adverse Drug Reactions in 4 months period, NSAIDS was found to be the most common implicating agent followed by Antimicrobials, Antipsychotics, Antacids, Vitamins and Minerals, Bronchodilators, Antihypertensive and oral hypoglycemic agent etc. were reported to have adverse drug reactions.

Most Affected organ system was Skin, followed by Gastrointestinal systems, Central nervous system, and Hematological system.

According to Naranjo’s Causality assessment scale(16) , 18 (72%) cases were Definite, 4 (16%) Probable and Possibly (Unrelated) 2 (4%) cases were reported as causing Adverse Drug Reactions.
As per the Hartwigs level of severity scale(13) 15 (60%) cases were found to have mild reaction and 5 (20%) cases each with moderate and severe reactions

According to Rawlins and Thomson(12) the type of reaction was classified as Type A (Predictable) with 21 (84%) cases and 4 (16%) cases with type B (Bizarre) reactions.

Looking for the Outcome of the patients, 15 (60%) cases were treated on OPD basis, and 10 (40%) cases required Hospitalization. Among them, 14 (56%) cases were recovered completely, 8 (32%) cases were in a state of recovering and 3 (12%) cases were continuing the treatment.

Most common route of adverse drug reactions was oral, followed by IV, IM, S/C, Topical and Inhalational routes.

Most patients recovered from adverse events taking suitable measures like complete stopping the offending agent, or were prescribed antihistamines and steroids.

**Discussion**

This study tried to find out the pattern of adverse drug reactions of drugs used in tertiary care hospital. The number of reports we received were 25 out of 30747 cases treated, which amounted to an incidence of 0.081% in our set up. In comparison with the study for search of adverse drug reactions in hospital patients in Embase and Medline found the occurrence of 2 – 27.7%, this can be considered as under reporting. It is a universal problem and many reasons are identified such as busy schedule of clinicians, lack of knowledge about the exact authority to report adverse drug reactions to, lack of incentives, reporting process being tedious and inadequate expertise. Our verbal discussions with clinicians revealed similar reasons for underreporting in our institution.

The demographic details of our study showed female gender predominance over males, which was similar to that reported in other studies found in the literature. This might be due to higher emotion quotient in females which makes them more sensitive to the pharmacological actions of medicines.

The most common category associated with adverse drug reactions was dermatology (44%). This finding is concurrent with the study carried out by Coelho et al. (2002) and Rajesh et al. (2008), but it differs from reports of Suh et al. (2000), where gastrointestinal manifestations had the highest rate. Of the dermatological reactions observed in the hospital, itching were seen in 45.45% and rashes in 36.36%.

The incidence rate of NSAIDS adverse drug reactions in this study was found to be comparatively high when compared to other drugs.

**Conclusion**

The reporting rate appeared to be low so there is need for increasing knowledge and awareness. Educational interventions like conducting CME and training programmes can improve the knowledge towards pharmacovigilance. However monitoring adverse drug reactions is an ongoing and continuing process. Since newer and newer drugs hit the market the need for pharmacovigillance grows more than ever before. Imparting knowledge and awareness of adverse drug reactions reporting of health care professionals would introduce the reporting culture among medical practitioners and increase the reporting rates of adverse drug reactions. Careful considerations involved in planning and monitoring of drug therapy will lead to preventions of adverse drug reactions.

**Acknowledgement:** We wish to thank all our clinicians, nursing staff, emergency staff of K M C H for kind support in carrying out this study. Also, we extend our thanks to Chairman, K M C H, and Principal for their constant and valid guidance, support, and encouragement.

Pattern of Homicidal Deaths at Raichur District Region – A Retrospective Study

Ravishankar M G¹, Sunil Kumar Kainoor², Suraj¹, S Sharmila³,
¹Final year Postgraduate Student, ²Assistant Professor, Department of Forensic Medicine and Toxicology, Raichur Institute of Medical Sciences, Raichur; Karnataka

Abstract

Background: It is a retrospective study carried out to find out the pattern of homicidal deaths in around the Raichur district region, among autopsies conducted at mortuary, RIMS, Raichur.

Materials and Methods: This is a two year retrospective study of autopsies conducted from January 2016 to December 2017 at Raichur Institute of Medical Sciences, Raichur. The objectives of the study were to know the pattern of homicidal deaths in and around Raichur district and to study the various socio-demographic factors influencing the homicidal deaths. Using a predefined and structured Performa, all the necessary details pertaining to the cases were collected from the inquest report and were analyzed.

Results: There were 757 total cases of autopsies conducted during the study period, of which there were 51 (6.73%) homicidal deaths. Male preponderance, 20-29 age group, blunt weapons - most commonly used, neck - commonest region of body involved constitutes 29.52%, most common cause of death - hemorrhage and shock 25.49%( 13) equally followed by Head injury, maximum homicide took place at the victim’s residence (58.82%), the most common motive behind the homicide was Infidelity (21.56%), maximum numbers of homicides were committed by Spouse (27.45%).

Conclusion: An attempt is made to know the socio demographic profile of the deceased so as to understand the sociological, economical, demographic and psychological aspects influencing homicidal deaths. The spurt in the homicidal deaths in our region may be attributed to the poor socio – economic condition, unemployment among young people, marital and family disputes, decreasing value based morality in the society, soft and sometimes toothless law enforcement agencies.

Key Words: Retrospective study, Homicidal deaths, Socio demographic analysis.

Introduction

Homicide means one human being causes death of another. Not all homicide is murder, as some killings are manslaughter, and some are lawful, such as when justified by an affirmative defense,

Like insanity or self defence.¹ A homicide is usually well-planned, therefore not normally witnessed.

Corresponding Author:
Sunil Kumar Kainoor
Assistant Professor, Department of Forensic Medicine and Toxicology, Raichur Institute of Medical Sciences, Raichur, Karnataka-584102

Killings remained the same v.i.z. lust for money, women and land. To commit murder, two elements (Mens–rea which means preplanning or afore thought and Actus Reus which means the actual execution).²

Homicide is defined as killing of one human being by another human being and is one of the leading causes of unnatural deaths.³ Unlawful killing of human being is murder (S.300 IPC). Culpable homicide cases may be amounting to murder (S.299 IPC) or not amounting to murder (S.304 IPC). Punishment of murder (S.302IPC) is death or imprisonment for life and also fine. The various patterns of homicidal deaths include assault by sharp weapon, blunt weapon, firearm, strangulation, homicidal hanging, smothering, drowning, burns, poisoning etc.⁴

DOI Number: 10.37506/ijfmt.v14i2.2791
Material and Method

This 2 year retrospective study was analyzed among autopsies conducted from January 2016 to December 2017 at Raichur Institute of Medical Sciences, Raichur. The objectives of the study were to know the pattern of homicidal deaths in and around Raichur city and to study the various socio-demographic factors influencing the homicidal deaths. Using a predefined and structured Performa, all the necessary details pertaining to the cases were collected from the inquest report- which includes police enquiry report, witness statement and relative statement, findings of post-mortem examination report, hospital case sheet extracts, histo-pathological examination report, toxicological (chemical) analysis report, crime scene photographs and was then tabulated to Microsoft Excel sheet 2007 for analysis and results were explained in number of cases and percentage. Prior to the study, ethical committee clearance was obtained from Institutional Ethical committee.

Results

There were 757 total cases of autopsies conducted during the study period, of which there were 51 (6.73%) homicidal deaths. The maximum cases were observed among age group 20-29 years (31%), followed by 30-39 years (21%), 60+ years (13.72%), 40-49 years (11.76%), 50-59 years and 0-9 years (7.84%) . The least number of cases were observed among the age group 10-19 years (6%).

More number of deaths were observed among males i.e., 51% (n=26), on cross tabulating age group with gender wise distribution it was observed that more number of deaths among males (23.04%) was seen in the age group 20-29 years and 32% of female deaths in the age group 40-49 years. (Table 1)

Most number of cases were observed during the winter season (42%) i.e., November to February (n=21) followed by summer season (33%) i.e., March to June and Monsoon (25%) i.e., July to October. Most deaths occurred instantaneously i.e., 58.82% (n=30), followed by within 12 hrs following assault (19.61%) and between 12-24 hours in 5.88% cases.

In our study the more number of deaths were due to assault by blunt force (37%), followed by asphyxial deaths (25% - which include throttling, smothering, drowning and poisoning cases), burn injuries (18%), no deaths due to firearm injuries were observed. (Table 2)

In our study more than half of the assault occurred in home (59%), the next most common was work place (20%) while 16% of assaults occurred in street.

In our study, a proper history or reason for homicide was uncertain in 13 cases (25%), followed by infidelity (22%), revenge (15%), heated arguments (14%) and 10% financial conflicts. (Table 5)

Most number of assaults were by spouses (28%), followed by acquaintance (21%), relatives (21%), unknown assailants (14%) and parents and strangers in 8% cases each. Most common cause of death in our study is hemorrhage & shock and head injury each being 25%, followed by asphyxia (18%), septicemia (12%) and hypovolemic shock in 8% cases.

**Discussion**

In our study duration, (2 yrs) there were totally 757 cases autopsied of these 51 cases (6.73%) are homicidal deaths. In a similar study by Courtnee clark et al with study duration being 5 years the total percentage of homicidal deaths are 5.32%. Similar studies by others
showed lesser proportion of homicidal deaths i.e., Shailesh Jhaveri et al6 - 2.34% (3 yrs), Dr. Basappa S. Hugar et al2 4.32% (3yrs) and Ashok K. Rastogi et al7 4.25% (1 yr).

Majority victims in our study were males 50.98%, the results are in similarity with other studies conducted by Dr. Basappa S. Hugar et al2, Shailesh Jhaveri et al6, Courtnee clark et al5 and Ashok K. Rastogi et al7.

The most common age group to suffer in our study is 20-29 years (31.37 %), the same results are observed in various other authors like Dr. Basappa S. Hugar et al2, Shailesh Jhaveri et al6, Courtnee clark et al5 except Ashok K. Rastogi et al7 - 18-40 yrs.

In our study most cases are reported during the winter season 41.17% i.e., November to February (Nov-Feb), while in most other similar studies by Dr. Basappa S. Hugar et al2, Shailesh Jhaveri et al6, Courtnee clark et al5 and Ashok K. Rastogi et al7 the most number of cases are reported during warmer climate (Summer).

Warren et al. (1981), who found homicide to have a seasonal pattern that changes from year to year. That is, a “peak month” in some years is a “trough month” in other years. The authors conclude that homicide is seasonal, but inconsistent.

Blunt weapons being the most common weapon used in our study (37.25%) and the same results observed by Shailesh Jhaveri et al6, Courtnee clark et al5 and Ashok K. Rastogi et al7 while study by Dr. Basappa S. Hugar et al2 the sharp weapons are the most common weapons of offence.

In our study the most common region of body involved sustaining injuries is neck (29.52%), the same results observed in other studies by Dr. Basappa S. Hugar et al2, Courtnee clark et al5 and Ashok K. Rastogi et al7. While in a study by Shailesh Jhaveri et al6 multiple body structures involvement was common.

In our study both Shock and Hemorrhage (25%) & head injury (25%) are the most common cause of death, similarly in a study by Ashok K. Rastogi et al7 shock and hemorrhage 46.34% followed by asphyxia 20.73% was observed. In another study by Shailesh Jhaveri et al6 head injury (26.42%) is the most common cause of death.

Victim residence is the commonest site of occurrence of crime in our study (59%), the same observation was made by Shailesh Jhaveri et al6, Courtnee clark et al5 and Ashok K.Rastogi et al7.

**Conclusion**

The present study pattern of homicidal deaths in the Raichur district region has provided a number of revealing information about homicidal deaths. There has been a steady increasing trend in the homicidal deaths in our area. The spurt in the homicidal deaths may be attributed to the poor socio-economic condition, unemployment among young people, marital and family disputes, decreasing value based morality in the society, soft and sometimes toothless law enforcement agencies.

The government and society should identify the various social, economical, moral and law enforcement agencies problems that are directly or indirectly leading to the rise in the incidence of homicidal deaths and should address it through proper agency or department.

Chronic Alcoholism and Drug Abuse Behavior: A Menace to Society- A Research Study

Rajesh Kumar Baranwal1, Pradeep Yadav2, Sanjeet Kumar3
1Professor, 2Assistant Professor, 3Assistant Professor, Forensic Medicine, BRD Medical College, Gorakhpur

Abstract

Background: The present study was conducted to assess chronic alcoholism and drug menace in adults.

Materials & Method: The present study was conducted on 1026 subjects which were screened in the department. A questionnaire was given to all and response was recorded.

Results: Out of 1026 subjects, male were 650 and female were 376. 340 male and 48 female were alcoholic and 126 male and 15 female were using drugs. The difference was significant (P< 0.05). 210 subjects were below 30 years of age and 319 were above 30 years of age, living standard was low in 410 and medium in 119, education standard was upto high school in 290 and graduation in 239, 380 subjects were married and 149 were unmarried. The difference was significant (P< 0.05).

Conclusion: Authors found that age more than 30 years, low living standard and low education level were risk factors for alcoholism and drug usage among adults.

Key words: Alcoholism, Drug, Education

Introduction

In the recent years there has been rapid proliferation of city bars and nightclubs and people are fast shedding their inhibitions about alcohol as a lifestyle choice.1 This has led to fears of an undocumented rise in alcohol abuse not only among poorer classes but also in other sections of the society.2 Having recognized the problem, the ministry of health has called for a policy that will regulate sales and the pricing of alcohol which many experts believe, may not be enough to curb the problem. The increasing use of alcohol and its drink-related problems has already emerged as a major public health concern in India and which needs to be addressed. A large majority of male drinkers meet criteria for hazardous alcohol use, defined as patterns of use that increase risk for harmful consequences for the user or others. Data from different Indian states indicate that 35% to 65% of all current drinkers meet criteria for hazardous alcohol use.3

Illegal drug economy plays a prominent role in national decisions made. Fortunately, cost-effective measures targeting drug abuse treatment are available. This fact increases motivation to conduct studies in order to improve interventions compatible with cultural issues.

Various countries have taken measures at society level to change knowledge and attitude of the society toward illegal drugs. These interventions aimed to prevent illegal drug abuse. Usually, focus of these interventions was teenagers and the youth, as these age groups are at more risk of drug abuse due to less information regarding this problem.4 The present study was conducted to assess chronic alcoholism and drug menace in adults.

Materials & Method

The present study was conducted in the department of Community medicine. It comprised of 1026 subjects which were screened in the department. All were informed regarding the study and written consent was obtained. Ethical clearance was obtained prior to the study.

Data such as name, age, gender etc. was obtained. A questionnaire was given to all and response was recorded. Results thus obtained were subjected to statistical analysis. P value less than 0.05 was considered significant.

The difference was significant (P< 0.05).

Discussion

Alcoholism does not only impacts the drinker but also their families and communities and making things worse, it makes it more critical to assess for prevention and intervention efforts. Despite the public health crisis and harmful consequences alcoholism represents, there is inadequate recognition of alcohol misuse as a public health issue in India. Information on screening measures is critical for prevention and early intervention efforts.

Drug abuse, as a psychological-social-biologic issue, in adolescents is one of the most critical issues for countries nowadays. This problem involves new chemical drugs (e.g. crack and ecstasy) besides traditional ones (e.g. opium and marijuana). In Iran, even though there is no official report about drug abuse, clinical observations in drug addiction consultation centers and medical centers for drug addiction rehabilitation show that addiction to new psychoactive drugs in adolescents has a high prevalence. Nowadays, instead of traditional single-factor approach to the etiology of drug abuse, multifactorial and interactive causal approaches are considered as the etiology of drug abuse. The latter factors assess related factors to drug abuse.

It has been noted in different studies that drug abuse is affected by knowledge and attitude toward drugs. To change a behavior, at first knowledge and attitude toward that particular behavior should be corrected. Iran has more than 15 million adolescent and young people and is considered the youngest country in the world. There are few studies in this age group about their knowledge and attitude toward drug abuse, while attention to these views can help them guide to safer behaviors. The present study was conducted to assess chronic alcoholism and drug menace in adults.

In present study out of 1026 subjects, male were 650 and female were 376. We found that 340 male and 48 female were alcoholic and 126 male and 15 female were using drugs. The difference was significant (P< 0.05).

Khushabi et al included 157 adult male in the study. The mean age of the study participants was 37.20
years. The prevalence of alcoholism among the study participants was 35.7%. Among them only 4.5% who presented with symptoms of chronic alcoholism had taken treatment. Reasons for not taking treatment for alcoholism among study population were mainly due to their family problems (55.2%).

We found that 210 subjects were below 30 years of age and 319 were above 30 years of age, living standard was low in 410 and medium in 119, education standard was upto high school in 290 and graduation in 239, 380 subjects were married and 149 were unmarried. Farhadinasab et al\textsuperscript{10} found current use of alcohol to vary between 19.6% and 27.8% amongst the 50+ age group. Community survey carried out in Mumbai, which was restricted to males aged 45 years or over had found the use prevalence decreased rather rapidly in higher age groups (from 21.5% in the 55–59 age group to 5.7% in the 85+ age group). Alcohol consumption was 51.43% among adult males aged 30 years and below and 31% among the 30 years and above age group which was found to be statistically significant (p-0.027).

**Conclusion**

Authors found that age more than 30 years, low living standard and low education level were risk factors for alcoholism and drug usage among adults.

Role of Physiotherapy on Quality of Life in Stroke Survivors – A Systematic Review

Kanase Suraj B1, G.Varadharajulu2, Pragati V. Salunkhe3, Mayuri D.Burungale3
1Associate Professor, 2Dean, 3Assistant professor, Faculty of Physiotherapy, Krishna College of physiotherapy, near Dhebewadi road, Malkapur, Karad

Abstract

Background: Stroke is one of the most common disease with lots of impairments and disabilities. Prevalence of stroke is increasing day by day globally. Young stroke is becoming very common. The overall functional capacity of the individual is hampered where the prognosis is question mark. It largely depends upon site, stage, duration of lesion. The overall quality of function is deteriorated. Patients live their lives with dependency. According to previous studies, role of various health care professionals have been analyzed and studied. Physiotherapy is a branch where use of exercise and electrotherapy plays their role in rehabilitating patients with stroke

Aim: To study the role of physiotherapy on quality of life in stroke survivors.

Methodology: A systematic narrative review was conducted to find out the efficacy of physiotherapy treatment on quality of life in stroke survivors.

Conclusion: Stroke has complex process of recovery. Stroke survivors are left with disabilities. It causes depression in patients as well as their family members. Physiotherapy has a significant role in improving impairments and disabilities. This in turn helps in improving quality of life

Keywords: Physiotherapy, Stroke, Quality of life, Systematic narrative review.

Introduction

The Constitution of the World Health Organization (WHO) defines health as “A state of complete physical, mental, and social well-being not merely the absence of disease.”

It involves accessing health not only in terms of effects of health care, indication and severity of diseases but also focuses on well being by measuring the quality of life related to health care. WHO defines Quality of Life as an individual’s perception of their position in life in the context of the culture and value systems in which they live and in relation to their goals, expectations, standards and concerns. It is largely affected by individual’s psychological beliefs, physical health and social involvement. It serves as a reference against which an individual or society can measure the different domains of one’s own life. It is the general well-being of individuals and societies, outlining negative and positive features of life. It observes life satisfaction, including everything from physical health, family, education, employment, wealth, safety, security to freedom, religious beliefs, and the environment.

Quality of life and general health has various domains. Broadly they include physical health, psychological, level of independence, social relations, spirituality/ religion/ personal beliefs and environmental factors.

Quality of life is largely affected by type of food consumed, education, family life, emotional security, opportunities for activities etc. Health is one of the major issues that affects a person's quality of life.

Stroke and quality of life:

In 1970, the World Health Organization defined stroke as ‘rapidly developed clinical signs of focal (or global) disturbance of cerebral function, lasting more than 24 hours or leading to death, with no apparent cause
other than of vascular origin.2

Globally, cerebrovascular accident (stroke) is the second leading cause of death and the third leading cause of disability.3 The ratio of stroke is largely based in low and middle income countries. Death and disability is very common after stroke. In past few decades the ratio of stroke is increased in these counties as compared to high income countries. Young strokes are very common nowadays with hemorrhagic type overtaking the ischemic. According to the World Health Organization, 15 million people suffer stroke worldwide each year. Of these, 5 million die and another 5 million are permanently disabled. High blood pressure contributes to more than 12.7 million strokes worldwide. In developed countries, the incidence of stroke is declining, largely due to efforts to lower blood pressure and reduce smoking. However, the overall rate of stroke remains high due to the aging of the population. Almost half of stroke-related mortality may be attributable to modifiable risk factors (i.e. hypertension, diabetes, dietary risks, impaired glucose intolerance, obesity, smoking, air pollution, alcohol use, hypercholesterolemia, and physical inactivity), which are mostly the outcome of poor clinical management, limited access to health care, and late detection of underlying risk factors.4

Studies have shown that the Quality of life in stroke patients were decreased.5 Even with progress in treatment approaches for stroke and its prevalence ratio, the quality of life and social-related events caused by stroke has received limited attention. Stroke is an medical emergency which puts burden on medical care services as well as personal where loss of productivity in terms of activities and quality of living is compromised. Stroke presents with both structural and functional impairments which largely affects the physical performance. Motor and cognitive impairments are common. Gait, balance, limb function, psychological issues contribute to decline in quality of work.

Variety of treatment approaches is available for management. Medicine, physiotherapy, ayurveda, homeopathy etc has its own contribution in reversing the loss and improving functional gain.

Anxiety is more important in determining health related quality of life (HQOL) than depression.6 Even alteration in upper extremity functions adds to impaired quality of function.

**Physiotherapy in Stroke:**

Physiotherapy is an established field in stroke rehabilitation but uncertainties remain about the most appropriate intensity of therapy input. Stroke tends to result in a wide range of disabilities which have been shown to benefit from rehabilitation, in particular physiotherapy. Varieties of approaches are used in order to regain functional independence in trunk along with upper and lower extremities. Most of the members of the therapeutic team in stroke rehabilitation take the effectiveness of physical treatments after stroke for granted. The evidence available today suggests that it does not matter which form of treatment is chosen and that any of the available approaches will improve the patient’s functional status. In other words, if an optimal treatment exists, we have, so far, failed to identify it. Until further evidence emerges, we should therefore select therapies that are most cost-effective and that can be given to the largest number of patients.7 Physiotherapists play an inherent role in the multidisciplinary palliative care team emphasizing on improving function and quality of life in patients who are deemed to require physical and functional dimensions of care.8 It is important to analyze the role of physiotherapy in rehabilitating stroke and understanding its importance on quality of life.

**Physical therapy techniques:**

Conventional exercises are traditionally practiced throughout the world. Its role in establishing upper limb control has been found to be effective. Biofeedback has been shown to have better results in both acute and chronic stroke patients along with routine exercises.8

**Exercise therapy:**

Consists of passive movement, assisted movements, active movement, assisted-resisted active movements, and resisted movement. The techniques are to be applied in anatomical planes or as functional movement direction. These techniques can be performed on land or in water. The latter is termed as “hydrotherapy”. Best examples of therapeutic exercise techniques are relaxation, massage, suspension exercise, muscle-education, progressive resisted exercise, floor aerobics, active mobility exercises, mobilization and stabilization exercise, proprioceptive neuromuscular facilitation (facilitation and inhibition techniques); breathing exercise; postural training; work simulation, work conditioning and work hardening; graded activity program and cognitive-behavioral training.10 In recent times many neurophysiologic approaches have come up
which work exactly at the site of lesion. They work on principle of neuronal plasticity thereby having a huge impact on quality of life in stroke survivors.

**Neurophysiological approaches:**

**(Bobath concept):**

Bobath concept, also known as neuro developmental treatment, is a widely used approach in the rehabilitation of hemiparetic subjects in many countries. Bobath therapy has shown to have better functional outcome. It works on principles of Normal postural alignment, Inhibition versus facilitation, Assessment versus treatment.

**(Constrained induced movement therapy):**

Original form of CIMT contains three components (1) Intensive graded practice of the paretic upper limb aimed at enhancing task-specific use of the affected limb for up to 6 hours a day for 2 weeks (i.e., shaping) (2) constraining or FU of the non-paretic upper limb with a mitt to promote the use of the more impaired limb during 90% of the waking hours; and (3) adherence-enhancing behavioral methods designed to transfer the gains obtained in the clinical setting or laboratory to the patients’ real-world environment (i.e., transfer package).

A total of 24 patients were randomized to constraint-induced movement therapy or Bobath Concept group. Main measures were the Motor Activity Log-28, the Wolf Motor Function Test, the Motor Evaluation Scale for Arm in Stroke Patients and the Functional Independence Measure. Constraint-induced movement therapy and the Bobath Concept have similar efficiencies in improving functional ability, speed and quality of movement in the paretic arm among stroke patients with a high level of function. Constraint-induced movement therapy seems to be slightly more efficient than the Bobath Concept in improving the amount and quality of affected arm use.

**(Proprioceptive neuromuscular facilitation):**

Pelvic proprioceptive neuromuscular facilitation (PNF) helps to improve control of pelvis which is a key point for maintaining trunk control, gait and balance. PNF has shown to establish significant changes in motor function and functionality after training, suggesting that this program can be useful for rehabilitation of chronic stroke survivors.

**(Motor relearning programme):**

MRP works on the concept of analysis, finding the missing component, practicing it and transference of training. Task related training has shown to improve walking performance post stroke. It works on concept of relearning phenomenon thereby enhancing neuronal plasticity.

**(Roods approach):**

For every motor output proper and sequential sensory input is required. Roods approach works on this concept through sequence of primitive reflexes and milestones in order to achieve motor output. Various inhibitory and facilitatory techniques are used in order to regain motor control.

**(Brunnstrom technique):**

The predominant basis of the Brunnstrom approach is the use of reflexes to develop movement behaviour through (1) sensory stimulation to inhibit spasticity and (2) functional retraining to enhance movement control. A strong functional emphasis remains a feature of the Brunnstrom approach as a therapeutic tool for neurological dysfunction.

**(Electrotherapy):**

It is a branch of physiotherapy where low, medium and high frequency currents are used to gain therapeutic effects in various disorders.

**(Electrical modalities):**

Various electrotherapy modalities are been routinely used in treatment of impairments secondary to stroke. Reducing Pain, improving sensory input, maintaining muscular properties are the primary uses. Electrical stimulation, hot moist packs and exercises have shown to improve shoulder subluxation in stroke which is a main barrier for improving upper extremity functions.

**(Functional electrical stimulation):**

Functional electrical stimulation (FES) is a treatment that applies small electrical charges to a muscle that has become paralysed or weakened, due to damage in your brain or spinal cord. Research on its use in stroke for both foot drop and to assist finger movements, was first published in the late 1970s. In the mid-1980s, a group based in Salisbury in the UK started to look at using FES. Originally their work was in people with spinal
cord injuries; from this initial work they went on to develop devices for people with MS in the early 1990s and it continues to be used today. Electrical stimulation of the nerves result in contraction of muscles supplied by them. This technique can be used to improve the muscle strength, control the movements, bowel, bladder and sexual functions, maintenance of posture, standing and walking. FES is becoming popular in the treatment of shoulder subluxation, spasticity and weakness of upper and lower limbs in hemiplegic patients.

**EMG and biofeedback:**

This is a technique by which subject is made aware of activity of muscles for better self regulation of the motor functions. Electromyographic biofeedback (EMG-BFB) is a technique that is believed to have additional benefit when used with standard physiotherapy for the recovery of motor function in stroke patients. EMG biofeedback helps to recall anagrams using the cues. Mentally subject improves the performance by knowing the results of previous activity.

**Activity of daily living training:**

Individuals with stroke have difficulty in gaining functional independence in order to perform their activities of daily living. Physiotherapy works with a primary goal of achieving it. Spastic muscles make it very difficult to achieve voluntary control. Variety of interventions have been tried out and have shown to have significant impact on achieving positive results. Task-oriented training resulted in improved hand function and activities of daily living in stroke patients. Therapeutic gymnasium consists of instrumental training for achieving functional mobility in upper and lower extremity. Super rider, multiple gym exerciser, wall ladder, shoulder wheel, static bicycle, parallel bar with mirror, activity of daily living training table are routinely used to improve quality of function in them.

**Bladder dysfunction:**

The incidence of incontinence depends on the interval between the stroke and evaluation. The reported figures are: 1st week - 60%, 6th week - 42%, and 12th week - 29%. The bladder dysfunction in a stroke patient may be due to inability to communicate, immobility, dementia or neurogenic bladder dysfunction. Valsalva and credes maneuver are common approaches used in practice to regain control. Bladder training program can be achieved by Intermittent catheterization and timed voiding program.

**Preventive complications:**

Stroke, can come up with number of complications like shoulder pain, pressure sores, DVT etc. shoulder pain interferes sleep and therapy. Physiotherapy should be thought of as a first-line management for patients with subacromial impingement syndrome. Both exercises and electrical agents play role is reducing pain. Positioning and bed mobility exercises helps to reduce pressure sores. Aim of positioning is to prevent development of abnormal posture, spasticity and contractures. Normal anatomical alignment of head, trunk and limbs should be maintained. I125 labelled fibrinogen leg scans of patients with hemiplegia have shown evidence of DVT in 30-75% during the first week after stroke. Mobilization of patient as early as possible reduces the chances of blood clot formation and risks of DVT.

**Conclusion**

Stroke has complex process of recovery. Stroke survivors are left with disabilities. It causes depression in patients as well as their family members. Physiotherapy has a significant role in improving impairments and disabilities. This in turn helps in improving quality of life.

Effect of Goal Oriented Exercises Versus Combined Physiotherapy Intervention on Functional Independence in Subject With Traumatic Brain Injury

Pragati V Salunkhe¹, Suraj B Kanase²

¹Assistant Professor; ²Associate Professor, Department of Neurosciences, Krishna College of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra India

Abstract

Background- Traumatic brain injury is a devastating neurological disorder and a leading cause of death and acquired disability in India. Traumatic brain injury leads the damage to the brain that result in impairment in physical, cognitive, speech/language, daily activities and quality of life and behavioural functioning. These impairments have direct impact on the individuals functional outcome after traumatic brain injury. In rural areas the health care delivery system is still an upcoming area. There is scarcity in rehabilitation units to provide health care. Many researches has been done on motor and balance impairment but there is lack of researches done on goal oriented exercises and combined physiotherapy intervention on functional independence. In this study we are given goal oriented exercises mainly concentrate on problem list of patients and combined physiotherapy intervention given combining all the exercises and give it to the patients. Indeed this made us to study the effect of Goal Oriented Exercises Versus Combined Physiotherapy Intervention on Functional Independence in Subject with Traumatic Brain Injury. Objectives- 1. To find out effect of Goal oriented exercises On functional independence In subjects with traumatic brain injury. 2. To find out effect of Combined Physiotherapy Intervention On functional independence In subject with traumatic brain injury. Method- 44 subjects diagnosed with Traumatic Brain Injury were included in this study. Subjects were divided into two different groups. Group A was Given Goal Oriented Exercises and group B was given combined Physiotherapy intervention. These subjects were allocated by convenient sampling method. During Pre and post treatment assessment functional mobility were assessed by outcome measures Functional Independence Measure and Barthel Index. These outcome measures were analysed. Result- Pre and Post functional independence and mobility was analysed by using paired and unpaired t test. Data analysis showed significance for FIM and Barthel Index (p value less than 0.001) for both the groups but comparative to group A (Goal oriented Exercises), group B (Combined Physiotherapy Intervention) is more effective. Conclusion- Goal oriented Exercises and Combined Physiotherapy Intervention is effective in improving the functional independence and mobility in the post Traumatic Brain Injury individuals but comparative to Goal oriented Exercises, Combined Physiotherapy Intervention is more effective.

Keywords- Traumatic brain injury, Functional Independence Measure, Physiotherapy Intervention.

Introduction

Traumatic brain injury is defined as an alteration in brain function caused by an external force. Brain tissue damage can be of two type: primary injury and secondary injury. Primary injury occurs due to direct trauma to the parenchyma. Secondary injury results from cascade of biochemical, cellular, and molecular events that occur due to an initial injury and injury related hypoxia, elevated intracranial pressure and oedema. (1) There is
open head injury and close head injury, open head injury is associated with skull fracture and close head injury occurs in isolation without skull fracture. Blood supply of brain may also get indirectly affected due to the injury of face and neck. Most TBI occurs due to road traffic accident (RTA). The severity of brain injury may be categorised as mild, moderate and severe head injury. (2)

In Mild traumatic brain injury there is minimal damage to the neuroanatomical structures with slight or no permanent impairment. Glasgow coma scale score of more than 13 is defined as mild TBI. In moderate TBI GCS between 8 -13 and the post traumatic amnesia lasting between 1 to 24 hours. Severe TBI is GCS score less than 8. (2)

After TBI – state of consciousness, sensorimotor changes, cognitive, emotional and behavioural changes, attention, balance, dizziness and visual dysfunction, spasticity and post traumatic headache. (2)

Functional Independence is a common consequence of traumatic brain injury. To maintain a mobility, it is important that central nervous system receives and integrates a somatosensory information, which includes both the tactile and proprioceptive system. The receptors which carry tactile sensations are Merkels cells, Pacinian corpuscles, Meissners corpuscles and Ruffini endings. And they are found in feet and might play an important role in maintaining body stability and balance in upright stance. The proprioceptive receptors are muscle spindle and Golgi tendon organs which carry the sense of joint position and joint motion. The proprioceptive receptors in feet are sensitive to ankle rotation and can give information about balance. (3, 4) Stimulation of these receptors may improve balance control in individual with post TBI. The rhythmic auditory stimulation (RAS) also improves the balance and gait of post TBI patients by stimulating brain functions involved in movement, cognition, emotions and sensory perception also RAS helps in execution of movements and normalizing gait parameters. (5, 6, 7) Balance incorporates two vestibular reflexes- the vestibuloocular reflex (VOR) and the vestibulospinal reflex (VSR). To improve balance after TBI the vestibular balance rehabilitation therapy and visual treatments are commonly used. (8)

Postural impairment and Functional Independence are common consequences of TBI which may result in instability while performing day today activities like standing, walking, grasping, difficulty while coordinating eye-head movement and problem while focusing on target. The postural and coordination defect result from damage to cerebellum. (9)

The motor disability following TBI is a common, motor performance can be affected by damage to various loci in the nervous system which can cause reduction in muscle power and tonus disorder which can result in impaired balance. (6, 7) Focal or diffuse spasticity may appear following TBI. Time post injury is an important consideration as spontaneous neurological recovery may continue for 9- 15 months post injury. Motor impairment can also result from prolong immobilization and bed rest during acute period, prolonged immobility can cause effect on multiple body system that impact the motor function the most. Motor rehabilitation is essential in helping the patient re-establishing independence post TBI. (7, 8)

Examination of Functional Independence in TBI patients is done by using Functional Independence Measure Scale and Barthal Index(10, 11, 12) Initially many therapist concentrate on the motor component of patient to improve his independence in this study we are going to give Combined physiotherapy intervention for Functional Independence in TBI Individuals.

Material and Method

This was a study to find the “Effect of goal oriented exercises versus combined physiotherapy intervention on functional independence in subject with traumatic brain injury. The study was carried out in hospitals from Karad. An approval for the study was obtained from the protocol committee and ethical committee of KIMSDU. Individual were approach and those fulfilling the inclusive criteria were selected. The purpose was explained and written inform consent was taken prepared in accordance with the Helsinki Declaration from those who are willingly to participate. Total 44 individuals were taken. The inclusion criteria was TBI patients, Patients with mild and moderate TBI, Both male and females, Age- above 18 years, Patients with functionally Dependent. The exclusion criteria was individual who are unable to follow simple commands, unconscious patients, unstable vitals and candidates with any fracture of spine, lower and upper limb. Their Functional Independence was assessed by FIMS and Barthal Index. Then the candidates were divided in to two groups for group A goal oriented exercises and for group B Combined Physiotherapy Intervention are
given. This was given for 4 days per week for 6 weeks up to 45-60 minutes per session including rest time. The time of session increased as the week progresses, initially it took 30-35 minutes per session and later progressed to 45-60 minutes per session on 6th week.\(^{(13)}\). Later evaluation and interpretation was done using statistical analysis.

**Finding**

The data was analyzed using INSTAT software. Descriptive statistics were used to analyze for demographic data: Pre and post treatment protocol was analyzed by using paired and unpaired t test and p value <0.0001 was considered to be statistically significant.

**Within Group Comparison**

Within group comparison was done by applying ‘Paired t-test’ to pre and post training values of Functional independence measure.

Discussion

The purpose of this study was to find out the effect of goal oriented exercises versus combined physiotherapy intervention on functional independence in subject with traumatic brain injury. About 40% of patients report Functional Dependence after TBI. In many research’s done before treatment was given mainly on motor component to improve balance in TBI patients. Many currently practicing physiotherapist mainly concentrate only on motor components of patients. In this study we have given Goal oriented exercises and Combined Physiotherapy Interventions.

Our study included total 44 post TBI candidates with Functional Dependence. Motor impairment is a common problem in post-TBI patients. This problem may persist for life time after TBI which can affect the Patients daily activities and his mobility. For this early management of patients in its acute stage plays an important role. Motor management alone with combined physiotherapy have a more effect in improving Functional Independence in post TBI patients. Vestibular apparatus has also been identified as sensory organ that controls sensations of balance and equilibrium in individual. In this study we found that candidates also had impairment in eye-head coordination movements which was improved by vestibular exercises which help in stabilizing gaze and eventually to improve the balance.

Motor disturbances following TBI includes reduction of power, tonus disorder (spasticity) and motor control disorganisation. Reduction of spasticity helps in improving ROM and functional activities. The static balance is improved by decreasing muscle tone of neck and upper trunk. Thus improving Functional Independence of an individuals.

Limitation of this study was that the study is done with small sample size and in limited geographical area.

Conclusion

Through this study, it is concluded that, Goal Oriented Exercises and combined physiotherapy intervention is effective in improving the functional independence and mobility in the post TBI individual but comparative to Goal oriented exercises, combined physiotherapy intervention is more effective.

Conflicts of Interest: There is no conflict of interest in this study.

Source of Funding

The study was funded by Krishna institute of medical sciences deemed to be university, Karad.

Ethical Clearance: This study has undergone ethical clearance through the university level ethical committee.

The Effect of Structured Physiotherapy Exercise Programme on Lung Function in Industrial Workers

Patil Poonam1, Kanase Suraj B2
1Assistant Professor, 2Associate Professor, Faculty Of Physiotherapy, Krishna Institute Of Medical Sciences, Deemed To Be University, Karad, District-Satara, Maharashtra

Abstract

Context: Repeated exposure to dusty environment in an industry causes airway diseases which may affect pulmonary function over a period of time. Aim: The effects of structured physiotherapy exercises programme on lung function in sugarcane industrial workers. Study Design: An experimental study was conducted on 60 sugar factory workers at in and around Karad area. Purpose of the study: To find out the effect of structured physiotherapy exercises programme on lung function in industrial workers. Materials And Methodology: -60 workers of age group 20-40 from sugar industry participated in this study. They were bounded in single group. The subjects were scrutinized based on the inclusion criteria. All the subjects signed a consent form prior to participation in the study. Before receiving any intervention, the peak expiratory flow rate and 6 min walk test was taken and abdominal strength checked by manual muscle testing of abdominal muscle (graded abdominal muscle testing). After recording the pre-intervention outcome measure, the specific exercise protocol was given to the subjects which was included abdominal muscle exercises (graded abdominal muscle exercises) and 6 minute walk test as exercises purpose and diaphragmatic breathing exercises (10 repetition for 3 sets), segmental breathing exercises (10 repetition for 3 sets), incentive spirometry (20 repetition 5 sets). Post treatment outcome measure were performed for peak expiratory flow rate, abdominal muscle strength and 6 minute walk distance. Statistical analysis was done using paired test. Result: In this study pre-intervention peak expiratory flow rate was 290±58.251 and post-intervention peak expiratory flow rate was 307±60.914. In peak expiratory flow rate statistically extremely significant difference and increasing peak expiratory rate post intervention with (p<0.0001) with t=5.633 with 59 degree of freedom. The six-minute walk distance (6mwd) increased from 215 to 297 meter. In the study the pre intervention values of abdominal muscle strength (MMT or grades of abdominal muscle) was 1.63±0.7357 and post intervention abdominal muscle strength was 2.5±0.7249. In abdominal muscle strength statistically extremely significant difference and increases abdominal muscle strength with (p<0.0001) with t=11.851 with 59 degree of freedom. Conclusion: Thus, the above study concluded that a structured exercises programme showed a significant improvement clinically as well as statistically significant on the peak expiratory flow rate and 6-minute walk distance and abdominal muscle strength in the sugar industry workers. Hence it accepts the alternate hypothesis.

Keywords: PEFR, 6 minute walk distance, graded abdominal muscle exercises, Breathing exercises.

Introduction

Maharashtra is one of the largest sugar producers state in India. “Bagassosis” is a respiratory disease. Bagasse is a by-product of sugarcane crushing, size range from 0.5-3 microns are called as repairable dust, to which sugar factory workers are exposed by virtue of their occupation. Respiratory disease is today an important clinical problem for industrial workers. Significantly increased risk of respiratory morbidity
and mortality among industrial workers. Bagassosis, an interstitial lung disease, is a type of hypersensitivity pneumonitis attributed to exposure to moldy molasses. It reduced FVC, TLC, PEFR in bagassosis patients. Since 1970 very few pulmonary function studies were reported in this field until recently in 2008 a study in western Maharashtra reported decreasing FVC, FEV1, PEFR in occupationally exposed groups to bagasse as compared to non-exposed group. However, this study was conducted during the operational period of a sugar factory1,3,4,8,9.

**Peak Expiratory Flow Rate** 3,11,19

The peak expiratory flow (PEF), also called peak expiratory flow rate (PEFR) is a person’s maximum speed of expiration, as measured with a peak flow meter, a small, hand-held device used to monitor a person’s ability to breathe out air. It measures the airflow through the bronchi and thus the degree of obstruction in the airways.

Graded abdominal muscle exercises include2,12,20,21

Upper abdominal exercises-

Starting position-The subjects were instructed to lie in supine with the hips at 45 degree and knees at 90 degree and hand at sides. In all these activities subjects were instructed to keep the low back flat.

Grade1-subjects were asked to perform the curl ups by contracting abdominal muscles and then lifting the head off table with flexed knees.

Grade 2-the progression was made by lifting the shoulders until the top of scapulae lift from table, keeping the arms extended towards knees.

Grade 3- The next progression was done by lifting the shoulders until the scapulae clear table, keeping the arms horizontal.

Grade 4- The subjects were asked to progresses further by keeping the arms crossed over chest, until scapulae clear table.

Grade 5- The subjects were asked to progress the difficulty of the curl ups by having the subject change the arm position from horizontal and then to behind the neck, until scapulae clear table.

6 minute walk test provides simple, inexpensive, non-invasive method for assessing cardiac or pulmonary functional capacity. The 6-minute walk test measures the distance an individual is able to walk over 6 minutes. The goal is for individual to walk as far as possible in 6 minutes. The individual is allowed to self-pace and rest as needed as they traverse back and forth along a marked walking. The vitals should be noted prior as well as after the test. 6-minute walk test is used for measuring the response to medical interventions in patient with moderate to severe heart or lung diseases. 6-minute walk test has also been used as a one-time measure of functional status of patient as well as a predictor of morbidity and mortality5,6,10.

**PARTICIPANTS**

60 workers of age group 20-40 from sugar industry participated in this study. They were bounded in single group. The subjects were scrutinized based on the inclusion criteria. All the subjects signed a consent form prior to participation in the study. Before receiving any intervention, the peak expiratory flow rate and 6min walk test was taken and abdominal strength checked by manual muscle testing of abdominal muscle (graded abdominal muscle testing). After recording the pre-intervention outcome measure, The specific exercise protocol was given to the subjects which was included abdominal muscle exercises (graded abdominal muscle exercises)and 6 minute walk test as exercises purpose and diaphragmatic breathing exercises (10 repetition for 3 sets), segmental breathing exercises (10 repetition for 3 sets), incentive spirometry (20 repetition 5 sets), post treatment outcome measure were performed for peak expiratory flow rate,and abdominal muscle strength and 6 minute walk test distance. Statistical analysis was done using paired’ test.

**Outcome Measures:**

1. **Peak expiratory flow rate** 2,10,19: The peak expiratory flow (PEF), also called peak expiratory flow rate (PEFR) is a person’s maximum speed of expiration, as measured with a peak flow meter, a small, hand-held device used to monitor a person’s ability to breathe out air. It measures the airflow through the bronchi and thus the degree of obstruction in the airways.

2. **MMT for abdominal muscle** 2,20,21 -

Graded abdominal muscle exercises include

Statistical analysis was done using paired’ test.

Results

1) Peak Expiratory Flow Rate: The pre intervention peak expiratory flow rate value were 290 ± 58.251, whereas post intervention the value was 307.33 ± 60.914. the post intervention change in peak expiratory flow rate values showed statistically extremely significant. The “P” value is <0.0001 considered extremely significant. This was done using paired’ test. “t” value is t=5.633 with 59 degree of freedom.

2) Manual Muscle Testing:

The pre interventional MMT value was 1.63±0.7357 whereas post interventional the value was 2.5±0.7249. the post interventional change in value showed statistically extremely significant. The “P” value is <0.0001 considered extremely significant. This was doing using paired” t” test. the “t” value is t=11.851 with 59-degree freedom.

3) 6 minute walk test:

The pre interventional 6mwd value was 1.63±0.7357 whereas post interventional the value was 2.5±0.7249. the post interventional change in value showed statistically extremely significant. The “p” value is <0.0001 considered extremely significant. This was doing using paired” t” test. the “t” value is t=11.851 with 59-degree freedom.

Discussion

Maharashtra is one of the largest sugar producers state in India. “Bagassosis” is a respiratory disease. Bagasse is a by-product of sugarcane crushing, size range from 0.5–3 microns are called as repairable dust, to which sugar factory workers are exposed by virtue of their occupation. Respiratory disease is today an important clinical problem for industrial workers. Significantly increased risk of respiratory morbidity and mortality among industrial workers. Bagassosis, an interstitial lung disease, is a type of hypersensitivity pneumonitis attributed to exposure to moldy molasses. It reduced FVC, TLC, PEFR in bagassosis patients. Since 1970 very few pulmonary function studies were reported in this field until recently in 2008 a study in western Maharashtra reported decreasing FVC, FEV1, PEFR in occupationally exposed groups to bagasse as compared to non-exposed group. However, this study was conducted during the operational period of a sugar factory.\textsuperscript{1}Nikhade N., Sharma P conducted a Study Of Pulmonary Function Test In this study Workers Of Sugar Factory, Pravaranagar, Maharashtra, in this study Significant reduction of FEV1 in Bagasse workers, Manufacturing department and Engineering department workers as compared with controls, indicated obstructive type of pulmonary abnormalities. Reduced FEV1 has earlier been reported by Bohadana et al\textsuperscript{23} showed that workers exposed to sugar dust in the sugar cubemanufacture workstation had significantly lower forced expiratory volume in 1s (FEV1) than the non-exposed ones. The Peak Expiratory Flow Rate (PEFR) was reduced in all the exposed workers in sub-occupational groups being higher in Bagasse workers followed by Manufacturing department. A highly insignificant decrease in PEFR was also reported from western Maharashtra by Patil S.N.\textsuperscript{3} PEFR is an index of expiratory airway resistance and is more effort dependent. The reduction in PEFR may involve the same mechanism already explained for obstructive lesion. In addition, the inflammatory reaction releases proteins from eosinophils which might be responsible for the hyper responsivenss of airways. In this study 60 sugar industrial workers of age 20-40 years in Karad area were been participated in the study. They were bounded in single group. The pre outcome measure was peak expiratory flow rate, abdominal strength and 6 minute walk distance. Peak expiratory flow rate measured by peak expiratory flow rate device, 6 minute walk distance was measured by 6min walk test abdominal muscle strength measured by grades of abdominal muscle. The specific exercise protocol was given to the subjects which was included abdominal muscle exercises (graded abdominal muscle exercises) and 6 minute walk test as exercises purpose and diaphragmatic breathing exercises (10 repetition for 3 sets), segmental breathing exercises (10 repetition for 3 sets), incentive spirometry (20 repetition 5 sets). Post treatment outcome measure were performed for peak expiratory flow rate, and abdominal muscle strength and 6 minute walk test distance. Statistical analysis was done using paired\textsuperscript{t} test. In this study pre-intervention peak expiratory flow rate was 290±58.251 and post-intervention peak expiratory flow rate was 307±60.914. In peak expiratory flow rate statistically extremely significant difference and increasing peak expiratory rate post intervention with (p<0.0001) with t=5.633 with 59 degree of freedom. The six-minute walk distance (6mwd) increased from 215 to 297 meter. In the study the pre intervention values of abdominal muscle strength (MMT or grades of abdominal muscle) was 1.63±0.7357 and post intervention abdominal muscle strength was 2.5±0.7249. In abdominal muscle strength statistically extremely significant difference and increases abdominal muscle strength with (p<0.0001) with t=11.851 with 59 degree of freedom. Thus, the above study concluded that a structured exercises programme showed a significant improvement clinically as well as statistically significant on the peak expiratory flow.
rate and 6 minute walk distance and abdominal muscle strength in the sugar industry workers. Hence it accepts the alternate hypothesis.

**Limitations:**

1. The sample size was small.
2. Limited literature review on industrial workers.
3. Limited literature review on peak expiratory flow rate.
4. Limited literature review on structured physiotherapy exercises programme on industrial workers.

**Conclusion**

Thus, the above study concluded that a structured exercise programme showed a significant improvement clinically as well as statistically on the peak expiratory flow rate, abdominal muscle strength and 6-minute walk distance in the sugar industry workers. hence it accepts the alternate hypothesis.

Effect of Integrated Neuromuscular Inhibition Technique on Frozen Shoulder

Amir A. Khan¹, Smita Patil², Khushboo Bathia³

¹Intern, ²Assistant Professor, ³Assistant Professor, Department of musculoskeletal Sciences, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed To Be University, Karad, Maharashtra, India

Abstract

Background: Frozen shoulder is a painful condition of the joint capsule leading to loss of range of motion of the joint. Due to pain and inability to move the involved shoulder, patients tend to avoid any movement of the involved arm. This leads to formation of Myofascial Trigger points and tender points in the muscles. This overall makes the prognosis more challenging as the focus is mostly on the joint. Integrated Neuromuscular Inhibition Technique is a soft tissue manipulation technique that has been proven to relieve trigger and tender points. Although proven to be efficiently effective in many disorders, this technique is not as such practiced as a common and regular approach by professionals. Thus, this technique was undertaken and experimented on Frozen Shoulder.

Objectives: Objectives of the study were to determine the effect of Integrated Neuromuscular Inhibition Technique in Frozen Shoulder and compare the effect of Integrated Neuromuscular Inhibition Technique with conventional treatment in frozen shoulder.

Material and Method: In this experimental study, 40 Frozen Shoulder subjects were assessed using Visual Analogue Scale (VAS), Goniometer for Range of Motion (ROM) and Shoulder Pain and Disability Index (SPADI). The subjects were divided into 2 groups, Group A included 20 subjects treated with Hot moist pack, Therapeutic Ultrasound, Exercises and Capsular Stretching and Sleeper stretch. Group B included 20 subjects treated with Hot moist pack, Therapeutic Ultrasound, Exercises and Capsular Stretching and Sleeper stretch and Integrated Neuromuscular Inhibition Technique.

Results: Within group statistical analysis of VAS, ROM and SPADI for both the groups were found to be extremely significant with a p value of <0.0001. On comparing between the two groups post treatment, there was extremely significant difference in Group B as compared to Group A regarding VAS (p=0.002), very significant difference for SPADI (p=0.0047), FLEXION ROM (p=0.0076) and ABDUCTION ROM (p=0.0026). But, there was no significant difference between the two groups regarding MEDIAL ROTATION ROM (p=0.1772) and LATERAL ROTATION ROM (p=0.7602).

Conclusion: The study concluded that Integrated Neuromuscular Inhibition Technique and Conventional Physiotherapy are both effective in the management of Frozen Shoulder. Also, Integrated Neuromuscular Inhibition Technique given with Conventional Treatment is significantly more effective as compared to conventional treatment alone on pain, range of motion and functional status of Shoulder and thus Alternate Hypothesis accepted.

Keyword: Frozen Shoulder, Integrated Neuromuscular Inhibition Technique, Pain, Muscle Release Intervention, Range of Motion.

Introduction

Frozen shoulder or adhesive capsulitis is a commonly occurring condition characterized by a capsular pathology associated with pain and progressive loss of passive and active movement. The incidence of Frozen Shoulder in General population is 2-5%, while
in patients with Diabetes Mellitus rises to 20-29% and is more common in females above 40 years of age.\textsuperscript{(1)}

This inflammatory condition that leads to fibrosis of the glenohumeral joint capsule is seen with gradually progressive stiffness and significant restriction of range of motion (typically external rotation).\textsuperscript{(2)} The causes for Frozen Shoulder have been classified according to two types namely Primary and Secondary Frozen Shoulder. While primary is idiopathic, secondary is ought to be due to conditions like Diabetes mellitus, Stroke, Thyroid disorder, Shoulder injury, Dupuytren’s disease, Parkinson disease, Cancer, Complex regional pain syndrome.\textsuperscript{(3)}

Subjects suffering with Frozen Shoulder often come up with symptoms of Pain usually Radiating to the deltoid insertion, nocturnal pain that interferes with sleep and restricted movement particularly abduction and external rotation.\textsuperscript{(4)} The condition is marked into four stages through its course starting from the first stage being An Acute Painful Stage, progressing to a Freezing Stage, followed by a Frozen Stage and lastly A Thawing Stage.\textsuperscript{(5,6,7)}

Diagnosis can be made on the basis of history and investigations. Other conditions causing a painful and stiff shoulder are ruled out, the affected shoulder is assessed to identify the stage of the disorder, Any History of previous trauma or surgery around shoulder is enquired. About 50% reduced range of motion may be seen. History of Cardiac or Neurosurgery, impaired consciousness and hemiparesis and other neurological conditions like Parkinson’s disease and brachial neuritis. Cervical spondylitis, Diabetes and thyroid disorders and a normal joint appearance in radiograph.\textsuperscript{(4)}

Integrated Neuromuscular Inhibition Technique is a combination of a few techniques in a stepwise application. It involves using the position of ease as part of a sequence which commences with location of a tender/trigger point, application of ischemic compression and introduction of positional release. After an appropriate length of time, during which the tissues are held in ease, the patient introduces an isometric contraction into the affected tissues for 5-7 seconds. After this, the local tissues housing the trigger point is stretched.\textsuperscript{(8)}

The rationale behind the technique is quiet similar to those of any other muscle release intervention. When a trigger point is being palpated by direct finger or thumb pressure, and when the very tissues in which the trigger point lies are positioned in such a way as to take away the pain (entirely or at least to a great extent), then the most stressed fibres in which the trigger point is housed are in a position of relative ease. At this time the trigger point would be under direct inhibitory pressure (mild or perhaps intermittent) and would have been positioned so that the tissues housing it are relaxed (relatively or completely). Following a period in this position of ease and inhibitory pressure, the patient is asked to introduce an isometric contraction into the tissues and to hold this for 5-7 seconds – involving the precise fibres that had been repositioned to obtain the positional release. The effect of this would be to produce (following the contraction) a reduction in tone in these tissues. The hypertonic or fibrotic tissues could then be gently stretched as in any muscle energy procedure so that the specifically targeted fibres would be stretched following an isometric contraction. The technique is proven to be effective in Non- Specific Myofascial Pains, Trigger Point Pain, Muscle Spasms, Fibromyalgia Syndrome and some other myofascial conditions.\textsuperscript{(8)}

As this technique is found to be effective in these conditions, this made a scope for this technique to be experimented in Frozen Shoulder. In order to find out the effectiveness of the current technique in Frozen Shoulder and enable faster and smoother prognosis of subjects with Frozen Shoulder towards normal functioning, the current study was undertaken.

**Materials and Methodology**

**Study Type:** Experimental study.

**Study Design:** Comparative study (Pre treatment and Post Treatment)

**Place of Study:** Karad.

**Sampling Method:**

Simple Random Sampling.

**Sample Size:**

\[ n = 4 \frac{pq}{L^2} \]

Total number of subjects in study \( n = 40 \)

**Inclusion Criteria**

1. Both male and female participants willing to
participate in the study.

2. Age: 40-65 Years

3. Subjects clinically diagnosed with frozen shoulder by certified physiotherapist/Orthopaedician

4. Subjects in second stage of frozen shoulder.

**Exclusion Criteria**

1. Recent Trauma around Shoulder.

2. Recent fracture around the shoulder.

3. Open wound or skin disease.

5. Previous shoulder surgeries.

6. Other shoulder pathologies such as Rotator cuff tear or Chronic Regional Pain Syndrome.

**Outcome Measures**

1. Visual Analogue Scale (VAS). (9)

2. Universal Goniometer. (10)

3. Shoulder Pain And Disability Index (SPADI). (11)

**Procedure**:

The study was carried out and the result was drawn by using VAS, SPADI and Joint ROM scores as the outcome measures. 40 patients (23 Males and 17 Females) were undertaken for the study. The age Group was between 40-65 years. Study place was Krishna College of Physiotherapy, OPD. Patients were evaluated and were divided into 2 Groups by convenient sampling with random allocation. Group A included 20 subjects treated with hot moist pack, Ultrasound, Exercises and Stretching (capsular and sleeper). Group B included 20 subjects treated with hot moist pack, Ultrasound, Exercises and Stretching (capsular and sleeper) and Integrated Neuromuscular Inhibition Technique. An informed Consent was taken from the subjects once they were filtered by the inclusion and exclusion criteria. Subjects were asked to fill the data collection sheets and were treated for 7 days after which. The scores of the outcome measures were measured post-procedures.

**Findings**

Statistical analysis was done manually and by using the statistics software INSTAT so as to verify the results derived. The statistical analysis within group value of VAS, ROM and SPADI was done by Paired ‘t’ test. Unpaired ‘t’ test was used for interpretation of post interventional values between Group A and Group B. Fisher’s Exact test was used for calculating the difference in the age groups and occupation.

**Table 1: Gender Distribution.**

A total of 40 subjects were taken for the study. Out of 40 subjects 23 were males and 17 were females.

<table>

Discussion

A total of 23 males and 17 females were divided in two groups randomly. Group A consisted of 12 males and 8 females, whereas Group B consisted of 11 males and 9 females. The difference between the two groups regarding Gender was found to be not significant. Although Frozen Shoulder is found to be more common in females, the current study had more number of males than females. The possible reasons behind this might be a small sample size and the characteristic flow of patients in the locality.

The mean age of subjects in Group A was 49 ± 6.456 and in Group B was 49.85 ± 6.515. With a p value of 0.5010 the difference in mean age of the two groups was found to be statistically not significant.

In Group A, which is the controlled group, extremely significant difference was obtained by the use of Hot moist pack, Therapeutic Ultrasound, Codman’s Pendular Exercises, Capsular Stretching and Sleeper Stretch. The rationale behind each of the treatment and their reasonable effect can be stated as follows. Hot moist packs that transfer heat from the packs to the patient’s body increase the temperature of the respective body part. With increase in temperature, the stress-relaxation ability of the collagen fibres is enhanced, which enable larger deformation in these fibres when subjected to stretch.

Therapeutic Ultrasound on the other hand has been proven in previous studies also for elevating collagen tissue extensibility, pain threshold and enzymatic reactions. Also, it causes alteration in nerve conduction velocity, and the contractility of skeletal muscles.

Codman’s Pendular exercises are a form of exercises that utilize the effects of gravity to provide a distraction of the humeral head from the glenoid fossa. These exercises help reduce pain via gentle traction and revolving movement and enhance early motion of the articulating parts and the joint synovial fluid.

Capsular Stretching and Sleeper Stretch follow the effects of general stretching with added benefit of going through the capsular pattern of the joint and increasing soft tissue mobility and further increasing joint Range of Motion by elongating the shortened and hypo mobile structures.

In Group B, which is the experimental group, extremely significant difference was obtained by
combining the above-mentioned conventional treatment with a new technique called Integrated Neuromuscular Inhibition Technique. This group showed significant difference when compared with the control group post-interventionally.

The added benefit obtained in this group goes to explain the rationale of use of a Manual Muscle releasing technique which was not used in the control group.

Muscle release interventions have been proven to improve blood circulation, reduce pain, alter the excitability of the alpha and delta motoneurons and thus enhance joint range of motion.\(^{(16)}\)

Studies prove that the Ischemic Compression component in the INIT decreases the threshold sensitivity of the pain nodules in the muscles. It is proposed that local pressure tends to equalize the length of sarcomeres in the involved TrP and thus reduces pain.\(^{(17)}\) Additionally, a mechanism called ‘unopposed arterial filling’ has also been put forward which enables improvement in tone of the muscles.\(^{(18)}\)

The P value for MEDIAL ROTATION ROM \((0.1772)\) and LATERAL ROTATION ROM \((0.7602)\) showed that the rotational movements ROM in the two groups did not differ significantly. This may have happened because these two movements being performed on a different axis and with shorter moment arms did not require much of muscle point pain corrections.

In this study an attempt was made to analyze the effect of Conventional Treatment and Integrated Neuromuscular Inhibition Technique in relieving pain and improving Joint Range of Motion as well as functional status and strength in Frozen Shoulder patients. This study was done to investigate the reduction of symptoms after application of Integrated Neuromuscular Inhibition Technique in conjunction with Conventional Treatment in Frozen Shoulder patients and its post treatment evaluation in a standardized manner using VAS, SPADI and ROM scores. The result shows that there is significant difference in improvement of pain, functional performance, Flexion and Abduction Range of Motions between the two groups. The group treated with Integrated Neuromuscular Inhibition Technique showed significantly better results for these outcome measures. Although, there was no significant difference regarding Medial and Lateral Rotation Range of Motions between the two groups.

**Conclusion**

The current study concluded that Integrated Neuromuscular Inhibition Technique and Conventional Physiotherapy are both effective in the management of Frozen Shoulder. Also, Integrated Neuromuscular Inhibition Technique given with Conventional Treatment is significantly more effective as compared to conventional treatment alone on pain, range of motion and functional status of Shoulder and thus Alternate Hypothesis accepted.

Comparison of Closed Kinetic Chain Exercises and Conventional Therapy on Cardiac Parameters in Post CABG Subjects

Ankita Ajit Patil1, Chandrakant Patil2, Smita Patil
1Intern, Faculty of Physiotherapy, 2Assistant professor, Department of Cardiopulmonary Sciences, 3Assistant professor, department of musculoskeletal sciences, Faculty of physiotherapy, Krishna Institute of Medical Sciences Deemed to be university, Karad, Maharashtra, India

Abstract

Introduction: Cardiovascular disorders are public health problems worldwide. In industrialized world they are the leading cause of morbidity and mortality. Coronary artery bypass grafting (CABG) has proved to be a major life saving operative method in cardiovascular disease. Physiotherapy interventions play major role in rehabilitation post CABG so the study was conducted with the aim to find the effect of closed kinetic chain exercises and conventional therapy on cardiac parameters in post CABG subjects.

Method: In this comparative study 20 subjects were treated for post CABG subjects between the age group of 40-50 years. Group A were given conventional treatment and Group B were given Closed Kinetic Chain exercise. The pre and post -test was measure blood pressure, respiratory rate, heart rate, oxygen saturation and borg scale.

Results: The statistical analysis for conventional therapy pre and post week1 day 1-systolic blood pressure(p=<0.0001), diastolic blood pressure(p=0.005), respiratory rate(p=0.001), heart rate(p=0.011), oxygen saturation(p=0.081) and borg scale(p=0.003). pre and post week6 day 3- diastolic blood pressure(p=0.018), respiratory rate(p=<0.0001), heart rate(p=0.005), systolic blood pressure(p=0.186), oxygen saturation(p=0.343) and borg scale(p=0). The statistical analysis for experimental group pre and post week1 day 1-heart rate (p=0.01) diastolic blood pressure(p=0.002), systolic blood pressure(p=<0.0001), respiratory rate(p=<0.0001), borg scale(p=0.0007), oxygen saturation (p=0.508). pre and post week6 day 3-borg scale(p=0), diastolic blood pressure(p=0.051), heart rate (p=<0.0001), respiratory rate(p=<0.0001), systolic blood pressure(p=0.26) and oxygen saturation(p=0.34).The study had found that conventional therapy is more effective than experimental group.

Conclusion: The study concluded that conventional treatment is more effective than closed kinetic chain exercises. However, it cannot be stated that CKC has no effect because of its additional benefits on functional capacity (improve joint integrity). Therefore, it can be concluded that further studies can evaluate the improvement noted with a right combination of both and obtain greater benefits.

Keyword: post CABG, cardiac parameters, closed kinetic chain, oxygen saturation, blood pressure

Introduction

Cardiovascular disorders are public health problems worldwide. In industrialized world they are the leading cause of morbidity and mortality. The annually recorded cardiovascular mortality is about 0.8%.1 In India cardiovascular diseases account for 25 % of death rate.2

Coronary artery bypass grafting(CABG) has proved to be a major life saving operative method and thereby aiding in prolongation of life, primarily by help relieving the symptoms of angina.3

The major complication that emerge after surgery are being bed ridden, oedema, wound pain, decreased physical activities and depression.4 In previous study
by Jenkins et al 1983, breathlessness, or dyspnea were investigated. It was found that 60% of patients experienced dyspnea before CABG, 54% of these were completely relieved of dyspnea, 22% reported some improvement, and 18% had no improvement 6 months following surgery. Another similar study by Mayou and Bryant 1987 reported that 71% of patients experienced dyspnea before surgery whilst 39% reported it 12 months post-surgery. In a study by Duprez D. it was found that during rehabilitation phase mean ambulatory blood pressure parameters were within normotensive range. Studies state Surgery affects physical activity, endurance, muscle strength, work in performance and quality of life to a certain extent.

In a study ShifaManhal found that the range of motion and function of the shoulder girdle and upper back are impaired following CABG, specially after median sternotomy, due to retraction of sternum. The chances of developing frozen shoulder increases after cardiovascular surgery. Thus broad spectrum of musculoskeletal problems affects quality of life of cardiac patients.

Cardiac rehabilitation (CR) is an outpatient secondary prevention program comprised of structured exercise training as well as comprehensive education and counselling. Therefore, it is necessary and considered useful for the patients. Numerous studies suggest greater physical fitness and quality of life after receiving exercise training for a long time and post-surgery education. Various physiotherapy approaches till date are Active exercises for upper and lower limb Breathing exercises, Inspiratory diaphragmatic breathing exercise, Expiratory pursed lip breathing exercise, walking, stair climbing, spirometry primarily addressing for return of quality of life post CABG.

In a study it was found that mean grade scores of physical limitations were significant pre-treatment with a substantial improvement post treatment. Exercise based rehabilitation lowers rate of cardiac death. Findings from a review of 22 randomized control trails revealed a 20% reduction in mortality rate.

Despite of these many musculoskeletal complications there are very few and limited studies performed and there are many reasons to believe the occurrence of shoulder dysfunction with increasing population of postoperative CABG patients.

Till date many approaches are carried out to overcome physical limitation primarily OKC approach. But no studies till date report the significance of CKC exercise alone. Therefore it is need to study the effect of Closed Kinetic Chain (CKC) exercises as these exercises have maximal surface contact and distal segment is fixed and movement of proximal joint. There is activation of many group of muscle while movement of joint takes place which might add to a better improvement in reducing physical limitations. However only caution regarding the proportion of drop outs need to be interpreted. However, a program of exercise that does not include all exercise components or achieve less than the recommended volumes of exercises is likely to have benefit, particularly in habitually inactivate persons.

**Material and Methodology**

An approval for the study was obtained from the Protocol committee and institutional Ethical Committee of KIMSDTU. 20 subjects were included post 6 week of CABG and between age group of 40 to 50 and those who have undergone CABG for the first time. Subjects with Neurological problems, musculoskeletal problems before surgery, with movement disability and impaired cognition were excluded. Subjects were explained about the procedure of the study and written consent was taken. Pre and Post assessment (week 1 day 1) of Blood pressure, Heart rate, Respiratory rate, oxygen saturation was taken to assess the subject. Target heart rate was decided according to age-adjusted predicted maximum heart rate formula: 220 – age. A total 20 subjects was equally divided into two groups. Group A (conventional) received active exercises for upper and lower limb, Breathing exercises, walking, stair climbing and spirometry where Group B (experimental) received standing wall side, partial squat, lunges, wall push up and dorsiflexion and push the wall.

**Discussion**

This present study “comparison of closed kinetic chain exercises and conventional therapy on cardiac parameters in post CABG subjects” was conducted to interpret impact CKC exercises on cardiac parameters such as blood pressure, respiratory rate, heart rate, oxygen saturation, borg scale. Post CABG decreased physical functioning has been noted. Recent study states that an investigation of exercise behaviour at 6 and 24 months post-surgery 67% of individuals were regular exercisers and therefore retaining pre-activity level and reducing deterioration of physical activity following surgery.5 CKC exercises improve joint integrity of the individuals, as these exercises have maximal surface contact and distal segment remained fixed.

The outcome measures used in study were Blood pressure, Heart rate, Respiratory rate, oxygen saturation
and Target heart rate.

Group A: pre and post week1 day 1-There was significant changes in systolic blood pressure (p=<0.0001), diastolic blood pressure (p=0.005), respiratory rate (p=0.001), heart rate (p=0.011), not quite significant change in oxygen saturation (p=0.081) and very significant change in borg scale (p=0.003). pre and post week6 day 3- there was significant changes in diastolic blood pressure (p=0.018), respiratory rate (p=<0.0001), very significant changes in heart rate (p=0.005), not significant change is systolic blood pressure (p=0.186), oxygen saturation (p=0.343) and borg scale (p=0).

Group B: pre and post week1 day 1-There was significant changes in heart rate (p=0.01) very significant change in diastolic blood pressure (p=0.002), extremely significant changes in systolic blood pressure (p=<0.0001), respiratory rate (p=<0.0001), borg scale (p=0.0007), not significant changes in oxygen saturation (p=0.508), pre and post week6 day 3- there was significant changes in borg scale (p=0), not quite significant change in diastolic blood pressure (p=0.051), extremely significant heart rate (p=<0.0001), respiratory rate (p=<0.0001) not significant change in systolic blood pressure (p=0.26) and oxygen saturation (p=0.34).

Between group comparison: Group A and B: post week1 day 1 – significant change in heart rate (p=0.415), very significant change in respiratory rate (p=0.003) and borg scale (p=0.005), not significant change in systolic blood pressure (p=0.307), diastolic blood pressure (p=0.897) and oxygen saturation (p=0.761) Group A and B: post week6 day 3- significant change in borg scale (p=0), not quite significant change in heart rate (p=0.056), not significant change in systolic blood pressure (p=0.30), diastolic blood pressure (p=0.77), respiratory rate (p=0.15) and oxygen saturation (p=0.18). Also a study by Gabriela Lima de Melo Ghissiit was found that cardiologist lack knowledge regarding CR and therefore barrier to secondary prevention. The major limitation of this study was the unwillingness of the patients to participate in the study. This study addresses the gap of adding CKC components in conventional treatment although with caution. Further studies need to be done on different age groups, different geographical area, for a longer duration, adding different stages of rehabilitation phase.

**Conclusion**

The study concluded that conventional treatment is more effective than closed kinetic chain exercises. However, it cannot be stated that CKC has no effect because of its additional benefits on functional capacity (improve joint integrity). Therefore, it can be concluded that further studies can evaluate the improvement noted with a right combination of both and obtain greater benefits.

Effect of Step Aerobics Applied Early in Phase 2 Cabg Subjects on Functional Capacity and Exercise Tolerance

Kaustubh G. Jadhav¹, T. Poovishnu Devi²

¹Internee, Faculty of Physiotherapy, ²Associate Professor, Department of Cardio-Pulmonary sciences, Krishna Institute of Medical Sciences ‘Deemed to be’ University, Karad, Maharashtra, India

Abstract

Background: In recent years, cardiovascular accidents are rising due to improper diet, ill habits, uncontrolled cholesterol levels, stress, etc. Coronary artery diseases are in the leading cause of death. After a coronary artery disease like myocardial infarction the individual’s general health is week and the quality of life of these individuals is reduced and hence, morbidity starts building, causing reduced functioning and reduction in overall health and functional capacity. 30 individuals participated in this study who had undergone coronary artery bypass grafting and were under phase 2 of cardiac rehabilitation. The individuals had performed low intensity Step Aerobics for 12 weeks and were evaluated for the efficiency of step aerobics on functional capacity and exercise tolerance in such individuals.

Objectives: To find the effect of step aerobics on the functional capacity and on exercise tolerance.

Methodology: In this study, 30 subjects who had undergone CABG of age from 30-65 years. These individuals were selected on the basis of their inclusion criteria. They were treated with step aerobics as form of exercises for 12 weeks. After pre-post assessment, the data was analysed with help of proper statistical methods.

Results: According to the result, there is extremely significant difference among the subjects six-minute walk test distance scores (p-value < 0.0001). Among the vitals assessed pre and post six-minute walk test, there was significant difference between the respiratory rate (p-value=0.0219), there was also very significant difference between the heart rate (p-value < 0.001). There was not quite significant change in the blood pressure levels i.e. systolic and diastolic p-value=0.0559 and 0.0862 respectively. Also, there was seen extremely significant difference in the peak O₂ consumption levels according to DASI p-value < 0.0001) and also in the MET scores in DASI (p-value < 0.0001), making the difference to be extremely significant.

Conclusion: The results obtained by studying the effects post treatment suggest that in rehabilitation of the CABG patients, implementation of step aerobics early has greater effects on functional capacity, exercise tolerance and general health including the quality of life.

Keywords: Coronary artery bypass grafting (CABG), step aerobics, functional capacity, exercise tolerance, peak oxygen consumption, Duke Activity Status Index (DASI).

Introduction

Coronary artery bypass grafting (CABG) is the most common open-heart surgery for myocardial infarction patients with major coronary artery blockages due to plaques. According to the Acute Coronary Treatment and Intervention Outcomes Network Registry in 2012, the NSTEMI subjects who did not have a past surgical history of CABG and subjects with three-vessel or left main coronary disease during angiography approximately 40% underwent CABG¹¹. Coronary artery disease is the leading cause of death worldwide. 3.8 million men and 3.4 million women die each year of coronary artery
diseases on global scale. Over last 60 years, prevalence has increased from 1% to 9-10% in urban areas and from <1% to 4-6% in rural areas. According to the survey of 2016, it was reported that 28.1% of total deaths due to coronary artery diseases. The prevalence of coronary artery disease in India was estimated about 23.8 million cases in 2016.

This surgery has complications such as postoperative pulmonary complications, changes in lung mechanics, restrictive breathing pattern and shallow breathing. Atelectasis is common in these cases causing reduced lung capacity and respiratory muscle strength. Due to sternotomy among these patients, immobility in bed and temporary dysfunction in diaphragm causes hypoxia and postoperative pulmonary dysfunction. Ejection fraction is reduced in these patients due to left ventricular ischemia. These all factors cause reduced functional capacity further poor quality of life.

CABG causes reduced peak oxygen consumption ($VO_{2max}$). Due to reduced aerobic capacity, reduction in the functional capacity of these individuals is also reduced due to morbid state and less functioning. They have shown great effects on improving the aerobic capacity and functional capacity. They improve cardiac output, $VO_{2max}$ and enhance the ability of the muscles to utilize the oxygen from blood. Studies have shown aerobic exercises to improve peak $VO_2$ up to 46%. Systolic function also increased by 35%, hence strengthening the advantages of aerobic exercises.

Physical activity is needed in these subjects along with fair interaction with the family and friends. Also, physical training causes decrease in body weight and improve emotional health and quality of life. Vascularity of muscles increases and peripheral oxygenation improves due to physical activity. Physical activity guidelines recommend that every healthy adult should engage in 92 minutes or more of low to moderate intensity physical exercises for a week.

Aerobic exercises have great effects on the functional capacity and exercise tolerance. Aerobics has all the benefits of a general high intensity workout. Aerobic exercise is believed to play a part in lowering the risk of cardiovascular disease by increasing the serum levels of high-density lipoprotein cholesterol. Effects of aerobic exercises on depression and anxiety are also seen. Mainly, it plays an important role in controlling the blood pressure and the blood sugar levels, reducing the risk of coronary artery diseases. In CABG subjects, aerobic exercises play an important role in most common contributory factor for morbidity, viz., peak oxygen uptake ($VO_{2max}$).

Studies have shown that aerobic exercises have great effects on the cardiovascular and physical functioning. Step aerobics also has shown great effects on cardiopulmonary functions and exercise tolerance. Previous studies have shown effects on cardiopulmonary fitness and cholesterol levels in young women with sedentary lifestyle, also some studies have shown the energy expenditure due to walking along with stair climbing and its effect on physical fitness.

Step aerobics is an up-tempo way to get your heart pumping and stay fit. Step aerobics training involves stepping up and down on a single bench/step in choreographed, group-led movements to music. Step aerobics intensity can vary from low to moderate intensity in health compromised subjects and moderate to high intensity in obese to normal subjects. It is a form of exercise to get benefits like high intensity cardio workout without putting stress on your joints. This can be done in presence or absence of music. It not only acts as a cardio workout but also has an effect on strength of legs.

Addition of low intensity exercises in phase 2, may induce increase in functional capacity and exercise tolerance. Hence, step aerobics should be incorporated in daily functional training for greater results.

**Methodology**

The ethical clearance was taken from ethical committee of Krishna institute of Medical Sciences, Karad. There were 30 participants in the study. The study was taken place in the Krishna Hospital. Treatment protocol was of 12 weeks. The subjects were assessed for functional capacity using six-minute walk test at first and exercise tolerance using the Duke Activity Status Index. The type of study was experimental study. The study design was pre-post.

**Procedure**

All the subjects for the study were selected according to the selection criteria. Demographic data and written consent were obtained from the subjects. The subjects...
were explained about the protocol and demonstrated. Pre and post assessment were taken before and after 12 weeks of the treatment period respectively with the help of outcome measures. Pre-treatment exercise tolerance was assessed using 6-minute walk test. Pre-vitals, blood pressure, heart rate, respiratory rate was assessed before starting the test. The patient was asked to walk a distance of 30m to and fro for 6 min at normal pace. There were chairs kept at regular interval for the patient to rest if fatigue or breathless. After completion or before completion of 6 minutes i.e. when the patient was found to be restless while walking, the patient was again assessed for vitals and noted. The distance covered by the patient in 6 minutes was calculated and kept as pre-treatment record. The patients were also given Duke Activity Status Index for functional assessment and rough estimation of the oxygen uptake and exercise tolerance. The patients according to the exercise tolerance calculated were trained with step aerobics for 12 weeks. Every session lasted for 45 minutes of step aerobics including the warm up and cool down exercises. The warm up lasted for 5 minutes which included neck flexion-extension, rotation, arm rotations, trunk lateral flexion, trunk rotation and basic stretches arm and legs. Once done with warm up, the protocol was performed in the sequence of basic right, basic left, A-step move, across the top move with deep breathing. Each move lasted for 1 minute and repeated after every 5 minutes. The exercises continued for 25 minutes and then followed by cooling down of the body which consisted of arm shaking, legs shaking, deep breathing. After completion of 12 weeks, the subjects had to undergo 6-minute walk test and DASI for the exercise tolerance and functional capacity assessment respectively. The data was collected and recorded. Later statistical analysis was performed.

Results

1. Distribution according to demographic data

Discussion

Aerobic exercises are the type of exercises which have effects of the aerobic capacity and improve the oxygen supply and avoid early fatigue. Step aerobic exercises not only improve the aerobic capacity but also helps in building the balance and agility in middle aged and old age population. It mainly has effects on the body composition in young and adult population. The repetitive stepping up and down improves the lower and upper body strength In this study, 30 individuals were selected on the basis of the inclusion and exclusion criteria. The mean age of these participants was 53.57 years. Out of the total participants, 13 (43.33%) were female and 17 (56.67%) were male.

6-min walk test was used to assess the participant’s functional capacity. It was performed at the commencement of the treatment i.e. in the beginning of 1st week and at the completion of treatment i.e. at the end of the 8th week. The mean score of participant’s distances covered pre intervention was 197.66 metres and the mean score of participant’s distance post intervention was 286.33 metres. Thus, there was a considerable increase in the distance traversed by the participants post administration of treatment.

The vitals of the participants were also assessed during the 6-minute walk test. Blood pressure (BP), heart rate and respiratory rate were the vitals assessed. The mean score of systolic BP pre intervention was 132.23 mmHg and mean systolic BP score post intervention was 125.05 mmHg. Similarly, mean diastolic BP score pre and post intervention were 94.41 mmHg and 87.17 mmHg respectively. The mean score of heart rate were also calculated similarly, mean score of heart rate pre intervention was 106.14 beats/min and that post intervention was 88.32 beats/min. Respiratory rate mean scores were also calculated in the same way, the pre intervention mean score was 22.86 breaths/min and the post intervention mean score was 19.34 breaths/min.

Duke Activity Status Index (DASI) was used to assess the participant’s estimate peak oxygen consumption and their exercise capacity on the basis of Metabolic Equivalent of Task (MET).

The questionnaire was provided to the participants before the commencement and after completion of the treatment protocol. The scores were then calculated. The mean score for peak oxygen consumption pre intervention 16.81 was and the mean score post intervention was 20.42. This shows that there was an increase in the peak oxygen consumption levels of the participants in turn improving their functional capacity.

The mean score pre intervention of MET was 4.80 and the mean score post intervention for MET was 5.83. Therefore, there is considerable improvement in the ability of the participants capacity to perform tasks as a result of the increased exercise tolerance.

Intra-group association for score of 6-min walk test within the population; pre and post intervention was done. Paired t-test was used which had a p-value of <0.0001 which was extremely significant with a t-value of 15.757. Thus, there is a significant increase in the distance covered by the participants post administration of our exercise protocol. Similarly, paired t-test was used to calculate the association between the vitals i.e. systolic BP which had a p-value of 0.559 which was not quite significant with a t-value of 2.019, diastolic BP with a p-value of 0.0862 which was not quite significant with a t-value of 1.796, heart rate with a p-value of <0.001 which was very significant with a t-value of 7.139 and lastly the respiratory rate which had a p-value of 0.0219 which was significant with a t-value of 2.377.

Association of DASI scores for peak oxygen consumption was also analysed, which had a p-value of <0.0001 which was extremely significant with a t-value of 10.866. DASI scores for MET also had a p-value of <0.0001 which is extremely significant with a t-value of 10.856.

In this study, we can say that there is a significant improvement in all the parameters, general health and vitals of the participants. This results in an overall increase in the functional capacity, quality of life and exercise tolerance of the participants. Hence, implementation of our treatment protocol may help individuals undergoing CABG recover faster and turn out healthier than the average patient. It may also improve the confidence in physiotherapists in turn promoting our profession as well improve the patient’s confidence in himself leading to a speedy recovery.
Conclusion

On the basis of the result of the study it is concluded that in rehabilitation of CABG subjects, early implementation of step aerobics has a number of effects on the functional capacity, exercise tolerance and quality of life.

Improving the Motility of a Scleral Shell prosthesis with an Acrylic Orbital Implant: A case report

Varsha Ignatious1, Umesh Y Pai2, Shobha J Rodrigues3, Thilak Shetty B5
1Post Graduate Student, 2Associate Professor, 3Professor and Head, 4Professor, Department of Prosthodontics, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, Manipal, Karnataka, India

Abstract

Evisceration or enucleation of the eye may be performed due to ocular injury, cosmetic deformity, infection or malignancy. After the surgical management, orbital implants can be placed to improve the cosmetic appearance, improve the motility of the scleral shell prosthesis and restore the loss of orbital volume. Various type of orbital implants are available amongst which, the acrylic orbital implant has gained popularity, over the years, due to its limited complications.

The following case report represents a 26 year old patient who underwent enucleation and had an existing scleral shell prosthesis. His chief concern was the motility of the prosthesis. The prosthetic rehabilitation was done with the help of an Acrylic Orbital implant and a customized scleral shell prosthesis.

Keywords: Eye, Orbital, Implant, Prosthesis, Rehabilitation

Introduction

Eye is a vital organ not only for function but also from an aesthetic point of view. Defects of eye can be classified as ocular or orbital defects which can be due to enucleation, evisceration and exenteration. These defects have aesthetic, psychological and physiological impact on the patient. Prosthetic rehabilitation of these defect often includes ocular and orbital prostheses.1 Acrylic ocular prosthesis can be stock or custom-made. Stock prosthesis are used for interim and post-operative purposes. Custom ocular prosthesis involves impression making of the affected socket and subsequently molding the scleral blank to achieve excellent adaptation with tissues.2 Custom ocular prosthesis has several advantages which include better eyelid movements, reduced incidence of ulceration, improved fit, better comfort, improved facial contours, and enhanced aesthetics gained from the control over the size of the iris, pupil and colour of the iris and sclera.3

Case Report

A 26-year-old male patient reported to the Department of Prosthodontics with the chief complaint of a non-motile artificial eye in his right socket (Figure 1). He lost his right eye in a road traffic accident a year ago and has been wearing the scleral shell prosthesis ever since. Examination revealed enucleation of the right eye with a healthy socket mucosa. Evaluation of the socket depth was deemed sufficient to retain an acrylic orbital implant followed by a scleral shell prosthesis for optimal fit and aesthetics. The Ophthalmologist then carried out the peritomy surgery by opening the conjunctival sac and tenon’s capsule under local anaesthesia and placement of the 18 mm acrylic implant(Figure 2). The conjunctival sac was then closed with 5-0 vicryl sutures. The eye was then patched up and post operative antibiotic coverage was prescribed.

The patient was then recalled after an 8 week period for the fabrication of the ocular prosthesis.
On examination after 8 weeks, the post operative healing was deemed satisfactory and there were no signs of implant extrusion. The patient was then prepped for the impression procedure for the ocular prosthesis.

Petroleum jelly was applied to the eyebrow, eyelashes and skin around the socket to prevent impression material from sticking to them. A thin mix of alginate impression material was mixed and loaded in a 2 ml plastic disposable syringe. Impression material was slowly injected into the socket. The impression was carefully removed from the socket and checked for any air bubbles. The impression was separated from syringe and invested in type III gypsum stone to make a two-part mold. Molten wax was poured in this mold to obtain the scleral wax pattern. It was tried in the patient and checked for proper contour and retention while performing the various eye movements. For iris positioning, the patient was asked to maintain a straight gaze at an object kept 6 feet away. Shade was selected as per the patient’s normal eye sclera. Flasking was done in a two-part metal flask followed by dewaxing, packing and curing. The retrieved prosthesis was trimmed, polished and inserted. Prior to insertion of the finished prosthesis, it was disinfected using 70% isopropyl alcohol and 0.2% chlorhexidine solution. After thoroughly cleaning the prosthesis with saline solution to prevent chemical irritation, it was inserted and checked for fit, contour, and movements (Figure 3).

Discussion:

Loss of eye has functional, aesthetic and psychological impact on the patient. Rehabilitation of such defects with ocular prosthesis can improve his/her physiological and psychological well-being. An ocular prosthesis should replicate correct gaze, shape, and colour of the natural eye. It should prevent collapse or loss of the shape of the lids, accumulation of fluid in the cavity and provides proper muscular action of the lids. A well-fabricated prosthesis not only restores function and aesthetics but also restore patient’s self-confidence and psychological health. 

2
After enucleation or evisceration, it is necessary to replace the lost volume in the orbit, which is a condition that was recognized since the beginning of the 20th century.4,5 The first orbital implants were produced by Mules in 1885, who used hollow glass spheres to restore the anophthalmic cavity volume. Subsequently, diverse materials were used to manufacture orbital implants; however, the advances in this field progressed relatively slowly until the 1940’s when various materials were suggested.6,7 The most successful were acrylic and silicone spheres, and the use of both has spread throughout the world. Acrylic and silicone implants are both smooth, non-porous, and non-integrated implants, which are inert and they cause little reaction in the host. These are still the most popular implants.8

A revolution in anophthalmic cavity reconstruction occurred when integrated implants emerged in the 1980s to improve the results obtained during anophthalmic cavity treatment, particularly in terms of the mobility of the external prosthesis.9

Unfortunately, many complications are associated with integrated implants. Rates of exposure and postoperative inflammation of integrated Hydroxyapatite implants range from 0% to 22%, while it is almost (0-7%) for acrylic and silicone implants.

Thus, the main reason for using integrated implants with a coupling system between the implants and external prosthesis was to improve mobility. However, numerous complications have been described, which are caused by dehiscence and the exposure of the implants, and they necessitate the removal or extrusion of the integrated implants. Therefore, the pegging system is rarely used at present. However, if pegging is not planned, there is no advantage in terms of mobility when using porous orbital implants instead of solid silicone and acrylic spheres.10

Previous studies provide no evidence that integrated implants are superior to non-integrated implants. The superiority of porous polyethylene has been reported but others note that porous polyethylene has the same rate of complications as other porous or non-porous implants.11

Several case reports indicate that complications have occurred with all of the different types of implants. Randomized studies and long-term follow-up are required to conclusively determine the performance of implants. Therefore, according to the current state-of-the-art and for the implants that exist in the market, it is possible to affirm that there is no ideal implant and that the integrated implants do not perform better than the non-integrated implant.12

An ideal orbital implant and surgical technique should yield excellent prosthesis motility and cosmesis, with very few complications. The technique includes choosing an appropriately sized implant, positioning the implant deeply in the orbit, meticulously closing the Tenon’s capsule over the implant, and securing the conjunctiva over the implant without tension.2

Size, shape, composition and cost determine the ideal type of implant. It must approximate the normal eye, occupy the excess orbital volume and must also be made of a material the body will not reject. Implant shape also plays a role in the mechanics of the prosthesis. It may be spherical or irregularly shaped (pyramidal, conical or egg shaped). We used the traditional spherical shaped implants to simulate the shape of the eyeball.1

Infection is less frequent with nonintegrated than the integrated implants because of the lack of pores which act as areas for potential complications.

The solid acrylic spheres are used commonly due to its low cost.1 The acrylic implant used here has improved the motility of the prosthesis to a great extent. We used the acrylic implant because of its inert properties, low cost and long history of use as an orbital implant.

Considering the Indian economic system and the socio economic status of Indian patients, the acrylic implant is definitely a poor man’s boon compared to the expensive porous implants with a very similar prosthetic motility.

Acknowledgement: I express my profound gratitude to Dr Ajay Kudva, Ophthalmologist at AJ Institute of Medical Sciences, Mangalore for the orbital implant placement.

Ethical Clearance obtained from Institutional Ethical committee, Manipal College of Dental Sciences, Mangalore.

Effect of Exercise Training Program in Pain, Muscle Strength and Functional Mobility in Post Cervical Decompression Surgeries

Kamble Jyotsna Prabhakar, Kanase Suraj B

1 Intern, Faculty of Physiotherapy, KIMSDU, Karad, Maharashtra, 2 Associate Professor, Department of Neurosciences

Abstract

Background: Cervical disease is caused by various factors like degeneration, disc protrusion. According to previous studies, there are 20 – 30% patients with cervical disc disease. There are various complications according to the level of lesions. Cervical disc diseases are the condition which affects the motor and sensory components of the body. This study specially emphasis on the sensory and motor components. This study focuses on the stage wise progression of the patient. The patients also have reduced functional ability. This study emphasis on the increasing the functional ability of the patients. Greater efficacy of rehabilitation can be brought about by early intervention for improving strength and increase sensory integration which might achieve activities of daily living goals.

Aim: To find the effect of exercise training program in patients with cervical decompression surgeries.

Methodology: There were 35 participants in the study. The type of study is experimental. The participants involved were assessed for strength, pain and functional mobility. The participants are treated for pain, strength and functional mobility.

Result: There is improvement seen in participants. The results of the participants are calculated by mean and standard deviation. The pre assessment is 56% and post assessment is 38% percentage for pain. The pre assessment is 1.74% and post assessment is 3.31% percentage for functional mobility. The pre assessment is 23.4% and post assessment is 50.8% percentage for right upper limb strength. The pre assessment is 23.2% and post assessment is 42.8% percentage for right lower limb strength. The pre assessment is 23.4% and post assessment is 48% percentage for left upper limb strength. The pre assessment is 23.4% and post assessment is 41.7% percentage for left lower limb strength. The pre assessment is 13.7% and post assessment is 42.8% percentage for trunk strength.

Conclusion: Structured exercises program effective in reducing pain and improving muscle strength and functional mobility in patients with post cervical decompression surgeries.

Keywords: Cervical decompression surgeries, physiotherapy, pain, strength, functional mobility

Introduction

Spinal cord diseases are the conditions were it actually affects the entire body in one or the other way. There is a classification of spinal cord diseases. Diseases are classified on the basis of compressive, vascular, inflammatory, infective, inflammatory, developmental, metabolic, congenital, degenerative, traumatic. Spinal
cord diseases can either cause quadriplegia or paraplegia. Complete lesion is in which all sensations and motor fibers below the level of lesions is lacking\textsuperscript{1}.

According to a survey it has been reported that cervical spine is injured in 2.4\% of blunt trauma victims\textsuperscript{2}. Classification systems have been developed in an attempt to predict instability, standardize the discussion of injury types and provide a means for applying a consistent approach to these injuries\textsuperscript{2}. These are divided into upper cervical spine and sub axial cervical spine\textsuperscript{1,2}. Cervical injury includes cervical disc degeneration, fracture at the cervical region, any neurological problems with nerve compression\textsuperscript{2}.

Cervical decompression surgery is a procedure that removes any structure compressing the nerves in neck\textsuperscript{3}. There are various sub types in cervical decompression surgeries\textsuperscript{3,4}. ACDF includes removal of cervical disc from an anterior approach and then decompresses the nerve\textsuperscript{24,21}. Posterior cervical decompression surgery enlarges spinal canal area, allowing the spinal canal to drift away from ventral compression, however, while doing this it also destabilizes the dorsal structures and can lead to progressive kyphotic deformity\textsuperscript{4,12}. Anterior decompression includes anterior cervical corpectomy\textsuperscript{16,17}. Posterior decompression includes laminoplasty and laminectomy\textsuperscript{3,4}.

Secondary complications are pain, weakness, loss of mobility, reduced range of motion, loss of doing functional activities etc\textsuperscript{4}. Strength of the patient is the most important and the basic requirement for the recovery of the patient\textsuperscript{26}. Strength in turn takes further part in improving range of motion and also to improve the functional mobility\textsuperscript{5}. Functional capacity is to act on, influence or change the surrounding environment has been studied as one important aspect of late adulthood and elderly life\textsuperscript{14}. The functional mobility is related to the physical activity\textsuperscript{5}. Joint range of motion and soft tissue flexibility are important elements of motor function\textsuperscript{5}. Limitation restricts the normal coordinated action of muscles and alter biomechanical alignment of body segments and posture\textsuperscript{6}. The resultant compensatory movement patterns are frequently dysfunctional, producing additional stresses and strain on musculoskeletal system\textsuperscript{6,7}. They do cost more energy consumption and can limit functional mobility\textsuperscript{8}. These are the problems which are to be treated for the betterment of the people. So that the individual should regain their mobility, increases range of motion, increases their strength, activities of daily living and return to the normal living\textsuperscript{10}.

Improvements in performance results from an understanding the task and practice and a frequently used measure of learning\textsuperscript{7}. Resistance exercise has been shown to be safe and effective method for improving strength and additional it improves cardiovascular endurance. A detailed, accurate, and specific determination of functional skills is usually delayed until the active rehabilitation stage when the patient is medically stable and cleared for activity. There are certain exercises given for the patients with pain, muscle weakness and less functional mobility\textsuperscript{8,22}.

In the project there are exercises which focuses on improving pain, muscle and functional mobility. For pain, the patient is treated with transcutaneous electrical stimulation and also ice\textsuperscript{8,25}. Active exercises for neck to reduce pain\textsuperscript{13,20}. Before starting the exercise the patient is started with stimulation. After this the patient is started with passive movement\textsuperscript{9}. This improves the range of motion. As the patient starts the regaining the range, the patient is started with strength training with the weight cuffs, elastic band\textsuperscript{18}. As the patient starts regaining the range and improving strength, the patient also starts get trained for functional mobility\textsuperscript{23}.

There are various studies on cervical decompression surgeries, where there has been treated with pain, muscle strength, range of motion, functional mobility\textsuperscript{15}. But these are treated with the separate aspect\textsuperscript{11}. And many times, the condition does not emphasis on functional training as soon as the muscle strength is gained. But to emphasis on the functional mobility is as important as training muscle strength. Specific trunk exercises including strengthening and conventional have been found to improve strength in paraplegia individuals\textsuperscript{27}. There is no combined structured exercises for treatment. There is a need to emphasis on the complication as a whole and a need to have structured exercise program for the improvement so that the patient gets back to the work as soon as possible\textsuperscript{19}. So the study focuses on the structured exercise program for cervical decompression surgeries. This study is to evaluate the effect of these structured exercise has improvement on pain, muscle strength and functional mobility.

**Material and Method**

There were 35 participants in the study. The study was taken place in Krishna institute of medical sciences.
The study is effect of exercises training program on pain, muscle strength and functional mobility in post cervical decompression surgeries. The treatment protocol was of 6 weeks. The participants were assessed for pain, strength and functional mobility at first. The type of the study is experimental study. Sample size was calculated by the formula $4pq/l^2$. Inclusion criteria is post-operative cervical decompression surgery patients, patients with sensory and motor impairments, age group above 40-60 years. Exclusion criteria is history of previous fracture, spinal infections, post-operative infection and previous spondylodiscitis. Outcome measure used for pain is visual analogue scale, for strength is manual muscle testing and for functional mobility is functional independence measure scale.

**Findings**

The study was taken place in Krishna institute of medical sciences. The results were calculated by the pre and post assessment. The mean and SD were calculated. The significance of the study was calculated. The instat software was used to calculate all the results. The values are calculated by paired ‘t’ test. The P value for pain, muscle strength and functional mobility is <0.0001 which is extremely significant.

**Chart no. 1:** Pre and post changes in pain after cervical decompression surgeries.
Interpretation: the mean and SD of pre pain is less than post pain.

**Chart no. 2:** Pre and post changes in functional mobility after cervical decompression surgeries.
Interpretation: the mean and SD of pre functional mobility is more than post functional mobility.

**Chart no. 3:** Pre and post changes in strength of right upper and lower limb after cervical decompression surgeries.
Interpretation: the mean and SD of pre strength is more than post strength of right upper and lower limb.

**Chart no. 4:** Pre and post changes in left upper and lower limb after cervical decompression surgeries.
Interpretation: the mean and SD of pre strength is more than post strength of left upper and lower limb.
Discussion

The study topic is on effect of exercise training program on pain, muscle strength and functional mobility in post cervical decompression surgeries. The aim of the study is to determine effect of exercise training program on pain, muscle strength and functional mobility in post cervical decompression surgeries. The treatment was given by a fixed protocol. The study was taken place in Krishna institute of medical sciences. The number of participants included were 35. Female included in the study were 15 in number and male included were 20. The participants were taken according to the inclusion and exclusion criteria. The participants were assessed for pain, strength and functional mobility before the treatment. The appropriate treatment for improving pain, strength and functional mobility is given. Treatment protocol was for 6 weeks. A consent was taken by the participants before the treatment. After the treatment again the assessment is taken.

There are various studies on the cervical decompression surgeries. According to a study by author AnneliPeolsson, which was on outcome of physiotherapy on cervical disc disease stated that there are better results of physiotherapy. This study supports the study as the outcome of the study is beneficial for the participants.1

To reduce pain icing is applied. To initiate movements of limbs passive movements are given, followed by active assisted movements then active movements along with electrical stimulation is given. To strengthen the limb, weights and elastic bands are used. And to improve functional mobility bed mobility and gait training is given.

In patients with cervical decompression patients, the intervention strategies selected is largely based on amount of preserved motor function. The pain of the participants is reduced by using ice. Ice is used to reduce pain, as it involves stimulation of cold receptors which passes into the spinal cord via posterior root and effectively blocks pain. Electrical stimulation stimulates the motor nerve. As the muscle contracts due to stimulation, the changes take place similar to those associated with voluntary contraction. The strength of the participants is improved by strength training program. It increases the production of maximal force due to changes in neural drive, increases connective tissue tensile strength, bone mineral density and improve functional performance and activity level.

Functional mobility of the participants is improved. For functional mobility bed mobility was included. This is because functional mobility training represents a shift away from some conventional rehabilitation approaches that utilize an extensive hand on approach to promote recovery. As the strength of the lower limb is regained, gait of the participants is improved. Gait is improved by using parallel bars progressing to the without support of walking. Then followed by stair climbing.

Conclusion

Structured exercises program is effective in reducing pain and improving muscle strength and functional mobility in patients with post cervical decompressionsurgery.

A Study on Bio-Medical waste Segregation Monitoring in a Tertiary Care Hospital at Telangana

Sachin Suresh Shinde¹, Kishore Babu Marivina², Shalini³
¹Research Scholar, KL University, Vijayawada, ²Professor & Principal-College of Management, KLEF, Vijayawada (AP), ³Research Scholar, KL University, Vijayawada

Abstract

The most appropriate way of identifying the categories of healthcare waste is by sorting the waste into color-coded plastic bags or containers.¹,² Since early recovery of patients and health of clinical staff directly depends on a clean and hygienic environment, excellent hygiene practices in health care facilities are the prerequisite for good medical waste management.³

Objective: Aim of this study is to see effectiveness of segregation practiced in the hospital and establish a monitoring system to monitor deficiencies in segregation.

Method: This cross sectional study conducted during the period of June to August 2012 in a tertiary care Hospital. Eighty Two (82) areas were identified as BMW generation area. As per the norms segregation was done in four different color coded containers. So, total segregation containers will be 82X4=328. Any mix up or wrong segregation will be noted in the register daily by the Infection Control Nurse. A Monthly report based on BMW Register was developed.

Results: The index named as Bio-Medical Waste Segregation Deficiency index (BMWSD index), calculated as number of deficiencies found in a area/areas divided by the possible number of deficiencies can occur in that area/areas. Daily data then entered into the Monthly report and monthly BMWSD index was made. Though this is a continuous process, for this study three months data (June, July and August 2012) were taken for analysis.

Discussion: In this Cross sectional study, it was found that there was a over all deterioration in segregation of BMW when compare to June, July and August reports. The areas with high BMWSD index or where segregation is poor will be reflected through this monitoring system.

Conclusion: This BMWSD index can be used as an indicator of Infection control Practice. This report is to identify the deficiency areas in the entire hospital in BMW segregation, which can be used for analysis and planning for better BMW Management like, training of the staffs of particular units, modification in methods etc.

Introduction

Bio-Medical Waste (BMW) Segregation is one of the most important steps to successfully manage Hospital Waste. Given the fact that only about 10-20% of the hospital waste is hazardous. Treatment and disposal costs could be greatly reduced if a proper segregation were performed. Segmenting BMW from Hospital
waste reduces also greatly the risks of infecting workers handling hospital waste and can be reduced to 2-5% if the hazardous part were immediately separated from the other waste. But, if 1% of the biomedical waste is mixed with the general waste, the whole becomes biomedical waste! Liquid wastes in particular. A worst case scenario of BMW management is in developing countries. 1,2,3 Hospital waste management is a part of hospital hygiene and maintenance activities. World Health Organization4 also states that 85% of hospital wastes are actually non-hazardous, whereas 10% are infectious and 5% are non-infectious but they are included in hazardous wastes. This range is dependent on the total amount of waste generated 5. Since the infectious waste gets mixed with municipal solid waste, it has potential to make the whole lot infectious in adverse environmental conditions6 The hazardous waste is a potential reservoir of the infection and diseases in patients are transmitted through it 7. The key to minimization and effective management of biomedical waste is segregation (separation) and identification of the waste. Since early recovery of patients and health of clinical staff directly depends on a clean and hygienic environment, excellent hygiene practices in health care facilities are the prerequisite for good medical waste management 8.

**Review of Literature**

Bio-medical waste classified as per WHO in nine different categories which includes Radioactive waste. 9,10 But as per Bio-medical Waste (Management and Handling) Rules, 1998; waste are classified into ten different categories without mentioning Radioactive waste.9 Based on Schedule I (Rule 4 and 7) Draft BMW Rules, 2011; Bio- Medical Waste were categorized into eight categories excluding Liquid waste and Incineration ash from 1998 rules. The Kuwaiti Environmental Public Authorities (KEPA) 20 divided the health waste into two categories: Non-hazardous and Hazardous. In few other literatures 11, 12, 13, 14, waste was classified into two namely, contaminated and non-contaminated waste. The unified medical system of the Gulf Cooperation Council Countries, 15 classified hospital waste into eight categories including Radioactive waste and Pressurized gas containers. Another source 16 categorizes the healthcare waste into seven types including radioactive waste and general waste. Total BMW volume generated in the hospitals is 611.5Kg/per day and 18345Kg / per month as found in all the surveyed hospitals in Lagos Metropolis in Nigeria. 17 According to Manyele (2006) 18, BMW generation is high and is increasing in Tanzania reaching up 0.75Kg/bed per day on average. Hospitals generate up to around 8 kg of waste per bed per day in USA, if not properly managed 19. Table shows the average quantity generated by various countries 20, 21, 22, 23,24.

<table>

</tr>
</tbody>
</table>

In a study 26 at Bangalore, India, found that solid waste generated from hospitals and nursing homes generally varies from ½ kg to 4 kg per bed per day in Govt. hospitals, ½ to2 kg per bed per day in Private hospitals, and ½ to 1 kg per bed per day in Nursing homes. Total quantity of hospital waste generated at Bangalore about 40 tons per day; out of it 45-50% infectious waste and segregation of BMW done in only 30% of hospitals 9, 26, 27. Based on hazard Hospital Waste in India can be divided as given in Table.

**Table 2: The basic types of the Hospital wastes in India.**

<td>15%</td>
</tr>
<tr>
<td>Hazardous but not infective</td>
<td>05%</td>
</tr>
<tr>
<td>Hazardous and infective</td>
<td>10%</td>
</tr>
</tbody>
</table>

Another study also says that 80% of the hospital waste are of generated waste and rest of the hospital wastes requiring specific management.28 The approximate chemical composition of health-care waste shows 50% carbon, 20% Oxygen, 6% Hydrogen and rest other elements. 29

The Segregation processes should: 30 Always take place at the source,
Be simple to implement and applied uniformly throughout the hospital;

Be safe and guaranty the absence of mixing in the domestic waste flow;

Be well understood and well known by the staff of the hospitals;

Be regularly monitored to ensure that the procedures are respected.

Mutilation / shredding must be such so as to prevent unauthorized reuse.31

**Indian BMW Legislation Status**

First law related to Bio-Medical Waste, is “The Bio-Medical Waste (management and Handling) Rules, 1998”.9 By this law India is become the one of the country having legal regulation regarding BMW. The said law is in the vicinity of Ministry of Forest and Environment, and executed through Pollution Control Board (PCB). The law has been amended twice in 2000 and 2003.9 A draft Rule has been formulated in 2011.

**Objective**

Aim of this study is to see how effective segregation practiced in the hospital under study. Also, to establish a monitoring system, that can pick up deficiencies in segregation properly and easily and segregation practice can be improved.

**Method**

This cross sectional study conducted during the period of June to August 2012 in a tertiary care super specialty hospital in the major towns of the state of Telangana. Through out the Hospital Eighty Two (82) areas were identified as BMW generation area. As per the norms segregation was done in four different color coded containers. So, total segregation containers will be 82X4=328. Any mix up or wrong segragation will be noted in the register daily by the Infection Control Nurse. A Monthly report based on BMW Register was developed. This report is to identify the deficiency areas in the entire hospital in BMW segregation, which can be used for analysis and planning for better BMW Management like, training of the staffs of particular units, modification in methods etc.

**Results**

Daily Infection Control Nurse, document any deviation in the segregation of BMW as per Rules, in those 328 containers. For every day and for each area a index has made for comparison with other areas and for subsequent future comparison. The index is named as Bio-Medical Waste Segregation Deficiency index (BMWSD index). The index is calculated as number of deficiencies found in a area/areas divided by the possible number of deficiencies can occur in that area/areas. Daily data then entered into the Monthly report and monthly BMWSD index was made. Though this is a continuous process, for this study three months data (June, July and August 2012) were taken for analysis.

First Top ten (10) areas with descending order of BMWSD index is shown in the below table.

Along with these, at a glance different area performing poorly will be identified and the probable reasons for the loopholes were searched through the interview with the corresponding unit in-charges and local observations listed at end. This will help to take necessary Corrective and Preventive Actions (CAPA).

**DISCUSSIONS:**

In this Cross sectional study, it was found that there was a deterioration in segregation of BMW when compare to June, July and August reports. This shows a gradual deterioration in BMW segregation. The BMW segregation (BMWSD) index of overall Hospital was increase in July (1.219) as compared to June (1.138) and again goes down in August (1.180) but still higher than June 2012. Which means the BMW segregation was good at in June but deteriorates in July and again improves a little in August as shown in Figure 1. In terms of generation areas, Casualty/ER shows a continuous improvement in segregation of BMW Management. BMWSD index in June (10) to in July (9.67) to in August (9.45). Similarly, in the generation area of 2nd C there is a deterioration in BMW segregation in July (6.45) as compare to June (3.33) and again improve in August (3.2). Also it can be seen that in the generation areas of 9th C, there was improvement in segregation of BMW (from 6.6 to 6.45) and in Sample Collection -I there was constant deterioration in BMW segregation (from July to August at 3.22).

Though only three months data has been taken for analysis, it is a continuous process. The areas with high BMWSD index or where segregation is poor will be reflected through this monitoring system. As shown in above in casualty/ER for the month of June (BMWSD -10) was high which after training the staff is gone down in August (BMWSD - 9.45).

**Conclusions**

Segregation of BMW is the prime and first step in the Bio Medical Waste Management. This study revealed that the BMW management requires proper monitoring for an effective tracking at all times. This BMWSD index can be used as an indicator of Infection control Practice. Control means that competent authorities can act rapidly to ensure the possibilities of minimizing inappropriate handling and segregation of BMW. Also there is an immediate need to train all handlers of BMW.
on methods and new techniques to adopt in effective waste management practices using WHO manual and Personal Protective Equipment (PPE). Furthermore, they should also be trained on how to make proper use of these PPE.

**Recommendations**

We recommend the following suggestions to improve BMW management service in this hospital under study from the point of view of Monitoring study of BMW segregation:

More Strict supervision and surveillance to be followed in day to day BMW management activities.

Intensive training and displayed information regarding risk associated to BMW on BMW at regular interval and also at the time of joining to all staff emphasizing the importance of segregation.

Effectiveness of Open Kinematic Chain Exercises and Closed Kinematic Chain Exercises in Adductor Groin Pain in Recreational Football Players

Raghavendra Sunilkumar Pandey¹, Trupti Yadav², Amrutkuvar Rayjade³, Radhika Chintamani⁴, Apoorva Kolhatkar⁵

¹Intern, Faculty of Physiotherapy, ²Assistant professor of Department of Musculoskeletal Sciences, Faculty of Physiotherapy, ³Associate professor of Department of Orthopaedic Manual Therapy, Faculty of Physiotherapy, ⁴Assistant professor of Department of Musculoskeletal Sciences, Faculty of Physiotherapy, ⁵Intern, Faculty of Physiotherapy, KIMS “Deemed to Be University” Karad, Maharashtra, India

Abstract

Background: Football has been growing considerably for the past decade in India. Many young adults have taken up football as their passion. However, the grounds are underdeveloped with limited number of facilities required for a safe game. Coaching facilities are inadequate and thus fail to provide basic information about the precautions to be taken during play or the necessary steps to be taken post injury. This leads to increased risk of injuries. Groin injuries comprise of 10-18% of all football injuries.

Objective: The objective of the study was to compare the effects of open and CKC exercises on groin injuries in young adults who play football for recreation. Pain Assessment, Tenderness assessment and MMT were used for assessing the individuals.

Method: There were total 40 subjects who were willing participants of this study of which 3 dropped out. This was a study conducted to find the effects of open and CKC exercises on groin injuries in young adults who play football for recreation. Here we evaluated the pain using VAS and tenderness grading. Muscle strength was assessed using MMT.

Result: There was a significant effect of open and CKC exercises on groin injuries. There was a reduction of pain; both on activity as well as on resistance (p=0.0065 and 0.0235) respectively. Tenderness was also less (p= 0.0130). Muscle strength did not show any significant change (p= 0.1775)

Conclusion: There is a significant effect of OKC and CKC exercises being administered together rather than giving only CKC exercises on reducing pain and reducing the risk of injuries in recreational football players.

Key Words: Recreational, Football, Groin Injury, Pain, Tenderness, MMT.

Introduction

Football is a sport that has been widely accepted in our country. Many young adults have taken up this sport. However most of the players only play for recreation. Such recreational players are those who play only for enjoyment and not to compete in any leagues.¹

The term ‘adductor related groin pain’ first originated in the literature in 1997.

Groin injuries are defined as any physical symptom in the groin related to participation in soccer training or match play, incapacitating the player while playing soccer or demanding special medical attention.²

Correspondence:

Groin injuries occur most commonly in non-contact situations (71%). Here, a rapid muscle contraction during rapid muscle lengthening is the fundamental mechanism. A quick reaction to a change in play, such as sudden change in direction, running, kicking etc. were the common modes of injury.6

Groin injuries make up 2-5% of all sports-induced injuries and 10-18% of all football injuries.

Prevalence of groin injuries in male cub football is 4-19% of all injuries. It was reported in 2002, that about 9.5% of all male football players had groin injuries.4,7

Despite groin injury being one of the most prevalent injuries in soccer, it poses a great amount of trouble to a sports physiotherapist. They are extremely difficult to treat, often presenting with long term symptoms8,9, unclear prognosis8, long period of absence10 from play and a high rate of recurrence11. This is further added to, by a lack of knowledge among the population about how to approach this subject as it can be a sensitive topic for some. Thus many players just ignore the symptoms which leads to worsening of the symptoms overtime making it more difficult to treat groin injuries.

The treatment of choice for groin injury is physiotherapy.10 Many forms of therapeutic exercise are chosen as treatment for groin injury, of which OKC and CKC exercises are frequently used.

OKC exercises are non-weight bearing exercises as they involve movement around a single joint. The distal segment is the focus of these exercises. This segment is free to move and also resistance is applied here. An example for the same is when resistance is applied over the ankle in seated knee extension. There is sequential activation of muscles, from proximal to distal, allowing rapid acceleration and speed of movement.12,13

CKC exercises are generally weight bearing. Here movement occurs at several joints and no joint is really free to move. Both the distal and the proximal joints are fixed and resistance is applied. Resistance can be applied to both the proximal and/or the distal segment. An example of this is a squat. These exercises imbibe early stability in the proximal joint.12,13

A review of various studies shows that the optimal treatment for long standing adductor groin injury is therapeutic exercise.8,9,10,11,14 A study by Hölmich et al. (1999), concluded that hip and abdominal strengthening exercises along with physiotherapy such as laser therapy, TENS, stretching and transverse friction massage lead to better pain reduction and quicker return to sports.8,9,15 However in Hölmich’s study, the average time taken from the beginning of the treatment to the subject’s return to sport was approximately 18.5 weeks. Unfortunately, such a long duration of recovery is not feasible for an athlete, especially elite as there is a lot of pressure on them to return back to their sports in the shortest period of time possible.13,16,18

Hence, it is necessary to create an exercise protocol that will benefit these recreational players and will in turn improve their performance and reduce their risk of injury.

Methodology

Included participants were divided in 2 groups (group A and group B) by convenience sampling method. Group A consisted of 19 players and group B consisted of 18 players. Demographic data was acquired. They were explained the purpose of the study. Pre and post assessment was taken with the help of the outcome measures.

Procedure

Group A received ckc and okc exercises 4 times a week for 5 weeks.

For the 1st and 2nd week leg press, squats with medicine ball between the legs, lunges, side-lunges, Resisted seated hip adduction, Resisted standing hip abduction, Resisted standing hip adduction, Supine leg abduction adduction and Resisted side lying hip adduction for 10 repetitions for a 5 sets. For the 3rd and 4th week they were for 20 repetitions for 5 sets. For the 5th week they were for 30 repetitions for 5 sets.

Group B received ckc exercises 4 times a week for 5 weeks.

For the 1st and 2nd week leg press, squats with medicine ball between the legs, lunges, side-lunges, for 10 repetitions for 5 sets. For the 3rd and 4th week they were for 20 repetitions for 5 sets. For the 5th week they were for 30 repetitions for 5 sets.

**Interpretation:** Table no. 5 shows the association between outcome measures pre and post treatment

**Discussion**

Pain assessment was used to note the severity of groin pain in all the participants. The discomfort or pain experienced by the players was divided into 2 categories; pain on activity and pain on resistance. Pain was assessed both before and after completion of the treatment protocol.

Intra-group association was studied using Wilcoxon signed ranks test for VAS and Paired t-test for tenderness and MMT. The results of current study indicate that the changes in groin pain observed from week 1 to week 5 after administering treatment for groin injury differed significantly in groups trained using OKC and CKC exercises versus only CKC exercises. Pain on activity and on resistance within group A post intervention had a p-value of <0.0001 whereas in group B the reduction in pain on resistance was not as significant; seen by the p-value of 0.0039 (VS).

Tenderness was assessed by palpation of the groin pre and post intervention. There was a more significant reduction in tenderness within group A after treatment compared to group B as seen by the p-value of <0.0003 (ES) and 0.0020 (VS) respectively.

MMT was checked by resisting adduction of the hip pre and post intervention. MMT grades again showed a better result within group A compared to group B having a p-value of 0.0204 (S) and 0.1628 (NS).

Thus, the intra-group results following treatment showed to be more significant for group A as compared to group B in terms of reducing pain, tenderness and improving strength.
Also, inter-group comparison between the results of group A and group B was done by Mann-Whitney test for VAS and Unpaired t-test for tenderness and MMT, which proved that the difference in the outcomes of group A and group B was significant, thus confirming that administration of both OKC and CKC exercises together had a better result than administration of CKC exercises only. This is confirmed by the p-value of 0.0065(VS) for pain on activity, 0.0235(S) for pain on resistance, 0.0130(S) for tenderness and 0.0774(NQS) for muscle strength.

Similar studies previously, have showed results supporting our study. A study conducted by Mikkelsen C, Werner S, Eriksson E. investigated the effect of CKC quadriceps rehabilitation versus the same program with addition of OKC exercises following ACL reconstruction on anterior knee laxity and isokinetic muscle torque. They concluded that the addition of OKC quadriceps training after ACL reconstruction results in a significantly better improvement in quadriceps torque without reducing knee joint stability at 6 months and also leads to a significantly higher number of athletes returning to their previous activity earlier and at the same level as before injury.  

When performing OKC exercises, the movement causes a rotatory stress on the joint. Also, they focus on a single muscle group. Thus, a combination of OKC and CKC exercises are better because of use of isokinetic training, which allows specific eccentric loading. Since, most of the movement occurring at the hip in football players is rotatory, leading to groin injury, this may be why addition of OKC exercises to the standard CKC exercises improves groin injury significantly.

Another study by Tagesson S, Öberg B, Good L, Kvist J assessed the impact of a CKC protocol versus that of a OKC protocol on knee pain in subjects post-ACL reconstruction. They concluded that people with ACL deficiency may need addition of OKC exercises to improve quadriceps torque.

OKC exercises have certain biomechanical advantages such as an increase in the rotational forces as well as an increase in the concentric acceleration and eccentric deceleration forces. This leads to a faster increase in muscle strength which is supplemental to CKC exercises in rehabilitation post injury. Hence, this may be a reason for greater improvement in those who received both OKC and CKC exercises.

There are numerous possible reasons for our results. It is important to first keep in mind all the sources of groin pain during the rehabilitation period. Various sources of pain will react differently to our treatment. As we know, the main muscle injured in adductor type of groin injury is the adductor longus. The main movement during OKC activation is hip adduction whereas during CKC activation it acts as a pelvis stabilizer, lower extremity stabilizer during the stance phase and also as a secondary hip rotator. Administration of both OKC and CKC exercises is therefore necessary as the muscles are trained in both the phases of activation separately. This improves the stability and strength of the adductors and the surrounding ligaments leading to a reduction in pain which is comparatively greater than the effect of administration of CKC exercises only.

During the phases of kicking a ball, according to Charnock BL et al, the adductor longus remains at a risk of injury for around 65% of the swing phase. Also, its maximal co traction is seen during the initial 455 of the swing phase and then lengthening occurs. The OKC and CKC exercises administered in our study cover the entire range of a football kick. This improves the strength of the muscles during the kicking motion thus reducing the risk of injury.

Thus, from the above mentioned effects of OKC and CKC exercises being administered together, we can state that they are more effective when administered together than just CKC exercises.

Conclusion

On the basis of the results of the study, it was concluded that there is a significant effect of OKC and CKC exercises being administered together rather than giving only CKC exercises in recreational football players.

Self Care Practices among Hypertensive Patients with the View to Develop Informational Pamphlet

Priyanka Mohan Mali¹, Mahesh B. Chendake², Samir K. Choudhari³
¹Final Year B.B.sc. Nursing, ²Associate Professor, ³Clinical Instructor, Krishna Institute of Nursing Sciences, Karad

Abstract

Background: Hypertension is condition approximately 25% affecting to adult population worldwide. Hypertension is said to be most common health problem all over the world. Prevalence of hypertension in India was 29.8%.

Objective: study investigated the effectiveness of Informational Pamphlet on Self Care Practices among Hypertensive Patients.

Method: One group pretest posttest design was used to conduct the study among hypertensive patients totally 60 patients were selected by Purposive sampling technique. Study conducted at Krishna hospital Karad. Data was collected by using structured questionnaire. Pre-test was conducted to assess the existing knowledge of self care practices regarding hypertension. Informational pamphlet was given to the patients then posttest level of knowledge was assessed by using same questionnaire.

Results: Results of the present study shows that in the pretest most of the samples were having average knowledge (70%) regarding self care practices regarding hypertension and in postest majority (99.66%) were having good knowledge. The pretets mean was 12.08 and post-test mean was 18.78 and calculated t value was 6.70 found significant at the level of p<0.0001.

Conclusion: Study concluded that information pamphlet was found effective to improve the Knowledge regarding self care practices among hypertensive patients.

Keywords: Self Care Practices, Hypertensive Patients and Informational Pamphlet

Introduction

Hypertension (HTN) or high blood pressure, also called arterial hypertension, is a chronic and common medical condition peoples often suffer. A person with HTN in which the blood pressure in arteries is elevated. High blood pressure is present if blood pressures range at or above 140/90 mm Hg.¹ Cardiovascular diseases are the most common causes of mortality and morbidity in both developed and developing countries.² Hypertension is condition approximately 25% affecting to adult population worldwide.³ Hypertension is said to be most common health problem all over the world. Prevalence of hypertension in India was 29.8%. The patients with stroke 57% deaths and 24% of all coronary heart disease (CHD) deaths in India due to the cause of Hypertension.⁴

In another studies it is estimated that about 31.1% of the world adult population living with hypertension, and 28.5% are in high-income countries while 31.5% are in low-and middle-income countries.⁵ Hypertension is responsible for risk factor for renal and eye diseases.⁶ Increasing awareness regarding hypertension and more effective treatment of patients with hypertension is the main focus of primary prevention of cardiovascular diseases.⁷ Management of hypertension relies on patient’s level of understanding of their condition and treatment and lifestyle changes and pharmacological treatment.⁸

Various studies have confirmed that the self-care practices are important for blood pressure control and reduction of further hypertension complications of cardiovascular and renal diseases. Most of the
hypertensive patients many times do not implement self-care practices and in the end they suffer from uncontrolled blood pressure. Self-care practice regarding hypertension includes medication taking at proper time, consumption of low-sodium and low-fat diet, exercise regularly, less alcohol drinking, not smoking, weight reduction, self-monitoring blood pressure, regular follow-up, and management of stress. In self-care programs, patients become aware about their own health conation, aware about when they need care, and gain adequate knowledge regarding the mode of treatment. Patients are able to monitor their symptoms and they do in time routine examinations without needing to refer to their physician. Health professionals can play a critical role in training general population about self-care activities.

Many of people in India ignore the symptoms like hypertension. Because of the ignorance and their lifestyle, in future they faces problems like acute myocardial infarction, angina pectoris, parallelize stroke, coronary thrombosis etc. and they get hospitalized. Then they realize, the present condition is due to the ignorance of small symptoms which were early observed. Thus it is very important to diagnose the early symptoms to avoid letter complication. Despite of different treatment & lifestyle intervention optimal control of BP remains challenge for many patients. Effective management of HTN depends on patient understanding of their condition & treatment and adherence to lifestyle & pharmacological treatments. Effective patient education material is feasible and widely transferable first step in promoting this goal. Thus the pamphlet should provide information reflecting the latest HTN guideline to provide a better quality life.

**Method**

One group pretest posttest desing was used to conduct the study among hypertensive patients totally 60 patients were selected by Purposive sampling technique. The samples included in this study were who fulfilled the inclusion criteria with who were willing to participate in the study, those who were suffering from hypertension and able to read and understand Marathi language Ethical permission was obtained before the data collection. After obtaining permission from the setting, the patients were asked their willingness to participate in the study and informed consent was obtained. Study conducted at Krishna hospital Karad. Data was collected by using structured questionnaire. Pre-test was conducted to assess the existing knowledge of self care practices regarding hypertension. Informational pamphlet was given to the patients then posttest level of knowledge was assessed by using same questionnaire.

**Statistical analysis used:** To compare the two means Paired t test was used and to find out association between demographic variables and pretest knowledge score Chi Square test was used.

**Results**

**Description of sample characteristics:**

Maximum number 25(41.66%) of Samples belongs to the age group of 46-60 years, 19(31.66%) Samples belong to the age group of 61-75 years. Majority of Samples 39(65%) belongs to male gender group and 21(35%) A sample belongs to female gender group. Maximum number of Samples 25(41.66%) belongs to secondary education, 18(30%) Samples belong to graduate education. Majority number of Samples 49 (81.66%) belongs to Hindu religion, 6 (10%) belongs to Christian religion, 3(5%) belongs to Muslim religion. 

Majority of Samples 40(66.66%) belongs to rural area, 20(33.33%) belongs to urban area. 

Maximum number of Samples 39(65%) belongs to their income of less than Rs.10000. Majority of Samples 22(36.66%) belongs to housewife, 17(28.33%) were doing job Maximum number of samples 60(100%) had got the information regarding their disease from the book.

**Knowledge of self care Practices among Hypertensive patients:**

Graph no.1 shows that majority of the samples (70%) had average knowledge level, (21.66%) had good knowledge level, (8.33%) had poor knowledge level in pretest whereas in the postest majority of the samples (99.66%) had good knowledge level, (3.33%) had average knowledge level, (0%) had poor knowledge regarding self care Practices.

**Effectiveness of Informational Pamphlet on Knowledge Regarding Self-Care of Hypertension:**

Table no. 1 shows that the mean and standard deviation of knowledge score obtained before and after the administering the Informational Pamphlet. This is considered to be extremely significant improvement in knowledge regarding self care practices. The pre-
The test mean was 12.08 and post-test mean was 18.78 and calculated t value was 6.70 found significant at the level of p<0.0001.

The association between pre-test knowledge score and selected demographic variables:

Table no.2 shows the association of pre-test knowledge level of hypertensive patients with their selected demographic variables, using chi square test. There was no significant association found between the knowledge level of hypertensive patients with Age of (2.923), Gender (0.2177), Residence (5.136), & Occupation (10.970). There was significance association between Education (19.627), Religion (16.244), and Monthly income (17.284).

**Discussion**

Results of the present study shows that in the pretest most of the samples were having average knowledge (70%) regarding self care practices regarding hypertension and in postest majority (99.66%) were having good knowledge. The pretets mean was 12.08 and post-test mean was 18.78 and calculated t value was 6.70 found significant at the level of p<0.0001.

There was significance association between Education
Religion and Monthly income with knowledge score at the level of p<0.05. The findings of different studies also indicate that self care practices were improved after providing education to the patients. a study conducted by Babaee Beigi MA et al. the mean knowledge scores improved from 2.77 ± 2.7 to 7.99 ± 1.78 after 3 months (P < 0.001). Also, the mean lifestyle scores changed from 3.15 ± 1.52 to 4.53 ± 1.23 (P < 0.001) the study indicated that the educational programs were effective in increasing knowledge, improving self-management, and controlling detrimental lifestyle habits of the patients with hypertension.13 Study conducted by Ademe S et al. the mean score for hypertension self-care was 37.7±8.2 and 51% scored below the mean. Divorced participants (AOR=0.115, 95% CI=0.026, 0.508, p-value<0.01) and those who lack source of information (AOR=0.084, 95% CI=0.022, 0.322, p-value<0.01) were less likely to have good self-care practice. Most of the study participants reported poor self-care practices.14 The education to the patient with hypertension is such a important factor to improve their self care practices related to the hypertension and it will help them to prevent further complications.

Conclusion

Based on the analysis of the findings, the study concluded that information pamphlet was found effective to improve the Knowledge regarding self care practices among hypertensive patients.

To Determine Tobacco Usage and Associated Risk Factors among Adolescents- A Survey

Sangamesh NC1, Vidya KC2, Atul Bhardwaj3, Jagadeesh KN4, Anuj Singh Parihar5

1Professor, Department of Oral Medicine & Radiology, 2Reader, Department of Oral & Maxillofacial Surgery, Kalinga Institute of Dental Sciences, KIIT University, Orissa, India, 3Senior Lecturer, Department of Prosthodontics, College of Dentistry, Majmaah University, Al-Majmaah, 11952, Saudi Arabia, 4Professor, Department of Prosthodontics and Implantology, Sree Siddhartha Dental College, Sree Siddhartha Academy of Higher Education, Tumkur, Karnataka, India, 5Reader, Department of Periodontics, Peoples Dental Academy, Bhopal, MP, India, 6Professor, Department of Orthodontics, Faculty of Dental Sciences, SGT University, Gurugram, Haryana, India

Abstract

Aim: To determine tobacco usage and associated factors among adolescents.

Material & Method: The present study was conducted on 1350 students age ranged 12- 17 years of age. Parameters such as type of school, type of tobacco use, type of family, grade, father occupation, mother occupation, monthly pocket money, history of parental use of tobacco and type of family was recorded.

Results: Age group 12-14 years had 780 and 15-17 years had 570 subjects. Subjects were from private school in 890 and government in 460. Grade was 7th in 110, 8th in 230, 9th in 450 and 10th in 560 subjects. Family of subjects was nuclear in 960 and joint in 390. Father occupation was service in 362, farmer in 290, business in 446 and laborer in 252, mother occupation was housewife in 440 and working in 910, parental tobacco usage habit was present in 830 subjects. The difference was significant (P< 0.05).

Conclusion: Authors found that later age, male gender, nuclear family, monthly income >5000 per month, parental use and private school was predictor and risk factor of tobacco usage among school children.

Key words: Tobacco, nuclear family, occupation, Parental use, school children

Introduction

The tobacco use among the young population is on rise. It has been found that an average of 80 thousand to 1 lakh youth start smoking any time. Most of the youth start smoking before 18 years of age.1

Chronic tobacco usage can be credited to sudden immature decision to experiment tobacco during the early adolescent period.2 The harmful effect of tobacco is more when it is stared at early childhood. Both smoking and smokeless forms are frequently used among adolescent. The most common reason for such high may be attributed to marketing strategies of various tobacco companies and its weak regulation.3 Excessive tobacco production, weak enforcement of tobacco control, easy accessibility to child led to increase use of tobacco among adolescents. Modernization, status symbol and social media are other etiological agents.4

Child are more prone to develop addiction and stay proximate till late adult life. Tobacco has the power to kill 250 million of children today a person every 6.5 second globally.5 The harmful effect of tobacco such as smokers melanosis, tobacco pouch keratosis, leukoplakia and oral cancer can be seen among tobacco users. There have been evidences linking youth-smoking with depression,
anxiety, and stress. Global Adult Tobacco Survey for Karnataka stated that the average age for beginning into daily usage of tobacco is 18.7 years.6 The present study was conducted to determine tobacco usage and associated factors among adolescents.

Materials & Method

This study was carried out in the department of Oral medicine. It comprised of 1350 student’s age ranged 12-17 years of age. This study was permitted from institutional ethics committee of Kalinga Institute of Dental Sciences, Orissa. Written consent of all participating subjects was obtained before the study.

Participants’ data such as name, age, gender was recorded in proforma. Other parameters such as type of school, type of tobacco use, type of family, grade, father occupation, mother occupation, monthly pocket money, history of parental use of tobacco and type of family was recorded. Data thus obtained were tabulated and entered in MS excel. Frequency was recorded. Statistical evaluation was carried out using SPSS version 20.0 using Binary logistic regression and Mann-Whitney U-test to detect significant differences for non-parametric data. The P value lesser than 0.05, was considered significant.

Results

Table I shows that multivariate analysis showed that tobacco use was associated male gender (OR: 10.2; 95% CI 8.6-12.4), late age 15-17 years (OR: 1.62 95% CI 1.14-2.16), private school (OR: 1.74 95% CI 0.98-1.84), nuclear family (OR: 0.72 95% CI 0.51-2.1), pocket money/ month (OR: 1.42 95% CI 1.06-2.04) and parental tobacco use (OR: 1.14 95% CI 1.02-1.28).

Graph I shows that type of tobacco usage was cigarette in 45% followed by pan masala in 22%, gutkha in 14%, bidi in 12% and chaini khaini in 7%. The difference was significant (P<0.05).

Graph II shows that reason for tobacco use among students found to be habit in 35%, status symbol in 24%, social media usage in 20%, 15% had misconception that it does not cause harm in and 6% found it to be stress reliever. The difference was significant (P<0.05).

![Graph I Type of tobacco usage](image)
Graph II Reason for tobacco usage

Discussion

Tobacco usage among adolescent in on rise and it is becoming pandemic. The high rate of tobacco related diseases such as moth cancer, stomach cancer, esophagus cancer, etc. is a matter of worry. It has been observed that those who start tobacco use early is life like school age are ore like to continue it for longer life. Tobacco is used in two forms, smokeless and smoking. Under smokeless form, pan masala, chaini khaini, gutkha, betel quid, snuff, mawa are common forms and in smoking tobacco, hooka, hukli, cigarette, bidi, chillum, chutta and dhumti are commonly used forms. The present study was conducted to determine tobacco usage and associated factors among adolescents.

In present study we enrolled 1350 students of which male were 1040 and female were 310. We found that maximum students were from age group 15-17 years (570) followed by 12-14 years (780). Duko et al assessed the prevalence of cigarette smoking among 564 school students by using Global Youth Tobacco Survey (GYTS). They observed that the student prevalence of cigarette smoking was established to be 11% of which 9.4% were current smokers. The prevalence of smoking among male was 8.2% and female students was 2.8%. Students having friends who smoke, khat chewing, age >18 years, alcohol consumption and illegal or illicit drug use were found to be significantly associated with cigarette smoking.

We found that maximum number of students (890) were from private school and grade 10th (560 subjects). Maximum students had habit of tobacco chewing those who were from nuclear family (960). Maximum students’ father occupation was service (362), mother occupation was working (910) and parental tobacco usage habit was present in 830 subjects. Dereje et al evaluated the prevalence of cigarette smoking among adolescents and found that 28.6% students were ever smoker, and 17.2% were current smokers. It was found that gender, alcoholism, parental tobacco usage, peer smoking, exposure to movie with actors smoking, not being exposed to anti-smoking media messages, not discussing in the class about ill effect of smoking.

We observed that tobacco use was associated male gender, late age 15-17 years, private school, nuclear family, pocket money/month and parental tobacco use. In present study cigarette smoking was present in 45% pan masala in 22%, gutkha in 14%, bidi in 12% and chaini khaini in 7%. George et al in their study found that out of the 407 children, 102 had tried cigarette smoking, while 7.9% had tried smokeless tobacco. It was seen in 14.3% of them bought it directly from shopkeepers. Majority of participants thought that smoking can definitely cause harm to health, while others conscious about the harmful effects of passive smoking.

We found that reason for tobacco use was habit in 35%, status symbol in 24%, social media usage in 20%, 15% had misconception that it does not cause harm in and 6% found it to be stress reliever. Pradhan et al found prevalence of ever use of any tobacco product in 19.7% out of 1312 students. Fifty percent used tobacco in
public places and seventy five percent of the consumers purchased tobacco from shops.

In spite of repeated education programme the number of daily tobacco users is increasing and school age is most common age group where one is more prone to get this habit. The large scale education and ban of tobacco products around schools is required. There is need to decrease accessibility of cigarette, totally ban smoking in the public places, and prohibit tobacco advertisement and promotions in Medias and movies.

The shortcoming of present study is small sample size. We evaluated tobacco usage by self administered response, chances of bias in responses exist.

**Conclusion**

Authors found that later age, male gender, nuclear family, monthly income >5000 per month, parental use and private school was predictor and risk factor of tobacco usage among school children.

Comparative Evaluation of MTA and Biodentine as a Restorative Material In Deciduous Teeth

Sravani Uppala
PG Student, Department of Conservative Dentistry and Endodontics, Drs. Sudha and Nageswara Rao Siddhartha Institute of Dental Sciences, Chinaoutpalli, Andrapradesh, India

Abstract

Introduction: Several medicaments have been used in pulpotomy procedures of primary teeth. The present study was conducted to compare MTA with biodentine as a restorative material in deciduous teeth. Materials & Methods: Specimens were prepared with MTA (group-I) and Biodentine (Group-II) with mold with 10 in each group using stainless steel ring molds. Polyethylene tubes of 1 mm long were filled with MTA and biodentine and placed in flasks containing 10 ml distilled water at 37°C. After 2 h, the flasks were removed from hot air oven, and the water was assessed for pH. Results were tabulated and subjected to statistical analysis.

Results: Each group had 20 teeth sample. In group I, MTA was used and in group II, biodentine material was used. The mean solubility value of MTA at 1st day was 1.55, at 4th day was 1.64, at 12th day was 2.15, at 30th day was 2.57 and at 45th day was 2.60. Similarly in group II at 1st day was 1.89, at 4th day was 2.11, at 12th day was 2.80, at 30th day was 3.61 and at 45th day was 5.34. pH at 2 hours was 9.28 in group I and 9.21 in group II, at 12 hours was 9.26 in group I and 9.39 in group II, at 24 hours was 9.64 in group I and 9.64 in group II, at 7 days was 8.76 in group I and 8.27 in group II, at 28 days was 7.62 in group I and 7.78 in group II. The difference was significant (P< 0.05). Conclusion: Authors found that both materials can be used in deciduous teeth. However, biodentine revealed higher solubility and pH as compared to MTA in deciduous teeth.

Key words: Biodentine, Deciduous, MTA

Introduction

Endodontic treatment of pulpaly involved primary teeth helps to preserve the teeth in non pathological state and to prevent unwanted movement of the neighboring teeth and consequent loss of space in the arch. Moreover, premature tooth loss can lead to malocclusion with aesthetic, phonetic and functional problems that may be transient or permanent teeth. Pulpotomy and pulpectomy are two major treatment modalities for deciduous teeth.

A pulpotomy is performed on a tooth with deep carious lesion, pulp exposure during the operatory process or after a traumatic pulp exposure. Pulpotomy is a treatment procedure that may be performed in healthy radicular pulp tissue with healing potential after surgical removal of the infected or affected coronal pulp. Pulpotomy therapy for the primary dentition can be classified according to treatment objectives as devitalization (mummification, cauterization), preservation (minimal devitalization, non inductive), and regeneration (inductive, reparative) procedure. Pulpectomy is complete removal of dental pulp.

To maintain vitality of primary pulp, to promote healing of the pulp remnants and to maintain the tooth until its natural exfoliation time, numerous pulp medicaments have been used. Among several materials, biodentine and MTA are widely used. Biodentine is composed of powder and liquid. The powder part
includes tricalcium silicate, dicalcium silicate (3 CaO SiO₂ and 2 CaO SiO₂), and calcium carbonate (CaCO₃). Zirconium dioxide (ZrO₂) is added as contrast substance and calcium chloride present as liquid (CaCl₂.2H₂O) for rapid setting time and to improve strength. Mineral trioxide aggregate (MTA) has become more popular, as it has low solubility and good sealing ability.⁵ The present study was conducted to compare MTA with biodentine as a restorative material in deciduous teeth.

**Materials & Method**

This *in vitro* study was performed in the department of Conservative Dentistry and Endodontics. The ethical clearance was obtained from institutional ethical committee before starting the study.

Specimens were prepared with MTA (group-I) and Biodentine (Group-II) with mold with 10 in each group using 20 ring molds of stainless steel having inner diameter of 2.1 cm and a height of 1.6 cm. Mixing of MTA and biodentine was done according to manufacturer’s directions. Following this, the molds were placed inside an incubator cabinet at 37°C.

The mass of dried glass bottles was measured. This procedure was repeated for 4, 12, 30, and 45 days. Polyethylene tubes of 1 mm long were filled with MTA and biodentine and placed in flasks containing 10 ml distilled water at 37°C. After 2 h, the flasks were removed from hot air oven, and the water was assessed for pH. Results were tabulated and subjected to statistical analysis. P value was considered significant at >0.05.

Table III Assessment of pH in both groups.
Table III, shows that pH at 2 hours was 9.28 in group I and 8.98 in group II, at 12 hours was 9.26 in group I and 9.39 in group II, at 24 hours was 9.20 in group I and 9.64 in group II, at 7 days was 8.76 in group I and 8.27 in group II, at 28 days was 7.62 in group I and 7.78 in group II. The difference was significant (P< 0.05).

Discussion

MTA and biodentine have become materials of choice in deciduous teeth. Calcium oxide and silicon dioxide are the two main components of MTA. When these raw materials are blended, they produce tricalcium silicate, dicalcium silicate, tricalcium aluminate, tetracalcium aluminoferrite, and other mineral oxides.6 Radio opacity can be improved with addition of bismuth oxide. Cement hydrates on addition of water, and form silicate hydrate gel. Initially gray MTA was introduced, and to improve esthetic, white MTA was developed later.7

High solubility and prolonged setting time more are the major disadvantages of MTA. Biodentine is consists of the powder component (tricalcium silicate, dicalcium silicate as a second core material, calcium carbonate, oxide as filler, iron oxide shade, and zirconium oxide as a radio-opacifier) and the liquid component (calcium chloride as a setting accelerator and a water reducing agent). There is ample evidence for positive effects of Biodentine on vital pulp cells, for stimulating tertiary dentin formation, and early formation of reparative dentin.8 The present study was conducted to compare MTA with biodentine as a restorative material in deciduous teeth.

In present study, we divided teeth into 2 groups. In group I, MTA was used and in group II, biodentine material was used. Carti et al9 conducted a study in which a total of 25 children with 50 human primary molar teeth aged between 5 and 9 years were selected. The patients were divided into 2 groups. Group I patients received MTA and group II patients received Biodentine. All treated teeth were restored with stainless steel crowns, followed by clinical and radiologic evaluation at 1, 3, 6 and 12 months. There was 96 and 80% of success rate on clinical and radiological evaluation in group I and 96 and 60% in Group II, respectively. There were no statistical significant differences among the groups (P > 0.05). There was decreased success rate on radiographic evaluation in the controls, but it was not statistically significant.

We found that mean solubility value of MTA at 1st day was 1.55, at 4th day was 1.64, at 12th day was 2.15, at 30th day was 2.57 and at 45th day was 2.60. Similarly in group II at 1st day was 1.89, at 4th day was 2.11, at 12th day was 2.80, at 30th day was 3.61 and at 45th day was 5.34. Zaror et al10 performed pulpotomies in primary teeth using MTA and ferric sulphate (FS) and found that radiographic success was 85.71% for the MTA and 83.33% for SF.

We found that pH at 2 hours was 9.28 in group I and 8.98 in group II, at 12 hours was 9.26 in group I and 9.39 in group II, at 24 hours was 9.20 in group I and 9.64 in group II, at 7 days was 8.76 in group I and 8.27 in group II, at 28 days was 7.62 in group I and 7.78 in group II.

Conclusion

Authors found that both materials can be used in deciduous teeth. However, biodentine revealed higher solubility and pH as compared to MTA in deciduous teeth.

Effects of Circuit Training Program on Quality of Life of Children with Hemophilia

Mandar Malawade¹ Amrutkuvar Rayjade¹, G. Varadharajulu²
¹Associate Professor, ²Professor, Faculty of Physiotherapy, KIMS, Karad

Introduction

Circuit training addresses both the components of exercise i.e. strength and aerobic which can be administered to participants in a playful manner. As the large number of children will have to gather at one place for the intervention, so it will be beneficial for the therapist also to conduct the session by incorporating them into small groups. Very few have shown the effects of circuit training in hemophilia Therefore it becomes necessary to provide an exercise regimen to children which will be interesting to perform in order to improve their general fitness level.

Methodology: Forty nine participants were selected and screened and were allocated into 7 groups. The intervention was given for 4 weeks period, once a day for 7min with 50 sec for exercise and 10 sec to move from one station to the next. Pre and Post parameters were assessed for VAS for fatigue and Subjective Exercise Experience Scale.

Results: Data was analyzed using Graph-Pad InStat software version-trial version 3.03. The statistical measures utilized were mean, standard deviation and test of significance such as Paired ‘t’ test to analyze the data. The results were concluded to be statistically significant with p <0.05 and highly significant with p < 0.01.

Conclusion: The present study concludes that the circuit training is effective in hemophilic children as its multipronged approach improves various body systems.

Key words: Haemophilia, Circuit training, Fatigue, Group Exercises, Physiotherapy

Introduction

The existence of life-long bleeding disorders and their familial occurrence was noted early by Alsaharavius during tenth century.¹ Bleeding disorders are due to either defects in the coagulation mechanism, the blood platelets, vitamin K deficiency or deficiency of clotting factor. Haemophilia is one of the bleeding disorders, has been recognized as a clinical entity since Biblical times.² Hemophilia is also known as ‘the royal disease’ as one famous carrier was Queen Victoria, Queen of England and Ireland, India who transmitted the condition to three of her children.³

Haemophilia has been recognized all over the world, an available estimate range for incidence of haemophilia is from 1 in 20,000 to as high as 1 in 10,000 persons.⁴⁵ It is an X-linked inherited recessive bleeding disorder that is characterized by a deficiency of clotting factor.⁶ Clotting factors are proteins in the blood that controls bleeding.⁷ Haemophilia is traditionally classified as ‘mild’, ‘moderate’, or ‘severe’, depending on the level of clotting factor available in the body compared with that found in the general population.⁸ Patients with severe haemophilia have <1% clotting factor activity,
moderately affected patients have 1-5% and mildly affected patients have 6-40\%\textsuperscript{9}.

Wound bleeding is the characteristic symptoms of all haemophiliacs. It is usually slow and persists for days to weeks. Bleeding into joint may be spontaneous or induced by minor trauma. The earliest joint hemorrhages appear most commonly in knee and ankle, because of the lack of stability of these joints as the toddler assumes an upright posture. Other joints that may be involved are the elbows, hips, wrists, shoulder and small joints of hand and feet.\textsuperscript{10} Prophylactic treatment with the use of coagulation factor is efficient in reducing bleeding episodes in haemophilic children.\textsuperscript{11} Frequent musculoskeletal bleedings ongoing in persons with haemophilia result in limitations and deficiencies of the musculoskeletal system, affecting the performance of daily living activities.\textsuperscript{12} Clinical manifestations may include pain, muscle atrophy, abnormal gait, haemarthrosis, reduced joint range of motion or even the development of degenerative alterations in joint. The damage resulting from haemarthrosis may cause periods of joint immobilization, tendon weakness, stiffness and joint destruction with a higher risk of fractures and osteoporosis.\textsuperscript{3}

Besides pharmacological treatment physiotherapy plays an important role in rehabilitation of haemophiliacs.\textsuperscript{13} Physical fitness is generally defined as ‘the ability to perform daily tasks without fatigue’.\textsuperscript{14} It is an umbrella term incorporating the characteristics of cardiovascular fitness, body compositions, flexibility, muscular strength and endurance.\textsuperscript{15} It is important for the individuals with haemophilia because their disabling condition itself may interfere with their activities like their ability to move efficiently.\textsuperscript{16} Benefits of regular physical exercise for haemophilic patients are numerous and cover various physical and psychosocial aspects. Physical benefits include improvement in range of motion of the joints, muscular strength protecting joint from injury. The psychosocial benefits include higher self-esteem and socialization which leads to a better quality of life.\textsuperscript{18} However physical activity has been linked to improving psychological conditions, such as limiting emotional distress and enhancing self-esteem. Therefore selecting appropriate exercises and fitness activities that are safe for people with hemophilia is essential.\textsuperscript{19}

Circuit training (CT) is a type of exercise which involves exercises to perform in a sequence in a circular manner and designed to improve cardiovascular fitness, muscular strength and endurance. It comprises both forms of exercises i.e. aerobic and resistance or strength training.\textsuperscript{20}

Circuit Training is a fun, cost and time effective way and able to be administered to large groups of individuals at the same time, while still being effective. There is some evidence to suggest that Circuit Training leads to positive changes in body composition, which also improves motor control and fundamental movement abilities. Development of such abilities at a young age may be beneficial in the long term. However, few studies have assessed the effects of Circuit Training on both physical fitness and movement abilities.\textsuperscript{21} Thus, the aim of the present study will be to determine the effectiveness of CT program on Fatigue level and Psychological well-being in children with haemophilia.

**Procedure:**

Forty nine participants were selected for the study. They were randomly allocated into 7 groups. Details about the study and intervention were explained to the participants and written informed consent was obtained. Demographic details of each participant were noted including clotting factor level. Participants were assessed pre and post data for Visual Analogue Scale for fatigue and Subjective Exercise Experience Scale.

The intervention was given once a day for 4 weeks period, once a day, for 7min with 50 sec for exercise and 10 sec to move from one station to the next in the form of Circuit Training. A demonstration was given to the participants to make them understand about how to perform the exercises and how to move in the Circuit. Exercises were done with music for having effective and enjoyable. At a time only one group was given Circuit Training followed by other in a circular sequence. Each participant in the circle performed respective exercise recommended to them at that particular station.

**Exercises for respective joints were the followings:**\textsuperscript{22}

**Exercise for Shoulder joint:** Keep both the hands on shoulders of the same side. Move the shoulders in
outward direction in a circular way simultaneously.

**Exercise for Elbow joint**: Stand facing the wall. Place hands flat on wall with arms straight. Lean body towards wall allowing elbow to bend. Return to upright position by pushing with arms and straightening the elbow.

**Exercise for wrist joint**: Place palm of hands together with finger straight (in a prayer position) while keeping the hands pressed flat together move both the wrists in extension alternately.

**Exercise for Hip joint**: Stand by facing the wall. Place both the hands on the wall for support. Extend the hip by keeping the knee straight. Perform the same for both the hips alternately.

**Exercise for Knee joint**: Stand with the weight evenly distributed on both feet. Squat down partway keeping weight distributed evenly on both feet. Do not bend knees far enough to cause pain. Hold for several seconds. Return to upright position.

**Exercise for Ankle joint**: Stand with both legs adequately wide apart. Place both palms of hands on wall for support. Do the dorsi-flexion and plantar-flexion alternately.

**Exercise for Trunk**: Keep both the hands on low back for the support and gently extend as much as possible. Then come back to upright position.

**Data Analysis**

Data was analyzed using Graph-PadInstat software trial version 3.03. It was entered into an excel spread sheet, tabulated and subjected to statistical analysis. The statistical measures utilized were mean, standard deviation (SD) and test of significance such as Paired 't’ test to analyze the data. Paired ‘t’ test was used to compare the differences of scores on pre and post intervention within a single group. The results were concluded to be statistically significant with p < 0.05 and highly significant with p < 0.01.

**Fatigue Score**:

The rates of perceived fatigue were assessed by VAS. The rating of fatigue scores were recorded on the scale. Paired ‘t’ test was used to compare score within the group. The pre-intervention average score of fatigue score in participants was 1.40 and post-intervention was 1.87. There was highly significant increment in fatigue score for the group after intervention.

**Table 1: Comparison of pre and post intervention score of Fatigue**

**Subjective Exercise Experience Scale (SEES)**: Paired ‘t’ test was used to compare score within the group. The pre-intervention average score of Positive wellbeing in participants was 14.32 and post-intervention was 16.97. There was highly significant increment in Positive wellbeing score for the group after intervention.

The pre-intervention average score of Psychological Distress in participants was 7.14 and post-intervention was 4.83. There was highly significant reduction in Psychological distress for the group after intervention.

The pre-intervention average score of fatigue was 5.51 and post-intervention was 5.10. There was highly increment in positive wellbeing component as well as significant reduction Psychological distress component of SEES after intervention, whereas Fatigue component found to be significant.

Discussion

The study was done to evaluate the effects of circuit training in Haemophilic Children. In children with Haemophilia reduced muscle strength and cardiovascular endurance are main contributing factors to have poor fitness level and reduced psychological wellbeing compared to typically developing peer which results because of fear of getting bleed.

Circuit Training showed good improvement in Positive wellbeing, reduced psychological distress and fatigue to some extent. Circuit training being multipronged in its approach addresses the improvement in various systems of body and even psychological aspects. CT program was specifically designed to provide variation and stimulation in order to maximally engage children and to ensure adherence and enjoyment, whilst achieving positive changes in health and fitness outcome measures. The effects seen in this study were due to gradual effects of exercise which imposes demands on the different systems of the body such as enhancement of oxygen delivery systems, expanded plasma volume, maximum minute ventilation and increased cellular enzyme activity.23, 24

Most of the haemophilic children are sedentary and having reduced physical activity. Therefore fatigue had set in early. In the present study there was significant difference fatigue score.

A pilot study was done to determine the effect of an acute bout of exercise on the subjective exercise experience of Vietnam Veterans, and to determine which exercise intervention results in the most positive acute outcome. Specifically, this study included the use of a combination of traditional exercise modes and innovative exercise. Overall this pilot study has demonstrated that an acute bout of exercise elicits improved positive wellbeing and reduced psychological distress, and therefore warrants further research with a larger cohort to determine which exercise intervention results in the most beneficial subjective experience. The identification of specific exercise interventions that elicit acute positive exercise experiences has important implications for long-term exercise adherence in at-risk populations.

In the present study there were significant differences in the components of Subjective Exercise Experience Scale (SEES) with increase in positive wellbeing. Psychological distress showed reduction in score after intervention, whereas fatigue component also showed significant difference.
A study has proved that a school-based CT program had beneficial effects on a range of fitness measures. These movement skills are helpful in ensuring good general posture, and effective movement in a variety of physical activities, sports and game play. For these reasons, and given its low cost and suitability for large groups, CT maybe a useful exercise method to adopt in schools. This is in accordance with the research studies, CT program on the health, fitness, physical activity levels, and movement competency in young children.25, 26

An overview of literature review concluded that aerobic and resistant training intervention elicits some benefits for physical fitness and blood coagulation mechanisms, suggesting the application of physical training as a non-pharmacological treatment in association with conventional treatment. Adequate and periodized resistance training considering the disease severity, accompanied by physical education professionals could improve muscle strength, balance and proprioception. Aerobic training could reduces the risks of obesity and several metabolic and cardiovascular diseases. Another review article concluded important evidence on the recommendation of physical exercise and sport in haemophilia, the consensus on its suitability for the physical and social wellbeing of the patients and the need to increase scientific works in this respect.27

Researchers analyzed the current state of management of haemophilia and to suggest a comprehensive concept of rational and effective rehabilitation of children with haemophilia. The study concluded that current rehabilitation care is of good quality and necessary for effective lifelong therapy of haemophilia.28

Thus many researchers have proved that for achieving general fitness and maintaining psychological wellbeing in haemophilic children, exercise regimen and physical activities contribute major role which occurs due to physiological changes in various systems of body in order to prepare the body to control the new imposed demands while performing the exercise and physical activities.

**Conclusion**

The present study concludes that the circuit training is effective in haemophilic children as its multipronged approach improves various body systems.

Assessment of Serum Levels of Salusin α and Salusin β in Cardiovascular Disease Patients Undergoing Transcatheter Therapy

Ayat Saeed Awad1, Hanaa Addai Ali2, Mohauman Mohammad AL-Rufaie3
1Post graduate Student, College of Science, University of Kufa, Iraq, 2Prof. College of Science, University of Kufa, Iraq, 3Prof. College of Science, University of Kufa, Iraq

Abstract

Cardiovascular disease (CVD) covers some disorders, such as the diseases of the cardiac muscles and the vascular system supplying the heart, brain and extra vital organs. CVD morbidity and mortality is mainly due to coronary heart disease and cerebro-vascular diseases. The aims of the present is to measure the levels of Salusin α, Salusin β, lipid profile, fasting blood sugar, insulin, insulin resistance and HOMA IR in the sera of cardiovascular patients who are subject to catheterization and to compare these levels with the ones of the healthy group and their correlation with Salusins. The results have made use of the appropriate statistical methods.

The results of the research have shown that there is a significant increase in the salusin-β in CVD patients compared with that of the healthy group but Salusin α (p›0.001) witnessed a significantly lower level. The present study has demonstrated that VLDL.C, HDL.C, TG.C and Salusin-β are in a significant correlation with Salusin α. Also, Age, BMI, HOMA-β, Insulin, HOMA-IR, FBG, CHO and LDL.C have no significant correlation with Salusin α. The results have shown that BMI and Salusin α levels are significantly correlated with salusin-β. In addition, Age, HOMA-β, Insulin, HOMA-IR, FBG, CHO, LDL.C, VLDL.C, HDL.C and TG.C have no significant correlation with Salusin-β. BMI and HDL.C have shown a positive correlation with Salusin α. Moreover, Age, Insulin, HOMA-IR, HOMA-β, FBG, CHO, LDL.C, VLDL.C and TG.C have shown a positive correlation with Salusin-β.

Key words: Cardiovascular disease, Salusin α, Salusin β.

Introduction

Cardiovascular disease (CVD) covers disorders like the cardiac muscles and the vascular system supplying the heart, brain and extra vital organs (1). CVD morbidity and mortality is mainly due to coronary heart disease and cerebro-vascular diseases (2). CVD is as a rule connected with atherosclerosis; an inflammatory disease characterized via the accumulation of lipids and fibrous elements in relation to medium arteries (3).

Salusins are taken as a category of bioactive peptides discovered through bioinformatics analyses of a complete length CDNA library. Recently, two associated peptides of 28 and 20 amino acids are renowned and characterized; they specified Salusin-α and Salusin-β. These peptides are believed to be biosynthesized of pre-prosalusin; an alternative-splicing production of the torsion dystonia–related gene (TOR2A), subsequent to frame shift reading and digestion at dibasic amino acids (4).

Salusins are synthesized ubiquitously in human tissues, counting the vasculature, central nervous system and the kidney. Salusin-α is present inside human plasma and urine (5). Salusin-β quickly induces hypotension, bradycardia, and cardiac dysfunction during a cholinergic mechanism (6). Salusin- β also stimulates human macrophage foam cell formation (7), proliferation of vascular smooth muscle cells and fibroblasts (4) and cardiomyocyte growth and anti-apoptosis (8,9).

Material and Method

A case control study is designed for a total of 60 subjects (44 males and 16 females, aged between 35 to
Indian Journal of Forensic Medicine & Toxicology, April-June 2020, Vol. 14, No. 2

65 years) who consecutively registered in this study. The subjects are 30 Iraqi patients with cardio vascular disease (CVD). They have participated in the current study (8 female and 22 males). These patients are registered as CVD patients in the “open heart Unit” at “AL-Sader Teaching Hospital” in Najaf, Iraq. The patients' serum in the pre - and post-cardiac catheterization is collected and compared with that of the control group. Thirty healthy adults are selected as the control group. The range of their ages is analogous to that of the patients (35-65) years. Subjects who suffer from the apparent diabetes mellitus, acute infections, chronic liver diseases, renal disorders, cancers and patients with surgical procedures in the last 3 months, and nonsmoker are all excluded.

Five milliliters of venous blood after 12 hours fasting are drawn from the CVD patients and the healthy group during (8:30-10 A.M) from antecubital venipuncture using G 23 needles.

Hypertension is diagnosed as a systolic blood pressure >140 mmHg and/or diastolic blood pressure >90 mmHg. The BMI is calculated as the ratio of weight (Kg) to height squared (m²), by unit kg/m². Fasting analysis of serum glucose, lipid profile (CHO, TG.C, LDLC, and HDL.C) levels are measured by colorimetric method for the quantitative in vitro diagnostic measurement using kit (BIOLABO (France)). The Salusin α and Salusin-β are also measured using the Competitive-ELISA principle (Elabscience (USA)). The concentrations of Insulin serum are determined by ELISA kits (Calbiotech (USA)). Insulin resistance index (Homeostatic model assessment-insulin resistance,HOMA-IR) is estimated as follows: HOMA- IR = [glucose (in mg/dL) * insulin (μU/ml)] / 405. HOMA-α = (360 × Insulin/(Glucose-63)) % (10). The results are subjected to statistical analysis and are analyzed using Microsoft Excel 2013 and SPSS-20 (statistical package for social science-version 20). The results are expressed as numbers and as mean ± SD (Standard deviation). The significance of difference is assessed using paired t-test for two dependent means. The correlation of parameters is determined using Pearson’s correlation coefficient, taking p≤0.05 as the lowest limit of significance (11).

Bio-statistical Analysis

The results are subjected to statistical analysis and are analyzed using Microsoft Excel 2013 and SPSS-20 (statistical package for social science-version 20). The results are expressed as numbers and as mean ± SD (Standard deviation). The significance of difference is assessed using paired t-test for two dependent means. The correlation of parameters is determined using Pearson’s correlation coefficient, taking p≤0.05 as the lowest limit of significance (11). The one-way ANOVA (Analysis of variance) and Fishers Least Significant Difference (LSD) are applied to compare the differences among the studied groups.

Results and Discussion

Clinical characteristics of the Studied Groups

The patients with cardiovascular diseases have shown a significantly higher level of fasting blood sugar (by definition, (p<0.001), higher level of insulin(p<0.001), respectively), higher level of HOMA IR(p<0.001), Lipid profile (p<0.001) and Salusin-β (p<0.001) in CVD patients (Group2), compared with the healthy group (Group1). Additionally, lower Salusinα and HOMA-β (p<0.001) are also seen, table (1). Table (1) shows significantly higher levels in the Insulin, FBG and HOMA IR (p<0.001), except HOMA-β which records a non significant level in pre-catheterization (Group2), compared with post-catheterization (Group3). No significant difference is registered regarding salusin-β and insulin (p<0.001)

But there is a significant increase in FBG, HOMA IR, HOMA-β,Lipid profile, Salusinα, when the control (Group1) is compared with post-Catheterization (Group3).

The demographics and laboratory data of the Salusin α and Salusin β groups are summarised in tables (2) and (3). The levels of VLDL.C, HDL.C, TG.C and Salusin β are significantly higher with Salusin α for all (p<0.05)( p =0.036) (p=0.022) (p=0.035), (p=0.048), respectively.

There is no significance correlation of Age, BMI, HOMA-β, Insulin, HOMA-IR, FBG, CHO and LDL with Salusin α (p›0.001), as in table (2).

BMI and Salusin α levels are significantly elevated with Salusin-β (p<0.05) (p=0.033) (p= 0.048), respectively. Moreover, Age, HOMA-β, Insulin, HOMA-IR, FBG, CHO, LDL.C, VLDL.C, HDL.C and TG.C have no significant correlation with Salusin-β(p›0.001), as in table (3).

This study has found that HDLC is positively correlated with Salusin α. In addition, Age, BMI, Insulin, HOMA-β, HOMA-IR, FBG, CHO, LDL.C, VLDL.C, TG.C and Salusin-β showed a negative correlation with Salusin α, as in table (2).
Furthermore, HDL.C and Salusin α showed a negative correlation with salusin-β. Also, Age, BMI, Insulin, HOMA-IR, HOMA-β, FBG ,CHO, LDL.C, VLDL.C and TG.C showed a positive correlation with Salusin-β., as seen in table (3).

CVD is as a rule connected with atherosclerosis (3). Atherosclerosis is a chronic vascular disease, in which the arteries are thicken and lose their flexibility as a result of cholesterol sedimentation in the artery wall. In the early stages of the disease, cholesterol accumulates in arterial macrophages, alter them to lipid-loaded bubbles cells. Wide atherosclerosis narrows the artery lumen to reduce blood flow, and the can enhance the complete blockage of the artery (12; 13). Atherosclerosis occurs due to a variety of reasons, the most significant of which is the deposition of large amounts of cholesterol and calcium in the blood. It may happen because of obesity overcharged as a result of absence of exercise. Additionally, the increased blood pressure raises the risk of developing atherosclerosis (14; 15).

FBG: fasting blood glucose, HOMA-IR: Homoeostasis model assessment-insulin resistance.Salusin-α has a mild hypotensive effect (4) and suppresses human foam cell formation via the down-regulation of acyl-CoA : cholesterol acyltransferase-1 (ACAT-1), which stores cholesterol ester changed from free cholesterol in macrophages. In previous studies, Serum salusin-α levels are significantly decreased in acute coronary syndrome (ACS) patients as compared with healthy people and are less in accordance with the severity of coronary atherosclerotic lesions amongst ACS patients. In coronary atherosclerotic lesions of ACS patients, the level of expression of Salusin-α is lower than that of Salusin- β (7).

Salusins essentially affect the cardiovascular system (6;7). Salusin-β is the most hypotensive peptide, its infusion is rapid and profoundly decreases blood pressure and heart rate. Moreover, it is demonstrated to cause cardiac dysfunction through a cholinergic mechanism in rats (6;8). It may have significant roles in myocardial growth and hypertrophy. Salusin-α and salusin-β show converse actions on atherosclerosis due to their opposite regulatory effects on acyl-coenzyme A: cholesterol acyltransferases-1 (ACAT-1). Both of the formation of macrophage foam cells and the enlargement of atherosclerosis are suppressed via Salusin-α. Serum Salusin-α levels are also reported to be significantly lower in patients with coronary artery disease and hypertensive patients where their Salusin-α level is inversely associated with carotid atherosclerosis (7;16).

P- Value ≤ 0.05 = significant, r : Pearson correlation

Angiotensin II is associated with the genesis of arterial hypertension and cardiovascular remodeling (17, 18). Renin-angiotensin system intervention in hypertensive patients has shown lower morbidity and mortality (19; 20). Salusin-β gene silence has normalized the increased circulating Ang II levels in addition to the local Ang II contents in both myocardium and mesenteric artery in spontaneously hypertensive rats (SHR). Additionally, the up-regulation of AT receptors within myocardium and mesenteric artery in SHR (4) are inhibited through the knockdown of Salusin-β.

The inhibitory effect of Salusin-β on the activation of angiotensin system may partially contribute to the attenuation of hypertension and cardiovascular remodeling. It is well known that increased oxidative stress is associated with endothelial dysfunction, apoptosis, hypertrophy, inflammation, fibrosis and cell migration relative to vascular remodeling of hypertension (21; 22).

### Conclusion

In conclusion, our results suggest that Salusin-α and Salusin-β prove contrasting effects on atherosclerosis and that Salusin-α and Salusin-β possess anti-atherogenesis and proatherogenesis, respectively.

The current study has concluded that in patients with CVD, Salusin β levels have recorded a significant increase in the serum of CVD.

Further, Lipid Profile changes are directed by the age of patients in CVD.

Salusinα increase in serum of post catheterization and Salusin β decrease in serum of post catheterization.

In order to improve diagnosis and treatment of CAD, the research community needs to understood how the immune response is analogous and how it differs in men and women with atherosclerosis.

Effect of Multi-Wall Carbon Nanotubes on the Microhardness of the Tooth Enamel

Mohammed K. Jawad1, Abbas F. Ali2, Ali B. Roomi3

1Specialized Dental Center Sumer, Thi-Qar Health Directorate, Thi-Qar, Iraq, 2College of Dentistry at The University of Baghdad, Baghdad, Iraq, 3College of Health and Medical Technology, University of Al-Ayen, Thi-Qar, Iraq.

Abstract

Background: The object of this study was to investigate the effect of addition of Multi-Wall Carbon Nano Tubes (MWCNTs) in different concentration (0.001g/20ml, 0.005g/20ml, 0.01g/20ml and 0.02g/20ml) in (dimethyl sulphoxide) to tooth enamel. It is intended to evaluate enamel hardness in (Kg .m-2) before and after the addition of (MWCNTs).

Materials and Method: Thirty specimens were prepared for this study, to measure the hardness of the enamel.

Results: The results enamel hardness after MWCNTs application With DMSO showed a significant increase (P<0.01) between groups of 0.001g/20ml, 0.005g/20ml, 0.01g/20ml and 0.02g/20ml concentration compared with control group. Where the highest mean value obtained was in 0.02g/20ml concentration which had a mean value of 527.18 ± 2.904 Kg .m-2, while the lowest mean value was for control group which had a mean value of 334.87± 2.904 Kg .m-2. Polished enamel surface groups showed a significant increase 452.59 ± 1.84 Kg .m-2 (P<0.01) in hardness when compared with unpolished enamel surface groups 430.16 ± 1.84 Kg .m-2 (P<0.01).

Conclusion: The highest mean value obtained was in 0.02g/20ml concentration in the hardness suspended in DMSO. The results showed a significant increase in the hardness for polished enamel surface samples compared with unpolished enamel surface samples in DMSO.

Key words: Multi-Wall Carbon NanoTubes (MWCNTs), enamel hardness

Introduction

Enamel, the outer hard tissue layer of tooth crowns, is a composite material that comparable to other biological tissues like bone or dentin exhibits a unique and complex hierarchical structure (1). The bulk of human teeth consists of two main mineralized tissues, collagen-rich dentine and highly mineralised enamel. They join forming a complex and mechanically durable dentine–enamel junction (DEJ) that contributes to the lifelong success of the tooth structure under thermo-mechanical loadings encountered in the oral cavity under the conditions such as mastication, chemically active environment and thermal shock (2, 3).

Enamel is the hardest tissue in the human body and is considered a nanostructured biocomposite in which its mineral phase predominates (95-96 wt. %) (4). In this mineral portion, large hexagonal carbonated hydroxyapatite crystals are tightly packed creating prisms with a keyhole-like structure of about 5 µm in diameter (5). Prisms are aligned and run approximately perpendicular from the dentin-enamel junction to the tooth surface (3). Each prism is separated from each other by a nanometer-thin layer of a protein-based organic matrix (6). The term “Nano” is derived from the Greek word “dwarf”. More simply speaking, one nanometer is one-billionth or 10-9 of a meter (7-9). Nanotechnology can be classified in terms of application in three broad and extensively overlapping categories (10):
\begin{itemize}
\item Nanoelectronics
\item Nanomaterials/particles
\item Nano-biotechnology
\end{itemize}

Carbon nanotubes (CNT) are a new crystalline form of carbon. Wound in a hexagonal network of carbon atoms constituting a graphene nanofoil, these hollow cylinders can have diameters as small as 0.7 nm with lengths that can range from a few micrometres, and reach several millimeters in length (11). Each end can be opened or closed by a fullerene half molecule. These nanotubes can have a single layer (SWCNT for single walled carbon nanotube) or several layers (MWCNTs for multi walled carbon nanotube) of coaxial cylinders of increasing diameters in a common axis. Multilayer carbon nanotubes can reach diameters of 100 nm (12).

Enamel surface microhardness refers to a tooth’s resistance to scratching, abrasion, and indentation. A substantial number of mineral ions can be removed from hydroxyapatite latticework without destroying its structural integrity; however, such demineralized enamel transmits hot, cold, pressure and pain much more readily than normal enamel. Microhardness tests are commonly used to study the physical properties of materials, and they are widely used to measure the hardness of teeth (13, 14). Knoop (KHN) and Vicker (VHN) hardnesses have reported approximately the same value (15). The average hardness value for enamel and dentin is in the range from 270 to 350 Knoop microhardness or from 250 to 360 Vickers microhardness and from 50 to 70 Knoop microhardness respectively (16).

**Functionalisation of Commercial Carbon Nano Tubes** (17). One gram MWCNTs was transferred into a mixture of nitric acid (10 cm3) and sulphuric acid (30cm3). This mixture was then heated at 50 °C for 24 hrs after which the MWCNTs were filtered off using Nylon filter paper (pore size 0.45 micrometer). This was followed by subsequent washing with distilled water until the pH was almost neutral. The MWCNTs were then dried under vacuum at room temperature. Then dried in furnace oven for 2hr.In the third step 0.02 g from MWCNTs were put in 20 ml DMSO. The MWCNTs is mixed with DMSO. The whole solution is transferred into sonicator. Twenty four sample in DMSO in different concentration for micro hardness test. The samples should be kept in a water. These samples were shaken in the vibrator for limited period extend 10min for 3 time in 6 continuous days.

**Grouping of Samples**

The group contains 30 samples to measure the hardness of the enamel. Samples were collected from healthy teeth of patients attending a dental teaching hospital at the University of Baghdad college of Dentistry, also Thi-Qar specialized dental center in department of Orthodontics of the ages ranging between 15 - 24 years. The first selection criterion for the sample was tooth quality. Only teeth with no visible defects were selected, not taking into account any damage at the micro structural level. They were without any caries, no attrition or erosion. The patients were non-smokers and do not consume alcoholic beverages. The second selection criterion was that the teeth belonged to mandibular first premolar.

**The Hardness of a material**

The hardness of a material its resistance to penetration under a localized pressure or resistance to abrasion. The baseline of the hardness of base lines was measured through the use of Micro -Vickers Hardness Testing Machine (CV-400 DM, Europe) (Figure1), with a load of 500 g and 1000 g, in 5 seconds.

**Principle of Hardness Determination**

The micro hardness test involves a microscopic and static method, of which the results are mostly expressed in terms of Vickers and Knoop hardness numbers. The micro hardness tester is provided with an optical magnifying system. The hardness is determined by penetrating a diamond pyramid indenter under a known test force into the surface of test piece and then measuring the diagonal of the indentation left on the surface after removal of the test force.

The hardness number is calculated upon the below equations.

\[
HV = \frac{1854}{4F/d}
\]

Vickers Test

HV: Vickers hardness number, in kg f. mm-2, F : Test force, in kg f, d :Diagonal length of the indentation, in mm2.

**Sample Preparation to Measure The Hardness**
The total number of samples were 30 samples to measure the hardness of the enamel, and divided the group to subgroups upon the following design.

**Control group**: (3 unpolished enamel surface and 3 polished enamel surface samples).

**Group (0.001g/20ml)**: (3 unpolished enamel surface and 3 polished enamel surface samples)

**Group (0.005g/20ml)**: (3 unpolished enamel surface and 3 polished enamel surface samples)

**Group (0.01g/20ml)**: (3 unpolished enamel surface samples)

**Group (0.02g/20ml)**: (3 unpolished enamel surface samples)

Groups (0.001g/20ml, 0.005g/20ml, 0.01g/20ml, 0.02g/20ml) treated with MWCNTs, the special area on the middle third of the labial enamel surface were chosen 5mm away about the cusp tip and whit a line representing axis (X) for all teeth. All have samples examined for the micro hardness.

**Statistical Analysis**

Statistical analysis was done using the software SPSS version 17.0; the results were expressed as mean ± standard deviations (mean ± SE). One way ANOVA was used to compare parameters in different studied groups. P-values (P < 0.01) were considered statistically significant.

**Results**

Statistical Analysis of the results was used to evaluate, enamel hardness in (Kg.m-2) after MWCNTs application with DMSO in different concentration treatment.

Enamel Hardness Test

Control group comport with groups dealing with MWCNTs application with DMSO in different concentration treatment and different surfaces treatment.

MWCNTs application with DMSO in different concentration treatment and different surfaces treatment.

Table (1) showed that the highest mean value found in 0.02g/20ml concentration which has a mean value of 527.18 ± 2.904 Kg.m-2, while the lowest mean value was for the control group which has a mean value of 334.87 ± 2.904 Kg.m-2. The results of LSD test showed a statistically significant differences between groups in different concentration treatment as in the figure (2). And also table (1) showed that the highest mean value represent in polished enamel surfaces which has a mean value of 452.59 ± 1.84 Kg.m-2, while the lowest mean value was for in unpolished enamel surfaces which has a mean value of 430.16 ± 1.84 Kg.m-2. The results of LSD test showed a statistically significant differences between groups in different surfaces treatment as in the figure (3).

Table (1) showed that the highest mean value present a concentration of 0.02g/20ml in polished surfaces which has a mean value of 547.07 Kg.m-2, while the lowest mean value was for the control group in unpolished surfaces which has a mean value of 330.30 Kg.m-2 and the results of LSD test showed a statistically significant differences between groups in different concentration treatment and different surfaces treatment.

**Discussion**

**Micro Hardness of Dental Enamel**

Based on the findings of the current study, the average value of Vickers enamel microhardness was 334.87 ± 2.91, which is similar to the findings of Panich and Poothong (18), enamel hardness depends on different factors such as degree of enamel mineralization, enamel prisms and enamel tufts variations in different areas of enamel, presence or absence of any structural defects in the enamel, type of the teeth (whether it is anterior or posterior), and procedures for preparing the samples to perform the hardness test (13). Other factors influencing enamel hardness are the bio environmental factors, fluoridation of the drinking water, age of the teeth, and different eating habits in different societies (19).

**Enamel Hardness After MWCNTs Application With DMSO**

The results of the hardness are reported in Table (1) and figure (2) from which it is observed that the highest mean value obtained was in concentration 0.02g/20ml which had a mean value of 527.18 ± 2.904 Kg.m-2, while the lowest mean value was for control group which had a mean value of 334.87± 2.904 Kg.m-2. The results showed a significant increase in hardness between groups in concentration 0.001g/20ml, 0.005 g/20ml, 0.01 g/20ml and, 0.02 g/20ml compared with control group. Peter Atkin’s and Julio de paula (20)
it’s well known that CNTs are thin cylinders of carbon atoms that are mechanically strong. At this time, the increase in hardness due to the increase in concentration of MWCNTs figure (4), the tremendous surface area of CNTs up to 200 m2.g-1 leads to formation of clusters due to Van Der Waals forces. Clustering and non-uniform dispersion of CNTs will lead to inhomogeneous property distribution in the structural component (21). The results of the hardness are reported in Table (1) and figure (3) from which it is observed that the highest mean value of polished enamel surface which had a mean value of 452.59 ± 1.84Kg .m-2 ,while the lowest mean value of unpolished enamel surface which had a mean value of 430.16 ± 1.84 Kg .m-2 . The results showed a significant increase in the hardness for polished samples compared with unpolished samples. Because the surface area for polished samples more than unpolished samples. Since the of the polished surface leads to increases the surface area of dental enamel attached to them MWCNTs material, which leads to increased the permeability of the materials to the inside enamel rods ,this leads to increased material inside dental enamel, gives an increase in the enamel hardness (22).

Evaluation of CEA, CA19-9, and CA242 Tumor Markers in Patients with Colorectal Cancer by ELISA Technique

Ahlam Shakir Hammood AL- Rubaiawi¹ Mukhtar Khamis Haba¹, Laith Raouf Ahmed AL- Hadad²

¹Department of Biology/ College of Science for Women/ University of Baghdad/Iraq., ²Consultant Digestive Surgery/ GIT Hospital/ FRCS/ FACS/Iraq.

Abstract

Colorectal cancer (CRC) is one of the common malignant tumors of gastrointestinal tract (GIT). A total of 40 patients with CRC were studied preoperatively and postoperatively while only 20 healthy persons were studied. Their ages ranged between 18-78 years. This study was carried out to investigate the possible association of some risk factors with CRC such as (age, gender, smoking, inflammatory bowel disease, and ulcerative colitis).

With application of ELISA technique, Serum levels of CEA, CA 19-9, and CA 242 was measured preoperatively and postoperatively. The results showed an increase in preoperative serum level of CEA in CRC patients when compared to both postoperative and control groups. There was a significant increase in the serum level of CEA (10.73 ± 4.01) comparison with the two other groups (postoperative 3.95 ± 1.55) and control (1.91 ± 0.27) at (P<0.05), but no significant differences between the two groups (postoperative and healthy) which have mean (3.95 ± 1.55 and 1.91 ± 0.27) respectively. Also showed a significant increase in serum level of CA19-9 in patients preoperative (23.28 ± 1.86), who were differed significantly from the mean of serum in patients postoperative (18.63 ± 1.40) and control group (19.11 ± 1.46) at (P<0.05), When compared the serum level of CA242 revealed a significant increase in serum level of patients preoperative (19.58 ± 3.46) as compared to postoperative (8.75 ± 1.77) and control group (9.85 ± 2.22) at (P<0.05).

Key words: Colorectal cancer, Biomarkers, Metastasis, CEA, CA19-9, CA242.

Introduction

Cancer is a disease that occurs when control is lost on cell division and growth as well as on the metastasis of abnormal cells. Reasons for cancer are both intrinsic, i.e. infections, smoking, radiant sources, and extrinsic, i.e. genetic and metabolic mutations, along with abnormal immune responses and hormone levels (1).

Cancers start in the cells that line the inside of colon (the longest fragment of the large intestine) and rectum (occupies the last several inches prior to the anus) (2). Stool blood, altered movement of bowel, continuous tiredness, nausea, vomit, malaise, anorexia, abdominal distension and losing of weight are among the main symptoms of CRC (3). Ageing and disturbed life style were reported to be the major reasons for developing CRC, with genetic abnormalities affecting only minor cases (4). Dietary influences which contribute to higher are red meat which is over processed, alcohol consumption, IBD (inflammatory bowel disease) (5). Tumor develops under strong influences from genetic and epigenetic disorders, while the survival can be best prognosis based on immunological microenvironment (6).

Materials and Method

Blood samples (5 ml) were collected from patients with colorectal cancer (preoperative- postoperative) healthy persons (control) by using plastic syringes. Serum samples were prepared by centrifuging the blood (5000 rpm for 15 min).

Tissue Biopsies: Biopsies were collected from tissues of CRC patients, followed by fixation in buffered formalin (10 %), embedding in paraffin wax, and finally staining by using hematoxylin-eosin. Tissue samples were collected from histopathological laboratories of Gastroenterology and Liver Diseases Teaching Hospital, Baghdad.
Immunological Assessments: Enzyme Immunoassay for Determination of Serum Tumor Markers by Using ELISA Kit: Quantitative determination of serum levels of three tumor markers (CEA, CA19-9 and CA 242) in both patient and control groups was performed by means of ELISA (Enzyme Linked Immunosorbent Assay).

Results

The study included 40 patients with colorectal cancer, 23 male (57.50%) and 17 female (42.50%), with an age range of 18-78 years. The selected patients were classified into two groups: the first group represented serum of preoperative patients and the second group was of serum of postoperative patients. These two groups were compared to the third healthy group which was used as control. The control subjects included 20 individuals, 11 males and 9 females with ages ranged between 24 and 58 years.

Distribution of patients with colorectal cancer according to different risk factors:
The age of the 40 adult CRC patients included in this study ranged between 18 and 78 years, the maximum numbers of colorectal cancer patients was found within age group more than 60 years (20: 50%), then 12 patients in the age group of 40-60 years (30%), and the minimum number was 8 patients in the age group of less than 40 years (20%). Results in Table (1) demonstrate that the total number of patients was 40, of which 23 were male (57.50%) and 17 were female patients (42.50%). This implies that colorectal cancer is more common in men than in women, with significant differences between the two genders at P<0.05, also the proportion of smoking included 21 smoker patients (52.50%) and 19 non-smoker patients (47.50%), with statistically non-significant difference.

Carcinoma groups grading of the present study revealed that well- differentiated adenocarcinoma (G1) was seen in 4 cases (10.00%) of the CRC group, while 30 cases (75.00%) of patients had moderate differentiated adenocarcinoma (G2), and 6 cases (15.00%) had poorly differentiated adenocarcinoma (G3 ).There were a significant differences at (P<0.05) among carcinoma groups according to their grading (Table 1).

In the current study, most of the patients had carcinoma as the type of colorectal cancer. Concerning the staging of the tumor, 6 patients (15.00%) had tumor that invaded the submucosa (T1), 12 (30.00%) had tumor that invaded the muscularis (T2), and 22 (55.00%) had tumor that invaded through the muscularis into the pericolorectal tissues (T3).

The results of our study showed that, among the 40 patients with CRC, 4 (10.00%) had genetic disease, 9 (23.00%) had polyp, 11 (27.00%) had ulcerative colitis, and 16 (40.00%) had diabetes mellitus type II. There were a significant differences at (P<0.05) among carcinoma groups according to the risk factors. Most of tumors are localized in different sites of colon. In this study, about 2 patients (5.00%) had tumor in the transverse colon, 3 (7.5%) in the right colon, 8 (20.00%) in the sigmoid colon, 12 (30.00%) in the rectum, and 15 (37.5%) in the rectosigmoid.

Serum Levels of CEA, CA19-9, and CA242 Tumor markers in patients with CRC According to their characteristics and risk factors:

Results in Table (32) exhibited a significant increase of serum levels CEA in patients with age range of 40-60 years as compared with those with age less than 40 years old. However, there were no significant differences between the serum levels of CEA in patients with age more than 60 years old and the other two groups at P<0.05.

Comparing serum levels of CA19-9 showed no significant effects of age in patients with age less than 40 years old, 40-60, and more than 60 years old.

Significant increases were recorded in serum levels of CA242 in patients with age range of 40-60 years as compared with serum levels in patients with age less than 40 years old and more than 60 years old at P<0.05. Also, the patients with age more than 60 had a significant increase in serum levels of CA242 in comparison with patients with age less than 40 years old at (P<0.05).

The results in table (2) show a significant increase in the serum level of CEA in females in comparison with that in males at P<0.05. Nevertheless, no significant differences were recorded in the serum levels of CA19-9 and CA242 between males and females. Also the results demonstrate a significant increase in serum level of CEA in smoker patients as compared with non- smoker patients at P<0.05. The statistical analysis showed non-significant difference in the serum levels of CA19-9 (and CA242 between smoker and non-smoker patients).
The results showed no significant difference in sera mean levels of CEA, CA19-9, and CA242 in patients with colorectal cancer in the T1, T2 and T3, while the relationship between serum levels of CEA and tumor grades of patients with colorectal cancer showed a significantly increased mean level of CEA in patients with G2 tumor as compared with G1 and G3 at P<0.05. There was no significant difference in mean levels of CEA between G1 and G3. The statistical analysis also showed non-significant difference in serum means levels of CA19-9 and CA242 in patients with G1, G2, and G3 (Table 2).

Discussion

The development of colorectal cancer is caused by a combination of genetic and environmental factors. Epidemiology studies have revealed a number of risk factors for colorectal cancer including age, gender, smoking, family history of colon cancer or inflammatory bowel disease. Various individual characteristics or behaviors are included among the risk factors since they enhance the possibility to develop CRC. Age is one of the major risk factors for CRC. The risk of CRC increases with age. Several hypotheses have been suggested to find explanations for such a correlation between susceptibility to cancers and the progression in age, ageing of individuals is associated with increased and accumulated exposure to carcinogenic materials from the environment. In addition, the cellular mutation repair ability can be declined with increasing age (7).

Our study demonstrated that CRC is more common in men than in women. The incidence and mortality rates are higher by about 30 and 40%, respectively, in men as compared to women, while full explanation for this gender differences is not yet available, it is believed to be due to several factors such as higher exposure to carcinogens, differences in sex hormones, in addition to the interactions among the different factors (8).

Also the proportion of patients who smoked was higher than non-smokers; many studies have reported a higher risk of CRC among cigarette smokers, especially among those with a long history of smoking (9). Smoke from tobacco was reported to be one of the main carcinogen sources, such as heterocyclic amines, polycyclic hydrocarbons and nitrosamines. However, the evidence about the roles of these materials in development of colon cancer is insufficient (10).

Patients with adult onset type 2 diabetes show greater risk of CRC (11). Despite that the two diseases have several risk factors in common, such as obesity and a sedentary lifestyle, the correlation between them remains even after accounting for physical activity, body mass index, and waist circumference (12). Patients with chronic inflammatory bowel disease (IBD), who commonly suffer from inflammation in colon for extended periods, were reported to show a two-fold higher risk of CRC development (13). The extent, severity and duration of ulcerative colitis (UC), the most frequently reported form of IBD, were shown to associate with an elevated risk to develop cancer, UC is a chronic IBD with an unknown reason, mainly influencing the large intestine mucosa (14). Family risks of CRC are of a greater risk of developing the disease, with that history is mostly driven by genetic mutations and environmental factors (15). Genetics contributes to CRC risk by both gene-regulated pathways directly involved in disease development and inherited mutations accounting for about 10% of cases (16). The polyp is the classical model of colorectal cancer pathogenesis and it describes the phases of transition from benign tumors into colorectal cancer over many years, primary factors of polyp to CRC sequence are gene mutations, epigenetic alterations and local inflammatory changes (17).

Conclusions

1. In our study, we found that elderly age, male gender, smoking, and other infection, appeared to be the most possible association factors for colorectal cancer.

2. The appearance of tumor marker and their concentration are related to the genesis and growth of malignant tumors in patients, and it should correlate with tumor stages and grades.

3. There was a significant elevation in mean levels of CEA, CA19-9, and CA242 serum of CRC patients, when compared with healthy subjects.

Abstract

Background: Unintended pregnancy is associated with an increased risk of problems especially when woman is not in her optimal health for childbearing. The problem of unintended pregnancy and its complication can be reduced by the use of emergency contraception.

Objective: To explore the knowledge of health care doctors in Baghdad/Al Karkh, Iraq regarding emergency contraception pills.

Participants and Method: A structured questionnaire was distributed to a total of 390 primary health care doctors (obstetrics and gynecology specialists, general practitioners and family physicians). The questionnaire contained two main domains: demographic characteristics and knowledge about EC.

Results: The majority of the sample were females 287 (73.6%), and the general practitioner (41.8%), family medicine specialists (34.6%). about one third of them were in age 40–49 years old, 72.1% of the physicians have no training about emergency contraceptive..

Conclusion: A deficit in knowledge shown by health care physicians lead to an insufficient use of emergency contraceptive pills methods.

Key words: Knowledge, Emergency Contraception, PHC physicians.

Introduction

Emergency contraception (EC) refers to methods of contraception that can be used to prevent pregnancy after sexual intercourse. These are recommended for use within 5 days but are more effective the sooner they are used after the act of intercourse, EC pills prevent pregnancy by preventing or delaying ovulation and they do not induce an abortion. EC cannot interrupt an established pregnancy or harm a developing embryo(1). Unintended pregnancy is associated with an increased risk of problems for the mom and baby. If a pregnancy is not planned before conception, a woman may not be in optimal health for childbearing(2). The problem of unintended pregnancy and its complication can be reduced by the use of emergency contraception (EC) (3). Unprotected intercourse that demand the use of emergency contraception include failure of barrier methods such as slippage, breakage or misuse of condom, sexual assaults, failed coitus interrupts, two or more consecutive missed oral contraceptive pills, or simply because intercourse was unexpected and therefore contraception had not been used(4).

Emergency Contraceptive pills can serve as a backup method and can reduce the number of unintended pregnancies and abortions. There are three types of ECPs: combined ECPs containing both estrogen and progestin, progestin-only ECPs, and ECPs containing an antiprogestin (either Mifepristone or Ulipristal Acetate). Progestin-only ECPs have now largely replaced the older combined ECPs because they are more effective and cause fewer side effects. Although this therapy is commonly known as the morning-after pill, the term is misleading; ECPs may be initiated sooner than the morning after—immediately after unprotected intercourse—or later—for at least 120 hours after unprotected intercourse. Combined ECPs contain the hormones estrogen and progestin. The hormones that have been studied extensively in clinical trials of ECPs and found to be highly effective and well
The antiprogestin mifepristone approved for use in many countries for early first trimester medication abortion and it is highly effective for use as emergency contraception, with few side effects (delayed menstruation following the administration of mifepristone is one notable side effect) (8).

The aim of the present study is to assess the knowledge about EC pills among healthcare physicians at Baghdad Al Karkh/Iraq

**Participants and Method**

A cross sectional survey was conducted among health care physicians in Baghdad Al Karkh District during the period from Nov 2017 to Mar 2018. The studied population included 390 physicians (Obstetricians & Gynecologists, General Practitioner, Family physicians) in primary health care (PHC) centers. They were recruited by convenient selection method. The questionnaires were delivered to participant personally by the researcher himself at their work place to ensure completing the questionnaire instantaneously. Anonymity of participants was insured.

**Questionnaire:** Structured questionnaire were developed as per objectives of the study, this questionnaire was adopted from study made in 2005 for Exploring Knowledge, Attitudes and Practices of EC in PHC provider Tribhuvan University with modification (9). Each participant was asked to complete the questionnaire which consist of two elements; Sociodemographic information “gender, age, specialty, marital status, years of experiences and formal training” and EC knowledge in PHC “17 main questions and 6 sub questions”.

**Statistical Analysis**

The data were coded and each questionnaire assigned with a serial identifying number then entered by the researcher into the computer using Statistical Package for Social Sciences (SPSS) version 24. Data were presented in simple measures of frequency, percentage, mean, standard deviation, and range (minimum-maximum values). The significance of difference of different percentages (qualitative data) were tested using Pearson Chi-square test with application of Yate’s correction or Fisher Exact test whenever applicable. Statistical significance was considered whenever the P value was equal or less than 0.05.

Results

Table 1 presents the demographic characteristics of the health care providers who completed the study questionnaire; the majority of them were females 287 (73.6%) while the rest were males (26.4%). Among them were general practitioner (41.8%), family medicine specialists (34.6%), obstetric & gynecological specialists (9.2%) and from other specialties (Pediatric, ENT, rotator … etc.) (14.4%). Regarding their age, about one third of them were in age 40–49 years old (33.8%), 27.4% were 30-39 years, 24.4% were 50-59 years, and 9.2% were 20–29 years while about 5.2% were 60 years and above. Most of the PHC physician were married (82.1%) with working experience less than 10 years in 27.7% of them, 10–19 years (29.2%) and 20 years and above representing about half of them (43.1%).

The term EC was known by 82.1% of physician with their source of knowledge from college study (66.2%), MOH (24.1%), mass media (4.1%), continuous medical education in PHCC (2.5%) and others (brochures, reading, journals, internet e-mails….etc.) in 3.1% (Table 2).

Among 320 PHC physician who heard about EC 244 (76.4%) knew the trade name of the available types of EC. The majority of those 320 PHC physician mention that EC were same as COC pills and/or high dose of hormones “Ulipristal acetate” (UPA) (88.4%)

Table 3 reveals that 67.9% of PHC physician know the mechanism of action of EC as inducing abortion (37.4%), preventing implantation and ovulation (31.3%), only preventing implantation (25.3%), or no exact mechanism is known (6.0%).

Among 320 PHC physician, 41.3% of them think that the client no need to do pregnancy test before take EC and the rest either they trust their clients and consider need for pregnancy test before EC. More than half of the PHC physician (61.8%) consider the effectiveness of EC in preventing pregnancy is good, 24.4% as very good, while the rest either did not know (8.5%) or assume it as fair (5.4%). Regarding safety, more than two-thirds of physician (77.9%) believed that EC have a safe profile (Table 3). Table 3 also demonstrates that larger number of PHC physician have known the right indication of EC (78.7%) as follow, condom rupture 90.2%, condom slippage 81.8%, for woman had been a victim of sexual assault 81.1%, IUCD expulsions 66.8%, miscalculation of the periodic absent method 61.2%, while those physician who mention the wrong indication was as follow, when contraception method has been used 57.3%, condom used perfectly 57.0%, correct coitus interruption 48.2%.

Discussion

Family planning programs in Iraq are unfortunately limited and based only on little consultancy clinics within PHCCs and the private clinics . The use of contraceptive methods by Iraqi women reached a rate of 56.1% . Present study showed that 82.1% of PHC physicians heard about emergency contraception (EC). This finding is lower than results of Batur et al study in Turkey of 53.7% of PHC workers who heard about levonorgestrel EC. However, rate of hearing about EC by our study is higher than that reported by Mandiracioglu et al study in Turkey of 53.7% of PHC workers who heard about EC. Differences in hearing about EC proportions between studies might be attributed to discrepancy in quality of medical education and training of physicians between different countries. Current study revealed that 76.4% of PHC physicians know the name of EC. This EC knowledge rate is close to knowledge rate of family physician working in PHC reported by
Abdulghani et al(14) study in Pakistan of 71% and that of health care workers reported by Zeteroğlu et al(15) Study in Turkey of 74%.

However, knowledge rate of EC in present study is higher than results of Harrison cross sectional study in Nigeria which stated that only 45% of medical doctors could correctly defined the emergency contraception(16). On other hand, knowledge of current study PHC physicians regarding EC is lower than that of 87% knowledge rate of physicians reported by Lo et al(17) study in Hong Kong. These differences in knowledge regarding EC between studies may be due to different reasons like differences in governmental interest in family planning programs, information given as part of the medical curriculum lectures in medical colleges or during postgraduate training and continuing medical education. Most of PHC physicians (88.4%) had knowledge in EC method of combined oral contraception pills (COCs) and/or high dose of hormones (Ulipristal acetate (UPA)). This finding is higher than results of Oriji and Omietimi study in Nigeria(18) which reported that although, 98% of medical doctors had good knowledge in EC, 58% of them could not recognize the EC types. More than half (63.8%) of PHC physicians believed that combined pills is the best choice. Current study showed that 67.9% of PHC physicians knew the emergency contraception mechanism of action and 37.4% of them thought that mechanism by induced abortion. This proportion of knowledge is higher than results of Ebuehi O et al study in Nigeria which found that 48.8% of health care providers have good knowledge in EC mechanism of action. Knowing mechanism of EC action is essential for physicians practice, effectiveness and dealing with complications(19).

This study showed that 24.4% of PHC physicians believed that EC is very good and 61.8% believed that it is good. These findings are close to Results of Lawrence et al(20) study in USA which revealed that 89% of physicians believed that EC and access to EC would lower the rate of intended pregnancy. Knowing emergency contraception indications was observed among 78.7% of PHC physicians in present study. The highest knowledge regarding the indications was for condom rupture (90.2%) and lowest for correct coitus interruption (48.2%). These findings are close to results of Fok study in USA which reported that 74.7% of physicians had proper knowledge regarding the indications of EC(21).

In conclusion, a clear deficiency in PHC physicians’ knowledge about EC pills methods which leads to an insufficient use of EC pills methods.

Relationship of Vitamin D with Some Electrolytes in the Serum of People with Rheumatoid Arthritis in the City of Samarra

Adeeb Mahfooth Farag Al-Samaria¹, Kader Abdullah Shanak Al-Esawi², Esraa Ali Abdul Kareem Al-Samaria³, Dhamer Ismael Madab AL-Khazraji⁴

¹Iraq/Ministry of Education / Directorate General of Salah Uddin Education, ²Iraq/Ministry of Scientific Research-University of Fallujah, ³Iraq/Ministry of Scientific research-University of Samaria, ⁴Iraq/Ministry of Education / Directorate General of Salah Uddin Education

Abstract

The study was conducted on 50 samples of 30 patients with rheumatoid arthritis. The samples were divided into 15 females, 15 males and 20 control group (healthy) without any disease. The sample was divided into 8 females and 12 males. 80 years) and collected samples from Samarra General Hospital and outpatient clinics of the city. The blood was then collected from the healthy and sick people and separated by centrifugation. Biochemical variables were measured (vitamin D, glutathione, Mallon dialdehyde, uric acid).

The results of the current study showed a significant decrease in the level of vitamin D in the serum of people with rheumatoid arthritis compared to healthy people, and the results showed a significant decrease in the level of glutathione in the serum of people with rheumatoid arthritis compared to healthy people, with no significant differences in Level of Mallon dialdehyde. We also note a significant increase in the level of uric acid in the serum of people with rheumatoid arthritis compared to healthy people.

Key Words: - rheumatoid arthritis, Vit. D, Oxidative stress

Introduction

Arthritis is often used to indicate any disorder affecting the joints¹, including symptoms such as Jointstiffness, Joint pain, Redness, Swelling, difficulty in movement, and may affect other organs. Rheumatoid arthritis, rheumatoid arthritis, gout (²) osteoporosis usually occurs with age and affects the joints near the ends of the fingers at the base of the thumb and neck and below. Back, knees and hips. (³) Rheumatoid arthritis is an autoimmune disorder that often affects the shoulders, hands, knees and feet and also affects cartilage, tendons, and bones through swollen vertebral tissue (²).

Rheumatoid arthritis is a multifaceted form of disease whose causes, symptoms, and treatment are different (⁴). Rheumatoid arthritis is a common health problem affecting millions of people worldwide, leading to higher health care costs (⁵) Of the world’s population, with a prevalence rate of 1-0.5% (⁶), while in Colombia it was 0.9% (⁷).

The treatment of arthritis is focused on alleviating the symptoms and improving the ability of the joints to function. It is sometimes necessary to experiment with various treatments or to combine different treatments with each other in order to be able to determine the best treatment for the patient. There are many drugs used to treat inflammation (⁸) Including analgesic drugs, nonsteroidal anti-inflammatory drugs or some dietary supplements such as Glucoseamine and Chondroitin sulfate. Studies have shown that corticosteroids use longer and higher, leading to peripheral joints. (⁹) There are many environmental factors that increase the risk of rheumatoid arthritis and the most serious risk is smoking. Previous studies have shown that smoking increases the development of the disease, especially in patients who have a positive result of ACP (¹⁰). Environmental factors are not just smoking, but factors such as food, alcohol, vitamin deficiencies, viruses and bacteria. (¹¹) These factors are all outside the body and have no genetic basis, so they are called non-genetic factors (¹²). Epstein Barr Virus (EBV) was also associated with rheumatoid arthritis. There was an abnormal increase in the number of B lymphocytes infected with this virus in the blood of the rheumatoid arthritis patient. This virus stimulates the
production of antibodies including the rheumatic factor (13).

Vitamin D is a type of fat-soluble vitamin, and sun exposure is the main source for the body’s needs of this vitamin, so it is called vitamin sun rays, which is different from the rest of the vitamins not necessary from food sources for this reason enough exposure to radiation sun for 10 to 15 minutes a day on sunny days, and two to three times a week to get vitamin D requirements in the majority of people (14).

Vitamin D is of biological importance to the body of the organism. It is essential for balance of calcium, bone growth and regulation of the immune system. Its deficiency can cause rickets disease, osteoporosis, osteoporosis and muscle weakness. Vitamin D deficiency is linked to cancer, cardiovascular disease and schizophrenia. Arthritis, type 1 diabetes, IDDM, psoriasis and vitiligo (15), as well as a decrease in risk associated with increased mortality (16) and increased risk of breast cancer (17).

Oxidative stress is defined as the imbalance between free radicals (ROS), Reactive Nitrogen Species (RNS), and antioxidants, which are important indicators of many pathological conditions, including atherosclerosis (18), as well as disorders Heart, blood vessels and arthritis (19) and an imbalance between it and antioxidants may also cause an increase in blood pressure Hypertension (20).

Since vitamin D may be related to rheumatoid arthritis, the current research target for measuring vitamin D in patients with rheumatoid arthritis.

Material and Method

Collection of specimens

The study was conducted on 50 samples of 30 patients with rheumatoid arthritis. The samples were divided into (15 females, 15 males) and 20 control groups (healthy) without any disease. The sample was divided into 8 females and 12 males. 80 years) and collected samples from Samarra General Hospital and outpatient clinics.

Blood collection

Collect about 6 cm³ of the blood of healthy and sick people and is divided according to the type of test. The blood is placed in the Jell tubes. It has an airtight cover, free of anticoagulant, leaving the blood at 25 °C until it coagulates and then placed in the centrifuge for 10 minutes at 3000 cycles/minute and then the serum was obtained and then placed in small test tubes and kept in the refrigerator at a temperature of 20 - M for the purpose of measuring the biochemical variables, including (vitamin D, glutathione, Mallon dialdehyde, uric acid).

Estimation of Vitamin D

The level of vitamin in the serum was assessed using the Kit kit and manufactured by German company Human by method (21).

Estimation of antioxidant

Glutathione-GSH was estimated by Sedlak, Tietz (22,23). The concentration of uric acid in the serum was estimated using the enzymatic method using several prepared analyzes prepared by the Tunisian Biomegrheb (24).

Estimation of Oxidative stress

Determination of the level of Mallon dialdehyde-MDA in Guidet (25).

Statistical analysis

The results of all tests were analyzed using statistical program SPSS14, mean Mean and standard deviation (SD), and the special differences between the infected groups and the control group were determined using T.Test (26).

Result and Dissection

Measuring the level of vitamin D

The results showed a significant decrease in serum vitamin D levels in people with rheumatoid arthritis compared to healthy subjects as shown in Figure 1.
Vitamin D deficiency may lead to rheumatoid arthritis. Lee (2016) (27) points out that vitamin D decreases in people with rheumatoid arthritis, which is consistent with current research results. Azzen (2012) (28) found that vitamin D has a role in reducing the risk of rheumatoid arthritis, as there are many immunosuppressive effects including vitamin D as there is a potential relationship between vitamin D deficiency and autoimmune disease (29).

Vitamin D has been studied as an important and potential measure of the causes of many diseases, including rheumatoid arthritis. (30) The reason for vitamin D deficiency may be due to insufficient absorption of the vitamin D, which may be associated with exposure to sunlight (31). Athanassion (2012) (32) also noted that vitamin D deficiency is very widespread in patients with rheumatoid arthritis and that its deficiency greatly increases the disease. There should also be vitamin D supplementation to prevent osteoporosis as well as relieve pain for patients with rheumatoid arthritis. (33) (2017), Hamad, noted that vitamin D levels were lower in rheumatoid arthritis patients as there should be comprehensive research studies on the role of vitamin D in the development of rheumatoid arthritis and its relationship to disease activity. Vitamin D has the function or function of regulating immunity associated with the potential effectiveness of vitamin D receptors. These include the treatment of many diseases, including rheumatoid arthritis and psoriasis, as well as many diseases (34).

**Glutathione concentration measurement**

Result shows the mean ± morbidity of the GSH level as the results showed a significant decrease in the level of GSH in the serum of people with rheumatoid arthritis in healthy people as in Figure (2).

In its study, Al-Maamory (35) reported a significant decrease in the level of glutathione in the serum of people with rheumatoid arthritis compared to healthy subjects, which is consistent with the results under study.

The low level of glutathione is due to several reasons, including the increase in the rate of consumption, which is one of the most important non-enzymatic antioxidants in the removal of free radicals and their products, transforming from the effective form to the ineffective form. The sulfur group in the GSH structure is a low-efficient factor. Between sulfur and hydrogen (SH) and the power of kin between carbon and hydrogen (CH) in the free radicals so they protect the cellular membranes from damage to free radicals.

One of the reasons for the low level of GSH is a deficiency in the raw materials of its structure, in particular the adjuvant enzyme (the reduced form) nicotine amide adenine deoxyribonide phosphatase, which is the catalyst for the action of the enzyme GRd, which works to restore the effective form of the collation of the ineffective form (36).

**Measurement of Mallon dialdehyde**

Result shows the mean ± standard deviation of the level of Mallon dialdehyde. The results showed that there was no significant difference in the concentration of Mallon dialdehyde in serum group of infected and healthy people as in Figure (3).

The results are not consistent with both Abbas (2011) (37) and 2008 (AL-Maamory)(35), who noted in their study that there was a significant increase in the level of MDA in the serum of people with rheumatoid arthritis.
Measurement of uric acid

Result shows the average ± standard deviation of uric acid level. The results showed a significant increase in serum uric acid concentration in people with rheumatoid arthritis compared to healthy subjects as shown in Fig. 4.

Sheania (2011) reported a significant increase in the level of uric acid in the serum of rheumatoid arthritis patients and this is consistent with the results under study. Das (2014) (39) indicated a rise in serum uric acid levels in people with rheumatoid arthritis.

Study of Thyroid Hormones for Vitiligo Patients in AL-Anbar Governorate

Yasser Q. Hussein1 Wajeeh Y. Mohammed1 Abdulla S. Al-Hasan2, Sabri M. Al-marsomi1

1Iraq/University of Anbar – College of Science/Biology Dep.,
2Iraq/University of Anbar – College of Medicine/Microbiology Dep.

Abstract

Vitiligo is a common acquired depigmentation disorder characterized by the loss of functional skin and mucosal melanocytes the reported incidence is 0.5% to 2% worldwide. Its pathogenesis is mostly consider autoimmune and this pigmentary disorder is strongly associated with autoimmune thyroid disorders. To evaluate the serum thyroid hormone in vitiligo patients of Al-Anbar governorate and to compare the results with other external studies. The study group included 80 patients with vitiligo, and 40 healthy volunteers. Blood thyroid hormone was determined using Monobind kits from reliable USA company. Their ages ranged form 1 to 70 years. Family history of vitiligo was positive in a percentage of (30%) of the patients. The mean levels of serum thyroid hormone (T3, T4) in patients with vitiligo were found to be no significant difference than those of healthy individuals. The TSH level in patient with vitiligo were found to be significantly higher than those of healthy individuals. This study strengthens the relationship between the thyroid hormones intake, formation, and metabolism with the pathogenesis of vitiligo. Therefore it is concluded that vitiligo patients should be evaluated for thyroid hormones.

Key Words: Vitiligo, Thyroid hormone, Autoimmune thyroid, T3, T4, TSH.

Introduction

Vitiligo is an acquired hypopigmentary skin disorder affecting the population of worlds without discrimination of race, age, gender and ethnic background(1). It is characterized by the formation of white patches and these patches associated with the loss of local melanocytes. Vitiligo involves the progressive loss of epidermal melanocytes and sometimes hair follicle melanocyte(2). Vitiligo is more significant in population of dark skinned individuals, due to its pigmentary disfigurement and has major impact on quality of life of patients(3). It produces social stigma in the affected individuals and is often confused with leprosy or other socially terrifying infectious diseases. It is a non-contagious disorder and the most commonly acqurid hypomelanosis(4). The lesions in vitiligo patients are most commonly found on the body areas that are exposed to sun like hands, arms, faces, feet etc. Patients suffering from vitiligo may have premature graying of the scalp hair and eyebrows along with the appearance of white patches on the skin. Vitiligo is linked with simultaneous occurrence of other autoimmune diseases as well as psychosocial difficulties (5)(6)(7). In certain cultures, patients having vitiligo are regarded as social outcasts(3). Several reports have suggested associations between vitiligo and a variety of other autoimmune diseases, including thyroid conditions, alopecia areata, type 1 diabetes mellitus, pernicious anemia, and rheumatoid arthritis. Autoimmune thyroid diseases are common in patients with vitiligo(8). Studies have reported that the incidence of thyroid disease is 0-52% in patients with vitiligo, and that 3% to 90% of vitiligo patients have antithyroid antibodies(9)(10). Therefore, routine screening for thyroid dysfunction is recommended for patients with vitiligo(11).

Patients and Method

A total 80 patient with vitiligo were enrolled. Half number of healthy individuals with matching ages were included as controls. The samples were collected from the patients during their visiting to dermatological clinic of Dr. Abdullah salih Alhasan in Al-Anbar governorate. The ages of the patients ranging between 1-70 years old from both sexes. Many questions were asked to the patients about his name, age, accommodation, occupation, chronic diseases, family history, time of
infection, the presence of psychological disturbances, smoking, most common diet, most common drinks, spiritual questions (prayer), time of disease exacerbation, and the factors that exacerbate vitiligo to avoid the interferences with the other diseases, and to find a cause for this disease. All of patients and healthy individuals were not smokers, have no any chronic diseases, and not alcoholic drinkers. A total of (10 ml) of venous blood was drawn in sterile syringe and centrifuged to separate the serum and then stored at -45°C until begin used. The estimation of triiodothyronine (T3), thyroxine (T4), and thyroid-stimulating hormone (TSH) levels were done by using a Microplate Enzyme Immunoassay(12)(13)(14) from Monobind company (made in USA).

Results

The study included a total of 120 persons. Among them 80 had vitiligo (30 male and 50 female) and 40 were healthy controls (8 male and 32 female). Their ages ranged from 1 to 70 years. Family history of vitiligo was positive in a percentage of (30%) of the patients. The duration of disease ranged between 1 month to 20 years. History of seasonal variation of disease was positive in (60%) patients. Out of these (10%) noticed exacerbation of disease in winter while (50%) in summer season. Bad emotional state exacerbates of about (70%) of vitiligo patients, while the other (30%) dose not affected. This study showed that there is no relationship between the occupation, accommodation, most common diet, most common drinks, and spiritual side and vitiligo. In the patient’s group T3 and T4 were not significant statistically than those in control group. while TSH was significantly higher than those in control group. The results are depicted in Table 1. The values are reported as mean ± SD and 95% confidence interval. For statistical analysis between groups paired t test was used. Pearson test was used for correlation analysis. The levels of each marker were compared between the study groups and control group, using SPSS computer package. P values of ≤ 0.05 were considered significant. The table above shows that T3 and T4 are not significant difference between patients and controls (P ≥ 0.05). While TSH is significantly higher in patients in a comparison with controls (P ≤ 0.05).

Table 1: the mean value ,S.D, t-value, and p-value of the parameters were tested.

Discussion: Thyroid functional disorders and autoimmune thyroid diseases have been reported in association with vitiligo, and it seems that the incidence of clinical and subclinical thyroid involvement the incidence of clinical and subclinical thyroid involvement is more common in vitiligo patients than controls(15)(16)(17). Many researches about vitiligo and thyroid disease have been done with different results, one of these Mubki et al.,(2017)(18) showed that thyroid functional abnormalities were generally found more in vitiligo patients were approximately 1.6 times more likely to have abnormal TSH than control. The mean TSH level was overall higher in the vitiligo group. Both high TSH and low TSH levels were seen more frequently in vitiligo patients. The vitiligo group had significantly higher prevalence (5%) of primary hypothyroidism (high TSH and low T4) as compared to the control group. Alissa et al.,(2011)(19) and Akay et al.,(2010)(20) showed the predominance of females among vitiligo patients can be attributed to the fact that females are more conscious
about their cosmetic appearance and thus more likely to seek medical attention. Vitiligo seems to be commonly associated with autoimmune diseases. Two studies have reported associated autoimmune disease in (19%) and (23%) of vitiligo patients.(21)(22).

One of the most commonly reported associations is thyroid disease, especially Hashimoto’s thyroiditis.(23). The reported prevalence of thyroid disease in the literature ranged from (4%) to (21%) to even higher in other studies.(22)(24)(25).

Conclusions

From our results we conclude that a strong relationship is found between the thyroid hormones and the pathogenesis of vitiligo.

Detection of Quorum Sensing Signal Molecules and Identification of espB and Crt4 genes among Biofilm Forming of Citrobacter freundii

Wathiq Abbas Hatite Al-Daraghi¹, Mautham Khazaal Kadhim AL-Behadili¹

¹Institute of Genetic Engineering and Biotechnology for Postgraduate Studies, University of Baghdad, Iraq

Abstract

150 samples from different clinical sources were collected from October 2018 to March 2019 from three hospitals in Maysan: Al Sadr General Education Hospital, Al Zahrawi Surgical Hospital and Maternity and Child Hospital to demonstrate the spread and distribution of Citrobacter freundii in several hospitals in Maysan. All isolates were identified based on morphological characteristics and biochemical tests. Results were confirmed by Api 20 E and Vitek 2 compact. A total of 14 isolates (9.3%) of 150 were found to be Citrobacter freundii. The isolates were considered as acute diarrhea in children, UTI, burns, wounds and most frequent ear swabs. PCR results showed that the LuxR 428bp genes were present in the Citrobacter freundii bacteria identified by previous diagnostic methods and this confirms the accuracy of the tests and methods used to determine this type.

Keywords: Citrobacter freundii; espB and Crt4 genes; Quorum sensing signal

Introduction

Citrobacter, a genus of the Enterobacteriaceae family, Gram-negative, facultative anaerobic bacteria that look as coccobacilli or rods (1). Citrobacter spp. are motile using their peritrichous flagella, can ferment mannitol with making of H2S, and can use citrate as their single source of carbon (2),(3). Citrobacter spp. are uncommon opportunistic nosocomial bacteria can cause urinary tract, hematologic, or neonatal infections (e.g. meningitis, sepsis, general bacteremia); intra-abdominal sepsis; brain abscesses; or pneumonia (4),(5). Citrobacter spp. infections can be mortal with 33-48% overall death rates being reported including 30% for children(6),(7). Children and immune deficiency, elderly, or weakened patients are at risk of infection (2), (9). Citrobacter spp. is prevailing worldwide, as it is a part of the normal intestinal flora of humans (10),(11). Less well known species that have also been implicated in foodborne disease like some strains of Citrobacter spp. (notably C. freundii), Klebsiella spp., Providencia spp. Enterobacter spp. and Proteus spp., may occasionally cause what is often described as opportunistic gastroenteritis (12), this study aimed to isolation and identification of C. freundii from chicken meat samples using cultural and molecular techniques.

Method and materials

Samples collection

150 samples from different clinical sources were collected from October 2018 to March 2019 from three hospitals in Maysan.

Isolation

each sample was inoculated on the Salmonella shigella (SS) agar medium, the plates were left to solidify at room temperature, and then were incubated at 37 °C for 24-48 hours. Later the grown colonies were further investigated

Identification

The Citrobacter isolates were identified to the level of species using the traditional morphological and biochemical tests (13). The identification of isolates was confirmed by vitek2 compact system.

Cultural characteristics on selective and differential media.

SS, MacConkey and Xylose lysine deoxycholate (XLD) agar
The organisms were cultured on S.S agar media and incubated overnight at 37°C. The colonies of C. freundii appear with black center after 24hrs incubation period. The suspected colonies of C. freundii cultured on MacConky media, the positive result appears pink (Lactose fermenters) after 24hrs incubation period, pale colonies further incubated for 24hrs to identify the (late lactose fermenters). The selected colonies were cultured on Xylose lysine deoxycholate agar, after 24hrs, the positive result appeared as yellow colonies (13).

Eosin Methylene Blue (EMB) agar

In order to differentiate Citrobacter from E.coli, the lactose fermenter isolates were subcultured on EMB for 24hr. at 37°C. Brown colonies were the positive result (14).

Identification of bacteria by Vitek 2 compact system.

Vitek 2 compact was used to identify the bacterial isolates. It is a compact system of two parts, Instrument and computer. The reagent cards have 64 wells that can each contain an individual test substrate. Substrates measure various metabolic activities such as acidification, alkalinisation, enzyme hydrolysis, and growth in the presence of inhibitory substances.

Identification of Bacteria by PCR

DNA Extraction

Genomic DNA was isolated from Bacteria according to the protocol of Wizard Genomic DNA Purification Kit, Intron. A PCR reaction with a specific primer (Table-1).

(25µl) of PCR amplification mixture contained (12.5 µl) Master mix, (1 µl) forward primer, (1 µl) reverse primer, (8.5 µl) nuclease free water, and (2 µl) DNA template. The protocol for PCR condition was initial denaturation 95°C for 5 min. denaturation 95°C for 30 sec., annealing 60 °C for 40 sec., extension 72 °C for 1 min. and final extension 72 °C for 7min.

Results and Discussion

Bacterial Isolation and Identification

Twenty five chicken meat samples were collected from local markets in Baghdad city. Citrobacter was detected in 3 samples, were all samples cultured on S.S. agar for initial isolation, after incubation at 37°C for 24 hr ; different types of bacterial isolates appeared on S.S. agar, of them: small pale flattened colonies with
black center due to their ability to produce H2S on S.S agar, then these colonies sub-cultured on MacConkey, XLD and EMB to differentiate Citrobacter from Salmonella because both of them are H2S. Citrobacter is lactose fermenter on MacConkey agar appeared as pink colonies while Salmonella is pale colonies (Non lactose fermenter) on XLD Citerobacter appeared as yellow colonies while Salmonella appeared as red colonies with black center. After incubation period; lactose fermenter (pink) on MacConkey and yellow colonies on XLD while on EMB they were brown in colour, these were depended as Citrobacter. To confirm the primary identification Gram stain was performed to examine the microscopic properties which were Gram negative bacilli. The ability of Citrobacter to produce urease enzyme was detected using urease test in order to differentiate it from the genus Proteus which was urease producer while Citrobacter isolates were non urease producers. Thus depending on colonial morphology; bacterial isolates were identified as Citrobacter Figure-1 (A, B, C, D) and (Table-3) showed these biochemical tests used to identify Citrobacter as described by(15),(16).

To confirm the identification of Citrobacter spp. Vitek 2 compact system was depended and the result showed that the isolated bacteria in this study was Citrobacter and the species freundii

In order to confirm the identification of Citrobacter to species level LuxR gene amplification was performed using monoplex PCR technique, 1.5 % agarose gel electrophoresis was used to detect the positive result as shown in Figure-2.

(Figure 2) Amplified PCR products of LuxR gene (428 bp): Agarose gel electrophoresis, ethedium bromide stained, 1.5 % agarose, electrophoresed in 75 volt for 2 hrs and photographed under ultraviolet trans-illuminator. M: The DNA molecular weight marker (100 bp ladder) and 1: the amplified PCR product of LuxR of C10 isolate of Citrobacter freundii.

One of the most gorgeous likely uses of 16Sr RNA gene sequence informatics is to offer genus and species or tax identification for isolates (17). Although 16SrRNA gene sequencing is highly valuable in regards to bacterial classification (18). PCR products were exposed to direct sequencing, both strands of PCR products were sequenced with an automatic sequencer. Sequences were analyzed with the Basic Local Alignment Search Tool (BLAST) in National Center for Biotechnology Information (NCBI).

Conclusion

The following conclusions were obtained from this study:

- The prevalence and distribution of Citrobacter spp. in some Maysan hospitals shows a relatively low percentage in its distribution.
- The dominance species of Citrobacter was Citrobacter freundii.
- All isolates of Citrobacter freundii produced Bioflim formation by Congo red agar, Christensen method and micro-titer plate assay.
- The effect of different temperature and pH values on Citrobacter freundii growth showed that best growth temperature was 37°C and the best growth pH for growth was 7.
• These data are of great significance as the signal molecules aid in biofilm formation which in turn confer various properties of pathogenicity to the clinical isolates including drug resistance. The use of quorum sensing signal blockers to attenuate bacterial pathogenicity is therefore highly attractive, particularly with respect to the emergence of multi antibiotic resistant bacteria.

The effect of Beta-amino Butyric Acid in Levels of Interleukin4 & Interleukin 10, Complement Proteins C3 & C4 and Immunoglobin IgM in Males Rats Sprague Dawley Infected with Pseudomonas aeruginosa

Zainab Makki Sagheer1 Mohammad Abas Jasim1
1Department of biology/ College for Women Education University of Anbar/Iraq

Abstract

B–amino butyric acid (BABA) non protein amino acid has effect on some immunological parameters of male rats Sprague Dawley species infected with pseudomonas aeruginosa. this study include 25 animal divided into five groups A, B, C, D and E each group contain five animals, A, B and C groups injected with three concentration of amino acid solution (25 mg/ml, 50 mg/ml and 75 mg/ml) with dose (0.2 g/kg, 0.4g/kg and 0.6 g/kg) respectively, intra peritoneal weekly for six weeks, group D (first control group) and E (second control group) injected with normal saline. At the fifth week the four groups A, B, C and D exposed to pseudomonas aeruginosa, while group E did not exposed to infections after the termination of period of treatment, The blood samples were collected to do the immunological tests, the statistical analysis P<0.05 results showed BABA did not enhance sensitivity through measuring interleukin IL4, and significant increase of IL10 and complement protein C4, while BABA didn’t have a negative effect on the complement protein C3 activation and increase the level of immunoglobulin IgM.

Keywords: Beta-aminobutyric acid, Sprague Dawley rats, Pseudomonas aeruginosa, Interleukin IL10, IL4, Complement proteins C3 & C4, Immunoglobin IgM.

Introduction

The bacteria considered important causes of disease, that include the most of diseases that infect humans in the word and the most important prefix and present and futurism epidemiological diseases(1), Pseudomonas aeruginosa considered important bacterial species due to its content of virulence factor that increase its pathogenicity(2). It’s considered dangerous for patients especially patients with wounds & burn inflammation, that it can invade blood supply and cause Septicemia especially patients with Immunodeficiency(3). P. aeruginosa characterized by its resistance to antibiotics and disinfectant, and this cause big problem in whole the word and the main cause of this resistance is random use of antibiotics without restriction(4), due to continues antibiotic residue lead to development of bacterial resistance to antibiotics(5), this what make researchers to new applications by using chemical materials other than antibiotics(6), that enhance body resistance to bacterial infections, the nominated materials to replace antibiotics is organic acids(5), Which are include many acids like Non-protein amino acids that present in the nature, more than 1000 non protein amino acid produced by plants and microorganism and other sources(7), these components did not have specific functions in the nature, but they noticed have many physiological functions In vivo studies(8), For the example, Gamma-amino butyric acid (GABA) work as stimulator and regulator of immune response that it boosted the Innate immunity and Adaptive immunity, that work on improvement of body resistance against bacteria by activation of Phagocytosis, and matureness of Macrophages and improve its response against microorganism(9), and activation of T cells and B cells, increase antibodies like IgG and IgM(10), GABA increase of Anti-inflammatory cytokines like interleukin IL10 and suppression of Pro-inflammatory cytokines and work on stimulation of Apoptosis of cells that damaged by pathogenic factors(11), also the Non-protein amino acids β-amino butyric acid (BABA) was improved recently that make hematological and immunological changes, that increase...
red blood cells, white blood cells, hemoglobin, packed cells volume and lymphocyte, also cause increase in immunoglobulin IgG\(^{(12)}\).

Due to rarity of studies about the effect of this acid in animal aspect with its availability in plant aspect, and due to BABA known with its ability to stimulate plant resistance against wide range of causative agent like viruses, bacteria, fungi and worms\(^{(13)}\), also have significant effect in plant resistance to insects\(^{(14)}\).

So this study aimed to identification of ability Non-protein amino acids BABA to induction of rats resistance to \(P. \text{aeruginosa}\).

**Materials and Method**

**Preparation of amino acid solution**

Amino acid solution prepared by dissolving 0.5g, 1g and 1.5g from acid in 20ml of normal saline to obtain the first concentration C1 (25mg/ml) and second concentration C2 (50mg/ml) and third concentration C3 (75mg/ml) respectively with continues mixing until acid dissolving then the wanted dose prepared according to animal body weight, with percentage of 0.2g/kg from first concentration C1 and 0.4g/kg from second concentration and 0.6 g/kg from third concentration.

**Preparation of the lab animals**

Experimental animals consist of 25 of Sprague Dawley male rats with age 10 to 12 weeks and weight ranged between (225-300) g, divided into five groups each groups five animals divided as following:

1- Group A first concentration group C1(25mg/ml)
2- Group B second concentration group C2 (50mg/ml)
3- Group C third concentration group C3 (75mg/ml)

The groups above injected with amino acid intrapersonal\(^{(15)}\) weekly for six weeks.

4- Group D first control groups: injected with normal saline intrapersonal.

The four groups above exposed to infection with \(P. \text{aeruginosa}\) Bactria.

5- Group E second control group this group injected with normal saline intrapersonal and did not exposed to infection with \(P. \text{aeruginosa}\).

**Animal infection with \(P. \text{aeruginosa}\)**

The animal infected after the fifth weeks of amino acid BABA injection at age (15-17) weeks with weight ranged between (265-380) g. the isolation activated with by obtain part of bacterial cultivation to inoculate nutrient broth tube and incubate with 37 C for 24 hours. After appear of the bacterial growth decimal dilution done by using normal saline and 1 ml of each diluent was obtained and inoculates on nutrient agar to count the colonies in the suspension. Rats anesthetized with Chloroform. Than shaved the area down the head from the back\(^{(16)}\). Wounded the skin deeply without damage the subcutaneous muscles, after sterilization by using forceps and Scissor, skin biopsy obtained in about 6mm diameter of five animal groups (A, B, C,D and E), by using Micropipette 200µm of suspension with turbidity (2 x 10\(^6\)) putted on the wound to contaminate it\(^{(17)}\) in four animal groups that include group A, group B, group C and first control group D, while second control group E did not contaminated with bacteria.

The animals examined for its nutrition and activity and wound healing after expend of seven days of infections the physiological and immunological tests were done.

**Serological tests**

Immunological tests were carried out on the serum of the rats to detect the level of IL-4, IL-10, C3, C4 and IgM in all groups. Blood was obtained from posterior vena cava\(^{(15)}\).

3 ml of blood was withdrawn in plastic tubes free of anticoagulant to obtain the serum using centrifuge 3500 rpm for ten minutes. The serum samples were kept at -20°C until the time of testing using (Elisa kit/ Elabscience Biotechnology Inc. /USA) and (Genus Kit/ Genrui Biotech Inc./China)

**Statistical Analysis**

The statistical analysis done by using One-way ANOVA test with statistical analysis program SPSS 22 edition and the mean calculated and stander deviation, finding LSD value from Multiple comparisons table at level of significance 0.05.
Results and Discussion

Effect of BABA on level of interleukin IL4

The results of statistical analysis as in table 1 which show the significant differences in LSD values between groups, and figure 1, show that A, B, C and D (three concentration group and first control group) that exposed to bacterial infection was recorded significant increase in level of interleukin IL4 compare with second control group that did not exposed to bacterial infection.

![Figure 1 show the means of interleukin IL4 values](image)

From the above the level of IL4 that increased in infected groups as the results of infection with bacteria not resulted from BABA amino acid that appeared the mast cells are activated to interact with wound repairing and wound healing at the same time with infection by microorganism, that have vigilant factors that disturb wound healing mechanism as Exotoxins of P. aeruginosa this cells stimulated presented in the subcutaneous tissue that migrate to the wound site and secrete its content due to expose to bacteria products, the studies conclude that the mast cells activated by its exposer to bacterial toxin or lipopolysaccharide (LPS) bacterial wall content, also fined that the mast cells that present in peritoneal layer execrate Histamine as the results of P. aeruginosa bacteria in rats, and it’s an important source of early response cytokines like IL4 that necessary to begin the immune response and inflammation of the host ageist invaders\(^{(18)}\), and considered main resource of IL4\(^{(19)}\), that the mast cells activated by bacteria that cause diseases also in the case of absence of antibodies and information and in this case be the source to generate IL4 and other regulating cytokines to do Non-opsonization reactions\(^{(18)}\), the mast cells response to many stimulators independently without interaction of IgE and release its component, in this situation did not considered hypersensitivity response because IgE not unclouded in the interaction, and this explain support absence of signs of hypersensitivity in animals.

Effect of BABA on level of IL10

The results of statistical analysis P<0.05 as in table 1 and figure 2 show the A group record significant increase in level of IL10 in compare with E and D control groups, also group C record showed significant increase in level of IL10 in compare with E second control group.

![Figure 2 show the means interleuken 10 value](image)

By notest the figure 2 showed that the mean of IL10 value elevated in animal groups treated with BABA amino acid in compare with E and D control groups but just group A recorded significant increase in compare with control groups E and D, and group C recorded significant increase in compare with E second control group, while group B did not recorded any significant increase for unclear causes, and this may explane the level of IL10 in group A and the dose 0.2 g/kg of BABA amino acid and this dose needed for production of IL10 with significant level and this agree with what mentioned by\(^{(11)}\), that the GABA which analogous with BABA, increase the production of IL10 significantly in case of colon inflammation induced in mice, that GABA work as stimulator for antiinflammatory cytokines and inhibit Pro-inflammatory cytokines and enhance Apoptosis for cells that damaged with diseases factors.

Effect of BABA levels of complement proteins C4 and C3 and immune globulin IgM

Results of Statistical Analysis P<0.05 showed as appeared in table 1 and figure 3 that the five group A, B, C, D and E did not show any significant increase in level of complement protein C3, with non-significant sharp decrease of C3 mean values in group A, also decrease the value of C3 in second control group E, and the decreased values indicate the activation of complement protein\(^{(20)}\).
Figure 3 show the means of complement protein C3 values

While the complement protein C4 the results of statistical analysis P<0.05 were showed as in table 1 and figure 4 that the group A recorded significant increase in level of C4 in compare with group B, while other groups did not recorded any significant differences, and this increase may cause by bacterial infections or may be due to the 0.2 g/kg dose of BABA acid is the optimal dose to increase complement proteins C4 significantly, as appear in figure 4 that showed means of complement proteins C4 values.

Figure 4 show the means of complement protein C4 values

From the compares between figure 3 and figure 4 noticed there are negative correlation between C3 and C4 values and this difference may return to activation of complement C3 to activate Alternative pathway or Lectin pathway as an innate immune response to infection, and lead to activation B cells to production of antibodies to activation of Classical pathway\(^{(21)}\). And this indicates that the BABA amino acid did not have negative effect to prevent complement C3 activation process. And have positive effect in activation of classical pathway of complement system that depends on C4 protein.

While measurement of immunoglobulin IgM, the results of statistical analysis (P<0.05) as in table 1 and figure 5, that the group A was recorded significant increase in level of IgM in compare with group B, C and E, that the 0.2 g/kg lowest dose suitable to production of IgM and this results did not agree with\(^{(21)}\) mentioned that the increase dose increase production of immunoglobulin IgG and this may returned to interactions with bacterial infections or may results category of antibody and molecular compound of each one.

Figure 5 show the means of immunoglobulin IgM values

By compare of figure 4 and figure 5 noticed that presence of clear positive proportions between complement protein values C4 and immunoglobulin IgM, and this may lead to activation classic pathway of complement system, the interaction of B cells that produce immunoglobulin IgM that stimulate activate of classic pathway of complement system, and activation

**Conclusions**

Current study assures that the non-protein amino acid BABA have clear positive effect in accelerate of wound healing process and decrease inflammation, the serological tests P<0.05 ensure that the BABA did not generate hypersensitivity in animal of experiment. BABA have positive effect in production of IL10 then it has role in regulation of immune response, BABA did not stop activation of complement system but lead to stimulation of B cells to production of IgM antibody and interaction between Innate immunity and Adaptive immunity.

The Toxic Effect of Cadmium Chloride on Lung Function and Tissue and the Protective Role of Pomegranate Seed Oil in Female Rabbits

Noor Ibrahem Hasan AL-Kraie¹, Israa Salman Dalas¹; Qasim Azeez Razooqi¹
¹College of Education for Pure Sciences, Tikrit University, Tikrit, Iraq

Abstract

The experiment was designed to determine the protective role of pomegranate seed oil on lung function and tissue against cadmium chloride toxicity.

In this experiment, 20 animals (rabbit females) were used. Lung efficiency was measured by measuring the size of red blood cells and hemoglobin, as well as studying the histological effects of cadmium chloride against lung tissue and the protective role of pomegranate seed oil. The results showed that the treatment of animals with cadmium chloride at a dose of 5 mg / kg bw for 30 days led to a significant increase in packed cell volume (PCV) and hemoglobin (Hb) compared to control group.

The treatment of animals with cadmium chloride has also shown that there is no possibility of distinguishing the alveolar of lung (AV) with the presence of focal infiltration of the inflammatory cells with a marked thickening of the wall of the blood vessel (TW) with blood congestion (CON). Pomegranate seed oil improves most of the negative effects caused by cadmium chloride.

Key word: Cadmium chloride, Pomegranate seed oil, Packed cell volume (PCV), Hemoglobin (Hb).

Introduction

Cadmium (Cd) and lead (Pb) are ubiquitous and non-biodegradable pollutants representing a great concern to human health. Both metals are naturally distributed, but industrial development has dramatically increased their concentrations in the environment (1). The World Health Organization (WHO) has published a list of 10 chemicals or groups of chemicals of concern for human health, which includes Cd (2). The toxicity of cadmium has attracted the attention of researchers in different countries of the world due to its toxic effect on the cells and tissues of the body. The focus of the researchers has been on reducing the effect of effective oxygen species and free radicals causing their formation, as well as increasing interest in reducing the impact of industrial pollutants in the environment in which we live (3). So researchers have sought to use a large number of plant-derived pharmaceutical products in traditional medicine or to use their extracts because of their useful properties. The plants are rich in a wide range of secondary compounds such as flavonoids, tannins, alkaloids and others (4). Mentioned that the damaged central nervous system and DNA or cancer progression appeared as consequences of Cd exposure. Cadmium also causes severe soft tissues and bone damages (5). After absorption, Cd and Pb are distributed in the organisms via red blood cells or proteins. A major amount of Cd in red blood cells is bound to high-molecular-weight proteins, while a minor amount is bound to hemoglobin (6). The hematopoietic system is one of the most sensitive systems and blood represents not only the mode of transportation, but also the critical toxicity target of Cd and Pb (7). Cadmium causes lung damage, pulmonary fibrosis, emphysema, and inflammation in human and experimental animals. Cadmium may also adversely affect the lungs by decreasing the viability or modifying the function of individual lung cells (8). The toxic mechanisms responsible for cadmium-induced lung cell damage are not well understood. One study (9).

The use of extracts from medicinal plants and their effective non-food chemical compounds has a preventive and therapeutic effect for many disease cases and has little or no side effect compared to chemically manufactured laboratory drugs (10). Pomegranate, Punica granatum L.,
is an ancient medicinal food plant which natively grows from the Himalayas in northern India to Middle East but has also been cultivated and naturalized in many other regions including Mediterranean, Southeast Asia, tropical Africa, and American Southwest (11). In addition to extensive uses of pomegranate in folk medicine of many cultures, pharmacological studies have shown that pomegranate fruit preparations have antioxidant and anti-inflammatory, (12) antimicrobial, (13) anticancer, and chemopreventive (14). Pomegranate seeds are rich in sugar, unsaturated- polyunsaturated fatty acids, vitamins, polysaccharides, polyphenols and minerals (15). In particular, pomegranate seed oil contains high levels of phenolic compounds which is punic acid, punicalagins (PNG), as well as important fatty acids such as linoleic acid, gallic acid and elagic acid (16). Ellagic acid is a polyphenol compound with antioxidant and anti-proliferative properties that also exists in many other fruits and plants such as raspberries, pecan nuts and strawberries. These components demonstrate anti-inflammatory and antioxidant effects by inhibiting the expression of pro-inflammatory enzymes and cytokines (17); anticarcinogen, antioxidant (18) anti-inflammatory, antimicrobial (19, 20), which are free radical scavenging compounds (21). Pomegranate is also rich in vitamins and minerals (22).

**Material and Method**

2.1. Experimental Design: After acclimatization, animals were randomly divided into four groups: Group 1 – Animals were given distilled water and kept as control.

Group 2 – Animals were given Pomegranate seeds oil (0.8 ml)/ kg b.w. for 30 days (23).

Group 3 – Female rabbits were treated at a dose of cadmium chloride 6 mg/kg b.w for 30 days, which promised an infected control. (24).

Group 4 – Animals were given Pomegranate seeds oil (0.8 ml)/ kg b.w. with cadmium chloride 5 mg/kg b.w for 30 days.

2.2. Hematological Examination:

Blood samples were taken from the retroorbital venous plexus of rats. The two blood samples were collected one with EDTA for hematological analysis and other for separate serum for biochemical analysis. Erythrocyte count (RBCs) was performed using improved Neubauer Hemocytometer and Gower's fluid as a diluting fluid according to (25). PCV% was determined by using microhematocrite centrifuge and microhematocrite capillary tubes method according to (26).

2.3. Histological study

Lung tissue samples were fixed in 10% formalin since 24 hours, dehydration by ethyl alcohol in increasing concentrations (70%, 80%, 95%, 100% and 100%), clearing with xylene and then embedded with paraffin. When analyzed, all paraffinembedded tissue was sectioned at 5 µm and stained with Hematoxilin and eosin. These specimens were examined under a light microscope at 40X magnification power. Corresponding digital images were captured for later analysis (27).

**Results**

![Figure (1) The lung segment control group shows pulmonary bronchioles (BR) and the alveoli (AV) within the lung tissue in its natural form H & E 400X](image-url)
Figure (2) The lung segment The treatment of cadmium chloride shows that it is not possible to distinguish alveoli (AV) with focal infiltration of inflammatory cells (IF) H & E 100X

Figure (3) The lung section The cadmium chloride treatment shows the renal variability (AV) with a marked thickening of the wall of the blood vessel (TW) with blood congestion (CON) H & E 100X

Figure (4) Lung section group treated with pomegranate seed extract showing normal the alveoli (AV) H & E 400X
Discussion

It is noted from the results above that treatment of animals with cadmium chloride at a dose of 6 mg / kg body weight for 30 days led to significant increase (P≤0.05), in blood volume and hemoglobin compared to control group, in consonance with found . ( 28) . While did not agree with (29), Who used a single dose with cadmium chloride (0.1mg / kg) . It was found that the treatment of mice With cadmium for 21 days led to a significant decrease in the value of Hb . while the protective role of pomegranate seed oil against chloride Showed a significant decrease in blood volume and hemoglobin compared with the cadmium chloride-treated animals group . The hematopoietic system is one of the most sensitive systems and blood represents not only the mode of transportation, but also the critical toxicity target of Cd and Pb. (7). Both metals may lead to anemia by various mechanisms (30). Cadmium and Pb are transported to the liver, in which they can cause damage and disturbed function. Liver damage can be confirmed by histopathological findings and is often accompanied by increased blood enzyme levels and reduced protein synthesis (31).

Changes in the size of red blood cells The cause is believed to be a physiological condition to compensate for the lack of oxygen in the body because of the thickening of the gas exchange membrane between the alveolar of lung and the blood and these changes lead to increase the formation of red blood cells from the reservoir of body (32) . This problem is also very important and interesting because there are many reports in literature that cadmium can result hypoxia (33). That’s why it is topical to research metabolical effect of cadmium ions and hypoxia and find out the biochemical and morphological changes of
blood indices of rats under cadmium loading as blood is a substance of organism that reacts on irritation from environment very quickly.

The decrease in RBCs count during the chronic treatment might be resulted from severe anemic state or haemolysing power of heavy metals (cadmium chloride) particularly on the red cell membrane. this agreed with (34). The reduction in erythrocytes count might be due to the destruction of mature erythrocytes and the inhibition of erythrocytes production . It is also noticed from the tissue sections of the lung tissue that the treatment of animals with cadmium chloride led to the possibility of distinguishing the pneumonia (AV) with the presence of central infiltration of inflammatory cells with a clear thickening in the wall of the vessel (TW) with congestive blood (CON), in consonance with(35,36).

Lung tissue is one of the main targets of cadmium toxicity (37), and the respiratory system is affected severely by the inhalation of cadmium-contaminated air. Shortness of breath, lung edema, and destruction of mucous membranes as part of cadmium-induced pneumonitis have been described Cadmium causes lung damage, pulmonary fibrosis, emphysema, and inflammation in human and experimental animals. Cadmium may also adversely affect the lungs by decreasing the viability or modifying the function of individual lung cells (8).

Abstract

Acne vulgaris is a common pilosebaceous lesion affects skin over the face and upper chest. It has about 14 million incidence rate that cost 100$ for each case. In this study, biometric outcomes of the combined retinol, levofloxacin, cloxacillin, ascorbic acid and the hydrocarbon base vehicle on different types of acne lesions in human were investigated. Twenty one person were included in two groups; test (N =10) and control (N = 11) with follow up of objective software based biometric analysis parameters including: keratolysis induction, redness reduction and healing of infected lesion. The test formula revealed a significant keratolysis induction as compared with control. Eight out of 10 individuals with the test formula had keratolysis in comparison with 2 out of 11 had no keratolysis in controlled group, P-Value = 0.005. Similar effects were obtained in redness reduction (redness reduction ratio induced with test formula = 2.5 with confidence interval CI over 0.95) and impetiginization healing at P < 0.05. From the overall results, the combined retinol, levofloxacin, cloxacillin, ascorbic acid and the hydrocarbon base vehicle showed significant improvement in biometric outcomes of facial acne lesions.

Key words: Facial acne vulgaris, RGB image processing, keratolysis, impetiginization

Introduction

Acne vulgaris is a common dermatological lesion characterized by progressive popular to nodular skin lesion over the face and sometimes upper chest, back and shoulders (1,2). Studies estimated 14 million presentations to the clinic suffering from acne vulgaris with 85% of cases were between 15-17 years of age(3-5). It is presented in different forms: close, open, and black and white. It affects both sexes with average age incidence(6). Acne vulgaris lesions cost 100$ for each case in average(7).

In Iraq and nearby countries prevalence of acne was 13.1% among skin diseases(8,9). Acne vulgaris has multifactorial causation. Androgen hyperactivity especially dihydrotestosterone(10,11) expression of binding factor (binding protein II and proline rich protein I) to Propionibacterium acne, excess inflammatory response to P. acne (12) and microcomidos formation with closure of sebaceous duct and accumulation of sebum (13,14). Different cytokines and chemotaxis factors are noticed in excessive amount in acne lesion like IL1, IL12, IL8 and prostaglandins (15). Of the most common complications that are associated with this dermatological disease, facial and neck impetiginization and scar.

Factors that predispose to acne complications include hormonal hypersensitivity, hormonal imbalance, bacterial infections, age, weight, cosmetics and skin histopathological typing (16,17). The most commonly used antiacne treatments include keratolytics, antibacterial and peeling agents (18-20). However, a fraction of acne lesions are refractory to treatment that mandate more therapeutic researches.

The objective of this study is that to assess biometric outcomes of the combined topical formula of;
levofloxacin, disintegrating agent, retinol, hydrocarbon mineral carboxylate, cloxacillin, pH buffering agent, ascorbic acid and vehicle base on different types of acne lesions in human.

**Samples, Materials and Method**

**Study design**

Controlled clinical trials of acne vulgaris was designed to exclude:

- Age: 25yr < age < 13yr
- Medications and antiacne intake
- Chronic medical illnesses like HT, DM and hormonal disturbances
- Weight: 70 kg < wt < 50 kg

Prerequisites of medical ethics (according to Geneva and Helsinki declarations) submitted to local ethical committee.

- All of the used drugs and excipients are FDA approved for safety and efficacy
- All of the used drugs were passing phase I (i.e. not used as a first time)
- Benefit is prevailed
- All individuals were informed about study design and expected side effects
- All individuals permission, autonomy and consents have been obtained
- All of the used drugs were through topical route of administration
- All individuals were prior tested for any skin hypersensitivity and side effects.
- All individuals names, private secrets, faces were respected and insured
- All rights were reserved.
- All were free to be subjected to medical treatment or test treatment.

**Material**

1) *Hydrocarbon cream o/w*

Of multiple esters; Myrsticate, glycol monostearate, Na palmitate, Na stearate, isopropyl alcohol and water 5.05 ml

2) **Active ingredient and vehicle base:**

- Retinol (Egypt, product date and expiry date; PD-ED: 2013-2015)
  Package of 200000 IU. The used dose in designing the topical test formula against acne was 0.05%.

- Cloxacillin (Ajanta, India, PD-ED: 2014-2015). The used dose was 0.1%

- Levofloxacin (Pharma International, Jordan; PD-ED: 2014-2015). The used dose was 0.1%.

- Ascorbic acid (Merck, PD-ED: 2013-2015). The used dose was 0.1%

- Hydrocarbon base was used as a vehicle of Myrsticate, glycol monostearate, Na palmitate, Na stearate, isopropyl alcohol and water 5.0 mL.

*Constituents of the combined antiacne formula;*

(Levofloxacin, disintegrating agent, retinol, hydrocarbon mineral acyls, cloxacillin, pH buffering agent, ascorbic acid, vehicle base)

*Constituents of the blank controlled formula;*

(Hydrocarbon base+ mineral oils+ pH buffer, disintegrating agent)

Pharmaceutical analysis is done to assess formula pH and physical consistency was assessed with PHELECT computerized pH meter electrode (USA). pH was buffered around 6.3.

**Methods**

Acne sample selection

The lesion to be monitored with biometric method was not randomly selected

Criteria of selection

- More prominent lesion in the face is selected to be monitored.
- Type of lesion was randomized (to include all presenting lesion types for further analysis and concluding the overall effect on all types)
Monitoring was done in conserved temperature but different ambient lighting because this was processed and normalized by software.

Selection of blank treated and test treated was randomized.

There was no person with any application of either test or blank to insure ethical requisites. On the other hand, no person was with standard medical treatment.

**Methods of observation and analysis**

Places of application were therapeutic research lab/Kufa College of medicine for assessment of students. Private lab for assessment of the volunteers out of the college as well.

**Ambient conditioning**

Lighting was objectively evaluated to be controlled

Ambient temperature has averaged 22-25 ºC

A prior imaging of the lesion was taken then after 4 day of the treatment another image was acquired for MIP.

MIP was a mathwork 2013a image processing blockset design by Dr Hussein AbdulKadhim for processing and analyzing RGB and lesion pattern for:

1- RGB shift
2- Lesion dimension
3- Pattern of lesion response (keratolysis, impetiginization, dimentions and bevel).

**Treatment Mode**

The entire face was messaged with the test combination and left overnight then morning washing. Another application was done for 1hr duration to be washed prior to attending time.

**Biometric Analysis Method**

The biometric set composed of a Microsoft combined thermographic tissue camera with MIP for objective image analysis.

Analyzing histogram vector RGB and lesion in form
of red pixelate shift was objectively monitored and data were analyzed statistically with spline interpolation and risk reduction at 0.95 C.I. Discrete data was analyzed with chi square test at P < 0.05. Statistical software packages were Matlab 2013 statistical toolbox and Minitab 2014 statistics.

**Results**

1- Findings and analysis of keratolytic activity of the test combined topical formula.

**Chi-Square Test: test; control**

Chi-Sq = 8.025; DF = 1; P-Value = 0.005

1 cells with expected counts less than 5.

Figure 2: Number of individuals who showed keratolysis in response to the applied test formula as compared to those used a blank cream base after 14 days of treatment. So that 8 out of 10 individuals with the test formula had keratolysis in comparison with 2 out of 11 had no keratolysis in controlled group. P-Value = 0.005.

2- RGB analysis findings for acne lesions

Color model interpolation and the mean red value estimation with redness reduction ratio.

In control group:

MIP red value was reduced from 240-200 = 40

In test group:

MIP red value was reduced from 250-150 = 100

So the redness reduction ratio of test formula = 2.5 at C.I. 0.95.

**Figure 3**: Mean values of red bins by which the MIP had shifted after 14 days of treatment. This was a direct indicator of acne reactivity in response to treatment.

3- Lesion impetiginization response

Discussion

A trial of assessment of topical antiacne formula has a significant consideration since it can be reasonably safe alternate to systemic administration of drugs for prolonged period.

The reason behind selecting combined active ingredients in designing the test formula was to induce synergism since P. acne, S. aureus and S. pyogen are rapidly emerging resistance against the commonly used antimicrobials\(^{21,22}\) and to potentiate peeling with retinol and keratolysis with ascorbic acid\(^{23,24}\). This principle causes augmentation of antiacne effect.

However this study concerned a limited number of population and needs for further confirmation in larger samples. Overall clinical and biometric outcomes are best to be included in further studies.

The clinical evaluation of keratolytic activity of the combined formula showed highly significant induced keratolysis \((\text{Chi-Sq} = 8.025; \text{DF} = 1; \text{P-Value} = 0.005)\) in comparison with blank treated group. That was a clinical sign of improvement since keratolysis can convert closed comedos to opened type. Moreover, keratolysis insure more antiacne drug absorption fraction since it causes thinning of the corneocytes portioning. Different studies showed the importance of the use of keratolytics in treatment of acne\(^{25}\).

Redness is a major indicator of inflammation. It could be assessed objectively by RGB shift analysis. Redness reduction ratio was 2.5 at C.I. 0.95.

Test formula revealed a significant remission of impetiginization in comparison with blank treatment \((\text{Chi-Sq} = 4.531; \text{DF} = 1; \text{P-Value} = 0.033)\).

That effect may be attributed to the synergistic activity of levofloxacin and cloxacillin. Some studies on assessment of comedolytic effects of ciprofloxacin and ampicillin revealed significant influence of these drugs on improving acne\(^{26-29}\).

Conclusion

From the overall results, the combined retinol, levofloxacin, cloxacillin, ascorbic acid and the hydrocarbon base vehicle showed significant improvement in biometric outcomes of facial acne lesions. Larger sample size is necessary for further confirmation of the antiacne activity of the test formula. We recommend that other congeners of the used antimicrobials and keratolytics are to be included. And, for future studies, other comparative studies between antiacne drugs alone and in combination to determine the synergistic ratio.

Assessment the Efficacy of Arthrocentesis with Corticosteroid and Arthrocentesis with Sodium Hyaluronate in Treatment Temporomandibular Joint Disorders: A Comparative Study

Samer Majeed Mohammed1, Muntathar Muhsen Hassan Abusanna2, Zina Ali Daily3

1University of Al-Ameed/College of dentistry-Iraq

Abstract

Background: Temporomandibular joint disorders (TMD) refer to a group of heterogeneous pain and dysfunction conditions involving the masticatory system, reducing life quality of the sufferers. Aim of study: The aim of the study was to evaluate the effectiveness of arthrocentesis with corticosteroid (betamethasone) injection and with sodium hyaluronate injection in treatment temporomandibular joint disorders, in conjunction with a stabilizing splint, for improving function and reducing pain, for preventing further deterioration of the TMJ dysfunction, to maintain improvements over time, and compare between them. Patients and methods: Fifty –four patients with TMJ disorders with age limit between 18 and 55 years of age, 9 males and 36 females, were enrolled in this study. Patients were randomly divided into two groups, in which one group received arthrocentesis with intra-articular corticosteroid (betamethasone) injection (1 ml), and another group received arthrocentesis with intra-articular sodium hyaluronate injection (1 ml) in superior joint space in single puncture. Patients were followed at regular interval of 7th day, one month, 3, 6, 9, 12 months (follow up) after last injection. Results: The mean age of patients was 8.873 ± 34.112 years in Group-A treat by betamethasone and10.973± 33.27 years in Group-A treat by sodium hyaluronate (ranged from 18.2 to 55.0 years). Keywords: Arthrocentesis, corticosteroid(betamethasone),Sodium hyaluronate, temporomandibular joint disorders

Introduction

Internal derangement of the temporomandibular joint (TMJ) is a progressive disorder which usually starts with clicking associated with normal mouth opening (anterior disc displacement with reduction),to a stage where clicking gradually ceases but restricted mouth opening ensues (closed lock). This was attributed to a nonreducible anteriorly displaced articular disc acting as an obstacle to the gliding condyle. In the meantime, the pathological changes were found in synovial membrane and synovial fluid. Hyaluronic acid is a principal component of the synovial fluid which plays an important role in nutrition, lubrication, anti-inflammation and cartilage protection and repairing. The synthesis, molecule weight, and concentration of hyaluronic acid are decreased during TMD and cause TMJ degenerative changes. TMD treatment can be divided into two categories: conservative method and surgical method. Among the surgical interventions, arthrocentesis is generally suggested for patients who are not responsive to conservative therapy.

Arthrocentesis is generally suggested for patients who are not responsive to conservative therapy. Arthrocentesis is an easy, minimally invasive, highly efficient procedure designed to decrease joint pain and increase the range of mouth opening in patients with closed lock of TMJ. This improvement in clinical outcomes after arthrocentesis can be attributed to the facts that the flow of liquid under pressure in joint causes flushing of catabolites, distension of joint with breakage of adhesions, and mobilization of disc.

Corticosteroids (CSs) are anti-inflammatory drugs that interrupt the inflammatory and immune pathways. They have been used for both therapeutic and diagnostic purposes. Also, they showed their palliating effects by suppressing inflammatory responses. Intra-articular corticosteroid injection alone or after arthrocentesis provides long-term palliative effects on subjective symptoms and clinical signs of TMJ pain.
Hyaluronic acid (HA) is a polysaccharide which is produced by chondrocytes and synoviocytes of the joints. HA has been shown to improve and restore normal lubrication in joint, provide nutrition to the avascular articulating disc, and stabilize the joint. The therapeutic mechanism of action of HA is chondroprotection, effect on proteoglycan and glycosaminoglycan synthesis, anti-inflammatory, mechanical (viscosupplementation), effect on subchondral bone, and analgesic2,9.

HA is a polysaccharide of low, medium, or high molecular weight, its properties can vary in relation to its molecular weight and shape, and has been used successfully as a TMJ injection to reduce inflammation, restore normal lubrication and cartilage repair2.

These have motivated us to perform the current study, to evaluate the effectiveness of arthrocentesis with corticosteroid (betamethasone) injection and with sodium hyaluronate (low molecular weight) injection in treatment temporomandibular joint disorders, in conjunction with a stabilizing splint, for improving function and reducing pain, for preventing further deterioration of the TMJ dysfunction, to maintain improvements over time, and compare between them during 12 months following injection.

Patients and Method

Fifty-four patients with TMJ disorders with age limit between 18 and 55 years of age, 9 males and 36 females, were enrolled in this study. All patients were examined clinically and radiographically. Based on the history and examination of patient a diagnosis of internal derangement was made. Patients were informed about the procedure, it is possible complication and about the material used and after the consent, patients were randomly divided into two groups, (27 in each group) and arthrocentesis was performed in each group following which 1 ml of betamethasone was given in first group and 1 ml of sodium hyaluronate in second group in superior joint space. Patients were followed at regular interval of 7th day, one month, 3, 6, 9, 12 months (follow up) after single injection. Assessment of clinical outcome was done in terms of reduction in pain (visual analog scale score), maximum mouth opening (MMO) in millimeters, painful/pain-free lateral or protrusive jaw movement, and clicking/crepitus of joint in pre-treatment visit about 1 week before injection and post-treatment follows up visits. This study was performed in Samir Dental Clinics in Karbala city, from October 2016 to Jun 2019. All patients were diagnosed with TMD based on Clinical finding supported by CT scan. In this study, selection of patients based on the following

Inclusion Criteria:

1- Clinical diagnosis of anterior disc displacement (Limitation of mouth opening, Pre-auricular pain, temporal and occipital tenderness, headache, Persistence of symptoms at least for 3 months, Clicking).

2- CT scan (soft tissue window depend on disk density) diagnosis of anterior disc displacement with reduction.

Each patient received pharmacotherapy and then if no or delay response splint fabricated then if no progression in treatment, arthrocentesis with intra-articular betamethasone injection and arthrocentesis with intra-articular sodium hyaluronate injection in superior joint space were done. Patients were informed of the use of their medical records. Ethical approval for the study was obtained from the ethical committee.

Also, we exclude other patients according to exclusion criteria: Systemic disease, Arthritis or history of condylar trauma, Degenerative change of condylar head, Facial asymmetry, retrognathism, prognathism, Fibromyalgia, use of NSAIDS within 48 hours, allergy to study medications, edentulous subjects pregnancy or breast feeding.

The statistical analysis was carried out using Statistical Package for Social Sciences (SPSS Inc). All quantitative variables were estimated using measures of central location (mean) and measures of dispersion (standard deviation). As data was normally distributed, paired t-test was applied for comparison of every two visits of each group. All statistical tests were two-sided and performed at a significance level of α= .05.

Results

The mean age of patients was 8.873±34.112 years in Group-A treat by betamethasone and10.973±33.27 years in Group-A treat by sodium hyaluronate (ranged from 18.2 to 55.0 years). A detailed sex and age distribution is shown in (Table-1). more reducing of mean and ±SD (standard deviation) values of the pain intensity, maximum mouth opening, joint click and deviation on opening were recorded in post-treatment visit at 12 month follow-up visit of Group-B(SH) than pre-treat visit, followed by Group-A(CS) is shown in (Table-2).
Inter study visits comparisons of each group regarding of the pain intensity, maximum mouth opening, deviation mouth opening and joint click revealed, Highly significant differences between pre-treatment visit and post-treat at 12 month follow-up visit after the single injection in both groups (Table-3) HS differences between post-treat at 12 month follow-up visit of Group -B(SH) and post-treat at 12 month follow-up visit of Group - A(CS) (Table -4).

**Discussion**

In the present study, clinical parameters such as pain, MMO, lateral and protrusive movement of jaws, and improved significantly in both the treatment arthrocentesis with intra-articular injection corticosteroid and arthrocentesis with Sodium hyalurate (SH). However, more significant improvement in pain, MMO, lateral and protrusive movement was observed in patients receiving arthrocentesis with intra-articular SH injection.

The outcome of the recent study is agree with systematic review of Eduardo et al. 2013, they were found that the effects of intra-articular injections with sodium hyalurate are similar to those regarding the injections with corticosteroids to control TMJ internal derangements at short and medium terms, while in long-term treatments, injections with sodium hyalurate showed better results.

The result of recent study is agree with study of Kapusuz G et al. 2014, that studied effectiveness intra-articular injections of hyaluronic acid, tenoxicam and betamethasone on the relief of temporomandibular joint disorder complaints, they found that HA produced better pain relief scores when compared to the other anti-inflammatory agents studied.

Radiological assessment preoperatively and postoperative 12 months follow-up with CBCT was showed significant difference. The erosion on condyles disappeared in the patients in both groups, it was significant, and showed radiological thin layer of new bone formation, remodeling of condyles and glenoid fossa in patients who treated by arthrocentesis with betamethasone, and cortical bone formation and remodeling of severe degenerative changes at 12months follow-up in patients who treated by arthrocentesis with sodium hyalurate, it is highly significant in patients receiving arthrocentesis with sodium hyalurate injection than significantly in patients receiving arthrocentesis with betamethasone.

The result of recent study is agree with study of Li et al. 2015, that studied changes of TMJ disorders in CBCT in patients who received HA injection in superior joint and reported cortical bone formation and remodeling of severe degenerative changes by 9 months follow-up.

This improvement in clinical outcomes after arthrocentesis can be attributed to the providing viscosupplementation to joints, HA has anti-inflammatory effects on inflammatory mediators, and protection against the disintegration of proteoglycans and cytotoxicity induced by oxygen free radicals. IL-1β is the key mediator in anti-inflammatory effects of HA and is regulated through HA-CD44 binding. IL-1β suppression results in downregulation of matrix metalloproteinases which also aids in anti-inflammatory effects of HA and further suppression of pro-inflammatory mediators IL-8, IL-6, prostaglandin E2, and TNF-α provides anti-inflammatory effects of intra-articular HA treatment. In addition, it affects leukocyte adhesion, proliferation, migration and phagocytosis; it directly influences the control mechanism of monocyte activation; in the cartilage it has been seen to suppress degradation of the cartilaginous matrix by fibronectin fragments.

Hyaluronic acid is found in the extracellular matrix of several connective tissues of high molecular weight, including joint cartilage and synovial fluid.
sites, HA molecules are predominantly synthesized. It is synthesized by synoviocytes, fibroblasts and chondrocytes present in the connective tissue. In addition, it is the largest natural component of SF and an important component of the articular cartilage. Moreover, activates intrinsic repair processes of the cartilage and normalizes the endogenous production of HA by the synoviocytes, stabilize the extracellular matrix, stimulate the proliferation of chondrocytes, regulate the production/degradation of type II collagen, and metabolic HA activity in cell renewal helps the nutrition of avascular zones of the disk and joint cartilage through its combination with glycosaminoglycans coming from proteoglycans produced by chondrocytes.

It is the major component of the synovial fluid and has an important role in lubrication. Its action stems from the ability of the polysaccharides to connect to each other when they are in solution, forming a network that provides a high degree of viscosity to the SF so that it reduce joint friction coefficient, that is the main risk factor for degenerative joint pathologies, maintaining intra-articular homeostasis by promote a better distribution of forces and load absorption of articular tissues. In cases of inflammatory and degenerative changes of joints, the concentration and molecular weight of HA acid reduced, therapeutical effect sodium hyaluronate increases the concentration and molecular weight of HA in the synovial fluid, restoring tissues lubrication and nutrition as well as minimizing mechanic stress. Moreover, intra-articular SH injection is avoided sensitization of pain receptors in joints disorders, by modulating neurotransmission and vasodilatation processes, provides an analgesic effect by blocking receptors and endogenous substances that cause pain in synovial tissues and. In addition, it promotes a release of adhesion areas between the articular disc and the mandibular fossa, increasing joint mobility and allowing better synovial fluid circulation.

Corticosteroids have a potent anti-inflammatory effect on synovial tissue and are known to reduce effusion, decrease pain and bring about an increase in range of motion of synovial joints.

Glucocorticoids have a very original mechanism of action, essentially genomic (transcriptional) and characterized by the activation (transactivation) or inhibition (transrepression) of numerous target genes. These molecules act in many cells, including not only innate immunity cells (macrophages, granulocytes, mast cells) and adaptive immunity cells (lymphocytes), but also other cells (fibroblasts, epithelial and endothelial cells).

Therefore arthrocentesis with sodium hyaluronate injection is more effectiveness than arthrocentesis with betamethasone injection in therapeutic and return TMJ of healthy status in long term palliative effects.

Conclusion

In this study, the technique of arthrocentesis using 0.9% normal saline solution with betamethasone injection, with occlusal splint in group A and arthrocentesis with intra-articular injection of sodium hyaluronate in superior joint space with occlusal splint wear in group B, where showed therapeutic benefits, simplicity, safety, patients acceptance of injection technique and lack of significant side effects and complication. Both techniques increased maximal mouth opening, lateral movements, and function, while reducing TMJ pain and noise. Although patients benefitted from both techniques, arthrocentesis with injection of SH is significantly superior to arthrocentesis with betamethasone injection. As well as, Radiological finding is showed highly significant in patients receiving arthrocentesis with HA injection than significantly in patients receiving arthrocentesis with corticosteroid.

Aqueous Extract of Date Palm Fruit (*Phoenix dactylifera*) Protect Liver Against Cyproterone Acetate Toxicity in Male Mice

Nuha Yaarub Al-Harbi¹, Eman Fadhel Abbas Awadh¹, Wasan Najim Abdul-Sada²

¹University of Babylon, College of Science, Dept. of Biology, Iraq. ²Basic Science Department, College of Dentistry, University of Babylon, Hillah, Iraq

Abstract

The cyproterone acetate (CPA) is an antiandrogen drug that is used in the treatment of prostate cancer, which is related to drug-induced liver injury (DILI). The aim of this study is the effect of the water extract of one of the local dates on the side effects of using cyproterone acetate on liver tissue in white mice. Forty from albino mice male were divided into 8 equal groups received orally in one ml as follows. Group 1: distilled water passive control, group 2: corn oil positive control, group 3: received with 5 mg/kg body weight CPA, group 4: received with 20 mg/kg CPA, group 5: received with 5 mg/kg CPA & 60 mg/kg date palm extract, group 6: received with 5 mg/kg CPA & 120 mg/kg date palm extract, group 7: received with 20 mg/kg CPA & 60 mg/kg date palm extract, group 8: received with 20 mg/kg CPA & 120 mg/kg date palm extract lasted for 21 days.

Showed a histological study of the liver remarkable degeneration of hepatocytes associated with interstitial necrosis and blood vessel congestion.

The current study proved that the water extract of dates has a weak effect in the repair of damage in the liver tissue to treatment for the low dose of cyproterone acetate only.

Keywords: Cyproterone acetate, Date palm fruit, hepatotoxicity, histopathology.

Introduction

CPA is synthetic progesterone and antiandrogenic compound administered. It is used to treat many physical conditions in prostate cancer and also in breast cancer, serious acne, womanly hirsutism, precocious puberty, hypersexuality (1).

Drugs can have direct toxic effects (dose-dependent) or elicit hypersensitivity or metabolic distinctive reactions (dose-independent) that can take place at any time during the course of therapy (2). Hepatotoxicity signs resulting from the use of both steroidal androgens and nonsteroidal antiandrogens causes many cases as immunoallergic cytotoxic reactions, cholestasis, autoimmune hepatitis (3 & 4), acute hepatitis, fulminant hepatic fail (5) cirrhosis (6), and ultimately, CPA has been imputed a hepatocellular mutagenic capacity leading to hepato-carcinogenesis (7). Many treatments are for natural products can use because they are cheap and easy to obtain. The Prophet Mohammed (Peace Be upon Him) recommended the use of natural products as medicine for certain diseases (8). In traditional medicine, herbal medicines are widely used around the world, where palm pollen grains are widely used as an antihepatotoxicity (9 & 10).

*Phoenix dactylifera* L. plant is one of the elderly cultivated plants in the Middle East and North Africa. The fruits of dried dates contain 8 phenolic acids (gallic acid, protocatechuic acid, p-hydroxybenzoic acid, vanillic acid, caffeic acid, syringic acid, p-coumaric acid, and ferulic acid (11) & (12). In addition, date fruits contain
Ascorbic acid, β-carotene, nicotinic acid, riboflavin and thiamine (13), and include twenty-one free amino acids (leucine, α-alanine, and proline were predominant), and the amides asparagine and glutamine were particular in P. dactylifera (14). Another study indicated that date palm fruit contains cholesterol, campesterol, stigmasterol, β-sitosterol, and fucosterol (15). Every date types are a user provenance of natural antioxidants It can be considered effective food (16) since date fruit extract had a powerful antioxidant and antimutagenic specialty (17).

Various studies have that the date fruit extract has been shown to ameliorate liver damage in rat, inhibit swelling and tumors, suppress the growth of Streptococcus pyogenes and improve sperm parameters (18) & (19).

**Materials and Method**

**Preparation of extract**

Fresh date palm fruits (*Phoenix dactylifera* L., *Palmae*) were provided from a local market in Hilla (Babil, Iraq), dried at room temperature, and were manually isolated from the pits. The flesh of the dried *P. dactylifera* fruits was ground. About 650 g of the powder was soaked in 2 L of cold distilled water. After 24 h, the solution was filtered and evaporated under vacuum and dried to a constant weight using a freeze-drier. The dry extract of the fruit was dissolved in distilled water instantaneously before treated the mice (20).

**Preparation of cyproterone acetate:**

Obtained cyproterone acetate anti-androgen from local pharmacies and called Androcur as a trading name and equipped from a company of a subsidiary of Filiale de Schering AG Germany, 20 mg concentration for each disc. Dissolved the drug used in this study in absolute ethyl alcohol and left exposed to the air until drought then added to the powder pure corn oil. Solute each disc in 12.5 ml from corn oil to obtained 20 mg/ml this study in absolute ethyl alcohol and left exposed to the air until drought then added corn oil and calculated required concentrations to conduct experiments depending on the dose given to human (21).

**Animals of the experiment:**

In the current study, 40 male white mice have used range ages from used 2-3 months. The mice were provided with eating and water *ad libitum*.

**Experimental protocols:**

Mice were randomly divided into eight groups each contains 5 animals treated daily with one milliliter orally as follows:

1-**First control group:** treated with distilled water for 21 days, as a negative control.

2-**Second control group:** treated with corn oil for 21 days, as a positive control.

3-**Third group:** treated with cyproterone acetate 5 mg/kg/BW for 21 days.

4-**Fourth group:** treated with cyproterone acetate 20 mg/kg/BW for 21 days.

5-**Fifth group:** treated with cyproterone acetate 5 mg/kg/BW and crude date extract 60 mg/kg/BW for 21 days.

6-**Sixth group:** treated with cyproterone acetate 5 mg/kg/BW and crude date extract 120 mg/kg/BW for 21 days.

7-**Seventh group:** treated with cyproterone acetate 20 mg/kg/BW and crude date extract 60 mg/kg/BW for 21 days.

8-**Eighth group:** treated with cyproterone acetate 20 mg/kg/BW and crude date extract 120 mg/kg/BW for 21 days.

Animals were sacrificed 24 hours after of the last dose, use diethyl ether to drugged mice, open the abdominal cavity and remove the liver, then fixed the fresh small pieces of each mouse liver in the formalin solution 10 % until the histological preparation.

**Histological study:**

Ordinary histological processing is prepared for the liver in order to study the histopathological changes that may be found in the experimental groups as compared with negative and positive control groups. According to (22), the processing steps and staining technique was as follow: small pieces of livers were dehydrated using a graded ethanol series, subsequently emb.edded in paraffin, wax blocks were cut by the microtome to prepare 5µm thick sections and stained with hematoxylin after deparaffinization of sections in xylene and hydrated in progressive descending ethanol series and stained with eosin after the washing and differentiate,
then wash again, dehydrate, cleared in xylene and mount with Canada balsam on glass slide for light microscopic examination.

**Results and Discussion**

Several studies have indicated in Liver enzyme aberration have in experimental animals treated with cyproterone acetate (23). This our study showed treated mice of 5 mg/kg body weight of CPA (group 3, fig. 1) revealed degeneration and necrotic changes in hepatocytes, sections of liver of CPA 20 mg/kg/ BW treated mice (group 4, fig. 2) showed congested blood vessels, necrosis in hepatocytes and moderate inflammatory cell infiltration in the portal triad as compared to other treated groups. The hepatotoxicity depend on both the dose and the duration of xenobiotics exposure will impact the type and grade of toxicity, there is often susceptibility to the toxicity based on the intralobular site of hepatocytes for xenobiotics that immediately affect the liver and hepatocellular necrosis, evidence of necrosis is generally apparent within forty-eight hour or previously(24).

One study noted an increase in serum aspartate aminotransferase (AST) and alanine aminotransferase. (ALT) activities in all patients with inprogress prostate cancer who are treated with CPA-induced liver damage, in 91% of those cases, the type of hepatic injury was hepatocellular damage. This damage is frequently involved hepatocytes damage that is associated with an elevated ALT level (25). It is generally synched progress that hepatocellular hypertrophy may be a serious qualitative metric, but classify the severity of hypertrophy is less accurate than relying on liver weight or quantitative measuration of enzyme induction. There is a substantial relationship between hepatotoxicity and enzyme induction with clinical pathology measurements are described (26). Changes may occur in liver histology without enzyme reduction but include fluid aggregation, fatty change in hepatocytes, inflammatory cell infiltration, fibrosis, and probably granuloma formation (27).

Examination of stained liver sections of animals treated with 5 mg/kg/BW of CPA and crude aqueous palm date fruit extract 60 mg/kg/BW (group 5, fig.3) showed a noticeable degeneration in hepatocytes, sections of the liver of CPA 5 mg/kg/BW and crude palm date fruit extract 120 mg/kg/BW treated mice (group 6, fig. 4) revealed congested blood vessels and necrosis of hepatocyte as compared with CPA treated mice with reducing severity in two groups. “The mechanism by which the aqueous date palm fruit extract induces its hepatoprotective activity versus oxidative damage caused by any drug is not clear. However, it is potential that polyphenolic compounds (flavonoids, anthocyanins, and phenolic acids), and trace elements (selenium, copper, zinc, and manganese), an extension to vitamin C present in the date palm fruit are the responsible compounds for this protection (28; 29; 30).

One of the studies conducted on the aqueous extract of date fruits It acts as an antioxidant and the antimutagenic activity, Where this extract on the inhibition of lipid peroxidation and protein oxidation and also by the aptitude to scavenge superoxide and hydroxyl radicals (31). In addition to that, there are many studies indicate the hepatoprotective activity of any drug is the ability of its components to block the aromatase activity of cytochrome P-450. On that basis, it is proposed that flavonoids in Phoenix dactylifera could be a factor contributing to its hepatoprotective ability through inhibition of cytochrome P-450 aromatase (32).

Tissue sections of the liver of CPA 20 mg/kg/ BW and palm date fruit extract 60 mg/kg/BW treated mice (group7, fig. 5) showed congested blood vessels and severe degeneration in hepatocyte, in the liver of animals treated with CPA 20 mg/kg/BW and palm date fruit extract 120 mg/kg/BW (group 8, fig. 6) Although comparative studies indicated that dried date palm fruit with phenolic content was higher than fresh date palm fruits(33) . However, the water extract of dried palm fruit used in this study did not have the ability to preserve the liver from the toxic effect of the drug CPA especially at a high dose. The direct effect of cyproterone is attributed to increased of hepatocytes of placental glutathione S-transferase, which are believed preneoplastic elements(34-35). Where it works Growth Factor-beta 1 (TGF) expression on the induction of apoptosis might account for both the liver damage and the expansion of liver tumors observed after giving a drug of CPA (36).
Figure-1: Histological liver section of (CPA) 5 mg/kg, group showed (a) Marked activation kupffere cell, (b) degeneration of the hepatocyte necrosis of hepatocyte.

Figure-2: Histological liver section of (CPA) 20 mg/kg group showed (a) sever degeneration of hepatocyte, (b) hypertrophied hepatocytes with deeply stained shrunken nuclei, (c) congested blood vessels.

Figure-3: Histological liver section of (CPA) 5 mg/kg + 60 mg/kg date palm extract, group showed (a) Some hepatocytes were free from nuclei and others contained pyknotic nuclei, (b) moderate hemorrhagic area.

Figure-4: Histological liver section of (CPA) 5 mg/kg + 120 mg/kg date palm extract, group showed (a) moderate hypertrophy of cells and (b) moderate hemorrhagic area.

Figure-5: Histological liver section of (CPA) 20 mg/kg + 60 mg/kg date palm extract, group showed sever degeneration of hepatocytes and multihemorrhagic Areas.

Figure-6: Histological liver section of (CPA) 20 mg/kg+120 mg/kg date palm extract, group showed (a) congested blood vessel (b) necrosis of hepatocyte (c) moderate inflammatory cells infiltration in the portal triad.

Conclusion

the present study has shown that CPA has a toxic effect and some histopathological changes have been detected, so care should be taken when CPA is prescribed as antiandrogenic treatment.

Molecular Detection of Pseudomonas aeruginosa and its Relationship with Multidrug Resistance and Transposons

Wathiq Abbas Hatite Al-Daraghi¹, Mohammed Sattar Abdulkadim Al-Badrwi¹, Haider Rida Jassim¹
¹Institute of Genetic Engineering and Biotechnology for Postgraduate Studies, University of Baghdad, Iraq.

Abstract

P. aeruginosa is currently one of the most frequently nosocomial pathogens and the infections due to this organism are often difficult to treat due to antibiotic resistance. P. aeruginosa is an important pathogen in hospitalized patient’s causative to their morbidity and mortality due to its multiple resistance mechanisms. Therefore, as a therapeutic option becomes restricted, the search for a new agent is a priority. One hundred and fifty samples were collected from different sources, divided into two main groups: clinical (80)samples and (70) hospital environment samples as a Nosocomial, collected all from October to the December of the year 2018. All of these samples were cultured by specific and differential media, Forty (40) isolates of P.aeruginosa bacteria were identified by using microscopic examination, biochemical tests. The identification of 40 isolates of P.aeruginosa bacteria confirmed by VITEK-2 system. A molecular detection the presence of Tnp-R gene in P. aeruginosa bacteria by conventional PCR to detect the Transposons and their relationship with multiple resistance of bacteria.

Keywords: Multidrug Resistance; P. aeruginosa; and PCR

Introduction

Pseudomonas aeruginosa is a Gram’s negative opportunistic pathogen has emerged as one of the most problematic of the nosocomial pathogens; considered multi-resistant infections in both community and hospital settings, It causes infections in cancer, burn, urinary tract, surgical wound, eye, blood, ear infection, sepsis cystic fibrosis, and (ICU) (1). Because of it’s an extremely ubiquitous organism and abundantly found in soil, water, plants, humans, animals, and in a hospital setting. P. aeruginosa is a common pathogen in hospital particularly in ICU although it has the ability to colonize healthy subjects, in addition to, bacterial exposure to some antibiotic classes may potentially induce endogenous resistance-conferring mutation in bacterial genes that encode drug targets (2). It has been progressively clear that resistance expansion in P. aeruginosa is their contexts with mutations in genes encoding porins, efflux pump, penicillin-binding proteins, and chromosomal β-lactamases, all contributing to resistance to β-lactamases, carbapenems, aminoglycoside, and quinolones(3). P. aeruginosa is an important pathogen in hospitalized patient’s causative to their morbidity and mortality due to its multiple resistance mechanisms. Therefore, as a therapeutic option becomes restricted, the search for a new agent is a priority (4). The pathogenicity of P. aeruginosa is largely caused by multiple bacterial virulence factors and genetic flexibility enabling it to survive in a varied environment. A number of these factors aid colonization, while others allow bacterial invasion(5). Antibiotic resistance in bacteria has reached a near-crisis point in nosocomial health care, with many bacterial isolates now multi-resistant as a result of the presence of additional DNA element. Earlier studies have shown that genes for resistance markers do occur on plasmids and they can be transferable, and most of them have demonstrated it by plasmid curing experiments alone. Resistance gene can occur on chromosomes, transferable plasmid, Transposons or jumping gene and specialized transposons called integrons that can assemble multiple resistance genes into the cassette (6, 7).

Materials and Method

- Specimens’ Collection:

During the period extended from October to the December of the year 2018, One hundred and fifty samples, divided into two main groups: (80)clinical samples and (70) samples hospital environment as a Nosocomial, were collected from hospitals. Clinical samples included: Urine samples from Urinary Tract Infections (UTI)patients, exudate samples from wounds
of the burn units patients, stool samples, Sputum samples from Cystic Fibrosis (CF) patients and Ear Swabs. The Nosocomial samples included many Nosocomial sources: Intensive Care Unit, Operations Hall, Birth Hall, Burning Hall, Devices and medical equipment, and hospital bed rooms.

- **Bacterial Isolation:**

In this study, the identification of 150 samples, we got 40 isolates of *P. aeruginosa* was performed by incubating these clinical and nosocomial isolates on different agar media (Nutrient agar , Blood agar, Maconkey agar, and Cetrime agar which are a selective media for *Pseudomonas spp.*) and the incubation at 37°C for 24 hrs. Forbes *et al.* (8).

- **Bacterial Identification:**

Identification of *P. aeruginosa* was confirmed by microscopically examination showed that it was single cells, a rod shape, not- spore-forming, and gram-negative, these results mention that this isolates may belong to *P. aeruginosa* growth on Cetrime agar for characterization of *P. aeruginosa* such as mucoid, smooth in shape with flat edges and elevated center, creamy green colour and have a fruity odour.

- **PCR amplification:**

DNA template of all isolates was prepared by boiling method (30 min in 100°C). The DNA of isolates was targeted for the *blaOXA-1* gene using the primers (Z.Tavajjohi, *et al.*, Iran) (9) listed in Table 1 and for the *Tnp-R* gene using the primers (Altaliby S. and Aldraghi w. , Iraq) and (Altaliby S. and Aldraghi w. , Iraq), and 8.5 μl of Nuclease Free Water. The experiment was continued according to the following program: initial denaturation at 94°C for 5 minutes, followed by 30 cycles at 94°C for 1 minute, 55°C for 1 minute, 72°C for 1 minute and a final extension at 72°C for 5 minutes. The PCR products were analyzed using gel electrophoresis (1% agarose) and stained with safe dye and visualized by Gel Doc apparatus (BioRad, USA) (Table 2).

Results and Discussion

Isolation and Identification of *P. aeruginosa*:

One hundred and fifty samples clinical and Nosocomial samples were analyzed for the presence of *P. aeruginosa*, and the results of bacterial isolation and identification revealed the detection of forty (40) isolates of *P. aeruginosa*.

Biochemical Tests:

Some biochemical tests were performed for more validation. showed 40 isolates of *P. aeruginosa* provided by some biochemical tests, showed positive results for oxidase test, catalase test, motility test, , and production of *B*-hemolysis while (40) isolations negative results to citrate utilization tests, indole production and urease production tests negative to Gram’s stain and capable of growing on cetrimide agar as yellow greenish colonies (at 42°C for 24 hrs.). (Figure 1).

At the species level, *P. aeruginosa* has a wide growth temperature range, optimum growth at 37°C. Slower growth rates are seen at 4°C. *P. aeruginosa* is distinguishable from other clinically *Pseudomonas* spp. by its capability for growth at 42°C. They also grow well at pH range 6.6-7.0. It was tolerant of a wide variety of physical conditions, including temperature and pH\(^{10}\). Also, it was resistant to high concentrations of salts and dyes. It is typically given a positive result to the oxidase test and catalase. It does not ferment carbohydrates, but many strains oxidize glucose\(^{11}\).

The identification was performed with the automated VITEK -2 system using the GN-ID cards which contains 64 biochemical tests, from (40) isolate of *P. aeruginosa*, (40) positive result of the *P. aeruginosa* demonstrated.

**Distribution of *P. aeruginosa* according to Type of Specimens**

According to table (3), Out of (80) clinical samples of burns, sputum, urine, stool, ear and wound, 28(70%) isolates were positive to clinical *P. aeruginosa* and the percentage of the positive results from (70)Nosocomial samples were 12 (30%), as reported in (Table 4).

The low percentage was found in burn specimens which accomplished 5%. Results obtained reported that the highest percentage of P. aeruginosa from ear swab (27.5%) was in opposite with our results. In comparison with Nosocomial isolates of Pseudomonas aeruginosa the highest percentage isolation of Operations Hall (4%) where are other isolate reported low present in comparison with clinical findings.

P. aeruginosa is pathogenic only when introduced into areas devoid of normal defences, the bacterium attaches to, and colonizes the mucous membranes or skin, invades locally and produces systemic disease. Ps. aeruginosa infects healthy tissues rarely, but, when defences are compromised, it can infect virtually all tissues. This explains why most infections are nosocomial(12). These infections are Pneumonia, Osteomyelitis (related to Wounds, Immunocompromised patients, Burn-wound infections, Urinary tract infections, Endocarditis, external otitis and Tissue layer infections (13).

Genomic DNA Extraction:

Using a Genomic DNA Purification Kit (Promega), Genomic DNA was extracted from (40) P. aeruginosa isolates that were confirmed as bands by gel electrophoresis. Quantus Fluorometer was used to detect the concentration of extracted DNA in order to detect the goodness of samples for downstream applications. all the isolates had DNA concentration between (10-40 ng/μl) by Quantus Fluorometer.

Molecular Detection of P. aeruginosa and co-strains by blaOXA-1 like gene:

The result of PCR analysis concerning of the found the blaOXA-1 in (10) positive isolates, showed that studies P. aeruginosa possess the blaOXA-1 like gene from 10(25%) isolates positive showed 4 (40%) from clinical isolates and 6 (60%) from nosocomial.

The ESBLblaOXA-1 of P. aeruginosa isolates exhibited co-resistance against most of the antibiotics tested. This is consistent with most of the recent findings (14). The blaOXA-1 ESBLs provide P. aeruginosa with an additional powerful resistance mechanism with potentially serious clinical implications, including limitation of the therapeutic options. ESBLs manufacturing organisms create distinctive challenges to clinical microbiologists, clinicians, infection control professionals and scientists engaged in finding new antibacterial agents (15). The development and spread of ESBLs are most likely caused by the overuse of expanded- spectrum Ciprofloxacin in the hospital setting. Proper infection management practices and barriers are essential to stop spreading and outbreaks of ESBL-producing microorganism (16).

Molecular Detection of Transposons of P. aeruginosa:

The result of PCR analysis concerning of the found the Tnp-R gene in (2) (12%) positive isolates from 10 blaOXA-1 positive P. aeruginosa isolates, which identified the presence of Transposon in this bacteria as reported in figure(2).

Figure(2): Agarose gel electrophoresis (1% agarose, 100 Vol / mAm for 75 min.) of PCR amplification products (Tnp-R gene) at 545bp for P. aeruginosa. lane 30and 31 show positive results for P. aeruginosa; ladder 100 bp DNA marker.

Two strains of nosocomial isolates of P. aeruginosa exactly show bands for Tnp-R gene which represent the nosocomial sample number (30) and (31) were collected from the hospital’s operation hall and birth rooms respectively.
Strains of bacteria resistant to antibiotics, particularly those that are multi-drug resistant, are an increasingly major health care problem around the world. This is achieved through the cooperative activities of mobile genetic elements able to move within or between DNA molecules, which include insertion sequences, transposons, and gene cassettes/integrons, and those that are able to transfer between bacterial cells, such as plasmids and conjugal elements. Together these types of mobile genetic elements play a central role in facilitating horizontal genetic exchange and therefore promote the acquisition and spread of antibiotic resistance genes in both Gram-negative and Gram-positive bacteria, focusing on the group of organisms (S. aureus, K. pneumonia, A. baumannii, P. aeruginosa, Enterobacter spp., and Escherichia coli), which have become the most problematic hospital pathogens.

Whereas one or two classes are left in presence of Integron and/or Transposons, extensive drug resistance (XDR) MDR/XDR has appeared in P. aeruginosa, Acinetobacter baumannii, E. coli, and K. pneumonia, producing extended-spectrum β-lactamases (ESBL), vancomycin-resistant enterococci, Enterococcus faecium (VRE), MRSA, vancomycin-resistant Staphylococcus aureus VRSA, Salmonella enterica serovar Typhimurium, Shigella dysenteriae, and Burkholderia.

Antifungal Activity of Silver Nanoparticles Using *Penicillium Chrysogenum* Extract Against The Formation of Biofilm for *Candida Glabrata*

Nada S. Salah¹, Thamer A.A. Muhsen¹, Mohssen H. Risan²

¹College of Education for Pure Science / Ibn Al-Haitham, University of Baghdad/Iraq,
²College of Biotechnology / University of Al-Nahrain/Iraq

**Abstract**

The results showed that 71 isolates of *Candida* spp were isolated from patients with leukemia both women and men. Isolate 59 from *C. glabrata* while the number of isolates of *C. albicans*, *C. tropicalis*, *C. krusei* and *C. kefyer* were 6,3,2,1 respectively. The size of the nanoparticle was measured using AFM, The highest peak was 455 nm due to the presence of surface plasmons and another 243 nm wavelength, SEM showed the presence of particle of different sizes and distributed regularly and small silver nanoparticle. Effect of synergistic silver nanoparticle and antifungal agent (fuconazole) on the biofilm of *Candida glabrata*, capable of *C. glabrata* on adhesion of epithelial cells in the absence of silver nanoparticle and fluconazole, no adhesion between epithelial and yeast cells when adding silver nanoparticles, Decrease in surface adhesion between biofilm of the yeast and the epithelial cell when adding fuconazole, When collecting silver nanoparticles with fluconazole and adding it to epithelial cells exposed to *C. glabrata*, It led to the inability of the yeast to adhere to epithelial cells and then died. All experiments showed the least significant differences at 0.001 level.

**Key Words:** *Penicillium chrysogenum*, silver nanoparticle, *Candida glabrata*, antifungal.

**Introduction**

*Candida* yeast is transformed from a saprophytic organism into a pathogen due to *Candida*’s factors such as adhesion, protease production, phospholipids, hemolysin proteins, biofilm and germ tube formation, Pathogenesis also depend on the host’s immune system. One of the factors causing an increase in candidiasis is the chronic illness of people such as diabetes, weak immune system, malignant tumors, pregnancy and excessive use of antibiotics, which are factors for the emergence of infection. *C. glabrata* is a mono-chromosome group (haploid) that has no dimorphic form and severe opportunism in the genitourinary system and in the bloodstream Candidemia is particularly prevalent in older people and infected with HIV. *C. glabrata* is common in 15-20% of infections and many of its isolates are resistant to fungal antibiotics such as Amphotericin B and Fluconazole. *C. glabrata* is a mono-chromosome group (haploid) that has no dimorphic form and severe opportunism in the genitourinary system and in the bloodstream Candidemia is particularly prevalent in older people and infected with HIV. *C. glabrata* is common in 15-20% of infections and many of its isolates are resistant to fungal antibiotics such as Amphotericin B and Fluconazole. (5) indicated that yeast has the ability to form a biofilm which is environmentally important and helps them to survive as human pathogens by allowing them to escape host immunity mechanisms, resist antifungal and compete with other microorganisms. The formation of the biofilm is a key factor in species survival.

*Penicillium chrysogenum* is common in temperate and subtropical regions and is found in food products such as citrus and grains. (6) noted that *P. chrysogenum* was widely used in the industry and in the treatment of certain plant wastes and the production of enzymes such as Polyamine Oxidae and Phospho-glucanate dehydrogenase. It also has a high potential for production of Penicillin antibody and the first commercially produced penicillin.

(8) noted that fungi contains some distinctive advantages when used as biosynthesis for the production of nanoparticle compared to bacteria by producing larger

amounts of Mechanism of action of silver nanoparticles (AgNPs) against yeast by targeting the biofilms of *Candida glabrata*, Analysis of the active electron microscopy revealed that the interaction between nano- Ag and *C. glabrata* cells during AgNPs exposure leads to changes in membranes which can be observed as holes on the surface of the membrane and lead to cell death(9). The technique of silver nanoparticles led to the movement of the drug into the tissues of the body, which was previously unreachable and was based on several factors including pH, temperature, solubility in the medicine, absorption of the surface-related drug and the spread of the drug through the matrix of nanoparticles(10).

**Materials and Method**

**Collections of Samples:** Collected 130 clinical samples taken from patients of leukemia from the City of Medicine/ Leukemia Department in Baghdad City

**Isolation of yeast:** Placing 100 microliters of blood on the sabroud dextrose agar (SDA)(11).

**Identification of *Candida***: For the purpose of diagnosing *Candida* was studied, Characterstions of Morphological(12), Purification of Colonies(13).

**Virulence of factor test:** The following experiments were performed, germ tube test (14). Biofilm formation test(15), Candida Chromgenic agar(16), the Vitek2 Compact System.

**Identification of *Penicillium chrysogenum***: The fungus of *Penicillium chrysogenum* according(17).

**Biomass of *Penicillium chrysogenum***: For the fungal biomass by(18).

**Preparation of silver nanoparticles in *Penicillium chrysogenum***: The silver nanoparticles were composed by observing in kind the color change of the yeast from the transparent color to the dark brown color(19).

**Characterization of nanoparticle using different microscopes:**

A. **Atomic Force Microscope**: Use this microscope to find out the size of nanoparticles and monitor the bio-processing of nanoparticles and know the particle size(20).

B. **UV-ViS Spectrophotometer**: The UV spectrometer is used to monitor the biotransformation of silver ions by means of UV spectroscopy of the reaction(21).

C. **Scanning Electron Microscope**: Use this microscope to determine the size and shape of the nanoparticles and to know the structural(20).

**Studying the synergistic effect of nanoparticle and antifungal for the biofilm agent of the *Candida glabrata***: This technique was used to test epithelial cells of the mouth on adhesion the biofilm to *Candida glabrata* (22) as follows:

A- First treatment: Take 0.5 ml of sediment containing epithelial cells (control treatment).

B-Second treatment: Take 0.5 mL of the sediment containing the epithelial cells and add 0.5 ml of *Candida glabrata*.

C- Third treatment: Take 0.5 ml of sediment containing epithelial cells and add 0.5 ml *Candida glabrata* and 50 microliters of silver nanoparticles composed with *Penicilium chrysogenum*.

D- Treatment 4: Take 0.5 ml of sediment containing epithelial cells and add 0.5 ml *Candida glabrata* and 100 mg of antifungal Fuconazole.

E- Treatment 5: Take 0.5 ml of sediment containing epithelial cells and add 0.5 ml *Candida glabrata* and add 100 mg of Fuconazole and add 50 microliters of silver nanoparticles with *Penicillium chrysogenum*.

**Results and Discussion**

**Distribution of infected patients with candidiasis:** The results showed that 71 isolates of *Candida* spp were isolated from patients with leukemia, both women and men, with 34 clinical cases of women. The 50-65 age group recorded 17 cases of 50% and 9 cases of the 20-30 years and 26.5%. The age group between 40-50 years recorded 5 cases and 14.7%. Finally, the age group of 17 years had the lowest rates of 8.8% and three clinical cases as in Table (1).
Table (1): Shows the distribution of women by age group Candidiasis patients due to leukemia.

This is consistent with (24) which showed that Candidiasis is the fourth most common type of infection of the bloodstream and causes candidasis for patients in hospital. The increase in infection in these age groups is due to the availability of appropriate conditions such as immunodeficiency, long-term use of antibiotics and malignant tumors.

Identification of Candida spp.: Table (4), 71 isolates were obtained from clinical samples of women and men with leukemia, 59 C. glabrata from 71 isolates and 83.1%, while the number of isolates of C.albicans, C.tropicalis, C.krusei and C.kefyer were 6,3,2,1 respectively. These results were consistent with (25), indicating that C.glabrata was the second most common cause and 24% of Candida in the United States of America. In 2004 Candida glabrata was the main cause of Candidemia, and mortality rates for Candida glabrata patients were detected. 50% in cancer patients, and 100% in bone marrow patients.

4. Biosynthesis of silver nanoparticles

Combining the biomass of Penicillium chrysogenum with the silver nitrate solution results in color difference. This indicates the formation of silver nanoparticle by the presence of surface plasmon, which is consistent with (26). The difference in color is due to the difference in the electron density of the nanoparticles that are different nano-size.

Characterization of silver nanoparticle.

Atomic Force Microscope (AFM) Results: The average square root value is equal to Root Mean Square = 2.12nm. The surface roughness of the membrane is
average Roughness = 1.54nm. This value is a proof of surface roughness. The particle size was found to be 18.83 nm. (27) showed that the nanoparticle were modified by Fusarium graminearum in different sizes and measured using AFM and began with a diameter of 1 nm.

UV spectrophotometer results:

The highest peak was 455 nm and another 243 nm wavelength and the highest peak due to the presence of surface plasmons either the second peak may indicate the presence of tyrosine and tryptophan residues found in the protein released from the yeast. This is explained(28) suggests that the reduction of silver nitrate to silver nanoparticles can be easily by using the UV spectrometer because silver nanoparticles can absorb light in the visible area due to Plasmon surface.

Scanning Electron Microscope (SEM) Results:

Fig. (1) showed the presence of spherical particle of different sizes and distributed regularly and small silver nanoparticles, this supports(29). That the surface of the plasmon reached a peak of 420 nanometers and that silver nanoparticles have a spherical shape.

Effect of synergistic silver nanoparticle of Penicillium chrysogenum and antifungal agent on the biofilm of Candida glabrata: Results showed the effect coefficients the synergy of silver nanoparticle particles For Penicillium Chrysogenum and antifungal agent against the Candida glabrata has different effects. Figure (5-A) shows the normal shape of the epithelial cells that represent the control treatment, between Figure (5-B) capable of C.gabrata on adhesion of epithelial cells in the absence of silver nitrate and antifungal. Figure (5-C) showed no adhesion between epithelial and yeast cells when adding silver nanoparticles with Penicillium chrysogenum. This indicates the inability of C.glabrata to adhere to the presence of silver nanoparticles. The exposure of epithelial cells with C.glabrata and antifungal fluconazole showed a decrease in surface adhesion between biofilm of the yeast and the epithelial cell as shown in Figure (5-D). When collecting silver nanoparticles with fluconazole and adding it to epithelial cells exposed to C.glabrata, Yeast inability was observed on adhesion with epithelial cell and then its death due to the presence of synergistic nanoparticle with fluconazole showed stable and strong antifungal activity as in Fig. (5-E). The results showed that silver nanoparticle have properties antifungal.It can also provide synergy with antifungal when evaluating the synergistic effect of silver nanoparticles and the fluconazole against the adhesion cells formed for the biofilm of C.glabrata, This is consistent with the study of silver nanoparticle antifungal such as floconazole against Candida albicans and a strong synergistic effect between silver nanoparticles and antifungal(30).

(31) showed that silver nanoparticles are associated with important cellular structures of proteins and DNA and cause cellular damage to yeast. (32) explain The association of the silver atoms with the thiol group (SH) in the enzymes, which change the composition and function of the enzymes in the cell membrane, which makes the adhesion ineffective.
Figure (2) A- Normal epithelial cells, B- Epithelial cells with C. glabrata, C- Epithelial cells with C. glabrata when adding silver nanoparticles, D- Epithelial cells with C. glabrata when adding Fluconazole, E- Epithelial cells with C. glabrata when adding silver nanoparticles with Fluconazole.

Study of Epidemiological Factors According to the Positive Response of IgG of Patients Infected with *Blastocystis hominis* in Diyala province, Iraq

Muna Hameed Ahmed Alazzawi¹, Nabaa Ali Jasim¹, Masar H. Ismail³

¹Lecturer: Directorate of General for the Education of Diyala, Iraq, ²Lecturer: Department of Community Health Technical Institute, Baquba, Iraq, ³Lecturer: Department of Biology, College of Education for Pure Sciences, Diyala University, Diyala, Iraq

**Abstract**

**Background:** *Blastocystis hominis* (*B.hominis*) is the most common intestinal parasite in humans and many other animals. Infections with the organism are spread worldwide and some of them have been asymptomatic, acute symptomatic and chronic.

**Materials and Method:** 100 blood samples were collected from patients with *B.hominis* which were reviewing to some Hospital and health center in Diyala province during the period from October 2018 to March 2019. To determine the extent of IgG antibody responses in serum patients infected with *B.hominis* for depending on the chromatic changes resulting from the association of antigens with antibodies.

**Results:** The results of the current study showed the percentage of infection among males was (56.25%), which is higher than that of females (43.75%), and the age group (3-6) years among males showed the highest rate of infection (33.34%) and the lowest in age groups less from one year and (9-12) years groups at (11.11%). The rate of infection in the age groups (1-3) years and (6-9) years was (22.22%) and in the age group of (1-3) years was the highest incidence among female groups (42.86%), while the age group (3-6) years showed less than that (28.57%) and significant differences at the level of probability less than (0.05). The percentage of *B. hominis* infection increased among the rural population by (56.5%), male infected, (57.14%) female, while the proportion of males among the urban population was (44.44%) and females reached (42.86%), with a standard deviation of (1.600 ± 0.495) and (1.480 ±0.505) respectively.

**Conclusions:** The presence of immunoglobulin IgG in serum patients has been shown to stimulate the cellular immune response and be indicative of long-term immunity against pathogenic antigens.

**Keywords:** *Blastocystis hominis*, diagnosis, parasite, infection, patients.

**Introduction**

*B. hominis* is one of the most common protozoa intestinal parasitic diseases worldwide and a common infected among humans and animals[1]. It isolated from stool specimens appear as unicellul and it has multiple shapes, such as vacuolar, granular, and amoeboid [2]. It was considered as harmless yeast, but it is now getting acceptance as an agent of human intestinal disease especially under immunosuppressive conditions[3]. The extent research on *B. hominis* is transmission mechanisms, incubation period, epidemiology, and treatment options[4]. It’s status as a true pathogen is controversial - while it has been found in patients with gastrointestinal symptoms with diarrhea or severe abdominal pain. Symptoms associated with human papillomavirus infection include: diarrhea, nausea, colic, abdominal distension, fever and chills. It is not proven to be the cause and many carriers are asymptomatic[5].
Diagnosis of B. hominis is used by clinical diagnosis of diarrheal symptoms and dehydration of the patient and laboratory methods. Direct microscopy of stool and cystic phase observation overlap with other causatives of diarrhea specially[6,7]. These data indicate that B. hominis induces as well as modulates the immune response in intestinal epithelial cells, and we conclude that different pathophysiological events may occur during B. hominis infection. [8]. The spread of disease is associated with poor hygiene, exposure to animals and the consumption of contaminated food or water [9].

Iraq has seen widespread outbreaks of gastrointestinal diseases. The Iraqi Ministry of Health and contributed many factors in the spread of the disease, including displacement of people to other places and water pollution. There are several studies that showed prevalence in different Iraqi governorates of the country. The rate of infection was recorded in 2013 (5.08%) for (31) children in Dohook in northern Iraq suffers from gastrointestinal symptoms[10]. 28 (4.1%) was infected with B. hominis from a total of 861 reviewers [11]. While in Muthana province in southern Iraq, the infection rate was 58 (45.67%) out of 127 patients infected with B. Hominis [12]. The aim of the present study is to investigate the most important immunological changes associated with infection in patients with B. hominis, the study has included measuring levels of certain cellular dynamics in the serum of infected by and based on the principle of color change resulting from the correlation of quality IgG antibodies and measured color change resulting mediated.

Statistical Analysis

Statistical analysis of the results of the current study using the Statistical Package for Social Sciences conducted (SPSS) metadata. Test was used T-test, variance analysis ANOVA, Chi-square, percentage, standard deviation and standard error in the present study to find a moral differences between groups with infection Blastocytis hominis and there were significant differences (P < 0.05).

Results

The present study included 100 patients with B. hominis, 50 males and 50 females. The positive response rate of IgG for males was higher than that of females, which recorded positive response rate of (56.25%) at (1.820±0.388). While the percentage of response to the antibiotic in the serum infected females (43.75%) at (1.860±0.351). Hence, the statistical analysis of this increase indicates that there isn’t a significant difference of statistical significance at the level the probability is less than 0.05 as shown in Table 1.

Materials and Method

Collection of samples

The present study collected 100 cases with Blastocystis hominis within the period from October 2018 to March 2019, of 50 male and 50 female, ranged in age less one year to 12 years. It has diagnosed the disease process and determined by dermatologists at some Hospital and health center in Diyala province and the injury was diagnosed based on the clinical symptoms and distinct phenotypic traits of infections.

Serological diagnosis

Serological diagnosis was performed by measuring the IgG level in the serum of patients with B. hominis to determine the response of the positive in the body of the infected patients. Blood samples were collected from patients. Was withdrawn 5 ml of venous blood for each of the infected persons, therapists and control the use of a syringe, put blood samples in test tubes and let the blood to clot at room temperature (20-25) minutes and then the separation of the serum Centrifuge device speeds of (3000) rpm and then it is kept freeze-preserved models when (-20°C) until the subsequent immunological tests.

Table 2 shows that the injuries spread within a wide range of age groups. The age of those infected was less than 1 to 12 years. In males recorded age groups the (3-6) year age group had the highest IgG response rate at (33.34%) and followed by tow the age groups (1-3) years and (6-9) years (22.22%) and less than at (11.11%) in tow groups less one years and (9-12) years age groups. Compared to the female group, the (1-3) years age group had the highest incidence of IgG infection and response 42.86%. The lowest response among the age group of females was 0.00% in the age group less than one year, so that no percentage is recorded. This is due to the visitors who visit the health centers at the time of collecting samples. While the age group 3-6 years by 28.57% and less than the age groups (6-9) and (9-12) years by (14.29%). Differences between the proportions of m and their response to IgG were statistically significant at the probabilistic level the level the probability is less than 0.05 as shown in Table 2.

The patients’ place of residence showed a clear difference between their urban and rural residence, but did not constitute a significant difference of statistical significance at the probability of p> 0.05. The prevalence of IgG immunoglobulin was significantly higher among urban than in rural areas as table3 showed. The proportion of males was 55.56% of respondents 5 patients of the total number is 20 cases, while females registered 57.143%, with 4 patients of the total number of 26 cases. The response rate in the urban group of infected males was 44.44% with 4 patients of 30 cases, less than 42.857% in urban areas, with 3 patients of the total 24 cases.

Discussion

B. Hominis is a protozoan intestinal parasite disease that caused by the emergence of various symptoms, including diarrhea, nausea, abdominal cramps, bloating, excessive gas, and anal itching. The timescale of infection with the parasite can range from weeks to years [13]. The present study showed an increase in IgG and positive response rate in males, with (56.25%) infection rate and (43.75%) female infection as in the table (2). This may be due to the number of hospital-reviewed cases and some male health centers more than females, and therefore dependent on individual immunity. This is consistent with the findings of Nayef et al. (2011) which indicated the percentage of male (23.99%) height on females (16.27%) and attributed the reasons for this to the above, attributed the reasons to as exposure to the infection increases with the top of nutrition and increased funding [14]. The percentage of infection between females and males does not make any significant difference at the probability level (0.05), which is consistent with the results of Mahmood and Khudher (2016) Indicating that there is no significant difference between the rates of infection of males and females and accounted for the percentage of infection B. hominis in Sammara city - Salah Al-Deen province was (9.09%) [15].

The current study indicates that the housing factor has a difference in the percentage of IgG positive response for patients with B. hominis for both sexes but does not register any significant difference at the probability level (P > 0.05). The positive response rate for patients with B. hominis who live in rural areas is higher than that of urban dwellers. This is due to the pollution of the environment and the environment of the rural inhabitants of B. hominis. They may be directly related to the reservoir stocks such as sheep, cattle, cats, dogs and other domestic animals. For rural males (55.56%) of respondents (5) patients of the total number is (20) cases, while females registered (57.143%), with (4) patients of the total number of (26) cases. The response rate in the urban group of infected males was (44.44%) between different age groups ranging from 6 months to over 61 years out of a total of (177) patients with B. hominis [16]. The main cause of diarrhea is B. Hominis among other pathogens, as explained by al-Kaissi and Majdi (2009), the highest proportion of whom were 82 cases with B. Hominis isolated from 200 patients suffering from diarrhea by 41% [17]. Where the current study recorded the age group (3 – 9) years is the highest response rate positive for IgG among males infected with B. hominis, which amounted to (33.34 %) and the lowest was in the two age groups less than one year and (9-12) years is (11.11%). While the age group (1-3) years among females infected with the highest rate of (42.86%) and less than in the categories of age (6-9) years and (9-12) years is (14.29%), while the category less than a year does not register any case among females and this is due to patients reviewing hospitals and centers when collecting samples as showed in table (2) .

The current study indicates that the effect of the age group in the incidence of B. hominis, whose age ranged between (> 1 - 12 ) years with a significant difference of (P < 0.05). As it was the highest rate of infection in both genus and is attributed to the lack of development of the immune system in the younger age groups compared to the large age and this is consistent with what Salman (2015), who pointed to a significant difference at level (P <0.05)
with (4) patients of (30) cases, less than (42.857%) in urban areas, with (3) patients of the total (24) cases as showed table (3).

Conclusions

The present study conclude that the disease’s ability to stimulate the cellular immune response leading to the production of IgG that observed height in patients groups.

Conflict of Interest: None

Source of Funding: There is no funded support for the implementation of this work, while the active role of us as joint researchers in the design of the study and the collection of samples and analysis and preparation of the manuscript and financial and moral support.

Abstract

The current study included an epidemiological prevalence study of appendicitis in Karbala province, where complete data were collected for the year 2018 from Al Hussein medical Hospital. The results showed that the total number of appendicitis in Karbala province was (636) cases, divided in to (299) and (286) for male and female respectively, while the secondary removal cases was (69). The percentage of infection was 47.012%, 42.12% and 10.85% for male, female and secondary removal. The statistical analysis showed that there were significant differences under (P> 0.05) between percentage of infection in male and female (0.01). Also this study included histopathological examination of appendectomy specimen. After surgical removal of appendix, the specimen directly fixed with 10% formalin and then do tissue processing. The microscopic examination showed obstruction of the lumen and infiltration of inflammatory cell within lumina properia, muscularis and adventitata. the mucosal epithelial was destruction with ulceration, also there are extensive lymphoid hyperplasia.

Keywords: appendicitis , prevalence, Karbala, gender, histopathological.

Introduction

Appendicitis is inflammation of the vermiform appendix, this is a hollow organ located at the tip of the Cecum, usually in the right lower quadrant of the abdomen, however it can be located in almost any area of the abdomen depending on if there were any abnormal developmental issues (situs inversus totalis) or if there are any other concomitant conditions such as pregnancy or prior surgeries (1).

The appendix develops embryonically at the fifth week, during this time there is a movement of the midgut to the external umbilical cord with the eventual return to the abdomen and rotation of the Cecum, this results in the usual retrocecal location of the appendix (2).

Appendicitis is more common surgical emergencies, and it is one of the most common causes of abdominal pain (3). The exact function of the appendix has been a debated topic, today it is accepted that this organ may have an immunoprotective function and acts as a lymphoid organ especially in the younger person, other theories contend that the appendix acts as a storage vessel for “good” colonic bacteria, still others argue that it is a mear developmental remnant and has no real function (4).

Appendicitis is most common between the ages of 5 and 40, the median age is 28, risk factors include being male, higher household income and living in a rural area (5).

In the United States, there were nearly 293,000 hospitalizations involving appendicitis in 2010. Appendicitis is one of the most frequent diagnoses for emergency department visits resulting in hospitalization among children ages 5–17 years in the United States (6).
Research aims:

1-study the epidemiological prevalence of appendicitis in Karbala province.

2-study the histopathological changes occur in appendix tissues during acute appendicitis.

Research methodology and procedures:

A database of patients with appendicitis was collected from Al Hussein Medical City in the Karbala city from January to December 2018. Also, samples were taken from the surgical theaters after being fixed directly with 10% formalin for tissue processing.

Results

1- Epidemiological study

All samples that collected in this study were under different condition, like; gender and age. The total number of appendicitis that show in this study in Karbala province was (636) cases divided into (299) and (268) for male and female respectively, while the secondary removal cases was (69). The percentage of infection was 47.012%, 42.12% and 10.85% for male, female and secondary removal, respectively. The statistical analysis showed that there were significant differences under (P > 0.05) between percentage of infection in male and female (0.01). Table (1).

2- Histopathological study:

In present study the histopathological changes observed in appendix were presence of extravascular polymorphs in the epithelium, lamina propria, or muscular layers was the main diagnostic feature of acute inflammation (Figure 1 B, C, D). The wall of appendix, was clearly visible and the mucosa was largely destroyed (figure 1(A, and D)), and there was extensive neutrophil infiltrate extending throughout the submucosa and into the muscularis externa. The was seen in all specimens. The glands of appendix was largely affected, and shows the mucosa glands was destroyed and pus present at the base of the gland and with only few remnant of glands in the section (Fig.21 B).

Figure (1) A: show lumen obstruction and mucosa destruction of appendix.  
Figure (1) B: Show the lymphoid hyperplasia
Discussion of Results

Our study was revealed increase incidence of appendicitis between males compare with females, that may be related with female sex hormones, which has been proposed because of lower incidence among women and incidence variations during the menstrual cycle \(^7\).

Anderson was found inverse relation between pregnancy and appendicitis, this suggests that pregnancy protects against appendicitis, especially in the third trimester. During pregnancy a range of physiological changes take place that may influence the pathogenesis of appendicitis \(^8\). Our finding was agree with \(^9\) who reported increase of incidence of appendicitis in males, this due to variation in body physiology between male to female.

In our study the highly percentage of infection is rang between age (10-20) years, that cited by \(^10\), who reported that incidence of appendicitis is generally a disease of young age. \(^11\) was reported in his study the incidence outcome of appendicitis are related to age in young people. It has been suggested that the peak in the development of lymphoid tissue which occurs during adolescence leads to an increased liability of the appendix to obstruct, and so accounts for the high incidence of the disease.

the present histopathological study showed lymphoid hyperplasia with increase in lymph nodules diameter, these lead to obstruction. Our study was revealed increase in wall thickness of appendix and narrow lumen, with increase infiltration of white blood cells was very visible, this finding agree with \(^12\) and \(^13\) they recorded infiltrate of neutrophile in the muscularis mucosa and sub mucosa.

Obstruction of the appendiceal lumen seems to be essential for development of appendiceal infection. This obstruction occurs due to mucosal inflammation and lymphoid hyperplasia, once obstruction occurs, continued mucus secretion and increase intraluminal pressure, which obstructs lymphatic drainage and edema, mucosal ulceration and may cause venous obstruction, finally ischaemic necrosis of appendix wall produces gangrenous appendicitis.

Conclusions

1- Appendicitis is one of emergency disease.

2-The total cases in Karbala province was 636 in 2018 year which is divided to (299) and (286) for male and female respectively, while the secondary removal cases was (69).

3- The percentage of infection in male is higher than in female 47.012%, 42.12% and 10.85% for male, female and secondary removal.
4- Highly percentage of infection in both male and female was in age between 10-20 years (35,82% in female and 42,47% in male), while the low percentage was in age between 60-70 years (1,11% in female and 0,66% in male).

5- The most histopathological lesions that found in appendectomy specimen was lumen obstruction and mucosa destruction of appendix, lymphoid hyperplasia, obstruction of the lumen and infiltration of inflammatory cell within lumina properia, muscularis and adventitia.

Molecular investigation of virulence factors genes in *streptococcus pyogenes* by PCR

Russell Issam AL-Daher¹, Maysa S. AL-Shukri², Hayam K. AL-Masoodi³

¹,²,³Dept. of Microbiology, College of Medicine, University of Babylon, Iraq

**Abstract**

This study was designed to detect some genes associated with important virulence factors in *streptococcus pyogenes*. A total of 200 throat swabs were collected from patients suffering from pharyngitis from both sex and age from (1 - 15) years. carried out from ENT unit in Al-Hilla General Teaching Hospital and Al Noor Hospital during the period from January 2018 to December 2018. Out of the 200 samples only 177 samples showed positive bacterial culture. No growth was seen in other 23 samples. The results indicate that the rate of *Streptococcus pyogenes* isolated from patient with pharyngitis is 30 (15%), others bacterial growth 147 (73%), and no growth 23 (12%).

Molecular detection of virulence factor genes was done like M protein (*emm*) gene, the result shows that these genes were detected in all isolates bacteria (100%) with molecular length (914 bp), *SpeA* gene was carried by using specific primer and it was found that (3.3%) isolates give positive result for this gene with amplicon (576 bp), *SpeB* gene the result shows that (100%) isolates contain the gene with molecular length (952 bp), *SpeC* gene also study by using specific primer at molecular length (405 bp) and the result shows that (75%) give positive results to this gene, the *mac* gene in all *S.pyogenes* isolates results show that (30%) give positive, results to this gene with molecular length (389 bp), *scpA* gene in all isolates the result shows that 17 isolates (56.6%) give positive result to this gene with amplicon size (622 bp)

**Keywords:** PCR ; *streptococcus pyogenes* ; virulence factors

**Introduction**

*Streptococcus pyogenes*, commonly known as group A streptococcus (GAS) is a fermentative, facultative anaerobe, nonmotile, nonspore-forming gram-positive coccus, which occurs in chains or pairs, having a diameter of 0.5-1.0 μm. GAS are beta haemolytic streptococci. They require an enriched medium containing blood to grow (1). The group A streptococci are fastidious organisms that have complex growth requirements. A highly nutritious growth medium that provides optimal growth GAS is generally grown on agar media supplemented with blood (2). Pharyngitis, or commonly known as sore throat or strep throat, is the most common manifestation of infection with *Streptococcus pyogenes* (GAS) Infection with this bacterium is diagnosed in 20 to 40% of pharyngitis cases in children and in 5 to 15% in adults (3). M protein considered one of the most important virulence factors, the M protein promotes host interactions and adherence to human epithelial cells; specially helping bacteria to escape from host immune response by inhibition of phagocytosis (4). Other important virulence factors include the streptococcal superantigens (SAgs). SAgs are bacterial toxins which bind to major histocompatibility complex class II and T-cell receptors (5).

*SpeB* plays a role in the pathogenesis of *S. pyogenes* infections by Destruction of host defense system proteins and cleavage of GAS surface proteins may help the bacterium to escape immune clearance, invade the deeper tissues, and disseminate from the primary infection site (6). *SPE-C* was the first streptococcal SAg SPE-C binds to the polymorphic MHC class II β-chain with the formation of a tetravalent zinc complex that includes three residues within the C-terminal domain of SPE-C (7). Mac-2 is a related IgG endopeptidase that prevents the recognition of IgG bound to *S. pyogenes* by competitively blocking

---

**Corresponding Author:**
Russell Issam AL-Daher
Email: issamrussell@gmail.com
IgG from recognition by Fc receptors on host cells. Given that IdeS/Mac have homologs across group A streptococcal strains (8). Streptococcal C5a Protease SepA, is a cell-bound peptidase anchored to the cell wall by sortase A. The streptococcal C5a protease (SCP) is expressed on the surface of all serotypes of *S. pyogenes* and most human isolates of groups B, C, and G streptococci, where it specifically destroys C5a. The enzyme also binds fibronectin and functions as a low level invasion for *S. pyogenes*, group B streptococci and group G streptococci (9).

**Materials & Method**

This study included 200 patients (aged 1-15 years) collected from throat swab who admitted to Al-Hilla Teaching Hospital, during a period extending from January 2018 to December 2018. The specimens were collected from patients with pharyngitis to detect *Streptococcus pyogenes* by bacteriological analysis and vitek 2 system in a proper way to avoid any possible contamination.

**Detection of virulence Genes by PCR technique**

**DNA extraction and purification**: This method was made according to the genomic DNA purification Kit supplemented by the manufacturing company Geneaid, (UK). The suspension containing DNA was stored at-20 C until used as a template for PCR.

**Primer Sequences**: The primer sequences and PCR conditions that are used in the study (10).

**Results and Discussion**

**Isolation of *Streptococcus pyogenes***:

In this study, a total of 200 throat swab were collected from patients suffering from pharyngitis from both sex with age (1-15) years. carried out from ENT unit in Al-Hilla General Teaching Hospital and Al Noor Hospital during the period from January 2018 to December 2018.

The results indicate that the rate of *Streptococcus pyogenes* isolated from a patient with pharyngitis is (15%), others bacterial growth (73%), and no growth (12%). as shown in Table (1).

The low percentage of *Streptococcus pyogenes* may be due to normal flora that found in the pharynx and other bacteria that cause secondary infection, there compete pathogenic bacteria in nutrient in culture media.

No growth was seen in other 23 samples which indicate the presence of other microorganisms that may be cultured with difficulties such as viruses, fungi and other agents or because of the misuse of antibiotics that cause the disappearance of the bacteria. Antibiotic treatment is recognized as an effective means to reduce transmission of the organism particularly for respiratory and cutaneous infections (11).

**Genetic detection of Virulence factors of *Streptococcus pyogenes* by PCR**

**Molecular detection of (emm gene)**

By using specific two primers for detection of M protein (emm) gene, the result shows that these genes were detected in all isolates bacteria (100%) with molecular length (914 bp) when compared with allelic ladder as shown in figure (1).
Figure (1) agarose gel electrophoresis at 70 volts for 50 min. for \textit{emm} gene in \textit{S. pyogenes}. PCR product visualized under U.V light at 320nm. After staining with ethidium bromide. L: Ladder with 2000 bp. 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 were positive for this gene with amplicon size 914 bp.

Khosravi \textit{et al}, (2016) found that the \textit{emm} gene detects in all isolates of GAS isolates isolated from throat samples in children with sore throat, and found that the types of \textit{emm} gene different according to the types of diseases\textsuperscript{(12)}.

\textbf{Molecular detections of pyrogenic exotoxins (\textit{SpeB} ,\textit{SpeC})}

In this study two primers were used to detect the \textit{SpeB} gene and the result show that (100\%) isolates contain the gene with molecular length (952 bp) when compared with allelic ladder as shown in figure (2)

Figure (2) agarose gel electrophoresis at 70 volts for 50 min. for \textit{speB} gene in \textit{S. pyogenes}. PCR product visualized under U.V light at 320nm. After staining with ethidium bromide. L: Ladder with 2000 bp. 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 were positive for this gene with amplicon size 952 bp.

Hytonen \textit{et al}.,(2001) found that the \textit{SpeB} gene is carried by all strains of \textit{S.pyogenes}, but the degree of expression varies from strain to strain, and \textit{SpeB} has been considered to produce only in a secreted form. the expression of \textit{SpeB} is controlled by the multiple gene activator \textit{mga}\textsuperscript{(13)}. Also in this study the \textit{SpeC} gene also study by using specific primer at molecular length (405 bp) and the result s show that (75\%) give positive results to this gene when compared with allelic ladder as shown in figure (3)

Figure (3) agarose gel electrophoresis at 70 volts for 50 min. for \textit{speC} gene in \textit{S. pyogenes}. PCR product visualized under U.V light at 320nm. After staining with ethidium bromide. L: Ladder with 2000 bp. 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 were positive for this gene with amplicon size 405 bp.
In this result it was found that SpeB is more prevalence than other gene SpeC this may due to that this gene coded by chromosome and SpeB is the key virulence factors in GAS pathogenesis.

Also the distribution in the prevalence these genes may attributed to site of infection or may the isolates contain other genes responsible for exotoxin, which it was found that there are (11) gene responsible for *Streptococcus pyogenes* exotoxin

**Complement membrane attack complex (Mac) gene detected by PCR**

Specific primer was used to amplify the mac gene in all *S.pyogenes* isolates the results show that (30%) give positive, results to this gene with molecular length (389 bp) when compared with an allelic ladder as shown in figure (4)

![Figure (4) agarose gel electrophoresis at 70 volts for 50 min. for mac gene in S. pyogenes. PCR product visualized under U.V light at 320nm. After staining with ethidium bromide. L: Ladder with 2000 bp. 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 were positive for this gene with amplicon size 389 bp.](image)

The different the percentage of this gene may be due to the bacterial contain other gene encoded for complement factor degradation other than mac like Endos and C5a peptidase.

**Molecular detection of scpA (streptococcal C5a peptidase) by PCR**

DNA was extracted from (30) *streptococcus pyogenes* isolates, PCR was carried out using these DNA from the amplification of specific primer (scpA) after the gel electrophoresis, the result shows that 17 isolates (56.6%) give positive result to this gene with amplicon size (622) when compared with allelic ladder as shown in figure (5)

![Figure (5) agarose gel electrophoresis at 70 volts for 50 min. for scpA gene in S. pyogenes. PCR product visualized under U.V light at 320nm. After staining with ethidium bromide. L: Ladder with 2000 bp. 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 were positive for this gene with amplicon size 622 bp.](image)

scpA decreases the rate of GAS clearance by inhibiting chemotactic recruitment of phagocytic cells to the site of infection, also shown to promote Fn independent GAS invasion of the human epithelial cell (14). The negative results may belong to that the isolates contain another gene responsible for protease gene like (speB and SPYCEP) or gene is non-functional gene.
Conclusion

Humans are the only reservoir for GAS. It is most common among children 5 through 15 years of age, presence of superantigen genes within the S. pyogenes genome suggests that they do play a significant role in S. pyogenes disease, high prevalence of emm, speB, sdaB gene in streptococcus pyogenes isolates.

Iron Deficiency among Patients with Febrile Seizures in Al Ramadi Maternity and Children teaching Hospital, Western Iraq

Sahar j. AL- Hiali

Assistant Professor. Department of Pediatrics, college of Medicine, Ibn Sina University of Medical and Pharmaceutical Sciences, Baghdad, Iraq

Abstract

Background: Febrile seizures are the most predominant neurological disorders in children between 6 months-5 years, at the same time iron deficiency anemia is one of nutritional insult that implicated as risk factor for occurrence of febrile seizures.

Objectives: to estimate the role of iron deficiency as a risk factor for febrile seizures in children aged 6 months -5 years, western Iraq.

Patients and method:- A case control study has been conducted in AL Ramadi maternity and children teaching hospital during January to October of 2016. All children with history of febrile seizures aged 6 months-5years were involved as cases group, others with febrile illness and no seizures were considered as control group. Data from 58 child of each group were collected. The data include age, sex ,temperature, causes of febrile illness, Hb ,hematocrit and s. ferritin levels. The data were subjected to statistical analysis run under IBM SPSS ver. 23.

Results: Means age ± SD were 27.48±14.83 & 23.24±14.37 months in cases and control groups respectively with no significant difference between them. Most of the children (65.52%) of those with febrile seizures were less than 3 years old. Mean temperature of cases group (38.86°C) was found to be significantly greater than that of the control group (38.52°C) at p-value <0.01. Mean Hb level ,PCV%, s. ferritin level were significantly lower in cases group than in control group. Proportion of iron deficiency anemia was significantly higher in febrile seizure group (65.52%) than in control group (31.03%) at p-value< 0.01.

Conclusions: Occurrence of IDA in cases group is found to be more than 2 times of that in the control group. Early detection and proper treatment of IDA can play a prominent role in limitation the prevalence of febrile seizures among children below 5 years.

Key words: febrile seizures, IDA, western Iraq

Introduction

Febrile seizures (FSs) is the most predominant neurological disorders in childhood with a multifactorial inheritance that occur in 2-5% of children in united states,5-10% in India and up to 14% in Guam\(^1\). FSs described as a seizures that come in association with high grade fever of 38 centigrade or more without brain infection or electrolytes disturbances involving age groups ranged from 6months-5 years with peak age of occurrence of 18-24 months\(^4\). \(^5\) 

Iron deficiency anemia (IDA) is another well pronounced easily correctable nutritional problem that can affect the intellectual development and occur predominately in a nearly similar age interval of FSs in young children 6months -24 months\(^6\). \(^7\)
In general, anemia was noted in a proportion 46-66% of children younger than 4 years of age in developing countries and approximately half of them were iron deficient\(^8\).

Indeed, iron is one of the micronutrients that have an important role in neuronal development (neurogenesis), maturation of myelin, energy and neurotransmitters metabolism\(^9,10\) as well as formation of hemoglobin.

Thus abnormal neurotransmitters functions as a sequence of iron deficiency, may in turn contribute to alteration of seizure threshold and initiation of febrile seizures in young children\(^7\).

So if we take into account the same age prevalence of IDA & FSs and the effect of iron deficiency on brain function, as well as the value of Hb in carrying O2 to brain, and since presence of fever can exaggerate the symptoms that result from effect of IDA on brain, so relation between FSs & IDA is probable.

Based on all the above considerations, and since no study was conducted in Al Ramadi province western Iraq about such problem, so our study was conducted to estimate the role of iron deficiency as a risk factor for febrile seizures among children from 6 months-5 years, western Iraq.

**Patients and Methods**

A case control study has been conducted in Al Ramadi maternity and children teaching hospital, western Iraq during the period January to October of 2016. The study approved by the ethics committee of AL Anbar University, Medical College. All children who admitted with history of febrile seizure and their age ranged from 6 months-5 years were involved in the study as a febrile seizure group (FSG). The control group collected randomly from children between 6 months -5 years who they admitted for same hospital during study period with febrile illness & no seizures (non-seizure group, NSG).

Detailed history and physical examination were done for them. Simple febrile seizure defined as single seizure that associated with peak of fever, last less than 15 minutes, once per day and generalized features, complex febrile seizures defined as seizure last more than 15 minutes, frequent per day or had focal features\(^11\). All patients with history of CNS infection and history of delayed developmental milestone were excluded.

Information that collected from studied groups include age, sex, degree of temperature at admission, causes of febrile illness (respiratory tract infection, gastroenteritis, otitis media, tonsillitis, others), nature of seizures, duration and frequency of seizure were all recorded for every patient. Five mls of blood was aspirated to assess Hb, hematocrit (PCV) and s. ferritin values in studied groups (ferritin Accu Bind, ELISA Microwells, USA).

IDA defined as Hb level less than 11gm/dl. PCV less than 30%, s. ferritin less than 12ng/ml\(^6,12\).

The data were statistically analyzed using IBM SPSS v. 23.0, p-value < 0.05 was considered significant.

**Results**

One hundred sixteen children aged 6 months-5 years were included in the study during the period mentioned previously. Patients were classified into two groups each of 58 patients. The cases group involved 34 males and 24 females which indicates a male to female ratio of 1.42:1, on the other hand, the control group consist of 36 males and 22 females with a male to female ratio of 1.64:1.

Regarding FSG, 48 (82.7%) of them had simple type febrile seizures, and the remaining cases had complex type (17.3%). Most of patients with febrile seizures 38 (65.52%) were below age of 3 years. Out of this group 22 (37.93%) their age ranged from 12-24 months. Only four patients (6.9%) were found in the age group 6-12 months (Table 1).

The means age were 27.48±14.83 and 23.24±14.37 in FSG & NSG respectively with no significant difference between them (p =0.120), (Table 2).

The Chi-square test revealed no significant association between gender and groups of the study (Chi-square=0.144, p-value=0.7). Percentages of gender groups were compared to each other in both groups and found to be not significantly different (Table 2). Mean temperature at admission was significantly higher in FSG than NSG, (p =0.120).

Respiratory tract infection was significantly the most predominant cause of febrile illness in FSG 30 (51.7%) as compared to NSG 10 (17.2%), whereas gastroenteritis was significantly lower in FSG 20 (34.5%) as compared to NSG 38 (65.5%) (Table 2).
Means Hb level, PCV% & s. ferritin levels were significantly lower in FSG than in NSG, p values were all lower than 0.05.

The proportion of IDA among FSG was significantly higher than that of NSG, 38 (65.52%) vs. 18 (31.03%), p-value=0.0003.

Discussion

Febrile seizures are the most common neurological disorder that occurs in children less than 5 years old without central nervous system infection or electrolyte disturbances.

In the current study FSs were pronounced predominately in children below age of 3 years (65.52%), mainly among 12-24 months age group which is in agreement with other studies (13,14).

The mean age of onset of FSs was 27.48 months which is nearly similar to others (4,5,15,16).

As described by other researchers (13,17) majority of patients with FSs had simple type of seizure (82.7%) and the remaining had complex type. The association between FSG, NSG and gender groups was statistically insignificant which is comparable with results of other reports (18,19).

Moreover, Like other reports (15,20,21), this study revealed a significant high peak temperature at admission in FSG than NSG. It was generally reported that fever is one the risk factors implicated in occurrence of FSs that may aggravate the worse effect of lack of iron on brain function which may precipitate seizure attack (17,22).

Regarding causes of febrile illness, respiratory tract infection was the predominant cause of febrile illness in FSG which is found to be significantly higher than that of the NSG and that is in agreement with other studies (23-25).

On the other hand gastroenteritis was significantly lower in FSG than NSG which supports the suggestion of its protective effect against FSs as reported by other studies (5,26).

Several previous publications from different countries worldwide clearly demonstrated the existence of association between IDA and FSs and they considered IDA as an important risk factor for occurrence of FSs (9,27,28).

This study carried out in the Western region of Iraq in order to cast light on some of the important concepts associated with main issue of the study. Accordingly, this study showed that there are statistically significant reduction in means Hb level ,PCV %, s. ferritin level of (FSG) compared to (NSG), in addition the proportion of IDA in FSG was more twice that in the NSG (table 2).

This results is in agreement with Daoud A S etal’s report, from Jordan, 2002 (29) who study the association between IDA & s. ferritin ,they thought that lack of iron could be possible cause of FSs. as they found a significant low mean s. ferritin levels and higher percentage of cases with low serum ferritin 30ug/dl among FSG than controls ,29±21mcg/L vs. 53.3±37.9mcg/L , ( p 0.000).

On other hand, Kumari et al, 2012 (30) used univariate and multivariate analysis for the data collected from the same purposes of this study, they observed a significant higher proportion of iron deficiency in FSG than controls, 63.6% vs.24.7% , p=0.001 which is complies with the results of the current study. The same conclusion reported by Momen A et al., 2010 from Iran (18) whom they confirm the existence of positive relation between febrile seizure and IDA.

Habibian N ,et al., 2014(31) conducted a meta-analysis study and observed that IDA was moderately increased the chance of FSs in children especially in the regions of low or moderate percentage of IDA.

Moreover, similar significant association between IDA &FSs was pronounced by El-Shafie et al., (32), 2017 whom conducted a prospective case control study of 60 cases aged 6 months -5 years from Egyptian children, they found that 21 (52.5%) of cases had IDA compared to 4 (20%) of controls p 0.05.

However, other studies had proved otherwise and denied any association between IDA and FSs and thus did not agree with results of this study. Amirsalari etal(33) Omen etal (34) and Abaskhanian A etal(35) deduced a lack relationship between IDA and FSs.

Furthermore, Derakhshanfar H, etal (5) suggested that IDA was less common in febrile seizure patients than healthy children. Whereas Talebian A ,etal (36) in a study involved 120 children aged less than 5 years, reported that IDA was more common in controls than FSG and concluded that IDA was not a risk factor but rather a protective factor against FSs.

Bidabadi E and Mashouf M,(15) in a case control study of 200 cases with febrile seizures and 200 controls aged 6 months-5 years, found that IDA was less frequent in patients with FSs than controls with no statistical difference between the two groups, but the protective effect of iron deficiency against FSs was not proved (odd ratio 1.175).
Indeed, these variation in results of these reports could be related to the variations in studies designs, different samples sizes and age groups involved, different measures used for diagnosis of IDA, nutritional status and prevalence of IDA among children involved in these studies from different regions. Unfortunately, no previous study was carried out in al Ramadi province, Western Iraq, regarding prevalence of IDA among children aged less than 5 years. Based on the results of this study, it can be concluded that IDA is about two times more predominant in FSs patients than in other patients with no FSs, and Iron deficiency is well recognized as a risk factor in children aged less than 5 year. In this context, early detection with proper correction of IDA will be effective in reducing rates of FSs among those children. Large sized prospective study is necessary to assess prevalence of IDA in children less than 5 years as well as to help evaluating nutritional problems that may contribute positively to the IDA.

Antibiotic Susceptibility of Bacteria Isolated From Under Nails

Zahraa AL-Taee¹, Sura Ihsan Abed Jabuk¹, Raflaa S.H. Hussinan, Zainab H. Kareem², Yasir H. AL-Mawlah¹

¹Lecturer Dr., ²Assistant Lecturer, University of Babylon, College of Science, Department of Biology, Hilla, Iraq

Abstract

This study was designed for isolation and diagnosis of bacteria from under long dinger nails of a wide population of student (kindergarten, primary schools, elementary schools and university students) and study the antibiotic sensitivity for isolated bacteria.

From 100 sample the bacterial isolate were Staphylococcus sp.(56 isolate), Bacillus sp.(1 isolate), Streptococcus sp. (1 isolate), Escherichia coli (40 isolate), Salmonella (2 isolate), Enterobacter (10 isolate), Klebsiella (10 isolate), Serratia (5 isolate) and Pseudomonad (6 isolate).

The most effected antibiotic on all types of bacteria isolated from under the long nail was Gatifloxacin and the lowest effect was Cefazolin antibiotic.

The concept of the study was isolating and determining bacteria, found under the long fingernails and studying their antibiotic sensitivity.

Keywords: Under Nails; Antibiotic; Bacteria Isolated; Health.

Introduction

The skin on the human body is in permanent contact with the environmental microorganisms, these contaminant microorganisms can easily be isolated in laboratories. These microbes can induce a range of diseases in the community or hospital, including urinary tract, respiratory tract, injuries and burns, bacteremia, neonatal meningococcalpitalis, empyema and osteomyelitis. The hand acts as a significant transmission platform for different microbes, including the enteric species [1].

The most in touch human body components with the outside world are the hands. People are using their hands every day for a wide range of different activities. Contacting distinct microbes and transferring them to other objects and perhaps even individuals is highly simple. Surprisingly, the larger number of bacteria discovered on human hands are under fingernails [2]. In many health-related problems, fingernails are progressively seen as a significant concern due to the ability to harbor many kinds of microorganisms [3].

The finger nail is a significant structure consisting of the protein, keratin, laminated layers. Nails have two key roles, in spite their tiny number. They function as a protective lamina and by acting as a counter-force to improve the feeling of the fingertip. Every nail comprises several components including: nail root, nail bed, nail plate, perionychium and hyponychium [4].

Even microbes may still occur under fingernails when hands are washed. Higher microorganism populations (2 to 3 log CFU / fingernail) happen commonly under the nails and are often more hard to remove than at other hand places (CDC, 2002). Length and texture of the fingernails also influence the effectiveness of microbial removal from below the nails. Long and polished nails usually contain more microbes after cleaning hands than brief and unpolished nails [5].

Therefore, using artificial fingernails can be a factor that influences the effectiveness of hand washing as artificial nails are generally longer than natural nails. Several studies have shown that greater populations of microbial are retrieved from artificial nails than natural nails [3]. Effective hand washing techniques are crucial in
stopping disease transmission via finger nails to remove microbes from artificial or natural [6].

The higher population of pathogenic microorganisms found under long nails were Escherichia coli, Shigella, Salmonella, Enterobacter, Klebsiella, Serratia, Proteus, Bacillus and pseudomonas [6, 7].

Materials and Method

Collection of samples

A total of 100 samples were collected from Kindergarten students, primary, secondary and university students. This study was conducted between October 2017 and May 2018 in Al-Hillah city. The samples were gathering by sterile tooth picking, the tooth picking was scrub throughout the surface of the under-nails and moved to the brain heart infusion broth to guarantee that bacteria remained alive, after the broth was incubated at 37°c for 18 h.

Methods of isolation and diagnosis

Culturing Methods

In the research, the nutrient agar medium was used for bacterial culturing. Detailed data was gathered under the samples of the nails (lengthy nails) depending on era and sex. The crops were incubated at 37 ° C and bacterial development was inspected at 24 hours. To achieve pure culture, separate colonies were sub-cultured into nutrient agar. Shape and color of colonies (morphological characteristics), gram stain tests and biochemical tests were used to identify bacteria.

Identification of Bacteria

Bacteria were diagnosed by using several selective media like, mannitol salt agar, maCconky agar, eosin methylene blue, SS agar and blood agar also bacteria were gram stained.

Antibiotic Susceptibility Test

Several antibiotic dicks were used (Aztreonam ATM(30mcg), Cefazolin CZ(30mcg), Cefotaxime CTX(30mcg), Clindamycin DA(2mcg), colistin CT(10mcg), Gatifloxacin GAT (5mcg), Nitrofuranton F(300mcg) and Trimethoprim/ Sulphamethoxazol SXT(25mcg)) to test the sensitivity of bacteria. The test was done by using Muller Hinton media.

Result and Discussion

Microorganisms existence under the nails has become the most widely health issue. A total of 100 samples from under nails by tooth picks were gathered from under the nails, 100 students were gathered in the left and right hands.

All students (100%) found that they were harboring bacteria under their nails. Bacterial pathogens that were isolated from the students ' lower nails were found in (table 1).

Rayan and Flournoy Clarify the presence of large bacterial growth under fingernails over 1 mm in length, showing that volunteers with short finger nails (cut correctly) had 64% bacterial contamination (bacterial count) and volunteers with lengthy finger nails had more (67%) bacterial count presence on their hands [8].

Lin indicated that more microorganisms tend to harbor lengthy fingernails than brief nails. Visibly smooth nails were only noted by the appearance of students ‘ finger nails, showing 62% bacterial contamination on their hands. Ray noted there was a reduction in the bacterial isolates after washing hands with soap [9, 10].

Tambekar also found the largest bacterial contamination (70%) in the hands of Kindergarten volunteers followed by 67% in the hands of primary volunteers, 66% in the hands of secondary pupils, 64% in the hands of PG volunteers and at least (57%) in the hands of undergraduate volunteers [11].
The microorganisms that isolated and diagnosed from fingernail tested for antibiotic sensitivity, eight antibiotic were used as mentioned in material and methods, (antibiotic resistance pattern were shown in table (2)).

**Diagram (1) Clear zone diameter by (mm) for different strain and antibiotic types**

As it is clear from the diagram above Gatifloxacin was the most effected antibiotic on the bacteria isolated from under nails and the lowest effect was belong to Cefazolin.

Kibret M. Says *E. Coli* isolates show high erythromycin, amoxicillin and tetracycline resistance levels. For experimental treatment of *E. coli*, nitrofurantoin, norflaxacin, gentamicin and ciprofloxacin are regarded suitable *E. coli* in the field of research. It is recommended to monitor regularly antimicrobial susceptibility [12] while the result of this study, *E. coli* show resistant to all antibiotics that had been studied.

The results of *Salmonella* sensitivity test show high level of resistance to cefazolin, nitrofurantion, clindamycin, cefotaxime and trimethoprim/sulphamethoxazole and had mild sensitivity to colistin, gatifloxacin and aztreonam; Mijovic etal noticed that there were increase in the susceptibility rate to many antibiotic between their two surveys [13].

The sensitivity was tested in vitro and on the basis of laboratory results, antibiotics were given to patients. Over the past 21 years, *Klebsiella* has shown a substantial shift in sensitivity pattern. These organisms' sensitivity to different antibiotics tested has decreased over time. The organism carries out most of the in vitro antibiotics it is subjected to. Srinivasan and his coworkers explained their efforts should be focused on reducing the use of antibiotics or a correct antibiotic policy that controls the meaningless and excessive use of antibiotics [14]. their fears about gaining bacteria multi-resistance drugs traits had been observed in this research as the *Klebsiella* isolate was resistant to all eight antibiotics used.

*Pseudomonas* antibiotic susceptibility test appear that *Pseudomonas* strains were resistance to almost all antibiotics and sensitive only to gatifloxacin, as clear from this study *Pseudomonas* resistant to colistin while Sader and his coworkers maintained that *Pseudomonas* show sensitivity >90% to colistin in the time between 2012-2015 [15].

*Streptococcus* isolate that obtained from this study was resistant to Aztreonam, Cefazolin, Clindamycin, colistin, Nitrofurantion and Trimethoprim/Sulphamethoxazole, while it was sensitive to Cefotaxime, Gatifloxacin, The highest resistance *Streptococcus* showed to erythromycin, clindamycin and trimethoprim-sulfamethoxazole and these should be avoided in the treatment [16].

*Staphylococcus* colonies showed resistance to most antibiotic that had been used in the study as listed in table (2), *Staphylococcus* spp. Also show sensitivity to three types of antibiotics (Nitrofurantion, Gatifloxacin and Clindamycin), many researchers reported that *Staphylococcus* which isolated from finger nail have multiple antibiotic resistant [6, 17, 18].

Removal of Tetracycline from Aqueous Solutions using Pomegranate Peels Residues Accessing to ZRL

Rajaa S. Abass1 Suad Turky Ali1, Tamara Sami Naji2

1Assistant Lecturer, 2Ph.D. Dr./Al Mamon University College, 14 Ramadan St, Baghdad, Iraq

Abstract

Antibiotics are harmful pharmaceuticals to ecosystems in general and aquatic systems in particular. Therefore, its remediation from water bodies is a topic of great importance for water treatment and purification workers. This research investigates the removal of one of the most famous types of antibiotics, which was tetracycline from simulated synthetic aqueous solutions by adsorption technique using non-toxic, low cost and available agricultural waste which was pomegranate peels. The adsorption experiments were performed in adsorption laboratory unit of batch mode at different operating conditions and laboratory temperature. The operating parameters studied included pH of solution, dose of adsorbent media, treatment time, agitation speed and initial concentration of tetracycline. The results showed the ability of pomegranate peels to extract tetracycline from aqueous solutions with high efficiency of 81.55%. The results also showed that the percentage of antibiotic adsorption from aqueous solutions was inversely correlated with increasing the initial concentration and acidic function of the tetracycline solution while it was directly proportional to the amount of pomegranate peels, agitation speed and treatment time. In this style, one of the most important types of antibiotics that contaminated water was disposed of by a cheap material and using a simple, economical and environmentally friendly method accessing to the principle of zero residue level (ZRL).

Keywords: Antibiotic, Tetracycline, Adsorption, Pomegranate peels, ZRL

Introduction

Antibiotics are defined as chemical compounds used in the treatment, prevention and diagnosis of diseases, thus preserving the physical and mental health of both humans and animals (1). Today, these products pose a threat to humans and the environment as they are increasingly present in the aquatic environment, even at low concentrations of up to parts per million (ppm) as a result of increased production due to overconsumption without any treatment before disposing (2). It enters wastewater with urine and excrement as well as industrial waste from pharmaceutical plants also; their environmental impact is increasing when there is a mixture of these substances with metabolites (3). Recent studies have confirmed the inclusion of these formulations as contaminants, as they pose a threat to groundwater and surface water, thus causing adverse effects on wildlife and aquatic life (4). These compounds include, for example, Nonsteroidal anti-inflammatory drugs (NSAIDs), antipyretics, antidepressants, diuretics, antibiotics, and anti-ulcers, whose metabolism produces new compounds that are also polluting the environment. Antibiotics come out with urine in low concentrations, and their metabolites come out with either with urine or excrement (5). Conventional methods of wastewater treatment are ineffective in eliminating the contaminated effect of pharmaceutical compounds due to the resistance of some types or metabolic products to biodegradation (6). Apart from traditional treatment methods, adsorption technology has recently received widespread attention as one of the candidate methods for solving the problem of water contaminated by antibiotics for its ease, efficiency and low cost (7). Studies have shown that the use of adsorption technique by activated carbon is very effective in the disposal of many organic pollutants such as dyes, pesticides and aromatic compounds generally (8). However, there are two problems facing this promising technique: the first problem is the high production cost of activated carbon and needed for continuous regeneration process, in addition to the part loss of this material during each regeneration process, while the second problem relates to the difficulty of sediments
disposal from the surface of activated carbon or other adsorbents (9). This led the researchers to seek for other sources to be used as adsorbents or raw materials in the preparation of activated carbon from them and also so that the amount of remaining materials are small (10). In the last years, the concept of zero residue level (ZRL) has been applied to remedy all the problems associated with the use of adsorption technology. This concept uses the non-valuable waste as adsorption media and then utilizes from the residue adsorption process so that the amount of residual waste is close to zero (11). The present paper aims to use the adsorption technique and the application of the principle of ZRL in the treatment of water contaminated with tetracycline, one of the common types of antibiotics through the use of pomegranate peels as a low-cost adsorbent in an economical, beneficial, low-cost and environmentally friendly method.

2. Experimental Work

Materials

2.1.1 Pomegranate peels (sorption media): The mature pomegranate peels used in this investigation were obtained from juice shops and cafes in Baghdad city as well as from domestic usage. After collection, pomegranate peels (in its originally size) were washed with excess tap water for several times before being washed with distilled water at normal temperature to get rid of any kind of impurities and dust that might be stuck to them. The washed peels were dried naturally by exposing them to the open air and sunlight for uninterrupted 48 hours and then placed in a metal bowl, immersed in fresh water and heated until boiled to remove the color and dye (tanner) from them. Finally kept in dark brown glass bottles and placed in the fridge until used.

3.1.2 Stock solutions: Real water contaminated with tetracycline (a studied antibiotic) contains many compounds and other elements that may be difficult to detect exactly or identify accurately in that type of water. Therefore, the adsorption experiments were carried out using simulated synthetic aqueous solutions (SSAS) containing tetracycline in various concentrations in order to evade nip up with any other kind of pollutants. For this purpose, an aqueous solution, called stock solution, of 1000 ppm of tetracycline, was prepared. In a volume of one liter of distilled water, 1 g of tetracycline powder packaged in capsules was dissolved to obtain the stock solution. All different concentrations SSAS of tetracycline antibiotic used in this research were prepared from dilution of the stock solution with distilled water to the desired concentration. Tetracycline concentrations were determined spectrometrically at a wavelength of $\lambda=529$ nm using a spectrophotometer according to the method described by (12). Figure 1 shows the spectrophotometer calibration curve intended for tetracycline concentrations.

![Figure 1 Spectrophotometer calibration curve of tetracycline @ wavelength of $\lambda=529$ nm](image)

3.2 Adsorption unit: In order to identify the behavior of pomegranate peels as an adsorption media and to determine the best operational conditions that achieve the maximum tetracycline removal percentage, a concatenation of functional experiments were conducted in a laboratory adsorption unit of batch mode. In each experiment 100 ml of tetracycline solution was prepared and laboratory experiments were carried out at different operational conditions of initial concentration of tetracycline, pH of SSAS, amount of adsorbent, agitation speed and contact time. Their ranges were from (1-50) ppm and (1-8) (0.25-2.5) g of pomegranate peels, (100-400) rpm and (10-150) min. respectively and at laboratory temperature (28±2) °C. Each experiment was triplicate to increase accuracy and to reduce the experimental error. To calculate the residual tetracycline concentration at the end of the experiment, the aqueous solution was filtered using vacuum filtration to separate any residue of pomegranate peels may be present in the treated solution. A sample of the filtered aqueous solution was drawn, tested by the spectrophotometer and the concentration of the antibiotic removed was detected. The efficiency of tetracycline removal from the SSAS was determined by calculating the percentage of removal that can be found from the following mathematical relationship:
Where: refers to tetracycline percentage removal, and refer to initial and final concentration of tetracycline (ppm) respectively.

Results and Discussions

As illustrated above, the study of adsorption technology as a suggested remediation method for SSAS contaminated with tetracycline antibiotic was conducted in a batch adsorption unit. The removal process was examined at different operating conditions and using pomegranate peels as a cheap and available adsorbent. This section discusses the effect of the operational conditions used on the tetracycline removal efficiency and determination of the optimum conditions for the maximum treatment efficiency of contaminated SSAS.

3.1 Effect of Initial Concentration of Tetracycline:
The results obtained from the experiments of changes the initial concentration to remove tetracycline using pomegranate peels as an adsorption media from SSAS showed that the percentage removal was increased by decreasing the value of the initial concentration and vice versa. The results also showed that the maximum percentage removal was 81.46% at the lowest initial concentration of 1 ppm while the percentage removal at the highest studied concentration which was 50 ppm was 23.19% as explained in Figure 2. Adsorption technology is great dependent on surface area and it is a constant property of adsorption media, representing the available sites on the surface of the adsorbent material at which adsorption process occurs. The number of these active sites is limited in the adsorbent and has a constant adsorption capacity for a specified number of contaminated matter particles. In the case of low concentrations of tetracycline, the pomegranate peels was able to adsorb more molecules than if the antibiotic concentration is higher; i.e., the number of non-adsorbed tetracycline molecules that will remain free in the solution will be lower at low concentrations at constant volume and therefore the efficiency of pomegranate peels as a medium of adsorption to remove tetracycline will be reduced by increasing the initial concentration of the contaminant in aqueous solutions.

\[
%R = \frac{C_i - C_f}{C_i} \times 100
\]

Figure 2 Effect of initial concentration on the percentage removal of tetracycline antibiotic

3.2 Effect of pH: Figure 3 shows the behavior of tetracycline adsorption process by pomegranate peels when the pH of SSAS is changed. It’s obvious from above Figure that the relationship between the percentage removal and the pH of solution is inversely and the maximum percentage removal was obtained at the lowest pH value. The pH has a clear effect on the adsorption process, as it affects the charge and ionization degree of the active sites at the surface of adsorbent media. This may be due to the dependence of tetracycline ionization on the value of the pH. On the other hand, increasing the pH leads to an increase in the concentration of negative hydroxide ions (OH⁻) in the solution, which generates repulsive forces between them and tetracycline molecules and thus competes for the active sites in the adsorbent, which is already limited. Therefore, the high percentage removal means that there are little competition and repulsion forces between tetracycline and hydroxide. In addition, the surface of the pomegranate peels will be ionized with positive hydrogen ions. This makes the adsorption process easier than if the number of hydroxide ions increases. This happens when the acidic function of the solution is raised.

Figure 3 Effect of pH on the percentage removal of tetracycline antibiotic
3.3 Effect of Adsorbent Amount: The experimental results related to the study of the pomegranate peels effect as an adsorbent on the percentage of adsorption showed that the latter is increasing by increasing the amount of adsorbent by keeping the other operational parameters at optimum values. The maximum removal was recorded at the largest amount of adsorbent, which is 2.5 g, as shown in Figure 4. The direct correlation between the percentage of tetracycline removal and the amount of pomegranate peels is due to the fact that pomegranate peels have a specific surface area per unit weight. Increasing the amount of adsorbent will increase the surface area of the adsorption medium, which means more active sites, which in turn will provide a greater chance of adsorption of more molecules of tetracycline if the amount of pomegranate peels is less.

![Figure 4 Effect of adsorbent media amount on the percentage removal of tetracycline antibiotic](image)

3.4 Effect of Agitation Speed: The correlation between the percentage removal of tetracycline and different values of agitation speed is shown by Figure 5. Increasing the agitation speed will increase tetracycline removal from aqueous solution using pomegranate peels as adsorption medium and keep the rest of the operational variables at optimal values. This results may be attributed for Increasing the agitation speed will reduce the thickness of the layer surrounding the adsorbent molecules, removing the surrounding obstacles and increasing the chance that tetracycline will bind to the active sites on the surface of the pomegranate peels, thus increasing the tetracycline removal from the aqueous solutions. This explanation is true up to the speed of 300 rpm, after this value the percentage removal remains constant and does never change whatever increasing the agitation speed. This may be due to the material is saturated with adsorbed molecules at optimum speed and that any increase in speed will not change the removal efficiency.

![Figure 5 Effect of agitation speed on the percentage removal of tetracycline](image)

3.5 Effect of Contact Time: The increase in contact time leads to a corresponding increase in the percentage of tetracycline removal from aqueous solutions as shown in Figure 6, with keeping the rest of the operational variables at optimal values. Increasing the process time will increase the time when tetracycline molecules come into contact with pomegranate peels, which in turn will increase the chance of tetracycline binding to active sites on the surface of the adsorbent and thus increase the rate of antibiotic removal from aqueous solutions. If the time is less, vice versa, the adsorbent molecules do not find the time required to complete the adsorption process of the molecules of the contaminant and thus remain free in the solution, which leads to a decrease in the percentage of adsorption.

![Figure 6 Effect of contact time on the percentage removal of tetracycline](image)

4. Conclusions: From the results of the present study, the following conclusions can be drawn:

- Adsorption technique showed high efficiency in the treatment of aqueous solutions contaminated with antibiotics in general and tetracycline in particular.
- The maximum percentage removal was 81.46% at 1 ppm of the initial concentration of tetracycline, pH of 1, pomegranate peels amounts of 2.5 g, agitation
c. Adsorption of tetracycline from aqueous solutions using pomegranate peels was directly proportional with the amount of adsorbent (pomegranate peels), agitation speed and contact time to a certain level and then constant. While the percentage removal was inversely proportional to the initial concentration of tetracycline and the pH of the aqueous solution.

Complications of Laparoscopic Cholecystectomy in a Sample of Patients Admitted to Al-Ramadi Teaching Hospital, Anbar-Iraq

Tarek Mahdi Salih
Assist prof. F.I.C.M.S., D.G.S., College of Medicine, University of Anbar /Iraq

Abstract

Laparoscopic cholecystectomy is currently thought as a surgical procedure that can be done with less risk of complications. However, intraoperative and postoperative complications were existing in 56 (15.01%) patients. Open surgery is the case when laparoscopic cholecystectomy fails to be proceeded with due to many causes such as difficult Calot triangle dissection and empyema of gallbladder.

The high occurrence of cholecystitis in the group of patients aged 40-60 (56%) with 151 female and 59 males initiating the floor to many arguments that may help give a good understanding for such a problem.

Iatrogenic perforation of gallbladder was the most common cause of intraoperative complications. Wound infection was the most cause of postoperative complications. Difficult Calot triangle dissection was the most common cause to convert to open surgery.

Keywords: Hospital; Laparoscopic cholecystectomy ; Infection.

Introduction

In the treatment of benign gallbladder disease, laparoscopic cholecystectomy became the first choice that may be taken instead of open surgery. On the other hand, surgeons believed that this procedure involved high risk of injury compared to open cholecystectomy. In this context, experienced surgeons are needed to proceed with such new technique of treatment.

It has been estimated that in USA about one million patients annually diagnosed with gallbladder disease in which about 75% of them underwent laparoscopic cholecystectomy.

Complications of this treatment procedure may vary according to the health status of patients, experience of surgeons, the post-operative care, as well as many other things that may affect negatively the success of the procedure. In this study a light will be casted on most of the common complications as recorded from patients underwent laparoscopic cholecystectomy.

In this technique a gallbladder is removed by a keyhole-sized incision usually using two 10mm ports and two 5mm ports in which this procedure believed to result with less postoperative complications.

This study aims to evaluate the intraoperative, postoperative complications and rate of conversion treatment in patients with cholecystitis.

Patients and Method

During the period Jan. 2012 to the end of Dec. 2013, 373 patients (102 male and 271 female) with history of cholecystitis admitted to AL-Ramadi General Teaching Hospital, Anbar province, Iraq, were considered in this study.

Data collected from each patient included age, gender, clinical signs and symptoms as well as relevant examinations. Medical investigations such as WBC counts, ultrasound findings, postoperative histopathological findings of gallbladder were recorded.

The collected data were classified in tables according to the purpose of presentation and descriptive and inferential statistics were made whenever needed in this paper.
Results

Table 1 shows the distribution of patients according to age groups with reference to their gender groups. Age ranged between 18-70 years with mean age of 49.28 years. Most of the patients were female and accounted for 72.65%. Patients aged 40-60 constitute the highest percentage among all other.

Out of the total patients involved in this study, 56 (15.01%) showed different complications. Table 2 shows the distribution of those patients according to gender and age groups. Males were accounted for relatively higher percentage 55.4% compared to 44.6% of females. About 88% of those patients were in the ages of 40 years or more.

Recorded complications are classified into two main categories, intraoperative and postoperative as presented in table 3. Out of the total patients of this study, 22 (5.9%) revealed intraoperative complications whereas 34 (9.12%) showed postoperative complications. Out of the intraoperative complications, 7 cases (22.58%) found to have vascular injuries. Iatrogenic perforation of GB was accounted for the highest percentage (41.94%) among all other types of intraoperative complications.

With regard to postoperative complications, wound infection was found the most common complication which accounted for 30.43% followed by bleeding from abdominal cavity with 21.74%.

Causes of conversion to open surgery are not identical, rather they vary from patient to another. In this study, only 20 (5.36%) patients were transferred to open surgery under different reasons as presented in table 4. The most common cause was difficult calot triangle dissection which accounted for 35% followed empyema of gall bladder with 25%.

It may be worthwhile referring the cases that presented with different complications to the medical procedure on which the decision of laparoscopic cholecystectomy was decided. In this context, table 5 showed the cases according to the type of complication.

With regard to WBC counts, cases with more than 10000/mm³ were more than others for all categories of complications. Acute cholecystitis was accounted for greater number of patients at all categories of complications for both ultrasound and histopathological findings.

Discussion

Since its first introduction in 1985, laparoscopic cholecystectomy is rapidly becoming very common technique. This technique enables surgeons to avoid complications of open surgery as well as the high cost of staying at hospitals waiting for recovery.

Most of the patients considered in this study were in the range of 18-70 years with mean age of 49.28 years. This mean age is less than that obtained by Chay CH, et al., 2006 (56.9 years) which also showed a wider age range (23-89 years)³. However, mean age of patients considered in this study is found to be less than that obtained by Al-Salamah SM, 2005⁶. Such a discrepancy can be either attributed to the sampling technique used to select the right patient, or to a certain situation that maybe the sample’ population concerned about. In Iraqi communities, people after 20 years of age become responsible about their families affairs and that they have to do more efforts in order to put their families in a good economic stands. As a result, they become gradually confronted with different health problems due to the food which is not healthy prepared or even do not suit their real needs.

Vascular injury is one of the intraoperative complications, the percentage of this type of complication in this study was found to be 1.88 which is much lower than that (9.97) obtained by Rooh-ul-Muqim, et al,2008⁹.

Iatrogenic perforation of gallbladder was found to have the highest percentage (3.49) among all other causes on intraoperative complications. This percentage is doubtless significantly lower (25.5) than that obtained by Zubair M, et al, 2010¹⁰. Iatrogenic perforation of gallbladder may be associated with the adhesion in right upper quadrant of gallbladder, or with other variables such as gender which is not the aim of this study.

Spillage of gall stones was found in 1.88% of patients in this study. This percentage was also much lower than that obtained by Zubair M, et al, 2010 which was 11.5. However, the percentage 1.88 was almost similar to that (2.02) obtained by Miodrag Radunovic, et al, 2016¹¹.

It is believed that the association of iatrogenic perforation of gallbladder and spillage of gall stones may
lead to abdominal infections which in turn can result in a number of abdominal problems.

With regard to the postoperative complications, the most type was found to be wound infection which was found in 14 (3.75%) patients of this study. Such problem may be caused by poor hygiene or to polluted environment where the patient(s) moved to after surgery. The second cause of postoperative complication was bleeding from abdominal cavity which occur in 10 (2.68%) patients in this study. The third type of postoperative complications in this study was the bile leak which found in 7 (1.88%) patients which is less occur when compared to 3.98% of patients in the study conducted by Rooh-ul-Muqim, et al.,2008.

Other types of postoperative types as found by this study seems very rare and the deep vein thrombosis do not appear to be mentioned in literature reviewed during the research.

Causes of conversion to open surgery are also vary according to the patient situation as well as potential complications during key-hole-surgery. However, in this study the main causes were difficult calot triangle dissection which was seen in 1.88% of the patients and empyema of gallbladder which seen in 1.34% of the patients. In general, 5.36% of the patients of this study were converted to open surgery and when compared to 3.13% that found by Rooh-ul-Muqim, et al.,2008, one may easily conclude that patients of this study were actually confronted by many problems that make their health stands in a serious situation.

Number of patients with intraoperative and postoperative complications as well as of those converted to open surgery, were cross-classified with respect to medical signs and findings. Patients with WBC counts more than 10000/mm³ are remarkable more than those with WBC counts lower than 10000/mm³. Acute cholecystitis was also found in a number of cases that essentially exceeds those with chronic cholecystitis. This is true for both ultrasound and histopathological findings.

**Conclusion**

Laparoscopic cholecystectomy is indeed well prevailed in surgical practice. It is not always the only good procedure to follow but a procedure with less pain and potential complications. Nevertheless, over the wide use of this procedure, different types of complications were recorded. Actually, complications may appear due to variety of factors including the health status of the patients.

In this study most of the admitted cases to undergo laparoscopic cholecystectomy were over 29 years of age and 68% of them were above 40 years old with male to female ration of 0.38:1.

Complications found in 56 of the patients, of them 31 males and 25 females.

Iatrogenic perforation of gallbladder, spillage of gall stones and vascular injury were the most common causes of intraoperative complications. On the other hand, wound infection, bleeding from abdominal cavity, bile leak, pneumonia and loss of gall stones in abdominal cavity were the most common causes of postoperative complications.

Difficult calot triangle dissection and empyema of gallbladder were the most common causes of conversion to open surgery.

Most of those converted to open surgery have WBC counts more than 10000/mm³ and acute cholecystitis in both ultrasound and histopathological findings.

Physiological Study Comprising the Sequelae of Magnetic Radiation on Human

Wissam Sajid Hashim¹, Azal Hamoody Jumaa², Noor Thamer Alsaadi ¹, Ayad Gaber Arean¹
¹College of Medicine, – Al Muthanna University / Iraq, ²Al-Yarmouk University College/Ministry of Higher Education and Scientific Research / Iraq

Abstract

The sequelae of magnetic radiation of the towers of cellular phones were evaluated in this study depending upon a random social volunteer human male samples of ages 25 – 50 years and they were dwelling in houses close to the towers of cellular phones of distances not more than 150 miters far. The samples of these people were labelled as “Subjected”. Seventy five samples of blood were gained on a base of ages as twenty five from ages 25 – 30, twenty five from ages 35 – 40, and twenty five from ages 45 – 50 in addition to seventy five samples of people who did not dwell close to the towers and of the same previous pattern of ages and their samples were labelled as “Non subjected”. The results have demonstrated a significant elevation in transaminases (AST, ALT), blood calcium (Ca++), blood potassium (K+), total serum cholesterol (TSC), triacylglycerols (TAGs), very low density lipoprotein (VLDL), and low density lipoprotein (LDL).

Keywords: Magnetic waves, Radiation, Lipids.

Introduction

In our recent life there is an increasing need for the use of cellular phones without the ability to get rid of them taking into our mind that these phones operate on base of radiofrequency emitting and receiving ranging from 400 to 2000 megahertz (1). We know that the radiofrequency usage is not limited to the phones but it is also comprised in the medical appliances and therapy use (2). The stress effects on different body systems is well known and the same like occur when the body is subjected to radiofrequency due to impact energy absorption which could afflict the cellular membranes structures and cause sever damages to various cellular and subcellular structures and body organs like the effects on glands such as pituitary, adrenal, hypothalamus and others and you know this will afflict the functions of the body as a whole (3). Lipid profile, liver antioxidant enzymes, hepatic enzymes, renal functions, neuronal milieu, and others all are subjected to the risk of radiofrequency (4, 5, 6).

Materials and Method

Specimens’ collection

The specimens of blood were gained randomly from social volunteer human males of ages 25 – 50 years who were dwelling in Baghdad governrate close to the towers of cellular phones of distances not more than 150 miters far. The samples of these people were labelled as “Subjected”. Seventy five samples of blood were gained on a base of ages as twenty five from ages 25 – 30, twenty five from ages 35 – 40, and twenty five from ages 45 – 50 in addition to seventy five samples of people who did not dwell close to the towers and of the same previous pattern of ages and their samples were labelled as “Non subjected”. Once blood samples were collected as 5 ml/ people by the use of disposable syringes, they were poured into gel tubes to get blood serum to accomplish the necessary study parameters.

Study parameters

Special kits and a UV spectrophotometer (Apel – PD 303 UV, Japan) were used to perform all the study parameters.

► Total Serum Cholesterol, TCH (mg/dl)
Total serum cholesterol (TSCH) was estimated by using a special kit (Spinreact/CHOD – POD, SPAIN) according to the method of (7).

► Low density lipoprotein, LDL (mg/dl)

Serum LDL was obtained according to the formula: LDL-C = TC – HDL-C – TAG/5 (8).

► High density lipoprotein, HDL (mg/dl)

This was measured by using a chemical kit (HDL-Cholesterol (PTA) / Biolabo SA, France) according to (9).

► Serum very low density lipoprotein-cholesterol, VLDL (mg/dl).

Serum very low density lipoprotein was calculated by method of (8). VLDL = TAG / 5VLDL (mg/dl).

► Triacylglycerols (TAGs)

Triglycerides (TGs) are estimated by using a chemical kit (Triglycerides (GPO) / BIOLABO SA, France), depending upon the method of (10, 11).

► Blood Calcium level (mg/dl)

Blood Calcium level was estimated by the use of a special kit (Biomaghreb) according to method of (12).

► Blood Potassium level (mEq / l)

Blood Potassium level was estimated by the use of a special kit (Cypress Diagnostics) based on the method mentioned by (10, 13).

► Serum transaminases activity determination (Unit/ml)

ALT and AST enzymes were determined by the use of a special kit (Biomerrioux, Lyon-France) according to method of (14).

► Statistical analysis

Anova tests was depended to find the least significant differences (LSD) among groups by the use of SPSS version 21 program. Numbers in tables represent the mean ± standard deviation.

Results and Discussion

It is obvious when looking at the results (tables, 1 and 2) that all the human ages groups when continuously subjected to the radiofrequency of cellular phone towers have shown a clear significant elevations in serum AST, ALT, TSCH, LDL, VLDL, K+, and Ca++ besides a significant declination in serum HDL comparing them with the values of people who were not continuously subjected to the radiofrequency of towers at (P ≤ 0.05).

Dyslipidemia might be caused by obesity or due to consuming medications (15) and it was found that any disturbance in lipid metabolism could result in vascular pathological diseases (16). Exposure to magnetic waves could result in different stages of peroxidation of lipids and formation of reactive radicals like oxygen reactive radicals and nitrogen ones and both of them besides the peroxidation could affect the different cellular compartments and affect also the lipid metabolism and carrying vehicles (17, 23). The hepatic enzymes AST and ALT are considered as markers of stress and destruction of different body tissues since they are formed also by another boy regions or tissues like muscles, kidney, and heart (18, 19). It was found that the exposure to radiofrequencies could result in elevations in cortisol which is a predisposing of stress besides their effects on redox cycles and peroxides production and hence the radiofrequencies cause the elevations of AST and ALT (22). The elevations of blood calcium and potassium could result also by the frequency exposure as that these ions of great equilibrium in intracellular and extracellular compartments and they are carrying positive charges making the attracted to the negatively charged cellular membranes hence the disturbances caused by radiofrequency to the cell membranes and the destruction of them making the affinity towards these ions to be declined and much more ions could escape to extracellular compartments making them elevated in serum (20, 21).

Abstract

Peripheral vascular diseases are group of disorders characterized by stenozing peripheral circulation as a complication of primary disease like diabetes mellitus. Peripheral vascular diseases affect 202 million around the world. Peripheral vascular complications of diabetes mellitus are common which affect 30 million over the world and may give rise to infectious necrotizing sequelae called diabetic foot. In a trial of assessment for transdermally applied vasodilator drugs, 30 individual had participated in a case controlled study. Test group (N =11) and control group (N =19) were assessed for the signs of vasodilatation over the dorsum of the hand and figure blood perfusion detection. There was significant increase in perfusion index (from 7 to 11) induced by the test vasodilator as compared with control (from 7 to 8) P <0.05 and parallel results were obtained in induction of redness (redness ratio of 7 with C.I. over 0.95 and thermal increase in degrees of (C) over the dorsum of the hand in comparison with the control group. From the overall results the combined vasodilatatory transdermal formula caused a significant peripheral vasodilatation which could be a candidate therapeutic effect in diabetic foot.

Key words: PVD; combined transdermal formula; peripheral blood perfusion; thermal effect; nitrate; RGB.

Introduction

Peripheral vascular disease (PVD) is the abnormality of vessels located outside of the heart and brain, mainly leg vessels characterized by complete or partial blockage and impairment of perfusion. PVD could affect both arteries (peripheral arterial disease PAD) and veins. PVD is one of the significant health challenges that affects up to 20% after the age of 60 year (1,2) and 202 million patients around the world (3,4).

Different etiologic and pathogenic factors might share common impacts on peripheral circulation. Of the most critical form of PVD presentation is the angiopathic complications of diabetes mellitus (5-7).

However, Burger disease and Raynaud phenomenon are also characterized by impaired peripheral circulation (8,9). Impaired peripheral circulation in uncontrolled diabetes is characterized by different pathological processes including occlusive ischemia (10-12), impaired immune response and peripheral neuropathy (13,14). Impairment of circulation and immune system in addition to hyperglycemia and neuropathy can severely deteriorate any skin lesion in the foot. That lesion may be refractory to treatment due to lacking of pharmacokinetic opportunity of drugs treatment to diffuse to extreme tissues of the lower limbs. This pathogenic fact make foot prone for untreatable infections that even cause ascending cellulitis, tissue gangrene and septicemia which is frequently necessates amputation of the foot or lower limb (15).

A potent systemic vasodilatatory approach like nefidipine, nicorandil can cause intolerable adverse effects like palpitation, throbbing headache and edema due to the need for extensive vasodilatation (16-18). Transdermal route of application gives opportunity for rational option of applying combined efficacious
vasodilators just proximal to the site of lesion that bypassing systemic impacts (19-21).

Different methods are used to assess peripheral circulation. These include: Doppler ultrasound, angiographic techniques in addition to the clinical assessment of peripheral pulsation. However, other methods like infrared detection of blood flow. Quantitative assessment of peripheral perfusion is detected by the perfusion index PI which ranges between 0.02% to 20% according to site whereas blood flow is 5000 ml/min (22,23). Tissue blood flow rate varies also according to type of tissue. Thermographic camera images are also reliable noninvasive methods for long term follow up of circulatory perfusion (24-26).

In the present work, the effect of transdermally applied combination of panthenol, mineral oil base, amlodipine, pH buffer, isosorbide dinitrate, stabilizer and betahistine with peripheral perfusion rate and thermographic analysis were assessed.

Sample, Materials and Method

A 40 individuals (20f/20m) aged 20-24 years (body weight 50-65 kg) have participated in clinical assessment of the effects for the designed formula.

Groups of the study:
1- Test group (N = 15: 8 f/ 7 m).
2- Control group (N = 25: 12 f/ 13 m).

All persons had no chronic medical illnesses.

Study design

The study was arranged in a pilot clinical trial design to determine the effects of test formula so that one group had transdermally applied vasodilators and the other had only the blank application.

Medical and Research ethics requisites

These considerations were fulfilling Geneva requisites guide for medical ethics. All of the participants were informed about the study design and the expected topical adverse effects of the agents used.

Free autonomy, drugs safety, rights reservation, individual consents and drugs benefits were considered and insured.

Materials used

All the materials used were processed, filtered, and confirmed with Fourier UV/V range 200-700 nm based on British Pharmacopia 2007 drugs standard spectrophotometry.

Drug dosages were weighed for base of transdermal formula design.

- Amlodipine ( Bristo, UK, production vs expiry:PD-ED: 2013-2016)
  7000 mg package. Used in 3% within transdermal design.

  100 mg package. Used in 0.05%.

  Used in dosage of 0.3%.

  Used in 0.02%.

- Hydrocarbone base vehicle.

Mineral laurate, stearate and solid excipients were prepared for 20 ml per dosage form.

Treatment Mode

Objective vasodilatation parameters were measured prior to application of both blank and test formula as a
Methods of assessment of vasodilatation

Peripheral blood perfusion was measured with Beijing Safe Heart Technology. Transducer was connected to PERFUSION-Kufa program of analysis developed by Dr. Hussein Abdulkadhim on Mathwork 2013a blockset for estimating model formula of perfusion in response to the transdermal test treatment.

Perfusion index PI is readily detected and calculated by the computer from which another measurement could be estimated which is the perfusion range is determined with in unit of time to calculate the rate of perfusion in ml/min and compared for the control and observational control group. The fixed level of the hand and index figure was carefully considered because it is important confounder.

Another assessment method for vasodilatatory activity of the test formula includes thermographic correlative analysis detected by combined spot tissue thermal camera.

Since temperature correlates proportionally with rate of peripheral blood perfusion, a rise in temperature of the dorsum of the hand correlates with a parallel rise in the rate of perfusion (parameters detailed in guidelines manual).

Image processing program was used to analyze RGB shift as an indicator of redness associated with vasodilatation by the test combination.

Lab techniques quality confirmation:

Accuracy of Safe Heart Technology was X +/- 0.2 PI. Efficiency of the thermographic camera was insured by software processing and calibration.

UV/V (Cecil, UK, Programmed wavelength, accuracy: X +/- 0.5%). Sensitive Balance (mini digital, China, accuracy: X +/- 0.01 mg). PHELECT, USA computerized pH measuring electrode is used to assess adjustment of formula pH around 7.5.

The Sample Size, Statistical Processing and Analysis

The sample size for this study was calculated based on the Cochran formula n= z^2 * p*q/e^2 where (e) is the margin error, p and q are the complimentary proportions and z is the score at confidence level 95% equals to 1.96. Although the margin error will be wide, however it’s preferred to reduce the sample size as much as it’s statistically possible in a pilot clinical trial in order to fulfill FDA approval guidelines where a sample size of 10 individuals is considered while conducting a phase zero trial.

Mathwork 2013a model interpolation was used to verify the perfusion curve. Perfusion index PI modification ratio was estimated with C.I. of 0.24 and a confidence level of 95%. Sample size was determined based on Cochran formula. Paired t test with Minitab 2014 at P <0.05.

Results

Calculation of the rate of perfusion.

![Figure 2](image-url): Matlab analysis of peripheral perfusion rate by model analysis and rate determination. The amplitude axis was calibrated to obtain perfusion rate in mL/min.
Figure (3): The mean perfusion index PI (normalized % +/- SD) taken from hand index finger for persons taking the test transdermal formula (raised from 7 +/- 2 to 11 +/- 2) as compared with the control (7 +/- 2 to 8 +/- 2 PI).

Figure (4): The objectively analyzed RGB to determine level of redness induced on the dorsum of the hand by the combined vasodilator formula after 10 minutes from topically being applied as a quantitative indicator of vasodilatatory effect.

Figure (5): The effect of the test formula on the RGB right shift of red intensity in comparison with the control. Red intensity shift was from 234 to 256 as compared to control which caused just a shift from 240 to 243.
Discussion

The sample of this study represented healthy nondiabetic population. It was taken as a model to assess the vasodilatation at the upper extremities where temperature, RGB and peripheral perfusion were measured from.

That sample was beneficial to estimate the vasodilatatory prior to recommendation in diabetic patients’ sample since this was in agreement with FDA phases of drug evaluation.

Transdermal approach is a promising way of treatment since many advanced techniques had made this route more reliable and superior to conventional systemic administration of drugs. Of these advances techniques are the nanoparticulate reservoir of active drug, sonophoresis, electrophoresis, microarray needle and matrix patches (27).

Transdermal application of drugs has many advantages like convenience, safety and it is easily controlled.

The results showed that a significant increase in perfusion index (PI) was obtained with the test formula (from 7 to 11%) in comparison with the blank base (from 7 to 8%) with ratio of increase 1.3 in PI. In one study, amlodipine showed a significant induction of increased forearm blood flow. Results of some studies concerned assessment of vasodilatory effect of transdermal amlodipine monotherapy have agreed with this current study (29). Panthenol in combination with other additives was used as a topical wounds healing enhancer (29). Betahistine effects in some applications agreed with this study (30), however there was no improvement of cold regional pain syndrome by using transdermal isosorbide dinitrate in a small controlled trial (31,32).

Redness parameters have confirmed and went parallel to data of perfusion rate increment. The mean RGB was raised from 234 to 256 in test formula group as compared with a mild raise from 240 to 243 in blank taken group. This indicates a redness ratio of 7 with C.I. at 0.95 (33).

Thermographic results revealed parallel findings with redness image processing outcomes. Hand temperature was raised from 36.0 to 37.8 ºC in vasodilatory test group in comparison with 35.5 to 36.1 ºC in the control. The temperature raising activity was 3 and C.I. at 0.95.

Conclusion

From the overall effects, the combined transdermal formula panthenol, mineral oil base, amlodipine, pH buffer, isosorbide dinitrate, stabilizer and betahistine showed a significant vasodilatory effects on the peripheral circulation. There was a significant increase of thermal effect due to the topical combination of vasodilators in comparison with the control.

Evaluation of Using Titanium Mesh in the Reconstruction of Traumatic Orbital Floor Fracture

Mukhalled Salim Alasady¹, Ihsan Abdullah Kumail¹, Alyaa Turky Alsultany², Ali B. Roomi³

¹Department of Oral and Maxillofacial Surgery, College of Dentistry, Al-Ayen University, Thi-Qar, Iraq, ²Directorate of Education Al-Muthanna, Al-Muthanna, Thi-Qar, Iraq, ³College of Health and Medical Technology, University of Al-Ayen, Thi-Qar, Iraq

Abstract

Background: Among the nonresorbable implants, Titanium mesh is the most common graft used for orbital reconstruction. It is continuously improved to achieve accurate restoration of orbital volume. To evaluate the using of Titanium mesh for the reconstruction of traumatic orbital floor fractures.

Patients and Methods: A total of (32) patients were enrolled in this study where operated under general anesthesia to repair the orbital floor fractures by using titanium mesh, and they were (24) males and (8) females. (16) patients had Enophthalmos,(10) patients had Diplopia,(6) patients had both enophthalmos with diplopia; all patients had ecchymosis, Subconjunctival hemorrhage, Parasthesia of infraorbital nerve.

Results: The results were well represented as the following: (29) patients (90.62%) had no both diplopia & enophthalmos. Postoperative complication had been found in only (3) patients (9.3%), Two patients (6.25%) had diplopia, one patient (3.1%) had Enophthalmos.

Conclusions: Titanium mesh has a long track record of reconstruction of large orbital floor defects and correction of globe malposition.

Keywords: Titanium mesh; orbital reconstruction and fracture

Introduction

Orbital floor fractures have specific clinical attention for many reasons. Failure to recognize and treat them early may result in severe sequelae. However, despite surgical intervention, orbital floor fractures are associated with the risk of persisting sensibility disorders, enophthalmos, and permanent diplopia. (¹) The choice of the ideal material for reconstruction of orbital floor and walls remains highly controversial. Many materials, from different sources, have been described for that task. The ultimate goals are the reconstruction of the bony orbital defect with restoration of anatomy, volume, function, and esthetics. Each type of material has advantages and disadvantages, but the most important characteristic of a material is to allow those surgical objectives to be achieved. (²) Titanium mesh is the most common grafts used for orbital reconstruction because of its biocompatibility, availability, rigid fixation and no donor site needed. (³) There is still controversy existing about the ideal material for orbital reconstruction; autogenous and synthetic materials have been used for many years, and both of them have merits and demerits. The common sources of autogenous graft are the calvarium (⁴), rib, iliac crest, and auricular or nasal septal cartilage. Sakakibara et al. (⁵) used the iliac cancellous bone of only 1 mm thickness for the reconstruction of the orbital floor. Numerous synthetic materials have been developed with the advantages of availability, no donor site morbidity, and decreased operation time. The choice of material for reconstruction is largely determined by the experience of the surgeon and implant cost. Among the nonresorbable implants, titanium mesh and Medpor (⁶) are the most common grafts used for orbital reconstruction. Both materials are being
continuously improved to achieve accurate restoration of orbital volume. During the past several decades, the standard of care for orbital reconstruction after trauma has been autogenous bone grafts, complications of bone grafts, including donor site morbidities such as scar alopecia and graft resorption with delayed enophthalmos, have inspired an interest in the use of alloplastic substitutes such as titanium, titanium’s role in orbital reconstruction was limited originally to small orbital defects, and as an adjunct to bone grafts, more recently, clinical studies have documented the sole use of titanium mesh to reconstruct large orbital defects. (7) Orbits reconstructed with titanium mesh show better results than those reconstructed with bone grafts. (8-10)

Titanium is a chemical element with symbol Ti and atomic number 22. It is a lustrous transition metal with a silver colour, low density, and high strength. (11) Titanium can be alloyed with iron, aluminium, vanadium, and molybdenum, among other elements, to produce strong, lightweight alloys. (11) The two most useful properties of the metal are corrosion resistance and the highest strength-to-density ratio of any metallic element. (12) In its unalloyed condition, titanium is as strong as some steels, but less dense. (12) Titanium is used in steel as an alloying element (ferro-titanium) to reduce grain size and as a deoxidizer, and in stainless steel to reduce carbon content. (11) Titanium is often alloyed with aluminium (to refine grain size), vanadium, copper (to harden), iron, manganese, molybdenum, and other metals. (13)

Medical applications: Because it is biocompatible (it is non-toxic and is not rejected by the body), titanium has many medical uses, including surgical implements and implants, such as hip balls and sockets (joint replacement) that can stay in place for up to 20 years. (13) The titanium is often alloyed with about 4% aluminium or 6% Al and 4% vanadium. (14) Because titanium is non-ferromagnetic, patients with titanium implants can be safely examined with magnetic resonance imaging (convenient for long-term implants). The features of 3D Titanium mesh are: malleable, 0.3mm thickness, 1-1.3mm screws, available for right and left sides. (15) Advantages of titanium mesh plates: (15)

1. availability, biocompatibility
2. ease of intraoperative contouring
3. rigid fixation
4. Radiopacity
5. No donor site needed
6. Tissue incorporation may occur

Disadvantages:
1. Irregular edges of the mesh may catch prolapsed orbital fat. (16)
2. Difficulties with ease of insertion
3. Difficult to remove if required

Complications of titanium mesh:
1. While a nonresorbable material, titanium cannot be replaced by new soft tissue or bone tissue and remains in situ indefinitely. This may cause possible late side effects, including toxicity due to metal ion release. (17)
2. The fibrous reaction between the implant and the orbital contents caused the eye movement restriction and the lid retraction. (18)
3. To avoid adherence syndrome, titanium mesh plates should be placed 2 mm away from the orbital rim. (18)

**Patients and Methods**

A total of (32) patients were enrolled in this prospective study was conducted from 2014 to 2016. There were (24) males and (8) females. Patients’ age ranged between (10-50) years. The mean age was 30 years. Inclusion criteria: Patients were included in this study according to the following criteria: Patients with orbital floor fractures regardless of their age or gender and type of missile injury (Blast or Bullet), Orbital floor defect (small to very large defects) confirmed by C.T. scanning, Patients with Enophthalmos and Patients with Diplopia due to mechanical obstruction. Exclusion criteria: Patients with the following criteria were excluded from the study: Serious general disease and unfit for surgery, Refused to participate, All orbital fractures regardless of the fracture site and Patient with diplopia due to neural causes.

**Measuring of Enophthalmos:**

The mean preoperative enophthalmos was about (4) mm measured by a ruler from the lateral orbital rim of the injured eye to the most anterior projection of the
globe in comparison to the intact contra-lateral eye.

Results

Sex and age of the patients:

There were (24) males (75%) and (8) females (25%) with a male to female ratio of (3:1), (Figure 1 and 2). The age distribution of the patients revealed a mean age of (30 ± 2.1) years furthermore, {2} patients (6.25%) aged (10-19) years, {10} patients (31.25%) aged (20-29) years, {8} patients (25%) aged (30-36) years, {7} patients (21.875%) aged (37-45) years, {5} patients (15.625%) aged (46-50) years.

Figure 1. Gender distribution of the patients, (N=32, Male to female ratio; 3:1) Figure 2. Age distribution as percentages of the studied group, (N=32)

Postoperative Complications

As shown in table 1, fortunately.

1. (29) patients (90.625%) had no complications,
2. Post-operative complication had been found in only (3) patients (9.375%).
3. Two patients (6.25%) had diplopia, 3. one patient (3.125%) had Enophthalmos and
4. No patient (0%) had extrusion.

Discussion

Age Distribution

In the current study, the highest risk group were the young patient (20-29 years) represented as (31.25%) and this was in agreement with Leibsohn et al., 1976 (19); Greenwald et al. 1979 (20); Crumley et al. 1977 (21); Andersen et al. 1985 (22). In fact that this age group represents the time of maximum activity in human life, especially males.

Sex Distribution:

Twenty four patients (75%) were males, while 8 patients (25%) were females. The predominant male to female ratio (3:1) can be explained by the fact that males spend most of their time outdoors, and due to occupational and recreational preferences. This result is consistent with the findings of the studies by: Thomas 2005 (23), Michael 2000 (24), David 2004 (25), Gordon 2004 (26), Joe 2005 (27), Geoffrey 2005 (28), Petrus 2006 (29).

Reconstruction material:

The orbital wall is one of the most frequently damaged parts of the maxillofacial skeleton after midfacial trauma. Regardless of the fracture site, blow-out fractures can cause various functional and aesthetic sequelae. Preventing these complications from becoming long-term problems is very important, and it depends strongly on the materials used for bridging the orbital wall defects. The prerequisites of an ideal material are good biocompatibility, easy to manipulate and insertion, and it should allow fixation to the host bone by screws, wire, or sutures. It should be cheap, readily available, and strong mechanical strength to support the orbital structure. Titanium mesh has a long track record in the reconstruction of large orbital defects and correction of globe malposition. The advantages of titanium mesh plates are availability, easy intraoperative contouring, and rigid fixation. According to our work, we found it can be adapted to complex structures easily, and it can also be cut to shape as well. The orbits reconstructed with titanium mesh showed better overall reconstructions than those reconstructed with bone grafts, and according to our work, we agree with Ellis E 3rd(1), Tan Y 2003 (8).

Complications

Pre-operatively enophthalmos occur in (16) patients (50%), diplopia occur in (10) patients (31.25%), and (6) patients (18.75%) had both enophthalmos and diplopia. After reconstruction, we have only one patient who has persistent enophthalmos presented with extensive injury to surrounding bony structures with loss of bony architecture. We agree with the finding of { Saikrishna Degala, 2012 (30)}.

Postoperatively, diplopia occurs in two patients, mainly in the upward gaze. This consistent with that reported by Amrith S et al. 2000 (31). Where they reported that diplopia is not uncommon postoperatively, it is typically only disturbing when occurring in the primary or downward gaze. However, titanium plates are permanent foreign bodies. Several late-onset complications related to the titanium mesh plate have been reported, such as infection, extrusion, implant migration, residual diplopia, etc. (32). But we found in our study, the postoperative clinical and radiographical examination verified the anatomical reduction of the orbital floor. There was no displacement or resorption of the orbital floor or loosening or extrusion of the screws or mesh (6-9) months after the operation, and no modifications in the visual acuity compared with autologous materials have several disadvantages, including high risk of nerve and blood vessel injury, donor site morbidity, cosmetic disturbance, minimal controllability and an unpredictable degree of absorption (33,34).

Conclusions

1. Missile trauma was the most frequent cause of orbital injury followed by road traffic accidents, sports injury, and falls from height.

2. Titanium mesh has less complication postoperatively, such as infection and migration of mesh.

3. This study highlights the ability of the
alloplastic mesh to satisfactorily correct post-traumatic orbital sequelae, including enopthalmos and diplopia.

4. Titanium mesh can be considered to be the excellent orbital floor repair material.

5. No extrusion of Titanium mesh or rejection by the host was seen in the studied group.

Association of Epstein- Barr Virus (EBV) with the Development of Nasopharyngeal Carcinoma (NPC) in Western Region of Iraq: Unmatched Molecular Case-Control Study

Mothana Ali Khalil1, Arkan Obaid Jasim Al-Essawi2, Mohammed Tafash Dagash3
1Assistant Professor /Department of Microbiology/Virology, College of Medicine, University of Anbar, Iraq, 2Assistant Professor /Department of Pathology, College of Medicine, University of Anbar, Iraq, 3Assistant Professor /Department of Surgery /Thoracic Surgery, College of Medicine, University of Anbar, Iraq

Abstract

Background: Nasopharyngeal Carcinoma (NPC) is uncommon in Iraq, but its incidence is raising due to increased exposure to diverse risk factors. Many of the NPC-related risk factors are becoming more and more apparent in Iraq. The exactly risk factors for nasopharyngeal carcinoma (NPC) in Anbar province, Iraq are not known.

Objectives: To determine the association between Epstein- Barr virus (EBV) infections and other risk factors with the development NPC of Iraqi patients.

Patients and Method: Sixty-seven paraffin-embedded tissues of NPC cases, 134 normal noncancerous nasopharyngeal biopsy samples, and tonsillectomy specimens from patients with chronic hypertrophic tonsillitis as controls were enrolled in the study that was conducted between 12 January 2012 and 21 January 2019. DNA of EBV was extracted from both controls and neoplastic tissues and analyzed by PCR technique using primers specific to EBV Latent Membrane Protein-1 Oncogene (LAMP-1) for the presence of EBV. A Questioners data form for all patients and controls were filled by the researchers regarding other risk factors of NPC including the patient’s age, sex, residence, radiation exposure, history of chronic rhinitis, family history of NPC, tobacco smoking, alcohol consumption, herbal medicines, tea consumption, exposure to formaldehyde and exposure to different inhalants.

Results: The following risk factors were found to be independently associated with illness: EBV (adjusted odds ratio [OR] 7.852, 95% confidence interval [CI] 2.22–27.72), herbal medicine (OR 19.051, CI 7.56–47.95) and Family history of NPC (OR 63.717, CI 6.67–607.96).

Conclusion: Combination of family history of NPC , EBV exposure and herbal medicine was a strong risk factor for NPC.

Keywords: Epstein - Barr virus, Nasopharyngeal Carcinoma, PCR, EBV-LMP-1, other risk factor, case-control study

Introduction

Nasopharyngeal carcinoma (NPC) is a human malignancy derived from the epithelium of the retro-nasal cavity and it is one of the most frequent head and neck cancers with elevated prevalence rates in Asia and western North Africa (1, 2) with, approximately 86691 incident cases of NPC and 50 831 NPC-related deaths in 2012 worldwide (3, 4).

Previous studies demonstrated Epstein –Barr virus (EBV) infection, genetic susceptibility, diet, chromosomal disorders, aberrant promoter hyper methylation and other genetic related factors and other environmental exposures (1, 5, 6), Cigarette smoking, alcohol consumption and Consumption of salted (1, 7, 8), Family history of NPC (1, 9). The present study to know the roles of EBV with
other Risk factor in development of NPC.

Materials and Method

Study design

Case-control sets were included for analysis, provided that two control was matched for each case by age, sex and general geographical location of the case’s residence. A standard questionnaire for all patients and controls were filled by the researchers regarding other risk factor of NPC. Including the patient’s age, sex, residence, Radiation exposure, history of chronic Rhinitis, family history of NPC, tobacco smoking with alcohol consumption, herbal medicines, Tea consumption, Exposed to formaldehyde and, exposure to different inhalants. This study was conducted in the Anbar province and its neighbor area and biopsies were collected over a 7 years period between 3 January 2012 and 1 January 2019. The protocol was approved by the Microbiology Department, Anbar medical College. All patients provided informed consent for participation in the study and for biopsy samples taken from the tumors and tonsillectomy specimens.

Molecular study of EBV

Patients and Methods:

Sixty-seven paraffin-embedded tissues of NPC cases and 134 normal noncancerous nasopharyngeal biopsy samples and tonsillectomy specimens from patients with chronic hypertrophic tonsillitis as controls were enrolled in the study that was conducted between 3 January 2012 and 1 January 2019 to investigate the presence of LMP-1 gene. Paraffin-embedded tissues of NPC cases were selected from the archives of private pathology laboratories in Anbar province and cases were classified according to the WHO classification (10). Archived slides were reviewed by two pathologists for confirmation of diagnosis and tissue adequacy for extracting of DNA. Controls were matched on gender, residence and year of birth. The molecular analyses were carried out at private laboratories in Baghdad city.

Tissue Processing, PCR Amplification and Gel Electrophoresis

The tissue samples were purified from archival paraffin embedded tissue blocks as described previously (11). DNA of EBV was extracted from both cases and controls using the same procedure described previously (12) and PCR amplification for detection of EBV-LMP1 gene were processed through using oligonucleotide (sense BN1, antisense BN2) as follow (sense BN1: 58-AGC GAC TCT GCT GGA AAT GAT-38 or antisense BN2: 58-TGA TTA GCT AAG GCA TTC GCA CCT CCA-38) as described previously (13). The products were then examined on 1.5% agarose gel electrophoresis in 1× Tris-boric acid–EDTA (TBE) solution and stained with ethidium bromide to verify the presence of 316 bp PCR product.

Statistical Analysis

A matched design and a case-control ratio of 1:2 was selected as the most appropriate strategy in order to maximize the study power. To detect an association with a matched odds ratio of 2.0 at the 5% significance level with 80% power (assuming 20% exposure level among controls), a sample size of 67 cases and 134 controls was required (14).

Epi Info Version 7.02 (15) and SPSS version 24 were used to calculate crude matched odds ratios (OR) with 95% confidence intervals (CI) and two-tailed P-values to estimate the association between various potential risk factors and NPC. Following the univariate analysis, SPSS were used to calculate adjusted odds ratios by conditional binary logistic regression of risk factors with a P-value < or = 0.25.

Results

During the study period, 67 NPC cases were collected and 134 normal lymphatic tissues registered as possible controls. From the total number of controls registered, 134 were included in the study, 67 cases matched to 2 controls. The demographic characteristics of the cases and controls are shown in Table 1. More males than females were enrolled in the study, with the majority of subject’s in age group 19 – 38 (40.3%) and 58 years old and over (49.3%). Regarding residence, rural patients more than urban.

Detection of EBV LAMP1

EBV were Detected in NPC cases and healthy cases on Agarose gel electrophoresis stained with Rad safe as shown on Fig.1.

![Fig. 1: Detection of EBV in NPC cases and healthy cases on agarose gel electrophoresis stained with Rad safe. Lane M shows a molecular size marker. Lanes 1-15 shows the positive bands of EBV-wt-LMP1 with product size 316 bp.](image-url)
Univariate analysis of risk factors

Potential risk factors for NPC (i.e. those with a matched odds ratio > 1) are shown in Table 2. Infection with EBV (OR 10.631, CI 3.654-30.930), Herbal Medicine (OR 20.7955, CI 9.531-45.457), history of chronic Rhinitis (OR 3.792, CI 1.069-13.447), Family history of NPC (OR 74.233, CI 9.752-565.051) and Exposed to formaldehyde (OR 2.375, CI 1.303-4.330), were highly and moderate risky and significantly associated with NPC.

Cigarette Smoking (OR 1.309, CI 0.727-2.356) with a low risk of illness, but this was not statistically significant.

In regard to Alcohol drinking (OR 0.715, CI 0.381-1.342), High Background Radiation Areas (OR 0.662, CI 0.068-6.484), Tea consumption (OR 0.557, CI 0.307-1.010) and Dust and/or exhaust exposure/domestic fumes intake (OR 1.031, CI 0.569-1.870) were non significantly associated with NPC.

Insufficient data were obtained on Cannabis intake, Salted fish consumption and history of chronic respiratory tract conditions that may be assumed or potential risk factor for NPC, and as such, no conclusions could be made about these exposures.

Table 2: Univariate analysis of selected risk factors for NPC (matched OR > 1)

Multivariate analysis of risk factors

Of the ten risk factors included in the conditional binary logistic regression model, a significant independent association with illness was found for the following three risk factors: exposure to EBV (adjusted OR 7.852), Herbal Medicine using (adjusted OR 19.051), and Family History NPC (adjusted OR 63.717) (Table 3).

Discussion

The results obtained from our study suggest a strong effect of exposure to EBV, herbal medicine using and family history of NPC on NPC risk. Exposure to formaldehyde and the history of chronic rhinitis were also related to NPC risk, whereas the exposure to high background radiation, cigarette smoking, alcohol drinking, tea consumption and dust and/or exhaust exposure/domestic fumes intake in Anbar province were not related to NPC risk even after adjusting for major risk factors of NPC. Epidemiological study have combined three suspected risk factors (EBV, herbal medicine using and Family History NPC) into a simultaneous analysis factors and study their possible synergetic effects, and reports of relatives with NPC using conditional multivariate logistic regression.

Therefore, it is strongly suspected that NPC risk is affected by cofactor(s) in addition to EBV infection like herbal medicine using and family history NPC were strong risk factors of NPC. This finding is consistent with that of Sriamporn et al.(1992) (16) who showed elevated VCA/IgA and neutralizing antibodies against EBV DNAse with a 20-fold increase in NPC risk for subjects seropositive for VCA/IgA antibodies, and a 30-fold increase for those seropositive for both biomarkers.

Our study agreed with two studies from Taiwan that showed high prevalence of the LMP1 DNA (94.7–100%) in swab samples from NPC patients but not from control groups and other study that demonstrated that NPC is well specimen that can demonstrate the transforming ability of EBV latent membrane protein which is expressed in approximately 65% of NPC tumors (5, 18, 19), So the plasma EBV-DNA level might be a sensitive and reliable biomarker for the diagnosis of NPC at a molecular level/clinical practice (20, 21) as EBV is a major etiologic factor for (NPC), and it is detected in tumor cells of virtually all NPC cases (22).

The results from Tables 2 suggest a synergetic effect between herbal medicine using and EBV. These results are in agreement with those obtained by West et al (23) that confirms a 2-4-fold excess risk of NPC in association with use of traditional herbal medicines through several case control studies. In contrast to other findings, however, no evidence of herbal medicine using links to NPC was detected (1). Herbal medicine using might be a strong risk factor of NPC through activation EBV in latent EBV infected cell or through a direct promoting effect on EBV-transformed cells (24).

Furthermore Family History NPC (indicated as a history of first degree relatives with NPC) was risky for NPC as approved by Busson et al, (2004) (5) who found there is evident that genetic factors might be of importance for the etiology of NPC. The mechanism of familial clustering is not understood and it may reflect genetic factors, shared environmental factors, or both (9). In accordance with the present results, previous studies have demonstrated that a strong association between our estimates of formaldehyde exposure and NPC (9).

The present study identifies cigarette smoking, Alcohol drinking, Tea consumption and dust and/or exhaust exposure/domestic fumes intake are statistically non-significant risk factors for NPC after adjusting these identified risk factors. These findings are in contrary to some studies that suggested these factors are risk factor for NPC. However, other studies which have suggested
that the relationship of NPC to these risk factors are less clear and inconsistent (1, 7-9).

To our knowledge, this study is the first study in Anbar province that illustrates the association between some risk factors including EBV and NPC development, hoping that a better understanding of the etiologic interactions between viral and environmental factors in the pathogenesis of NPC.

Conclusion

Combination of family history of NPC, EBV exposure and herbal medicine was a strong risk factor for NPC.

Molecular Detection of Toxogenic Cyanobacteria Isolated from Tigris River in Baghdad City –Iraq

Zainulabdeen H. A. AL-Khafaji¹, Ahmed S.Dwaish²
¹Department of Biology, College of Education, University of Mosul. (Msc.Assist.lecture) ²Department of Biology, College of Science, Mustansiriyah University. (PhD.Assist.Professor)

Abstract
Algae and their contamination are being increasingly reported worldwide that cause a serious hazard to environmental and human health. Cyanotoxin was the most algal toxin reported to be produce by several orders of cyanobacteria. In 2017 cyanobacteria were isolated from fresh water of Tigris River and identified by light compound microscope as well as conventional PCR. Five isolates of cyanobacteria which successfully amplified a gene fragment from the phycocyanin shared by all cyanobacteria and only four isolates successfully amplified a gene fragment from the myc E belonged to microcystin. Our results concluded that PCR assay can be used for early detection of microcystin producing algae in fresh water that useful to stations responsible for the preparation of drinking water.

Keywords: Algae, Cyanotoxin, phycocyanin and microcystin.

Introduction
Cyanobacteria, cyanophytes or blue green algae are widely distributed in natural environments and are considered a major component of microbial populations in terrestrial and aquatic habitats worldwide. Harmful algal blooms have been identified in fresh water, Estuarine, and marine system. In fresh water some cyanobacterial may produce dermal toxins, neurotoxins and hepatotoxins which including nodularins and microcystins (1).

They are also an interesting functional food source (2). These microbes have also been reported to be rich sources of healthy nutrients such as proteins, carbohydrates, vitamins, minerals amino acids, and fatty acids.

Among all the cyanotoxins, microcystins are the most frequently studied because of their wide distribution and high toxicity. Up to now, more than 80 different structural variants have been identified, among which microcystin-LR is the most common and potent variant, followed by microcystin-RR and microcystin-YR (3).

Monitoring systems are needed to prevent water users from these toxins. Good methods, such as ELISA and high performance liquid chromatography have been recorded for most cyanotoxins, but they extremely use laborious sample preparation protocols as well as priced machinery and purified toxin standards that are often difficult to obtain. Nevertheless, molecular detection techniques such as conventional PCR, quantitative real-time PCR and microarrays/DNA chips that are rapid, extremely sensitive and specific for detecting toxic cyanobacteria in water supplies (4; 5).

The delivery of phycocyanin in the cyanobacterial makes the study of phycocyanin genes good idea for the classification of cyanobacteria (6). Phycocyanin operon contains genes coding for two bilin subunits and three linker polypeptides. The intergenic spacer (IGS) between the two bilin subunit genes, designated as b (cpcB) and a (cpcA) showed variations in their sequences which are useful of differentiating genotypes below the generic level make it capable for the identification of cyanobacteria via PCR (7).
Conventional PCR could be useful to detect microcystin producers and several primers are available \(^{(8)}\). \(mcyE\) primers were successfully used to get PCR product from all known microcystin and nodularin producers \(^{(9)}\).

Baghdad city have two main sources of drinking water for Iraq. Tigris River is the most important once in serving population approximately seven million people settled in this city, this river usually affected by industrial eutification as well as the sewage effluent and agricultural which provide enhancement of cyanobacteria growth and potential mycrocystin production. Therefore, this study was aimed to use Molecular PCR technique for identification of cyanobacteria and mycrocystin producing isolates from Tigris River for early detection of toxic species that could be useful to companies responsible for the provider of drinking water to this city.

**Material and Method**

Water samples were collected from the higher superficial layer of Tigris River from a depth of 20-30 cm monthly in April 2017 by using 20μ mesh net. Sampling site located in civil region in AL-Great region near AL-Great bridge, located on longitude 44°20’37.52''E and latitude 33°25’3.49’’N. Samples were transported to the laboratory on ice. 10 ml of water sample was added to chu-10 culture medium and incubated at 28ºC for two weeks with continuous illumination of 50 μE/m²/s. one ml of growth inoculated on agar plates containing BG-11 and incubated in the same condition for one week to isolate unialgal \(^{(10)}\). Microscopic examination were performed to ensure the culture were unialgal.

Extraction of DNA from chlorophyta and cyanbacterial isolates

Genomic DNA was extracted from the chlorophyta isolates for specificity test using CTAB method \(^{(11)}\). While the Genomic DNA was extracted from the cyanobacterial isolates using the genomic DNA mini Kit (plant)

Polymerase chain reaction test

Polymerase chain reaction was performed with two sets of primers. PC\(\beta\)F (GGCTGCTTGTTTACGCGACA) and PC\(\alpha\)R (CCAGTACCACCAGCA ACTAA)\(^{(12)}\) to amplify cpc\(B\)-IGC-cpc\(A\) region in phycocyanin operon while the HEPF (TTTGGGTTAACTTTTTTGGG CATAGTC) and HEPR (AATTCTTGAGGCTTAATCGGTTT)\(^{(13)}\) used to amplify \(mcyE\) gene of the microcystin synthetase. PCR protocols involved an initial denaturation for 2 min at 95°C; 35 cycles of denaturation for 90 sec at 95°C, annealing for 30 sec at 52°C (PC\(\beta\)-PC\(\alpha\) primer set) and for 90 sec at 95°C (HEP primer set), extension for 1 min at 72°C and final extension for 8 min at 72°C. 10μl of PCR product was separate in 1.5% agarose gel electrophoresis stained with ethidium bromide and visualized on a UV transilluminator, the size of amplified products were compared with the 100pb DNA ladder to determine the exact size of these products.

**Results**

Isolation and identification of algae from water samples five isolates of cyanobacteria were obtained from the Tigris River included, Westellopsis sp , Oscillatoria sp , Spirulina sp , Chroococcus sp and Lyngbya sp. Which belonged to four cyanobacterial orders: Oscillatoriales, Chroococcales, Stigonematales and Nostocales as well as one isolate of chlorophyceae included Cladophora glomerata ( Macro algae ) where used as negative control test.

Molecular detection of cyanobacteria by PCR test

The gene fragment of the phycocyanin operon containing the IGS (cpcBA-IGC) from cyanobacteria was amplified. A distinct amplicon patterns was produced from all of the DNA extracts with a size of 650 bp when analyzed in gel electrophoresis (Fig. 1), confirming the presence of cyanobacterial DNA from isolates collected from fresh water of Tigris River in Baghdad. While lysates of a green alga Cladophora glomerata does not possess pycocyanin operon, gave no PCR product suggested the highly specificity of used primers.

Detection of Microcystin by PCR assay

In this study, conventional PCR used as a tool to identify potentially microcystin producing cyanobacteria possess aminotransferase enzyme. The HEP primers were successfully amplified the 472 bp fragments of \(mcyE\) gene from all microcystin-producing cyanobacterial isolates except spirulina sp. (Fig. 2). The specificity of HEP primers appeared to be highly specific for isolates producing microcystin since there was no DNA amplified from chlorophyta used in this study.
Fig. 1. Gel electrophoresis of amplified cpcBA-IGC (650bp) in cyanobacterial isolates. Agarose (1.5%), 5 V/cm for 2 hrs, stained with ethidium bromide and visualized on a UV transilluminator. Fig. 2. Gel electrophoresis of amplified mycE (472bp) in cyanobacterial isolates. Agarose (1.5%), 5 V/cm for 2 hrs, stained with ethidium bromide and visualized on a UV transilluminator. M. 100 bp DNA ladder. Lane 1-5. Westellopsis sp, Oscillatoria sp, Spirulina sp, Chroococcus sp and Lyngbya sp. Lane 6. Cladophora glomerata. M. Marker.

Discussion

The microscopic results revealed that all species of cyanobacteria that isolated from Tigris River related to toxic dominant genera which produce microcystins except *Spirulina platensis*. This might be related to the capability of these species to highly competition to remain dominant utilizing all environmental conditions such as high temperature, optical density and abundance of nutrients, all these factors allowed to form the blooming and can increase microcystin production rates (14).

Morphological identification is time consuming and it requires high expertise. In fact, morphological features used for the identification of species such as
colonial form, mucilage patterns and cell arrangement in the colony is frequently variable and dependent on the environment (15). Furthermore, the co-occurrence of toxin producing and non-producing cells that are morphologically indistinguishable (16; 17). Therefore, the development of a molecular method for the identification of cyanobacteria is essential for the rapid and accurate analysis members of cyanobacterial population (6). 

Several investigators used PCβ-PCα primer set for cyanobacterial detection and showed the same results revealed in this study (12; 18). Except in (6) study, he was reported that phycocyanin gene fragments from Nostoc commune and Nostocpunctiforme were unable to be amplified using these primers while strains of all of the cyanobacterial genera were successfully amplified. In recent research, found that Nostoc punctiforme had short sequence and incomplete of cpcBA-IGC region resulting in high variability in these genes and cause heterogeneity of genus Nostoc(19).

The detection of cyclic peptide hepatotoxin genes by using HEPF and HEPR primers was developed to identify potentially microcystin or nodularin-producing cyanobacterial blooms that possess the aminotransferase domain of either mcy E or nda F, involved in the production of microcystin or nodularin from four order of cyanobacteria included Oscillatoriales, Chroococcales, Stigonematales and Nostocales (13).

The aminotransferase domain was chosen as the target sequence because of its essential function in the synthesis of all microcystins as well as nodularins that catalyzes the addition of D-glutamate to Adda, an essential step in the synthesis of both microcystin and nodularin (20). Thus, can use these described primers to amplify a 472 bp PCR product from the aminotransferase domains of all tested hepatotoxic species and bloom samples. In addition, these primers can be used for distinguished between toxic and non-toxic populations of cyanobacteria that coexist simultaneously in a single ecosystem and are indistinguishable by microscopy (13).

Tigris River usually affected by agricultural and industrial eutrification as well as the sewage effluent, high turbidity, river discharge or by agricultural runoff which provide protected mesocosms of cyanobacteria growth and potential microcystins production. The results by (21) and (22), suggested that eutrophication increased the co-occurrence of potentially microcystins producing cyanobacterial genera, raising the risk of toxic-bloom formation.

Flame Atomic Absorption Spectrophotometry Analysis of Heavy Metals in Some Food Additives Available in Baghdad Markets, Iraq

Wasan Abdulwahid Jasim1, Jassim Dawood Salman2, Jasim Mohammed Shamar Jamur3
1Assistant Lecturer, 2Assistant Professor, 3Dr. Lecturer, Department of Chemistry, College of Education for Pure Science (Ibn Al- Haitham), University of Baghdad, Iraq

Abstract

Flame atomic absorption spectrophotometer (FAAS) was used in this study to determine the concentrations of heavy metals such as Ca, Fe, Mn, Cd, Co, Cr, Ni, Cu, Pb and Zn in some food additives of Iraq. The order of metal contents in food additives was found to be Ca ˃ Mn ˃ Fe ˃ Cu ˃ Zn ˃ Pb ˃ Cr ˃ Ni ˃ Co ˃ Cd. The concentration level of each metal was compared with that recommended by food agriculture organisation (FAO) and world health organisation (WHO). Calibration curves were linear for all standard solutions of heavy metals in the range starting from 0.02-0.4 mg/kg for Cd to 11-100 mg/kg for Ca. The correlation coefficients values (R^2) of calibrations were investigated and ranged from 0.9971 for Cr to 0.9999 for Ca.

The limit of detection (LOD) and limit of quantification (LOQ) were found to be in highest value for Ca (1.6569 mg/kg and 5.5232 mg/kg), while they were found to be in lowest values for Cd (0.0150 mg/kg and 0.0499 mg/kg).

Keywords: Heavy metals, Food additives, Flame atomic absorption spectrophotometer

Introduction

Several elements are important for a wide range of biological processes due to their conjugation with proteins to form metalloproteins which are an important component in the enzymatic systems. Despite the importance of some metals including Cr, Al and Ni for plants, they can be toxic with high concentrations. Furthermore, some heavy metals such as Pb and As in food are a major health problem due to their carcinogenic effects. In addition, the presence of metals in soils during wastewater are environmental problem, and the main cause of the agricultural pollution.

The last three decades have seen increasing the production of spices about 3.5% per year, and play a key role in the history of civilisation around the world. Although spices are essential, there is increasing concern that some of them are being disadvantaged. This attributed to the accumulation of toxic trace elements.

In addition, the spices may be contaminated with trace and heavy metals, and this could lead to health problems. Therefore, researches have shown an increased interest in examine the effect of metals on air, water and food and their impact on human consumption. Concentrations of trace and heavy metals in spices are an important components in the healthcare systems due to their medicinal effective on human health. Some metals such as lead (Pb), arsenic (As), nickel (Ni) and cadmium (Cd) can be extremely harmful to human beings even in trace levels. However, spices are one of the most widely used groups of antibacterial, antioxidant and anti-diabetic agents.

A number of studies have been made to investigate the concentration of metals in spices. On the other hand, information about the efficacy of heavy metals and safety of spices are limited. The heavy metals in food need to be monitored in order to protect human and animals from the hazards of these metal ions; WHO has determined the maximum level for each toxic element in foodstuffs. Several analytical methods have been used to determine the metal concentrations in spice samples.
different countries. Krejpcio and co-workers have shown the quantification analysis of some heavy metals such as Cd, Pb, Cu and Zn in popular spices used in Polish market using atomic absorption spectrophotometer (AAS)\(^{11}\). In the study by Nkansah and Amoako, AAS has been successfully used to monitor the concentration levels of heavy metals including Ni, Fe, Cu, Co, Pb and Zn in many different types of spices in Ghana\(^{9}\). The quantification analysis of some toxic metals such as As, Pb, Cd and Ni in a number of common spices in Pakistan using AAS method were carried out by Baig \textit{et al}\(^{8}\). In a study conducted by Karadas and Kara, it was shown that geometric methods such as principal component analysis (PCA) and cluster analysis (CA) can be used to analyse the trace metal concentrations such as Co, Mn, Fe, Mg, Cr, Cu, Ca, Cd, Ba, As and Sr in some spices in Turkey\(^{15}\).

The experimental work presented here provides the levels of heavy metals in some food additive available in the local markets of Baghdad, Iraq. This study therefore set out to assess the effect of some heavy metals such as Ca, Cd, Co, Cr, Cu, Fe, Mn, Ni, Pb and Zn in some popular food additive in Iraq such as qayima, dolma, kubba, seven, pizza, biryani, judur, chicken, kubsa, burger and sumac using FAAS technique. Both qualitative and quantitative methods were used in this investigation.

**Materials and Method**

**Apparatus**

Flam atomic absorption spectroscopy (FAAS) model AA-7000 Shimadzu was used as instrumental detection system using hollow cathode lamps. Absorbance measurements of blank (solvent) were recorded using deuterium lamp. Air/ acetylene burner head was used as a carrier gas for all samples. The wavelength used for each metal was: Ca (422.7 nm), Fe (248.3 nm), Mn (279.5 nm), Cd (228.8 nm), Co (240.7 nm), Cr (357.9 nm), Ni (232 nm), Cu (324.8 nm), Pb (283.3 nm) and Zn (213.9 nm).

**Chemicals**

All chemicals were used without any further purification and all solutions were prepared by deionised water. Nitric acid (65 %) was supplied by Riedel-de Haen. Standard solution of each metal that used for the calibration curve was prepared by stock solution (1000 mg/L) supplied by Aldrich. Deionised water was provided by Daihan Labtech CO., LTD (Model WD-2008F) with a volts of 220V 50 Hz.

**Preparation of samples**

Eleven samples of food additives such as qayima, dolma, kubba, seven, pizza, biryani, judur, chicken, kubsa, burger and sumac that used in the study were collected by the local markets of Baghdad, Iraq. One gram of each sample was weighed and digested by mixing with 2 ml of concentrated nitric acid and heated for 1 hour. Then, the produced samples were cooled at room temperature. After digestion, the samples were filtered and diluted to 25 ml with deionised water.

**Analysis of sample**

All prepared sample solutions were analysed by FAAS method to determine the concentrations of heavy metals such as Ca, Fe, Mn, Cd, Co, Cr, Ni, Cu, Pb and Zn that used in this study. Blank solution was also measured before the sample analysis using the same conditions.

**Quantification**

For quantification, calibration curves of five different concentrations of each standard solution were applied. All calibrations curves showed a good linear correlation between the concentrations of standard solutions and absorbance. Some statistical analysis including the standard deviation (S.D.), standard error of the mean (S.E.M.) and correlation of coefficients (R\(^2\)) were done in order to check the validation of FAAS method. All R\(^2\) were found to be ≥ 0.997. The limit of detection (LOD) and the limit of quantification (LOQ) were also determined by considering standard deviation to the slope:

\[
\text{STEYX means the standard deviation of the y-value and x-value.}
\]

**Results and Discussion**

FAAS has been used to determine many heavy metals such as Ca, Fe, Mn, Cd, Co, Cr, Ni, Cu, Pb and Zn in some food additives such as qayima, dolma, kubba, seven, pizza, biryani, judur, chicken, kubsa, burger and sumac. The results obtained from the analysis are presented in Table 1. The samples were prepared in the same solvent used for the analysis. The wavelength was set for each element (see the material and method section). It can be seen from the date in Table 1 that the level of Ca in all samples is higher than levels observed.
of other metals. Interestingly, the samples of qayima and judur did not detect any value of Cr and Co. The results of the study are in agreement with those obtained by WHO. Therefore, there was no evidence that the levels of heavy metals concentrations in these food additives has an influence on human consumption.

The results obtained from the Figure 1, it can see that the burger recorded the highest level of Ca (69.058 mg/kg), whereas the lowest level was found in sumac (7.896 mg/kg). From the data in Figure 1, it can see that the study resulted the concentration levels of Fe in the samples and found to be between 3.133 mg/kg in kubba and 6.683 mg/kg in judur. These values are lowest than that of determined by FAO and WHO, 2009 (20 mg/kg). Compared to permissible limit of FAO and WHO, 1984 (2 mg/kg), there was the higher Mn content in all food additives samples (> 4 mg/kg) except sumac, Figure 1.

Figure 1: Levels of Ca, Fe and Mn in different food additives
As can be seen from the Figure 2, the concentrations of cadmium in all food additives were lower than that determined by FAO and WHO, 1984 (0.2 mg/kg). They found to be in the range from 0.005 mg/kg in dolma to 0.023 mg/kg in biryani. As shown in Figure 2, the concentrations of “Co” in all samples were under the permissible limit of FAO and WHO, 1984 (0.4 mg/kg). They were in the range of 0.015- 0.034 mg/kg in seven, biryani and pizzaa, whereas judur sample did not show any content of Co. Only trace amounts of Cr were detected in the food additives samples, however, FAO/WHO (2009) suggested that the concentration of Cr should be zero in these samples. When Cr was found from 0.008 mg/kg in kubaa to 0.134 mg/kg in sumac, no amount in qayima was detected. The results also shows that the greatest value of Ni was in sumac (0.129 mg/kg), while the lowest value was in judur (0.009 mg/kg). This data can be compared with that determined by FAO and WHO, 1984 (1.63 mg/kg). As shown the maximum obtained values were too far from the permissible limit of FAO and WHO, therefore, the selective food additives in this study appeared to be unaffected by these levels of Ni.

It can be seen from the Figure 3 that the food additives samples reported significantly high concentrations of copper compared to those of some heavy metals such as Cd, Co, Cr, Ni and Pb. It found to be between 0.273 mg/kg in judur and 3.047 mg/kg in seven. However, these observed concentrations were in general under the maximum limit of FAO and WHO, 1984 (3.00 mg/kg). From the data in this Figure, it is apparent that the Pb levels in food additives were higher than those of Cd and Co and lower than other metals. The range of concentrations were found from 0.024 mg/kg in both qayima and sumac to 0.270 mg/kg in biryani. This results indicated there was no evidence that Pb has an influence on human health due to their levels were under the permissible limit of FAO and WHO, 1984 (5.00 mg/kg). The results also shows that the levels of Zn ranged from 0.575 mg/kg in burger to 1.360 mg/kg in biryani. Therefore, they were too far from the maximum level that recommended by FAO and WHO, 2009 (50 mg/kg).

Correlation analysis of five different concentrations including the blank of each metal were tested to predict the linearity. Calibration ranges of standard solutions are set out in Table 2. From the Figure 4, it can see that all calibrations showed a good linearity over the range of concentrations. The LOD and LOQ of Ca is expected to be higher than others, whereas for Cd they were found to be lower than others. Other values of LOD and LOQ were listed in Table 2. Standard deviation (S.D.) and standard error of the mean (S.E.M.) were calculated by the equations:

\[ S = \sqrt{\frac{\sum_{i=1}^{n} (x_i - \bar{x})^2}{n - 1}} \]

\[ \text{S.E.M.} = \frac{s}{\sqrt{n}} \]

Where \( S \) is standard deviation, \( n \) is number of values in the sample, \( x_i \) is data value, \( \bar{x} \) sample mean, S.E.M. is standard error of the mean and \( s \) is size of the sample. The results of the mean, S.D. and S.E.M. are summarised in Table 2.

**Figure 4. Calibration curves for the standard solutions of heavy metals by FAAS**

**CONCLUSION**

The present study was designed to determine the levels of some heavy metals in different samples of food additives available at local markets in Baghdad, Iraq using FAAS technique. This has shown that the method is simple, fast and sensitive. The obtained concentrations of metals were acceptable with that recommended by FAO and WHO. The study has shown that highest correlation coefficient (R²) of calibrations was found to be for Ca (0.9999), while the lowest was found to be for Cr (0.9971). The LOD and LOQ for Cd were found to be lower than others (0.0150 mg/kg and 0.0499 mg/kg) followed by Zn (0.0209 mg/kg and 0.0698 mg/kg). This could attributed to that the Cd and Zn are sensitive enough even at low concentrations.

For recommendations, the findings of this study have several important applications for future work. The method can be applied for determination of other metals in different samples of foodstuffs. Further research should also focus on determining the toxic and carcinogenic heavy metals in food additives and how can be able to reduce their effects by reducing their amounts.

Detection Malta Fever by Interferon-gamma and Steroid Hormone S Level

Ali Anok njum1, Layla Saleh Abdul-Hassan2 Ihasan A. Hashem3
1Assist Prof., 2Lecturer, 3Assistant lecturer/Al-Furat Al-Awsat Technical University/College of Health and Medical Techniques/kufa / Iraq

Abstract

Malta fever is one of the most common bacterial zoonosis, its causes abortion of pregnant women. Abortion is the chief obvious manifestation of Brucella infection. Brucella like better cattle placenta as a result of great concentration of erythritol sugar, whereas human placenta there is no erythritol sugar only steroid hormone, for this reason designed the our project . In this study, 100 aborted women were included , where referred to maternity and children hospital of Babylon province \ Iraq. Diagnosis of Brucella infection in these abortions was concentrated on serological and bacteriological technique. Serological studies included the use of RB and ELISA tests. Aggressive differences between RB and ELISA results have been shown. Brucella isolated and identified from aborted placenta and blood samples were 7 (7%) isolates from aborted women.

Hormonal assessment by Immunohistochemical technique in Brucella infected women, showed significant decrease in progesterone expression in comparison with that aborted due to other causes, in other hand Brucella infected women showed high expression in estrogen hormones . ELISA technique was the valuable serological test to confirm the diagnosis of brucellosis as compared with RB test.

Keyword: Malta fever , Brucella , Interferon-gamma , Steroid hormone

Introduction

Malta fever also called Brucellosis, is a zoonotic disease effecting humans and animals in many countries e.g, Mediterranean area, Iraq, middle east, India, and America(1). Reports from the regions where Brucella melitensis infection is endemic, propose that there is an increased rate of abortion in asymptomatic pregnant women. The diagnostic method acknowledged to produce the best results in terms of specificity is the isolation of Brucella organisms from the suspected human , Different Brucella species are recognized as causative agents of brucellosis and some of them are acknowledged to be pathogenic to humans (2-8). However, Because of the variety of the disease and its non-specific clinical manifestation, the clinical diagnosis of Malta fever remains a challenge. Malta fever (Brucellosis) mimics other infectious and non-infectious diseases, resulting in a delay in diagnosis or misidentification of the disease(9). The diagnosis is importantly dependent on a epidemiological history , clinical signs , patient’s medical, biochemical testing , hematological, radiological examination and, necessarily, on Brucella-specific laboratory tests. Very important sides for correct and fast diagnosis are the disease-specific laboratory tests and knowledge of their weaknesses, proper analysis and correct assessment of their results (10). Rose Bengal (RB) is the main serological test used to identify antibodies against brucellosis. Because of the difficulties in the method and low sensitivity of the isolation methods, laboratory diagnosis relies largely on serological tests. The major antigens of Brucella being used in serological testing are the internal-cytosolic proteins and lipopolysaccharide (smooth-S LPS) (11). Brucella Lipopolysaccharide is a strong immunogen but its epitopes are the chief etiology of cross-reactions with other Gram-negative bacteria , a condition that creates evaluation more difficult(12). Cytokines have an important role in the pathogenesis of Malta fever and the Th1/Th2 balance may include in the resistance or susceptibility to the disease (13).
are responsible for control of the infection. Experimental studies showed that IFN-γ is essential for exclusion of Brucella and for host survival in case of virulent Brucella challenge (14). The aims of the present work were:

1- Trophism of Brucella to uterus of women that it not has erythritol sugar

2- Evaluate steroid hormones level in placenta and blood is specific method to detection of Malta fever.

3- Evaluate interferon-gamma level in blood.

Materials and Methods:

Human brucellosis kit was provided by Elabscience/China. Gram’s stain solution. Rose Bengal antigen was provided by Omega company, UK. antibrucella abortus, antibrucella melitensis and Monospeciic antiserum were supplied by Difco, USA.

Methods

Samples collection.

1. Clinical signs of aborted women were recorded by physician to show pregnancy period and sings of abortion.

2. Blood samples: Hundred blood samples from women were obtained. serum samples have been obtained for serological and immunological assessments using RB and ELISA tests.

3. Aborted Placentas:

   Hundred placenta samples from aborted women have been obtained, at maternity and children hospital of Babylon province, placenta samples were cultured directly on Brucella selective medium and blood agar.

4. Immunohistochemistry for placenta specimens was performed as described by (Dako, UK). The expression of “estrogen and progesterone hormones were measured as the same scoring system” used by Mao et al., (15). The positivity of cells for expression of hormones were seen as brown staining. It was graded as four grad of the cells staining positive for hormones.

5- IFN-gamma ELISA performed as described by (RayBiotech. Inc).

Statistical Analysis:

The results are expressed at percentage by Chi-square test, (SPSS) for Windows program was used to compare between the frequencies. Student t test was used to compare between means of groups. The significance was accepted as P value < 0.05.

Results

Clinical signs in women included fever and bleeding, most women infected with Brucella were aborted at first stage of pregnancy.

Serological tests:

ELISA, RB test revealed that RB results were positive in 27 cases (27%). ELISA results were positive in 14 cases(14%) . according to Pearson Chi-Square test, the difference in RB and ELISA positive cases was significant (P<0.05) show in Table (1).

Bacterial isolation & identification:

Out of the 100 aborted women, 7 (7%) were positive for culture, from 14 patient blood samples that positive for positive ELISA, 7 isolates were positive by culture, after 2-4 days the Brucella culture recognized on the basis of colonial morphology (translucent , round with pearly appearance).

Isolates from blood and placenta samples were Gram-negative, coccobacilli, arranged singly in short chain or small groups stained with modified ziehl-
neelsen stain , Biochemical test of Brucella show in table (2)

*Significant (p≤ 0.05)

According to study the estrogen particles , there is obvious rise for estrogen stain for placenta tissue through Brucella infection , as determined by staining of biopsies , the immune staining of estrogen were positive at high level in 85.71% (6 out of 7) in Brucella infected patients, with highly statistical association (p≤ 0.05) between the infected & non infected groups (table 4).
Interferon-gamma assessment by ELISA technique

Patients with Malta fever had significantly (P<0.05) higher serum levels of IFN-γ (175.078 ± 69.821 pg/ml) compared to control group (39.358 ± 29.847 pg/ml) shown in (Figure 1).

Discussion

RB gave positive result in aborted women but were negative for ELISA and bacterial isolation infection, because the RB test is rapid and screening test and may be give cross-reaction with other Gram negative bacteria example : E.coli O:157, Yersinia enterocolitica O:9, Vibrio cholerae O:1, Salmonella spp., Francisella tularensis and Pseudomonas maltophilia, and give false positive for RB (16).

Antibodies to Brucella appear in the serum within (1-2) weeks of infection. The initial response is the appearance of IgM isotype (which can be easily detected by RB) followed by a switch to IgG, after a while titers of both Immunoglobulins classes increase distinct most of the usual serological tests, ELISA is effective in distinguishing all immunoglobeline (antibodies) classes and sub-classes essential in diagnosis and appears to be the most sensitive serological test increase in IgG but not IgM. IgA titres roughly paralleled IgG titers (17). ELISA using S-LPS Ag can be used to measure the development of immunoglobulin isotypes following infection and after treatment (18). Steroid hormones concentration in aborted women positive for brucellosis were showed decrease in progesterone levels and increase in other hormones due to Brucella infection, aborted women negative for brucellosis notice significant increase in hormone , this certified that other cause of abortion may be not effect on progesterone synthesis.

Estimation of hormones are more effective method to conformation of Brucella infection, while other serological methods may be causes cross-reaction and false positive results.

There are two HSD3B1 proteins, labeled type I and type2 that are expressed by different genes and function in different regions of the body (19). HSD3B1 has too been shown to be there a highly specific and sensitive trophoblast-associated marker, also showed that expression of 3β-HSD in trophoblast more than 50% considered as positive cells for 3βHSD (20). To form steroid hormones, the subsequent processing of pregnenolone requires enzymes related to smooth endoplasmic reticulum, such as 17-α-hydroxylase (P450c17α) and 3β-hydroxysteroid dehydrogenase/isomerase (3βHSD) pregnenolone is converted to progesterone by the enzyme 3β-HSD, which in turn, is converted to androstenedione by the enzyme 17α-hydroxylase/C17, 20 – lyase (P450c17α) (21).

In this study, have high serum levels among patients with Malta fever compared with control. These results are in agreement with earlier studies (22) who reported height this cytokine in Malta fever patients.
Most studies specified that CD4+ T lymphocytes are the main producer of IFN-γ although other subsets such as “CD8+ T lymphocytes, γδ T lymphocytes and NK cells also participate in the production of this cytokine (23). As there are relatively high serum levels of IFN-γ, it indicates an enlarged number of CD4+ which, in turn, indicates a chronic infection” (24).

**Conclusion**

In conclusion, placental immunohistochemical and assessments for steroid hormones (progesterone) and interferon-gamma have an efficient diagnostic values which can be included for confirmation of brucellosis.

Hepatic Toxicity in Patients with Rheumatoid Arthritis and Psoriasis Taking Methotrexate Therapy

Haider Hamza Omran¹, Basim Mohammed Mothlum¹
¹Assist Prof./FICM. Internal medicine Merjan Teaching Hospital-Ministry of Health/Iraq

Abstract

Background: We had made a study to demonstrate the adverse hepatic effects of MTX in patients taking MTX for treatment of RA and psoriasis taking in consideration the following variables: BMI, gender, cumulative dose, age, weekly dose, duration of treatment, serum level of cholesterol and creatinine.

Patient and method: We had a prospective study of 85 patients with RA and 50 patients with psoriasis. All patients were analyzed by history, clinical examination and investigations in the form of liver enzymes, blood sugar, serum cholesterol, serum creatinine, HBS Ag and anti HCV antibody. Persistently elevated level of liver enzymes 2 to 3 times the upper limit of normal on two occasions 3 months apart indicate hepatic toxicity.

Results: We found that 7 patients with psoriasis and 6 patients with RA have significant elevated liver enzymes which reflect MTX hepatotoxicity.

Conclusion: Our study show that patients with psoriasis at significantly greater risk of elevated liver enzymes than patient with RA (14% and 7% respectively) were gender, BMI, cumulative dose, weekly dose and serum cholesterol level are risk factors for hepatic toxicity due to MTX therapy.

Key words: Hepatic Toxicity, MTX therapy, Arthritis

Introduction

Methotrexate is a folic acid antagonist that inhibits dihydrofolate reductase. DNA synthesis is inhibited as the concentration of thymidine and purines falls after treatment with methotrexate. The relevant targets of low dose methotrexate have not been defined with precision, but an attractive candidate is the enzyme 5- amino-imidazole -4- carboxamide ribonucleotide (AICAR) transformylase. Inhibition of AICAR transformylase leads to accumulation of AICAR, which in turn stimulate the extracellular release adenosine which has a number of anti-inflammatory and immunomodulatory effects that may contribute to the therapeutic effect of methotrexate. Recently, in vitro studies showed that methotrexate was 10-100 times more effective at inhibiting the proliferation of lymphoid cell lines than cultured keratinoocytes, suggesting that lymphoid cells may be a more important cellular target than epithelial cells in psoriasis and also inhibits polymorpho nuclear leukocyte chemotaxis. These actions may explain its clinical effect.

Methotrexate is now the most widely used disease modifying antirheumatoid drug (DMARD) in the developed world. It was first used in the treatment of psoriasis and psoriatic arthritis in 1951, and has been shown to be of clinical benefit in this condition.

Methotrexate has been used for the treatment of diseases characterized by inflammation or cellular proliferation. In 1985, the first randomized placebo-controlled trials were published that demonstrate the short term efficacy of low dose weekly methotrexate in Rheumatoid arthritis.

Comparative studies of methotrexate with azathioprine, gold sodium thiomalate and cicolospirone in the treatment of Rheumatoid arthritis show that methotrexate is well tolerated, with retention rates between 93% and 95%.

Oral therapy is given once a week. Daily dose schedules are dangerous and have been abandoned. The oral triple-dose regimen is the most common method
used. A dose is taken at 12 hours intervals during a 36 hours period once each week. An initial test dose of 2.5 to 5mg is given and complete blood cell counts and liver function tests are obtained once week later. Maintenance doses should be achieved by gradual increases of 2.5-5mg per week up to 20mg/week (12).

The most common adverse effects are gastrointestinal, such as anorexia, nausea, vomiting, stomatitis and diarrhoea. Central nervous system toxicity including headache, dizziness, fatigue and mood disturbance may occur. Haematological toxicity is not common, and although all types of cytopenia has been documented. Pulmonary complications such as methotrexate pneumonitis may be linked to risk factors as increased age, diabetes mellitus and pre-existing pulmonary diseases (13). It is now thought that the frequency of severe liver disease occurring in rheumatoid arthritis patients receiving long term methotrexate is not high; the incidence of mild fibrosis has been reported as being between 0% and 2% (14-15).

Base line monitoring include history, physical examination, complete blood count, platelet count, renal function test, liver chemistry including (AST, ALT, alkaline phosphate, albumin) and viral serology mainly for hepatitis B, C and HIV antibody and chest radiography to exclude pulmonary fibrosis. Follow up monitoring include monthly complete blood count and differential, platelet count for the first and second dose then every two months, liver chemistries monthly or every two months, and renal function test including blood urea, serum creatinine at three to four months interval.

Persistently elevated liver enzymes more than two times would preclude further therapy. Although combined sensitivity of liver enzymes for detecting a significantly abnormal liver biopsy is 86%, whereas the predictive value of negative test result 93% (16), liver biopsy remain more reliable predicator of liver damage. Current study aimed to Assess the prevalence of liver enzyme abnormality in patients with RA and psoriasis taking MTX therapy and to identify the possible risk factors for MTX induce hepatotoxicity in these patients.

Patients and Method

Eighty five patients with rheumatoid arthritis diagnosed according to American college of rheumatology criteria (17) and 50 patients with psoriasis diagnosed by the presence of psoriasis with or without seronegative peripheral arthritis (18), underwent a prospective study

The study was performed in Marjan Teaching Hospital in Babylon for outpatient clinic of rheumatological and dermatological disease. After taking the verbal consents of the patients, full history regarding age, gender, MTX dose per week, MTX duration, and cumulative dose defined as dose per week multiplied by duration of treatment, MTX adverse effects mainly the gastrointestinal problems (nausea, vomiting, abdominal pain and anorexia). Oral MTX therapy and folic acid supplement prescribed for all patients (5mg once daily). Drug history concentrated on (NSAIDs, statins, cordaron, oral hypoglycemic drugs, psoraline+UVA treatment, gold, oral contraceptive pills, long term steroid and extreme obesity), any patient on these drugs for the last month were excluded, history of alcoholism so any patient drunk alcohol in the last 5 years were excluded from the study.

History of other comorbid disease like congestive heart failure, chronic viral hepatitis, autoimmune hepatitis, Wilson’s disease, chronic renal failure and diabetes mellitus were excluded from the study. Clinical examination include jaundice, ascites, organomegaly was performed, BMI represent the height and weight recorded as Wt. in Kg / Height in m² were 18 - 25 considered normal, 25 - 29.9 considered overweight, 30 – 39.9 considered obese and >40 considered extreme obesity (19). Investigations in the form of liver enzymes (normal reference values for ALT, AST <20 U/100 ml, normal reference for ALP, 85 U/100 ml) done by colorimetric method, random blood sugar normal reference value <11.1 mmol/L by glucose oxidase method, cholesterol level normal reference value <5.2 mmol/L by cholesterol oxidase method, serum creatinine normal reference value <124µmol/L by alkaline picate with Deprot method and viral serology for HBS Ag, anti HCV Ab. By bioelisa color method (direct immune enzymatic method). Persistently elevated level of liver enzymes 2 – 3 times the upper limit of normal on two occasions 3 months apart is indicate hepatic toxicity (20).

Statistical Analysis

Statistical significance of liver enzymes between patients with RA and psoriasis, and each risk factors were assessed by t-test and of the proportion, were p-value < 0.05 indicate Statistical significance the results were expressed as tables.
Results

The average age of patients with RA was 48 years and for patients with psoriasis was 50 years, female outnumbered male in RA group were 56 to 29 and for psoriasis group, the female outnumbered male 23 to 27. Body mass index in RA group was 24 kg/m² and for psoriasis group was 27 kg/m². The average duration of MTX therapy was 4 years in RA group and 3 years in psoriasis group. The average dose of methotrexate therapy in RA group was 10 mg/week and for psoriasis group was 15 mg/week [Table 1].

Regarding gastrointestinal symptom as nausea and vomiting were found in 20 patients (23.5%) with RA and in 10 patients (20%) with psoriasis [Table 2], statistically not significant.

Sustained rise in liver enzyme were seen in 6 patients (7%) in RA group while in 7 patients (14%) in psoriasis group [Table 3] which was significantly significant. The gender, liver enzyme abnormalities were found in 2 males (33.3%) and in 4 females (66.6%) in RA group while 4 males (57.1%) and in 3 females (42.8%) in psoriasis group [Table 4], statistically not significant. The age, the average age in RA was 46 and 52 years in psoriasis group [Table 5], statistically not significant. BMI, in RA group was 23 kg/m² and in psoriasis group was 28 kg/m² [Table 6], statistically significant.

Discussion

The study showed that gastrointestinal problems like nausea, vomiting in RA group was 23.5% and in psoriasis group was 20% which was statistically not significant, in agree to study in 2006, where nausea and vomiting in psoriasis group (9.8) and in RA group was 13% which also statistically not significant. A significant rise in liver enzymes were seen in 6 patients (7%) with RA group and in 7 patients (14%) with psoriasis group, our study agrees with study in 2006 showed that significant rise in liver enzymes in psoriasis group (14.5%) and 7.5% in RA group. The study showed that the gender in RA group and psoriasis group not significantly correlated with hepatic toxicity in contrast to other study, one in 2006(20) other in 2004(34), both showed male in psoriasis group significantly more affected than male in RA group. The study showed no significant correlation of both the age, duration of MTX treatment with the level of liver enzymes abnormality in agree to a study in 2006(21) and other in 2004(22) The study showed that both BMI, cumulative dose, were significantly correlated with hepatic toxicity in psoriasis versus RA group in agree with study in 2004(23) The study showed a significant association between weekly dose of MTX with hepatic toxicity in psoriasis group versus RA group in contrast to study in 2004(22) The study showed a significant association between serum cholesterol level and hepatic toxicity in psoriasis group versus RA group in agree to study in 2006(24) but in contrast to previously reported studies(25--26) were total cholesterol level did not correlate with hepatic toxicity. This study showed no significant association between serum creatinine level and hepatic toxicity in psoriasis group versus RA group, a study in 2004(22) show that renal impairment, diabetes and obesity were significantly correlated with hepatic toxicity Current study show that liver enzymes (transaminases and ALP) both increased
in both groups (RA and psoriasis), although increase level of ALP more correlated with hepatotoxicity \textsuperscript{(27)}. The study recommended encouragement of life style modification for patients who are overweight or obese with psychological support especially for patients with psoriasis. Viral serology for HBS Ag and HCV as baseline because MTX therapy in patient with positive serology may enhance viral replication and result in fulminant hepatitis and Baseline lipid profile as hyperlipidaemia is an independent risk factor for MTX hepatotoxicity.

**Conclusion**

MTX related hepatic toxicity was more significant in patient with psoriasis than patient with RA. BMI, cumulative dose, weekly dose and serum cholesterol level are risk factor for hepatotoxicity in psoriasis group than in RA group.

Scolicidal Activity of Zirconium Oxide (ZrO$_2$) nanoparticles Against Protoscolices of Hydatid Cysts

Amenah Abdul-Jabbar Ibrahim

University of Baghdad, College of Education for Pure Science/Ibn Al-Haitham, Department of Biology /Iraq

Abstract

Hydatidosis is a sickness that affects human and farm animals. This disease is deemed as a public health problem in different regions of the world until nowadays. Surgical overlaps is the best way to treat the disease, while the risk of surgery lies in the possibility of cyst rupture and leakage of protoscolices and the recurrence of infection again, this prompted researchers to use scolicidal agents before surgery such as ethanol, plant extracts, to reduce parasite spread and recurrence of infection, recently researchers have been using nanoparticles as a scolicidal agent, like gold nanoparticles, silver nanoparticles, selenium nanoparticles, and others. This research aims to evaluate the fatal effect of zirconium oxide (ZrO$_2$) nanoparticles to protoscolices of hydatid cysts. The Protoscolices were collected from sheep livers infected with hydatid cyst disease. The protoscolices were treated with different concentrations (250, 500, 1000, 2000, and 4000 μg/ml) of ZrO2 NPs. The viability of protoscolices was determined by using an eosin staining method after 15, 30, and 60 min. The results showed that the concentrations of 1000, 2000, and 4000 µg/ml were significantly effective in the killing of protoscolices after 60 min., where the fatality rate of protoscolices was 49.6%, 52.7%, and 53.1% respectively when compared with the control group 38.5% (p<0.05).

Key words: ZrO$_2$, Zirconium oxide nanoparticles, protoscolices, Scolicidal, hydatidosis.

Introduction

Echinococcosis is a zoonosis, including two types of hosts, definitive (carnivores) and intermediate (wide range of mammalian species). The parasites of genus Echinococcus are small cestodes (1-6 mm) (1). The metacestodes of E. granulosus are cysts of different sizes filled with clear liquid and are called hydatids. The first discovery of hydatid disease dates back to the time of Hippocrates (2). Cystic echinococcosis (CE) is a growing health problem in various parts of the world, including the Middle East (3). The liver is the first organ in which the parasite settles and develops into the larval stage (hydatid cyst) (4). The germinal inner layer of hydatid cyst represents the origin of protoscolices, which are the infective form to the definitive host, and the source of secondary infection when naturally or experimentally released within mammalian tissues or peritoneal cavity (5, 6). Surgery and/or chemotherapy are a common treatment for CE, chemotherapeutic of this disease has been sophisticated in several animal model studies, and both albendazole and mebendazole are considered to have identical efficiency (7). Surgery is used in special cases depending on the characteristics of cysts, such as large cysts that contain multiple daughter cysts, single superficial cysts at risk of rupture, and cysts interlaced with biliary tract. PAIR (Percutaneous, Aspiration, Injection and Re-aspiration) is an alternative way to surgery, with minimum risks (8). Efforts were dedicated to finding out new protoscolicidal materials from plant sources, those efforts concentrated on some plant extracts that showed high effectiveness against CE (7). Due to the unavailability of effective treatment for CE, there is an urgent need to find this treatment, so that the nanotechnology-based materials may be useful in the cure of diseases (9). Nanotechnology is a technique that is concerned with the development and use of chemicals, devices, and systems of unfamiliar characteristics because of their small size (1-100 nm), in addition to their unique physicochemical properties which had great importance in many fields of research, including science and medicine (10).

ZrO$_2$ NPs have been studied extensively because of their unique mechanical, thermal, optical, and electrical properties (11). They have broad applications because
of remarkable biocompatibility, high strength, and low cost (12). ZrO2 NPs are also able to possess noticeable antimicrobial properties (13).

**Materials and Method**

1- **Collection of protoscolices.**

Samples of hydatid cysts were collected from livers of naturally infected sheep in a slaughterhouse in Baghdad/Iraq. The hydatid fluid was withdrawn from the cysts by using a 20 ml syringe and transferred into flasks. The fluid was left for enough time to enable all protoscolices to precipitate. The germinal layers of the cysts were also collected and placed in a petri dish and washed very well to assemble all protoscolices. The protoscolices were suspended with normal saline. The viability of protoscolices calculated according to the method of Smyth & Barrett (14).

2- **Preparation of nanoparticles suspension.**

Zirconium nanoparticles (29.8 nm) were purchased. Jeng & Swanson (15) method was adopted to prepare nanoparticles suspension with modulation, where 0.4g of nanoparticles were weighed and suspended in 100 ml of distilled water and sonicated for 20 minutes before use. Five concentrations of the ZrO2 NPs (250, 500, 1000, 2000, 4000) µg/ml were prepared according to the method of Napooni et al. (16) with some modifications.

3- **Solicidal activity of ZrO2 nanoparticles.**

The efficiency of five concentrations (250, 500, 1000, 2000, 4000) µg/ml of ZrO2 NPs were tested against protoscolices of hydatid cysts at different exposure times (15, 30, 60) min. 0.5 ml of protoscolices suspension (1000 ps) were mixed with 0.5 ml of each concentration of nanoparticles, then incubated at 37°C for 15, 30 and 60 min. Then the viability of Protoscolices calculated after exposure to each concentration/time.

4- **Statistical analysis**

The data were analyzed by using statistical software package IBM SPSS (version 25). The differences between experimental groups and control groups estimated by using ANOVA and T-tests at a significance level of 0.05.

**Results**

Fatality rate (%) of protoscolices after exposure to ZrO2 NPs at various concentrations following various exposure times as shown in Figure 1.

![Figure 1: Fatality rate (%) of protoscolices after exposure to ZrO2 NPs at various concentrations following various exposure times.](image-url)
* The difference between the experimental group and control group is statistical significance (p<0.05)

Discussion

The results of this study showed that the highest fatality rate of protoscolices was 49.6%, 52.7%, and 53.1% when treated with ZrO2 NPs suspension at concentrations 1000, 2000, 4000 µg/ml, respectively, after 60 min., and the difference between these groups and control group (38.5%) was statistically significant (p<0.05). Because of the importance of nanoparticles in medicine and science, the researchers studied its effects against some harmful organisms, especially bacteria and parasites, like the studies of Yalcinkaya et al. (17) and Kumaresan et al. (18), which proved the great effect of ZrO2 against E. coli, Bacillus subtilis, Salmonella typhi. Rahini et al. (19) studied the effect of green synthesis silver nanoparticles against protoscolices, and they found that the highest mortality rate was 90% (0.15 mg/ml, 120 min.). While the highest mortality rate was achieved when using the green synthesis gold nanoparticles (94%, 0.3 mg/ml, 120 min.) (20). Naponi et al. (16) have also used gold nanoparticles at the same concentration for the current study and after 5, 10, 20, 30, and 60 min., they proved that all concentrations had a potential effect against protoscolices, while the highest mortality rate reached 76% (4000 µg/ml/ 60 min.).

Conclusion

It was concluded from this study that the ZrO2 was effective in the killing of the protoscolices of hydatid cysts, and the highest mortality rate reached 53%. It can be used other concentrations to elevate the efficiency of ZrO2 or combine these nanoparticles with plant extracts or drugs. It is suggested to study the effect of ZrO2 against hydatid disease in vivo, to ensure its safety and possible use as a treatment against this disease in the future.

Molecular Study of Fimh Gene in Klebsiella Pneumoniae Isolated From Urinary Catheter Patients

Israa Abdul Ameer Al-Kraety1, Zahraa Hameed Oda Alquraishi2, Aqeel A Alsadawi3

1Lecturer Department of Medical Laboratory Techniques, Faculty of Medical and Health Techniques, University of AlKafeel, Najaf, Iraq, 2 Lecturer College of health & Medical tech., Al-Furat Al-Awsat Technical University, Kufa, Iraq, 3Assistant lecturer Medical Laboratory Techniques Department, College of Medical Technology, The Islamic University, Najaf, Iraq

Abstract

This study aimed to isolate and diagnose K. pneumoniae from clinical specimens of urine from urinary catheterized patients and molecular Detection of FimH fimbrial adhesin in Klebsiella pneumonia in Najaf governorate from October 2018 to March 2019, which includes 40 clinical specimens (urine). The diagnosis of K. pneumoniae isolates was based on culture and biochemical characteristics as an initial diagnosis. The final diagnosis by the Vitek-2 compact system is automated besides the use of PCR technique to detect on fimH fimbrial adhesion gene.

The biochemical results showed that 40/40 isolates gave positive result of K. pneumoniae. These results were confirmed by Vitek showed that 40/40 were positive for K. pneumoniae isolated and PCR technique by using fimH gene where 14/40 were positive for K. pneumoniae isolated from urine urinary catheterized patients.

The study, which was conducted in the diagnosis of bacteria, concluded that the technique of compact Vitek-2 automated. The ability of bacteria to stick to the formation of biofilm was investigated by phenotypic method.

Keywords: K. pneumonia, fimH gene, urinary catheterized.

Introduction

Catheter-associated urinary tract infections (CAUTIs) are most frequent as a nosocomial infection with increased patient morbidity and health care costs. Klebsiella pneumoniae is a prominent opportunistic pathogen causing infection in 10% of the patients with urinary catheters. The catheter insertion provides site for bacteria attachment that is typical in Gram-negative enterobacteria (1, 2). Furthermore, about 30% of K. pneumoniae isolates are resistant to broad-spectrum antibiotics with many virulence factors that have been identified. Fimbrial adhesins play an important role in the bacteria pathogenicity that facilitate adherence to specific tissue surfaces. Type 1 fimbriae, especially FimH subunit, found in many members of Enterobacteriaceae and play an important role in UTI (3-5). Fimbriae are encoded by Fim gene cluster containing all fimbrial structure genes coding for repeating FimA subunits with an adhesin molecule (FimH) at the tip (6).

Material and Method

Patients and clinical specimens

A total of 40 urine samples were collected from urinary catheterized patients from different hospitals in Al-Najaf provenance from Oct. 2018 to March 2019.

Urine specimens were cultured on MacConkey and Blood agar figure (1), then inoculated at 37°C for 18-24 hours (7).
Identification of bacteria

It studied the colonial characteristics such as (shape, volume, color, borders and texture) and examined microscopically after staining with gram-stain (8) and biochemical test for diagnosis of *K. pneumoniae*. Finally, identification was performed with automated VITEK-2 compact system using G-ve ID cards.

Molecular study

Extraction of Genomic DNA

Genomic DNA was extracted by using boiling method DNA was extracted from colonies grown on agar plates by boiling method according to , taking colonies of bacteria grown on MacConkey agar plates were suspended in 300μl of Tris-EDTA Buffer buffer in Eppendorf tube, then vortex and boiling at 100°C for 15 min and immediately freeze at -20°C for 20 min to lyses the organisms and release the DNA, then centrifuged at 8000 xg for 5 min ,supematant transferred to new Eppendorf tube and stored at -20°C until used.

Polymerase Chain Reaction Protocol

The DNA extract of *K. pneumoniae*. Isolates were subjected to flageller gene genes listed in (Table 1) by using PCR. The protocol was used depending on Promega Biosystem manufacturer’s instruction. Single reaction (final reaction volume 20μl as in table (1). All PCR components were assembled in PCR tube and mixed by refrigerated microcentrifuge at 50 rcf for 10 second.

**Results and Discussion**

**Prevalence of *K. pneumoniae* specimens**

This study was conducted on 40 specimens from urine urinary catheterized patients during the period from October 2018 to March 2019, all these specimens 40 were inoculated on MacConkey and Blood agar medium as at 37°C for 18-24 hours (7).

**K. pneumoniae identification**

Morphologically characterization

The bacterial isolates obtained from clinical samples were identified initially according to cultural morphology, microscopic characteristics and biochemical tests. From those isolates, the cultural identification of *K. pneumoniae* was depended on the colonial morphology. Since the colonies of *K. pneumoniae* were grown on blood agar appears non-haemolytic smooth white colonies and red colour like shaped and smooth colonies when grown on the MacConkey agar, indicated that *K. pneumoniae* is able to ferment lactose sugar (Figure 4-1).

The results of biochemical tests that recorded in table (3) were considered as a complementary of the initial identification of *K. pneumoniae* isolates. The isolates confirm to general characteristics, isolates were negative for oxidase test. Urease production and Simmons citrate utilization and catalase test positive result. All the result (morphology and cultural) were identical with (10).

Table 3: The Biochemical features of *K. pneumoniae*

</tr>
<tr>
<td>Catalase test</td>
<td>+</td>
</tr>
</tbody>
</table>

Upon detailed bacteriological investigation based on the morphological, cultural and biochemical tests were 40 isolates as tentatively identified as *K. pneumoniae*.

The final identification was performed with the automated VITEK-2 compact system using GN-ID cards.
which contained 47 biochemical tests and one negative control well (Appendix1). The results demonstrate that 40 isolates from urine urinary catheterized patients were confirmed as *K. pneumoniae* with ID message confidence level ranging between very good to excellent (Probability percentage 99).

**Virulence factors of *K. pneumoniae***

**Adherence Variation**

Biofilm forming ability is highly linked to bacteria swarming in, which is represented as an important virulent factor \((11, 12)\). All of the tested isolates showed \((2cm-8cm)\) swarming (increase in colony diameter) after 24 hrs of incubation. The rates of the migration were measured at 0, 6, 12, 18 and 24 hr. At 0 hr, *K. pneumoniae* isolates appeared with no migration. At 6 hr and 12 hr, *K. pneumoniae* isolates appeared with same rate of migration. After 18-24 hrs, most of the *K. pneumoniae* isolates covered the entire media surface. These results agree with the findings of \((12)\) who reported more than \(1.5Cm - 7.7Cm\) after 24 hrs of incubation.

**Molecular Study**

**Genomic DNA Extraction**

DNA Genomic was successfully extracted from *K. pneumoniae* isolates by using boiling method. The concentration and purity of extracted DNA were directly determined by spectrophotometry, extracted DNA purity ranged between \((1.8 - 2)\). Extracted DNA were confirmed and analyzed by gel electrophoresis.

**Molecular Detection of fimH gene of *K. pneumoniae***

The results showed that *fimH* gene was detected in 14 / 40 of *K. pneumoniae* isolates as in figure (2).

![Figure 2: PCR amplicon of *K. pneumoniae* fimH gene. Product size 688bp. Lane (L), DNA marker (100-bp ladder), Lanes (1 to 14) positive results.](image)

Fimbriae are assumed to play critical roles in attachment to epithelial cell surfaces. Binding to specific host receptors, fimbriae mediate the bacterial colonization, host cell signaling. Fimbrial adhesins determine the fate of the bacterial pathogen in the host as well as the progress of the corresponding disease process. Type-1 fimbriae also play an important role in deciding the virulence of the organism. Experiments conducted by Jaroni indicated that a mannose-resistant haemagglutinin was required for the attachment of Klebsiella to target cells \((13)\). The present result assumed important role of fimbriae 1 in attachment to epithelial cell surface (mediates the bacterial colonization) and deciding the virulence of the *K. pneumoniae*. The relationship between mannose – sensitive hemagglutinin (MSHA) or type 1 fimbriae and pathogenesis of bacteria was established from adherence of bacteria in mucous surfaces or epithelial cells of gastric tract \((14)\).

**Conclusions**

The use of Vitek-2 system, is necessary to confirm precise identification of this pathogen. Clinical isolates of *K. pneumoniae* possess number of virulence factor that associated with Urinary Catheter such as adhesion factors (biofilm). The *fimH* gene that encoded for adhesion factors (biofilm) was found almost in *K. pneumoniae* isolates.

Chemerin Level as a Marker in Preeclampsia and its Relation to the Disease Severity and Neonatal Outcome

Ali Mohammed Murad1, Marwa Jaafar Sadac2, Hanan Hazim Mohammed Noori3

1Department of Obstetrics and Gynecology, College of Medicine, Mustansiriya University, Baghdad, Iraq, 2Ministry of Health, Al-Yarmouk Teaching Hospital, Baghdad, Iraq, 3Head of Department of Gynecology and Obstetrics, Al-Qaim Hospital, Al-Anbar Province, Iraq

Abstract

Aim of study: To detect serum chemerin level in patient with preeclampsia and evaluate the association between maternal serum chemerin, disease severity and neonatal outcome.

Patients and Method: A case control study included 100 pregnant women with singleton pregnancy, gestational age of 20 weeks or more, normal fetal morphology, and absence of concomitant diseases, who were collected from inpatient during delivery was conducted in the Department of Obstetrics and Gynecology at Al-Yarmouk Teaching Hospital during the period from 1st of June 2018 till end of May 2019. They were divided into three groups (control, mild preeclampsia, and severe preeclampsia). Patients with history of chronic hypertension, diabetes mellitus, cardiovascular disease, neurological disorder, renal impairment, or premature rapture of membrane were excluded from this study. blood sample was taken from all patients and sent for human chemerin assay. After delivery, birthweight of baby, APGAR scores at one and five mints, neonatal intensive care unit and adult intensive care unit admission, and hospitalization time were also noted.

Results: There were no statistically significant differences between the study groups in age, BMI level, and parity. Chemerin level was significantly elevated in patients with severe preeclampsia (435.06 ng/ml) and mild preeclampsia (227.49 ng/ml) than that in non-preeclamptic patients (202.6 ng/ml). It was negatively correlated with each of gestational age, birth weight, Apgar score at one and five minutes. While it was positively correlated with admission’s duration. Serum chemerin > 228.5 ng/ml is predictive for diagnosis of preeclampsia and level > 380.9 ng/ml is indicator for severe preeclampsia.

Conclusion: Chemerin may play a role in the pathogenesis of preeclampsia as maternal serum chemerin level was significantly higher in patients with preeclampsia

Keywords: Preeclampsia, chemerin, APGAR score, birthweight, Iraq

Introduction

Preeclampsia (PE) is a syndrome that chiefly includes the new onset of hypertension and either proteinuria or signs of other end-organ dysfunction (e.g. hepatic abnormality, pulmonary edema, thrombocytopenia) (1). PE affect between 3% and 5% of all pregnancies and account for more than 60,000 maternal and 500,000 fetal deaths per year worldwide (2). It is one of the most important causes of maternal, perinatal, and fetal morbidity and mortality in the world (3). Deficient spiral artery remodeling, placental ischemia, release of mediators into the maternal circulation, systemic endothelial dysfunction, inflammation, and consequent increased vascular constriction are biological mechanisms that contribute to preeclampsia (4, 5). Additionally, abnormal placentation, imbalance of angiogenesis regulators, and maternal immune
maladaptation are other possible factors associated with preeclampsia (6). Moreover, the future risk of vascular and metabolic disease is significantly increased after a preeclamptic pregnancy (7). However, the pathogenesis of this life-threatening condition remains unclear (8). The placenta is thought to be a major source of endogenous nitric oxide (NO) during pregnancy. Endothelial NO, which is synthesized by endothelial NO synthase (eNOS), is an important regulator of blood flow and vasomotor tone via its inhibition of smooth muscle contraction. Thus, it is hypothesized that NO–eNOS system abnormalities are associated with the onset of preeclampsia (9, 10). Chemerin, named also as tazarotene-induced gene protein 2 or retinoic acid receptor responder protein 2, is a novel adipocytokine that is mainly expressed in adipocytes, liver, placenta, and ovaries (11). Evidence has been presented that chemerin is linked to facets of the metabolic syndrome in vitro and in vivo (12) hence this adipokine is correlated with insulin resistance and body fat accumulation (13). Hypertension, coronary disease (14), diabetes mellitus (15), atherosclerosis (16), obesity and metabolic syndrome (17) are also associated with chemerin. Although its specific biological functions are controversial, chemerin may play a role in the pathogenesis in preeclampsia. The aim of this study is to determine whether serum chemerin concentrations are elevated in preeclamptic women and whether serum chemerin levels differ according to severity of preeclampsia and to evaluate the association between maternal serum chemerin and neonatal outcome.

Patients and Method

Study design, setting: This is a case control study that was conducted in the Department of Obstetrics and Gynecology at Al-Yarmouk Teaching Hospital during the period from 1st of June 2018 till end of May 2019.

Study Population and Sample Size: The study included 100 pregnant women with singleton pregnancy, gestational age of 20 weeks or more, normal fetal morphology, and absence of concomitant diseases, who were collected from inpatient during delivery in labor room. They were divided into three groups:

- Severe Group: Included 33 pregnant women who had diagnosed with severe PE.
- Mild Group: Included 33 pregnant women who had diagnosed with mild PE.
- Control Group: Included 34 pregnant women with uncomplicated pregnancy who were selected after matching for age and gestational age of another one in the other two groups after proof that she was normotensive by history, examination and investigation.

Mild PE is diagnosed when hypertension with two readings (separated by 4-6 hrs. apart) of systolic blood pressure ≥140 mmHg and / or diastolic pressure ≥90 mmHg. Another characteristic feature of mild PE is the development of proteinuria ≥300 mg / 24 hrs. (18). Severe PE can be identified by presence of sustained elevation in blood pressure, systolic blood pressure ≥160 mmHg or diastolic blood pressure ≥110 mmHg, proteinuria of >2 gm in a 24-hrs urine specimen, serum creatinine of >1.2 mg/dl, platelets of <100,000/dl, increased lactate dehydrogenase, elevated serum transaminase levels, persistent headache, and oliguria (urinary output<400 ml/24 hours). In addition, any patient with cerebral or visual impairment, persistent epigastric pain, pulmonary edema or cyanosis, impaired liver function, or thrombocytopenia (platelet count less than 100,000/ml) was diagnosed with severe PE (3). Pregnant women with history of chronic hypertension, diabetes, cardiovascular disease, neurological disorders, renal impairment, or with premature rapture of membrane were excluded from this study.

Data collection: All patient told about the nature of the study and verbal consent was taken from them. Information about maternal age, gestational age, parity, gravidity, mode of delivery, previous history of preeclampsia, family history of any previous medical history. Then both group undergo to general examination, vital signs (systolic and diastolic blood pressure), abdominal and obstetric examination, laboratory investigation and sonographic examination. Then, from all study patients, we took 10 ml blood sample which was divided into two equal parts, the first one was sent to our hospital laboratories for CBC, blood group and Rh, blood sugar, b. urea, s. creatinine, SGOT, SGPT, coagulation profile and platelet count. In the other part, serum was separated by centrifugation at 2,500 rpm for 10 min and frozen at -70 °C. The serum chemerin levels were measured by enzyme linked immunosorbent assay according to the manufacturer’s instructions. The lowest level of human chemerin that can be detected by this assay is 31.2 ng/ml.

After delivery, birthweight of baby, APGAR scores at one and five mints, neonatal intensive care unit
(NICU) and adult intensive care unit (AICU) admission, and hospitalization time were also noted.

**Statistical analysis**

The data analyzed using Statistical Package for Social Sciences (SPSS) version 25. They presented as mean, standard deviation and ranges. Categorical data presented by frequencies and percentages. Analysis of Variance (ANOVA) (two tailed) was used to compare the continuous variables accordingly. Pearson’s correlation test (r) was used to assess correlation between continuous variables accordingly. Receiver operating characteristic (ROC) curve analysis was used for prediction of chemerin level as diagnostic of preeclampsia. A level of P – value less than 0.05 was considered significant.

**Results**

In this study, 100 pregnant women were enrolled. The age was ranging from 17 to 40 years with a mean of 25.9 ± 6.13 years. Regarding general characteristics, there were no statistical significant differences (P ≥ 0.05) between the study groups in age, BMI, and parity. Concerning blood pressure, SBP and DBP were significantly higher in severe group than that in mild and control groups (169.34 versus 148.93 and 123.81 mmHg, P= 0.001; and 107.1 versus 95.9 and 75.53 mmHg, P= 0.001 respectively).

About investigation, AST, ALT, s. urea and chemerin level were significantly higher in severe group than that in mild and control groups (155.06 versus 45.48 and 30.37 U/l, P= 0.001; 126.0 versus 35.36 and 25.71 U/l, P= 0.001; 31.65 versus 25.0 and 25.78 mg/dl, P= 0.001; and 435.06 versus 227.49 and 202.6 ng/ml, P= 0.001 respectively). Mean of platelet count was significantly lower in severe group than that in mild and control groups (101.65 versus 149.21 and 198.09, P= 0.001)

No statistical significant differences (P ≥ 0.05) between the study groups in WBC and s. creatinine as shown in table (1).

**Discussion**

Recently, it has been reported that circulating chemerin concentrations were strongly correlated with the key markers of the metabolic syndrome, including insulin resistance, hyperlipidemia, and high blood pressure. In the current study, we found that maternal serum chemerin level was significantly higher in severe and mild preeclamptic patients compared to healthy pregnant women, and elevated serum chemerin level (>228.5 ng/ml) indicated preeclampsia with 89.3% sensitivity and 94.1% specificity and > 380.9 ng/ml indicated severe preeclampsia with 93.9% sensitivity and 100% specificity. These result was agreed with results conducted by Cetin et al study 2017 (3), Xu QL et al study 2014 (19), Wang L et al study 2015 (8), Duan DM et al study 2012 (20), and Stepan H et al study 2011 (21) when they all showed that serum chemerin was significantly higher in patients with preeclampsia than that of healthy pregnant women. These findings indicate that differential expressions of chemerin may be responsible for pathological changes in patients with preeclampsia. Chemerin was identified in maternal circulation during pregnancy. Placenta releases the major part of chemerin during the gestational period and also it plays a critical role in controlling/contributing to metabolic processes (22, 23). The signaling pathway between high expression of chemerin and its receptor CMKLR1 is the common pathogenic factor of obesity, diabetes, hypertension and metabolic syndrome (24).

In this study, chemerin level was negatively correlated with each of gestational age, birth weight, Apgar score at one and five minutes, while it was positively correlated with admission’s duration. This is similar to studies conducted by Cetin et al 2017 (3), and by Duan DM et al 2012 (20). Additionally, preeclampsia can lead to higher frequency of induced labor, neonatal respiratory difficulties, and increased frequency admission to neonatal intensive care unit (25). In conclusion, maternal serum chemerin level is significantly increased in preeclampsia, especially in severe preeclampsia. Larger studies and work are needed to better determine the mechanisms by which serum chemerin is increased in preeclampsia.

Production, Analysis and Optimization of Inulin Produced from *Pseudomonas fluorescens*

Alyaa Razooqi Hussein¹, Alaa Raheem Kadhim²
¹Assist. Prof. Dr., ²Lecturer. Dr. Department of Biology, College of Science, University of Baghdad, Baghdad-Iraq

**Abstract**

Inulin is a natural polysaccharide produced from organisms and microorganism. Inulin is a type of fructan that α-amylase cannot digest it and cannot hydrolysis by hydrolytic enzymes. It was used to get non-fat fermented milk and it’s a type of prebiotics that induce growth and activity of probiotics bacteria, thus improving the health. *Pseudomonas fluorescens* have the capacity to produce inulin when grown in media supplied with sucrose. Twenty-two of bacterial isolates were belong to *Pseudomonas fluorescens* depending on structural features, microscopic checking, biochemical analysis and flourescent pigments that produced on King B medium. Ten isolates of *P. fluorescens* had strongly degree of mucous growth on solid production medium, the gummy and mucous manifestation on agar medium containing sucrose were give rise to inulin production. Inulin produced from *P. fluorescens* was analyzed by Fourier Transform Infrared Spectroscopy to detect functional groups which it was (C-O, CH, OH and C=O) and by Thin Layer Chromatography to determine its components of monosaccharide. Inulin distinguished as dark spot on white background and the Rf of it was (0.58). The best product of inulin were in production salt agar medium containing 20% sucrose, pH =7, Temperature =37°C without nitrogen sources and the inoculum size 1%, it was (3.2 gm ∕100 ml). The effects of bacterial inulin on the growth of *Saccharomyces cerevisiae* was studied by culturing it in medium supplemented with 3% of bacterial inulin at 30°C for 48 hrs. The results showed there was no remarkable effect of inulin on *Saccharomyces cerevisiae* growth in comparison to control.

**Keywords:** Inulin, Fructan, Levan, *Pseudomonas fluorescens*, *Saccharomyces cerevisiae*, Probiotic, Prebiotics, Biochemical test.

**Introduction**

Inulin is a natural polysaccharide produced from organisms and microorganism (¹, ²). It is a type of fructan that α-amylase cannot digest it and cannot hydrolysis by hydrolytic enzymes (³, ⁴). Inulin have protective effect on the survival and activity of lactic acid bacteria when storage and use it as final product (⁵, ⁶), and it was stimulated the growth of probiotic bacteria thus improving the health (⁷). In food technology inulin use to improve body mouthful, as stabilizers, fat replacers, and flavour enhacers (⁸, ⁹), *Pseudomonas fluorescens* capable for adaptation at different environments by extracellular substances (¹⁰). Living micro-organisms and its products are widely used for therapeutic purposes, *Saccharomyces cerevisiae* also possess some medicinal efficiency, and the beneficial properties of it are well documented (¹¹, ¹²).

At present day many pharmaceutical preparations with microorganisms products are commercially available (¹³, ¹⁴).

The aim of this study was to seek the capacity of local isolate of *Pseudomonas fluorescens* to produce inulin in different conditions and the effect of inulin on *Saccharomyces cerevisiae* growth.

**Materials and Method**

**Samples collection**

Thirty-five of different food samples were collected from different local markets in Baghdad governorate in sterilized utensil and imparted to the laboratory until using.

**Sorting and Identity of bacteria**

Half-gram were taken from specimen and 4.5 ml of sterilized peptone water were added, next dilutions were done, MacConkey agar was prepared and inoculated with 100 μl from the adequate dilution (1×10⁷), incubated at 37°C for 24 hrs. Fluorescing colonies were taken
and streaked again on the same agar medium several times till a pure culture was obtained. Bacterial isolates were identified by using selective medium (King B medium), structural features, microscopic checking and biochemical analysis (15).

**Checking of Inulin generating isolates**

Purified bacterial isolates were activated in Brain Heart Infusion broth (BHI), after incubation periods (0.1 ml) of culture suspension was streaking on production medium (3gm KH2PO4, 3gm K2HPO4, 0.5 gm MgSO4.7H2O, 20% w/v of sucrose and 2% agar-agar), incubated at 37°C for 24hrs. Mucoid consistence of bacterial colonies gave marked of inulin production.

**Quantitative checking in liquid medium**

The highly mucous isolates were selected, 10 ml of (BHI) broth were prepared and inoculated with bacterial isolates then incubated for 18hrs at 37°C, after incubation periods 100 ml of mineral broth (supplied with 20% of sucrose) was cultivated with 1ml of isolates, incubated for 24hrs, 37°C. Centrifuge were using (6000rpm, 30 minutes) for extracting inulin by mixing the cell free supernatant with ethanol at rate (1:4) and allowed to stand overnight, the aqueous layer was removed and the layer of inulin was collected in sterilized petri-dish and dried at 60°C.(16).

**Diagnosis of Inulin:**

a) **Fourier Transform Infrared Spectroscopy (FTIR):** Inulin dried weight was analyzed by using the crystal of potassium bromide (KBr) at rate 1:10 (w/w) (17)

b) **Thin Layer Chromatography (TLC):** This method was done according to (Shida et al. (2002)) (18) as following:

1. Inulin was dissolved (0.01gm) in 1N HCL and incubated at 70°C for 3 hrs.

2. About 10 µl of this suspension was taken and spotted plentiful of time away from the below end of TLC plate.

3. Sucrose, Fructose and Glucose solutions were destined and spotted in the same manner and they used as marker.

4. The plate of TLC placed in a closed jar containing separation system (butanol: propanol: D.W.: acetic acid at proportion of (7:5:4:2,v:v:v:v), until spread through the plate at 15 cm.

5. TLC taken and drying up.

7. Inulin demonstration as dark spot and the space of it were determination.

8. Relative flow (Rf) estimation as the following:

Distance of the sample mobilized across the plate / Distance of the solvent (20).

**Influence of some factors on inulin product**

1. **Carbon**

   A. Production broth (supplied with 20% of glucose and lactose) were prepared, inoculated with bacterial growth culture, incubated for 24hrs, 37°C.

   B. Extraction of inulin and determination of dry weight.

   C. Comparison with inulin dry weight which extracted from mineral broth containing 20% sucrose.

2. **Nitrogen**

   A. Production broth with best carbon source were prepared with addition of 1% (yeast extract and peptone), inoculated with bacterial growth culture, incubated for 24hrs, 37°C.

   B. Extraction the product and determination the weight.

3. **pHs**

   A. Production broth with best carbon source prepared at pHs (5, 6, 7, 8, 9 and 10), inoculated with bacterial growth culture, incubated for 24hrs, 37°C.

   B. Extraction the product and determination the weight.

4. **Temperature**

   A. Production broth with best (carbon source and pH) prepared, inoculated with bacterial growth culture, incubated for 24hrs, at (37, 45 and 50°C).

   B. Extraction the product and determination the
weight.

The effect of inulin on *Saccharomyces cerevisiae* growth

In order to investigate *Saccharomyces cerevisiae* growth in existing inulin, *S. cerevisiae* was cultivated in potato dextrose broth, incubated at 30°C for 48hrs then centrifugation for 15 min with 2500×g at 4°C. The precipitate was taken and washed by (PBS) (0.1 M phosphate buffer pH 7.4, 0.9% saline) and re suspended in PBS.

The suspension was cultured in medium supplied with 3% inulin, incubated at 30°C for 48hrs. The turbidity of cultured medium was measured at 600 nm for up to 48 hrs and compared with control cultured medium free from inulin (21).

Results and Discussion

Sorting and Identity of *Pseudomonas*:

Thirty-five of different food samples were collected from different local markets in Baghdad governorate. Twenty-tow of this isolates were diagnosed as *Pseudomonas* according to structural features and microscopic checking (17). Fluorescent producing on King B medium and Microscopic examination showed Gram-negative bacilli, non spore former bacteria and biochemical analysis showed (urease+, oxidase +, Gelatine hydrolysis +, Catalase +, Starch hydrolysis -) these results showed that they were identified as strains of *Pseudomonas fluorescens* (22).

Checking of Inulin generating isolates

*Pseudomonas fluorescens* streaking on production medium; for checking their capability to generate mucus manifestation as marking for Inulin production.

Inulin production was varied from species to species. The gummy and mucous manifestation is coming from manufacturing of polysaccharide (23).

Quantitative checking in liquid medium

Ten isolates of *P. fluorescens* with strongly degree of mucous growth had selected for checking their capability to generate inulin in broth medium that supplied with 20% of sucrose.

The highly mucous appearance of these isolates were taken for creation of inulin in mineral salt broth and the highly product was 3.2 gm/100 ml.

Diagnosis of Inulin:

a) Fourier Transform Infrared Spectroscopy (FTIR): Inulin generated by *P. fluorescens* was analyzed by FTIR spectroscopy to detect the effective structure of inulin.

The results showed the presence of C-O stretching group in 1122.49 cm⁻¹, bending group CH,OH in 1336.58 cm⁻¹ and 1434.23 cm⁻¹, stretching C=O in1649.02 cm⁻¹, stretching CH in 2891.10 cm⁻¹ and 2931.60 cm⁻¹, stretching OH in 3367.48 cm⁻¹ and 3431.13 cm⁻¹ as showed in figure (1). All these groups (C-O, CH, OH and C=O) are functional groups found in carbohydrates (17),

Figure 1: FT-IR for inulin production from *P. fluorescens*
Kazim AR. (2015) \(^{17}\) reported that polysaccharide extracted from \textit{Pseudomonas} does not contain lipids or nucleic acid in structures.

b) Thin Layer Chromatography (TLC): Inulin production from \textit{P. fluorescens} was analyzed by TLC chromatography to determine its components of monosaccharide.

Inulin extracted from \textit{P. fluorescens} was hydrolyzed with HCL before application on TLC and standard sugars (glucose, fructose and sucrose) were prepared and used as marker.

These sugars distinguished as dark spot on TLC plate when using TLC diagnosis solution (ethanol:H\textsubscript{2}SO\textsubscript{4} at proportion of 9:1, v:v.) as showed in figure (2).

Rf of these sugars (inulin, fructose, sucrose and glucose) were estimated according to Ghosh, S. and Chandra, A. (1980) \(^{20}\) and the results were (0.58, 0.59, 0.57 and 0.55) respectively.

Rf for the same compound differed according to (separation system, diagnosis solution and type of solvent) \(^{24}\).

![Figure 2: TLC for Inulin production from \textit{P. fluorescens}: Note: (1) inulin, (2)fructose, (3)sucrose and (4)glucose.](image_url)

**Influence of some factors on inulin product**

1. **Influence of carbon**

   Inulin product may be Influence by the (type, kind and concentration) of carbon substance.

   For investigation the influence of carbon, production medium supplied with 20\% of glucose, lactose and sucrose inoculated with \textit{Pseudomonas flourescens} and incubated for 24hrs, 37\(^{0}\)C.

   From study of the results, the best product of inulin from \textit{Pseudomonas flourescens} was obtained from production medium supplied with sucrose (3.2 gm/100 ml) and the minimum productivity was in existence of glucose (0.2gm/100 ml) as shown in figure(3).

   The amount of inulin was varied and the highest inulin production was produced when \textit{Pseudomonas flourescens} was cultivated in medium containing 20\% of sucrose.

   Microorganisms catabolized polysaccharide such as sucrose by levansucrase enzyme which degradation of sucrose \(^{15}\).

![Figure 3: Influence of carbon sources on the productivity of inulin from \textit{Pseudomonas flourescens}](image_url)

2. **Influence of nitrogen**

   By studying the results showed that there was reducing in productivity of inulin when supplying production medium with 1\% of yeast extract and peptone.

   The productivity decrease from (3.2 gm/100ml) to (2.1 gm/100) when supplied production medium with yeast extract and to (1.8 gm/100ml) in the present of peptone in medium as shown in figure (5).

   Microorganisms required nitrogen to complete the metabolic pathway, also nitrogen enhances and increase the microorganism growth; these increasing in growth may be decreased the production of inulin.

   The effect of yeast extract in production medium was studied previously, rising concentration of yeast extract responsible for an increase in the \textit{Zymomonas mobilis} and reduction the productivity of inulin, yeast extract also improves and enhancement of substrate consumption, increasing in consumption of substrate verified only a small part of consumed sugar and converted it to Inulin \(^{25}\).
3. **Influence of pHs**

From the results revealed; inulin productivity was varied with pH of production medium, the productivity decrease in pHs less than 7 and more than 7 as showed in figure (5).

Inulin is chemically stable in a natural and alkaline environment and its stability decreases in an acidic environment (25).

4. **Influence of temperature**

It was revealed that the best productivity of inulin at 37°C (3.2 gm/100ml) and the productivity was decrease at temperature above than 37°C, it was 2.1gm/100ml at 45°C and 0.1gm/100ml, figure (6).

From the result, the best temperature for the productivity was 37°C and at this temperature enzyme responsible for inulin may be synthesis.

Fructosyltransferase enzymes (FTFs) is bacterial enzymes responsible for synthesis of inulin and frctun from sucrose in three reactions (25).
**Fungal Growth study**

In order to investigate *Saccharomyces cerevisiae* growth in existing inulin, *S.cerevisiae* suspension was cultured in medium supplied with 3% inulin, incubated at 30°C for 48hrs. The turbidity of cultured medium was measured at 600 nm for up to 48 hrs and compared with control cultured medium free from inulin.

From the results of OD, (OD of control (2.8278), OD of test medium supplied with 3% inulin was 3.0158) there was no remarkable effect of inulin on *S.cerevisiae* growth when compared with the growth of control. *S.cerevisiae* had not enzymes responsible for degradation of inulin and used it as carbon sources.

Inulinases hydrolysis of inulin to glucose and fructose; already these molecules can be used as carbon sources to produce many beneficial products for microorganisms.

**Conclusion**

These studied seeking for the capacity of inulin production from local isolate of *Pseudomonas fluorescens*. The results showed no remarkable effectiveness of inulin on the proliferation of *Saccharomyces cerevisiae* compared with control.

Epidemiology of Hepatitis B and C in Al-Muthanna Province

Adian Abd Alrazak Dakl1, Wafaa Ayad Alnuaimy1

1Department of Biology, Science College, University of Al-Muthanna, Iraq

Abstract

This study systematically reviewed and synthesized available records of hepatitis B and C prevalence in Al-Muthanna province through the last five years from early 2014 till the end of 2018 in Women and Children Teaching Hospital at Al-Muthanna province. The study recorded high prevalence of hepatitis virus at this region, most of the patient were females and HCV was the most prevalent between them, the year of 2016 recorded the highest infection rate. Conclusion: High rate of Hepatitis C virus infection among of thalassemia patients

Keywords: hepatitis, blood donor, thalassemia

Introduction

Hepatitis is an inflammation of the liver, most commonly caused by a viral infection. There are 5 main hepatitis viruses, referred to as types A, B, C, D and E. These five types are of greatest concern because of the burden of illness and death they cause and the potential for outbreaks and epidemic spread. In particular, types B and C lead to chronic disease in hundreds of millions of people and, together, are the most common cause of liver cirrhosis and cancer. Hepatitis A and E are typically caused by ingestion of contaminated food or water. Hepatitis B, C and D usually occur as a result of parental contact with infected body fluids. Common modes of transmission for these viruses include receipt of contaminated blood or blood products, invasive medical procedures using contaminated equipment and for hepatitis B transmission from mother to baby at birth, from family member to child, and also by sexual contact.

The most common diseases that are transmitted through blood are hepatitis B and hepatitis C viruses. Infections with hepatitis B virus (HBV) and hepatitis C virus (HCV) are a worldwide public health problem. In Iraq, viral hepatitis prevention and control program was started during early seventies.

The transmission of HCV is primarily through exposure to infected blood. Risks for transmission include blood transfusion before 1992, intravenous drug use, high risk sexual activity, solid organ transplantation from an infected donor, occupational exposure, hemodialysis, household exposure, birth to an infected mother, and intranasal cocaine use.

Review

Hepatitis B and C

Hepatitis B virus is a member of the Hepadnavirus family. The virus particle, called Dane particle (virion), consists of an outer lipid envelope and an icosahedral nucleocapsid core composed of protein. The nucleocapsid encloses the viral DNA and a DNA polymerase that has reverse transcriptase activity similar to retroviruses.

Viral infection by hepatitis B virus (HBV) causes many hepatocyte changes due to the direct action of a protein encoded by the virus, HBx, and to indirect changes due to a large increase in intracellular reactive oxygen species (ROS) after infection. HBx appears to dysregulate a number of cellular pathways. HBx causes dysregulation in part by binding to genomic DNA, changing expression patterns of miRNAs, affecting histone methyl transferases, binding to SIRT1 protein to activate transcription, and cooperating with histone methylases and demethylases to change cell expression patterns.

HBx is partly responsible for the approximate 10,000-fold increase in intracellular ROS upon chronic HBV infection. Increased ROS can be caused, in part, by localization of HBx to the mitochondria where HBx decreases the mitochondrial membrane potential, in addition, another HBV protein, HBsAg, also increases
ROS through interactions with the endoplasmic reticulum\(^{(10)}\).

Hepatitis C (originally “non-A non-B hepatitis”) is caused by hepatitis C virus (HCV), an RNA virus of the family Flaviviridae. HCV can be transmitted through contact with blood (including through sexual contact if the two parties’ blood is mixed) and can also cross the placenta. Hepatitis C usually leads to chronic hepatitis, culminating in cirrhosis in some people. It usually remains asymptomatic for decades. Patients with hepatitis C are susceptible to severe hepatitis if they contract either hepatitis A or B, so all persons with hepatitis C should be immunized against hepatitis A and hepatitis B if they are not already immune, and avoid alcohol. HCV viral levels can be reduced to undetectable levels by a combination of interferon and the antiviral drug ribavirin. The genotype of the virus is the primary determinant of the rate of response to this treatment regimen, with genotype 1 being the most resistant. Hepatitis C is the most common chronic blood-borne infection in the United States\(^{(11)}\).

**Material and Method**

The results of the last five years were collected from (Al-Muthanna Women and Children Teaching Hospital) and organized in tables and charts based on gender, age, year of injury, accompanying diseases and residential areas.

**Results and Discussion**

Thirty three cases were identified through the last five years 13 (39%) of them were infected with HBV and 20 (61%) were infected with HCV, this indicates that the type C was more prevalent during these years. 85% of infection were females as the results were collected from delivery hospital.

The age group (21-30) years was the most infected\((39.3\%)\) because it is the appropriate age for maturation and pregnancy and women are eligible for delivery in this age group, also the hospital was especially for women and children, while the age group \((≥10)\) years recorded the lowest rate, the CDC also notes that infections are rising among women of childbearing age, while the virus is not always transmitted from a pregnant woman to her baby, it is possible: About 6 infants in 100 born to mothers with the virus are infected\(^{(12)}\). Most cases were rural areas \((52\%)\) due to the use of drug injection is common. The year of 2016 recorded the
highest infection rate (36.3%) comparing with the year of 2015 which recorded no infections.

Fig (1): Distribution of HBV and HCV according to years of diagnosis

Three of the HCV cases had thalassemia as accompanying disease as hepatitis C virus (HCV) is the major cause of post-transfusion hepatitis infection (PTH). Patients with thalassemia major are at high risk of HCV(13).

The Impact of Congenital Heart Diseases on Growth Parameters in Children and Their Correlations with Leptin Levels

Fouad Shareef¹, Amal Salih Mahdi Bayee²

¹Assist. Prof. Dr. University of Kufa, College of Medicine./Iraq, ²Diploma. Researcher. Al-Hilla Teaching Hospital, Neonatal Care Unit./Iraq

Abstract

Children with congenital heart disease (CHD) prone to stunted growth by different parameters including weight, height and head circumference compared to a control groups, to accomplish such aim (110) children aged ranged (20 days – 13 years with CHD) have enrolled in this study, (83) patients with a cyanotic CHD (75.45%) and (27) cyanotic type (24.54%) were compared with (171) healthy controls of similar age and sex groups. This study was done in Al-Hilla teaching hospital during the period November 1, 2017 to October 11, 2018. The results indicate a significant (2.06) retardation in all parameters in patients with CHD related to control and there is a significant retardation in weight (z = 3.06) in children with cyanotic CHD related to a cyanotic type. Also there is a significant retardation (z = 1.01) in height gain in children with cyanotic related to a cyanotic type and finally there is a significant (z = 2.09) decrease in head circumference in children with cyanotic CHD related to a cyanotic type. Serum leptin levels were also lowered in all patients with CHD. The results concluded that children with (CHD) experience early and continues decrement of all growth parameter during their life.

Keywords: (children, congenital heart diseases, growth parameters, leptin levels)

Introduction

Congenital heart disease is defined as gross structural abnormality of the heart or intrathoracic great vessels that is actually or potentially of significant¹. It is considered as third congenital diseases in children and a leading cause of death in infant during first year of life². It prevalence is 5 to 8 per 1000 live births that varied in different parts of the world, in a recent study the prevalence has been reported to be ranged 4 to 50 cases per 1000 live Births²,¹⁴,¹⁶.

Several genetic and environmental risk factors have been introduced for CHD, and most important factors include genetic mutation, alcohol drinking, abusing some drugs (most famous thalidomide and cocaine using during pregnancy)⁴,¹⁷. The cytokines in many studies were found to have a strong effect on feeding, weight and energy intake in patients with CHD⁵. Impaired absorption can also be an important cause of malnutrition in CHD, therefore, children with CHD and delayed growth due to increased work of a cardiopulmonary and consequently, fatigue and loss of appetite, dyspnea, tachypnea and chronic hypoxia were directed to malnutrition⁴,⁸,¹⁵,²¹.

Recent studies shows series of serum factors such as leptin, ghrelin and tumor necrosis factor alpha (TNF-) will be changed in these patients. Consequently the rate of absorption of nutrients, growth, weight, energy consumption and storage are changing¹¹. These children with CHD have normal growth when receiving more calories compared to healthy ones⁹,¹² and malnutrition in these patients effects on the metabolic response to injury and complications and outcomes of cardiac surgery including sepsis, renal dysfunction, necrotizing enterocolitis, hospitalization days¹³,²¹.

The CHD is divided into four major groups of cyanotic with and without an increase in pulmonary artery pressure and a cyanotic heart defect with and without an increase in pulmonary artery pressure¹,²⁰. Since it has been shown that the prevalence of growth parameters retardation with CHD were increased in the
last decade in Iraqi population and since leptin hormone has been shown to be involved in long-term regulation of energy balance by suppressing appetite and stimulating weight loss(18) and such correlation has not been studied in Hilla (Babylon province), therefore, this study was undertaken to investigate:

1- The effect of CHD on anthropometries measurements of growth in children involving Weight, height and head circumference between control and cyanotic and a cyanotic CHD.

2- The variation in the effect of cyanotic and a cyanotic CHD on growth parameters.

3- Correlation of serum leptin levels with CHD.

**Materials and Method**

A study of (110) patients with CHD, (83) with a cyanotic CHD and (27) cyanotic CHD and (171) controls was carried out between November 1, 2017 to October 11, 2018 in AL Hilla Teaching Hospital. These patients divided into four groups according to their age. The criteria used for including the patients in the study are:

a) Patients with cyanotic and acyanotic CHD.

b) The age of patients ranged from (20 days – 13 years).

c) Parental consent.

The patients with other congenital anomalies, with chronic disease or acquired heart diseases were excluded from the study. The control groups were selected from general paediatric and neotal care clinics, and no pathological findings had been shown in their clinical examination. The patients and control were subjected to the following:

- Complete history and physical examination.

- Anthropometric measurement including length in cm, weight in kg and head circumference in cm.

- Investigation including:
  1- CXR interpreted by a radiologist
  2- E.C.G. standardized at 25 mm/s
  3- Echo Philips clearvue 350. USA. Used modes: M-mode, 2D and Doppler both continues and colour.

4- Blood samples were collected by venipuncture from all patients and controls. Samples were centrifuged at 3000 rpm for 20 minutes. Clear sera were separated and kept frozen at -20°C until the time of assay. Leptin was measured using the DRG Elisa (DRG international, Inc., USA) by indirect enzyme linked immunosorbent assay according to the protocol provided by manufacturer. The intensity of the colour developed is proportional to the concentration of leptin in the sample, the absorbance is measured at 450 nm and concentration were determine from standard curve.

**Statistical Analysis**

The -Z- Statistical test was done to the significance in difference of cyanotic and a cyanotic CHD on growth parameters in comparison with control (Daniel, 2009) (19).

The level of significance taken 95%

\[ Z_C = \]

If \( Z_C > 1.96 \) mean there is significant differences

**Results**

The hundred ten children with CHD represented by (83), 75.45% acyanotic group compared with cyanotic CHD (27) 24.54%. The patients were classified into four groups according to their age. (table 1).

P3: Cyanotic versus control groups.

Discussion

The study shows a statistical significant (z = 2.06) retardation in all growth parameters involving all age groups (below 1 year, 1-2 years, 2-5 years and above 5 years) but there is no significant (z = 1.2) differences between cyanotic and a cyanotic CHD in relation to any group. Table (1) shows more details, however, there is early presentation and diagnosis for children with cyanotic CHD possibly due to more aggressive clinical presentation in the infancy which attracts the parents attention to seek early medical help.

This study shows significant (z = 3.06) retardation in weight between groups of children with CHD and control, also shows significant (z = 2.04) retardation in children with cyanotic CHD, compared with a cyanotic groups, and this is an expected result due to more harmful effect of CHD (cyanotic) on the nutritional
status of children related to shortness of breath which presented as early failure to gain weight that may lead later on to growth retardation with its complications, (Figure 1) shows that weight retardation below the third centile (100%) in children more than 5 years with cyanotic CHD, also more effect of a cyanotic CHD on both groups (<1 year and 1–2 years, Figure 1) more than other groups (<1 year, 53.48%) at the third centile and more details can be shown on (Figure 1), these findings were consistent with other reports(14), mentioned that children with CHD experience early simultaneous decrease in growth trajectory across weight, length and head circumference, this decrement suggests a role for altered growth retardation in child with CHD.

There is a statistically significant (z = 2.28) retardation in height in children with CHD in comparison with controls, but there is a non-significant (z = 1.01) variation between cyanotic and a cyanotic type. These results were also comparable with finding where (52%) below the 16th centile for both length and weight and 27% were below the 3rd centile for weight and lengths, these comparable results probably indicated that the cause of growth retardation in CHD was multifactorial which could be due to inadequate caloric intake and feeding difficulty(11), in our study there was (25.92%) of cyanotic CHD retardation in height and (42.16%) of a cyanotic type with retardation in height, (Figure 2) shows that 50% of children with cyanotic CHD above 5 years at third centile mostly in cyanotic type.

Head circumference was significantly (z = 2.56) reduced in CHD children in comparison with controls, also there was significant (z = 2.09) retardation in cyanotic type related to acyanotic, this may be explained by early affection of children with cyanotic CHD related to severe symptoms associated with severe growth retardation that lead to affection of skull development later on, (Table 2, Figure 3) shows (50%) of cyanotic CHD children aging above 5 years their head circumference on the 3rd centile comparing with acyanotic type (8.33%) reach 95th centile, also (50%) of cyanotic type below 3rd centile while there is less effect of a cyanotic CHD in early infancy, these results were also agreed with Barbara(3) who mentioned that children with CHD had stunted growth and require feeding supplementation in nearly a quarter of them (during infancy) to meet the definition of failure to thrive in first year of life(3).

Leptin is a hormone that is produced mainly by the fatty tissue and released into peripheral circulation and binds to receptors in the hypothalamus to transmit information about triglyceride content of adipocyte, in addition to macronutrient content and energy composition of newly administered food(10). Low levels of leptin have been found to increase activity of orexigenic peptides and decrease activity of anorexigenic peptides, thereby, increasing appetite and stimulating weight gain(17). Our study demonstrated that serum leptin levels were significantly lowered compared with controls. These results were consistent with a researcher who found that children with CHD had lowered leptin levels than healthy controls(18), while other researcher found no significant difference in plasma leptin levels between cyanotic and acyanotic patients, however, these studies did not include a healthy control groups to compare with(11,18). This study also showed that all the anthropometric parameters in all groups were positively correlated with leptin levels. These findings were supported by others(9,11,12).

This study has some limitation since it was a single center study done in Babylon Province and in addition to hemodynamic variability associated with various types of CHD(11). It was concluded that children with CHD are at increased risk for poor growth parameters and reduced leptin levels in these patients suggesting a role for such hormone in regulating food intake, energy balance and maintenance of body weight. The abnormal hemodynamics and the hypermetabolic state of these patients will compromise nutrition and decreases IGF-1 synthesis with subsequent slowing of linear growth weight gain(20,16).

The incidence of growth disorders in these patients can emphasized that growth retardation in patients with CHD compared with healthy children can be attributed to differences in the factors affecting the growth of CHD children including gender, age, cardiac abnormalities simultaneous multiple valvular lesions and ultimately congestive heart failure that leads to multiple growth problems(3,17).

**Conclusions**

- There was significant decrease in all growth parameters (z = 2.06) in children with CHD related to control.
- There was a significant retardation in weight (z = 2.09) and head circumference (z = 2.09) between cyanotic and a cyanotic CHD.
- There was a non-significant retardation (z = 1.01) in height between cyanotic CHD and a cyanotic CHD.

- Serum leptin levels were lowered in both cyanotic and acyanotic patients with CHD.

Hormonal and Mineral Imbalance Effect on Bone Resorption in Predialysis Iraqi Patients with Chronic Kidney Disease

Inaam Ahmed Ameen¹, Sarah Hashim Mhaibes², Shahad Wisam Ahmed³, Kaled Nather Taha⁴ And Dhiakra Abdul Hameed Dawood⁵

¹Assistant Professor, ²Assistant Lecturer, ³Pharmacist / Department of Clinical Laboratory Sciences, College of Pharmacy, University of Baghdad, Baghdad, Iraq, ⁴Clinical Immunologist, ⁵Clinical Biochemist, Ministry of Health / Medical City / National Center for Educational Laboratories, Baghdad, Iraq

Abstract

Introduction: Chronic kidney disease mineral bone disorder is a metabolic bone disease present in almost all uremic patients. The aim of this research to indicate the stage of chronic kidney disease (CKD) that affect the bone metabolism that leading to the mineral and hormonal imbalance by studying the relationship among osteocalcin, glomerular filtration rate (GFR), parathyroid hormone, calcium and phosphorus levels in the blood.

Method: The study included 52 patients with predialysis chronic kidney disease stage 3-5 and 40 apparently healthy relatives accompanying the patients. Glomerular filtration rate (GFR) was calculated for each patient. Renal function tests, including serum levels of urea, creatinine, a biochemical marker of bone metabolism: osteocalcin (OSN), calcium, phosphorus, and parathyroid hormone (PTH), were measured for each participant.

Results: Serum urea and creatinine levels were significantly higher in CKD patients than that of apparently healthy control. There is significantly higher serum parathyroid hormone, serum phosphorus, serum osteocalcin (P<0.01, P<0.01, P<0.01 respectively) in CKD patients than that of the healthy control group. While low serum calcium level in CKD patients as compared to the corresponding group (P<0.01).

Conclusion: Hyperphosphatemia and hypocalcemia in the end stage of predialysis CKD patients lead to increase parathyroid hormone secretion, which causes high bone turnover characterized by significantly high serum osteocalcin in these patients. Parathyroid hormone and osteocalcin were used as a biomarker for the development of bone and mineral disorders in predialysis CKD patients.

Keywords: CKD, parathyroid hormone, osteocalcin, calcium, phosphorus

Introduction

Chronic kidney disease (CKD) has become a public health problem. The definition of CKD was introduced by National Kidney Foundation in 2002 and later adopted by the international group Kidney Disease Improving Global Outcomes in 2004, a decrease in kidney function with a glomerular filtration rate (GFR) < 60 mL/min per 1.73 m² and/or kidney damage for 3 months or more [1]. Chronic kidney disease, mineral bone disorder (CKD-MBD) is a metabolic bone disease present in almost all uremic patients. With uremia, bone is relatively resistant to parathyroid hormone (PTH) action, such that the average level of PTH is required to maintain bone turnover [2]. Relative hypoparathyroidism is associated with low-turnover or a dynamic bone disease [3]; severe secondary hyperparathyroidism leads to high turnover bone disease [4]. Secondary hyperparathyroidism occurs in CKD produces an imbalance between osteoclast activity and osteoblast synthetic activity, leading to enhanced bone breakdown at the end stage of renal disease [5].

Corresponding Author:
Sarah Hashim Mhaibes
E-mail: phsarahhashim@gmail.com
Osteocalcin (OSN) is a non-collagenous, vitamin K-dependent protein with 46–50 amino acid, produced by osteoblasts, it is a marker of bone formation [6]. High blood OSN levels are also in older adult humans, high levels in the blood are a predictor of lower bone density and a sign of fracture risk, including hip fractures and this because OSN levels can increase in the blood as a result of the breakdown of bone tissue [7]. The circulated OSN is removed by the kidney and liver [8], which increase in the blood when the renal function is declining. Patients with CKD show a progressive increase in serum OSN levels that closely corresponded with intact PTH and alkaline phosphatase levels. More fundamentally, such increases in serum OSN levels reflect the severity of the bone lesions [9].

Small increases in serum OSN were found in some patients at a severe stage, while a significant increase in blood OSN is shown in patients with end stage predialysis. In such patients, this elevation either due to decreased renal clearance of OSN or also reflected increased bone metabolism [10, 11]. There is a negative correlation between glomerular filtration rate (GFR) and plasma osteocalcin levels in predialysis patients [12].

The aim of this research to indicate the stage of chronic kidney disease that affects the bone metabolism that leading to the mineral and hormonal imbalance by studying the relationship among OSN, GFR, PTH, calcium and phosphorus levels in the blood.

Method

The case-control study was conducted from March to Jun 2019, at the National Center of Teaching Laboratories of Medical City Institute, Baghdad, Iraq. Data of predialysis CKD Iraqi patient’s attendant to Ghazi Alhariry hospital in Medical City in March 2019 for renal evaluation function were included in the study. The study was approved by the Ethics Committee of the University of Baghdad, Faculty of Pharmacy (UBCP-RECA-M62019A). 52 patients with predialysis chronic kidney disease stage 3-5 were enrolled, and 40 apparently healthy relatives accompanying the patients were selected. The purpose of the study and nature of all procedures were explained to participants, and informed approval was obtained before the commencement of the study. Patients were excluded if they had an acute infection, cancer, acute myocardial infarction, pulmonary edema, and patients on medication (steroid, bisphosphonates, calcium or vitamin D). The diagnosis of predialysis CKD patients was made by nephrologist based on the estimation of GFR together with renal function tests [table1]. GFR was calculated by the Modification of Diet in Renal Disease (MDRD) equation: 186 x (Creatinine/88.4)+1.154 x (Age)-0.203 x (0.742 if female) x (1.210 if black). Moderate reduction of GFR (30–59 mL/min/1.73 m²) in stage 3, severe reduction of GFR (15–29 mL/min/1.73 m²) in stage 4 preparation for renal replacement therapy and established kidney failure or end-stage renal disease (ESRD) (GFR <15 mL/min/1.73 m²) in stage 5 requiring permanent renal replacement therapy (RRT).

The serum OSN was determined by Chemiluminescent enzyme immunoassay using Immulite 1000 autoanalyzer [13] (LKON1Siemens, USA). Serum urea nitrogen was measured by using urease/glutamate dehydrogenase coupled enzymatic technique (Dimension clinical chemistry System, DF21 Siemens, USA). Serum creatinine was measured by using modified kinetic Jaffe technique (Dimension clinical chemistry System, DF33B Siemens, USA). Serum intact PTH was measured by using two-site chemiluminescent enzyme-labeled immunometric assay [14] (DPC Immulite 2000, Siemens, USA). Serum calcium and phosphorus levels were quantified by using Ca(DF23A), PO₄ (DF61A) Dimension Rxl Siemens autoanalyzer as per International Federation of Clinical Chemistry (IFCC) guidelines, modifications of calcium O-cresolphthalein complex one reaction (OCPC) and classical phosphomolybdate method, respectively [15, 16].

Statistical Analysis

It was performed by using the SPSS Statistics version 20.0 The results were expressed as mean and standard deviation. Results were analyzed utilizing One-way ANOVA was used to determine the significance degree between parameters. The p-value ≤0.05 was considered significant. ROC curve was used to identify the validity of markers as an indicator of the disease.

Results

Serum levels of both urea and creatinine levels were significantly higher in CKD patients than apparently healthy control. These results were used together with the estimated GFR (< 60 mL/min per 1.73 m²) to determine the stage of CKD in patients group [table 1].

HS=Highly significant difference (P<0.01)

Discussion

In the present study, the end stage of CKD patients has significantly higher serum concentration of the urea and creatinine as compared to stages 3-4 of CKD patients which is in agreement with other study[17]. This is due to the progressive reduction of GFR at the end stage of CKD patients. As the GFR decreases blood levels of both urea and creatinine are increased [18]. Significantly higher serum PTH levels at the end stage of CKD group among all studied patients groups, which is agree with the other findings which reported that the serum PTH was significantly higher in more advanced renal failure (stage 5 CKD), which confirms the relationship between severity of hyperparathyroidism and the degree of renal impairment [19,20]. Secondary hyperparathyroidism result from a decreased renal function, which is a common complication of CKD that leads to an overproduction of PTH caused by several changes that occur in bone and mineral metabolism because of decreased kidney function [21]. In this study, the CKD patients have hyperphosphatemia and hypocalcemia that leads to significant hyperparathyroidism when compared to healthy control patients with normal renal function.

At the end stage of CKD, when the remaining nephrons can no longer sufficiently excrete the phosphorus load, hyperphosphatemia is detected. The calcium and phosphorus form an insoluble complex in serum. This process may lead to extraskeletal calcification and potentially calciphylaxis or cardiac disease [22]. Retention of phosphorus also indirectly causes excessive production and secretion of PTH through lowering of ionized Ca\(^{2+}\) and by suppression of calcitriol production [19]. Vikrant S et al. was found increase serum PTH level in the end stage of CKD inversely correlated with GFR and serum calcium and positive correlation with serum phosphorus which is in agreement with this study [23]. Hyperphosphatemia is recognized as the primary initiator of the various cascades of the promoters of renal bone disease [24].

The present study shows increment serum osteocalcin levels associated with progressing stage of CKD up to higher concentration in the end stage CKD. Rix et al. who reported that patients with predialysis CKD had elevated serum levels of OSN with the more severe stage of CKD corresponding to the level of secondary hyperparathyroidism [25] as in agreement with this study.

In patients with impaired renal function plasma OSN levels are markedly elevated due to increased bone turnover and decreased renal elimination [26]. The effects of increased parathyroid hormone (PTH) resultant...
resistance to adaptive stimulation of bone formation by parathyroid hormone, permits the effects of kidney injury to inhibit bone formation despite the development of secondary hyperparathyroidism [27].

Phosphate retention, hypocalcemia, and bony resistance to the action of PTH all these factors may contribute to overactivity of parathyroid gland to increase synthesis and secretion of PTH in end stage CKD. High levels of OSN in blood at the end stage of CKD occurs due to elevated PTH which stimulate bone demineralization that characterized by accelerated rates of bone absorption and resorption.

Conclusion

Hyperphosphatemia and hypocalcemia in the end stage of predialysis CKD patients lead to increase parathyroid hormone secretion, which causes high bone turnover characterized by significantly high serum osteocalcin in these patients. PTH and OSN were used as a biomarker for the development of bone and mineral disorders in predialysis CKD patients. It is recommended that attending physicians monitor and control biochemical parameters early in the development of CKD before the need for dialysis to protect the CKD patients from any complications that will result in response to PTH.

Abstract

In this study, we proposed and designed a new control method for an electromyographically (EMG) controlled prosthetic hand. The objective is to increase the control efficiency of the human–machine interface and afford greater control of the prosthetic hand. The process works as follows: EMG biomedical signals acquired from Myoware sensors positioned on the relevant muscles are sent to the robot that consist of hand, Arduino and MATLAB program, which computes and controls the hand position in free space along with hand grasping operations. The Myoware device acquires muscle signals and sends them to the Arduino. The Arduino analyzes the received signals, based on which it controls the motor movement. In this design, the muscle signals are read and saved in a MATLAB system file. After program processing on the industrial hand which is applied by MATLAB simulation, the corresponding movement is transferred to the hand, enabling movements, such as, hand opening and closing according to the signal stored in the MATLAB system. In this study, hand and fingerprints were designed using a three-dimensional printer by separate recording finger and thumb signals. The muscle signals were then analyzed in order to obtain peak signal points and convert them into data. These results indicate the effectiveness of the proposed method and demonstrate the superiority of the method for amputees because of the improved controllability and perceptibility afforded by the design.

Keywords: Arduino controller., Electromyography, Hand robot, Prosthetic hand.

Introduction

Nowadays, the development of science and technology has led to prosthetic devices with promising functional capabilities and esthetic appearance in research domain in favor of commercialization¹.

The design of prosthetic hand is multidisciplinary, compelling knowledge of physiology, anatomy, electrical and electronics, mechanical design, software, and so on, depending on the nature of control Robotic prosthetic hands have attracted considerable attention in terms of their practical use by amputees. Artificial neural network is used to classify the signal features and subsequently recognize the performed movement ². Along this research line, Sumit et al. conducted real-time identification of active hand-movement EMG signals based on wrist-hand mobility for simultaneous control of prosthetic robotic hands ³. In another system, a fully wireless, mobile platform used for acquisition and communication of sEMG signals is embedded in a mobile control system, and Ottobock 13E200 EMG electrodes are used to acquire the EMG signals. The electrodes are attached to the patient’s remaining forearm stump. In addition, a laptop is used to provide the required computational power for the control of the prosthetic robotic hand ⁴. In the light of reducing costs, some studies have utilized an open-source design for the implementation of affordable, modular, compliant, under-actuated prosthetic fingers that can aid amputees who suffer from partial amputations (e.g., amputations of one or several fingers of the human hand, with the exception of the thumb) to regain lost dexterity ⁵. In general, the control design of a robotic arm employs fuzzy algorithms to interpret EMG signals from the flexor carpi radialis, extensor carpi radialis, and biceps brachii.
muscles. In one type of control approach, the control and acquisition system consists of a microprocessor, analog filtering, digital filtering and frequency analysis, and a fuzzy control system, and electromyographic grasp recognition together with an 8-bit microcontroller is used to control a veneered robotic hand to emulate six grasp types that are used for over 70% of daily activities. A new configuration of sEMG electrodes has been reported to reduce interference resulting from electrode shift depending on muscles movement. The authors suggested that optimizing electrode configuration can improve the EMG pattern discrimination, wherein the proposed electrode configuration has a reference value.

Myoelectric prosthetic hands are primarily intended for adults but are also made by many companies for commercial purposes as prosthetic hand for children. It is also noteworthy that almost all robotic hands designed in university research projects consist of numerous actuators and sensors, which makes them unsuitable for manufacturing along with being too expensive for the typical user. In general, the medical industry can greatly benefit from providing low-cost portable systems that allow visualization of patient data easily and remotely while also providing quick access to accurate data in real time, thereby enhancing the efficiency of doctors and specialists along with providing the patient with greater ability and care.

Today, robotics considered as one of the best technologies that deal with design, working and applications of robots, computer systems their control and information processing. These technologies help physiotherapists and robotics engineers to model and design robotic hands. We aim something more than material and physical. As a result, we want to create opportunities for people with no hands and ability to last their daily lives.

**Aim and Objectives**

In this study, hand and finger prints were designed using a three-dimensional printer by separate recording finger and thumb signals. The muscle signals were then analyzed in order to obtain peak signal points and convert them into data. These data are classified according to muscular positions and used for hand control.

**Materials and Method**

**Mechanical Hand Design**

The prototype hand used in the study was a 3D printed version of the Flexy Hand. Therefore, the corresponding STL file was exported into the Makerbot platform and directly printed without any scaling or modification. Along with the separate parts of the hand, the printing of the entire hand took about 11 hours to be completed. The completed hand was strung with a fishing line and a stretched disposable pipette. The disposable pipette was used to clear any excess material from the 3D printing that would hinder the fishing line’s path through the interior of the hand and fingers, and to aid in threading the line through the palm of the hand. Each finger was strung with about two feet of fishing line to ensure that there would be sufficient material to reach down the length of the arm and attach to the servos.

**Motor Control**

A servo motor with three wires, power wire, ground wire, and pulse-width modulation (PWM) wire, was used to drive the hand. The PWM wire was connected to one of the six PWM ports of an Arduino UNO board. The power and ground wires of each servo were connected to the horizontal positive and negative rows on the breadboard that was connected to a 6-V battery pack. The battery pack housed four 1.5-V D-size batteries. The PC module was plugged into the USB cable.

**Hand Control**

In this section, we used an Arduino UNO unit in this study to analyze the EMG signals acquired from the muscles. The signal is handled by the motor, and the UNO board is also used to send PWM information to the motor for hand control. By Using Myo arm band to provide the signal for MATLAB for recording it and simulating the signal after passing from equalization then the command which has been created by MATLAB will be pass to the microcontroller which has the all control to the hand by using servos.

Another benefit of having a simulation of the hand model is that it allows representing the results as functions of parameters (such as, the weight or type of material) to work on further improvements. Lastly, the grasp quality and optimization of the finger positions for different grasps are other crucial aspects that can be tested with a good model. The Simulink program is designed for multidomain simulation and model-based design. As mentioned previously, Simulink has the ability to simulate and generate automatic code, and allows conducting various tests along with verification.
of the embedded systems. Further, Simulink enables users to incorporate their MATLAB algorithms into models and export the simulation results to MATLAB for additional analysis.. The Simulink program consists of the following commands: constant, Slider Gain, (Sum, Add, Subtract, and Sum of Elements), Sine Wave, and Arduino IO servo Write. The constant is used for generating a real or complex constant value. The Slider Gain is used for varying the scalar gain during the simulation by using the slider; this block has one input and one output. The sine wave is used for generating a sinusoidal waveform, thus indicating that the output of this block is sinusoidal. The sine wave and Slider Gain signals are directed to the mixer, whose output is the summation of the sine wave and Slider Gain signals. The output of the mixer forms the input of the servo Write.

**EMG Signals**

In this study, we used an EMG shield to obtain the signals from the arm muscles, and because the signals were not very clear, we used another high-sensitivity device to obtain clear signals.

\[ y = \frac{1}{N} \sum_{i=1}^{N} |X_i| \]  .......................................(1)

Where \( N \) is the length of the signal and \( X_k \) represents the EMG signal in a segment. A simple way to measure the level of muscle activity is absolute value and this feature is common for use in myoelectric control. This feature is used for all classification in this project.

Root mean square:

\[ y = \frac{1}{N} \sqrt{\sum_{i=1}^{N} X_i^2} \]  .......................................(2)

Slope sign change:

\[ y = \sum_{i=1}^{N-1} (|X_{i+1} - X_i|) \]  .......................................(4)

Zero crossings:

\[ y = \sum_{i}^{N-1} f(X) \]

\[ y = \sum_{i}^{N-1} f(|X_{i+1} - X_i|) \]

**Cost Analysis**

Table 1 lists the cost breakdown of the entire system, including the price of 3D printing. The prices of electronic components (resistors, capacitors, wires, solder), and mechanical component (screws, nuts, bolts, crimps, silicone) are not listed since they can be acquired easily from campus laboratories and machine shop. The cost of the project stayed well within the estimated limit. Compared to the existing advanced robotic hands that are available on the market, which cost around 90,000 $, a 350 $ robotic hand solution seems more viable to the general population of users.

**Results and Discussion**

In this section, we compared the performances of our device and other existing devices in the market. Here, we remark that while our hand design is based on the ideas underlying the normally manufactured industrial robotic hand, we have also added a servo motor and EMG-based grip control in order to improve the device performance as well as ensure weight reduction relative to the weights of previously manufactured hands. The full weight of our device is 500 g, and the cost is as low as $250. These benefits are possible due to the use of EMG and grip control. The table 2 compares our device
with certain other devices in the market. Comparison parameters include type, weight, and grip pattern along with other key parameters. From the table, it is obvious that our device is more feasible for practical application than other existing devices. In terms of device weight, our hand lies in the weight range of the myoelectrically controlled powered hand prosthetic and the BeBionic (RSL Stepper), whose weights are considered suitable for prosthetic hands. Overall, our findings indicate the proposed robotic hand delivers a satisfactory performance, particularly in terms of improved controllability and perceptibility over other devices. An added benefit is the fact our device is less expensive than other devices.

Due to an experimental limitation and difficulties problems or complications with reliably dependably performing each every gesture, different users had the latency check was solely done on one user. Every gesture was performed five times from an amount of rest and control till the motion completion time may well be determined resolute whereas the myogram activity and sophistication labels tags were unendingly recorded. Table 3 shows the results of testing the hand on 7 persons who were missing an arm. The data set is for two movements; namely, the closing and opening of the hand. Some of the results have different rates of errors due to errors beyond the control of the designed system. One of common reason are the differences in the human muscles. In general, with regard to the design of robotic prostheses, the primary challenge involves developing a flexible experimental setup for closed loop control of a prosthetic device with integrated augmented reality that allows changing the extent and type of provided visual and vibrotactile feedback. Several studies have focused on the control approach as well. In one study, thirteen volunteers participated in the experiments by controlling the Ottobock Sensor Hand Speed prosthesis 12. The results indicated that the recorded vibrotactile patterns were able to replace visual feedback. In another study, in a multi-sensory, five-fingered Bio-Mechatronic hand with an sEMG interface, each finger was integrated with torque and position sensors that offered the hand more grasping patterns and complex control methods13. Arduino code could be uploaded to an online repository and made freely available for download. This code would incorporate controller programming, and a Graphical UI (GUI) that would enable the client to tune the control calculation to their inclination. The client would then have the option to purchase modest diversion gadgets, transfer the product themselves to the controller, and introduce the controller into the Talonhand themselves14.

Study the Genotoxicity of Aqueous and Alcoholic Extracts of *Adhatoda Vasica* on the Roots of *Allium cepa* L. by RAPD-PCR Technique

Adnan Owayez Jasim¹, Mohammed Mahdi Jawad¹

¹Iraq/University of Baghdad – College of Education /Ibn-Al-Haitham-Biology dept.

Abstract

The Molecular technique RAPD-PCR used to detect the genotoxicity of different concentrations of aqueous and alcoholic extracts of *Adhatoda vasica* leaves on onion *Allium cepa* L. roots. Five concentrations (1%, 2%, 3%, 5%, and 7.5%) and (10%, 15%, 20%, 30%, and 40%) were adopted for alcoholic and aqueous extracts respectively. Ten arbitrary primers used in this study, only eight showed polymorphic bands in the gel and two primers were neglected because they did not show any polymorphic bands for all samples. The aim of this study is to detect the toxic effect of the extracts on the root of onion. The emergence and disappearance of bundles in the genome of onion plant *Allium cepa* L. Treatment with extracts was studied. The genetic relationship tree was established and the genetic distance calculated based on the results obtained from the gel electrophoresis to clarify the toxic effects of the extracts. The results showed that the concentrations that gave the highest effect and the most toxic for aqueous extract is 40% and for the alcoholic extract is 7.5% which are recommended as effective concentrates if used as a pesticide.

**Key words:** RAPD, *Adhatoda vasica*, Extracts, genotoxicity, *Allium cepa* L.

Introduction

Acanthaceae a family that composed of many well-known medicinal plants comprises approximately of 3,400 species and 364 genera. The name *Adhatoda vasica* Nees, whose synonym is *Justucia adhatoda* L.¹ was selected for experiments on its extracts in this study. *A. vasica* is an evergreen plant. It grows in the form of herbaceous trees distributed all over the world and in various environmental conditions, it lives at an altitude of 1300 m above sea level in the Indian Himalayas²,³.

*A. vasica* leaves contain a number of chemicals such as alkaloids, flavonoids, turines, and saponins⁴. Alkaloids as Vasicinine. Vasicinol. Adhatodin. Adhatonine. Antisotine and pegainine⁵. The leaves contain two major alkaloids vasicine and vasicinone⁶. Vasicine alkaloid is one of the most effective substances that can be obtained from the leaves of the plant of the seven throat and by 95% of the isolated alkaloids⁷. The leaves and flowers of *A. vasica* are used as a medicine because they possess many chemical components such as carbohydrates, protein, phenolsas well as flavanoids and alkaloids⁸. *A. vasica* contains saponins and tannins too⁹, and the roots contain many alkaloids as vasicol, vasicinolone, vasicinone, adhatonine, vasicine and vasicinol¹⁰. Medicinal herbs are a very important source of medicine throughout human history. *A. vasica* is a plant known in ancient Greek medicine as a medicinal plant and used in the medical system for more than 2000 years¹¹, and it is widely used today, indicating that herbs are an increasingly important part of modern medicine. About 25 - 30 percent of the prescribed drugs today contain chemicals derived from plants¹². *A. vasica*, with its various parts of high potential plants, is used for the development of the pharmaceutical and drug industries¹³. The plant was used as an anti-asthma and bronchodilator and in the treatment of wounds, ulcers, allergies and pulmonary tuberculosis. Genotoxicity is the sum of DNA damage that causes mutations. When medicinal plants are used to treat diseases, genetic toxicity must be detected. Genotoxicity of *A. vasica* plant extracts. In this study, genotoxicity was detected using the DNA of the onion *Allium cepa* L. roots as a biomarker to confirm the genotoxicity of *A. vasica* extracts.
Materials and Method

Plant sampling

*A. vasica* leaves were collected during the month of September 2018 from the gardens of the University of Baghdad / Baghdad-Iraq, leaf lengths were 12-27 cm and classified by the herbarium of the college of agriculture - University of Baghdad.

Preparation of extracts

Aqueous extract prepared from 25 g of *A. vasica* leaf powder added to 125 mL of distilled water (in boiling degree) so that the solution is easy to filtrate. Then put the solution on the hotplate stirrer for two hours and filter the solution through 4 pieces of gauze, and centrifuged at 3000 rpm. Place the filtrate in Petri dishes and enter the oven at 40 °C. Scrape the extracted leaves after drying and store at room temperature until use (14).

To prepare the alcoholic extract, 125 ml of ethyl alcohol at 70% concentration added to 25 grams of dry powdered leaves and transfer the solution in a 50 °C for 24 hours in the shaking water bath. The steps were followed as in the preparation of aqueous extract (15).

Selection of samples and concentrations of extracts

Onions were selected in medium sizes (1.5, 2.2 cm) and 30 g weight, growing well at root lengths (2.5, 3.5 cm) the old roots were removed with dissecting blade and then the onion bulbs transferred to appropriate sized test tubes containing distilled water for 24 hours, then transferred to bottles containing a series of needed concentrations of alcoholic and aqueous extract of *A. vasica* leaves, adopted five concentrations (1%, 2%, 3%, 5%, 7.5%) and (10%, 15%, 20%, 30%, 40%), for alcoholic and aqueous extracts respectively, the onion bulbs still in their concentrations each for 7 days with considering the change of each solution every 24 hours to avoid increasing of concentration by water evaporation. After expiry of the exposure period, roots removed for further studies (16).

DNA extraction

DNA was extracted from onion roots that grown in each concentration solution studied by CTAB (Cetyl Trimethyl Ammonium Bromide) method (17, 18, 19) following the steps recommended by researchers in those references with some modifications.

Measuring the concentration and purity of DNA

The purity and concentration of DNA were measured using the Nano drop spectrophotometer by placing 2μL of each sample in a designated place of the device. The results appeared in private computer software. The DNA purity ranged from (1.7, 1.9) with different DNA concentrations measured in ng/μl. The quality of the extracted DNA was determined by electrophores the samples onto 1% agarose gel.

PCR-RAPD technique

Primers used in RAPD-PCR reaction shown in Table (1) arbitrary primers supplied by Interganti DNA Technology (IDT,USA), and Polymerase chain reaction PCR program shown in Table (2):

Results and Discussion

RAPD –PCR technique

RAPD-PCR technique can be used effectively to detect DNA damage, therefore be used in genotoxicity studies (21, 22). It can be used without prior knowledge about the genome (23). It uses random primers with DNA template sequences (24). It has the ability to detect DNA damage and verify mutations in the DNA when toxic substances are used (25). Using RAPD-PCR technique in this study revealed the genotoxicity of A. vasica leaf extracts as shown in Figure 1. The emergence or acquisition of bands in gel electrophoresis occurred as a result of changes in the structure of the DNA (fracture, transfers or deletions). As for the deletion or loss of bands, it was due to the reduction of the number of areas of binding with the polymerase (25) or mutation or damage at the site of primer binding to the DNA strand, as well as that loss is as a result of DNA damage, point mutation, chromosomal rearrangement, deletion and addition to the sequences of nitrogenous bases in the DNA strands due to genotoxicity effect (26). The primers OPA3, OPA7 were neglected because they did not show any polymorphism in gel bands for all samples.

After determining the purity and concentration of the extracted DNA of the extracts exposed roots, a high concentration of 800 ng/μl was found. Concentrations were reduced to 150 ng/μl for each extract. The results of the RAPD technique showed a variation in the PCR results of samples that exposed to aqueous and alcoholic extracts compared with the control treatment. Table 3 and 4 and Figure 1, show the RAPD-PCR results. It is clear from the results that the eight primers used gave fifty-five bands in control treatment and the molecular weights were between (140-2109). As for the number of lost and gained bands, it was found that the alcoholic extract was more toxic to the onion roots genome than the aqueous extract.

Table (3) Lost and gained gel bands after PCR in roots of onion plant treated with aqueous extract concentrations.

The present study has shown a decrease in viability to death of the roots of *Allium cepa* when treated with different concentrations of both extracts, suggesting that it can be used as a pesticide to weed. Our findings evoke that Low concentrations were cytotoxic to onion roots while high concentrations of 40% and 7.5% of aqueous and alcoholic extracts respectively were prevented cell entry into mitosis. So it was more harmful to the food chain receptors. Consequently, the plant is unable to absorb it for this reason it is recommended to use low concentrations of both extracts as a pesticide (27).

**Cluster analysis**

UPGMA analysis was used to map the genetic relationship tree (28,29,30) using Jaccard’s similarity coefficients the tree results showed groups below (Figure 2).

Group A contains two groups, A1 group included control sample and onion sample exposed to alcoholic extract at 7.5% control (distilled water) and aqueous extract concentrations 20%, 30%, 40%. Group A2 included onion samples exposed to the aqueous extract concentrations of 10% and 15%.

Group B comprised two groups. Group B1 onion samples exposed to the concentration of alcoholic extract 1%, 2%. Either group B2 included samples exposed to alcoholic extract concentrate 3%, 5%.

The results of the genetic relationship tree showed the isolation of the results of aqueous extract from the alcoholic extract, and the isolation of the results of the exposure to control sample and the alcohol concentration of 7.5% were observed clearly.
The tree showed the isolation of the control sample and the concentration of 7.5% alcohol compared to other samples treated with the extract (aqueous and alcoholic). This indicates that all the concentrations had an effect on the onion genome.

Conclusions

This study revealed that the concentration that gave the highest effect and the most toxic for aqueous extract is 40% and for the alcoholic extract is 7.5% because with these concentrations the plant cells started to die.

Histological Study of the Effect of Isoxicam on Ovary of Albino Mice Mus Musculus

Ali Khudheyer Obayes¹, Wurood Mohamed Mutar², Rasha Hamid Ayub³, Sahar Abdullah Mohammed⁴

¹Dep. Biology/ College of Education / University of Samarra/Iraq, ⁴Education of Salahaldin / Dept of Aldor, Tikrit, Iraq

Abstract

Non-Steroidal Anti Inflammatory Drugs (NSAIDs) are the most prescription as therapeutic drugs, used to treat of rheumatic diseases, due to analgesic, antipyretic and anti-inflammatory activity. Isoxicam is a member of NSAIDs group use to stop inflammation, pain associated with arthritis, osteoarthritis, ankylosing and spondylitis. The goal of the present study is to revealed the effect of different doses of Isoxicam on ovaries tissue in mice. Twenty four female mice are randomly divided into control (n = 6) and experimental (n=18) groups. The experimental groups are subdivides into three groups . Each administrated by (0.0714, 0.1428, 0.71428)mg/kg/day for twenty days, respectively; however the control group just injected by distill water. In twenty day, mice were killed and ovaries tissue was prepared for light microscopic examination. All the experimental animals were injected by drug revealed a hyperplasia of germinal cells on the surface of ovary, tongue like projection of primordial oocytes extend to the medulla, multiple oocytes with disarrangement of follicles and deficient of follicular fluid associated with disappearance of oocytes, vacuolation in the cortical layer of the ovary, compressed premature follicle, hypercellularity of follicular cells, degeneration of germinal layer of cortex surface and hyperplasia of primordial oocytes, therefore it is recommended that using of this drug have many side adverse on female fertility.

Key word : Histological , Isoxicam , ovary , albino mice .

Introduction

Isoxicam and Meloxicam these drugs are belonging to the oxicam group. Nonsteroidal anti-inflammatory drugs which display a potent analgesic activity and used for treated rheumatoid arthritis, osteoarthritis and other joint diseases. The pharmacological actions of these oxicam are related to inhibition of cyclo-oxygenase (Cox1,2), an enzyme of prostaglandin biosynthesis at the site of inflammation¹. Prostaglandin, It have been involved as a regulator of several physiological processes in human body such as inflammatory processes in immune response, vasodilator, vasoconstriction, pain perception and fever. Prostaglandin are produced in every tissue of the body (brain, lung, kidney, intestinal digestive system, male and female reproductive system) (²). NSAIDs have many adverse effects of liver, dermis, skin eruption and many physiological disorders in rats’ testis ³-⁶. There are an association between use of prescribed NSAIDs and miscarriage ⁷. The modern NSAIDs that belong to tenoxicam, lonoxicam, Piroxicam and Isoxicam which belongs to oxicam family prescribed as inhibitors of both types of Cox ⁸. A few research consider these drugs a very good antioxidants ⁹. The oxicam family acts on inhibit cyclooxygenases COX-1 and 2, It is also inhibits leucocytes activities.

Fertility in females are affected clearly by COX-2. A study on mice female fertility throughout disruption of COX-2, lead to fails in ovulation, fertilization, implantation, and decasualization. These defects were the direct result of the targeted organ-specific COX-2 deficiency(¹⁰).

The aim of this study was elevate effect of Isoxicam on the ovary after application of different concentration on mice ovary.
Materials and Method

This study was done in medical laboratory department of biology/ Education college/ university of Samarra. Twenty four mature (70 days old) albino Swiss mice Mus musculus Balb/c were employed, weighing (25±3gm) obtained from college of medicine, Tikrit university. They were maintained on 12:12 light: dark bases, and 24 ±2°C with mouse pelleted food and water adlibitum. Female mice were housed in group not bigger than five animals (all from the same experimental group) in plastic cages with metal cover (13*16*30) cm, with wood shavings as bedding material. Twenty four male albino mice were randomly divided into control (n =6) and experimental(n =18) groups. The experimental groups are subdivides into three groups which divided into four groups of mice, each one is injected Intra Peritoneum. with different doses of Isoxicam once daily for 20 days.

Drug administration

Isoxicam ample 200 mg/2ml. Female were injected daily Intra Peritoneum (I.P.) administrated in three doses: Therapeutic dose, over dose1 and over dose2 (0.0714, 0.1428, 0.71428) mg/kg for 20 days respectively 11, and Control group were injected with normal saline 0.9 mg/L.

Surgical procedure

In twenty one days, the female were anesthetized by chloroform, and the peritoneal cavity was opened through a lower transverse abdominal incision. The ovaries was immediately removed and kept in normal saline. At the end the experimental animals were killed by decapitation.

Histological preparation

The collected tissues Each segments of skin was taken and immersed in 10 % formalin foe 24 hours followed by immersion in graded series of alcohol from 70, 80, 90 and 100 %, then clearing with xylene and embedded in paraffin wax at 60 c°. Blocking of the samples were done and the sectioning were performed using a rotary microtome. The thickness of the sections were 6 micrometer. The tissue sections after application of staining with Hematoxylin and Eosin were mounted on the slides using D.P.X and covered by cover slides 12. The slides were examined using light microscope and photographed by manipulated camera prepared for this purpose.

Results

Control group

Histological sections of the ovary in the control group show, intact ovarian surface (germinal layer) directly beneath it are tunica albuginea contain numerous primordial follicles, primary oocytes and secondary oocytes, the cells ranged from flat to cuboidal and low columnar cells. Cortex and medulla regions was continuous, Ovarian follicles are various sizes surrounded by theca interna and theca externa as shown. Each follicle contains a single oocyte in the stroma of the cortex. The oocyte within the secondary oocytes was envelop by the zona pellucida and granulosa cells fig (1).

T1 : Therapeutic group

The histological sections of ovarian cortex in this group shows hyperplasia of germinal cells on the surface of ovary, hyper cellularity in follicular cells around follicular cavity, tongue like projection of primordial oocytes extend to the medulla fig (2A), multiple oocytes with disarrangement of follicles and deficient of follicular fluid associated with disappearance of oocytes , hyperplasia of follicular cells primordial oocytes fig (2B).

T2 : Over dose 1

This group showed degeneration of germinal cells layer on the surface of cortex with thickening of collagen fibers around premature oocytes, disappearance of oocyte with vacuolation in the cortical layer of the ovary fig (3A). In other sections showed hypercellularity of follicular cells of oocytes in the cortex , degeneration of follicular cells and secondary oocytes with vacuolation of interstitial connective tissue fig (3B). In tertiary follicle increased a multiple layer of follicular cells around oocytes, disappearance of oocytes with decreased amount of follicular fluid and detachment of follicular cells from surrounded connective tissue fig (3C) .other sections of cortex demonstrated compressed premature follicle , degeneration of germinal layer of cortex surface and hyperplasia of primordial oocytes fig (3D).

T3 : Over dose 2

In this group the microscopical examination were show degeneration of germinal epithelium cells of cortex surface, vacuolation in granulosa layers of premature follicle with remnant of oocyte of premature follicle fig (4A). In the surface of cortex showed
disappearance of germinal epithelium, disarrangement of the other primary follicles with compressed it and partial congestion of blood vessels fig (4B). In other section showed degeneration of follicular cells layer in premature follicle hyper cellularity of connective tissue and vacuolation in between collagen fibers fig (4C). In medulla of ovary showed empty of blood vessels, spaces in between follicular connective tissue, and hypertrophy of the stromal cells fig (4D).

Fig (1) primordial follicles (1), primary oocytes (2), secondary oocytes (3) and cortex (4). H&E, 40X.

Fig (2): hyperplasia of germinal cells (1), hyper cellularity in follicular cells (2) and tongue like projection of primordial oocytes (3). A. multiple oocytes with disarrangement of follicles with disappearance of oocytes (1), hyperplasia of follicular cells (2) B. H&E, 40X.

Fig (3) degeneration of germinal cells layer (1), vacuolation in the cortical layer (2), thickening of collagen fibers around premature oocytes (3) disappearance of oocyte (4). A. hypercellularity of follicular cells (1), degeneration of follicular cells (2), vacuolation of interstitial connective tissue (3) B. increased a multiple layer of follicular cells (1), disappearance of oocytes (2), decreased amount of follicular fluid (3) and detachment of follicular cells from surrounded connective tissue (4) C. compressed premature follicle (1), degeneration of germinal layer of cortex surface (2) and hyperplasia of primordial oocytes (3). D.
Discussion

The present study was designed to demonstrate the effect of Isoxicam after application on mice for 21 continuous days, so the Isoxicam was intraperitoneal injection for three different doses. The application of this drug demonstrated many histopathological changes in ovaries was affected at different degrees, which means that increasing the concentration lead to severely effect. The female reproductive system is considered to be the most important organ. It characterized by two main functions, synthesis of sex hormones and produce the oocytes (13). Non-steroidal anti-inflammatory drugs (NSAIDs) are the more effectively to reduce pain and inflammation (14).

COX-2 produce prostaglandin which plays a major role in ovulation and fertility. NSAIDS or COX-2 inhibitors which effect on follicle rupture, ovulation, fertilization, luteolysis and parturition when treated rats with indomethacin (15).

Our data was in agreement with (16) who described the effect of ibuprofen at therapeutic dose in mice which induced a histological alteration such as a sequence of events of development and growth of ovarian follicles, increased the number of atretic follicles, Degenerated oocytes of matured follicles with vacuolated stroma. The administration Sodium Metabisulfite on rats which induced histological changes represented by reduced volume of the ovary as well as a decrease in the number of growing follicles, corpus luteum and an increase in the number of atretic follicles. Due to increased lipid peroxidation in the ovarian tissue (17) this study was agreement with our results. The administration of tarragon extract flavonoids reduces cyclooxygenase enzyme and nitric oxide, and thus reduces the amount of prostaglandin which effect on follicle growth (18). Oral administration with indomethacin causes ovulatory dysfunction, represented by the occurred of abnormal follicles at the, with degenerated granulosa cells and reduced follicular fluid of secondary follicle, all these
defect due to COX-2/ prostaglandin synthesis inhibition.

Treated rats by atropine sulphate was induced degeneration of granulosa cells and disappearance of antrum the inhibition gonadotrophin release and prostaglandin synthesis. The application of this drug was indicated the insult of Isoxicam in any concentration even therapeutic dose, so our suggestion that this drug must not be used by owner, just used by supervision of the doctors.

Conclusion

The present study revealed that Isoxicam caused a clear histological alterations in ovarian tissue, including hyperplasia of germinal cells on the surface of ovary, hyper cellularity in follicular cells around follicular cavity, tongue like projection of primordial oocytes extend to the medulla, disappearance of oocytes with decreased amount of follicular fluid, vacuolation in granulosa layers of premature follicle with remnant of oocyte of premature follicle. Therefore it is recommended that usage of this drug have harmful side effects on female fertility.

**Genotyping of Tumor Necrosis Factor-α in Inflammatory Bowel Iraqi Patients**

Inas Fadhe¹, Wafaa Sabri Mahood²

¹Post Graduate, ²Assistant Proff. Dr., College of Education for Pure Sciences- Ibn Al-Haytham, University of Baghdad/Iraq

**Abstract**

The TNF-α gene considered as strong candidate for immune modulator and pro inflammatory cytokine responsible for genetic susceptibility of chronic disease such as the initiation and development of inflammatory bowel disease (IBD). The aim of this study is to investigate the genetic polymorphisms of -1031 in TNF-α gene with susceptibility of Iraqi IBD patients.

**Method:** The total number of this study 95 blood samples (75 Iraqi IBD patients and 20 from healthy individuals as a control group). The genetic polymorphisms in TNF-α-1031 gene was investigated using restriction fragment length polymorphism (RFLP) and Sanger sequences techniques.

**Results:** The genotype allele frequency of -1031 polymorphism was significantly higher in CD Iraqi patients (\(P=0.042\), Chi 4.612. OR= 0.72-1.64). C allele may be have protective role, whereas the T allele may increase susceptibility to IBD.

**In conclusion:** The TNF-α -1031 gene polymorphisms in promoter region have an important role in the occurrence of inflammatory bowel disease of Iraqi population especially in CD patients although some results didn’t give us a significant differences. It’s possible that C allele may be have protective role, whereas the T allele may increase susceptibility to IBD.

**Key words:** TNF-α -1031, Tumor necrosis factor, inflammatory bowel disease, ulcerative colitis and Crohn’s disease.

---

**Introduction**

IBD include both Crohn’s disease (CD) and ulcerative colitis (UC). Patients with IBD suffer from some common symptoms such as acute diarrhea, abdominal pain, fatigue and weight loss. The location of the two type of inflammation is different, it affects entire gastrointestinal tract in the CD where the UC affects the ileum and colon. Environmental factors, genetic and immune regulation play a key role in development and progression of IBD which characterized by an irregular immune response of the mucous layer in the intestine to bacterial antigens within the intestinal lumen. Regulation of cytokines such as TNF-α and IL-6 play a key role in activation of T helper cells which causes inflammation disease. TNF-α is the important cytokine for inflammation as it participates in immune response to IBD. TNF-α characterized with a wide range of inflammatory activity it is usually produce by macrophage and monocyte although there are other types of cells that are produced but in limited quantities. Inflamed mucous layer of the intestine in IBD patients have increased gene expression of TNF-α gene. TNF-α not only stimulates the acute stage of inflammation but plays role for the occurrence apoptosis, proliferation and differentiation of cells and several immune disorders.

There is a correlation between the genetic polymorphisms of the encoded gene of TNF-α and the susceptibility to IBD. The TNF-α - gene have shown several polymorphisms in its four exons. However, most of the common reported polymorphisms are identified in the promoter region of this gene. The TNF-α promoter region include various a single nucleotides...
polymorphisms that have shown a significant association with IBD\(^{(11)}\), like \(\text{TNF-}\alpha\ -(308G/A)\)\(^{(12)}\) and \(\text{TNF-}\alpha\ -857\) polymorphism\(^{(13)}\). The response to anti TNF-\(\alpha\) agents is increased and reduced by the effect of genetic factors of individuals\(^{(14)}\).

The aim of this study is to detect the \(\text{TNF-}\alpha\ -1031\) gene polymorphisms as its important factor in IBD development and treatment.

**Materials and Method**

**Patients:**

Blood samples were obtained from 75 Iraqi patients suffering of IBD who were attending the Gastroenterology and Hepatology Disease Center in Baghdad between September–Desember, 2018. Patients samples were selected after the diagnosis was made by the specialist doctor, in addition to 20 blood samples were collected from apparently healthy individuals. Ethical permission to conduct the research was obtained from this hospital and from all participants in this study.

**DNA Extraction**

Genomic DNA was isolated from blood sample according to the instructions of ReliaPrep™ Blood gDNA Miniprep System kit (Promega, USA).

**Polymerase chain reaction (PCR)**

PCR was done for \(\text{TNF-}\alpha\ -1031\) gene amplification, each 20 \(\mu l\) mixture of PCR reaction include 10 \(\mu l\) of master mix, 1 for each primer and 5 distilled water and 3 of genomic DNA. The forward and the reverse primers were 5’-TATGTGATGGACTCACCAGGT-3’ and 5’-CCTCTACATGGCCTGTCTT-3’ respectively\(^{(15)}\).

PCR amplifications were achieved in Thermal cycler (Applied Biosystem 96). PCR reactions were started through initial denaturation at 95 °C for 5 min followed by 30 cycles of denaturation at 95 °C for 30 s., annealing at 55 °C for 30 s. and extension at 72 °C for 30 s. followed by a final extension at 72 °C for 7 min. then hold at 4 °C.

**Restriction Fragment Length Polymorphism (RFLP):**

PCR products were digested with restriction enzyme, 1\(\mu l\) from BbsI enzyme (Biolabs, England) was added to 5\(\mu l\) of PCR product for each sample. RFLP was performed using Thermal Cycler (Bio Rad, USA) with the following temperature program: 37 °C for 3 hour, enzyme inactivation at 65°C for 5 minutes followed by 10 min incubation at 4°C to stop the reactions. The restriction enzymes fragments were separated on 2% agarose gel stained with ethidium bromide stain.

**Sequencing**

PCR products were send to Macrogen Corporation – Korea for Sanger sequencing using (ABI3730XL, automated DNA Sequencer). The results were analyzed using genious software.

**Statistical analysis**

The Hardy-Weinberg equilibrium was used by the chi-square test to evaluate the frequency of genotypes and correlation of the \(\text{TNF-}\alpha\ -1031\) genotypes or alleles between IBD patients and controls group. Calculated Odds ratio (OR) with 95% confidence interval (95% CI) for assessing the correlation strength. All data were analyzed using SPSS (2012). A \(p\) value of <0.05 was considered significant\(^{(16)}\).

**Results and Discussion:**

**Clinical Characteristic of Patients**

The total number of this study was 95 blood samples including 75 blood samples from IBD Iraqi patients in addition to 20 blood samples from healthy individuals as a control group. The IBD patients whose enrolled in this study divided into two groups: the first group 47 UC patients and 28 CD patients. Table 1 refer to the clinical characteristics of IBD patients, the ages where ranged between (19-57) years. High rate of patients less than 50 years (81%) with IBD were found in this study while the older age group or more than 50 years was (19%) with high significant association (\(P<0.01\)). This result was agreed with\(^{(17)}\) they stated that the peak occurrence of the IBD occurs in the second or third decade of life. High incidence of IBD in females, it was (57%) compared with (43%) in males, significant association (\(P<0.05\)), was appear depend on patients gender. Statistically significant differences were observed between IBD patients and controls depend on type of disease, patients with UC were (60%) higher than patients with CD (40%), these results consist with other Iraqi study from Erbil city\(^{(18)}\), this data may be indicate to that UC has more prevalent than CD in Iraqi population.

Genotyping of \textit{TNF-}\alpha - 1031 gene and Alleles frequency in IBD patients

The genetic polymorphisms in \textit{TNF-}\alpha gene considered as strong candidate for immune modulator and pro inflammatory cytokine responsible for genetic susceptibility of chronic disease and the initiation and expansion of IBD \cite{19}.

The genetic polymorphisms in the -1031 (T→C) of \textit{TNF-}\alpha gene promoter (db SNP accession number 1rs1799964) was investigated in Iraqi patients with IBD by PCR-RFLP technique and Sanger sequences to determine the genotypes/allele frequency, at this site there are three genotype of \textit{TNF-}\alpha T-1031C in promoter was found , TT with band sizes 251bp and other small band 13 pb that emerge with primer dimer while TC and CC that have band sizes (251/180/ 71) bp and (180/71) pb respectively Figure 1. The sequences analysis of \textit{TNF-}\alpha – 1031T>C showed in Figure 2.

Figure 1: Genetic polymorphism in T -1031 C of TNF-\alpha gene on 2% agarose gel with ethidium bromide dye after digestion with Bbsl enzyme, M : DNA molecular size marker (100bp) , Lane (11) TT genotype (251/13) bp , Lanes (16,20) TC genotype (251/180/ 71) bp and line (25) CC genotype (180,71)bp.
The frequency distribution of genotypes and alleles of \(TNF-\alpha\)-1031 in IBD patients and control groups are summarized in Table 2. The present results showed 62.7\% vs 70\% \((p=0.061, \text{Chi}=3.091 \text{NS, OR}=0.377)\) for homozygous T allele in IBD patients and control group, the homozygous CC genotype was (5.33\% vs 5\%) in IBD patients and control group \((p=0.872, \text{Chi}=0.055 \text{NS, OR}=0.0162)\) The T>C heterozygous genotype in IBD patients (32\%) was higher ratio than control(25\%) \((p=0.069, \text{Chi}=2.983, \text{OR}=0.352)\) the data showed no significant difference was found in correlation to the three genotypes, our results agreed with Iranian population \(^{(20)}\).

Alleles frequency for T and C alleles in IBD patients and control group were (0.97, 0.83) and (0.21, 0.17) respectively. The results revealed that there was no significant association regarding genetic polymorphism in \(TNF-\alpha\) (-1031T/C) polymorphism in IBD patients, statistical analysis indicated that \(TNF-\alpha\) (-1031T/C) was not a risk factor to IBD.

**NS:** Non-Significant.

OR = Odd Ratio CI = Confidence Interval EF = Etiology fraction PF= Preventive fraction
Our study demonstrate that the TT genotype has clearly indicates an etiology for IBD, as it had an OR of 0.377 and Etiologic Fraction (EF) of 0.511 (Table 3), in contrast, the TC and CC genotype have rather preventive role as it had Protective Fraction (PF) of .376 and 0.152 respectively with low OR (0.352 and 0.0162) .With the possibility of C allele may be have protective role , whereas the T allele may increase susceptibility to IBD.

Genetic polymorphisms of TNF-α gene in UC patients

Genotype of the TNF-α genes (-1031) polymorphisms in 45 UC patients (Table 3) .The data revealed that homozygous TT genotype was found 63.83% vs 70% in UC patients and control group respectively (p=0.067,Chi=3.055 NS,OR=0.362) while homozygous CC genotype in UC patients and control group 6.38% and 5% respectively .Heterozygous T>C genotype in UC patients(29%) was higher than control group (25%) however , the three genotypes in current work didn’t give significant differences . The heterozygous T>C genotype in this study similar with (21).

Our results also similar to data by Asghar and his colleagues (22),they investigated the possible association between five single nucleotide polymorphism (SNPs) in TNF-α gene promoter polymorphisms including -1031T/C in a Japanese population with endometriosis, their results revealed that –1031 (65.1%) TT , (31.7%) TC, (2.8%) CC, (81.4%)T (18.6%)C, the -1031C polymorphism with no significant difference in the frequency of in the TNF-α-1031 gene promoter .

The T allele in promoter region of TNF-α gene at -1031 site gave a significant risk for development in Turkish and Iranian IBD especially UC patients and also found that C allele was very low in patients and could have a protective role ,the variation in TNFα-1031 T allele may increase the risk for developing UC , single nucleotide polymorphism -1031 T > C could have important effect in pathogencity of IBD that lead to increase TNF-α levels in IBD patients (23). Increased expression of TNF-α , high serum levels have been documented in intestinal tissues and IBD patients (24).

Table 3: Genotyping of TNF-α-1031 gene in UC patients

Conclusion

This paper suggests that TNF-α -1031 gene polymorphisms in promoter region has an important role in the occurrence of inflammatory bowel disease of IBD patients in Iraqi population especially in CD patients although some results didn’t give us a significant differences. It’s possible that C allele may be having protective role, whereas the T allele may increase susceptibility to IBD. Other studies are needed with
large number of IBD patients to support our results.

Abstract

This research was achieved with the aim of detecting the Antibacterial efficacy of the watery extract Eruca of Sativa seeds toward human pathogenic bacteria, four Pathogenic species of bacteria (Enterococcus faecalis, staphylococcus aureus, pseudomonas aerogenoso, and Salmonella typhi) were isolated from different clinical samples at al. Kademia teaching hospital Laboratory. Results: The results showed The extract inhibits gram positive bacteria and the mean inhibitory zone for strepto coccus faecalis and S. aureus was 10.4 mm and 14.0 mm respectively. Conclusion: The extract had no effect on gram negative bacteria.

Keywords: Eruca Sativa, seeds aqueous extract, pathogenic Bacteria

Introduction

Eruca sativa Miller (synonym Eruca vesicaria Rocket) , usually called as Tarmira, Garden salad or Rocket salad or Jarjeer. E. sativa is one of the endemic species from the family of Brassicaceae which is cultivated in most cases in countries of Mediterranean sea like Greece, Turkey, and Italy. It is an annual dark-green plant, with height around 20-50 cm, with a taste of spicy pungent (1). Its seed is commonly yellow, but sometimes is reddish yellow or spotted with brown-green spots (2).

The seeds have long been used in folk medicine as a lactagogue, aphrodisiac, diuretic, antis -corbutic, antimicrobial, to disintegrate renal calculi and induce vomiting

This used seeds were taken long time in traditional medicine as an aphrodisiac, diuretic, lacagog, antimicrobial, anti-bacterial, to induce vomiting and destroy kidney stones (3). However, Flanders and Abdel-Karim (4) indicated that oil of seeds of Eruca sativa contains 93.8% fatty acids (11 ones) including 58.5% erucic acids, 6.7% saturated acids, 28.5 % linoleic acid, 1-2 % linolenic acid and 4.5% oleic acid. Depending to to EL-Gendy (5), oil of Eruca sativa rises count of RBCs and the content of haemoglobin.

S. aureus is one of the Gram-positive bacteria, has a coccus shape and it is usually considered as a member of the microorganisms in the human body frequently. It is a member of the Firmicutes and it is exist on the human skin and in upper tracts of the respiratory system (6).

Usually, Staphylococcus aureus behaves the commensalism role, atypically colonizing approx. 30% of the population of humans. It can occasionally cause some diseases. Particularly, it is mostly one of the common pathogens of infective endocarditis and bacteremia. In addition to, it can lead to different infections of soft tissues and skin, especially when mucosal barriers or the skin have been penetrated (7).

Pseudomonas aeruginosa have a common capsule, bacili-shaped, Gram-negative bacterium which can leads to occurrence some diseases in humans, animals, and plants. A species of great medical significance.
Pseudomonas aeruginosa is an opportunistic pathogen in hospitals for individuals with immunodeficiency. It archetypically infects burns, urinary tract, the airway, wounds, and other infections of the blood.

This is the most frequent cause of the infection of external ear (otitis externa), injuries, and burns, which is the most common colonizer of the medical devices such as catheters. P. aeruginosa can be spreading by the contaminated equipments and isn’t carefully cleaned or by the hands of health care workers. It can rarely cause pneumonia acquired from the community (8).

Salmonella typhi, the Gram-negative bacterium also called as S. enterica serotype Typhi, which grow in blood and intestines. Typhoid fever or Typhoid is spreading by drinking water or consuming food contaminated with stool of the infected people.

Typhoid is an infectious bacterial disease caused by S. typhi which causes differential symptoms. Symptoms may vary from severe to moderate and always start 6-30 d after the exposure to this bacteria (9).

**Objective**

This study was carried out with the aim of detecting the antibacterial efficacy of the watery extract of Eruca Sativa seeds toward some pathogenic bacteria to humans.

**Material and Method**

a. **Bacterial isolates:**

Four Pathogenic species of bacteria were isolated from different clinical samples at al. Kademia teaching hospital Laboratory.

The isolates were Gram positive coca, Enterococcus faecalis and staphylococcus aureus (S. aureus). And Gram negative loacilli, pseudomonas aerogenoso, and Salmonella typhi.

Bacteria were isolated and diagnosed according to cultural, morphological and biochemical characters according to (10).

b. **subculturing of bacterial isolates**

From stock culture, Nutrient broth tubes were inoculated for each bacterial species separately, and the tubes incubated at 37 °C for 24 h.

d. **susceptibility test:**

The susceptibility of the seed aqueous extract was determined by disc diffusion method according to (11).

From stock culture, Nutrient broth tubes were inoculated for each bacterial species containing approximately 10^7 cfu / mL was transferred aseptically and spread on the surface of plates of MullerHinton agar (MH-agar).

Serile discs prepared from the filter paper (6 mm) were impregnated with 20 micro liters of the extract, a standard antibiotic disc gentamicin 40 mg/ml has been used as a positive-control and a disc containing 20 micro liters of sterile distilled water as a negative-control. However, all the done discs have been placed on the surface of MH medium and then the dishes have been incubated at 37 °C for 24 hr. The test was done in triplicate for each bacterial species.

**Results**

The average of inhibition Zone diameter was determined after the end of the incubation period.

The extract inhibits gram positive bacteria and the mean inhibition Zone for strepto coccus faecalis and S. aureus was 10.4 mm and 14.0 mm respectively.

The extract had no effect on gram negative bacteria, the results were shown in table 1.

- : means no inhibition zone.
Discussion

The increasing occurrence of resistant bacteria could be due to overuse or misuse of commercially available antimicrobials in addition to side effect and toxicity of some of these antimicrobials, this made scientist try to develop aneefective, alternative, affordable, safer and nontoxic antimicrobials of plant origin.\textsuperscript{(11, 12)}.

Eruca sativa seed extract contains several secondary mrtabolites [ glucosinolate isothiocyanate, Alkaloids, and theic derivaties, Flavonoid, phenols, Tannins, and erucin which are responsible for their antioxidant and antibacterial activity.\textsuperscript{(13, 14)}.

Enterococcus Faecalis and S. Aurus was sensitive to the extract and this may be due to mesh like peptidogly can Layer in their cell wall\textsuperscript{(15)}. While Pseudomonas aerogenosa and Salmonella typhi were resistaut to the extract due to the selective permeability of Lipopoly saccharide membrane to hydrophilic solutes which restrict the entry of the extract\textsuperscript{(16)} and the extraction method used and type of solvent may affect the result too.\textsuperscript{(17, 18)}.

The absence of antimicrobial activity of the extract does not indicale that the plant was inactive or not contain bioactive substances\textsuperscript{(19)}.

Possible Role of Toxoplasmosis on Gene Sequence Alteration in Patients with Cardiovascular Diseases

Nazar Sh. Mohammed1, Ammer Abd. Mohammed2, Salwa S. Muhsin1
1Department of Medical Laboratory Techniques/ College of health and Medical/ Medical Technical University/ Baghdad/ Iraq (MTU), 2Department of Community / Medical-Technical Institute/ Baghdad, Middle Technical University /Iraq (MTU)

Abstract

Toxoplasmosis is one of the risky infection my lead to cardiovascular diseases. One hundred therein patients samples were collected with Heart Diseases and there were infected with Toxoplasmosis, in Baghdad educational Hospital from period 1st January 2019 to 1st September 2019. The results show that prevalence of *Toxoplasma gondii* among Hypertensive disease and Myocardiopathy with Heart Diseases. The genotype of *MYLK3* exon to Human cardiac gene by gel electrophoresis, Lane M markers correspond to 500 bp ladder lane 2 of gene band with 600bp. Mutation occurrence in exon 8 the gene sequence CCCAGCCGG were change to CCCATCCGG, and in exon 9 the change occurrence in sequence CTCAAGCGG to CTCAAGGTACAA.

**Keywords:** *Toxoplasma gondii, Alteration, gene sequence, cardiovascular diseases.*

Introduction

Toxoplasmosis is generally a mild infection with signs of lymphadenopathy, but some patients may develop chorioretinitis which can progress into blindness(1). Severe neurological disorders may be shown by those immunocompromised patients who are infected with *Toxoplasma gondii* (2). Congenital disorders of newborns may also result from primary toxoplasmosis during pregnancy (3). In humans, heart may be affected by toxoplasmosis (4) with myocarditis (2), myocarditis with pericarditis (21, 22) as well as the acute heart failures (5). Patients with toxoplasmosis who develop myocarditis may present with congestive heart failure, arrhythmias, pericardial effusion and constrictive pericarditis (2). There are few studies on the sero-epidemiology of patients suffering from heart diseases due to toxoplasmosis (6). Our study aimed to determine the association between exposure to *Toxoplasma gondii* and patients with cardiac diseases who attended to Baghdad teaching hospital/ Medical city and the association between seropositive patients and behavioral, demographic as well as the clinical features of patients.

Materials and Method

One hundred therein patients samples were collected with Heart Diseases and there were infected with Toxoplasmosis, in Baghdad educational Hospital from period 1st January 2019 to 1st September 2019, all these patients were diagnosed with Toxoplasmosis by ELISA, Anti *Toxoplasma* antibodies IgM and IgG. Genetic test were done by conventional PCR Primers used for amplifying *MYLK3* exons

Discussion

Toxoplasmosis is one of the risky infection my lead to cardiovascular diseases. Cardiovascular diseases are common conditions in adults that may be in the heart muscles or vessels. *Toxoplasma gondii* due to its presence within the cellular tissue may affect the heart. 12% of people with Hypertensive disease are infected with Toxoplasmosis and they are mainly cardiovascular disease. These finding matched with (Flegr, J. *et al*, 2014) who found that 24% of cardiovascular diseases complaining hypertension and they have toxoplasmosis. 22.2% of myocardiopathy patients suffer from cardiovascular patients, also they have toxoplasmosis. This report agreed with (England, J. H. *et al*, 2019), who reported that 26% with cardiovascular disease and they complaining myocardiopathy with Toxoplasmosis. Cardiovascular disorders are heart conditions, this
also result from the weakened heart (9). The tropical known as arrhythmias. Heart valve disorders may and it may lead to heart failure or irregular heartbeats normal electrical rhythm also becomes less than usual, the heart becomes less throughout the body and maintaining the heart becomes weaker. Pumping of blood by the conditions, the ill tissue of the cardiac muscle is replaced with scar tissues. When cardiomyopathy worsens, then the heart becomes weaker. Pumping of blood by the heart becomes less throughout the body and maintaining normal electrical rhythm also becomes less than usual, and it may lead to heart failure or irregular heartbeats known as arrhythmias. Heart valve disorders may also result from the weakened heart (9). The tropical pulmonary eosinophilias, which have a characteristic of restrictive lung disease and progressive interstitial fibrosis, can lead to PH and then to a course of filarial infection. Intracardiac rupture of Echinococcus cyst and Toxoplasma gondii may lead to the membrane or secondary cyst embolization of the organs or lungs that are supplied by the systemic circulation. cardiac involvement by parasites must be considered in the differential diagnosis, despite unusual reasons of heart diseases outside the endemic areas, especially in myocardial or pericardial patients of unknown causes. In this study, the present knowledge on the main cardiac diseases caused by the protozoan and metazoan parasites have been updated and summerized, including the heart muscle either directly adversely, (Nunes, M. C. P et al, 2007), (10). The genetic mutation of cardiovascular disease patients associated with toxoplasmosis has been found to exacerbate the pathological condition and alter the gene trajectory of the infected. These findings were in harmony with (Webster, J. P. et al, 2013) who reported the behavioral alterations seen in the infected hosts indicate the following: (1) The active manipulation of the parasite’s selective benefit; (2) the active manipulation of the host’s selective benefit to improve the effects of the infection; (3) The general pathological response of the host of no clear parasite’s or host’s selective benefit; or, finally, the subtle distinction of the latter grouping known here as (4) the ‘by-product pathology’ as a result of the accidental toxoplasmosis selected for behavior manipulation in the alternative host species or the stage of the life cycle. In addition, as this perspective study evaluates the applicability of studying Toxoplasma gondii in rats (and/or mice), the intermediate hosts as models to help us understand both evolutions and mechanisms that underpin parasite-changed behaviors (ranging from rodent’s predation to some conditions of human schizophrenia), for the first time in this review we have introduced the novel term of ‘T. gondii–rat manipulation–schizophrenia model’ (11). The genetic mutations that occurred in exon 8 and exon 9 on the MYLK3 gene proved that there was a genetic sequence change in this muscle tissue of the heart due to the involvement of Toxoplasma gondii in the exacerbation of the disease. These work agreed with (Ngô, H. M. et al.2017) who reported that these data were de convoluted using three biology system topics: “Orbital deconvolution” elucidated upstream, regulatory pathway interconnecting human susceptible genes, biomarkers, proteomes in addition to transcriptomes. “Cluster deconvolution” showed visual protein-protein interactions included in a process that affects brain function and circuitry, such as leukocyte migration, lipid metabolism and olfaction. Eventually, “disease deconvolution” which identifies correlations between epilepsy and parasite-brain interactions, movement disorders, Alzheimer’s as well as cancer. This “reconstruction-deconvolution” provides templates of the progenitor cells’ potentiating influences and components affecting human brain parasitism and disorders (12). Little research has been done on the incidence of people suffering from heart disease may be involved in Toxoplasma or may be conducive to these injuries and therefore has been proven that there is a direct relationship with Toxoplasma infection and cases of heart disease and this report works for the first time in Iraq.

Study the Cytochrome P450 Gene Expression Changes in Iraqi Patients with Chronic Liver Disease

Areej GH Al-Charak1, Hamza H Kzar2

1Lecturer, Department of Physiology and Chemistry, Faculty of Veterinary Medicine, Al-Qasim Green University, Iraq, 2Lecturer, Department of physiology and Chemistry, Faculty of Veterinary Medicine, Al-Qasim Green University, Iraq

Abstract

The cytochrome P450 is a chemical group of heme-containing proteins which speaks to one of the biggest and most practically various superfamilies’ found in nature. Chronic liver disease (CLD) is a process of the liver that involves a process of progressive destruction and regeneration of the liver parenchyma leading to fibrosis and cirrhosis. The aim of this study was to assess the cytochrome P450 gene expression changes of three variants, CYP1A2, CYP2B6, and CYP2E1 in Iraqi patients with chronic liver disease (hepatitis+ alcoholism and hepatitis+ non-alcoholism). CYP1A2, CYP2B6, and CYP2E1 mRNA gene expression were assessed by quantitative real-time PCR (qRT-PCR) in 50 cases with CLD and 50 subjects as controls. Primers for genes of interest, CYP1A2, CYP2B6, and CYP2E1 mRNA and housekeeping gene (GAPDH) were designed using NCBI tools. Fatty acid synthase (FAS) was estimated by ELISA technique. The results showed statically significant differences in FAS levels (ng/ml) between study groups, HC, HNC, and control (p-value < 0.05). GEF in CYP1A2 gene showed no change between HC and control but with statistical variations in GEF in HNC and both HC or control. GEF in CYP2B6 and CYP2E1 genes showed highly significant differences between control and both HNC and HC. In conclusion, CYP2B6 and CYP2E1 gene expression were risk factor for progression HC but not HNC through stimulation of increasing levels of FAS.

Keywords: chronic liver disease, cytochrome P450, Fatty acid synthase, gene expression.

Introduction

The cytochrome (P450) is a chemical group of heme-containing proteins which speaks to one of the biggest and most practically various superfamilies’ found in nature (1). The primary capacity of P450s is to encourage the biotransformation of mixes by expansion of practical gatherings reasonable for conjugation and extreme disposal from the life form. The aim of this study was to assess the cytochrome P450 gene expression changes in patients with chronic liver disease (2). In the clinical context, Chronic liver disease (CLD) is a process of the liver that involves a process of progressive destruction and regeneration of the liver parenchyma leading to fibrosis and cirrhosis (3). Patients with either diagnosed or undiagnosed chronic liver disease occasionally present with an acute deterioration of liver function caused by direct or indirect insults to the liver (4). The expression of CYP450 enzymes is influenced by endogenous factors such as genetic polymorphisms, gender, age, and the levels of endocrine hormones (5). The expression of CYP45 enzymes is also influenced by exogenous factors such as drugs and environmental chemicals, as well as the physico-pathological conditions (6). CYP1A2 is a member of the cytochrome P450 with a mixed-function of oxidase system, it is involved in the metabolism of xenobiotics in the body and in humans, the CYP1A2 enzyme is encoded by the CYP1A2 gene (7). This quality, CYP2B6, encodes an individual from the cytochrome P450 superfamily of proteins. The cytochrome P450 proteins are monooxygenates which catalyze numerous responses engaged with medication digestion and amalgamation.
of cholesterol, steroids and different lipids. This protein restricts to the endoplasmic reticulum and its appearance is initiated by phenobarbital. The catalyst is known to use some xenobiotic, for example, the counter malignant growth drugs cyclophosphamide and ifosphamide (8). CYP2E1 is a layer protein communicated in significant levels in the liver, where it makes about half out of the absolute hepatic cytochrome P450 mRNA(7) and 7% of the hepatic cytochrome P450 protein.[8] The liver is thusly where most medications experience deactivation by CYP2E1, either legitimately or by encouraged discharge from the body. CYP2E1 uses for the most part little, polar particles, including dangerous research facility synthetic substances, for example, dimethyl formamid, aniline, and halogenated hydrocarbons. While these oxidations are frequently of advantage to the body, certain cancer-causing agents and poisons are bio activated by CYP2E1, involving the catalyst in the beginning of hepatotoxicity brought about by specific classes of medications (9). CYP2E1 also carries out the metabolism of endogenous fatty acids such as the ω-1 hydroxylation of fatty acids such as arachidonic acid, involving it in important signaling pathways that may link it to diabetes and obesity. Thus, it acts as a mono-oxygenase to metabolize arachidonic acid to 19-hydroxyeicosatetraenoic acid (19-HETE) (10). The aim of this study to assessment the cytochrome P450 gene expression changes of three variants, CYP1A2, CYP2B6, and CYP2E1 in Iraqi patients with chronic liver disease (CLD), (hepatitis + alcoholism and hepatitis + non-alcoholism).

Materials and Method

1- Subjects of the study:

The samples of fresh blood were collected in GIT Centre in Merjan teaching hospital from 50 patients with CLD and 50 healthy subjects as control group. The aged and gender of both groups were matched (p-value > 0.05).

2- Methods: Gene Expression Analysis of CYP1A2, CYP2B6, and CYP2E1

Total RNA was extracted from fresh blood of patients and control by using the TRIzol reagent (USA). The concentration of total RNA was measured by spectrophotometry and the OD260/OD280 ratio was obtained to assess the RNA purity. cDNA synthesis performed by reserve transcript and conducted by PrimeScriptTM RT-PCT reagent Kit (Korea) in a 50 μL reaction mixture following the supplier’s instructions. The qRT-PCR was performed by using cDNA as a template in the Exicyclere Real-Time PCR System (Bioneer, Korea) with SYBR green kit as fluorescent dye according to the protocol of manufacture. The PCR conditions were 95 °C for 1 min, followed by 40 cycles of 95 °C 15 s, 62 °C 45 s. The primers used in the RT-PCR were designed by NCBI tool and not showing here. The relative gene expression levels were calculated on the basis of 2−ΔΔCt. GAPDH was conceder as housekeeping gene as control. The results are presented as fold change of CYPs in patients group compare to control (GEF).

3- FAS levels estimation: Assessed by ELISA depending on Elabscience™ protocol by manufacturer instructions provided with kit.

4- Statistical analysis: Data have been analyzed statistically using SPSS program version 21. Analysis of quantitative data was done using t-test and ANOVA analysis.

Results

Clinic-pathological characteristics of patients with CLD included in this study are illustrate in table 1:

Table (1): Clinic-pathological characteristics of patients included in this study

<table>
<thead>

From the above table, there were statistical significant differences in levels of FAS ng/ml in HC and HNC subgroups ≥ 30 and < 30 (p-value< 0.05) and this mean that age was risk factor for HC and HNC but the gender in HC was no statistical differences (p-value>0.05) while in HNC the gender was risk factor and increased in males compare to females.

The cytochrome P450 gene expression changes fold of three variants, CYP1A2, CYP2B6, and CYP2E1 in Iraqi patients with chronic liver disease (CLD), (hepatitis +alcoholism and hepatitis +non-alcoholism) compare to control group were illustrated in figure 2:
Discussion

The present study examined the fold of major drug metabolizing P450 (CYP1A2, CYP2B6, and CYP2E1) gene expression fold GEF and FAS levels in 50 Iraqi chronic liver disease (CLD) (hepatitis +alcoholism and hepatitis +non-alcoholism), and compared with 50 normal subjects. FAS is a multi-enzyme protein that catalyzes synthesis of fatty acid. FAS is not a single enzyme but a whole enzymatic system composed of two identical 272 kDa multifunctional polypeptides, in which substrates are handed from one functional domain to the next (11). In the present study, the serum FAS levels of the HC patients were found to be significantly higher in comparison to the HNC and healthy controls, indicating that high concentrations of FAS in serum may result from enzyme secretion by abnormal liver cells. Dorn C et al (2010) were reported that the transcriptional induction of FAS expression in hepatic steatosis is impaired in nonalcoholic steatohepatitis, while hepatic inflammation in the absence of steatosis does not affect FAS expression, suggesting that FAS may be serve as a new diagnostic marker or therapeutic target for the progression of nonalcoholic fatty liver disease (12). Li M et al (2018) were suggested that the accumulation of free fatty acids in hepatocytes induces lipotoxicity, leading to non-alcoholic fatty liver disease (13). GEF in CYP1A2 gene showing no change between HC and control and there were no statistical variations in GEF in HNC and both HC or control, this means that CYP1A2 was not involved in progression of HC and HNC to promoting of chronic liver disease. CYP2B6, and CYP2E1 genes were found help to progression of HC and HNC of chronic liver disease because of highly alteration in GEF in different these groups and this agreement with other studies that using genetic markers as diagnostic agents(14,15). These results suggest a significant role of CYP2B6, and CYP2E1 genes in the regulation of hepatic lipid metabolism via the fatty acid synthesis pathway and FAS, a critical factor for lipid synthesis. In conclusion, The identification of effective gene expression of CYP2B6, and CYP2E1 genes and FAS as molecular and bio markers of HC and HNC could improve the early detection of CLD.

The Reliability of Orthodontic Treatment, According to the Needs of Patients Using the Dental Aesthetic Index

Esraa Salman Jasim¹, Noor F. K. Al-Khawaja²
¹Assist. Prof., ²Lecturer, Department of Orthodontics, College of Dentistry, University of Baghdad, Baghdad, Iraq

Abstract

Objectives: Malocclusion was and remains one of the most common problems which affects the psyche and social status of the individual, so the estimation of the malocclusion severity and needs a percentage of orthodontic treatment of Iraqi patients is the aim of this study.

Method: A randomly selected 150 pairs of study models (48 male and 102 female) were involved in this study for patients attending an orthodontic clinic at College of Dentistry/ University of Baghdad seeking for treatment. The DAI scores were collected according to WHO guidelines directly from the study model with a digital caliper, score was calculated using the regression equation of 10 occlusal traits. The dental casts were classified into four groups to determine the treatment needs. SPSS software version 25 was used to analyze the results.

Results: 8.7% of orthodontic treated patients were with normal or mild malocclusion (DAI≤25) and did not need treatment, while 56% of them were handicapped and needed mandatory treatment. In between them, patients with definite and severe malocclusion were 18.7% and 16.6% respectively. Molar deviation (72.6%) represents a high prevalence rate among occlusal traits, while negative overjet (7.3%) is the least one.

Conclusions: Not all patients who are treated in an orthodontic clinic are really in need, and it must be the implementation of treatment need index to determine the treatment priority for patients.

Keywords: Dental aesthetic index, Treatment need, Study model, Orthodontic patient.

Introduction

Malocclusion is and remains one of the most common problems which affects the psyche and social status of individual. In addition, a good appearance of the teeth improves acceptance among peer group and increase successful life outcomes in comparison with people of less attractiveness.¹,²,³ One of the major problems in the evaluation of malocclusion is the presence of suitable and objective method to assess and record the severity, complexity, prevalence of malocclusion and the treatment needs.⁴ For that this reason many orthodontic indices have been developed since for decades.⁵

William Shaw and colleagues in 1995 classified occlusal indices into five groups;⁶ Diagnostic indices, Epidemiologic indices, Orthodontic treatment need indices, Orthodontic Treatment Outcome indices and Orthodontic Treatment Complexity Indices.⁷ The Dental Aesthetic Index (DAI) is one of treatment need indices, developed by Cons et al (1986, USA), It has been adopted as a cross-cultural index by the World Health Organization (WHO), a number of researches revealed that the DAI is valid and reliable.⁸,⁹ The index show single score which combine subjective, objective and clinical esthetic factors with a threshold limit (i.e. 31 or higher) to regularize with the needs for orthodontic treatment according to the severity of malocclusion.¹⁰,¹¹ It has been used in several researches within different countries in clinical and epidemiological studies of malocclusion.¹²

The purpose of this study was to estimate severity of malocclusion and needs percentage for orthodontic treatment of Iraqi patients who seek treatment in orthodontic clinic using DAI to know whether they have serious orthodontic problems or not.
Method

Data for this project were retrospectively collected from the orthodontic clinic at College of Dentistry/ University of Baghdad for attending patients who received treatment during the period of September 2017 to January 2019.

A randomly selected 150 pairs of study models (48 male and 102 female) were involved in this study. The patients age ranged from 18 to 25 years with no previous orthodontic treatment, cleft lip and palate, great restorations/crown and/or prosthetic treatment.

The DAI scores were collected according to WHO guidelines directly from the study model with a digital caliper; the index consists of 10 occlusal characteristics including; visible tooth loss, crowding in the incisor region, spacing in the region of incisors, diastema, anterior maxillary misalignment, anterior mandibular misalignment, anterior maxillary overjet, anterior mandibular overjet, vertical anterior open bite and anteroposterior molar relationship.

The core was calculated using the regression equation of 10 occlusal traits: “(visible missing teeth x 6) + (crowding) + (spacing) + (diastema x 3) + (anterior maxillary misalignment) + (anterior mandibular misalignment) + (anterior maxillary overjet x 4) + (anterior mandibular overjet x 4) + (anterior vertical open bite x 4) + (anterioposterior molar relationship x 3) + 13”.14

Then the dental casts were classified into four groups to determine the treatment needs: Those with score of ≤25 were considered as normal or mild malocclusion with little or no need for treatment, scores of 26-30 were defined as malocclusion with elective need for treatment, 31-35 were considered as severe malocclusion with highly desirable need for treatment and if the score ≥36 then it was considered as very severe or disabling malocclusion with mandatory treatment.15,16

Statistical analyses. The results were analyzed using SPSS software version 25. The statistics will be:

1) Descriptive statistics: including frequency and percentage.

2) Chi square: To test genders differences.

Calibration: To estimate the reproducibility and validity of the research, 20 dental casts were examined by a specialist orthodontist, and re-examined by the same orthodontist with an interval of 2 weeks to realize intra-examiner accuracy in the employment of the DAI. The intrarater correlation coefficient for repeated examinations was 0.96 (P < 0.001), indicating high accuracy.

Results

From the hundreds of patients seeking treatment, who visited orthodontic clinic at college of dentistry every year, 150 pairs of dental casts for pretreated patients have been used for this study. Chi-Square test showed no significant difference between male and female at a p-value (0.412) as shown in table 1.

The DAI scores were explained in Table 1 and 2, 8.7% of casts with normal or mild malocclusion (DAI≤25), 18.7% of casts with definite malocclusion (DAI 26-30), 16.6% of casts with severe malocclusion (DAI 31-35) and finally 56% of casts with handicap malocclusion (DAI ≥35). The distribution of the total sample according to their DAI scores is illustrated in Table 2, the lowest DAI score recorded was 18 (0.67%) while the highest DAI score registered was 91 (0.7%) and the most commonly recorded DAI score was 34 (7.3%).

The distribution of malocclusion components according to the DAI show molar deviation, crowding and anterior maxillary misalignment is the most common among patients which represent 72.6%, 68.7% and 66.7% respectively, and the negative overjet is the lowest among patients (7.3%) as explained in Table 3 and 4.

Discussion

The orthodontic clinic at the college of dentistry receives a large number of patients annually from across the country due to lack of specialist orthodontists and the cost of treatment.

In this research, measurements were performed on studying models instead of patients in order to examine a wide variety of patients within a short time, in addition to knowing the patients who visit the orthodontics clinic, the eligible ones for treatment.

The DAI has been supported by WHO due to its simplicity, reliability and wide use in researches, in addition to its high sensitivity in predicting the high proportion of persons requiring orthodontic treatment correctly as well the no-treatment need.

The components of the DAI show the percentage of malocclusion traits and those results can highlight the most commonly presented one as explained in Table 3.

Only one Iraqi study of Kurdish people and few studies of other populations have DAI analysis of malocclusion traits. Also, because this study is the first study carried out for orthodontic patients who attend the orthodontic department so the results were completely different from previous Iraqi studies. Besides the differences in genetics and race, lead to differences from other populations.

Concerning orthodontic treatment needs, 8.7% of treated patients represent mild or normal occlusion with little or no need for treatment (DAI≤25), while 16.6% (DAI 31-35) of patients have severe malocclusion and 56.2% (DAI≥35) are considered as being handicapped and in need of mandatory treatment. The female represents 68% of the total sample and that indicate the concern of female about their occlusion and appearance more than male.

Regarding the handicapped malocclusion, the results of our study is close to the results of Poonacha et al. (55%) and Goyal et al. (51%); Also, because this study is the first study carried out for orthodontic patients who attend the orthodontic department so the results were completely different from previous Iraqi studies. Besides the differences in genetics and race, lead to differences from other populations.

But what attracts attention is that orthodontic patients with (DAI≤25) are clearly different from those of other studies which depends on patients who visited the clinic in general. While, our study uses the study models of previously treated patients.

The percentage of each parameter of DAI is explained in Table 3. Where tooth loss was present in 20% of total samples, Crowding in 68.7%, spacing in 36%, median diastema 19.3%, anterior maxillary misalignment 66.7%, anterior mandibular misalignment 54%, overjet (> 4mm) 44.7%, negative overjet 7.3%, anterior openbite 14% and molar deviation from the normal relationship 72.6%.

As we have clarified, the result of each anomaly show much higher rate in comparison with other studies because it harmonious with the fact that the sample was composed entirely of patients referred to an orthodontics clinic with malocclusion, in addition to the racial, genetic, social behaviors, cultural differences and the most common effects are economic and political reasons.

Conclusion

Not all treated patients in the orthodontic clinic are with a true need for treatments, but few of them are with mild malocclusion and no need for treatment; since the therapeutic possibilities are minimally available and poor economic situation for most of the people, the treatment needs should be provided for patients who really deserve.

The DAI is the simplest and easiest index to be used by a general dentist for examination of attending to patients and assessing the severity of their malocclusion to be treated as a priority treatment need.

Study the Protective Role of Arabic Gum Extract on Some Physiological and Histological Criteria for Liver of Male Rabbit Treated with Atrazine

Noor Rahi AL-Shimmari¹, Rasha Abdulameer Jawad¹
¹Department of Biology, College of Education for pure Sciences, Karbala University, Iraq

Abstract
The study involved fifteen health adult male rabbit white (*Lepus arcticus*), weight ranged (1480-1550) kg. and age between 6 to 8 month, divided to three groups the first group treated 10 ml of atrazine orally for five rabbits daily for two weeks and second group is treated with aqueous extract of Arabic gum (AG) (*Acacia Senegal*) 30% and atrazine 10 ml between one day and another for two weeks and third group was the control group given 10 a normal saline. In the search the levels of hepatic enzyme were presented (AST) Aspartate transaminase, (ALT) Alanine transaminase and (ALP) Alkaline phosphate, also the rate of diameters of liver sinuses, the diameters of central veins and hepatocellular diameter, and found through this study:

- The presence of a significant increase (P≤0.05) in the levels of hepatic enzyme (AST), (ALT) and (ALP) and rate of diameters each of liver sinuses, central veins, and hepatic cells in atrazine group compared with the control group.

- The presence of significant decrease (P≤0.05) in levels of hepatic enzyme (AST) and (ALT) in the group treated with aqueous extract of AG in 30% concentration and 10 ml of atrazine compared with control group, and did not occur significant differences (P≥0.05) in the level of (ALP) and in rate of diameters each of liver sinuses, central veins, and hepatic cells in aqueous extract of *Acacia Senegal* and atrazine group compared with the control group.

**Keyword:** Atrazine, Acacia Senegal, AST, ALT, ALP, Hepatocytes.

Introduction
Medicinal plants containing active substances used for therapeutic purposes or in the pharmaceutical industry and that the natural products of these plants are an effective source to discover vital effectiveness like anticancer, antioxidant (¹), antibacterial and antiparasitic (²). Where these plants are a food source on one hand and medication against various diseases on the other due to the contents of its parts of chemical compounds of great interest and importance because of therapeutic activity of humans (³), where used as catalysts for growth (⁴), the orientation for medicinal plant treatment is justified and taking chemically manufactured drugs has been shown to have serious side effects that may appear over time and cumulatively (⁵).

AG is a substance collected from the secretion of the stems and branched of *Acacia Senegal* tree, it consists mainly of large molecules carbohydrates, proteins, minerals and amino acid (⁶). AG has a high molecular weight as polysaccharide it contains galactose, rhamnose, glucuronic acid and arabinose also calcium, potassium and sodium salts. It also contains 1.5%-2.6% protein, 0.22%-0.39% nitrogen and amino acid mainly like hydroxyproline, serine, proline, and aspartic acid, it has high solubility in water but does not dissolve in alcohol (⁷). And has many uses in the industrial section such as textiles and cosmetics, and pharmaceutical and nutritional uses where in the pharmaceutical field as a pharmaceutical compound because of its antioxidant activity and positive effect in treatment of urinary tract, cardiovascular and digestive system also improves the liver, kidney & heart tissue (⁷).
Atrazine effects on the body’s various organs, including the liver, which is the main organ for detoxification of the body. Research has shown a decrease in the accumulation of hepatic glycogen and the presence of early symptoms of liver cytotoxicity, this is due to the toxic effects of atrazine on the liver that inhibit the activity of major enzymes such as hexokinase, glycogen synthase and glucokinase(8); this explains the low body weight has been observed to lead to decrease in glycogen and increase fat in liver(9). In addition, bile duct hypertrophy and renal tube necrosis have been observed (10). It has also been found to lead to changes in insulin resistance and disturbance in fat digestion (11). Atrazine also attacks fats, proteins and DNA molecules, causing metabolic changes in severe cases, it can lead to cell death and lead to oxidative stress and emergence and development of many diseases such as atherosclerosis, cancer, psoriasis, Alzheimer’s, high blood pressure, heart disease, liver, kidney and brain (12).

Materials and Method

AG samples were collected from Babylon governorate in October 2018, Gum Arabic powder was moistened with water by 1:5 where 50 of gum Arabic was mixed with 250 ml of distilled water (13). a horizontal shaker GFL type, 3015 modules for 30 minutes and the sample was left static and then filtered using filter paper three times, after that centrifuge was used 3000 rpm for 15 minutes. the extract was concentrated using a rotary evaporator and dried 45 in an oven.

Experimental design.

The experiment was designed to investigate the effect of aqueous extract of AG and atrazine on liver tissue and its effect on some functional blood parameters in local male rabbits. then divided into three groups, including 5 rabbits are:

1- Atrazine group 10 ml for two weeks daily.

2- Aqueous extract of AG and atrazine group from day to day at dose of 10 ml and at concentration of 30% of AG and 10 ml of atrazine and for two weeks daily.

Anatomy of animals and blood collection

The animals were then numbed with chloroform and anatomy by opening the abdominal cavity and draw blood through heart puncture to get the most amount of blood. Blood samples were placed directly into sterile anticoagulant –free test tubes its capacity 10 ml, it was left for 15-20 minutes at laboratory temperature and then transferred to a centrifuge 3000 rpm for 15 minutes for the purpose of obtaining the serum stored in the refrigerator at temperature -4 C(15)for the purpose of physiological testing that including AST and ALT (16) ALP(17). The liver was removed after fatty substances were removed fixed with formalin concentration 10% so as to preserve the cellular structure and the natural structure and the natural state of the tissue, after two days 48 hours I was extracted from formalin and washed with tap water for a (3-6) hours, then a series of operation took place to prepare tissue slides colored Eosin and Hematoxylin then the prepared tissue slides were examined using a compound microscope and under a 10X magnification force, and measured the rate of diameters of liver sinuses, the diameters of central veins and hepatocellular diameter.

Results and Discussion

Physiological study: The results of the physiological study are shown in Table 1 for atrazine group 10 ml in rabbits’ serum there is a significant increase (P ≤ 0.05) in the average level of ALT, AST and ALP enzymes for two weeks compared with the control group. The results of this study are consistent with which reached Jested and his group (18) in his study with doses rats 300mg/kg from atrazine for one month noting an increase in the levels enzymes mentioned above , consistent with the results of this study of Hussein and his group (19) which he made on rats by taking them 400gm/kg from atrazine for two weeks ,the cause of the increase in rate of enzymes levels in the blood serum indicates the extent of damage to the liver and heart tissues the result of treatment with atrazine leading to a change in hepatic metabolic functions through damage to hepatocytes or the increase may due to kidney damage due to heart damage which leads to the occurrence of chronic renal insufficiency due to necrosis, degeneration or damage to renal cells leading to enzymes leaking into the blood serum (20) Or due to increased oxidative stress resulting from the high proportion of oxidant from the liver because atrazine is an oxidizing agent capable of attacking the cell membrane and antioxidant molecules which cause damage and breakdown in DNA , protein and fat(21).consistent with this result what he pointed out Mohammad and his group (22) .to born of free radicals (ROS) Reactive Oxygen Species leads to the breakdown of mitochondria containing the enzymes listed, because oxidative stress increases the process of lipid peroxidation leading to cirrhosis.
The results of the physiological study are shown in Table 1 for atrazine group 10 ml that treatment with aqueous extract of AG at concentration in rabbits to presence of significant decrease (P≤0.05) in AST and ALT, there is no significant difference (P≥0.05) in rate of ALP for two weeks compared with the control group. Consistent with the results of our study (23), noting when dosing mice with 10% from AG for three month leads to decrease in the concentration of enzymes mentioned above, the results of the atrazine group with the results of this group treatment with AG to increase in average level of liver cell enzymes that lead to oxidative stress of the kidney and liver that results born of free radicals capable of attacking the cell membrane and antioxidant molecules which cause damage and breakdown in DNA, protein and fat (22). Also the study of Ayaz and his group (24) referred to the protective role of aqueous extract go AG when give 0.5 g/kg daily for two weeks to mice treated with toxic substance Trichloroactate where they notice a decrease in the levels of hepatic enzymes mentioned above perhaps due reason to improvement in the liver functions due to increased enzymatic antioxidants such as Catalase and Glutathione peroxidase, and non-enzymatic such as vitamin A,C, and because the plant contains phenolic compounds which working on decrease free radical formation (25).

Table (1): effects of aqueous extract of AG in concentration 30% on levels rate of some enzymes in serum of rabbits that treated with atrazine.

**Histological study:** Figure 1 represents the normal histological structure of the control group for two weeks for a rabbit liver, the liver consists of a central vein and hepatic cords surrounding cubic cells distributed between hepatic cord and hepatic sinuses. The results have shown the formal and histological measurements in Table 2 and Figure 2 to section of liver tissue for atrazine group treated with AG 30% to absence of significant differences (P≥0.05) in diameters rate each of hepatic sinuses, central vein and hepatic cells compared with the control group, as for the histological composition for atrazine group treated with AG 30% note a slight improvement in liver tissue represented by lack of central vein expansion compared with group treated with atrazine alone, absence lack in sinuses and less cellular infiltration.

The study of (26) pointed to that oral dosage with alcoholic extract of AG plant 400,800mg/kg daily for one week for mice treated with toxic carbon tetrachloride prevent necrosis, fatty infiltration and liver damage resulting from this toxic substance CCL4 that the histological structure of the hepatic cords and tissue normal appears addition to low in hepatic enzymes. This confirms the effectiveness of AG as a medicinal plant used in folk medicine because it contains many effective chemical compounds such as carbohydrates rhamnose, galactose and arabinose, acids such as glucuronic and mineral salts such as calcium, potassium, magnesium and sodium, addition to medically effective compounds such as phenols, flavonoids and alkaloids (27). Also the study of Ram and his group pointed to a role of alcoholic extract of gum Arabic plant when dosing rabbit 500mg/kg daily for forty five days leads to remain the liver, kidney, heart and aorta tissues similar to normal, addition to low in hepatic enzymes and liver lipids that pointed to the possibility of the plant in the treatment of cases of
fats and atherosclerosis\(^{(28)}\).

Relation between Working in Petrol Station and Blood Hemoglobin Levels for the Filling Workers in Al-Najaf City/ Iraq

Fulath Abdul-Redah Muhsin
Community Health/The Head of Community Health Department / Al-Kufa Technical Institute / Al-Furat Al-Awsat Technical University

Abstract
Petrol station workers were exposed to several pollutants like air pollutants by inhalation, or skin contact with petroleum derivatives like benzene, and another port of entry. This comparative cross-sectional study was conducted to find a relationship between working in petrol stations and hemoglobin blood levels of the workers in Al- Najaf-city. The exposed worker’s group was (50 male) of petrol station workers aged 20-50 years, the years of working was (1 ≥15 years) of ( ≥7 h/day) that included in this study, the comparison group was 50 healthy male service and office workers aged (20-50 years) matching with the study group from al-Kufa Technical Institute, Al-Furat Al-Awsat Technical University.

Blood samples were tested at the field by using a digitized portable device (hemochromax plus) which gave the blood hemoglobin concentrations at mg/dl of the petrol stations worker. The results of blood hemoglobin were compared between both groups. There was a highly statistically significant difference (HS) between Gas station workers and Control group at the $P$-value of (0.001) of Hb blood concentration levels and the mean of gas station worker and control group were (11.57 and 15.58 mg/dl) respectively. there was a highly statistically significant difference (HS) between not anemic and anemic workers at the $P$-value (0.000), and there were 47 workers (94%) out of all 50 workers had anemia after the field test.

There was a statistically significant difference (HS) between Hb levels of Gas station workers and Standard Normal Hb Level at the $P$-value = 0.007. There were a moderate inverse negative correlated between the time of exposure in the year and blood hemoglobin levels in mg/dl at the ($r = -0.57$), which mean there were decreases of blood hemoglobin levels of the worker when increases of the duration of service employment. The study concluded from all results that were finding that decreased blood hemoglobin concentration than the normal value of the petrol stations workers for all stations, which might be due to the adverse effect of the workplace pollutant on bone marrow. Attention should be given by a periodical medical assessment of all workers in the petrol stations, and Obligate the petrol stations managers for supplies all personal protective equipment for all workers.

**Keyword:** workplace pollutants, Hemoglobin, Anemia, Filling Workers, Al- Najaf city.

Introduction
Health impact of occupational exposure to petrol and air pollution from the exhaust of automobile sources and un discover through petrol station workers (1). Lack of ventilation &unused of the personal protective device at the work place when using benzene will arise the occurrence of Toxic effects of benzene and petrol derivatives in workers (2). Repeated exposure can lead to inflammation of the respiratory tract and hemorrhage in the lung. Different air pollution like benzene and atmospheric polluted air like car exhausts, absorbed into the human body by respiratory tract or via epidermal contact (3).
Air pollutants and other chemicals like benzene or other heavy metals and carbon monoxide (CO) and carbon dioxide (CO$_2$) can cause adverse health effects by body metabolites and interference with biochemical or physiological processes of the human body (4). Petroleum derivatives were used for different reasons by human beings at home, in manufacturing and petrol station (5).

Petrol station workers are exposed to a mixture of hydrocarbons in a fuel vapor through dispensing fuel and to the gases from car exhaust (6). In the petrol station; the amount of fuel spread as well as the ambient temperature interaction significantly to the arising emission of volatile hydrocarbons. Most people have a greater risk of exposure to gasoline vapors, these include petrol station workers, service station and drivers of cars (7).

The nature of the petrol station workers makes them readily available of the most time to exposed by skin or ingestion and inhalation. Benzene & other derivatives affect blood production by affecting the bone marrow. the most characteristic effect resulting from intermediate and chronic benzene exposure was reduced the development of blood cell (8).

And causes aplastic anemia in human. The clinical finding in petrol. Hepatotoxicity cytopenia; which was a decrease in several cellular elements of circulating blood as manifested as anemia; leukopenia and thrombocytopenia in humans. The inhalation of petrol derivatives like benzene vapor is rapidly absorbed into the blood and distributed through the body. Several studies of benzene-exposed workers agreed that chronic exposure to benzene at air resulting in the adverse hematological effects (9).

The aim of this study: To find a relationship between exposures to workplace pollutants and hemoglobin blood levels of the petrol station filling workers of Al-Najaf city.

Material and Method

Study Design: Comparative cross-sectional study.

Place of the study: The study was conducted in «Al-Najaf city that located to the South of Baghdad about 165Km, Iraq».

Period of the study: Data Collection was lasted from (30/1/2018 to 19/2/2018).

Sampling collections: All petrol stations that belong to governorate in Al-Najaf city were included in this study. The blood samples were collected from 7 government gas petrol stations in Al-Najaf city, the samples were tested at field of the petrol stations. From 50 person that working on it.

Questionnaire: A well-designed questionnaire was applied in this study.

Field tests: Samples were tested by using a portable digitized device portable, on each petrol station in Al-Najaf city. was used in this study to test the Hb % level of the petrol station workers (Hemochromax plus) of Korean made which was need only one blood drop to give the Hb levels results.

Statistical methods: Descriptive and analytical statics were carried out in this study by using a statistical package from social science (SPSS) version 18. Z-test was applied to obtain only statistical significance difference and Pearson correlation coefficient (r) was used to find the correlation between exposure time in years and hemoglobin concentration in blood.

Figure (1): Show that there are a moderate inverse negative correlated between the time of exposure in the year and blood hemoglobin levels in mg/dl at the \( r = -0.57 \), which mean there are decreases in blood hemoglobin levels of the worker when increases of the duration of service employment.

**Discussion**

Air pollution and the dealing with petrol derivatives still have more priority for the worker when risk assessed, as well as its toxicological effect for the bodyworker. The study in the Al-Najaf petrol station could be considered the first study with this result finding, most of the worker of the study group were in the second decade of the life, the study group of the petrol station worker and healthy control group was matched for age to find if there is any significant difference for achieving the study aim.

All the results that we’re found in the present study between the study group of the worker and the comparison group were significantly more among the petrol station workers than the other (control group) from the normal parameter.

The present study was showed a highly statistically significant difference when comparison was made between the petrol station worker and control group in hemoglobin concentration levels, this defect might be due to the damage to the bone marrow by the toxic effect of the pollutant hydrocarbons gases that emissions from the car exhaust in the ambient air of the petrol stations and the entrance of the petroleum products like benzene or gasoline oil through the respiratory tract by inhalation or ingestion and entrance by skin contact way.

The results data in present study was showed that the most numbers and the percentage of the worker that represent of studied samples have anemia through the clear decrease of the blood hemoglobin concentration 47 (94%) respectively, with the higher statistical significant differences in comparison with non anemic worker, the same finding results were obtained by Okoro A.M. (10), of study in Nigeria of anemic worker in petrol stations at 2010.

While the different results were found in Gaza, Palestine with that mentioned by Sirddah M.M., et al in 2013, who found that the hemoglobin levels of the blood concentration levels were increases in the blood of the petrol stations workers (11).

The present study was showed a highly statically significant difference between Hb levels of petrol station workers and standard normal hemoglobin Level at the \( P\)-value = 0.007, The results agreement with that mentioned by Anthony Seaton, et al, 2016 in United Kingdom (12), who found that there was a high difference when compared with the normal Hb value. In addition, the same results were found by Tunsaringkarn T, et al, in Bangkok, at 2013, Thailand (13).

The present study showed that there was a moderate inverse negative correlated between the time of exposure and blood hemoglobin levels, \( (r = -0.57) \), which mean there was a relationship between exposure time and blood hemoglobin levels, in another meaning the decreased in blood hemoglobin levels of the filling petrol station worker was happened when increased in years of service, this results might be due to continuity in exposure to workplace pollutants, the same finding results were obtained by Sahb AA, of study in Baghdad in 2013 (14).

**Conclusions**

The following conclusions can be derived from this study:

1. There was a highly statistically significant difference (HS) between gas station workers and control group at the \( P\)-value of (0.001) of Hb blood concentration levels.

2. There was (HS) between nonanemic and anemic workers at the \( P\)-value ( 0.000).

3. There was an (HS) between Hb levels of gas station workers and standard normal Hb Level at the \( P\)-value = 0.007.

4. There were a moderate inverse negative
correlated between the time of exposure in (years) and blood hemoglobin levels in mg/dl at the \( r = -0.57 \), which mean there were decreases of blood hemoglobin levels of the worker when increases of the duration of service employment.

Effect of Preoperative Breathing Exercise on Postoperative Patients’ Lung Functions

Dhiaa A. Al-Reda, Rajha A. H.

1Adult Nursing, University of Kufa, Faculty of Nursing, Iraq

Abstract

Pulmonary complications after surgery are a major cause of morbidity and mortality and therefore are a source of concern in both developed and developing countries. Presently, surgical patients didn’t acquire education about deep breathing activities that were adequate and many of them only received some education post operation. Aim of the study: To investigate the Effect of Preoperative Breathing Exercise on Postoperative patients’ Lung Functions. A quantitative quasi-Experimental, Pre-Test and Post-Test design. A non-probability (purposive sample) of (60) patients divided into two equal groups distributed as the case and control groups (30) patients for the case group are exposed to the breathing exercise program, Pursed-lip method, and (30) patients without exposed to the breathing exercise program categories as control group. The study have been carried out in Al-Diwaniyah teaching hospital, This study conducted from 22nd of October 2018 to 25th of June 2019. There were statistically significant difference between case and control groups, patients in the case group had improvement in all parameters of lung functions than control group ( P < .05) in the two periods of measurement post-operatively. The program show obvious difference between the lung function for both study and control groups during the post-test.

Keywords: Preoperative, Breathing Exercise, Postoperative, patients’ Lung Functions.

Introduction

Impairment in lungs functions after surgery are one of important postoperative complications, strength of respiratory muscles could be decreased and that one reason lead to lung function change.

During surgery, using of general anesthetics can affect the central regulation of breathing by changing the neural drive to respiratory muscles such as the diaphragm, and because of this, the respiratory function cannot be separated from anesthesia. The components that can alter the pulmonary function contain unconsciousness, ventilation (whether its mechanical or spontaneous), a patient’s position, anesthetics drugs, that were used during the anesthetic process on the respiratory muscles. General anesthesia can alter mucociliary function, promoting retention of secretions, causing bronchoconstriction, decreased surfactant production, inhibition of alveolar macrophage activity. Moreover, anesthesia may cause atelectasis instantaneously in majority of the patients as an outcome of chest wall deformation, decreased inspiratory muscle tone, and reduced functional residual capacity which may considerably influence gas exchange.

The effect of these factors on pulmonary function are appear in the early postoperative period. Lung function, measured as vital capacity (VC) and forced expiratory volume in one second (FEV1), is usually decreased by 35-60%, and a 6-13% Decreased lung function can linger for four months. In the first days following an operation, a decreased lung function can impact impaired gas exchange, and the strength of the respiratory muscle will also decrease during the first days after surgery. This may be explained by insufficient diaphragmatic breathing or by the respiratory fatigue that some patients experience during the post-operative period. The complications that related to anesthesia, tissue damage, immobilization, inhibition of cough, and incision of abdominal muscles which results in postoperative pain, major causes to decreased the lung volumes and limited airway clearance, which can lead to Post-operative pulmonary complications (PPC).

Methodology

Study Design:
A quantitative quasi-Experimental, Pre-Test and Post-Test design have been carried out to study the effect of preoperative breathing exercise on postoperative patients’ lung functions, in Al-Diwaniyah teaching hospital, This study conducted from 22nd of October 2018 to 25th of June 2019.

Setting of the Study:

The study is conducted in Al-Diwaniyah City, Al-Diwaniyah Health Directorate, Al-Diwaniyah teaching hospital, Surgical Wards. This hospital is a governmental, and the largest general hospital, and presents different of the medical therapeutic services in Al-Diwaniyah city.

Study Sample:

A non-probability (purposive sample) of (70) patients undergoing abdominal surgery. (10) patients of the sample for pilot study and (60) patients of the sample is divided into two equal groups distributed as the case and control groups (30) patients for the case group are exposed to the breathing exercise program, Pursed-lip method, and (30) patients without exposed to the breathing exercise program categories as control group.

Criteria for Including the Sample:

1. Adult patients age from 20 years and above.
2. Patients undergoing abdominal surgery under general anesthesia.
3. Stable condition as reported by the physician.
4. Patients with normal respiratory and cardiac functions.

Validity of the Instrument:

The face validity of the study instruments are determined by a panel of (16) experts, have experience more than ten years, from different specialties from nursing faculties.

Reliability of Instrument:

In order obtains the reliability of the study instrument five patients undergoing abdominal surgery are selected from Surgical wards for the purpose of testing the instrument their lungs capacities (FEV1, FVC, FEV%) was measured in preoperative period by used two spirometer at one time, one of them is used in the present study and the other used at Al-Diwaniyah teaching hospital. A comparison between the results of them, The result indicate, spirometer which used in present study is a reliable instrument to measure the purpose of the study.

Through developed questionnaire for Arabic version, demographic and clinical data were collected. While physiological data (Lungs volume) are collected by using the pulmonary function test machine (Portable Diagnostic Spirometer, Mir, Italy) through preoperative and postoperative assessment. During preoperative phase, the assessment was obtained ( before one day of surgery for case group and, in the same day for control group), while in the post-operative phase, the assessment was done at 8th hours and 24th hours after surgery based on the previous scientific references such as 10 Regarding case group the assessment of the lungs volumes applied before and after the application of the program. For the control group, the assessment was performed only without the application of the program. The data collection process has been performed from 11th January to 14th March 2019.

The data have been collected through the use of a constructed questionnaire tool. The data analysis was done through statistical package of social science (SPSS) version (25). The methods of analysis of data include; Descriptive Data Analysis and Inferential Data Analysis

Table (1) represent the clinical data of the case and control groups. Regarding body mass index (BMI) the table shows most of the sample in both groups are overweight (46.7%) in control group while (43.3%) in case group. In smoking status condition the table shows the majority in control group (76.7%) is nonsmoker and (70%) in the case group. Regarding type of smoking in both groups are cigarette smokers with duration of smoking (66.6%) with period of (10-19) years for control group and (57.1%) for case group who spend more than 30 years in smoking. Regarding chronic disease the study results presents that chronic disease (60%) of case group with chronic disease and (66.7%) in control group with chronic disease (50%) of both group with hypertension. Regarding previous surgery (50%) in case group have previous surgery (20%) of them with Caesarian surgery.

Table (4) shows there are a strong negative correlation between patient’s lungs volumes (FEV1, FVC,) and age (r=-0.895;0.001) (-0.619; 0.001) respectively, FEV1 and body mass index (r = 0.722; 0.041), as well as a significant correlation among other studied parameters.

Discussion

Regarding Table (1) there was a high percentage of patients at age groups (50-59) years old, and the majority of study samples were male. This could be agreeable with 11 as their study have the same range age group, and the gender was also mainly male. The present results show that most patients are primary school graduate, many people might live with number of social and economic barriers to stressful and conflict environment, this can prevent them for achieving higher educational levels, this result could be supported by 12 majority of their study are primary school graduate were (78.5%). It is show that there is non-significant difference between both groups in the baseline pulmonary functions parameters mentioned in the pre-operative period. This may be due to both groups were had resemble characteristic and functionally comparable to each other. The present result is similar to a study conducted by 13,14 are similar with the result of present study, and the pulmonary function test parameters did not differ between two groups before operation. After the application of the breathing exercise pursed lip methods through the present study, the results indicated that there is an improvement in the case group lungs volumes compared with those patients in the control group. The result shows that there is a significant difference between groups. Patients in the study group who demonstrate breathing exercise had a higher pulmonary function in all parameters than in control group at P- value less than 0.05 in all the post-operative periods. The applied method is an effective way to improve the post-operative patients’ lung function. The results of this study agree with the observations of 15, they concluded that the pre-operative deep breathing exercise improves the pulmonary functions, with significantly improved for lungs parameters such as FVC, FEV1 at P-value = 0.003, and P-value less than 0.001 respectively). The study shows that there is a relationship between the patient’s lung volume with their age and body mass index at p-value less than 0.05 after 24 hours postoperatively, while the other results indicate there is no relationship between patients lungs volumes and other demographic and clinical data at p-value more than 0.05. Pulmonary function may decrease and affected by age. The rate of respiratory and blood circulation are increases in childhood and become in a maximum level at age group between (20–30) years, then decline again in the older age. About high body mass index there are some reasons for decline the lung function. Firstly, the diaphragm position in the thoracic cavity is elevated obviously when individual increase weight. Secondly, it appears that fat accumulation on the chest wall will impede the movement of thoracic cage by a direct resistance or the abnormal function of intercostal muscle 16,17.

Conclusion

There were no differences between lung function in both case and control groups in the pretest. There is an improvement in the postoperative patients’ lungs function in study group after exposure to an educational breathing exercise program. The program show obvious difference between the lung function for both study and control groups during the post-test. Control group does not present any modification in their lung function post-
operatively. In addition, there is relation between study groups and demographical data in age and body mass index only.

**Conclusion**

Glomerular Diseases: Systemic Lupus Erythematosus is Most Common Finding: A Cross-Sectional Study

Fadhil Handhal Khleif¹, Haider Jebur Kehiosh², Salman Azeez Aljubori³, Sabah Nemah Alfatlawi⁴
¹ M.Sc. microbiology/Al-Hindiyah Primary Health Care Centre /Karbala Province / Iraq, ² Ph.D. pathology Consultant / Al-Hussein Teaching Hospital / Karbala Province / Iraq, ³ Ph.D. microbiology / Professor / Department of Microbiology / Faculty of Medicine / University of Kufa / Al-Najaf province / Iraq, ⁴ Ph.D. pathology / Consultant / Al-Sader teaching hospital / Al-Najaf province / Iraq

Abstract

The objective of this study was to assess the connection amongst’s immunological and histopathological findings of renal biopsy acquired from patients with glomerular diseases. This cross sectional study was done in Al-Kafil private hospital and included 110 patients who were diagnosed by nephrologist as having glomerulonephritis as per clinical introduction, physical examination and laboratory findings of biopsy. The age scope of patients enlisted in the present investigation was between 2.8 to 72 years. The study included 67 male patients (60.9%) and 43 female patients (39.1%). The examination began at January 2016 and reached out through January 2017. At the point when clinical introduction and the entire workup of examination were at long last joined, with exceptional accentuation on histopathology and immunofluorescent tiny examination, the accompanying classification was gotten. Cases with glomerular association optional to foundational lupus erythematosis represented 27 out of 110 (24.5%). Consequently lupus nephritis is the most incessant reason for glomerulonephritis observed in the present examination. As indicated by the International Society of Nephrology (ISN)/Renal Pathology Society (RPS) grouping of lupus nephritis, the most incessant compose was ISN/RPS class IV (A/C) represented 14 case (12.7%), trailed by ISN/RPS class III (A/C) (8 case, 7.3%)

Key words: Glomerular disorders, SLE, immunoflourescent, Iraq

Introduction

The kidney in spite of the fact that being moderately little size in examination with add up to body weight plays out a great deal of capacities that keep human body at ideal physiological conditions. These capacities incorporate water and electrolyte adjust, corrosive base direction, endocrine capacities and discharge of waste items, for example, urea and creatinine. Infection influencing the kidney may include the veins, glomeruli and tubulointerstitial compartments. Glomerular sicknesses represent a huge extent of dreariness and mortality in the populace. Glomerular sicknesses are regularly because of some type of immunological affront. Immunological bases for glomerular damage can be expected do humeral or cell invulnerable reaction. Humeral resistant reaction includes a counter acting agent that is independent from anyone else poisonous to certain segment of the glomerulus, for example, Good Pasteur disorder in which the immunizer is coordinated against glomerular cellar layer. Then again humeral reaction might be because of affidavit of insusceptible edifices that are either framed in situ or effectively flowing in blood, for example, glomerular damage found in relationship with foundational lupus erythematosus (SLE). Likewise, humeral insusceptible reaction might be because of enactment of elective supplement pathway. The established introduction of glomerular sickness is as proteinuria and/or hematuria. The time of beginning is exceptionally factor and is amazingly wide so glomerular ailment might be found in youngsters, immature, youthful grown-up and elderly people. The particular order of the sort of glomerular damage is basic for both treatment system portion and guess of
the sickness to be cleared up. For distinct conclusion of glomerular ailment, renal biopsy ought to be performed. Three principle steps take after renal biopsy got for suspected glomerular ailments; these are normal and extraordinary histogical stains, electron minute examination and immunofluorescent tiny examination. The innovation of tissue immunofluorescent strategy, by Coons and Kaplan in 1950 and its application on renal biopsy by Mellors in 1955, constrained the requirement for electron microscopy in symptomatic renal biopsy. Immunofluorescence allows the recognizable proof of the guilty party immunoglobulin (IgG, M and An) and furthermore the included supplement segment (C3 and C1q) and furthermore allow the distinguishing proof of safe testimony whether membranous or mesangial. In Iraq there is extremely set number of concentrates that managed this subject and the greater part of studies took a set number of cases and was constrained to a solitary or various glomerular issue. The vast majority of these examinations featured the histogical adjustment as well as clinical angles. The absence of an Iraqi immunologic investigation that arrangements with extensive example and different sorts of glomerular infections defended the conduction of the streams think about.

The Aim of this study was to assess the connection amongst’s immunological and histopathological discoveries of renal biopsy acquired from patients with glomerular infection.

**Patients and Method**

This cross sectional examination was done in Al-Kafil private doctor’s facility and included 110 patients who were analyzed by nephrologist as having glomerulonephritis as per clinical introduction, physical examination and discoveries of research center examinations. The age scope of patients enlisted in the present investigation was between 2.8 to 72 years. The example included 67 male patients (60.9%) and 43 female patients (39.1%). The examination began at January 2016 and reached out through January 2017. The procedure of patients’ determination begun at the nephrology meeting room. Any patient having the accompanying highlights was incorporated into the present investigation:

- Patients with regular picture of nephritic disorder
  - Massive proteinuria, summed up edema, hypoalbuminemia, hyper-lipidemia and lipiduria.
  - Patients with regular highlights of nephritic disorder
    - Hematuria, hypertension, azotemia and oliguria
  - Patients with highlights that are not suggestive of glomerular association; in any case, urinalysis of them indicated critical proteinuria as well as glomerular hematuria
  - Patients with intense or constant disappointment with extra clinical highlights suggestive of glomerular malady

Any patient with highlights that are not suggestive of glomerular sickness and have no proof of huge proteinuria and/or glomerular heamturia was barred from the investigation. Routine histological appraisal, immunoflourescent ponder were the fundamental examination to which all patients were subjected, adjacent to hematological, serological, biochemical examinations and urinalysis.

**Results**

Demographic characteristics of the study sample

The present study included 110 patients with glomerulonephritis, 67 male patients (60.9%) and 43 female patients (39.1%) with a male to female ratio of 1.56:1. Mean age of patients enrolled in the current study was $31.28 \pm 13.83$ years and it ranged from 2.8 to 72 years, as shown in table 4.1. According to 10 years age intervals patients were distributed as following: 2 patients less than 10 (1.8%), 21 patients from 11-20 (19.1%), 39 patients from 21-30 (35.5%), 23 patients from 31-40 (20.9%), 13 patients from 41-50 (11.8%), 6 patients from 51-60 (5.5%), 5 patients from 61-70 (4.5%) and a single patient older than 71 (0.9%), as shown in figure 1.
Mean duration of disease is 1.88 ± 1.66 years and it ranged from 2 weeks to 7 years. Patients with disease duration of less than one year accounted for 34 (30.9%), patients with 1 to less than 2 years accounted for 19 (17.3%), patients with disease duration of 2 to less than 3 years accounted for 17 (15.5%), patients with disease duration of 3 to less than 4 years accounted for 22 (20%), patients with disease duration of 4 to less than 5 years accounted for 9 (8.2%), patients with disease duration of 5 to less than 6 years accounted for 7 (6.4%), patients with disease duration of 6 to 7 years accounted for 2 (1.8%).

**Lupus nephritis**

Cases with glomerular involvement secondary to systemic lupus erythematosus accounted for 27 out of 110 (24.5%). Hence lupus nephritis is the most frequent cause of glomerulonephritis observed in the present study. According to the International Society of Nephrology (ISN)/Renal Pathology Society (RPS) classification of lupus nephritis, the most frequent type was ISN/RPS class IV (A/C) accounted for 14 case (12.7%), followed by ISN/RPS class III (A/C) (8 case, 7.3%) and lastly by ISN/RPS class III (A) (5 cases, 4.5%). Immunofluorescent study is shown in figure 2 and 3 in which there was mild diffuse segmental granular mesangial deposition of IgG and mild diffuse segmental granular mesangial deposition of IgM.

![Figure 2: Section of renal biopsy from patient with lupus nephritis stained with IgG immunofluorecence showing mild diffuse segmental granular mesangial deposition of IgG (red arrow) (10 X).](image-url)
Discussion

In this investigation Cases with glomerular association optional to foundational lupus erythematosis were the most regular and represented 27 out of 110 (24.5%); the most incessant write was ISN/RPS class IV (A/C) represented 14 case (12.7%), trailed by ISN/RPS class III (A/C) (8 case, 7.3%) and ultimately by ISN/RPS class III (A) (5 cases, 4.5%). In one Iraqi investigation, it was demonstrated that 25 (45.5%) cases were because of lupus nephritis 14 and in another Iraqi examination just two cases (3.4%) satisfied the clinical, serological and histopathological criteria of lupus nephritis 1. We concur with 14 that lupus nephritis is the most incessant reason for glomerulonephritis in Iraq and can’t help contradicting 1 who depicted a predetermined number for lupus nephritis in his investigation. In another examination in India, 3 assessed the clinicopathologic parts of crescentic glomerulonephritis and found that 14.7% of cases were because of SLE. Lupus renal malady gives off an impression of being more common in certain ethnic gatherings 10, and this may clarify the high rate of lupus nephritis in Iraqi patients. A similar investigation of SLE in three ethnic gatherings announced that renal malady, which is characterized by American College of Rheumatology (ACR) criteria as persevering every day proteinuria of >500 mg within the sight of cell throws or biopsy proof of lupus nephritis, happened in 45% of African Americans, 42% of Chinese, and 30% of Caucasian patients, individually 10. Another multi-ethnic US companion of SLE patients revealed that renal malady happened in 51% of Africans and 43% of Hispanics however in just 14% of Caucasians 2. In a planned investigation of 216 Chinese patients with new beginning SLE, 31% patients had dynamic renal sickness as the underlying introduction 8. The general combined frequency of renal sickness was 60% at 5 years post-SLE finding. These investigations delineated that lupus renal association is more typical in Africans, Hispanics, and Chinese than in Caucasians 9.
Conclusion

At the point when clinical introduction and the entire workup of examination were at long last joined, with exceptional accentuation on histopathology and immunofluorescent tiny examination, the accompanying classification was gotten. Cases with glomerular association optional to foundational lupus erythematosis represented 27 out of 110 (24.5%). Consequently lupus nephritis is the most incessant reason for glomerulonephritis observed in the present examination. As indicated by the International Society of Nephrology (ISN)/Renal Pathology Society (RPS) grouping of lupus nephritis, the most incessant compose was ISN/RPS class IV (A/C) represented 14 case (12.7%), trailed by ISN/RPS class III (A/C) (8 case, 7.3%) and in conclusion by ISN/RPS class III (A) (5 cases, 4.5%). In Iraq, SLE is the fundamental driver of glomerular damage.

Synthesis of Diimidazole Has Pyrazole, Isoxazole and Pyrimidine Derivatives and Evaluation as Antibacterial

Sahar Abdullah Kadham.1, Abdul Jabar Kh. Atia2
1 Department of Biology, 2Department of Chemistry, College of Science, Mustansiriyah University, Baghdad, Iraq

Abstract

New diimidazole contains pyrazole , isoxazole and thiopyrimidine were synthesized by using simple methods. All compounds were synthesized by using hippuric acid (1) as stating material which was obtained from benzoil and glycine with. pyrazole derivatives (6a – b ) was obtained from reaction (5a – b) with hydrazine hydrate while reaction of (5a – b )with hydroxyl amine isoxazole derivatives (7a – b) were obtained,finally reaction of thiourea was reacted with 5a – b thiopyrimidine derivatives were get (8a –b) . FTIR and 1HNMR spectra were used to characterized derivatives several bacterial species like Pseudomonas aeruginosa , Staphylococcus aureus, and Acinetobacter baumanii were used to tested antibacterial activity

Keywords: pyrazole, isoxazole, imidazole, thiopyrimidine

Introduction

Heterocyclics were found good biological molecules like imidazole 1 molecules with five and six membered rings mostly are high activity 2 . All natural products with heterocyclics are important in biologically active system 3 and medicinal to approved drugs , imidazole derivatives in heterocyclic chemistry considered most important compounds and drugs 4 such as Antioxidant activity 5 anti-microbial (6-7), antiangiogenic 8 , antitumor 9 , analgesic 10 , pyrazoles and isoxoles play important role to synthesis biologically active drugs like Antifungal11 , antimicrobial12 , antitumor13 , analgesics14 , Anthelminthic15 , Ant pathogenic16 , anti-inflammatory17

Method

Synthesis of [(phenyl carbonyl)amino]acetic acid(1)

Glycine (0.1mol ) in 15ml of 1N NaOH was cooled to 5 and then benzoyl chloride (0.1 mole ) was added to cold drop wise . The reaction mixture was stirring for one hour. The aqueous layer was acidified with 2N HCl and the product was collected and recrystallized from ethanol and product was collected as white powder

Synthesis of (Z)- 2-phenyl -4-benzylidene oxazol-5(4H)-ones (2a - d)

To a mixture of compound (1) ( 0.01 mole ) , acetic anhydride (20 ml) and acetic acid (5 ml), (0.01 mol) of aromatic aldehyde was added. And the mixture was refluxed for 4hr and the temperature was reached to 80°C. The reaction mixture was allowed to cool. , then poured into crushed ice and it was allowed stirred for 30 min. the product was recrystallized from ethanol.

Synthesis of 3-(2-amino)-5-arylidine-2-phenyl-3,5-dihydro-4H-imidazol-4-one (3a – d)

To a mixture of (2a – d ) derivatives (0.01 mole) in (20ml) triethyl amine , (0.01 mole) of hydrazine was added. And then it was refluxed 2 h. after that the mixture was cooled to RT. And the desired compound was obtained after recrystallizing from ethanol.

Synthesis of 1-[(4Z)-4-(arylidene )-5-oxo-2-phenyl-4,5-dihydro-1H-imidazol-1-yl] thiourea (4a – d)

Potassium thiocyanate was added to a mixture of compounds [3a - d] (0.01 mole) in ethanol (27 ml) and then stirred for 30 min. the mixture was poured in to could water and then filtered, the solid (desired compound) was recrystallized from ethanol.

Synthesis of (5Z)-5-(4-chlorobenzylidene)-3-(4-oxo-2-thioxoimidazolidin-1-yl)-2-phenyl-3,5-dihydro-4H-imidazol-4-one (5a – d)

To solution of (4a – d) (0.01 mole), in 30 ml of dry benzene chloro acetyl chloride was added and the mixture was heated in water bath at (60 0C) for 3 hrs. with stirring after that the solvent was evaporated, and
the product desired compound was recrystallized from appropriate solvent.

Synthesis of 1-[3-(Aryl)-5-phenyl-3,3a-dihydroimidazo[4,5-c]pyrazol-6(2H)-yl]-2-thioxoimidazolidin-4-one (6a – b)

To solution of (5a – b) (0.01 mole), in 20 ml of acetic acid hydrazine hydrate was added and the mixture was heated (refluxed) for 5 hrs. with stirring after that mixture poured to water (200ml), and the product desired compound was recrystallized from appropriate solvent.

Synthesis of 1-[3-(Aryl)-5-phenyl-3,3a-dihydro-6H-imidazo[4,5-c]isoxazol-6-yl]-2-thioxoimidazolidin-4-one (7a – b)

To solution of (5a – b) (0.01 mole), in 20 ml of acetic acid hydroxyl amine hydrochloride was added and the mixture was heated (refluxed) for 5 hrs. with stirring after that mixture poured to water (200ml), and the product desired compound was recrystallized from appropriate solvent.

Results and Discussion

Scheme (1) shown all compounds were synthesized

\[
\text{Ar} = \text{p-NO}_2, \text{p-Cl}, \text{p-Br}, \text{p-NMe}_2
\]
Synthesis of target (1) was done by the reaction of amino acid with benzoyl chloride through nucleophilic mechanism. (93%). m.p (186-188), color (White). The FT-IR spectrum of compound (1), shows stretching vibration of (OH) of carboxylic acid at (2610-3390) cm⁻¹ and appearance of new band at (3350) cm⁻¹ for NH.

Compound (1) was treated with aryl lead to formation of compounds (2a - d)

2a : yield (79%), FT-IR cm⁻¹ C=N(1646), C=O(1729), (C=C)ar (1601,1551), (C-H)ar (3083), (NO₂)(1534-13), 1H-NMR(ppm), s,6.92 for(C=CH), (7.25-7.76) (m, aromatic protons).

2b : yield (82%), FT-IR cm⁻¹ C=N(1646), C=O(1729), (C=C)ar (1601,1551), (C-H)ar (3083), (NO₂)(1534-13), 1H-NMR(ppm), s, (6.88) for(C=CH), (7.25-7.76) (m, aromatic protons).

2c : yield (75%), FT-IR cm⁻¹ C=N(1646), C=O(1729), (C=C)ar (1601,1551), (C-H)ar (3083), (NO₂)(1534-13), 1H-NMR(ppm), s, (6.76) for(C=CH), (7.25-7.76) (m, aromatic protons).

2d : yield (80%), FT-IR cm⁻¹ C=N(1646), C=O(1729), (C=C)ar (1601,1551), (C-H)ar (3083), (NO₂)(1534-13), 1H-NMR(ppm), s, (6.51) for(NMe₂), s, (5.67) for(NH₂), s, (6.48) for(C=CH), (7.25-7.76) (m, aromatic protons).

Treatment of (2a – d) with hydrazine gives (3a – d)

3a : yield (78%), FT-IR cm⁻¹ NH₂ (3345,3213), C=N(1656), C=O(1701), (C=C)ar (1601,1553), (C-H)ar (3079), (NO₂)(1545-1351), 1H-NMR(ppm), s, (5.66) for(NH₂), s, (5.68) for(C=CH), (7.11-7.69) (m, aromatic protons).

3b : yield (69%), FT-IR cm⁻¹ NH₂ (3401,3234), C=N(1661), C=O(1709), (C=C)ar (1600,1500), (C-H)ar (3060), (C=Cl), (1109), 1H-NMR(ppm), s, (5.23) for(NH₂), s, (5.31) for(C=CH), (7.51-7.77) (m, aromatic protons).

3c : yield (73%), FT-IR cm⁻¹ NH₂ (3389,3143), C=N(1666), C=O(1712), (C=C)ar (1599,1501), (C-H)ar (3069), (C-Br) 977, 1H-NMR(ppm), s, (5.46) for(NH₂), s, (6.76) for(C=CH), (7.55-7.92) (m, aromatic protons).

3d : yield (61%), FT-IR cm⁻¹ NH₂ (3345,3207), C=N(1643), C=O(1718), (C=C)ar (1607,1500), (C-H)ar (3070), (C-H) alph (2879-2980), 1H-NMR(ppm), s, (3.61) for(NMe₂), s, (5.66) for(NH₂), s, (6.48) for(C=CH), (7.11-7.69) (m, aromatic protons).

Reaction of compounds (3a – d) with KSCN in ethanol, compounds (4a – d) was formed

4a : yield (71%), FT-IR cm⁻¹ NH₂ (3311,3225), NH (3112), C=N(1646), C=O(1731), (C=C)ar (1601,1551), (C-H)ar (3083), (NO₂)(1534-13), 1H-NMR(ppm), s, (9.21) for(NH), s, (8.47) for(NH₂), s, (6.43) for(C=CH), (7.19-7.68) (m, aromatic protons).

4b : yield (56%), FT-IR cm⁻¹ NH₂ (3432,3267), NH (3152), C=N(1657), C=O(1723), (C=C)ar (1603,1500), (C-H)ar (3035), (C-Cl), (1097), 1H-NMR(ppm), s, (9.71) for(NH), s, (8.62) for(NH₂), s, (6.53) for(C=CH), (7.33-7.78), (m, aromatic protons).

4c : yield (60%), FT-IR cm⁻¹ NH₂ (3415,3270), NH (3165), C=N(1643), C=O(1715), (C=C)ar (1604,1509), (C-H)ar (3065), (C-Br) 975, 1H-NMR(ppm), s, (9.22) for(NH), s, (8.41) for(NH₂), s, (6.69) for(C=CH), (6.79-7.94) (m, aromatic protons).

4d : yield (58%), FT-IR cm⁻¹ NH₂ (3411,3272), NH (3149), C=N(1632), C=O(1708), (C=C)ar (1603,1508), (C-H)ar (3066), (C-H) alph (2884-2987), 1H-NMR(ppm), s, (3.54) for(NMe₂), s, (9.49) for(NH), s, (8.61) for(NH₂), s, (6.59) for(C=CH), (6.76-7.85) (m, aromatic protons).

Cyclization of compounds (4a – d) with chloroacetyl chloride gives compounds (5a – d)

5a : yield (75%), FT-IR cm⁻¹ NH₂ (3415,3270), NH (3110), C=N(1638), C=O(1721), C=O thio imidazole (1751), 1H-NMR(ppm), s, (4.21) for(CH₂), thio imidazole, s, (9.23) for(NH), s, (6.62) for(C=CH), (7.71-7.90) (m, aromatic protons).

5b : yield (68%), FT-IR cm⁻¹ NH₂ (3176), C=N(1650), C=O(1702), C=O thio imidazole (1757), C=O thio imidazole (1757), (C=C)ar (1612,1509), (C-H)ar (3067), (C-Cl), (1019), 1H-NMR(ppm), s, (4.25) for(CH₂), thio imidazole, s, (9.11) for(NH), s, (6.59) for(C=CH), (7.18-7.73) (m, aromatic protons).

5c : yield (60%), FT-IR cm⁻¹ NH₂ (3134), C=N(1657), C=O(1728), C=O thio imidazole (1749), (C=C)ar (1600,1501), (C-H)ar (3070), (C-Br) 912, 1H-NMR(ppm), s, (4.42) for(CH₂), thio imidazole, s, (9.68) for(NH), s, (6.68) for(C=CH), (7.26-7.53) (m, aromatic protons).
5d : yield (58%), FT-IR cm\(^{-1}\) NH (3190), C=N(1648), C=O (1716), C=O thio imidazole (1746) (C=C)ar (1615,1529), (C-H)ar (3079), (C-H) aliph. (2879-2956). 1H-NMR (ppm), s, (3.29) for (NMe\(_2\)), s, (4.22) for (CH\(_2\), thio imidazole), s, (9.39) for (NH), s, (6.14) for (C=CH), (7.17-7.65) (m, aromatic protons).

Compounds (6a – b), (7a – b) and (8a – b) were obtained by cyclizing compounds (5a – b) with hydrazine, hydroxyl amine and thiourea respectively.

6a : yield (65%), FT-IR cm\(^{-1}\), NH (3213), NH of pyrazole, (3171), C=N (1645), C=O thio imidazole (1735), (C=C)ar (1611,1500), (C-H)ar (3060), (NO\(_2\)), (1555-1353). 1H-NMR (ppm), s, (4.29) for (CH\(_2\), thio imidazole), s, (9.22) for (NH), s, (8.27) for (NH, pyrazole), (7.53-7.98) (m, aromatic protons).

6b : yield (61%), FT-IR cm\(^{-1}\), NH (3269), NH of pyrazole, (3199) C=N(1661), C=O thio imidazole (1739) (C=C)ar (1600,1501), (C-H)ar (3071), (C-Cl), (1021). 1H-NMR (ppm), s, (4.19) for (CH\(_2\), thio imidazole), s, (9.82) for (NH), s, (8.79) for (NH, pyrazole), (6.89-7.24) (m, aromatic protons).

7a : yield (71%), FT-IR cm\(^{-1}\), NH (3245), C=N (1651), C=O thio imidazole (1743), (C=C)ar (1605,1516), (C-H)ar (3079), (NO\(_2\)), (1532-1350). 1H-NMR (ppm), s, (4.02) for (CH\(_2\), thio imidazole), s, (9.46) for (NH), (6.92-7.48) (m, aromatic protons).

7b : yield (77%), FT-IR cm\(^{-1}\), NH (3211), C=N(1670), C=O thio imidazole (1728) (C=C)ar (1609,1511), (C-H)ar (3079), (C-Cl), (1011), 1H-NMR (ppm), s, (4.10) for (CH\(_2\), thio imidazole), s, (9.32) for (NH), (6.89-7.24) (m, aromatic protons).

8a : yield (57%), FT-IR cm\(^{-1}\), NH (3311), NH of pyrimidine, (3165) C=N (1649), C=O thio imidazole (1741), (C=C)ar (1601,1511), (C-H)ar (3092), (NO\(_2\)), (1539-1355). 1H-NMR (ppm), s, (4.20) for (CH\(_2\), thio imidazole), s, (9.71) for (NH), s, (8.16) for (NH, pyrimidine), (6.72-7.30) (m, aromatic protons).

8b : yield (54%), FT-IR cm\(^{-1}\), NH (3302), NH of pyrimidine, (3190) C=N(1644), C=O thio imidazole (1733) (C=C)ar (1600,1500), (C-H)ar (3085), (C-Cl), (1077). 1H-NMR (ppm), s, (4.51) for (CH\(_2\), thio imidazole), s, (9.76) for (NH), s, (8.36) for (NH, pyrimidine), (6.99-7.59) (m, aromatic protons).

Antibacterial activity of derivatives

It might be observed that derivatives which, when tested, were active but 8a, 8b, 4b and 6a have high activity toward all types of tested bacterial while compound 5a and 5d have weak activity toward all types of tested bacteria. Compound 8a showed high inhibition with E. coli and Proteus mirabilis.

Conclusion

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Faculty of Dentistry, University of Babylon, Hillah city, Iraq, and all experiments were carried out in accordance with approved guidelines.

Novel approach and Cloud Point Extraction Method for Determination of Acetazolamide Drug

Muna Iskandar Mahdi 1, Kassim Hassan Kadhim1
1Chemistry Department, College of Science, Babylon University, Iraq

Abstract

Acetazolamide was hydrolyzed to primary aromatic amine by using (0.4) M NaOH under reflux. The product was evaluated by two ways. The first way, Diazotization coupling reaction (approach) as simple, sensitive, rapid and selective Spectrophotometric method, using 8-hydroxyquinoline as Chromogenic reagent to give Azo dye (red) in basic medium. The second way involves applying Cloud point extraction, using Triton-x114 as surfactant. The Azo dye was diagnosed by FT-IR, 1HNMR and UV-Visible technique. The analytical data for Approach and Cloud point extraction method, involve concentration rang (5-150), (0.5-6) µg.mL-1, molar absorptivity (2.3×103), (1.3×104) L.mol^-1.cm^-1, Sandall’s sensitivity (0.096) µg.cm^-2 (0.017) µg.cm^-2 and detection limits (0.952) µg.mL^-1 and (0.043) µg.mL^-1 respectively. In addition the measurement enrichment factor (100) and preconcentration factor (6.30), The proposed methods don’t affect by the existence of excipients so the methods were applied successfully in determining Acetazolamide in pharmaceutical preparations.

Keywords: Hydrolysis Acetazolamide, spectrophotometric determination, Cloud point extraction, Diazotization coupling reaction, 8-Hydroxyquinoline.

Introduction

Acetazolamide a carbonic anhydrase inhibitor, which is used primarily to reduce intraocular pressure by decreasing aqueous humor formation, therapeutically for treatment of glaucoma, epilepsy and as a diuretic and has been used clinically since 1954 1-4. Acetazolamide in either medicinal forms or biological fluids were estimated in several techniques and methods have been declared in the literature, including HPLC for the quantification of acetazolamide in human and rat plasma 5-7, LC/MS and GC/MS 8-10, LC-UV 11-13, and spectrophotometry for determination acetazolamide and other sulfonamide drugs 14-19. Applications of cloud point extraction techniques for estimation of some elements and drugs 20,21. The present paper involves a novel determination of acetazolamide in pure and pharmaceutical formulations by Diazotization coupling reaction (approach) and Cloud point extraction spectrophotometric method, depending on basic hydrolysis of acetazolamide to primary aromatic amine, and coupling the product with 8-Hydroxyquinoline as a chromogenic reagent to give Azo-dye in alkaline medium.

Experimental

Instruments

The scanning of all spectrums and measurements of the absorbance at selected wavelengths achieved by T80 UV-Visible Spectrometer PG Instrumental Ltd, UK, with quartz cell matched 1 cm, Infrared spectra were registered using FT-IR, Shimadzu, Japan, 1HNMR spectrum was registered using NMR Burker DPX 400 spectrophotometer operating at 300 MHz. the chemical shift δ is quoted in ppm relative to DMSO-d6, while the pH was adjusted using 340i pH-meter WTW, Germany, and Heating-Cooling Water Bath – Haak Fe, Sartorius

Chemicals and reagents

Highest purity of Acetazolamide (C4H6N4O3S2) was gained from state company for drug Industries and Medical Appliance-(SDI) Samarra-Iraq, 8-hydroxyquinoline (C8H7NO),Sodium nitrite (NaNO2),Absoluteethanol(C2H5OH), Sodium hydroxide (NaOH), Sodium carbonate (Na2CO3) were gained from the BDH Company with Purity 99.00%. Hydrochloric acid (HCl) was gained from a BDH Company with
concentration 37.00%. Triton X-114 from Arcos organics, New Jersey, USA with purity 100%. Pharmaceutical preparations that were used in this study were Cidamex and Diamox 250mg/acetazolamide from CID Egypt and France respectively.

Hydrolysis of Acetazolamide

0.1 g of Acetazolamide was hydrolyzed in alkaline medium by using 0.4 M NaOH under reflux for 2 hours. During the reaction, the secondary amide is converted to the primary amine. The synthetic path of the product is shown in Scheme I. The hydrolysis product was cooled and diluted to suitable volume using distilled water to obtain a stock solution (2000 µg mL⁻¹). More dilute solution was prepared daily by neutralize of stock solution with dilute hydrochloric acid and dilute to final suitable volume using distilled water. The tablet sample (Cidamex and Diamox 250mg/acetazolamide) were prepared in the same manner.

2 mol. from the hydrolysis product was converted into dizonium salt ion by using 0.3 mL HCl 1 M and 0.2 mL NaNO₂ 1%. The dizonium salt ion was coupled with 1 mol. 8-hydroxyquinoline in alkaline medium to give azo-dye. The synthetic path of the azo-dye is shown in Scheme II. The azo-dye was precipitate, purified and diagnosed by FT-IR, ¹H-NMR and UV-Visible technique as shown in Fig.2, 3 and 4.

Identification of the prepared drug and Azo Dye

Identification of the Hydrolysis product and Azo Dye. The hydrolysis product was prepared as explained in paragraph 2.3. The qualities experimental were involved tests for amine group by using Nitrous acid test and Azo-dye test. The hydrolysis product (5-amino-1,3,4-thiadiazole-2-sulfonamide) give yellow solution result from a reaction between a primary aromatic amine with concentrated HCl and NaNO₂ to formation diazonium salt ion, while the acetazolamide before hydrolysis not reaction. The two compounds were tested also by azo-dye test. The hydrolysis product after formation diazonium salt ion was coupled with 8-Hydroxyquinoline in alkaline medium to give azo-dye, while the acetazolamide before hydrolysis not reaction. This azo-dye was prepared by taking a stoichiometric amounts was precipitate, purified and diagnosed by FT-IR, ¹H-NMR and UV-Visible technique.

IR spectrum of azo-dye showed in Fig.1. one peak at 3417 cm⁻¹ assigned for stretching (O-H) of phenolic group, peak at 1426 cm⁻¹ assigned of stretching (N=N), and other peak 1575, 1145 and 879 cm⁻¹ assigned for stretching (C=N) thiadiazole, (S-C) and (C-S-C) groups respectively. This mean the formation of the aromatic primary amine group by hydrolysis of Acetazolamide and converted the amine in to diazonium salt in the presence of HNO₂ and coupling the last with 8-Hydroxyquinoline in alkaline medium. The ¹H-NMR spectrum (DMSO-d₆, 400 MHz) of azo-dye complex showed chemical shifts at δ 1.66 (1H, -SO₂NH₂), Singlet broad band at δ 3.5 refer to water in the solvent, DMSO, where its band δ 2.5, δ 5.5 (1H, aromatic -C-OH), δ 7.1(2H,C-H₅).
quinoline), δ 7.4 and 7.5 (3H,2H, C-H$_{22}$ quinoline), δ 8.3 and 8.85 (2H,1H, C-H$_{21}$ quinoline) 26-28 as shown in Fig.1. The qualitative and quantitative study of drug after hydrolysis, also done by UV-Visible technique. The Azo-dye complex (color product) scanned at (700-400 nm), and give a maximum absorption $\lambda_{\text{max}}$ at (502 nm) versus blank solution. while the scan of the blank solution versus water doesn’t give any absorption at $\lambda_{\text{max}}$ for colored product as shown in Fig.3. This property was adopted in the estimation of trace amounts from Acetazolamide in pure and pharmaceutical preparations.

Optimization of Experimental Conditions

Selection Optimal Experimental Conditions of Approach method

The effect of various experimental conditions as concentration, volumes from 8-Hydroxyquinoline reagent, volumes of HCl (1M), volumes of (1%) Sodium Nitrate, different types of bases, various volumes of Sodium Hydroxide (0.4 M) and temperatures of formation of (40 µg.ml⁻¹) azo dye were studied. The starting point involves using (0.5mL) from (1M) Hydrochloric acid with (0.5 mL) from (1%) Sodium nitrate, stand for (5 min), then (0.5mL) from (0.05M) 8-Hydroxyquinoline, and (0.5mL) from (0.4 M) Sodium hydroxide were added in (10 mL) volumetric flask. The absorbance of the solutions was measured at (λmax=502nm) against blank solutions after (5 min) since the beginning of the coupling reaction. The effect of various experimental conditions shown in Fig.2.

Selection Optimal Experimental Conditions of CPE method

The effect various concentrations, volumes of 8-Hydroxyquinoline reagent, volumes of HCl (1M), optimum pH value, volume of Triton X-114 5%, also effect of temperature and incubation time on formation of surfactant of (5 µg.ml⁻¹) azo dye were studied. The starting point involves (0.3 mL) of Hydrochloric acid (1M) fellow (0.2 mL) of Sodium nitrate (1%), stand for (5 min ), then (0.3 mL) from 8-Hydroxyquinoline (0.005M), at (pH = 7) Sodium carbonate with (0.3 mL) Triton X-114 5% were added in (10 mL) volumetric flask. The mixture was heated (10 min) at 55°C in water bath. The mixture was separated by centrifuge Ramp=3500 at (10 min). The surfactant rich phase was diluted with (0.3 mL) absolute ethanol and the absorbance of the solution was measured at (λmax=502nm) against the blank solution The effect of various experimental conditions shown in Fig.2.

Figure 2 The effect of various experimental conditions on formation of Azo dye
Calibration curve

After fixing all the optimum conditions for the reaction of acetazolamide after hydrolysis with 8-Hydroxyquinoline of approach and cloud point extraction method the calibration curves were constructed as shown in Fig.3. The all analytical values were calculated with accuracy and precision result are summarized in Table.1. The results shown each method has a good accuracy and precision.

Table.1 Summary of analytical value of calibration curves with accuracy and precision resulting of approach and CPE method with

Stoichiometry of Reaction and mechanism

The methods of Mole ratio and Continuous variation, Jobs method were used to detect the stoichiometry of azo-dye formation from reaction 8-Hydroxyquinoline reagent with acetazolamide drug. The results obtained in Fig.4 shown that 2:1 acetazolamide to 8-hydroxyquinoline was formed at 502 nm. And The average conditional stability constant of the colored products in water at optimum conditions was $6 \times 10^{12}$ L² mol⁻². The azo dye has high stability because the acetazolamide have electron with drawing group (sulfonamide) makes $\text{N}\equiv\text{N}$ group more positive charge and 8-Hydroxyquinoline have electron donating group makes ring very active so easy formation of high stability azo-coupling reaction between acetazolamide and 8-hydroxyquinoline[26]. The proposed mechanism of reaction illustrated in Scheme.II.

Pharmaceutical applications

The proposed methods approach and cloud point extraction were applied successfully for determination of
three concentrations form Acetazolamide in (Cidamex and Diamox 250mg) tablets as shown in the Table.3, after studying the effect of additives by adding separately excess amounts about (10:1) from additives to (40 µg.mL⁻¹) acetazolamide solutions under optimum reaction conditions followed in the calibration curves. As shown in a Table. 2.

Abstract
Successful osseointegration of dental implants depends on many factors, including implant stability, bone quality, implant surface condition, and implant materials. Implant surface is coated using different techniques to enhance osseointegration. Sol–gel technique is one of the modern and easy techniques in the production of more bioactive hydroxyapatite (HA).

In this study, nano-HA and chitosan were used to coat titanium disc via the sol–gel technique.

Materials and Method: The nano-HA/chitosan composite was prepared using calcium nitride and phosphorus pentoxide solutions. The solutions were drop wisely mixed on a magnetic stirrer. Then, 3 mg of chitosan was added to the mixture, and the mixture was stirred for 15 h. Titanium samples were dip coated in the mixture of chitosan/HA on the stirrer at slow speed for 90 min to precipitate the coating layer. Afterward, the samples were removed and dried in a hot air oven. They were sintered at 400 °C for 1 h. X-ray diffraction (XRD), light microscopy, scanning electron microscopy (SEM), energy-dispersive x-ray spectroscopy (EDX), FTIR analysis, and atomic force microscopy (AFM) were used to analyze the surface and thickness.

The results of XRD test showed that HA particles had sharp diffraction peaks, indicating high crystallinity of the structure due to the sol–gel preparation. Results of optical light microscopy showed that the coated layer was fairly distributed on titanium samples. SEM results of the coated samples showed different surface features, which present a roughness with the appearance of a crystal pool with irregular accumulation of small, spherical-like granules. EDX analysis showed the presence of ions that comprised HA. AFM analysis of the coated sample indicated peaks and projections with average surface nano-roughness (10.1 nm) and grain size (2022–2057 nm). FTIR analysis showed the presence of a band associated with HA particles and amide groups associated with chitosan. The average of thickness readings was 60 μm.

Keywords: dental implant, dip coating, sol–gel, chitosan, hydroxyapatite, nanoparticles.

Introduction
Osseointegration is the apparent direct attachment or connection of osseous tissue to an inert, alloplastic material without intervening fibrous connective tissue; it is the process and resultant apparent direct connection of an exogenous material’s surface and the host bone tissues. Several factors affect the success of osseointegration. One of these factors is implant stability, which is composed of two types: primary stability, which occurs due to mechanical support of implant to the surrounding bone immediately after implant insertion and secondary stability, which occurs due to biological support after bone regeneration and remodeling. Other factors include bone quality, surgical technique, implant surface condition, implant material, and implant surface. The type of material that covers the implant surface is an important factor in enhancing osseointegration for initial stability. Therefore, several attempts have been made to enhance osseointegration at the bone/implant interface by making various coatings to support the main implant. Titanium and its alloy are commonly
used in the fabrication of artificial joints and tooth roots due to their excellent mechanical properties that closely resemble natural bone \(^6\). Hydroxyapatite (HA) is a commonly used material for coating implant surface because it resembles human bone in its chemical and crystallographic structures, and it has the advantage of acting as a barrier that reduces the release of metallic ions \(^7\). The use of nanophase particles of HA increases the number of particles and surface areas, thereby increasing the reactivity of HA and enhancing bioactivity \(^8\). The sol–gel technique is one of the modern techniques for preparing HA to enhance the surface bioactivity of implant and increase bone attachment \(^9\). Anuar et al. (2013) produced HA nanoparticles using the sol–gel method \(^10\). Taherian et al. (2014) studied the effects of different sol–gel synthesis processes on HA nanopowders \(^11\). Chitosan has many medical applications because of its biocompatibility and non-toxicity \(^12\). It can clot blood to aid in hemostatic action, and it can stimulate macrophages to initiate collagen deposition, which accelerates the healing process \(^13\).

**Materials and Methods**

**Preparation of sol–gel**

Nano-HA was prepared using the sol–gel technique according to a previously reported method with slight modifications \(^16\).

Preparation of first solution: An electronic balance (accuracy 0.0001 g, Germany) was used to weigh 10.78 g of calcium nitride (Ca(NO\(_3\))\(_2\)). Ca(NO\(_3\))\(_2\) was then mixed with 125 ml of ethyl alcohol on a magnetic stirrer (SH – 3, England). Stirring was performed for 1 hour until the solution was completely dissolved.

Preparation of second solution: The solution was prepared by mixing 5 g of phosphorus pentoxide (P2O5) with 125 ml of ethyl alcohol on a magnetic stirrer for 1 hour until completely dissolved.

After the two solutions were mixed, Ca(NO\(_3\))\(_2\) was added drop wise on P2O5 for 2 h under continuous stirring. Next, 5 g of potassium hydroxide (KOH) was added to the mixture to complete the reaction. Finally, 3 g of chitosan was added to the mixture, and the mixture was stirred for 15 h.

**Sample preparation**

Circular commercially pure titanium (Cp-Ti) discs of 10 mm diameter and 2.5 mm thickness were prepared as follows: Cp-Ti rod grade 2 (Orotig S.r.l., Italy) was cut and mirror polished using 500 micron roughness silicon carbide for 15 min. The discs were then cleaned in an ultrasonic bath with ≥99.8% ethanol to eliminate debris and contamination. After 15 min, the cleaning process was completed; the discs were washed with distilled water for 10 min and left at room temperature to dry \(^17\).

**Dip coating procedure**

The titanium samples were dip coated in the mixture of chitosan/HA on the stirrer at slow speed for 90 min to precipitate the coating layer. Then, the samples were removed and dried in a hot air oven (200 °C) (IMS/406, France).

**Heat treatment (sintering)**

Sintering was performed using a tube furnace (Carbolite Type MTF 12/38A. BAMFORD, England). A pilot study was performed using the three heating methods as follows:

A. Coated at the sol stage and sintered at 400 °C for 1 h
B. Coated at the gel stage and sintered at 125 °C for 1 h
C. coated by gel stage and sintering at 400 °C for one hour.

Examination of specimens after sintering by X-ray diffraction analysis revealed that samples of titanium were coated with nano-hydroxyl apatite and chitosan at the gel stage and sintered at 400°C for one hour showed the best results.

**Analysis of coating layer**

The coated surface of the specimens was analyzed as follows:

**Thickness measurement:**

The thickness of the coating layer was measured by using microprocess coating thickness gauge (TF-C-UVIS-SR, USA). Three readings were obtained, and their average was 60 μm.

**XRD analysis:**

The Shimadzu XRD-6000 (Japan) diffractometer was used to provide information about the chemical composition and crystallographic structure of materials.
The indexing of peaks was based on the Joint Committee of Powder Diffraction Standards (JCPDS).

Optical microscopy examination (light microscopy):

The features of the coating surface were examined by using a light microscope (Nikon Eclipse ME 600 L/441002, Japan) and compared with those of the control sample. The analysis was performed by using a digital camera (DXM1200F) connected to computer with a software program for analysis.

Structural surface characterization by SEM:

- Surface analysis: The surface morphology and topographical characteristics of the coated sample were determined by SEM (TESCAN Vega 111, Czech Republic).

- Material characterization: Material characterization was performed using EDS, and SEM was used for chemical analysis of the sample, depending on the interaction and excitation of X-ray.

AFM:

AFM was used for analysis of surface roughness. It is an advanced type of profile meter used to produce topographical image where a very sharp and inert tip was scanned over the surface of the coated sample.

**Results**

**Thickness measurement**

The thickness of the coated layer was measured using a microprocess thickness gauge. The thickness of the coating film increased with time. The average of three readings was 60 μm.

![Graph showing thickness measurement](image)

**Fig.1 Thickness of nano-HA and chitosan coating layer at 0.5, 1, 2, and 3 min**

**X-ray diffraction analysis:**

According to standard pattern of (JCPDS09 – 0432) the peaks of HA were indexed according to, as shown in Fig. (2) a and b. the Stoichiometric of HA particles displayed peaks with sharp diffraction that representing high crystallinity of the structure. By XRD, There was no identification of impurity phase.
FTIR analysis

FTIR analysis results show the coated surface with peaks of HA and chitosan. In Fig. 3.2, FTIR spectra illustrated an OH\_ band at 3569 cm\(^{-1}\) and PO\(_4\)\_4 bands at 472, 565, 603, and 1032 cm\(^{-1}\) associated with HA. The sharp peak (1637 cm\(^{-1}\)) and broad bands for adsorbed water (3000–3500 cm\(^{-1}\)) prove water absorption due to the high specific surface that precipitated powders usually have. The CO\(_2\)\_3 groups, which can substitute both PO\(_4\)\_4 and OH\_ ions in the HA structure, appeared as 1461, 1423, and 875 cm\(^{-1}\) wave numbers. The presence of amide groups I, II, and III at 3500–3700, 1630–1690, and 1735–1750 cm\(^{-1}\), respectively, corresponded with chitosan particles.
Light microscopy examination

Light microscopy examinations revealed the surface image of coated and non-coated titanium samples at 250 μm magnification, as shown in Fig. 3.4; lines appeared on the uncoated samples, which resulted from machining, whereas the coated sample showed homogenous coating layer without cracks.

![Fig. 4 Light microscopy examination of coated and uncoated samples](image)

AFM analysis

Figure 3.4 shows the surface features of coated surface with mixture of HA and chitosan. Peaks and projections with average surface nano-roughness of 10.1 nm and grain size (2022–2057 nm). Table 1 lists the roughness values obtained from AFM images.

**Discussion**

HA has hydroxyl groups that can promote nucleation of phosphate and calcium, which enhances bone formation after implantation \(^{18}\). Chitosan has high viscosity in solution \(^{19}\), so it was hybridized with sol–gel HA to enhance apatite formation \(^{20}\). Therefore, the present study used a HA/ chitosan composite.

HA was successfully coated with titanium via HA sol–gel process. The sol–gel process produces more bioactive HA compared with other techniques \(^{21}\).

Dip coating technique was used to successfully implant HA on titanium \(^{22}\). Dip coating/sol–gel technique has the advantages of controlling coating thickness \(^{23}\).

SEM of the coated film revealed different surface features that appeared as rough surfaces with homogenous and crack-free distribution of the particles, as well as the appearance of crystal pool with accumulation of small, spherical-like granules. This manner of accumulation is one of the properties of HA prepared via sol–gel method \(^{24}\). This result is considered as good property, which indicates wide area of contact with living tissue, and is consistent with the results of A. Balamurugan et al., 2002 \(^{25}\), who studied the biomedical applications of sol–gel HA. Figure 3.6 shows the existence of O, P, and Ca elements, which are related to HA nanoparticles. The EDX results ensured that the coating layer was evenly distributed with no elements being concentrated in some areas more than others \(^{26}\).

FTIR spectra illustrated an OH_ band at 3569 cm\(^{-1}\) and PO\(_3\_4\) bands at 472, 565, 603, and 1032 cm\(^{-1}\) associated with HA. The sharp peak (1637 cm\(^{-1}\)) and broad bands for adsorbed water (3000–3500 cm\(^{-1}\)) prove water absorption because of the high specific surface area that precipitated powders usually have. The CO\(_2\_3\) groups, which can substitute both PO\(_3\_4\) and OH_ ions in the HA structure, appeared at 1461, 1423, and 875 cm\(^{-1}\) wave numbers. The presence of amide groups I, II, and III at 3500–3700, 1630–1690, and 1735–1750 cm\(^{-1}\), respectively, corresponded with chitosan particles. The result ensured the formation of HA by the appearance of phosphate bands, at 3500–3700, 1630–1690, and 1735–1750 cm\(^{-1}\), respectively, corresponded with chitosan particles. The result ensured the formation of HA by the appearance of phosphate bands \(^{27}\).

**Conclusion**

Sol – gel technique was successful method to prepare composite of nano HA/chitosan that showed uniform and homogenous thickness of coatings that improved surface properties of titanium implant when compared with uncoated surface. The use of dip coating procedure was benefit to achieve thin, homogenous and crack free coating film on CP – Ti surface.

In this paper, a cellulose paper was impregnated with silver nanoparticles (AgNPs) for the purpose of removing Enterococcus faecalis from drinking water. AgNPs papers were prepared by chemical reduction of silver nitrate (AgNO3) with various concentrations (0.005 M, 0.01 M, 0.015 M, and 0.025 M) using sodium borohydride (NaBH4) as a reducing agent. Two ratios of NaBH4/AgNO3 of 2:1 and 10:1 were used to show the effect of reduction on the formation and removal efficiencies of AgNPs. AgNPs papers were characterized using SEM and TEM. TEM images showed that the silver nanoparticles size in the papers varies from 1.3 to 75 nm.

**Keywords:** Enterococcus Faecalis, Drinking Water, Silver Nanoparticles.

**Introduction**

Disinfection of potable water is the specialized treatment for destruction or removal of organisms capable of causing disease; it should not be confused with sterilization, which is the destruction or removal of all life. Although disinfection methods currently used in drinking water treatment can effectively control microbial pathogens, researches in the past few decades have revealed a dilemma between effective disinfection and formation of harmful disinfection byproducts (DBPs). Three categories of human enteric pathogens are of concern in drinking water: bacteria, viruses, and amebic cysts. Disinfection must be capable of destroying all three. Destruction or removal of these organisms is essential in providing a safe potable water supply. Some bacteria, viruses, protozoa, and larger organisms ingested from contaminated water cause diseases varying from mild illnesses to life-threatening. The Enterococcus genus is placed in the Enterococcaceae family and consists of species that occur in human and animal gastro-intestinal (GI) tracts, as well as in the guts of insects traditional fermented food and dairy products, and in various environments including plants, soil and water. Enterococcus faecalis is a non-spore-forming, fermentative, facultatively anaerobic, Gram-positive coccus. Enterococcus faecalis cells are ovoid and 0.5 to 1 μm in diameter. They occur singly, in pairs, or in short chains, and are frequently elongated in the direction of the chain. They typically have an optimum growth temperature of 35°C and a growth range from 10 to 45°C. They currently rank among the most prevalent multidrug resistant hospital pathogens worldwide as the third most commonly isolated healthcare pathogen, and are capable of causing a variety of infections including endocarditis, sepsis, surgical wound infections, and urinary tract infections. The organism has the natural ability to acquire, accumulate and share extrachromosomal elements encoding virulence traits, which help to colonize, compete with other bacteria, resist host defense mechanisms and produce pathological changes directly through production of toxins or indirectly through induction of inflammation. Nanotechnology and its application is one of the rapidly developing sciences. Silver nanoparticles have proved to be most effective as it has good antimicrobial efficacy against bacteria, viruses and other eukaryotic microorganisms.

**Experimental Procedure**

**Sampling**

The samples were taking from Shatt al-Hilla, at Al-Hilla city/Iraq and during the period (November 2018 – March 2019). 500 ml of water as grabbed and kept in precleared plastic bottle. The samples were analyzed immediately to prevent any change in their quality that
may occur.

**Preparation of AgNPs papers**

A (10 cm * 10 cm * 0.8 mm) off-white paper, 100% alpha cellulose was used to be embedded with silver nanoparticles. AgNPs papers were prepared by in situ reduction of AgNO₃ with various concentrations (0.005 M, 0.01 M, 0.025 M and 0.05 M) with two reduction ratio of 2:1 and 10:1. Each paper was soaked in 40 ml of AgNO₃ solution for 30 minutes, then it was washed with ethanol for 1 minute to remove the excess Ag ions which not absorbed by the paper. To form AgNPs, the paper was placed in 40 ml of NaBH₄ solution for 1 hr. After that, the paper was soaked in de-ionized water for 30 minutes. Then the paper was dried in the oven at 60 °C for 2.5 hrs.

![Fig. 1: (a) AgNPs paper during preparation with NaBH₄/AgNO₃ ratio of 2:1. (b) AgNPs paper during preparation with NaBH₄/AgNO₃ ratio of 10:1.](image)

**Characterization**

The synthesized AgNPs papers were characterized by Scanning Electron Microscopy (SEM), type Quanta 450 available at the University of Babylon/College of Pharmacy and Transmission Electron Microscopy (TEM) available at Al-Nahrain University/College of Medicine.

**Acid Digestion**

To determine the silver content in the AgNPs paper, an acid digestion of the paper was performed and then analyzes the amount of dissolved silver with an Atomic Absorption Spectrometer (AAS) (AA320N) available at the University of Babylon/College of Material Engineering. Approximately a 100 mg of the dried AgNPs paper was reacted with 5 ml of nitric acid (HNO₃) and 5 ml of water. The mixture was boiled until the paper was disintegrated. 5 ml of 30% hydrogen peroxide (H₂O₂) was added to the mixture to assist in the complete oxidation of the organic matter to release additional metals into the solution. The mixture was boiled again and left to be cooled, then filtered through a filter paper and then diluted by adding a 100 ml of water. The diluted mixture was tested for silver content using an AAS.

**Microbiological Test**

The raw water samples were cultured using serial dilutions method, 1 ml of the sample was diluted in 9 ml of distilled water (1:10 dilution). 1 ml of 1:10 dilution mixed with 9 ml of distilled water (1:100 dilution), etc. the filtered water samples were cultured without dilution. 0.1 ml of each sample was spread over a media plate and then the plates were incubated in 37 °C for 48 hrs in an incubator (LIB-030M).
Results and Discussion

Paper Characterization

The AgNPs papers were characterized by SEM and TEM. Fig. 2 represents the images obtained by SEM to show the presence of AgNPs in paper fibers. Fig. 3 represents the images obtained by TEM to determine the particles sizes of AgNPs. Table 1 represents the particles sizes of AgNPs obtained by TEM test.

![Fig. 2: Images obtained from SEM. (a) 2:1 NaBH4/AgNO3 ratio. (b) 10:1 NaBH4/AgNO3 ratio.](image)

![Fig. 3: TEM images. (a) 2:1 NaBH4/AgNO3 ratio. (b) 10:1 NaBH4/AgNO3 ratio.](image)

The acid digestion of AgNPs papers showed silver content ranging from 3.9 to 8.7 mg Ag per dry gram of paper. The increase in silver content of the paper correlates with the increase in precursor silver ion concentration of the solution in which the papers were soaked, prior to reduction. For the same concentration of AgNO3, the NaBH4/AgNO3 ratio of 10:1 resulted in more silver content than 2:1 ratio.

**Bactericidal Effectiveness of AgNPs papers**

Fig. 4 shows the effect of the silver content in the AgNPs paper on the removal efficiency of Enterococcus faecalis of filtered water samples and raw water samples with a NaBH4/AgNO3 ratio of 2:1 and 10:1 respectively.

![Graph](image)

Fig. 4: Effect of silver content on the removal efficiency of Enterococcus faecalis of raw water samples with a: (a) NaBH4/AgNO3 ratio of 2:1. (b) NaBH4/AgNO3 ratio of 10:1.

Fig. 4 shows that removal efficiency Enterococcus Faecalis of the raw water samples for both ratios ranges from 99.9 % to 100% for all silver contents.
Analysis of silver content in The Effluent

Due to possible human health effects from silver exposure, the silver content in the effluent water was analyzed by AAS. Table 4 represents relationship between the silver content in the paper and silver release in the effluent.

Table 4: The relationship between the silver content in the papers and silver in the effluent water.

<table>

<tr>
<td></td>
<td>10:1</td>
<td>0.082</td>
</tr>
</tbody>
</table>

As shown in Table 4, the average silver content in the effluent water for the three replicates range from 0 to 0.082 which meets the United States Environmental Protection Agency (US-EPA) guideline for drinking water of less than 0.1 mg/L [EPA, 2018]. This was due to the stability of silver nanoparticle in the cellulose paper. Sodium borohydride acts not only a reducing agent but also as an ion stabilizer, which prevents silver ions from aggregation. Moreover, hydroxyl and ether groups in the cellulose fiber play an important role in the stabilization of metal nanoparticles.

Conclusions

Silver nanoparticles used in this study were well dispersed and stabilized on the paper fibers. Chemical reduction of AgNO3 by using NaBH4 as a reducing agent resulted in spherical silver nanoparticles. The NaBH4/AgNO3 ratio of 10:1 resulted in smaller sizes of silver nanoparticle and more silver content than the ratio of 2:1 for the same AgNO3 concentration. (99.9-100)% inhibition of Enterococcus Faecalis was obtained with all the concentrations of AgNO3 and NaBH4 and for both NaBH4/AgNO3 ratios.

Assessment of the Correlation between the Salivary Flow Rate and Dental Caries Experience among Children with β-Thalassemia Major

Mudhafar Fadhil Jaddoa1, Alhan Ahmed Qasim2

1M.Sc. Student, 2Assistant Prof., Department of pediatric and preventive dentistry/College of Dentistry/Univ. of Baghdad, Iraq

Abstract

Thalassemia constitutes a group of congenital blood disorders which characterized by a defect in synthesis of one or more globin chains of human hemoglobin molecule and the resultant microcytosis and hypochromia of the RBCs. It is of two main divisions, α- and β-thalassemia and several other subdivisions. The study group composed of 40 patient years previously diagnosed with β-thalassemia major attending the thalassemia center in Thi-Qar province/Iraq. The control group, matching the age and sex of the study group, and consisted from 40 child selected from a number of primary schools. Unstimulated salivary samples was taken from each subjects under standardized conditions. The mean value of flow rate of saliva was lower among β-thalassemias (0.466±0.024) than for controls (0.829±0.048). The (mean±SE) for the primary teeth (dmfs) in β-thalassemias (1.450±0.324) was higher than that for controls (1.250±0.808), this difference was not significant (P> 0.05). The (mean±SE) of the caries experience (DMFs) in β-thalassemias (6.850±0.782) was higher than for the control group (3.600±0.489).

Keywords: β-Thalassemia major, Salivary flow rate, Dental caries experience (dmfs/DMFs).

Introduction

Thalassemia is a very worldwide common autosomal and recessive genetic disorder with a large geographical incidence difference, it is a so severe and incurable disease because prevention is the only way to evade the disease [1]. Thalassaemias are caused by markdown or complete absent in the synthesis of one or more of the globin chains that constitute the hemoglobin (Hb) unit [2,3]. About 60,000 to 70,000 newly born children are born yearly with a severe form of thalassaemias around the world [4], and unfortunately most affected children are those who born in areas of low sources of income [5]. β-Thalassemia major is the most severe type of thalassemia and occurs due to a defect in the synthesis of β-globin chain [6]. Beta- homotetramers in α-thalassemia are more stable than alpha- homotetramers in β-thalassemia; therefore, in beta thalassemia α-homotetramers tend to precipitate priorly in the RBCs life span, producing marked RBCs haemolysis [7]. Few of the pro-erythroblasts beginning their maturation and can survive [8,9], the resultant few RBCs will bear an inclusion bodies that identified in the spleen, shortening the RBC lifespan and producing severe haemolytic anaemia [10]. The produced anaemia stimulates the production of erythropoietin stimulating hormone from the kidney and liver with a compensatory erythroid hyperplasia, but the marrow response is disrupted by ineffective erythropoiesis. [11]. Later on, massive bone marrow expansion will happened and the end result is skeletal deformities[12]. In thalassemias, high caries index, pallor of oral mucosa, atrophic glossitis, sialadenitis, retained deciduous teeth, shortened and spiked roots of teeth and thinning of the lamina dura could be seen [13]. Oral health, on the other hand, can also affect child’s personality, knowledge, and social relationships [14]. Dental caries is a chronic disease resulted from a complex intercommunication of a mass of cariogenic oral microorganisms which grow on the teeth surfaces within the dental [15]. Dental caries is widely spread and can affecting all ages. The experience of dental caries could

Corresponding Author:
Mudhafar Fadhil Jaddoa
E-mail: moadhafar_fi@yahoo.com.
be modified by several important factors, including diet, age, gender, socioeconomic level and some medicines [16]. Saliva is a heterogeneous mixture of fluids mainly produced via the major and minor salivary glands and contains oral bacteria and food debris from the gingival crevicular fluid [17,18]. Saliva have an important role in the maintenance of a healthy oral environment through a variety of physicochemical and biological properties. Unstimulated (resting) saliva includes secretions that enter the mouth without any exogenous stimuli [19,20]. Flow rate is the most important salivary parameter affecting oral health status and it represents the rate of salivary secretion and it is expressed in milliliters per minute [21]. Flow rate is very important protective factor against dental caries throughout its washing and buffering effect [22], any minimization in the normal salivary flow rate can results in establishment of dental caries [23]. Al-Jobouri and Al-Casey [24] and Kataria et al. [25]

**Materials and Method**

The total sample included in this study was (80) subjects. The study group was consisted of a (40) child suffering from β-thalassemia major and aged (11-12 years old). The control group, the non-thalassemic children, matching the age and gender of the study group, and consisted of a (40) child selected from the primary schools. An ethical approval was firstly obtained from the Ministry of Health and the Ministry of Education to perform the clinical examination and laboratory biochemical analysis. Also, a written consent form as well as patient information sheet were provided to each participant for gaining the acceptance of the child’s parents or his/her caregiver. Children having other diseases whose known to affect the experience of dental caries or the characteristics of saliva such as diabetes mellitus, were excluded. The oral examination was performed under standardized conditions of oral health surveys (WHO 1997). During examination, a suitable chair is used with noticing that it supports the head of the child. Clinical examination was performed using plane mouth mirror and dental probe. The reported caries experience was based on the criteria suggested by Manjie et al. [26]. Unstimulated salivary samples was taken from each subjects under standardized conditions suggested by Navazesh and Kumar [27]. Statistical analyses were done using SPSS computer programme, version 21. Descriptive statistics including (the mean and SE) of each clinical variable were determined for all the subjects. Student t-test was used to compare the caries experience between the study and control groups. Pearson’s correlation coefficient (r) was used to assess and compare the correlations among the variables. (P> 0.05) was considered statistically not significant. (P≤ 0.05) was considered statistically significant and (P≤ 0.01) was considered to be statistically highly significant.

**Results**

Table (1) illustrates the results showed that the (mean±SE) in β-thalassemias (1.450±0.324) was higher than that for the control group (1.250±0.808), This difference was not significant (P> 0.05).

Discussion

In the present study, the mean value of salivary flow rate was founded to be lower among β-thalassemias (0.466±0.024) than in their control subjects (0.829±0.048). This result was also documented previously by Norri [28] and by Al-Jobouri and Al-Casey [24]. This minimization in the salivary flow rate among the study group might be attributed to the fact that the salivary glands function in thalassemic patients can be affected directly by the excessive iron deposits, and the resultant painful inflammation of the salivary glands, with either regular or diminished salivary flow [23]. However, Siamopoulou et al [29] concluded in their study that the difference in salivary flow rate between the two groups is not significant. These results were in disagreement with Luglie et al. [30] and Greenberg et al.
whose showed in their studies that salivary flow rate was similar in both study and control groups.

The present study also concluded that the mean value of caries experience by surfaces in primary dentition (dmfs) among β-thalassemias was higher than that recorded in their controls. This result was corresponding with Gomber et al. [32], Kaur et al. [33], Dhote et al. [34]. On the contrary, this result was disagree with Scutellori et al. [35], Qureshi et al. [36] and Arora et al. [37] who were concluded that there is no difference between the two groups.

Furthermore, the results of the present study revealed that the mean value of caries experience by surfaces in permanent dentition (DMFs) among β-thalassemias was higher than that recorded in their controls. This results was in agreement with Hattab et al. [38], Al-Raheem et al. [39] and Al-Hadithi [40], while it was in disagreement with the results of Scutellori et al. [35] and Arora et al. [37] who were founded a similar mean value between the two groups.

In present study, there was a negative correlation between salivary flow rate and caries experience. Salivary flow rate may play an important role in relation to dental caries in which the flow rate of saliva exert cleansing activity which is critical in the clearance of food remnants and bacteria [41]. It was documented that the caries experience is obviously increased when salivary flow rate is stunted and this fact sign that the chronic decrease in flow rate is a risk factor for dental caries initiation and progression [42]. In thalassemic patients, reduced salivary flow rate can help in colonization of cariogenic S. mutans, which may have a role in the higher caries experience. Al-Zaidi [43] has documented an indubitable correlation between oral mutans streptococci and dental caries in β-thalassemia patients.

However, the higher caries experience in β-thalassemias than the normal controls can be related to factors other than a reduced salivary flow rate. This could be explained on the idea that these patients are less concern with their oral health, their parents are more worried about the serious physical condition, they paying less care to the oral health care, and seeking professional oral care just when the child experience severe pain [23, 44].

Al-Wahadni [45] and Gomber and Dewan [32] concluded in their studies that skeletal changes as enlargement in maxillary arch that occur in thalassemias in could result in protrusion of anterior segment, increased space between upper and lower teeth, over-bite or open-bite which all could predispose to dental caries.

**Conclusion**

Dental caries experience was higher among beta thalassemias compared to the control group. The salivary flow rate among β-thalassemias was lower among β-thalassemia patients than for their control subjects. The reduced salivary flow rate detected in β-thalassemia major patients could be considered as a modifying factor for the increased experience of dental caries in these patients.

1 Ph.D., Adult Nursing, Instructor, Adult Nursing Branch, College of Nursing, Al-Muthanna University, Iraq, 2 Ph.D., Pediatrics Nursing, Instructor, Pediatrics Nursing Branch, College of Nursing, Al-Muthanna University, Iraq, 3 Ph.D. of applied statistics in University of information technology and communications, Baghdad, Iraq, 4 Ministry of health, Thi Qar Directorate, Endocrine and Diabetic Center

Abstract

Background: Diabetic foot is a serious complication of diabetes that aggravates the patient’s condition whilst also having significant socioeconomic impact. Increasing physicians’ awareness and hence their ability to identify the «foot at risk,» along with proper foot care, may prevent diabetic foot ulceration and thus reduce the risk of amputation.

Objectives: 1. Determine the socio demographic data on diabetic foot and leg ulceration
2. Determine the relationship of socio demographic data on diabetic foot and leg ulceration
3. Determine the Effecteness of Carbothera therapy upon diabetic foot and leg ulceration improvement

Methodology: A descriptive study was conducted on a sample consisting of (50) patients is having diabetic foot and leg ulceration who were selected randomly from Endocrine and Diabetic Center in Nasiriya City. Diabetic patient who have diabetic foot and leg ulceration, carried out in Nasiriya city / endocrine and diabetic Center starting from January/ 2019 to July /2019

Results: 40% the age between 60-69 years, males was 68%, the patients residing in the city (urban) by 66%,78% of them consider that their monthly income is not enough, infected with diabetes For diabetes for a period of 10 years and more is 76%, the average age of patients was 59 years, patients discovered diabetes disease was 66% , improvement in their health through the carbothera therapy 66% indicated a positive effect on the patients, a significant mean relationship at level of 8% between the urban and rural environment variable with improved carbothera therapy indicates that therapy is more effective when the patient has a more urban than rural. In addition, a very weak and statistically insignificant relationship between the patients is other demographic data and the improvement of carbothera therapy

Keywords: Diabetic, Carbothera therapy, foot and leg ulceration

Introduction

Diabetic foot and leg ulceration is one of the most significant and devastating complications of diabetes, and is defined as a foot affected by ulceration that is associated with neuropathy and/or peripheral arterial disease of the lower limb in a patient with diabetes. The prevalence of diabetic foot ulceration in the diabetic population is 4–10%; the condition is more frequent in older patients 1-3. It is estimated that about 5% of all patients with diabetes present with a history of foot ulceration, while the lifetime risk of diabetic patients developing this complication is 15% 1. The majority (60–80%) of foot ulcers will heal, while 10–15% of them will remain active, and 5–24% of them will finally lead to limb amputation within a period of 6–18 months after the first evaluation. Neuropathic wounds are more likely to heal over a period of 20 weeks, while neuro
ischemic ulcers take longer and will more often lead to limb amputation \(^4\). It has been found that 40–70\% of all no traumatic amputations of the lower limbs occur in patients with diabetes \(^5\). Furthermore, many studies have reported that foot ulcers precede approximately 85\% of all amputations performed in diabetic patients \(^5\). The risk of foot ulceration and limb amputation increases with age and the duration of diabetes \(^6,7\). The prevention of diabetic foot is crucial, considering the negative impact on a patient’s quality of life and the associated economic burden on the healthcare system \(^8\). Diabetic foot ulceration is a major health problem and its management involves multidisciplinary approach. This review aims to provide a synopsis of the current management strategies of diabetic foot ulcers, from prevention to the options for therapy. The authors believe that it may be useful to primary care physicians, nurses, podiatrists, dialectologists, and vascular surgeons, as well as all healthcare providers involved in the prevention or management of diabetic foot ulcers of skin integrity, providing a site vulnerable to microbial infection \(^12\). Peripheral arterial disease is 2–8 times more common in patients with diabetes, starting at an earlier age, progressing more rapidly, and usually being more severe than in the general population. It commonly affects the segments between the knee and the ankle. It has been proven an independent risk factor for cardiovascular disease as well as a predictor of the outcome of foot ulceration \(^13\). Even minor injuries, especially when complicated by infection, increase the demand for blood in the foot, and an inadequate blood supply may result in foot ulceration, potentially leading to limb amputation \(^14\). The majority of foot ulcers are of mixed etiology (neuro ischemic), particularly in older patients \(^15\). In patients with peripheral diabetic neuropathy, loss of sensation in the feet leads to repetitive minor injuries from internal (calluses, nails, foot deformities) or external causes (shoes, burns, foreign bodies) that are undetected at the time and may consequently lead to foot ulceration. This may be followed by infection of the ulcer, which may ultimately lead to foot amputation, especially in patients with peripheral arterial disease. Structural foot deformities and abnormalities, such as flatfoot, hallux valgus, claw toes, Charcot neuroarthropathy, and hammer foot, play an important role in the pathway of diabetic foot ulcers since they contribute to abnormal plantar pressures and therefore predispose to ulceration. Other risk factors for foot ulceration include a previous history of foot ulceration or amputation, visual impairment, diabetic nephropathy, poor glycemic control, and cigarette smoking. Some studies have shown that foot ulceration is more common in men with diabetes than in women \(^14,16\). Social factors, such as low socioeconomic status, poor access to healthcare services, and poor education are also proven to be related to more frequent foot ulceration \(^14,16\).

**Methodology**

Non-probability (purposive) sample application was conducted on a sample consisting of (50) patients having foot and leg ulceration who were selected from endocrine and diabetic center in Nasiriya city. An assessment format was constructed and designed depending on open format information and after reviewing the related literature, the objective of this assessment was to evaluate the need for the educational program. The assessment was conducted from january-2019 to July -2019 and the format was comp each respondent a period between 30-40 minutes. Researcher were fill out the format by himself. For those who were unable to ask to read and write, the researcher filled out the format herself with their original responses.

The data of present study were analyzed through the application of two statistical approaches, which may assist for the determination of the study results.

**Statistical Analysis**

A statistical questionnaire on diabetic foot disease was prepared and a sample of 50 patients was selected. The form consisted of two axes: The first on the socio-demographic aspect of the patient and the second on the clinical medical aspect.

The data from the form were classified and the variables were coded according to the requirements of the statistical program SPSS.

Since the variables used are qualitative and not quantitative, the correlation coefficient has been used to measure whether there are links between some variables and their analysis. The Spearman correlation coefficient is based approximately the vocabulary of each of the descriptive variables in question, with each given numeric value showing its order. Using these ranks, the correlation coefficient, called “grade”, can be calculated. The correlation coefficient can be calculated through the following formula:
\[
R_s = 1 - \frac{\sum D^2}{n(n^2 - 1)}
\]

Where \( n \) = number of observations

\( D \) = differences between two ranks of two observations

Table (3) showed that the majority of patients discovered diabetes through their reviews, not the same thing. The proportion of patients diagnosed with the disease was 66% of the total sample. The percentage of patients who reported an improvement in their health through the therapy of carbothera therapy 66% indicated that the therapy had a positive effect on the patients, the form of the number of patients who responded to exercise daily, which is very useful to them, the number of patients who responded that they are walking Which were very useful to them, constituted a high rate of 82% of the patients in the sample.

</tbody>
</table>

Table (4) showed the majority of patients (23 patients and 46% of total patients) who responded to therapy were among the 1 to 15 session sessions supporting the patient’s response to therapy after attending only one and a half sessions (two sessions a week). The relationship between Spearman and (0.248) indicates that a significant mean relationship at an error level of 8% between the urban and rural environment variable with improved carbothera therapy indicates that therapy is more effective when the patient has a more urban than rural environment. The patient to the consequences of disease in the city be committed to therapy and get better results, While the relationship between the mean and moral level of error does not exceed 9 per cent between the variable and the presence of monthly salary of the patient due to lack of improvement in the therapy of carbothera, indicating that the therapy is more effective when the patient a monthly salary. This result is for the patient’s mental state and the state of safety provided by the continuous monthly salary.

The correlation is very weak and there is no daily walk to the patient with improved therapy of carbothera through the value of the link (Spearman) and the amount (0.007), may appear this way because the patient has difficulty walking because of the disease and declare that he walked but did not exceed the steps were not simple you remember.

**Discussion of the Results**

The study comprised 50 participants with confirmed diagnosis of diabetes mellitus. Were more males than females, age between 60-69 years that is (due to the customs and traditions that require men to accompany women during their visit to the hospital for therapy). The patients residing in the city (urban), Which indicates that the incidence of the disease may relate to the nature of nutrition in the city and the natural nutrition in the countryside, the adequacy of the monthly income of the patient or not, of them consider that their monthly income is not enough, which indicates that insufficient income leads to “malnutrition and the lack of a suitable environment for living”. Improvement in their health through the therapy of carbothera therapy indicated that the therapy had a positive effect on the patients, the form of the number of patients who responded to exercise daily, the number of patients who responded that they are walking Which were very useful to them, constituted a high rate of the patients in the sample, but the statistical results did not show a correlation with the improvement of their health condition due to their inability to walk already and the decline of a few daily plans, which makes it useless healthily. This agree with the study by Bakker et al. 2016 (International Working Group on Diabetic Foot Editorial Board. The development of global consensus guidelines on the management and prevention of the diabetic foot.

**Conclusion**

The management of diabetic foot and leg ulcers remains a major therapeutic challenge, which implies an urgent need to review strategies and therapy in order to achieve the goals and reduce the burden of care in an efficient and cost-effective way. Questions remain as to which types of intervention, technology, and dressing are suitable to promote improvement, and whether all therapies are necessary and cost-effective as adjunctive therapies. Diabetic foot ulcers should be carefully
evaluated and the gold-standard therapy should be strictly applied in order to prevent amputation. Further clinical studies are needed to support the existing evidence regarding the clinical benefit of new approaches for the therapy of diabetic ulcers, and these approaches should be used only as add-on therapies to the gold-standard wound care.

Abstract

Cerebrospinal fluid rhinorrhea occur when there is communication between skull base and the nasal cavity. Nowadays endoscopic endonasal repair of CSF rhinorrhea become the preferred surgical intervention.

Setting: ENT department at Ghazi AL Hariri Hospital for specialised surgeries, Medical City, Baghdad, Iraq.

Aim: To assess the effectiveness of fascia lata as sealing graft in the endoscopic endonasal repair of CSF rhinorrhea.

Patients and Method: Fifteen patients present to our department with possible clinical diagnosis of CSF rhinorrhea. The patients submitted to full history, examination including nasal endoscopy, radiological investigation (CT and MRI) of the nose and paranasal sinuses and skull base and CSF analysis. Operative technique was endoscopic endonasal repair using fascia lata graft. With monthly follow-up.

Results: Successful rate noted in 93% of the patients. No recurrence of meningitis attacks among those who reported meningitis on their presenting illness.

Conclusion: Endoscopic endonasal repair of CSF rhinorrhea has less operative and postoperative complication. Fascia lata graft offers a good choice for the repair.

Key words: CSF rhinorrhea, fascia lata graft and endoscopic endonasal repair.

Ghazi AL-Hariri for specialised surgeries Hospital, Medical City Complex, Baghdad, Iraq. Fifteen patients (eight males and seven females) were with a possible clinical diagnosis of CSF rhinorrhea. The duration of symptoms ranged from two months to twelve years. All patients had failed conservative treatment.

All patients underwent a thorough clinical history, endoscopic examination of nasal cavity, and the glucose concentration of the nasal discharge (CSF) was analyzed. All our patients underwent computed tomography (CT) and magnetic resonance imaging (MRI); CT scan was helpful in showing fracture site in post-traumatic CSF rhinorrhea while MRI was beneficial in detecting meningocele. Inclusion criteria was both the traumatic and non-traumatic CSF leak. Patients with skull base tumor were excluded from the study. Endoscopic examination where done using local decongestant and topical anesthesia using 0 degree rigid scope and the findings were difficult to localize the exact site of CSF leak, but the leak was noted coming from sphenoethmoidal recess or frontoethmoid area other patients with an obvious meningocele was noted specially in pediatric age group. Our surgical option was endoscopic endonasal repair of CSF rhinorrhea using tensor fascia lata as sealing graft. All surgeries done under general anesthesia with oral endotracheal intubation. Patients lie in slightly reverse trendelenberg position. In cases werethe defect in the cribriform area or from sphenoethmoidal area ,we laterialized the middle turbinate to get access to those areas ,sometimes we did compete ethmoidectomy to get access to the fovea ethmoidalis, In cases were a meningocele is present we follow it till reaching its neck and visualize the defect which coming from. The most critical step in the repair was to cauterize all the mucosa surrounding the defect and denuded the bone by using a bipolar suction diathermy to help get a good ground for the graft. A fatty tissue which obtained from the patient thigh plugged into the defect (underlay),after that an appropriately sized tensor fascia lata graft ( 30% larger than the defect due to later shrinkage of the graft ) is insinuated into the defect a few millimeters.then a gelfoam sponge was inserted to support the graft and a Merocil (Kennedy) pack was inserted and it was removed at third or fifth day; once the packs were removed; an endoscopic examination is done to remove any crustation and to get the first look after the surgery .The patients were instructed to minimize their daily activity like weight lifting, upstairs, sex, and avoid constipation by eating rich fiber diet. Patients were advised for monthly visit for endoscopic examination and assessment.

Results

Fifteen patients were with diagnosed of CSF rhinorrhea their age range from two years to fifty five years. Duration of symptoms range from two months to twelve years, eight patients were male and seven patients were female (figure 1); six patients experienced CSF leak from the left side while the other nine patients had the leak from the right side (figure 2).
Eight patients had history of head trauma (of those, three patients had previous nasal surgery) while the remaining seven patients had non traumatic CSF rhinorrhea (figure 3).

Figure (3) traumatic versus spontaneous CSF leak

Of those fifteen patients, five patients reported history of meningitis (ranging from one to several attacks during their illness); the other patients had no such history, figure (4).

Figure (4) meningitis rate
Eight patients were found to have a meningocele during the surgery; five meningoceles were originated from the cribriform plate, two meningoceles were originated from fovea ethmoidalis, while one patient had a sphenoidal meningocele, figures (5),(6).

Regarding CSF rhinorrhea without meningocele; the sites of the leaks were; three patients had leaks from the cribriform plate; three patients had leaks from fovea ethmoidalis and one patient had leak from frontal sinus.
Only one patient presented with recurrence of CSF rhinorrhea one month after surgery. Other patients did not report any rate of CSF rhinorrhea all over the follow up period. Patients with previous attacks of meningitis, they were free from it after the surgery.

**Discussion**

In our country, CSF rhinorrhea had been treated surgically by neurosurgeons using open approach (craniotomy) for many years with its highly morbidities and mortalities. In the last few years a great move done in our otolaryngology department Ghazi AL Hariri hospital to treat such cases with CSF rhinorrhea by endonasal endoscopic approach. In our study male with CSF rhinorrhea more common than female. Yong-Gang Kong et al (2013), found seventeen male and five female among 22 cases with CSF rhinorrhea. Thibaut Van Zele et al (2013), found five female and one male among six patients. Majority of our cases (53.3%) were traumatic, which is similar to most other study. S. Schmerber et al (2006), found six pateints had spontaneous leak and sixteen patietns had traumatic CSF leak. Muhammad Umar Farooq and Murtaza Ahsan Ansari (2011), also found the same rate. In our study all patients submitted MRI, Bernardo Cunha Araujo Filho et al (2005), Order MRI only for suspected cases of meningoencephaloceles. José Alberto Landeiro et al (2004), ordered MRI for all patients. We had five cases of meningitis, Bernardo Cunha Araujo Filho et al (2005), report one case among 44 cases. Yong-Gang Kong et al (2013), found four cases among twenty two patients, Mazhar Husain et al (2006), found three pateints had meningitis among nine patients. Antibiotics cover used for all our patients, Friedman JA et al (2001), adopted antibiotics for all patients. We have eight cases with meningocele among our patients. Yong-Gang Kong et al (2013), had two cases among 22 patients. In our study, majority of our cases had leak from lateral lamella of cribriform plate 53.33%. Bernardo Cunha Araujo Filho et al (2005), found the same. Silva et al (2006), found sphenoid bone involved more commonly than ethmoid bone. The success rate was of CSF closure in our study was 93.33%. Kirtane et al (2005), had success rate of 96.63%. Bernardo Cunha Araujo Filho et al (2005), 80% success rate. Schick et al (2001), report success rate of 80%.

**Conclusion**

Nowadays endoscopic endonasal repair of CSF rhinorrhea become the preferred option for the repair of CSF rhinorrhea with fascia lata graft offer a good choice for the repair in both traumatic and spontaneous CSF leaks with high successful rate.

Genotype and Haplotype of HLA-Class II in Type I and Type II Diabetes Mellitus in Iraqi Patients

Abeer Mazin¹, Abdalnabi J Abid²

¹Postgraduate, ²Professor, Department of Microbiology, College of Science for Women, University of Babylon

Abstract

Background: Diabetes is one of the common complicated disease associated with multiple influenced factors, immunological serological and molecular factors play a great role in susceptibility and diagnosis of this disease. HLA genotyping were reported to have an influencing in both types of diabetes.

Aim: The current study was conducted to investigate the association of human leukocytes genotypes in Diabetes patients.

Method: Case-control study enrolled 225 blood samples collected from patient attended to the Marjan Teaching Hospital- Hilla and 25 apparently healthy from October 2018 to May 2019. Class II HLA genotyping was performing for 60 patients with diabetes mellitus and 25 healthy unrelated controls by means of the PCR-SSP method. The diagnosis of T1D and T1ID was set up according to American Diabetes Association criteria.

Results: both types of diabetes were significantly associated with HLA-DR3. Associations were also observed with HLA –DQA105:01, the appearance of these two alleles differs in both T1D and T1ID. Conclusion. Certain HLA class II alleles, haplotypes, and genotypes have related to diabetes mellitus so it can be dependent as a genetic marker for susceptibility of this disease in Iraq.

Keywords: Type II diabetic, Type I diabetes, HLA class II, genotype, haplotype.

Introduction

Diabetes mellitus (DM) is a group of metabolic disorders characterized by a chronic hyperglycemic condition resulting from the defects in insulin secretion, insulin action or both.¹ Type 1 and type 2 diabetes consider the two main types, with type 2 diabetes constituting for the majority (>85%) of the total diabetes mellitus prevalence, According to the latest estimates, there are 425 million people with diabetes in 2017 and this number is expected to rise in 2045 to 629 million.² The genetic loci involved in the rejection of foreign organs knew as the major histocompatibility complex (MHC), and the MHC encodes highly polymorphic cell surface molecules. The human MHC is representing as the HLA (Human Leukocyte Antigen) system because these antigens first identified and characterized using alloantibodies against leukocytes.³ The encoding of HLA-DQ proteins are belongs to HLA-DQ genes and expressed on α and β chain at cell surface.⁴ The DQ region of HLA include two gene clusters, DQA1 and DQB1.⁵ The polymorphism of HLA had serologically significant impact and the Polymorphism at the HLA-DQB1 locus used to be determined serologically and recognized the specificities DQ1, DQ2, DQ3 and DQ4.⁶ The use of DNA typing techniques has increased the number of alleles. The allelic sequence diversity is also predominantly present in exon 2 and, except for DQB1*0201 and DQB1*0202, all alleles can be discriminated by PCR-SSOP in this exon. A large number of studies have demonstrated that specific alleles at the DRB1, DQA1, and DQB1 loci are strongly associated with diabetes.⁷,⁸ However, allelic variation at these loci cannot account fully for the pattern of HLA haplotype sharing among affected sib pairs.⁹

Material and Method

Patients and controls

Two hundred twenty-five blood samples were
collected from clinically diagnosed diabetes patients who regularly admitted by medical committee specialized diabetic center of marjan hospital (Babylon) from October 2018 to May 2019, the age of patients between (2-80) years including both sex male (112) and female (113), in addition to (25) samples were taken from apparently healthy human were taken from Babylon province as control. The study was approved by the Research Ethics Review Boards of the University of Babylon. This work was done by self funding and it is a part of M.Sc project for the first author with the agreement of university .

All participants provided written informed consent. Case Ascertainment. Patients with diabetes were diagnosed by a physician on the basis of the following criteria: a fasting glycemia ≥ 1.26 g/dL, an unexplained weight loss, signs of hyperglycemia (polyuria, polydipsia, polyphagia, and asthenia). These criteria were defined according to the recommendations of the American Diabetes Association.10.

Blood sampling

For each individual enrolled in the study, 3 ml of venous blood was collected in EDTA-treated tubes for DNA extraction, which performed according to the protocols recommended by the manufacturer (Favorgen / Taiwan).

**HLA genotype analysis**

HLA –DQA105:01 and HLA-DR3 genotyping was performed with PCR-sequence-specific primers (PCR-SSP).11. In a 20 µl mixture of 2.5 µl DNA, 1.5 µl from each forward and reverse of the primer, 5 µl master mix and 9.5 µl nuclease free water. The DNA amplification for HLA-DQA1 is includes an initial denaturation of 2 min in 94°C, 32 cycles of amplification (every cycle consists of a denaturation of 30 s in 94°C, a hybridization of primers during 30 s in 63°C, and an extension of 30 s in 72°C), and a final extension of 10 min in72°C, 11. While the process of DNA amplification for HLA-DR3 is same as DQA1, (exception the hybridization temperature was 52°C), then the PCR products were separated in 1.5 % agarose electrophoresis system using ethidium bromide then visualized with the gel documentation, with 100 bp-ladder (Bioneer, Korea) and photographed. The sequences of primers used for the amplification of the genes are presented in table 1.

**Statistical Analysis**

All data were statistically analyzed according to software program version20 SPSS statistical software (version 17; SPSS, Inc., Chicago, IL, USA). The association between TID, TIID and each identified HLA-DR/DQ alleles, haplotypes, and genotypes was assessed using the odds ratio with its 95% confidence interval (OR, CI 95percentage)

**Results**

The present study reveals a noticeable variety with HLA haplotype among type I and type II diabetes. HLA alleles discriminated by PCR assay. The distribution of HLA-DQA1 show high appearance in both types, out of 30 samples 26 show positive result 86.66% in type I and out of 33 samples 26 show positive result 78.78% in type II finally, statistical analysis showed no significant differences comparing diabetes patient and control subjects table 2.

Discussion

Diabetes mellitus is a combined metabolic disorder that includes several complications and the incidence of diabetes has been increasing worldwide therefore various are relentlessly working out the possible role of a vast number of genes associated with this disease\textsuperscript{12}. Human leukocytes antigen represented many proteins that encoded by HLA genes, therefore HLA-DQ genes expressed as heterodimers of alpha and beta chains at the cell surface\textsuperscript{13}.

The distribution of HLA-DQA1 in the present study show high appearance in both types, out of 30 samples 26 show positive result 86.66% in type I and out of 33 samples 26 show positive result 78.78% in type II finally, statistical analysis showed no significant differences comparing diabetes patient and control subjects table 2.

Although the high appearance of this HLA-DQA1 type in both types of diabetes TID and TIID, statistical analysis show no significant differences between patients and control, this led to conclude that this haplotype had no risky effect on this population sample of diabetes patients.

HLA allele and haplotype frequencies vary considerably across ethnic groups\textsuperscript{14}. Researchers pointed that HLA-DQA1 \(\square\) 05:01, HLA-DQA1 \(\square\) 03:01 play arole in diabetes susceptibility particularly TID\textsuperscript{15}.

The analyses of HLA disease associations in different ethnic populations, due to differences in allele frequency distributions and patterns of linkage disequilibrium, can allow important general inferences of disease risk associated with specific alleles and their combinations.

The distribution of HLA-DR3 in type I and II showed that type I diabetes revealed percentage 46.66% and type II revealed a percentage 36.66% whereas the control revealed percentage 32%. Statistical analysis showed significant differences comparing two types of diabetes patient.

On contrary of HLA DQA, HLA DR3 appear in less percentage in diabetes patients particularly in TIID, this may be due to the protective role of this haplotype in this population samples of diabetes. The increased risk of DR3/4-DQB1*0302 heterozygotes relative to DR3/3 and DR4/4 genotypes has led to the hypothesis that the trans-complementing DQ heterodimers are more effective in presenting diabetogenic epitopes to T-cells\textsuperscript{16}.

Type I diabetes has the strongest association with HLA-DQA1 and DR3 similar result were also reported by\textsuperscript{15}.

Studies on DRB1 and DQB1 allele distributions and the importance of genotype context support the genetic associations observed in previous studies\textsuperscript{17,18}.

Variable results on DQA1 and DR3 genotypes in...
this study observed the risky and protective role of these genotypes in TID, TIID and healthy individuals. This is compatible with the DQ heterodimer encoding by DQA1*0501 and DQB1*0302 explanation.19

**Conclusion**

This study was designed to assess the associations of HLA class II alleles, haplotypes, and genotypes with the risk of developing T1D and T2D in Iraq. Certain HLA class II alleles, haplotypes, and genotypes were related to diabetes and may be used as genetic susceptibility markers to diabetes. Further studies of HLA and diabetes mellitus in Iraq are needed to confirm the present results and to provide data for the development of screening assays and for better management of patients with diabetes at the onset of disease.

Cloud Point Extraction, Preconcentration and Spectrophotometric Determination of Co (II) and Cu (II) using 15-Crown-5

Yussra O.Mussa¹, Azhar A. Ghali², Ashwaq S. Hussein¹

¹Department of Chemistry, College of Education, University of AL-Qadisiyah, Diwaniyah, Iraq
²College of Pharmacy, University of AL-Qadisiyah , Diwaniyah, Iraq

Abstract

In the current study, a cloud point extraction (CPE) with UV-vis spectrometry for detection of Cu (II) and Co (II) ions with 15-crown-5 as a chelating agent was developed to be more selective and sensitive. The CPE method is improving the analytical signal and permits the preconcentration of metals ions. After phase separation induced by change temperature to become higher more than the temperature of the cloud, the point is performed with centrifugation. The Co (II) and Cu (II) ions are determined in the enriched phase by UV-vis spectrometry. Several factors affecting the extraction efficiency were optimized, e.x. pH, the concentration of the chelating agent, non-ionic surfactant concentrations, and cloud point temperature. Under optimum conditions, a linear calibration graph in the range of 0.5-5 μg mL⁻¹ of Co (II) in the initial solution with r² = 0.9994 (n=8) and 0.2–7μg of Cu (II) in the initial solution (mL-1) with r² = 0.9991 (n=8) were obtained. Detection limits of 0.4and 0.1μg are for Co(II) and Cu(II) along with preconcentration factors (66 and 50) for these ions, respectively. The method was used for detection of Co(II) and Cu(II) in some food samples.

Keywords: Cloud point extraction, preconcentration, spectrophotometric

Introduction

CPE Cloud Point Extraction method which is interest with the separation method metal ions field by forming small volume of the surfactant-rich phase (colloidal system) as a result of heating non-ionic aqueous solution of surfactant to a certain temperature at which the solution become turbid ,then the colloidal solution is separated into a small volume of surfactant-rich phase and an aqueous phase(1-6). A list of advantages of this method other than analytical methods because of i-it green method to avoid hazardous solvents ii- its selectivity for obtaining high coefficient of preconcentration iii-its economic for capital cost iv- its rapidity for reduce the time(7-9) iv-simplicity application for separation and purification of a variety samples of pharmaceutical products, vital and solid,and enviromental(10-16).

A previous study used CPE methodology coupled with flame atomic absorption,(17-22) high performance liquid chromatography,(23) Ultrasonically modified Amented,(24-25) Ultrasound,(26-27) atomic absorption spectrometry,(28)Spectrophotometric technique(29) and total reflaction X-ray fluorescence(30).

Supramolecular chemistry are strong linked to molecular recognition chemistry ,which investigates now host molecules that do the recognizing quests molecules that are recognized although molecular recognition chemistry is sometimes called host-guest chemistry ,the main concept associated with molecular recognition is the “Lock and Key “concept proposed by Email Fisher at the end of the nineteenth century 31. According to the structures and sizes of various crown ethers are forming stable and selective complexes with metal ions including alkali and alkali earth metal catoin although ability of these macro cyclic ligands as electron pair molecules towards neutral molecular iodine and with δ- or π- acceptors(35-37). In this present work we report the formation of complex 15Crown5 with copper and cobalt in ethanol solution. This work focused on the suitability of CPE combination with UV-Visible spectrophotometer.
The experimental

The apparatus

Spectrophotometer (A Shimadzu UV–vis 2101) was used for making experiment studies. Determinations of pH were measured using a (Wellhem, Model 7110) (Germany) digital pH meter. The water bath is used for studying temperature (OPTIMA co, made in Japan). A centrifuge (Hettich co., made in Germany) was used to the separation.

Reagents and Solutions

Doubly Distill water was used in the study. The nitrate salts of cobalt and copper (Merck) solution of 1000 μg/mL were prepared by dissolving the appropriate amount of nitrate salt. The solutions were produced by dilution by doubly distil water. The nonionic surfactant Triton X-114 was provided (Acros Organics company, New Jersey, made in the USA).

Suggested methods for Cloud point extraction

For making cloud point extraction, it requires 10 ml aliquot solution containing 0.5–5 μg mL⁻¹ of Co(II), 0.2–7 μg mL⁻¹ of Cu(II). Then, a solution containing 15C5 dissolved in Triton X-114 was added to the aliquoted solution at a suitable pH. The phase separation occurs when heated the solution in the water bath at 60 °C for 15 min, So accelerating phase separation by using centrifuging the solution at 5000 rpm for 10 min. Then cooling, the surfactant-rich phase changed to viscous, and the aqueous phase was easily removed using a syringe pipette. The surfactant-rich phase was made up to 1.0 mL by adding ethanol and Trans to a quartz cell to the determination of the absorbance at 290,252 Nanometer.

Application of foods samples:

Heating spinach sample (40) gram for three hours in silica crucible on heater and the charred substances was moved to oven for heating 24 hours at 650°C. then cooled, after that treated by nitric acid (10) mL and H₂O₂ (3) mL at concentration (30) and return to the oven for two hours at 650 °C, and shouldn’t any organic compound. Treatment of final residue by nitric acid (3) mL and convert by evaporated to the fumes. Final solid was kept in distal water, then keep at pH (4) made up to 25 mL. Black tea one gram, green tea one gram and tomato sauce one and a half gram were digested with the mixture of 8 mL concentrated nitric acid, H₂O₂ (2) mL at a concentration (30%) in microwave and dilution it by deionized water (50) mL. Also, the blank digest too submitted for the same way. The CPE methods were used to the final solutions. The analyte ions levels were determined by the procedure provided in section 2.3.

The Results and the Discussion

Absorption spectra and Characteristics of the method:

The absorption spectra of Co (II)-15-C-5 and Cu (II)-15-C-5 complexes in the surfactant-rich phase after CPE procedure against reagent blank are shown in Fig. 1 the detection wavelengths were chosen to be 290 and 252 nm. The stoichiometry of 15-Crown-5 complexes with Co (II) and Cu (II) was examined by mole ratio method, and the continuous variation was found to be 1:1. The preconcentration factor results in by dividing aqueous phase volume to the preconcentrated phase volume. Table 1 summarizes the analytical characteristics of the method under the optimum experimental conditions.

![Fig. 1: Absorption spectra (a) Co(II)-15-C-5 complex, Co (II) = 2.5 μg mL⁻¹, 15-C-5 = 1 x 10⁻² M , pH = 4 , 0.4 mL of 2 % (v/v) Triton X-114 (b) Cu(II)-15-C-5 complex, Cu (II) = 2.5 μg mL⁻¹, 15-C-5 = 9 x 10⁻³M , pH = 4 , 0.5 mL of 2 % (v/v) Triton X-114.](image-url)
Table (1): showed parameter methods that used for detection values of cobalt and copper by using CPE.

Optimizing of CPE parameters:

**Effect of pH:**

The separation of ions includes primary production sufficient hydrophobic with metal-chelate to be extraction of a little amount of surfactant-rich phase \(^{(38)}\). pH test is the main parameters \(^{(39)}\). PH effect to the CPE method was applied in (1–5) range. Adjusting of PH values is with \(\text{HNO}_3\). Figure (2) showed a pH effect on the percentage of extraction; it included the extraction percentage increasing with nitric acid decreasing. The final results, pH (4) were chosen.

![Fig. 2: PH effect on the determination of Cu (II) and Co (II)](image)

Conditions: Co (II) = 2.5 µg mL\(^{-1}\), 15-C-5 = 1×10\(^{-2}\) M, 0.4 mL of 2 % (v/v) Triton X-114 (b) Cu(II)-15-C-5 complex, Cu (II) = 2.5 µg mL\(^{-1}\), 15-C-5 = 9×10\(^{-3}\) M, 0.5 mL of 2 % (v/v) Triton X-114.
Effect of 15-Crown-5 concentration:

The effect of 15-Crown-5 on the extraction and determination of Co (II) and Cu (II) complexes were investigated in the range $2.0 \times 10^{-3}$ to $2.0 \times 10^{-4}$ mol L$^{-1}$, the results present in Fig. 3. The extraction will result in high concentrated of 15-Crown-5 and remained almost constant. That explains that micelles are filled by the chelating agent. At higher concentration, extraction efficiency was decreased. That due to the free 15-Crown-5 competes with the complexes in extraction to surfactant-rich phase results in low extraction$^{(40,41)}$. Therefore, a concentration of $1.0 \times 10^{-2}$ and $9.0 \times 10^{-3}$ mol L$^{-1}$ of 15-Crown-5 was selected as the optimum concentration Co (II) and Cu (II).

Triton X-114 Effect:

One of a critical factor that in the CPE is the concentration of surfactant, Triton X-114 is non-ionic surfactant wide using in CPE due to its achieves a good cloud point extraction that means increase the extraction efficiency by reducing the phase volume ratio, results in improvement of concentration factor. Where Triton X-114 present in markets at high purity, with low point temperature, low cost and toxicity and the surfactant-rich phase (high density)$^{(42,43)}$. The preconcentration efficiency depends on the Triton X-114 level (0.001-0.015) as range M, as shown in Fig. 3. At lower concentrations of the surfactant, The highest extraction efficiency for cobalt and copper ions was obtained with 0.007 and 0.009 M Triton X-114. The extraction decreases with increasing of the surfactant amounts. That may be belonging to increasing in viscosity and volume of the micellar phase leading to poor sensitivity$^{(44)}$. An amount of 0.4 and Triton X-114 (0.5 Ml) were selected for subsequent experiments.

Fig. 4: Effect of Triton X-114 concentration on the determination of Co (II) and Cu (II) Conditions: Co (II) = 2.5 μg mL$^{-1}$, 15-C-5 = 1 x 10$^{-2}$ M, pH = 4, Cu(II)-15-C-5 complex, Cu (II) = 2.5 μg mL$^{-1}$, 15-C-5 = 9 x 10$^{-3}$ M, pH = 4.
Effect of Time and Temperature of Equilibration Incubation:

Determination of incubation is done by temperature and time. As well as, the extraction process depends on temperature. Figure (5) showed the influence time and temp of the incubation of Cobalt and copper. The cloud point temperature of Triton X-114 is (23-25) °C in (0.1–5) weight percentage, heating more than ten °C is important for getting good separation (45). When temperature or incubation time is an increase, it will increase Co (II) and Cu (II) extracted amount in the surfactant-rich phase with quantitative separation after fifteen minutes in 60 °C (water bath). The prolonged times is necessary to apply it at high temperatures for satisfactory mange extraction (46).

Wide ranges are used in our study (30–70) °C as temperature degree and (5–30) minutes as a time. Time (15) minutes and temperature (45) °C were optimum conditions for extraction.

![Fig. 4: Effect of Triton X-114 concentration on the determination of Co (II) and Cu (II) Conditions: Co (II) = 2.5 µg mL⁻¹, 15-C-5 = 1 x 10⁻² M, pH = 4, 0.4 mL of 2 % (v/v) Triton X-114, Cu(II)-15-C-5 complex, Cu (II) = 2.5 µg mL⁻¹, 15-C-5 = 9 x 10⁻³ M, pH = 4, 0.5 mL of 2 % (v/v) Triton X-114.](image)

The effect of centrifuge conditions:

Centrifugation was accomplished for separating the aqueous and surfactant-rich phase in the suggested procedure. (5000) recycled per minute and ten minutes are best phase separation (47,48).

Effect of Foreign Ions:

The interferences are studied in the preconcentration stage, 15-crown-5 react cations or analytes may react with species and the extraction efficiency become low. The solution (10) ml consist of (3) µg mL⁻¹ Co (II) and Cu(II) as Table (2).

**Conclusion**

Extraction of ions of cobalt and copper is done with 15-crown-5 in non-ionic surfactant Triton X-114 phase. Extraction of complete elements was done by 15-crown-5 because of the hydrophobic production. The molar ratio is determined. Simplicity, Ecological safety, metrological characteristics, the sensitivity and convenience of the procedures used for extraction of the organic compounds. The results found these methods could use it for preconcentration and separation of cobalt and copper ions.

Hormonal and Immunological Study in Serum of Pregnant albino rats Treated with Nickel Oxide Nanoparticles

Haneen M. Alsoltane, Amel A. Altaee

1Babylon University/College of Science, Iraq

Abstract
The present study was aimed to elucidate the effect of Nickel oxide nanoparticle (100mg/kg b.wt) on some parameters in pregnant Albino rats which including serum reproductive hormonal level, Leutinizing Hormone (LH), Follicle stimulating Hormone (FSH) and Testosterone (Test), and some Immunoglobulin levels (IgA, IgG, IgM) for different period of pregnancy (12 and 14 days). The hormonal results showed significant (P≤0.05) increased of treatment groups as compared with control groups. Immunological results showed significant decreases in treated groups as compared with control groups. It could be concluded that increasing concentrations of NIO-NPs and durations of exposure leads to negative effects on the pregnant albino rat.

Key words: NIO, nanoparticles, albino rats, hormones, immunoglobulin.

Introduction
Nickel is a silver-white metallic chemical element that is naturally present in the Earth’s crust. Because of its unique physical and chemical properties, being tough, harder than iron, ferromagnetic, having good plasticity and highly resistant to rusting and corrosion, nickel and its compounds are widely used in industry. Nickel is an essential element for at least several animal species. These animal studies associate nickel deprivation with depressed growth, reduced reproductive rates, and alterations of serum lipids and glucose. Nickel is known as a potentially harmful element for humans. Its concentration in the environment can rise due to industrial activities. Human exposure to nickel or its compounds has the potential to produce a variety of pathological effects, which may include cutaneous inflammations such as swelling, reddening, eczema and itching on skins, and may also include allergy reactions and teratogenicity in the human body. Nickel is capable of evoking dual responses in the human immune system. Experiments conducted in humans and in rodents have shown that nickel exhibits both immune modulatory and immune toxic effects. Number of immunological and lymphoreticular effects have been reported in humans and animals exposed to nickel. In 38 production workers exposed to nickel (compound not specified), significant increases in levels of immunoglobulin G (IgG), IgA, and IgM and a significant decrease in IgE levels were observed. Significant increases in other serum proteins, which may be involved in cell-mediated immunity (including α1-antitrypsin, α2-macroglobulin, ceruloplasmin) were also noticed. Nickel and chromium significantly depressed the circulating antibody response of rats immunized with a viral antigen, with the greatest decrease in antibody titers noted in animals receiving the metal two weeks before the initial antigen dose. Several studies have examined the relationship between nickel exposures and acquired immune function. Exogenous chemicals can interfere with the normal functioning of the HPG axis, resulting in reduced fertility or even infertility in both females and males. Ni NPs effect the serum sex hormone levels (FSH, LH, E2 or T) in female and male rats. Some study demonstrate that Ni NPs increased significantly the level of serum FSH and LH, and decreased E2 this effect associated with dose-dependent in females. The results indicate the effects of Ni NPs on the female rat ovarian reserve. It is probably an indication of the decreased level of serum E2 and ovarian hormone secretion following ovarian damage with Ni NPs, which increased the level of serum FSH.

and LH by negative feedback. Meanwhile, the male rat serum FSH, LH and T content analysis showed the levels of FSH and T were decreased significantly by Ni NPs treatment.

Materials and Method

Animals

Animals with weight of 195-280 gm and aged of 2.5-3 months were obtained from the animal house of the Biology Department/College of Science at University of Babylon. Animals were put inside special cages for breeding with length of 25 cm, 18 cm width and 19.5 cm height and stayed about 30 days. The cages were covered with sawdust, which replaced three times weekly with the care of hygiene and sterilization. The animals were provided with food and water ad libitum. The animals were housed in special rooms with controlled conditions of temperature (24±10°C) and natural light periods (12 hours light/dark). Each two females were put with one male (for mating) in special plastic cages and strung metal caps with dimensions of 40 cm length, 25 cm width and 19.5 cm height. After ensuring the pregnancy by observing vaginal plug and vaginal smear, this day regarded as 0th day of gestations (GD=0). Pregnant rats divided in five groups (n=4). Each two females were put with one male (for mating) in special plastic cages and strung metal caps with dimensions of 40 cm length, 25 cm width and 19.5 cm height.

Nanoparticles Dose Preparation

Determination of Nickel oxide doses were depended on the animals body weight. 25-PPM doses of nanoparticle suspension was prepared and mixed with distilled water.

Animals Anesthesia

The pregnant rats were anesthetized with chloroform in 12 and 14 days of pregnancy. Pregnant rats were put after anesthesia on dissection bowl, the fore and hind limbs were fixed by fine pins, the pregnant’s abdomen was opened by a sharp scissors and take blood sample by heart puncture.

Blood collection: Blood samples were collected via the left ventricular cardiac puncture into sterilized EDTA tubes and gel tube to separate the serum quickly and then centrifuged at 3000 rps for 5 minutes. The serum samples were stored frozen until used.

Hormonal Assay: Serum Follicle Stimulating Hormone (FSH), Luteinizing Hormone (LH) and Estradiol were measured by using ELISA (Monobind Company, USA) for both control and treatment animals.

Results

Effect of Nickel Oxide nanoparticles on Luteinizing Hormone in Pregnant Albino Rats for 12, 14 Days of Pregnancy.

The result of the present study showed that the LH hormone means increases significantly (P≤0.05) in treated group (12, 14 days) with NIO (100 mg/kg b.wt) (1.1 ±0.010, 1.28 ± 0.043) (pg/ml) respectively, as compared with control group (0.8263 ± 0.0251, 0.836 ± 0.0251) for 12, 14 days respectively (Figure-1).

Effect of Nickel Oxide Nanoparticles on Follicle Stimulating Hormones in Pregnant Albino Rats for 12 and 14 Days of Pregnancy.

FSH means in present study increases significantly (P≤0.05) in treated group with NIO (100 mg/kg b.wt ) (1.023 ±0.032, 1.16 ± 0.051) (pg/ml) as compared with control group (0.8 ± 0.004, 0.8 ± 0.003 pg/ml) 12 and 14 days respectively (Fig.2).
Effect of Nickel Oxide nanoparticles on Testosterone Hormone in Pregnant Albino Rats for 12 and 14 Days of Pregnancy.

The present study showed significant increases (P≤0.05) of Testosterone in treated group with NIO (100 mg / kg b.wt ) (0.61 ±0.001 , 0.63 ±0.001 pg/ml), as compared with control group (0.541 ±0.013 , 0.52 ±0.08 pg/ml) for 12 and 14 days respectively (Figure-3).

Effect of Nickel Oxide nanoparticles on Immunoglobulin A in Pregnant Albino Rats for 12 and 14 Days of Pregnancy.

The result in the (Figure-4) revealed that the IgA, showed significant (P≤0.05) decreases in the treated group with NIO (100 mg / kg b.wt) (16.29 ± 0.292, 14.3± 0.22 pg/ml) as compared with control group (19 ± 0.386, 18.63± 0.52 pg/ml) for 12 and 14 days respectively.

Effect of Nickel Oxide Nanoparticles on Immunoglobulin G in Pregnant Albino Rats for 12 and 14 Days of Pregnancy.

The result in the (Figure-5) revealed that the IgG, showed decreases significant (P≤0.05) in the treated group with NIO (100 mg / kg b.wt) (95 ± 1 , 82.66± 1.52 pg/ml) respectively, as compared with control group (119 ± 1 , 118.3± 1.52 pg/ml) for 12 and 14 days respectively.

Effect of Nickel Oxide Nanoparticles on Immunoglobulin M in Pregnant Albino Rats for 12 and 14 Days of Pregnancy.

The result in the (Figure-6) revealed that the IgM showed significant (P≤0.05) decreases in the treated group with NIO (100 mg / kg b.wt ) ( 16.35 ± 0.19 , 14.46± 0.21 pg/ml) respectively, as compared with control group (19.62 ± 0.06 ,18.24± 0.02 pg/ml) for 12 and 14 days respectively.

Discussion

Effect of Nickel Oxide Nanoparticles on Luteinizing, Follicle stimulating and Testosterone Hormones in Pregnant Albino Rats for 12 and 14 days of pregnancy.

The present study showed significant (P≤0.05) increases in treated group with NIO (100mg /kg b.wt) as compared with control group for 12 and 14 days of pregnancy this change of hormones could be resulted
from the hypothalamic–pituitary–gonadal (HPG) axis is the hormone system whereby the hypothalamus secretes so-called releasing hormones, which are transported via the blood to the pituitary gland. There, the releasing hormones induce the production and secretion of gonadotropins (i.e., LH and FSH), which in turn are transported by the blood to the gonads (i.e., the ovaries and testes).

Generally speaking, in females, LH and FSH stimulate the ovarian follicle that contains the maturing egg to produce estradiol. After ovulation has occurred, LH also promotes production of progesterone. Both hormones participate in a negative feedback mechanism through most of the menstrual cycle, suppressing GnRH release from the hypothalamus and LH release from the pituitary (11).

Exogenous chemicals can interfere with the normal functioning of the HPG axis, resulting in reduced fertility or even infertility in both females and males, the effects of Ni NPs on aspects of serum sex hormone levels (i.e., FSH, LH, E2 or T) in female and male rats. Increases of Ni NPs level in serum FSH and LH, with significant and dose-dependent in females. It is probably an indication of the decreased level of serum E2 and ovarian hormone secretion following ovarian damage with Ni NPs, which increased the level of serum FSH and LH by negative feedback 12.

The change of hormone reproductive levels indicates the abnormal reproductive axis function, which correlated with male and female infertility 13. However, the mechanisms by which NPs alter the functions of HPOA ultimately resulting in female infertility have not been investigated thoroughly 15. Meanwhile, the amount of researches about NPs having negative effects on HPOA is relatively small. It is certain that NPs with size of 36 nm were significantly accumulated in cerebrum and cerebellum translocation via the olfactory nerve and increased with the exposure time 16. The sizes of NPs less than 90nm could disturb the balance of GnRH, FSH and LH, such as Ni, PEG-b-PLA(17) 18.

Other study showed that gold nanoparticles reduced the level of testosterone An- other assumption is that the nanoparticles could affect the gene expression of the protein that is involved in the transport of cholesterol into the inner membrane of mitochondria, and eventually inhibit the conversion of cholesterol to pregnenolone and reduced the level of testosterone. Karpenko (2013) studied toxic effects of cerium oxide nanoparticles on sex hormones and concluded that nanoparticle reduced glandular and testosterone secretion, the gold nanoparticles reduced the level of testosterone 19.

Effect of Nickel Oxide Nanoparticles on Immunoglobulin A, G and M in Pregnant Albino Rats for 12 and 14 Days of Pregnancy.

The results of the current study as in the table () revealed that the IgA, IgG and IgM, showed significant (P≤0.05) decreases in the treated group of (12, 14) days with NIO (100mg/kg b.wt), as compared with control group. The decreases of Immunoglobulins levels in pregnant females due to that the nanoparticles can also suppress the immune system which can weaken immune response against infections and cancerous cells. These immunosuppressive properties, on the other hand, can make nanoparticles useful in preventing transplant rejection, in treating inflammatory and autoimmune diseases, and in delivering immunosuppressive drugs 20.

Nanoparticle properties are responsible for immunosuppressive effects. While some nanoparticles are used to deliver immunosuppressive drugs, others have their own immunosuppressive properties. Shen et al. 22 have shown that Fe3O4 nanoparticles weaken the antigen-specific humoral response and T cell cytokine expression in ovalbumin-challenged mice. Mitchell et al. 23,24 reported that multi-walled carbon nanotubes (MWCNTs) suppressed systemic humoral immunity in mice. Some nanoparticles have been shown to possess anti-inflammatory properties. CeO2 nanoparticles were reported to reduce ROS and the level of inflammatory cytokines IL-6 and TNF-α in murine macrophages 25. After the immunization of mice with a C60 fullerene derivate conjugated to bovine thyroglobulin, they produced IgG antibodies specific to fullerenes. Other researchers were not able to detect fullerene-specific antibodies, even when they used a carrier molecule 25.

Conclusion

The hormonal results showed significant (P≤0.05) increased of treatment groups as compared with control groups. Immunological results showed significant decreases in treated groups as compared with
control groups, It could be concluded that increasing concentrations of NIO- NPs and durations of exposure leads to negative effects on the pregnant albino rat.

Assessment of Mental Health of Healthcare Professionals Working in the Infectious Diseases Units: Comparative Study

Maysaa Niama Aboalshon¹, Hayder H. AL-Hadrawi², Ammar Abbas Shalan²

¹ MScN, ² PhD, College Nursing, University of Babylon

Abstract

Background: Health care professionals working in infectious diseases units or hospitals are at higher risk for being affected by certain contagious pathogens than other professional groups through direct contact, equipment, and contaminated supplies; therefore, they are working under ongoing stress that negatively impacting their psychological well-being.

Aims: This study aims to assess the mental well-being of healthcare professionals working in infectious diseases units and compare these results to the score of other healthcare professionals working in other units.

Methodology: A comparative study design using a convenience sample of (N=300) healthcare professionals (150 working in the infectious diseases units and 150 working in different units). The General Health Questionnaire-28 was used to assess the mental health of study subjects.

Results: Recent findings indicate a statistically difference between study group and comparative group (p= <0.05), which means that healthcare providers working in the infectious disease units are at higher risk for psychological disturbance than the comparative group. Moreover, other work factors are found to have significant relationship with professionals’ mental health, such as infection prevention trainings, years of experience in infectious diseases units, availability of personal protection equipment and hand hygiene, and number of patients in the unit.

Conclusion: Working in high risk work environment increases the concern about personal safety and impose ongoing stress, which negatively influence professional’s mental well-being. More training about infection prevention and provide personal protection materials help reducing the risk of disease transmission among patients and to health care providers.

Keywords: Emotional Intelligence, Work-related Stress, Psychiatric Nurses

Introduction

Most healthcare professionals are vulnerable to the risks of workplace; especially those who expose to blood, body fluids, and injuries that could be contaminated with infectious microorganisms (15,20). Death rates are more likely to be higher among healthcare professionals (especially nurses and doctors) who work in infectious diseases units, as a result of their role as frontline professionals in caring for clients with different infectious diseases 14. Health care professionals working in infectious diseases units or hospitals are at higher risk for being affected by certain contagious pathogens through direct contact, equipment, or contaminated supplies; consequently, they are working under an ongoing stress that affects their psychological health. Working in such units increases the demand on health professionals to increase the quality of hospital care, controlling infection, and protecting themselves at the same time, which impose additional stress and impact the professionals’ general health outcomes 4. The purpose of study is to assess the mental health outcomes of healthcare professionals working in the infectious diseases units and measure the difference in the mental health outcomes among healthcare professional working in the infectious diseases units and other units. Mild stress is consider essential to promote professionals’ productivity and responses; however, when the stress level is high, it negatively impact the health of individuals. Workplace challenges do not
often reported to psychological complaints; however, psychological health of professionals is impacted when they are unable to adapt effectively with these challenges. Stress is described an imbalance among the perceived needs, understand resources, and ability to cope with those needs, which can cause physical and psychological distress. Stigma is not only affecting clients with infectious diseases, it is another issue that faces healthcare professional who care for those clients as a result of the possibility of infection transmission to healthcare care employees. Consequently, it is also considered one of the main causes of perceived stress, depression, and anxiety. Professional mental health is directly and indirectly influenced by the stigma associated with infectious diseases through stress. The Importance of risk awareness and patients safety have been indicated in several research. According to, “nurses are expected to maintain a high level of awareness towards an infectious disease outbreak and ensure the safety of the public.” This critical role highlights the reason behind the high level of stress among nurses who work in communicable diseases units. Identifying the risk factors that cause professional stress among health professionals is a crucial approach to create healthy workplace environment and maintain professionals’ mental well-being.

Methodology

Study Design and Sampling Plan:

Comparative study design using a convenience sample of 300 healthcare professionals for both groups (150 in the study group and 150 in the comparative groups). Health care providers who participated in this research study were selected regardless of their gender group, specialty, or work time. This strategy was used to clarify the general characteristics of healthcare providers of either group. About 400 healthcare providers received the questionnaire and agreed to be a part of the study; however, only 310 subjects responded to the questionnaire (150) subjects from the first group and (160) subjects from the comparative group. To make the sample size equal in the both groups, 10 subjects were randomly excluded from the comparative group.

Study instrument:

The General Health Questionnaire (GHQ28) is used to assess the mental health of healthcare providers working in the infectious diseases units and the mental health of the comparative group. This scale was developed as a screening tool to detect those likely to have or to be at risk of developing psychiatric disorders. This screening tool was developed by Goldberg in 1978. It is a 28-items that is measure a four levels scale ranged from (0 to 4 ) respectively; 0 indicates no, 1 indicates less than usual, 2 indicates more than usual, 3 indicates more often than usual. The levels of psychological distress among healthcare providers are determined based on the sum of items scores (minimum score 0 and maximum score 84). The cut score is 23/24 and individuals with higher scores are considered having higher level of psychological distress. This scale is includes four subscales in which that each scale consist 7 items, divided as follow: 1) Items (1-7) measure somatic symptoms; 2) Items (8-14) measure anxiety/insomnia; 3)Items (15-21) measure social dysfunction; 4) Items (22-28) measure severe depression. The Arabic version of the scales had good reliability level, Cronbach’s alpha level (0.89).

Ethical Considerations

Healthcare professionals were asked for voluntary participation. Research objectives, risks, and benefits were explained to participants to help them decide whether to participate or not. After they agreed to be a part of the study, participants were given anonymous questionnaire to maintain participants’ confidentiality.

Results and Discussion

The recent study indicates that there is a statistically significant difference between study group (healthcare providers working in infectious diseases units) and comparative group (healthcare providers working indifferent units) in respect to their mental health. More than half of the healthcare professionals working in the infectious diseases units were symptomatic for psychological distress; whereas, 30% of the comparative group (working in non-infectious units) were symptomatic for psychological distress. It indicates that nurses working in high demand or high risk environment anticipated a greater likelihood of developing depression and stress symptoms as a consequence of the continuous concern about their safety. Mentioned that healthcare professional who work in hospitals settings are more likely to be vulnerable to depression, and the risk is greater than the risk compared to the general population. However, highlighted that healthcare workers who are in contact with communicable diseases are at higher risk for stress, anxiety, and depression than other groups of
healthcare providers. Moreover, the various types of infectious diseases add to the work stress of healthcare professionals and increase their vulnerability to the risk of infection (2,20). A literature review study was conducted on the workplace factors that influence the psychological health of healthcare professionals involved in caring for clients with various infectious diseases. This research discovered that those employees had higher baseline depression and anxiety than those who care for clients with non-communicable diseases. These psychological effects related to the nature of environment as a high risk, loss of social support (isolation), stress attached to their role, and risk perception 1. Health care professionals who had direct contact with the affected patients were at great risk for physical and psychological risks. Even though, providers uses personal protection equipment, they still experience barriers of communication and difficulties in diagnosis and caring process, which extent the time needed for each patients and increase the risk for stress. Working in such conditions indicated considerably higher social isolation and felt considerably more vulnerable to somatic symptom, sever anxiety, depression, and fatigue 7. Analysis of variance (ANOVA) was used to find the differences among healthcare providers in response to psychological disturbances as a result of working in high risk environment. The findings indicate that technicians had the highest mean score than other groups of professionals, which represents their vulnerability to psychological disturbance, followed by physicians and nurses. The study of 17 compared the phenomenon of burnout among healthcare professionals working in the same situation. Researchers indicate a significant difference across professional groups in terms of being subjected to burnout and emotional disturbance. The difference was explained by several factors, including the responsibilities and roles assigned for each group, as well as the type of patients they care for. Being at the frontline in contact with patient can also increase the vulnerability of work stress. In addition, training programs can have positive impacts on reducing work-related stress. Significant relationships were found between psychological health and professionals’ working conditions, including training about infection control, availability of the personal protective equipment, and availability of hand hygiene. Several studies have highlighted the importance of providing training for infection prevention and control, as well as the importance of using personal protection equipment for all healthcare professionals working in the infectious diseases units to prevent the potential risk and reduce work stress 10. The study that carried out by 3 showed that healthcare professionals who had not received infection prevention training were less likely to have knowledge of infection prevention than those who had received infection prevention training. Therefore, lack of knowledge increases their vulnerability to stress. Moreover, training has positive impact on the attitude of the respondents in the study group compared to the control group (16, 3). Health practitioners need to safeguard themselves with barriers such as gloves, face masks, gowns, protective eyewear and face shields to reduce work-related microorganism transmission. Despite that, the threat cannot be secured completely, such as the threat results from needlestick injury, using personal protective equipment (PPE) regularly can protect both the professional and the patient from potentially infectious body fluids 5. The research of 21 linked the increased risk for professionals’ infection to their noncompliance in using hand hygiene before and after caring process. Most providers of healthcare underestimate the significance of hand hygiene as it is not correctly stressed. As a result, many nurses lack the expertise and resources necessary to promote their compliance. Re-education; therefore, enables them by emphasizing the importance of compliance with hand hygiene, which increases the quality and safety of provided healthcare services. In addition, studies have also shown that personal protection equipment are not all available for healthcare professionals; however, even with the availability of required equipment, some professionals are careless to use the protective materials. Therefore, hand hygiene is critical to reduce the risk of infection transmission among patients and prevent the risk for healthcare providers (0,5).

**Conclusion**

This study aims to assess the mental well-being of healthcare professionals working in infectious diseases units and compare these results to the score of other healthcare professionals working in other units. Workplace stress has been found in all healthcare providers as a result of various types of stressor factors, which impact their mental health. However, healthcare providers who are in contact with infectious diseases are at higher risk for depression, stress, anxiety, and sleep disturbance than others who work in different healthcare settings. Consequently, feeling stressed and concerned about personal safety impose a negative effect on professionals’ mental health. More training about infection prevention help raising professionals’
knowledge and practice of preventing infection from being transmitted to other patients or to the healthcare providers. Likewise, using personal protective equipment and hand hygiene play an important role in reducing the risk of infection among healthcare professionals. Therefore, it is important for healthcare professionals to be aware of the effective strategies that reduce their vulnerability to the risk of infection. More training about infection prevention and provide personal protection materials help reducing the risk of disease transmission among patients and to health care providers, which indeed helps reducing the psychological stress among healthcare professionals.

Emotional Intelligence and Work-related Stress among Nurses Working in Psychiatric Hospitals

Zaman Ahmed Hrefish¹, Hayder H. AL-Hadrawi²
¹ MScN, ² PhD, College Nursing/University of Babylon

Abstract

Background: Emotional Intelligence is a broad concept that connecting various personality and cognitive traits of human beings. The concept of emotional intelligence is described as the individual’s capability of recognizing their own emotions and the emotions of others, and practice this understanding to navigate important interactions successfully.

Aims: The purpose of this study is to assess emotional intelligence among nurses working in psychiatric hospitals, as well as the relationship between emotional intelligence and workplace stress.

Methodology: A descriptive correlational study design using a convenience sample of (N=109) nurses working in two main psychiatric hospitals. Two separated scales (The Emotional Intelligence Scale-34 items and The Work-related Stress scale-24 items) was used to meet the study objectives.

Results: The study findings indicate that emotional intelligence levels were ranged between moderate to high among study participants. However, the majority had moderate work-related stress about (61%). Nurses’ work stress was found to have significant relationship with their emotional intelligent level.

Conclusion and Recommendations: Despite the positive levels of emotional intelligence nurse have, working in psychiatric hospitals is still cause of stress for nurses. The statistical relationship found in this study highlights the importance of enhancing emotional intelligence among nurses working in psychiatric hospitals settings by engaging them in effective training programs to maximize their abilities of adjustment and reduce their levels of work-stress.

Keywords: Emotional Intelligence, Work-related Stress, Psychiatric Nurses

Introduction

Emotional Intelligence (EI) is a broad concept that connects different personality and cognitive traits of humans, including emotional processing, emotional understanding, integrating affects and management of feeling states. The concept first introduced by Salovey and Mayer in 1990, and it was defined as cognitive skills that introspectively can detect and regulate affective states and assess the emotional state of others. In general, emotional intelligence is described as the ability of an individual to recognize own emotions and others emotions, and to practice this understanding to navigate important interactions successfully. A clear understanding of EI and its difficulties is helpful in the practice of nursing; due to the understanding of how emotions merge with cognition. Generally, EI helps nurses to improve relationships, manage their patients more effectively, make better decisions, and positively affects the quality of care provided to patients and families. The study aims to assess emotional intelligence among nurses working in psychiatric hospitals, as well as the relationship between emotional intelligence and workplace stress. Emotional intelligence is mainly focus on people with the ability to express, evaluate, and adjust enthusiasms and emotions of themselves and others, as well as those who can properly guide and control the thought and performance. Therefore, emotional intelligence is considered as an effective power to deal with job stressors. Also, nurses with high emotional...
intelligence and emotional managements are able to direct positive feelings exchanged by healthcare individuals to decrease the negative effects of job stress. Nurses experience and suffer from stress and health problems have less traits related of their work characteristics and less contact with patients. Emotions can have an impact on job outcomes and emotional intelligence, which could explain the differences among individuals in dealing with work stress. Emotional intelligence can have a direct influence on the quality of the provided healthcare services or indirect influence, through other mediator, variables such as individual’s job satisfaction and professional conflict. Studies have shown that nurses communication skills and job satisfaction play significant role in the emotional intelligence of nurses and the quality of the provided services. Moreover, work-related outcomes are more likely to be impacted when nurses feel stressed and insecure in their work environment.

**Methodology**

**Study Design and Sampling Plan:**

A descriptive correlational study design using a convenience sample of (N=109) psychiatric nurses working in the main psychiatric hospitals in Baghdad Province. Both male and female nurses were included regardless of their working shift. Their age ranged between 20 – 60 years old, with at least one years of experience in the psychiatric hospital.

**Study instrument:**

Two separated scales were used to meet the study objectives. The first scale is the Revised Emotional Intelligence Scale-(34) items. The original emotional intelligence scale was developed by, which contains (65 items); then, it was reduced to (34 items). The revised scale is widely used to measure the emotional intelligence cross-cultures. This scale is a self-reported instrument that is measured and rated on three levels rating scale; 1= not applicable to me, 2= applicable to some extent, 3= highly applicable. The levels of emotional intelligence are determined based on mean scores of the total items as follow: 1) nurses with means scores of (1 - 1.66) are considered having low emotional intelligence; 2) nurses with means scores of (1.67 – 2.33) are considered having moderate emotional intelligence; 3) nurses with means scores of (2.34 - 3) are considered having high emotional intelligence. The second scale is the Karasek Professional-Related Stress Scale was adopted and modified to be used in this study to assess workplace stress among psychiatric nurses. The original scale was developed by Karasek in 1980. This scale is also a self-reported instrument; however, it is measured and rated on four levels rating scale; “1= strongly disagree, 2= disagree, 3= agree, 4= strongly agree”. Coding for negative statements was reversed for statistical purpose. The levels of work stress are determined based on total scores of the scale items as follow: 1) nurses with total scores of (58 – 69) are considered having high work related stress. 2) nurses with total scores of (70 – 81) are considered having moderate work-related stress; 3) nurses with total scores of (82 - higher) are considered having low level of work-related stress.

**Scale Validity and Reliability**

The Revised Emotional Intelligence Scale and The Karasek Professional-Related Stress Scale were translated to Arabic by two bilingual content experts. The Arabic versions of both scale were presented to panel of content experts related to the fields of mental health, psychology, and community health to maintain the validity of the Arabic versions. Both scales had good reliability levels with a Cronbach’s alpha level (0.89) for the emotional intelligence scale and a Cronbach’s alpha level (0.78) for the work stress scale.

**Ethical Considerations**

Nurses were asked for voluntary participation. Research objectives, risks, and benefits were explained to participants to help them decide whether to participate or not. After they agreed to be a part of the study, participants were given anonymous questionnaire to maintain participants’ confidentiality.

**Results and Discussion**

This study indicates that majority of the study sample (60.6%) had high level of emotional intelligence, and (39.4%) had moderate level. The results of this study show that female nurses have higher level of emotional intelligence, than male nurses. Recently, there are some studies have been conducted to study nurses’ emotional intelligence in several fields. Empathy, emotional awareness, and problem solving were the most common attributes of emotional intelligence that have been reported by nurses. Researchers discovered that the nurses’ emotional intelligence was higher than other professionals. This difference is related to the fact that nurses get more training about caring process and
Another research was conducted in the Netherlands showed higher emotional intelligence scores among mental health nurses compared to the general population. Engaging in more ethical behavior have been indicated by nurses who reported high levels of emotional intelligence. Moreover, it has been found that the high level of emotional intelligence among clinical nurses play a role in organizational justice, specifically regarding interpersonal and informational aspects of relationships. The outcomes of this study show moderate level of work-related stress was identified in (60.6%) of psychiatric nurses; while (14.7%) had high level of stress related to their workplace. Nursing personnel are considered as professionals with increased level of stress, anxiety, and depression due to their daily routine, which is particularly demanding since they are forced to cope with pain, sadness, and death. Stress also comes from the fatigue resulted from an increased workload, as well as the inability of nurses to cope with the emotional needs of patients and their families. Nurses who work in psychiatric settings are more likely to experience work violence than other nurses who work in different healthcare settings. Violence is negatively impact the provided quality psychiatric care and increase the level of stress among nurses. Shu-Fen Niu et al. (2019) have highlighted alarming percentages about the experienced violence by nurses that cause higher level of work-related stress among nurses population. Researchers indicate that more than 50% of the psychiatric nurses involved in their study experienced physical violence and more than 80% experienced psychological violence by psychiatric patients. Resilience of nurses is another concept could explain the work-related stress among psychiatric nurses participated in this study. Most recent systematic review study was conducted on 38 articles that targeted nurses resilience and work-related factors. Researched pointed out that “Job demands (stress, burnout, posttraumatic stress disorder, and workplace bullying) were negatively associated with resilience, while job resources (coping skills, self-efficacy, social support, job satisfaction, job retention, and general wellbeing) were positively related to resilience.” A significant inverse relationship between emotional intelligence and work-related stress was identified among psychiatric nurses, in which that stress decreased when emotional intelligent increased. Several studies have highlighted the link between emotional intelligence and work-related stress among nurses. Nurses who have a high level of emotional Intelligence build relations within an organization and with the people they serve; whereas, those with low level of EI may tend to create problems for the organization through their individual behaviors. Therefore, developing emotional intelligence should be emphasized in order to overcome stress at workplace and accomplish goals and cope with stress. The study of represent that emotions play an important role in a profession that requires not only technical expertise, but mainly relies on the psychological and physical care of human beings. The positive effects of EI with respect to the quality of nursing work and the ability to mitigate the impact of a difficult working environment via the contribution of emotional self-management and the personal stress management capacity in environments that is full of stress. EI enables nurses to effectively manage and deal with stress at work. Furthermore, the ability of individuals to regulate emotion can have positive effect on group cohesiveness and that the emotional intelligence level of team leaders can improve team empowerment and minimize stress among workers. It has been found that longer careers, job retention, and participation in clinical ladder programs are related to higher emotional intelligence scores of clinical staff nurses. Moreover, there is relationship between emotional intelligence and nurse reports of self-compassion that affect positively on their performance, higher nurse emotional intelligence is associated with lower levels stress and less burnout. In addition, less confrontational anxiety was associated with the ability to regulate emotion.  

**Conclusion**

The recent study aims to measure the phenomenon of emotional intelligence among nurses working in psychiatric hospitals and the relationship with their stress at work. The findings show that more than half of nurses working in psychiatric hospitals had high emotional intelligence level. However, despite the positive results, working in psychiatric hospitals is still a source of stress for nurses. The statistical relationship appears in this study between emotional intelligence and workplace stress highlights the importance of enhancing EI among nurses, as it improves the capacity to exercise skills in a manner that benefits patients, families, peers, and themselves as practitioners. Furthermore, increased emotional intelligence can lead to more successful management, job satisfaction, organizational commitment, better patient health outcomes, and less workplace stress.

The Relationship Between Smoking and Urokinase gene 3’-UTR T/C Expression on Occurrence of Bladder Cancer

Zainab Nizar Jawad 1, Kamal Abdul Rasool 1, Weaam Awad 2

1Department of Biology, College of Education for Pure Sciences, University of Kerbala, Kerbala, Iraq,
2College of Medicine, University of Kerbala, Kerbala, Iraq

Abstract

Bladder cancer (CA Bladder) is the malignancy that affects the lining of the bladder (which is the most common types of urinary epithelial cancers that associated with the most invasive types of cancers and has the highest incidence of recurrence and infections). This study was designed to investigate the role of cigarette smoking on expression of urokinase gene that has a prominent role in the incidence of CA bladder. The samples were collected from 90 patients after being clinically diagnosed by the specialist surgeon of Imam Hussein Center for Cancer Diseases, Holy Kerbala, Iraq who were heavily smokers (more than one pocket/day). These patients were compared to 90 non-smoker patients with CA bladder and 90 persons who apparently healthy individuals as a control groups, DNA was extracted from all blood samples. The level of gene expression was correlated with cycle threshold value calculated by using real time PCR.

The results showed significant association between smoking and occurrence of CA bladder (by increased expression of urokinase 3’-UTR T/C gene) in comparison to both control and non-smoker patients groups.

Keywords: CA bladder DNA, cigarette smoking, Urokinase gene 3’-UTR T/C, real time PCR.

Introduction

The genetic investigations for polymorphisms help to distinguish between the different inherited forms of the gene and their impact on the occurrence of many human diseases include cancer 6. The extent of the risk factors like smoking and genetic predisposition of many affect the occurrence of many diseases such as cancer, heart disease and diabetes 1. The urokinase-type plasminogen activator uPA system is a responsible for transforming plasminogen into plasmin, which has different physiological functions 10. It additionally assumes a key signaling protein in disease intrusion and metastasis both locally and spread away for far destinations 4.

The urokinase gene is located at chromosome 10q24 9. Polymorphisms of a C/T transversion at the 3’ UTR (+4065 nucleotide) were demonstrated by C/T substitution in exon 6 and a T/C substitution in intron 7 8. Among the risk factors that participate in the occurrence of CA bladder, smoking was detected as one of major one 3. High levels of urokinase have been depicted in bladder tumors especially in those who were heavily smokers 5.

Methodology

Blood samples were collected from males of age group ranging from 50-60 years old by the Imam Hussein Center for Cancer and Hematology at the Imam Hussain Teaching Hospital in Holy Karbala province, Iraq. The samples were include a 90 heavily smoker patients after the clinically determination of bladder malignancy (transitional cell carcinoma) by authorized specialist, 90 patients with CA bladder with no history of smoking for at least the past 25 years, and 90 apparently healthy non-smoker individuals as a control group. Both patients and control groups were matched regarding age, body weight, past medical history and any associated confounding factors. This study was extended for period from January to August 2018. DNA was extracted from all blood samples by DNA extraction
kit (Bioneer,Korea). Polymerase chain reaction (PCR) was adopted for amplification of gene, The premiers were Designed by STS Accession No. G27040: forward primer 5'-CCGCAGTCA- CCAAGGAAGAG-3'and backward primer 5'GCCTGAGGGGTAAGCT-ATTGTCGTGCAC-3'.

The RT-PCR protocol involve the following steps: (a) initial one cycle of denaturation for 5 minutes at 95°C, (b) followed by annealing at 58°C for 40 seconds, (c) then extension at 72°C for 40 seconds, (d) with final step of holding the specimen at 8°C. Real time PCR was used for quantitative assessment of urokinase gene 3'-UTR T/C expression by measuring cycle threshold (cT) value (which is inversely proportional to the level of gene expression).

Statistical Analysis

Data were statistically represented as mean±SD and analyzed by detection of variance of significance using ANOVA test by sigma plot software version 12.5.

Results and Discussion

Smoking was thoroughly studied as a predisposing factor for many human disease include cardiovascular disorders, respiratory diseases malignancies, neurological deficits and many other organic dysfunction. In current study, the aim was to demonstrate the

Table (1): the cT value of urokinase gene 3'-UTR T/C (expressed as Mean±SD) estimated by real time PCR.

<table>
<thead>
<tr>
<th>Group Name</th>
<th>No.</th>
<th>Mean±SD</th>
</tr>
</thead>
<tbody>
<tr>
<td>CA smokers</td>
<td>90</td>
<td>12.58±2.692</td>
</tr>
<tr>
<td>CA non smokers</td>
<td>90</td>
<td>23.21±3.569</td>
</tr>
<tr>
<td>healthy non smokers</td>
<td>90</td>
<td>24.86±2.861</td>
</tr>
</tbody>
</table>

The difference in cT values were quite significant between smoker patients as compared to both non-smoker patients and non-smoker healthy persons (12.58±2.692 versus 23.21±3.569 at P<0.001 and 12.58±2.692 versus 24.86±2.861 at P<0.001 respectively). On the other hand, no significant difference was detected between non-smoker patients in comparison to non-smoker healthy individuals (23.21±3.569 versus 24.86±2.861). These findings suggested that smoking has potential inducing effect for expression of urokinase gene 3'-UTR T/C which has crucial role in occurrence of CA bladder in heavily smokers. Other finding was noticed that the occurrence of CA bladder in non-smoker patients may be attributed to other sort of predisposing factor or gene.

This association was mentioned in certain study, which suggested that chronic exposure to cigarette smoking had strong association with development of urothelial carcinoma.

In another study done to evaluate the effect of smoking on soluble 3'-UTR isoforms(regulatory pathway of bronchial epithelial cell function), similar results were founded supporting the potential role of smoking as predisposing factor for CA bladder in our study.

This effect of smoking was explained in certain study as a result of the effect of smoking on p53 pathway that mediate apoptotic signaling that responsible for eradication of cancer cells.

Effect of Carcinogenic Substance (7,12 Dimethylbenz [a] anthracene (DMBA)) on Tissue, Hematology Character and Enzyme Activity in Rat

Abdulridha Mohammed Al-Asady1, Ntisar Kadhum Ghaleb2, Abeer Muhammedali Jasim Alnasrawi3, Thoalffakar A. Alhamed4
1College of Nursing, University of Warith Al-anbiya’a, Iraq, 2Department of biology, college of science, university of kerbala, Iraq, 3Department of Clinical Laboratories, College of Applied, Medical Science, University of Kerbala, Iraq, 4College of Nursing, University of Warith Al-anbiya’a, Iraq, Assist. Lecturer

Abstract
This study aimed to investigate the effects of 7,12 dimethylbenz [a] anthracene (DMBA) on some blood parameters and hepatic histopathology in rats and antioxidant enzyme. Twenty female Wistar albino rats, weighing 180–200 g, were randomly divided into two group. DMBA group (positive group) who received 20 mg DMBA/kg body weight/ (single Douse). Control group (negative group) don’t received any thing. The animals in the groups were sacrificed at the end of the 90 days: The histological structure of the liver tissues in the control group was normal. the liver exhibited hydropic degeneration and coagulation necrosis in hepatocytes, severe dilation in the sinusoids, congestion in the central and portal regions, DMBA groups, was degenerative and necrotic changes were detected. MDA levels increased in the DMBA group, compared to the control group, Antioxidant activity CAT, SOD and GPX, the results showed increased enzyme activity in positive control compared with negative groups, the hematological parameter was increase in WBC, PLT, GRA, and LYM and decrease in RBC value. Keywords: 7,12-dimethylbenz[a]anthracene (DMBA); Blood parameters; Antioxidant enzyme ; MDA ; Rat.

Introduction
Cancer, also termed as malignant neoplasm, is a type of diseases where in a group of cells show abnormal proliferation, invasion and sometimes metastasis. Cancer begins when cells in a part of the body start to grow out of control. There are more than 100 types of cancer have been identified. The substances that promote cancers are called carcinogens, and agents that have the ability to change DNA in ways that are inherited by daughter cells are called mutagens. Most cancers are related to environmental, lifestyle, or behavioral exposures. The term “environmental”, as used by cancer researchers, refers to everything outside the body that interacts with humans. Other chemicals, like benzene, ketones, vinyl chloride, ethylene bromide, and dichloro-diphenyl-trichloroethane (DDT), are known carcinogens. The accumulation of multiple factors, carcinogens and altered genes, transform a normal cell into a cancerous one. Carcinogens that have the ability to promote cancer have various sources. The factors responsible for cancer development are classified as exogenous and endogenous. The first group includes nutritional habits (food preservation and preparation), socio-economic status, lifestyle, physical agents (ionising and non-ionising radiation), chemical compounds (natural and synthetic) and biological agents (Helicobacter pylori, Epstein Barr virus, human T lymphotropic viruses I and II, human papilloma virus and the hepatitis B virus).

Material and Method
Experiential animals and Tumor induction in rats:
Twenty female of Wistar albino rats and aged between (7-8) weeks were weighing between 150 – 250 g used in this study. All they were kept in ventilated cages, with temperature of 25±2C. A 12:12 h light:dark cycle is also regulated for these animals. Balanced rodent food pellet and water is provided. The rats were randomly assigned to 2 groups of 10 rats each.

The groups were as follow:
Group 1: Received a single dose of DMBA (positive control) 20 mg DMBA/kg body weight/ (single dose)

Group 2: Did not received any treatment (negative control).

DMBA administration: Mammary tumors were induced by 7, 12-

Dimethylbenz (a) anthracene (DMBA) 10 . A single dose of DMBA dissolved in corn oil was given by oral gavage to two groups using the syringe and needles. DMBA was purchased from Sigma Aldrich and dissolved in corn oil. The concentration of the solution was 20 mg DMBA per 1 ml corn oil for each rat 10 .

Preparation of tissue sample

The liver was exteriorized and excised. All specimens were immediately fixed in 10% formaldehyde solution. After fixation they were processed in usual manner, and embedded in paraffin for subsequent histopathological examination for liver. A scoring system (of no abnormalities, mild, moderate, severe) was used to classify the liver changes according to the severity of the damage and extent of histological changes. The histological sections were evaluated by a pathologist without prior knowledge of the treatment given to the animals 11 .

Blood parameters were determined in whole blood by the using rat mode of veterinary practice with a blood cell counter (Abocus Junior Vet-5, Austria). Measurements of biochemical parameters were made with a Modular PP autoanalyzer (Mindray BS800, China).

Results

Histopathological findings: The control group showed normal histological structure in the liver tissue (Figure 1A). In the DMBA group, the livers exhibited dilatation of the sinusoids, cholangiohepatitis in the portal region, and congestion in the sinusoidal and portal regions (Figure 1B). Hematological parameters also change in negative group compared of positive group Table 1 , in positive group : white blood cell (WBC) , LYM, MON,GRA and PLT while other parameter such as RBC was decrease. The state of free radicals and antioxidants is given in Table 2. As seen in Table 2, the levels of MDA increased in liver groups compared to the control group, also SOD, GSH-Px, CAT, and GSH values decreased.

Discussion

7,12-dimethylbenz(α)anthracene (DMBA) is a well known carcinogen and immunosuppressor used in rodent models to study cancer. DMBA is reported to induce mutations by making DNA adducts. Although, it is a well known skin carcinogen, yet many researchers have reported the deleterious effect of DMBA in liver. Liver is the primary site of metabolism and is often prone to damage by xenobiotics. Evidently, liver cancer is the second most common cause of cancer deaths worldwide. Several haematological and haematochemical parameters were changed when treated with DMBA and found that DMBA induced hepatocellular carcinoma. Experimental studies showed that DMBA-induced skin, oral, mammary and ovarian tumors. The carcinogenic and mutagenic effect of DMBA requires its metabolic activation by mixed function oxidases. The hydroxylation of DMBA at 7-methyl group is a crucial step towards its carcinogenesis. Further metabolism of DMBA leads to formation of a wide range of metabolites with varying toxicity. Among these, trans-3,4-dihydrodiol-1,2-epoxide is the carcinogenic product of DMBA. The metabolic products of DMBA, when present inside body, hampers ROS-antioxidant balance by overproduction of free radicals and the body in turn reacts by modulating activities of antioxidant enzymes to curb the damaging effects of an increased ROS. Hematological and biochemical parameters may be affected by a variety of factors such as race, age, gender, pregnancy, lactation, muscular activity, region, season, environmental heat, maintenance, and nutrition. In the present study, the effects on blood parameters and hepatic, histopathology of fluoride. Oxidative products derived from mutagen metabolism, such as DMBA, might impair vital cellular function by damaging proteins and lipid membranes. Consequently, these changes induced by the chemical carcinogen 7,12-dimethylbenz[a]anthracene, have been reported to be leukemia, and the development of anemia. Reactive oxygen species (ROS) are important as pathological agents for many diseases. Increased oxygen radical production and lipid peroxidation are associated with the pathogenesis of many diseases and the toxic effects of a wide range of compounds increase in total leukocyte count (WBC), eosinophil, neutrophil and monocyte values for rats exposed to DMBA was also reported. Hematological and biochemical parameters may be affected by a variety of factors such as race, age, gender, pregnancy, lactation, muscular activity, region, season, environmental heat, maintenance, and nutrition. A significant increase in the GPX, CAT, SOD level in rat treated with DMBA only was reported. On other hand find MDA content increase significantly with rat treated with DMBA only.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Nursing, University of Warith Al-aniyia’a, Iraq and all experiments were carried out in accordance with approved guidelines.

Psychological Factors Affecting on Developing Reading Skills and Evaluation of Reading Strategy Knowledge

Wathiq Al – Husseini 1, Asst. Prof. Dr. Diaa Oued Al Arnousi 1, Qassim Raheem 1

1University of Babylon / college of Basic Education, Iraq

Abstract

The questions are one of the most common and used methods in the educational process and in schools all over the world and are the most important educational strategies. Because questions are a great place in teaching, which is the mainstay of the dialogue method and is like the driving force in the lesson. The educators say (If you want to become a highly competent educator, it is important that you begin to apply and develop educational questions). These questions also occupy great importance in the educational process after which the standard means of knowing the readiness of the students and the level of information they received, in a good question, we achieve the desired goal and achieve a desirable educational product. Besides, the exams are a means to help educators to make different educational decisions, so that, there have been wide concerns calling for the reform of the test questions and the evidence of that conferences that discussed this problem, studies and research aimed at diagnosing them in order to address, improve and develop their defects to achieve best results in education.

Key words: evaluation, Arabic Language Questions, six Grade Students, Standard Specification Table.

Introduction

Education is the basis for the reform of humanity and its success. It is a force that can develop individuals, sharpen their talents, sharpen their minds and ideas. The education of the individual means comprehensive education that is integrated in all aspects, spiritual, mental, physical, psychological, social and aesthetic. 1

The method of education is the language that benefits the individual in understanding cultural aspects is the means of understanding and the means of education and the collection of cultures, a tool for the transfer of ideas, but is a tool of thinking and sense and feeling. 2 In summary: Language is one of the tools of public life, and it does not perform its duty unless fulfills its purpose for, and does not reach its real status with its people unless they are concerned about what they are and about. 2 Through this way, the Arabic language is one of the most important elements of our Arab nation. It is the language of the Holy Quran, which says: “We have sent down Arab villages.” (2) As the Quran absorbed the characteristics of the language and it’s all stylistic features and its characteristic expression until tomorrow, the basis for which they control the validity of the language and the reverberation in the knowledge of its secrets and facts. 3

Thus, Arabic is one of the most important elements of our Arab nation and by which the nation held fast and boycotted the sermons. As well as it is the language addressed by God Almighty Prophet Muhammad (peace be upon him and peace) as it is the language that came down the Koran by saying: (We sent down Arab villages that you may know) ( Yousif / 2). The Holy Quran absorbed the characteristics of the language and it’s all stylistic features and its characteristic expression Until become the basis for the validity of the language and the state return to know the secrets and facts. 6

The Arabic language is a branch of a large group called the Semitic languages, and the first to be known as the German orientalist Schlutzer in 1781. 3 The evaluation of exam questions is a component of the curriculum, because it is the process of ensuring the achievement of goals, the relationship between the evaluation process and the educational goals, the evaluation process aims at knowing the extent to which these goals are achieved, or the extent of their progress towards the educational goals to be achieved. The importance of the evaluation is clear because of its great impact in the process of change and development in the educational process, because on the basis of a sound objective evaluation can be achieved a lot of educational principles, in addition to showing and treating weaknesses and showing positive aspects and
1. Evaluation: “It is the last stage that depends on measurement and decision-making, and then the feedback that makes teaching and teaching circular rather than linear”.

2. Questions: The field in which the student acquires knowledge and mental skills and intellectual capacities and works on their development and development.

3. Exam: A systematic objective method for measuring a sample of a person’s skills or abilities or a group of individuals in a particular time and place.

4. Bloom classification: A classification that contains a range of public areas, which include the possible educational data, and the expected educational process.

The theories and models of evaluation are very numerous and difficult to define each model that has many positives that make it suitable under conditions. And certain educational programs, and no matter how many calendar models, for the good qualities that should be characterized by any model of the calendar and any measure or any test are:

1. The Objectivity: - Objectively means that the procedures of evaluation and its components or measurements are accurate without falsehood away from self-impact and personal impressions of the transient to be true and consistent.

2. It is appropriate that the evaluation be appropriate in its tools, procedures and results for the subject of evaluation.

3. The Inclusion: - that the evaluation process is comprehensive so that the study programs or the subject to be evaluated in all its aspects and not by a certain aspect of it.

4. The Stability: that the evaluation process results in the same results if the results are re-analyzed or the application of measurement and evaluation tools is repeated.

5. The Honesty, ie, the evaluation means what is intended to evaluate it cannot study something and measure something else.

6. The Easiness: - That the evaluation and its tools process can be easily applied within the available material and human resources available and under the local conditions designed for them. The researcher will discuss the classification of Bloom and the criteria adopted in the analysis of the questions of Arabic grammar for sixth grade students. The scientific and literary branches in detail in the third chapter.

**The Results of the study are as follows:**

1. The questions of reading subjects in the primary stage are markedly concerned with the level of understanding and remembering. The percentage of questions of comprehension (47.3%) and the level of remembering (40.8%). The levels of application, analysis, installation and evaluation were very small.

2. - The questions of reading topics are concerned with the skills of direct understanding of the text, and the skills of understanding the conclusion of a greater interest in higher thinking skills such as the skill of criticism and taste, the proportions were respectively: (57.6%), the deductive understanding (34.5%), the critical comprehension (6.9%), and the final taste (1.7%). The test questions focused on the questions of understanding the direct meaning by 68% and the deductive questions by 32%.

3. Reading comprehension questions (50.3%), comprehension level (31.1%) and application (9.1%), followed by the remaining levels at low rates.

4. The predominant type of questions in subjects of reading is the most important questions (34.8%), while the balance of questions is (51.4%) compared with (48.6%) for the objective questions.

**The research methodology and procedures:**

It includes a presentation of the procedures that have been carried out to achieve the research objectives, starting with the research methodology and descriptive design, defining the research community and its design, preparing the research materials and tools, and presenting the statistical means used.

The Descriptive Design: The researcher followed descriptive research methodology to analyze the content of test questions because it is the appropriate method for analyzing questions, which is one of the research methods used in education and psychology. The aim of this approach is to provide data and facts about the problem of the subject to be interpreted and to identify...
its implications.

**The research community and design:**

The research society includes the general (ministerial) examination questions for the Arabic grammar for the third grade in the Republic of Iraq for the academic years of the academic year (2014/2015) to the academic year (2018/2019), and the first two and the third and the number of (11) exam paper, (5) papers for the first round and (5) exam papers for the second round an examination paper for the third round and as Annex 1, as the research community represents the questions of the ministerial examinations of the sixth scientific grade therefore, the whole research community will be a basic sample that will be adopted by the researcher in his procedures.

The research Tool:

**A - Sources of building the tool:**

The structure of the criteria for the evaluation of the ministerial examinations of Arabic grammar through:

- Building an open survey questionnaire addressed to teachers and specialists in the methods of teaching Arabic language and measurement and evaluation.

- See a collection of previous studies and literature relevant to the current research topic that examines the standards of good questions. By means of exploratory resolution and the sources of tool construction, the orthodontic criteria that analyzed the test were built. The study consisted of six criteria and these criteria were analyzed by the questions of the ministerial examinations of the grammar of the Arabic language for the sixth grade in the scientific branches on the grounds that these criteria are the most important criteria that should be available in the examination questions are:

  - Independence.
  - Direct and indirect questions.
  - Objectivity.
  - Inclusion.
  - Bloom’s levels of knowledge.
  - Technical aspects.
B - Tool credibility:

These criteria were presented to a sample of experts and arbitrators with expertise and experience for the purpose of identifying the validity and importance of each paragraph of the questionnaire, in order to achieve the apparent honesty. A standard was established to measure each paragraph (valid, not valid, observations). In this respect, Ebel points out that the test is true if its verbs measure what has been measured.

The researcher relied on the arbitrators to indicate the validity of the paragraphs of the questionnaire in their precise reference to the paragraphs, which is an indicator of the apparent authenticity of the questionnaire, and after collecting the questionnaires from the arbitrators, the researcher determined the proportion of agreement (90%) and more than the opinions of experts on the validity of the paragraph, because it represents the view of the majority, Agreement as follows:

- Independence 100%
- Objectivity 100%
- Bloom levels of the field of knowledge 100%
- Inclusive 100%
- Direct and indirect questions 95%
- Technical aspects 97%

In addition, some experts and arbitrators suggested that another criterion be increased, namely the proportion of correspondence to the textbook questions. The criteria were as follows:

- Independence
- Objectivity
- Bloom’s levels of knowledge
- Inclusion
- Correspondence to textbook questions
- Direct and indirect questions
- Technical aspects.

Steps to analyze the test questions:
A - Reading the contents of my book Arabic grammar rules for the sixth grade scientific reading good to know all content and topics.

B - Reading the questions a good reading and answer them as appropriate.

C) The question which contains several branches, each of which is treated as an independent question.

D - matching the questions to the criteria adopted by the researcher.

E) Unloading the results of the analysis into the criteria for analyzing the questions.

Evaluation criteria for ministerial examination questions:

There are scientific educational foundations that must be available in any exam to trust its results and benefit from it. The good exam is the one that is fit to perform the purpose for which it was set up in the fullest manner. Such a test will not be complete unless there is information on its validity for measurement.

Bloom’s Levels of Knowledge:

Many of the studies in Bloom’s classification (1956) indicate that this classification is one of the most important works that can help to analyze questions in general and in a procedural manner to contain all levels that reflect the desired objectives of the education process.

The Bloom classification is one of the most important attempts to address behavioral goals and the most widely used. It has an advantage in the identification and identification of educational goals.

Bloom’s classification helps teachers gain a clear idea of the patterns of behavior emphasized by a particular set of educational schemes. As well as it represents an educational system and benefit for all teachers, administrators and those interested in education and researchers who are in the Department of specialization in the issues of curriculum and evaluation.

Therefore, the researcher chose this classification because it is one of the most common classifications because it contains a very wide range of behavioral patterns of goals that most educational programs and systems are expected to achieve. It also benefits educators in general, and teachers who seek to define their educational goals in special behavioral terms.

Those who are interested in measurement and evaluation, led by Bloom, set behavioral goals in three areas. A meeting of the University of Chicago in 1956 resulted in an agreement to classify goals into three areas:

(Cognitive / mental, emotional / emotional, and motor).
Statistical means:

The researcher used the following statistical means:
- percentage
- Equation (scott) to find the stability of analysis.

Conclusion

The ministerial examinations are of great importance, because it represents the boundary between the stage and the other, especially since each stage characteristics and advantages differ from the stage that precedes it, especially the transition from secondary level to university; The current research problem revolves around the validity of ministerial examination questions for the Arabic language for the sixth scientific grade and the extent to which the characteristics of good questions. In the light of the criteria standard and the analysis of questions according to this standard. The importance of the current research stems from the importance of the Arabic language and its importance to all the subjects, the importance of the ministerial examinations also stems from the fact that they are the most important evaluation tools currently used in our schools.

Comparison between Photoselective Vaporization of Prostate by Diode Laser and Monopolar Transurethral Resection of Prostate in Single Center Experience

1Zaid Ali Abdul Hussein, Ali Hamdan Fahad2, Falah Mahdi Al Khafaji3
1M.B.Ch.B/Al-Diwaniyah Teaching Hospital/ Department of Urology/ Al-Diwaniyah Province/ Iraq, 2M.B.Ch.B/ F.I.C.M.S.F.E.B.U./ College of Medicine/ University of Al-Qadisiyah/ Department of Surgery/ Al-Diwaniyah province/ Iraq, 3M.B.Ch.B / F.I.C.M.S urology, College of Medicine/ University of Al-Qadisiyah

Abstract

Background: Transurethral resection of prostate has been regarded as the gold standard surgical management of benign prostatic hyperplasia (BPH). With the evolution of new technologies, laser prostatectomy emerged as an alternative.

Aim of the study: To compare the rate of outcome of diode laser vaporization of prostate and Transurethral Resection of Prostate in Al Diwaniya governorate.

Patients and methods: From October 2017 to October 2018, forty patients with surgical indications of prostatectomy were enrolled in this study. Their ages ranged from 60-75 years with a mean age 68.6 years and prostate size ranged from 40-80 ml with a mean size 62.175 ml. Twenty patients underwent diode laser vaporization of prostate and another 20 patients underwent Transurethral Resection of Prostate. The choice based on surgeon preference and patient ability. Preoperative evaluation was done for all patients by history, physical examination and investigations. International Prostate Symptoms Score, maximum flow rate, digital rectal examination, prostate specific antigen, abdominal ultrasound, urinalysis, blood urea, s.creatinine, complete blood count were all done preoperatively. One pint of compatible fresh blood prepared.

Results: The rate of significant bleeding and transfusion in diode PVP and TURP was (zero vs. 35% respectively), in PVP and TURP the mean irrigation amount perioperatively was (10.10 vs. 33.15 pints respectively), mean operative time was (70.80 vs. 50.00 min respectively), mean hospital stay was (16.03 vs. 30.09 hours respectively), mean time to urethral catheter removal was (24 vs. 81.71 hours respectively), postoperative complication rate (mainly dysuria) was (75% vs. 65% respectively), mean postoperative IPSS was (14.40 vs. 14.20 respectively), mean postoperative Qmax was (15.45 vs. 16.30 ml/sec respectively). There was no statistical difference between both groups in regard to lowering IPSS or increment in Qmax. The mean cost was (1500 vs. 500.42 dollars) in diode PVP and TURP respectively.

Conclusion: Diode laser vaporization of prostate is a good alternative to TURP with comparable results in treatment of BPH especially in patients taking anticoagulant drugs who cannot stop their medication. However, the high cost of this procedure and dysuria as a complication may prevent the common use of this technique.

Key word: Photoselective vaporization of prostate, Transurethral resection of prostate, Benign prostatic hyperplasia.

Introduction

Benign Prostatic Hyperplasia (BPH) is a histologic diagnosis that refers to the proliferation of smooth muscle and epithelial cells within the prostatic transition zone.
BPH is commonly characterized by lower urinary tract symptoms (LUTS). The prevalence of histologically diagnosed BPH increases from 8 percent in men aged 31 to 40, to 40 to 50 percent in men aged 51 to 60, to over 80 percent in men older than age 80. The prevalence of moderate or severe LUTS for men in the fifth, sixth, seventh, and eighth decades of life to be 26, 33, 41, and 46 percent, respectively. Patients often present with LUTS as storage irritative symptoms (frequency, urgency and nocturia) due to bladder response to obstruction (increased pressure) and voiding obstructive symptoms (straining, weak stream, intermittency and feeling of incomplete bladder emptying). BPH is a progressive condition that can lead to serious long-term complications such as acute urinary retention (AUR), renal insufficiency, development of gross hematuria, bladder calculi, urinary incontinence, and recurrent urinary tract infections (UTIs). Medical history can establish the severity of LUTS by IPSS. PSA should only be performed if life expectancy is greater than 10 years and if a diagnosis of prostate cancer would modify the management approach. Medical treatment includes Alpha 1 antagonist, 5-alpha reductase inhibitors, Anti-muscarinic agents and Phosphodiesterase-5 inhibitors, when medical treatment fails to control patients' complaints, surgical intervention is mandatory; however, surgery is associated with a number of complications. Surgical approach includes TURP. Laser prostatectomy is either coagulation or vaporization (or both), resection or enucleation depending on the wavelength applied. The usage of TURP is gradually decreasing (nearly 5%/year). Types of laser procedures includes HoLEP which can be used in large glands (100-150) and has comparable efficacy and good outcome compared to open prostatectomy and TURP but longer operating time. In this study, we want to compare the rate of intraoperative bleeding and the need for blood transfusion, the amount of irrigant, operative time, hospital stay, time of urethral catheterization, postoperative complications and the cost of diode laser vaporization of prostate and TURP in Al Diwaniya governorate.

Patients and Methods

From October 2017 to October 2018, forty patients with surgical indications of prostatectomy were enrolled in this study. Their ages ranged from 60-75 years with a mean age 68.6 years and prostate size ranged from 40-80 ml with a mean size 62.175 ml. Twenty patients underwent diode laser vaporization of prostate and another 20 patients underwent Transurethral Resection of Prostate. The choice based on surgeon preference and patient ability. Preoperative evaluation was done for all patients by history, physical examination and investigations. International Prostate Symptoms Score, maximum flow rate, digital rectal examination, prostate specific antigen, abdominal ultrasound, urinalysis, blood urea, s.creatinine, complete blood count were all done preoperatively. One pint of compatible fresh blood prepared.

Results

Our patients data were comparable between the two groups with a mean age of 68.6±4.14 years (range 60-75 years) and mean prostate size of 62.175 ± 10.885 ml (range 40-80 ml). Their mean PSA was 3.615 ng/ml (range 1.5-8 ng/ml). Regarding vesical stones, one patient (5%) of laser group was with 18 mm stone and 3 patients (15%) of TURP group with 18, 13 and 15 mm vesical stones which were removed before beginning of the procedure. Four patients (20%) were on anticoagulants who could not stop their medications (all of them on warfarin 5 mg, 2 patients with cardiac stents, 1 patient with prosthetic mitral valve and 1 patient with deep lower limb venous thrombosis). All of them were enrolled in laser group as shown in table 1.

The mean operative time in laser group was 70.8 min. (range 60-80 min.) , while in TURP group was 50 min. (range 40 – 60 min.) (figure 11). Regarding intraoperative complications, no patient developed significant intraoperative bleeding in laser group. In our study, we determined significant intraoperative bleeding as reduction in blood pressure that required transfusion, while seven patients (35 %) in TURP group developed significant intraoperative bleeding and required intraoperative blood transfusion. No patient in laser group developed obturator reflex in comparison with TURP group in which 3 patients (15 %) developed obturator reflex, as shown in table 3.

The mean follow up period was two months. All of the patients were assessed clinically by calculating IPSS and Q max. The mean pre-operative IPSS was 17.65 (range 13 – 27) and significantly decreased post operatively in both groups (mean IPSS 14.3 with range of 9-18), with the mean IPSS of laser group decreased from 20.1 to 14.4 and that of TURP decreased from 18.75 to 14.2.

Discussion

In this study, we compared the rate of intraoperative bleeding, the amount of irrigation fluid needed, operative time, hospital stay, time to urethral catheter removal, postoperative complications, follow up results and the cost. In our study, no patient in laser group developed significant bleeding, while in TURP 35% of patients had significant bleeding and needed transfusion. Kuntz RM reported that bleeding and need for transfusion is reduced significantly in diode laser PVP compared to TURP. 19 Erol A. et al reported 1 patient with diode PVP developed bleeding that needed catheterization and irrigation. 20 Seitz M. et al stated no patient had significant bleeding in diode PVP. 21 Our study is comparable to these results. Reich O. et al reported rate of 7.1% of blood transfusion in TURP in 10,654 patients, 22 while in our study it is 35 %. This high rate may be due to small sample study. The amount of irrigation needed for laser group is much less (mean 10.10 pints) than TURP group (33.15 pints) and this is because less encountered bleeding in laser group. Mithani MH. et al had mean of 16.44 pints for laser group. 23 In our study, the operative time of laser group is longer than that of TURP by about 20 minutes. Razzaghi MR also reported higher operative time of laser because the time it takes for the light energy absorption by water and Hb. 24 In our study, the mean hospital stay for laser and TURP groups was 16.03 and 30.09 hours respectively. This less stay for laser can be attributed to less bleeding and uncomplicated procedure.

Conclusion

Diode laser vaporization of prostate is a good alternative to TURP with comparable results in treatment of BPH especially in patients taking anticoagulants who cannot stop their medication and this advantage make it better than TURP. However, the high cost of this procedure and dysuria as a complication may reduce the common use of this technique.

Tympanometric Findings among Adults with Chronic Nasal Obstruction Due to Sinonasal Pathology

Salim Hussain Ibrahim
Department of surgery-Otorhinolaryngology Head and neck surgery; Tikrit Medical College –Iraq

Abstract

**Background:** The nasal obstruction is one of the causes that affect the middle ear function, but the physiological mechanism of this effect is not well understood. This study aims at 1st; evaluation of the middle ear function among adults with chronic nasal obstruction due to sinonasal pathology using tympanometry, and 2nd, at comparison between the anatomical and mucosal inflammatory causes of nasal obstruction and its impact on the middle ear function.

**Patients and Method:** A prospective case study of (310) adult patients with chronic nasal obstruction were subjected to tympanometry for study of middle ear pressure in the private ENT clinic for a period of two years in the Salah Al-Deen governorate.

**Results:** this study found that (13%) of adults with chronic nasal obstruction had abnormal tympanogram (type B or C), (17.2%) was due to mucosal inflammation and (7%) due to anatomical and structural cause. Commonly one ear affected (unilateral) was (67.5%). Myringotomy and aspiration of middle ear found that (64%) had OME and VT was inserted.

**Conclusion:** The study statistically proved that adults with chronic nasal obstruction due to mucosal inflammation differs from others due to anatomical and structural causes in the followings; 1. The incidence of abnormal tympanogram (type B and C) is more. 2. The type B (OME) was more than type C (Eustachian tube dysfunction). 3. In the treatment, it was found that the need to VT insertion was more.

**Keywords:** Tympanometry, Chronic nasal obstruction, Otitis media with effusion, Nasal polyposis, Chronic rhinosinusitis.

Introduction

One of the major ENT complaints is chronic nasal obstruction. A definite relation between nasal obstruction and middle ear diseases, where Eustachian tube dysfunction (ETD) caused by nasal obstruction, that may cause middle ear hypoventilation resulting in otitis media with effusion (OME), that may be definitely diagnosed through use of otoscopic findings associated with a B tympanogram (1,2,3). Some previous researches have been carried out on how the nasal obstruction that influence middle ear function, but the physiologic impact of this effect is not well defined (4,5,6). The evaluation of the middle ear function with a high rate of success in the management and follow up of middle ear diseases can be carried out by Tympanometry, because of its compliance, flexibility of the ear drum to changing air pressure 7. This study aims at 1st; evaluation of the middle ear function among adults with chronic nasal obstruction due to sinonasal pathology using tympanometry, and 2nd, at comparison between the anatomical and mucosal inflammatory causes of nasal obstruction and its impact on the middle ear function.

Patients and Method

A prospective case study of 310 adult patients with chronic nasal obstruction (>3 months) were subjected to tympanometry (620 ears) for study of middle ear pressure in a private ENT clinic during a period from 1st January 2017– 1st January 2019, in the salah El-den governorate. Iraq. Male were 184 (59%) and female were 126 (41 %), age ranging from 18–63 years (mean age...
The diagnosis of nasal pathology was based on detailed history taken, proper ENT examination includes nasal endoscopy and investigation includes computed tomography of the nose and paranasal sinuses. Ear examination includes otoscopic examination, Tuning fork tests. Tympanometry, PTA when abnormal tympanometry. Exclusion criteria includes nasoapharyngeal mass or tumor, recent history of acute rhinitis or middle ear infection, chronic suppurative otitis media, previous nasal or ear surgery, tympanosclerosis, no case with nasal malignancy. Patients were classified according to the causes of nasal obstruction into:

1. Patients with nasal obstruction due to anatomical and structural causes includes Septal deviation, hypertrophied turbinates, concha bullosa, nasal valve collapse, synchia, choanal atresia.

2. Patients with nasal obstruction due to Mucosal inflammation, such as allergic rhinitis with or without nasal polyposis (NP), non-allergic rhinitis, and chronic rhinosinusitis (CRS).

Tympanometry was carried out using viola middle ear analyzers from inventis audiology equipment / Italy to conduct automatic tympanometry tests at low frequency (226 Hz).

The tympanometer probe was inserted into the clean ear canal. The types of tympanogram are classified according to Jerger/Fiellau-Nikolajsen in to the following:

1. Type A is a normal peaked curve with pressure between +50 and -99 daPa, Compliance from 0.3-1.5 ml. Suggests normal middle ear functioning

2. Type B is a flat curve without peak, Compliance less than 0.3 ml suggests middle ear effusion

3. Type C is a peak curve with negative pressure (-100 or more negative), compliance from (0.3-1.5 ml). Suggest Eustachian tube dysfunction.

Results

From total 310 patients with chronic nasal obstruction 40 patients (13%) had abnormal tympanogram (type B or C). (Table 1). An abnormal tympanogram was found in patients with chronic nasal obstruction due to the mucosal inflammation was 31/180 patients (17.2%), and in patients due to anatomical causes was 9/130 patients (7%), Which is statistically significant association p-Value 0.018. (Table 1). Patients complaining of nasal obstruction due to mucosal inflammation the type B/C tympanogram were as follows, in allergic and non-allergic rhinitis was 7/57 patients (10.5%), nasal polyposis (NP) was 17/94 patients (18%), and in chronic rhinosinusitis (CRS) was 7/29 patients (24%), anatomical and structural causes 9/130 (7%) as shown in (Table 2). Patients who had an abnormal tympanogram in one ear (unilateral) were 27/40 patients (67.5%) and in both ears (Bilateral) were 13/40 patients (32.5%) (Table 2). Regarding the type of tympanogram, the normal type A was in 567/620 ear (91.5%), type B was 25/620 ear (4%), and type C was 28/620 (4.5%), this statistically very strong association p-value =0.005 (Table 3).

Patients who underwent surgical treatment were 31/40 patients (77.5%) (9 patients refused to carry out the operation or were missing). Total number of ears who have abnormal tympanogram was 39 ear (8 patients were in both ears and 23 patients in one ear). Those patients have undergone myringotomy and aspiration of middle ear and found that 25/39 ear (64%) fluid was aspirated (OME) so that a VT was inserted. Shah VT was inserted in 23/39 patients (59%) and Good T-tube in 2/39 patients (5%) who had adhesive otitis media, this results was statistically significant association P-value =0.05 (Table 5). The study found that the Shah VT was inserted in 23/33 ear (70%) of patients with chronic nasal obstruction due to mucosal inflammation, and in 2/6 ear (33%) of patients with anatomical causes. (Table 4) The research found that 24/40 (60%) of Patients who had abnormal tympanogram were complaining from hearing loss or fullness of ears and tinnitus and (40%) of patients deny the presence of such ear symptoms.

$X^2=2.9$, P.value=0.05, d.f.=1
The incidence and severity of middle ear diseases has been found to be related to the cause of nasal obstruction, whether anatomical and structural causes or mucosal pathologies. There are several suggested theories about the effect of nasal obstruction on the Eustachian tube, one theory suggest that nasal obstruction leads to turbulence of air flow in the nasopharynx. The turbulent air flow may leads to Eustachian tube dysfunction (ETD) by the following supposed mechanisms. 1. Dryness of mucosal film leads to increased viscosity of the mucous and the surface tension at the tubal orifice interfering the opening of the Eustachian tube. 2. The air pollutant and microorganisms deposited in the ET orifice causing tubal or pre tubal inflammation and obstruction. 3. Stimulation of the mechanoreceptors, leading to reflex alteration of (ET) function. Many studies have been conducted to assess the correction of nasal obstruction due anatomical causes and the study of its impact on the middle ear dysfunction. Nanda. et al, & Osama G. et al have found that septoplasty improve hearing and middle ear function by improving ET function, but Şahin, et al found that no effect of septoplasty on middle ear pressure and ET function. The whole mucosa of the upper respiratory tract, including the nasal cavity, sinuses, nasopharynx, eustachian tube, and middle ear, which belong to a system called the rhino-pharyngo-tubal unit or the “unified airspace”. Therefore, the presence of inflammatory disease that affects both the nasal and middle ear mucosa is considered the more likely physiologic mechanism that leads to middle ear diseases.

The mucosal inflammation in Allergic rhinitis, NP and CRS contribute to congestion, including increased venous engorgement, nasal secretions from nasal glands and tissue swelling (edema), the accumulated secretion and edema block the eustachian tube. This can reduced middle ear ventilation leading to negative middle ear pressure. There is a significant association between OME and persistent symptoms of allergic rhinitis, these results suggest a direct involvement of the middle ear mucosa. Parietti-Winkler et al. they reported an association between OME and nasal polyposis. They concluded that the mechanism causes of OME in NP and CRS is more likely the presence of inflammatory disease that affects the nasal and middle ear mucosa, and less likely the obstruction of the ET by polyps or by congestion of the nasopharyngeal mucosa. There is a study concluded that the OME seem to be an inflammatory disease that extends to the middle ear rather than a consequence of the nasal disease itself. Because even when the symptoms of nasal obstruction are well controlled, the OME can develop or persist.

The current study found that patients with CRS and NP are at greater risk of developing abnormal tympanogram (24%) and (18%) respectively (Table 2), as found by other authors Rennie et al., study on Eustachian tube dysfunction found that 69% were due to CRS with NP, 28% CRS without NP, and 14% due to allergic rhinitis. In CRS the muco purulent or purulent Secretions pass over the pharyngeal end of Eustachian tube and it can lead to inflammation of ET and hypertrophy of tubal tonsil results in ET obstruction. Patel et al (2016) found that symptoms of ET dysfunction are frequent in CRS, and respond well to endoscopic sinus surgery. The current study found that the VT was indicated in 70% of patients with sinonasal mucosal inflammation because of glue like aspirate of the middle ear (OME). While in the anatomical causes VT was indicated in (33%). This results goes with Mary, et al who found that by, where they found that patients with severe CRS with NP are at greater risk of developing OME, and often highly viscous middle ear effusion.

Limitation in this study that combined pathology may be found commonly septal deviation and/or hypertrophied turbinates with allergic rhinitis, nasal polyposis or chronic rhinosinusitis. In this study they were classified with mucosal inflammation causes. This study statistically proved that adults with chronic nasal obstruction due to mucosal inflammation differs from patients with nasal obstruction due to anatomical and structural causes in the followings; 1. The incidence of abnormal tympanogram (type B and C) is more. 2. The type B (OME) was more than type C (Eustachian tube dysfunction). In the treatment, it was found that the need to VT insertion was more. This study has the following recommendations recommendation: It is preferable to do tympanometry for patients with chronic nasal obstruction, especially when it is due to NP and CRS, even if they not complain of hearing loss, tinnitus or fullness in the ear.

The Impact of Mindfulness Education on Elementary School Students

Rawaa Saadoun Al-Abedi¹, Ibtisam Al-Zaywaini¹, Rassem Ahmed Al-Jerayi¹
¹University of Babylon / college of Basic Education, Iraq

Abstract

The current research aims at evaluating the reading for the fourth grade of primary school in the light of the habits of mind and followed the researcher descriptive approach to suitability the current research procedures to achieve the research objective, the researcher prepared a list that included the criteria of habits of mind based on this researcher prepared a questionnaire (6) standards and (141) paragraphs after verifying the authenticity of the tool from its presentation to a group of arbitrators the stability of the analysis using Holistic equation (0.83) The tool consists of (128) paragraphs distributed in six areas The researcher has developed three alternatives (valid), (invalid), (need to be modified), and the researcher used the appropriate statistical means for their research. The data obtained from the analysis process are: Holistic equation, centimeter weight, square cay, and weighted mean.

Keywords: Evaluation, Arabic Reading Book, Habits of Mind

Introduction

The students are the real wealth of the nation and society must be prepared for life, including the development of writing and reading skills, the maximum extension of the hand of reform is the book must be a systematic evaluation of the curriculum to learn the extent to which the goals set for them ¹ Reading is very important in the elementary stage as a natural entry point for learning and primary school fails miserably if it fails to teach its students to read because the student’s success and progress in all subjects depend on his literacy ability is not material with content that can be taught separately from other subjects But is a fundamental part of every other material. It has become clear that there is a need for something new if schools are to start from a traditional mindset that is focused on capacity only so that students can have a kind of mind-set to create a productive self-fulfilling life and therefore the need for effective and effective mental habits such as the need to develop educational goals that reflect The belief that ability is a repertoire of skills that the individual stores and continues to be constantly expanding as one can increase the skill of thinking through man’s efforts. Education in its general form is a familiar process for all reflect an activity produced by human societies across many times and places. It is not only a reflection of social, economic and political life, but it is an important tool in the development and formation of this life, including from different social systems the prosperity of nations and the attainment of their goals are linked to their concerns. These nations raise and nurture a strong generation to take responsibility for the leadership of the nations and hand them over from fathers to sons, therefore, attention to education means providing the right direction and congratulating the environment for the emergence of righteous individuals. Language has a great role in the twenty-first century because it is a new world in which information prevails in all spheres of life as the individual is able to get the information he needs as quickly as possible in the least effort and language is the basic goal through which he knows what he wants ¹. One of these languages is the Arabic language that every speaker has the right to be proud of and is magnified by our Arabic language, which is characterized by the beauty of its methods and the strength of its expression and its vast wealth of words and meanings. reading is the means of the numbers of the individual scientifically and morally is a means of personal harmony and social assistance to the individual to autonomy and adaptation with others and reading helps to quickly understand and gain desired attitudes and behaviors. The textbook offers opportunities for the teacher to use many of the teaching methods, especially those that need to have a textbook in the hands of the student when the teacher assigned a student or several students to read a paragraph of
the book to develop information or a comparison with external information is the basic premise in front of students to the world of research, knowledge, thinking and knowledge.

**Methodology**

The researcher followed descriptive research methodology to analyze the book of Arabic reading for the fourth grade of primary school because it means describing the facts to identify the data related to a particular educational phenomenon and follow closely and analyze and interpret and investigate the relationships and connotations and then access to the explanatory and complementary instructions can be used. The researcher relied on the analytical descriptive approach because it is a method that is compatible with the nature of the research and its requirements. The descriptive approach is a method for studying scientific phenomena or problems through scientific description and then reaching logical explanations with signs and bar Yen and that research is descriptive of a wider use of research in educational and psychological field it is usually looking at the present and diagnose existing phenomena and the relationships with the discovery by classifying them and their works on the interpretation of those phenomena.

**Identify the research community and its sample:**

The research community is identified and identified by the researcher to define their research community as well as to define their own identity so that the current research community is determined the fourth grade reading book in the Republic of Iraq, the tenth edition 1437/2018. Karim Obaid Al Waeli and Dr. Abdul Abas Abdul-Jassim and Turki Abdul Ghafoor Al-Rawi ,the book consisted of (147) page excelled by the researcher’s title book title , the exclusion of these parts of the content is familiar to previous studies and does not affect the analysis procedures directed towards the content related to the objectives of the book and its subjects, which is the subject of physical and moral construction of the student and has the ability to achieve educational experiences, information and facts Concepts, values and trends. Here is a description of this book:

**A table showing the content of the reading book, the number of pages, their sequence and percentages**

**The Research Tool:**

As regards to lack of a ready and appropriate tool to gather information commensurate with the purposes and objectives of the research, the researcher adopted the questionnaire as a tool for research and to prepare this tool, the researcher followed the following steps:

- **List habits of reason:**

In order to reach the list of habits of mind and use that list in the analysis of the book of reading for the fourth grade of primary The researcher adopted the following steps:

1 - Review previous studies on the habits of reason
2 - Access to literature and books that dealt with the habits of mind
3 - The preparation of the preliminary list of the habits of reason based on the researcher’s knowledge of past efforts
4 - Directing an open survey questionnaire for supervisors and teachers of the Arabic language in
primary schools, including the following questions:

- What habits should be read in the fourth grade reading books? Please specify in terms of relevance to the primary stage

- Do you think that the book of Arabic reading meets the habits of mind appropriate for the primary stage?

5. Distribution of the preliminary list of the habits of the mind to a group of specialists in the Arabic language to analyze them and determine whether the principles and their sub-indicators belong to the domains received and have been compiled and studied and used to reach the final list.

The tool’s credibility:

Honesty is one of the important characteristics of educational tests and standards psychological and different and is one of the old concepts so it is subjected to a lot of modification and change as a result of the spread and the expansion of the movement of tests and standards in the various humanities and the truth of several types of the researcher has used what fits the nature of her research which is the apparent truthfulness of the initial examination of the content of the instrument and is reached by the consensus of the arbitrators’ assessment of the measure of the instrument to which it was prepared and to achieve the credibility of the tool based on the credibility of arbitrators and specialists in Arabic language and literature and curricula and methods of teaching as well as those who teach Arabic reading for the fourth grade of primary school.The researcher presented the tool in its initial form in order to ascertain the apparent honesty. The arbitrators expressed their observations about the tool and took the researcher. The researcher has adopted (80%) of the opinion of the arbitrators on the validity of the paragraphs, this is indicated by Bloom, as 80% and more of the arbitrators are evidence of an investigation virtual honesty.

The Analysis:

A – The analysis unit: The researcher used the unit of thought in its analysis of the book of Arabic reading, if it is one of the most important units of analysis and the largest and may be the unity of the idea or phrase contains the idea that revolves around the subject of analysis.

B- The analysis steps:

1- Reading each topic of the Arabic reading book for the fourth grade of the primary to identify the ideas contained in the subject in general

2 - Second reading of each line in the subject for the purpose of reaching the phrase or sentence that contains a particular idea

3 - The identification of the phrase containing a specific idea added by the researcher to the principles prepared in advance and work to determine the suitability of this idea with each paragraph of this principle in a special analysis form

4 - Give a repeat of each paragraph correspond to the idea extracted

5 - Calculate the frequencies obtained by each paragraph in one principle and then calculate the frequencies of each principle individually.

The stability analysis:

While the method of content analysis is a scientific tool, there is a need to satisfy the conditions of objectivity, and achieving objectivity requires knowledge of the stability of the analysis. In terms of consistency, the results obtained from applying the analysis tool to the same sample are not changed and one of the most prominent methods of verification of the stability of the most common analysis of the presentation of a sample of the analyzed article on a group of experts and specialists and the people of know-how and experience in the analysis of content.

So the researcher used two experts who have knowledge in the analysis of the content given each of them a random sample and 10% of the analyzed material from the topics of the book of reading and the researcher calculated the correlation between them and the two experts was the correlation coefficient between them and the first analyst (92,0) And between them and the other analyst (85,0%)

The statistical means:

The researcher used the program (spss) statistical means to analyze the results as follows:

1 - The weighted average to measure the extent to which each concept of the questionnaire

2-Square Kai to calculate the honesty of building concepts
3 - Holistic coefficient to calculate the stability of concepts

4-Percent weight to be used in interpreting the results.

Results

The researcher reached the following results: Taking into account the book of Arabic reading of some habits of the mind, which means taking into account individual differences between students. The habits of the mind give a wide range in the educational process to help the teacher to understand the minds of students and enhance their role in providing opportunities for students to learn and think in different ways. The planning and preparation of lessons through the habits of the mind left a great impact on the students, which led to an understanding of the students to read and assimilate well.

Conclusion

The researcher has developed three alternatives (valid), (invalid), (need to be modified), and the researcher used the appropriate statistical means for their research. The data obtained from the analysis process are: Holistic equation, centimeter weight, square cay, and weighted mean.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the University of Babylon / college of Basic Education, Iraq and all experiments were carried out in accordance with approved guidelines.

Prevalence of Bronchiolitis among Hospitalized Children less than Two Years in Babylon Province

Maha. A. Kadim¹, Nuhad M. AL-Doori²

¹M.Sc. Student in Child and Adolescent Health Nursing, College of Nursing, University of Babylon, Hilla City, Iraq. ²Assistant Professor, Ph.D. in child and adolescent health nursing, Babylon University, College of Nursing, Hilla City, Iraq

Abstract

Background: Bronchiolitis is one of viral lower respiratory tract infections that constitute a heavy burden to public health in the Pediatric population worldwide, which occurs most frequently before age 2 years in the winter and early spring months and most frequently induced by a viral infection (respiratory syncytial virus).

Settings and Design: A survey descriptive study conducted in Babylon Province through-out the period of “1st January 2019 to 30 March 2019” (three) special hospitals of pediatrics.

Method and Materials: Non-probability “purposive” sample consists of 3374 subjects, which collected through a review of patient records for (2016, 2017, 2018) in the statistical units in Babylon hospitals. The information of data was collected retrospectively through-out the special questionnaire obtained from the patient’s sheets in the statistical unit.

Statistical analysis used: The data are coded and tested by the application (SPSS) through the descriptive and inferential analysis.

Results: The analysis of the study indicated that the majority of the children (62.7%) were aged (1- 6) months old who lived in rural areas, the male percentage was higher than the female. In addition, the study indicated that the prevalence of bronchiolitis progressed during the last three years.

Conclusions: The study concludes that the higher morbidity of bronchiolitis was in 2018, most of them admitted to the hospital in January months. Also, the duration of hospital stay was > 4 days.

Key-words: Epidemiology, Prevalence, Bronchiolitis, children.

Introduction

Respiratory disorder is considered the most frequent reason for hospitalization and illness in children. Bronchiolitis is the most relevant infection of the LRTI during infancy through the 1 year of life. “Respiratory syncytial virus” (RSV) is the main cause of this condition as it is considered a major leading cause of increasing the rate of morbidity and hospitalized patients number and cost. As long as, the epidemiology of RSV in developing countries has identified that the most common viral cause of LRI globally, bronchiolitis constitutes a heavy burden to public health in the Pediatric population worldwide, particularly in the United States, which causes significant morbidity and mortality in infants and young children. Bronchiolitis mortality rate is roughly 2 per 100 000 infants and is higher in developing than in developed countries, and statistical data showed that globally there are 150 million new cases of bronchiolitis annually. Also, it has been reported that hospitalization of children during seasonal Respiratory syncytial virus epidemics about 2-3 % of all infants less than 1 year. In the United States, there is significant season-to-season variation in RSV with the period of the peak prevalence varying by as much as 7 weeks (ranging from early January to late February) between seasons. In Egypt, during the period between “October 2016 and March
2017; found that most of the children 53.3% were diagnosed with bronchiolitis and 31.7% were diagnosed with pneumonia. The median duration of the hospital stay four days. Prophylaxis is considered the most effective and safe method that is used in the prevention of respiratory syncytial virus (RSV) disease in infants.

**Methodology**

The study aims to determining the prevalence of bronchiolitis among hospitalized children less than two years

Study design: A cross-sectional descriptive study that conducted through the period of 1 January 2019 to 30 March 2019.

Setting study: the study conducted in in Babylon province at “Pediatric Teaching hospitals”.

Sample of study: A total of 3374 is selected by a convenience non-probability sample through a review of statistical records which were selected out from the main hospitals in Babylon province.

Study instrument: The information of data was collected retrospectively through-out the special questionnaire obtained through a review of patient records for (2016, 2017, 2018) in the statistical units in Babylon hospitals.

Data Analysis: The data are coded and tested by the application “statistical package of social science (SPSS)(Version 24)”. A descriptive analysis includes frequencies and percentage; inferential data analysis included the correlation coefficient, ANOVA test.

**Results**

![Graph showing prevalence of bronchiolitis disease in Babylon province for the last three years (2016-2017-2018). (Total=3,374)](image)

Figure above clearly indicated that the prevalence of bronchiolitis progressed during the last three years and the peak percent 1,442 (42.7%) of the sample occurred in 2018.

Table (1) reveals that the majority of children were male in the past three years which signified as (60.8%) with (62.7 %) of babies aged less than 6 months; most of them admitted in January and recovered within a short period of hospitalization stay( less than 4 days). The highest percent 57.9 % were lived in the rural area.

The findings in the table above also reported that the prevalence of bronchiolitis was raised in the last three years, particularly in 2018.

**Discussion**

Prevalence of bronchiolitis disease for the last three years (2016-2017-2018)

The findings in the figure (1) reveals that the higher morbidity of bronchiolitis was in 2018. The researcher indicated in the present study that bronchiolitis was increased gradually in the last three years (2016,2017,2018) consequently. This study go along with a retrospective study carried out in Italian about “Comparing of two different epidemic seasons of
bronchiolitis”, which done to evaluate the differences of bronchiolitis frequency and characteristics of the bronchiolitis-related hospitalization between two seasons; S1(2015-16), S2(2016-17). The author indicated that the bronchiolitis morbidity rising from 17% in 2015-16 to 26% in 2016-17. Also, it showed an increased rate of hospitalization11. Another study conducted at Al-Zarqa Government Hospital, Jordan. It’s goal to analyze the epidemiology of RSV infection on 271 children less than 24 months with bronchiolitis, from January 1997 and May 1999. The results indicated gradual rising with peak incidence were in 1999(12). Rationally speaking, Iraqi children’s displacement and migration, particularly during the winter season, live in a crowded situation with bad earnings and health facilities that increased the incidence of communicable diseases with missing or dropping out in the immunization follow-up timetable.

**Distribution of Bronchiolitis prevalence data from statistical records**

In related to the prevalence of bronchiolitis as shown in the table (4.6), the study underhand proved that the majority sample was males aged less than six months who lived in a rural area, admitted in January, 76.5% stayed less than four days in the hospital which increased within two years progressed. a prospective study at Al-Bashir Hospital, Jordan, on children’s admission < 24 months. The author mentioned that the majority sample 60% were male,(53%)were < 6 months, with the annual peak during January and February. In reason, low immunity and high incidence of RSV in children less than 6 months during the winter season. Furthermore, the research showed that the duration of hospital stay was 4 days, the length of stay as indices for the severity of bronchiolitis and linked with absence of breastfeeding, reduced age, greater viral load and sepsis. Certain study indicated that the length of hospital stay was 3 days. The period varied in this study from 4 days in 2010 to 3 days in 2015, and the mean length of stay similar to that reported in Spanish studies13. In the term of discharge outcome in the present study, more than half 64.7% were well status. The outcome discharge and LOS are dependent on effective management. Evidence study conducted at Meherpur General Hospital, about the RSV outbreak to determine the etiology and explore possible risk factors. Which indicated that no death among analysing cases, (36%) Still sick after 5 days of illness and (39%) recovery within 5 days14.

**Conclusion**

The study concludes that predominant age is (1-6) months with a majority to male than female, the higher prevalence of bronchiolitis was in 2018, LOS was less than four days in majority of children, with improved status.

Nanotechnology Issues Included in the Subjects of the Department of Biology in the Colleges of Education

Mazin Thamer Shanef 1, Mustafa Abdel Amir Raheem Al-Zamili1
1University of Al-Qadissiyah, College of Education, Iraq

Abstract

This research aimed to: Recognize how much including in content of subjects in the Department of Biology College of Education in accordance with the Nanotechnology Issues. To achieve this aim, the researchers built a standard for the Nanotechnology Issues, were verified validity by presentation to a group of arbitrators specialists in the methods of teaching the Biology, and that standard is finalized be from (8) Nanotechnology Issues and emerged of them (90) sub- Issues, then the researchers analyzed the content of subjects of the Department of Biology in Colleges of Education for the academic year (2018-2019) in the light of this criterion as the number of analyst was (12201) page, and it adopted the explicit idea and implicit idea as units for registration and repetition unit of the census, The results were: weakness of subjects in the Department of Biology in Colleges of Education to contain Nanotechnology Issues compared with the ratio based on the opinions of experts (20%), (16) only of 90 terms were achieved, that was equal of (17.77%)

Keywords: Nanotechnology - Nanotechnology Issues - Understanding Students

Introduction

In the midst of rapid and successive developments in most fields of science and knowledge, university institutions and research centers are undertaking these developments as an important tributary to them and a rich resource for their productions in the invention 1, discovery or development, and therefore university education adopts those developments learning and education at the very least, and perhaps the most important science that split its path to global scientific interest is nanotechnology because of the science it has enormous applied fields in various sciences, including Biology, and the first to be the outcome of this science is abundant and based on university students, including students 2 of Biology departments in the colleges of to be educators in the future and need to develop their understanding and awareness of scientific knowledge achievements and provide the latest science and cognitive transformations 3. Technological Despite its many applications, importance, challenges and gravity, it did not receive the required attention from the thought and educational research in Iraq, as it notes the weakness of educational institutions in keeping with the amazing development in this field through its programs and plans 4. Through the information obtained by the researchers from the exploratory questionnaire distributed to a group of teaching specialists in the departments of Biology in the colleges of education and the number (9) include a question on the importance of nanotechnology and the most important issues related to the content of subjects in the departments Biology in the colleges of education, the researchers found that there is a certain desire and urgency of the teachers to address the topics and issues related to nanotechnology because of its global interest in scientific institutions and research centers, and its impact on the intention of the cognitive process for students and their lives, and the above is determined by the following research problem by asking:

Second: The Importance of Research:

Human societies are striving to pay attention to future science in order to face the challenges and developments of the times. Today, our world is witnessing rapid and successive changes as a result of major technological and scientific developments in all fields of life and at all levels. Humanity, and
education, and educational practices allow the learner to take advantage of technological innovations in the development of achievement and skills. Among the technological innovations are nanotechnology which takes care of the study and characterization of nanotechnology materials and their properties at a size less than (100 nm), and precise control of the interaction of molecules and rearrange the atoms and place them in order to produce new materials unprecedented, so that it is possible to design smaller robots from the head of a pin can enter and movement in the blood vessels and be able to perform accurate operations within them and treat blood clots tumors and incurable diseases. 6

Given the importance of nanotechnology in education, many conferences have been held, most notably one, Nanotechnology organized by the University of Jordan in Amman from 10-13 / 10/2008, in cooperation with the University of Illinois at Urbana-Shampeen, under the name of “developed nanomaterials” (14) In Iraq initiatives have emerged related to nanoscience and technology in light of the national education strategy and education that started work formulated and organized since (2009) and launched in (2013) for (10) years, and in this regard published the University of Technology research in the field of nano, and the University of Baghdad with (120) research {15} and given all the above interest in technology Nano and its issues in all fields have emerged many studies and research, including the study Ahmed and others (2015) that sought to investigate the impact of an educational program - learning according to the concepts of renewable energy and know its impact on technological enlightenment in the Department of Chemistry, and showed results the program assists students in acquiring knowledge and concepts related to nanoscience and technology and in technological development. 1

**Nano materials:**

Hijazi defines nanomaterials as “very small materials that are prepared in the laboratory or already present in nature and whose measurements of lengths or diameters of granules range from 0.1 to 100 nanometers.” 2

Forms of nanomaterials: nanomaterials are prepared in various forms including:

The Fullerene: nanoparticles composed of triple bonded carbon atoms, which give the shape of pellets that have a structure similar to graphite, but instead of containing pure hexagonal form, they contain pentagonal forms and potentially sevenfold carbon atoms. 9

Thin Films: a thin layer of a specific material, less than 100 nanometers thick, and their length and width may be in micrometers. These thin layers are used in the field of semiconductors such as silicon and gold bars.

**Nanofibres**

Perhaps the most famous nanofibers are those made of polymer atoms because the ratio of surface area to volume is large in the case of nanofibers, and this gains those fibers characteristic mechanical properties such as rigidity and tensile strength and others, which can be used in biomedicine, and in organ transplantation such as joints, and transport of medicines.

**Nanoballs:**

One of the most important carbon nanoparticles, which ends in the class of Foloreinat, of the material C60, but they differ slightly from the composition as they are multiple crust. 11

**Second: Field Applications in Pharmacy:**

Nanotechnology is one of the most important scientific fields that scientists rely on in the development of drug mutations that change the concepts of treatment and medication for many diseases, and perhaps the most important applications of nanotechnology in pharmacy:

1- Nano-biotics: compounds that have the ability to identify bacteria and viruses, and then eliminate them without exposure to any other cell

2 - delivery of the drug to tissues: It depends on the manufacture of nanomaterials that work to improve the bioavailability of the drug (Bioavailability) This means the presence of drug molecules in the target place of the body 7 Nanotechnology can offer drug delivery solutions in the following areas:

a- Drug Coating: Using pharmaceutical packaging materials such as liposomes and polymers (such as polylactide –PLA, and lactide combined with PLGA glycolide)

b- Drug carriers:Another type of drug delivery system, nanotechnology offers important, manageable solutions to link with the drug, the target and the imaging material, 18
Research Approach

The researchers adopted the descriptive analytical approach for the analysis of subjects in the Department of Biology in the Colleges of Education.

Search procedures

First: Research Community (Community of Subjects)

The community of subjects covered represents all subjects for the four stages of the Biology department in the Colleges of education.

Second: Research sample (sample content of subjects): The analysis process included the content of subjects in the Department of Biology in the College of Education, as the number of analyzed subjects (15) of the 35 articles, or 43% of the total community. The total analyzed pages are (12201) pages, (1689) pages of the first stage materials, (2291) pages of the second stage materials, (4367) pages of the third stage materials and (3854) pages of the fourth stage materials. The scientific, drawings, tables and charts after the indexes and glossary of terms for the analyzed materials were excluded.

Analysis of the content of the subjects of the Department of Biology

The researchers relied on the explicit idea and the implicit idea as the two recording units because the subjects in the Department of Biology are scientific materials and expressions are often clear and explicit, but their use of the idea implicit, because some topics can suggest ideas that reflect the issues or sub-issues of the standard nanotechnology.

Validity of the analysis

To ensure the validity of the analysis conducted by the researchers were hired two experts * in the methods of teaching Biology and presented to them three subjects (cytology, biology, algae) with the standard of nanotechnology issues that were built and ideas extracted from the content of analyzes to make sure The analysis was valid, and they unanimously agreed on the validity of the analysis, which was prepared by the researchers in truth to the analysis he conducted.

Stability of analysis

In order to be objective analysis and to obtain acceptable stability, the researchers used two types of stability:

1- Agreement over time

To calculate the stability coefficient in this way, the researchers re-analysis after thirty days as the value of the coefficient of stability calculated (0.98) using the Holste equation, a very high value and reflect a high degree of stability.

2- Agreement between analysts

The researchers used external analysts to analyze the content *. This was done by selecting a random sample of the total analyzed content of (12201) pages. The proportion of the stability sample represented about (20%) (2790 pages), which included books (cell biology, biology, algae) and using the equation (Holst) was extracted the stability coefficients calculated in this way and was equal to (0.82) For the researcher with the first analyst and (0.80) For the researcher with the second analyst (0.83) between the first and second analyst, and thus the coefficient of stability is good, and some studies have indicated that the acceptable stability ranges between (0.50 or 0, 60) and above 12 as in Table 1

Determine the spoken ratio to compare the results of the analysis
Depend that the percentage (20%) to be a hypothetical ratio to compare the results of the analysis based on the agreement of the arbitrators and experts on this ratio, the researchers presented a questionnaire to find out the ratio (2). The agreement was (80%) of the experts and arbitrators on this ratio.

The results will be presented according to the research objective and discussed as follows:

Identify the extent to which the content of subjects is included in the Department of Biology, College of Education for Nanotechnology Issues.

After the subjects were subjected to the four stages, the pages subjected to analysis included (12201) pages and the results were as shown in Table (2).

From the data recorded in Table (5) it is clear that the subjects in the third stage were the most interested in the contents and issues of nanotechnology, where it obtained 68.75% of the percentage out of (16) elements of the sub-issue extracted, followed by the first stage by 25% and the second by 6.25% and then the fourth by (0%) and the researchers attribute this to the algae materials and practical environment and educational laboratory. In the third stage, it received the most attention, followed by the first stage, which was the theoretical and practical biology and theoretical cell which focused on the issues of nanotechnology and microscopes. Then the second stage materials represented theoretical histology material while the fourth stage materials were weaker and poorest as it did not get any repetition despite the importance of the fourth stage materials in the formation of specialization for students of the Department of Biology in the colleges of education and this is a take on the materials of that stage, which was expected to the strongest of the four stages because the first stage represents the beginning of specialization and the second and third stages represent a transitional stage to the end of the specialization of the fourth stage.

As for the issues, the diversity of interest in the main and sub-issues and their components, as in Table (3).

</table>

Through Table (3) we note that the issues in general did not get sufficient attention in the subjects of the four stages, which indicates the weakness of keeping up with these materials to the developments of science and its applications, including nanotechnology, but when looking at the same table we note that the identification issues of nanotechnology have been obtained more interest of the subjects has obtained (11) repetitions out of (16) recorded for all subjects and the rate of (68.75%) and the researchers attribute this to the fact that most of the study material deals with these tariff issues as an introduction to nanotechnology as well as the standards and microscopes that adopt this technique.

Conclusions

Through the results of the research, the researchers reached the following conclusions: The subjects of the Department of Biology in the colleges of education were weak in their inclusion of nanotechnology issues. The subjects of the third stage in the Department of Biology got the highest frequency, followed by the first stage and then the second stage, while the fourth stage did not receive any repetition. The nanotechnology knowledge issues with the greatest interest in the content of the subjects were the four stages.

Financial Disclosure: There is no financial disclosure.

Color Stability of Different Aesthetic Resin Composite Materials: A Digital Image Analysis

Shatha Abdul-Kareem¹, Ahmed G. Al-Marooof ¹, Noor H. Fadhil²

¹ Lecturer, ² Assistant lecturer, Department of Conservative and Cosmetic Dentistry, College of Dentistry, University of Baghdad, Baghdad, Iraq.

Abstract

This study aimed to evaluate and compare the color stability of three commercially available resins composites after exposure to different staining solutions using digital image analysis. A total of ninety-disc shape specimens of a microhybrid composite (Amelogen plus), ultrafine hybrid composite (Essentia), and nanohybrid composite (Beautifil II) were produced in Teflon mould (n=30/resin composite type). Specimens of each resin composite were then divided into 5 subgroups (n=6/subgroup) and immersed in 200 ml of Pepsi, orange juice, tea, coffee and artificial saliva (control group), respectively. Digital images of the specimens were taken before (baseline) and after 28 days immersion against a black and white background. Adobe Photoshop CS6, Ver.13.0.1 graphic program (AdobeSystems Inc., San Jose, CA, USA) was used to analyze the digital images and calculate the change in color (ΔE). Data were submitted to statistical analysis using one-way ANOVA and Tukey Posthoc test at a significance level of p<0.05. This study concluded that all resin composites exhibited color changes after immersion in all staining solutions. However, Amelogene Plus showed better resistance to staining compared to Beautifil II and Essentia.

Keywords: aesthetic resin, composite materials, image analysis

Introduction

Composite restorative materials are the most popular esthetic materials used in dental practice. The color instability of composite materials may be the main reason for the replacement of restorations. Discoloration of composite resin caused by extrinsic or intrinsic factor. Intrinsic factors include physical-chemical discoloration reactions in the composite matrix, in surface and deeper layers of the material, triggered by heat, humidity, or UV irradiation. Chemical discoloration has been attributed to a change or oxidation in the amine accelerator, oxidation in the structure of the polymer matrix, and oxidation of the unreacted pendant methacrylate groups ¹. Extrinsic factors are related to the surface absorption of staining agents from exogenous sources or due to the accumulation of plaque ², or superficial degradation of the restorative materials and their adsorption of staining agents ³. The degree of color change can be influenced by various factors such as incomplete polymerization, chemical reactivity, water sorption, oral hygiene, diet, and surface smoothness of the restoration⁴. The composition of the composite resin and the characteristics of the particles have a direct effect on the surface smoothness and susceptibility to extrinsic staining ⁵. Consumption of certain drinks such as Tea and coffee may affect the physical properties and aesthetic of composite restoration. The effect of drinks on the properties of restorative resins may be directly related to the amount and frequency of its intake ⁶. The aim of this study was to evaluate and compare the color stability of three commercially available resins composite: Amelogen Plus (Microhybrid), Essentia (ultrafine hybrid), Beautiful II (Nanohybrid) after exposure to different staining solutions for 28 days using digital image analysis. The null hypothesis tested was that there is no difference in color changes (ΔE) between the tested composite materials after 4 weeks of immersion in different staining solutions.

Materials and Method

One microhybrid composite (Amelogen plus, Ultradent), one ultrafine hybrid composite (Essentia, Ultradent), one nanohybrid composite (Beautifil II, GC America).
GC), and one nanohybrid composite (Beautifil II, Shufo) were evaluated in this study. For each brand, the enamel shade was selected. A total of ninety-disc shape specimens of composite materials were produced in Teflon mould (10 mm diameter x 1 mm thick). After filling the mould with the composite, the discs were covered with glass slides, to exclude atmospheric oxygen, and then cured by visible light for 40 s, using a dental curing unit (Optilux, Demetron Res Crop, Danbury, USA) with an irradiance of 850 mW.cm⁻², which monitored with a radiometer (Kerr/Demetron, Danbury, USA). Light-curing was repeated on the opposite surface for another 40 s. After which, specimens were stored in an incubator at 37°C for 24 hours. Specimens of each resin composite brand were then divided into 5 subgroups (n=6/subgroup) according to the immersion solutions represented by Pepsi, orange juice, tea, and coffee or artificial saliva which constituted the control group. The digital images acquisition of all specimen groups was taken before immersion (baseline) by digital imaging technique using an SLR camera (Nikon D5200, Nikon Corporation, Japan) with a 105mm camera macro lens (Sigma 105 EX Macro, Sigma, Japan). The camera was fixed perpendicularly on stand clamp holder (10 cm distance from the specimen) and set on manual mode, which allowed total control of shutter speed 1/6, ISO 1250, f-stop 3.5. These measurements were remained unchanged during taking shots and three images were obtained for each sample against a white as well as a black background. For the digital imaging method, four fluorescent tubes were mounted on a costume made photostand with tubes perpendicular to the front plane that hold the discs, being 20 cm away from the specimen and illuminating at an angle of 45°. Two 6,500-K fluorescent tubes (Philips PL-C 18W/865, Koninklijke Philips Electronics N.V., Eindhoven, Netherlands) were placed in the lower sockets and were combined with two 2,700 K (Philips PL-C 18W/827) fluorescent tubes placed in the upper sockets. After baseline images acquisition were made, specimens were then immersed in 200 ml of each staining solution and kept in an incubator at 37°C for 28 days. Staining solutions were changed every week to avoid bacteria or yeast contamination. After the staining period, the specimens were gently rinsed with distilled water and air-dried. Imaging measurements were repeated for each sample to determine the color variation.

The digital images were transferred to a personal computer (PC), saved as TIFF images and were analyzed using the Adobe Photoshop CS6, Ver.13.0.1 graphic program (AdobeSystems Inc., San Jose, CA, USA). For standardized calculations, a measurement template was created in the middle third of the samples that consisted of a square area of 50 pixels. The CIE L*a*b* values of these particular areas were calculated using the eyedropper tool. The color data obtained directly in color picker palette tab for (L, a and b) parameters (Figure1). Color changes (ΔE) were calculated as follows:

\[
\Delta E = \sqrt{(L_1^* - L_2^*)^2 + (a_1^* - a_2^*)^2 + (b_1^* - b_2^*)^2}
\]

where L* is lightness (0 = black; 100 = white), a* is green-red component (−a* = green; +a* = red), b* is blue-yellow component (−b* = blue; +b* = yellow), subscript 1 is the baseline measurement before the immersion and subscript 2 is the measurement after 28 days immersion in staining solution.

Figure 1: Adobe photoshop program shows how to pick the color data from the sample (L=47, a=−8, b=10) red dotted area.
Data of color change acquired from black, white backgrounds were submitted to statistical analysis using one-way ANOVA and Tukey Posthoc test for multiple comparisons between groups at a significance level of p<0.05. Statistical analysis performed using the Statistical Package for the Social Sciences (Version 24; SPSS Inc., IBM, Chicago, Illinois, USA).

**Results**

Tables 1 and 2 show ΔE±(SD) of all tested composite resins after 28 days immersion in different staining solutions on a black and white background, respectively. The lowest ΔE value observed for Amelogen Plus composite resin in artificial saliva on a black background (1.42±(0.45)), on the other hand, the highest ΔE value observed for Essentia composite resin in coffee on white background (28.0±(1.12)). Regarding staining solutions, coffee caused the highest ΔE in all composite resins, followed by tea, orange, Pepsi and artificial saliva, as shown in tables 1 and 2.

In the black background data set (Table 1), there were significant differences in ΔE in each brand of resin composite between the different staining solutions (p<0.05), except between the artificial saliva and Pepsi, there was no significant difference in ΔE in all brands of resin composites (p>0.05). Also, there were significant differences (p<0.05) in ΔE between the three composite resins in each staining solution except between Amelogen Plus and Beautiful II in artificial saliva, Pepsi, orange and tea (p>0.05), there was no significant difference in ΔE. Similarly, there was no significant difference in ΔE between Essentia and Beautiful II composite resins in orange staining solution (p>0.05), as shown in table 1.

**Table 1:** Change in color ΔE ± (SD) measured on the black background of all tested composite after 28 days immersion in different staining solutions.

Discussion

As a composite restorative material are continuously exposed to saliva, food stains and beverage pigments, it is important to determine its susceptibility to color change. In the present study, we investigated the effects of beverages tea, coffee, Pepsi and orange juice on the color stability of different composite materials. The artificial saliva constituted the control group. The results of the present study showed that there is a difference in color changes ΔE between the tested resin composites after immersion in different staining agents.

For standardization of staining conditions, we perform an “in vitro” study to control all variables such as food or drinking habits, tooth brushing. All the tested composites were of enamel translucency A2 shade, enamel translucency was selected because it is used as the most external layer and being in contact with staining agents. The immersion time for each composite group was 28 days in accordance with previous studies. Ardu et al. in 2017 reported that the immersion time for 28 days simulated about 2 years of drink consumption. Ertas et al. considered 28 days is equivalent to about 2.5 years of clinical aging (24 h in vitro staining corresponds to 1 month in vivo).

Digital imaging system is a reliable method for determining the color of teeth and gingiva when used with the appropriate calibration protocols. In this study, the digital imaging system was selected to evaluate the color changes against white and black background which were used to allow a double evaluation to simulate two different clinical situations; black background can mimic the situation, where no tooth structure exists in the back. i.e., class IV composite filling. White background can mimic class I, II, III, V and veneers, where one of the walls is still present.

Results of this study revealed that all tested composite showed significant color changes after immersion in the tested solution. Amelogen Plus was more stain-resistant followed by Beautiful II, while Essentia seems to be the most prone to staining. It seems that Essentia extensively colored in these staining solutions. The slightly different ranking obtained with the two different backgrounds may be related to different opacity of the composites which might modify the color perception on different backgrounds. The general behavior trend of the tested composites is confirming that Essentia has less color stability than Amelogene Plus and Beautiful II.

Findings of this study may depend on the hydrophilicity of the resin matrixes of these three resin composites and their filler particles. The differences in the staining resistance between these resin composites may be attributed to the different filler size and load which may affect the overall resin content in the cured composite. Essentia contains prepolymerized filler of resin, which together with the resin matrix, may increase the resin content in the composite, hence the water sorption and staining susceptibility consequently. It has been reported that increased resin content in the composite may increase the water sorption significantly especially in the first week of immersion in the staining solution.

The structure of resin matrix and filler type may have a direct impact on the susceptibility to extrinsic staining. Changes in ΔE value were greater for the tested staining solutions than for the control group, so the staining effect of a staining solution varied according to its ingredients. These results are in agreement with many previous studies which shown various staining potential of these drinks and this may be related to their composition and properties.

Regarding the staining solution tested, coffee showed the most staining capacity, followed by tea, orange, Pepsi and artificial saliva (Control group). The highest values of ΔE reached was in coffee and this could be related to its acidity (pH 4.5), both adsorption and sub-surface absorption of coffee colorant. The degree of polarity of the staining agent determines their degree of penetration into the resin materials. Less degree of polarity, such as coffee, can easily penetrate into the polymer matrix. Both coffee and tea contain a large amount of staining agents like Gallic acid, which could be another reason for the staining capacity of these materials. This finding is in agreement with the study conducted by Ardu et al. Some studies reported that a solution with a lower pH can attack the composite surface, causing some changes and increasing pigment absorption. Although Pepsi had a low pH, which can damage the surface integrity of the materials, it did not
cause as much staining as coffee and tea. This may due to the absence of yellow colorant, which is abundant in coffee and tea\(^1\), these findings were in agreement with other studies which found that coffee and tea produced more discoloration than cola\(^{17,18}\).

**Conclusion**

This study concluded that staining solutions affected the color stability of the tested resin composites significantly in a clinically unacceptable level, except for Amelogene Plus and Beautiful II in artificial saliva and Pepsi, which were acceptable clinically. Also, Essentia resin composite performed inferior to Amelogene Plus and Beautiful II in terms of color stability.

Bergamot Essential Oil Effect against Candida Albicans Activity on Heat Cure Acrylic Denture Base

Zinah Salah Mawlood1, Ghassan Abdul-Hamid Naji2

1 M.Sc. Student, 2 Ass. Prof. (Department of Prosthodontics, College of Dentistry/ University of Baghdad, Iraq

Abstract

The aim of the current study is to evaluate the antifungal efficacy of several different percentages of Bergamot Essential Oil (BEO) incorporated into heat cure PMMA denture base material against Candida albicans.

Materials and Method: Eighty samples were divided into eight groups including six various percentages of BEO (2%, 3%, 4%, 5%, 6% and 7% by volume) and 0% BEO as a control group, in addition to 1.4% by weight of nystatin which represent the positive control group. All these additives were incorporated into heat cure PMMA denture material. After 48h incubation in distilled water, all samples were assessed by Candida albicans colonies viable count test.

Results: For Candida albicans activity test; the experimental groups (2%, 3%, 4%, 5%, 6% and 7% of BEO) showed highly significant decrease in the mean values of the viable count of Candida albicans when compared to the control group (0% BEO) (p<0.01). In contrast, a non-significant difference among experimental groups and 1.4% nystatin group.

Conclusion: Bergamot essential oil was successfully incorporated into heat cure PMMA denture base material and could act as potential antifungal agent with a drug delivery system against Candida albicans. It seemed that adding of 5% and 6% BEO was the most beneficial effects against the growth of fungi.

Key words: Heat cure PMMA, Denture base, Bergamot essential oil, Nystatin, Candida albicans

Introduction

Walter Wright discovered poly(methyl methacrylate) (PMMA) after publishing the results of his clinical evaluation of PMMA in 1937, since it is introduced has become most superior, popular and satisfactory of all polymeric denture base materials. Acrylic denture base is used in removable dentures fabrication, and its popularity and universal use has attributed to low cost, light weight, ease of processing, ease of reparability, low water sorption and solubility, biocompatibility, satisfactory aesthetic properties and accurate fit, in spite of that this material until now remain not ideal denture base material due to the presence of several drawbacks like susceptibility to microbial colonization and formation of biofilm on its surface and this make the denture a source of different infections because it harbor the microorganisms in addition to lack of manual dexterity among the old age patients which make the effective biofilm removal not possible. Denture stomatitis is a disease related to denture use, and considered chronic atrophic oral candidiasis, which affect up to 65% of denture wearer, its etiology is multifactorial, but Candida albicans considered the main pathological microorganism which is the mostly isolated type from the oral cavity in patient with denture stomatitis. The most common line that is used in treatment of denture stomatitis is prescribing of topical antifungal medicines, but maintaining optimal oral drug dose and lacking of motor dexterity of geriatric patient who had impaired cognition, limit their use and make it challenging to get a maximum benefit of these topical drugs. To overcome these obstacles it is
better to incorporate the antifungal drugs into denture base materials. Unfortunately fungal resistance and side effects of these drugs make it necessary to obtain naturally derived medicaments as a substitution to these synthetic drugs. Herbal medicines are a powerful alternative treatment for microbial infections in the oral cavity which have less or no side effects; and this made a worldwide trend to make a lot of researches about them in order to find biologically safe herbal-based medicines with effective antifungal properties. Plants oils are herbal medicines and various researches, recently, have been done to test their antifungal efficiency against Candida albicans and they reported that these oils are considered a promising line of therapy which have effective antifungal properties and can be used for treatment of denture stomatitis. One of the recent research was done through the incorporation of virgin coconut oil into heat cured acrylic-based denture soft lining and proved the antifungal efficiency of this oil against Candida albicans. Bergamot is the popular name for Citrus bergamia Risso et Poiteau, Citrus bergamia is defined as “a hybrid between a sour orange (C. aurantium L.) and lemon (C. limon L. Burm.F.) or a mutation of the latter. Other authors considered it a hybrid between a sour orange and lime”.

Materials and Method

Regular- conventional heat cure acrylic resin denture base material (Vertex, Netherlands) was utilized. Bergamot essential oil (bergaptene-free) from (Aura Cacia pure essential oils, USA) was added to the liquid part of acrylic resin in six different percentages (2%, 3%, 4%, 5%, 6% and 7%), these percentages were selected to discover which one is as effective as 1.4% nystatin group (positive control group). This proportion of nystatin was calculated by the conversion of International Units (U) to milligrams. Every 6079U corresponded to 1 mg of nystatin. Therefore, for this group (500,000U) the amount of nystatin used was 90 mg for every 6.6 g of acrylic powder. In general, 500 000 units was the most common concentration used by many authors and result in decreased yeast count compared to control group. Also this percentage of nystatin start to change the color of acrylic resin into orange so it is objectionable to use it above this percentage especially in aesthetic area.

Study design

Total of eighty samples were prepared, 10 samples for control group, 10 samples for each percentage of BEO groups (2%, 3%, 4%, 5%, 6% and 7% BEO) and 10 samples for positive control group. All samples were tested by viable count of Candida albicans colonies test at the same time and circumstances and they stored in distilled water for 48h prior to test procedure to reach the state of standardization.

Candida albicans colonies viable count test

Samples preparation

Plastic models were prepared with dimensions of 10×10×2.3 mm in length, width and thickness, respectively using laser cutting machine. Then, the models were invested in freshly mixed type IV extra hard dental die stone to create stone molds where the acrylic resin samples will be packed. For control group the acrylic resin denture base materials were proportionate and mixed as directed by the manufacturer instructions. Regarding BEO incorporated samples, the required amount of oil were measured by micropipette and subtracted from the volume of monomer, then mixed manually in dry clean glass beaker with monomer. Following which, the mixture was added to acrylic powder and mixed thoroughly.

Isolation and identification of Candida albicans

Candida albicans were obtained from oral cavity of patient with an indication of a denture induced stomatitis by using cotton swab which then cultured on the surface of a sabouraud dextrose agar SDA (Oxoid, United kingdom) plates and incubated at 37°C for 48 h. The identification of candida albicans was done according to the following order: Firstly, the colony morphology (macroscopic examination) in which the Candida albicans appear as creamy, pasty, smooth and convex colonies on SDA. Secondly, microscopic examination using Grams stain procedure , candida seen as small gram-positive oval or budding yeast cells. Thirdly, Germ tube formation. Fourthly, Biochemical identification using analytical profile index API Candida system (bioMérieux, France) and API 20 C AUX system.

Assessment of Candida albicans viable count

Candida albicans suspension of about 10^7CFU/mL which equal to 0.5 McFarland standards was prepared by diluting a small quantity of inoculums in a test tube containing normal saline and measuring this solution with McFarland densitometer device as shown in Figure 1(A). Then, 100μL of Candida suspension was added
to each tube contain 9.9 mL of sabouraud dextrose broth (Oxoid, England) to obtain 10 mL broth mixture this done by using micropipette. The samples after that immersed in tubes (Figure 1 (B)) and incubated at 37 °C for 24 h. After incubation, about 100µL was taken from all tubes of broth mixture and added to other tube contain 9.9 mL normal saline so tenfold dilution obtained. A second dilution made from this dilution by the same procedure as in Figure 1(C). About 100 µL taken from the second dilution and spreaded on SDA plates by using disposable inoculation loops (Figure 1 (D)). The SDA plates incubated aerobically at 37 ºC for 24 h. This dilution was chosen because it demonstrated a countable range of 30-300 CFU.

Following incubation, the Candida albicans colonies were visible on SDA plates, all these colonies counted and this viable count analyzed statistically so the material antifungal efficacy (AFE) was calculated using following formula (Equation 1):

$$AFE [%] = \frac{V_c - V_t}{V_c} \times 100 \%$$

In this formula the number of viable colonies of control samples was represented by $V_c$ and number of viable colonies of experimental samples was represented by $V_t$

**Statistical analysis**

The data of this research were collected and analyzed using SPSS (statistical package for social science – version 21) computer software. Descriptive statistics were made which include Means, Standard deviation, Minimum, Maximum. Inferential statistics include ANOVA (one-way ANALYSIS OF VARIANCE) test which was used to evaluate the significance of difference among the mean values of all groups, then multiple comparison using Dunnett t-tests which treat one group as a control, and compare all other groups against it was used.
Results

The viable count of Candida albicans colonies test was performed on six experimental groups (2%, 3%, 4%, 5%, 6% and 7% BEO) and two control groups (negative control 0% BEO group and positive control 1.4% nystatin group for comparison). After 48 h of samples incubation in distilled water, the results of viable counts of Candida albicans showed a reduction in the mean values for experimental groups in comparison to negative control group. So 5% and 6% groups showed the lowest mean value among all groups, while other experimental groups (2%, 3%, 4% and 7%) revealed higher mean values than positive control group. Antifungal efficiency (AFE) for the experimental groups are as follows: 55.53% for 2% BEO group, 67.21% for 3% BEO group, 68.64% for 4% BEO group, 76.43% for 5% BEO group, 74.18% for 6% BEO group, 66.80% for 7% BEO group and 69.87% for 1.4% nystatin group.

Descriptive statistics (mean, standard deviation, maximum and minimum) and statistical test of viable count of C. albicans results using One-Way ANOVA for comparison of means of all studied groups listed in Table (1) the difference between groups was highly significant. For multiple comparison purpose the Dunnett t (2-sided) a test was used. In this test the 1.4% nystatin group taken as control group and all other groups compared against it. The 0% BEO group showed a highly significant difference while all other experimental groups showed a non-significant difference in comparison to 1.4% nystatin group as listed in Table (2).

Figure 2: Viable counts of Candida albicans after 48 hours incubation of: a) Control samples; b) some experimental samples with BEO; c) positive control sample (1.4% nystatin). Medicinal Plants extracts are very good replacement to antimicrobial drugs with less or without side effects, as a result this encouraged the worldwide tendency towards herbal-based medicines and a lot of researches were done to obtain herbal medicine that is biologically safe and have excellent antifungal properties. Essential oils are examples of naturally derived herbal medicaments which are concentrated, hydrophobic liquids extracted from plant and have wide spectrum of pharmacological activities, these essential oils considered as a promising therapeutic line for oral infections and in the last few decades a lot of kinds of oils have been tested for efficacy against Candida albicans, each one of them has special active component that affect the fungi in particular mechanism. Bergamot essential oil has been used for its antiseptic, anti-inflammatory, diaphoretic, appetizing, and analgesic effect.

Conclusion

Within the limitations of the present study; the following conclusions can be obtained that Bergamot essential oil was incorporated successfully into heat cure acrylic resin denture base material and worked as a powerful antifungal herbal medicament against Candida albicans that is comparable with the effect of nystatin. Moreover, the samples with 5% and 6% BEO revealed a better antifungal efficiency compared to all other control and experimental groups.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Dentistry/University of Baghdad, Iraq and all experiments were carried out in accordance with approved guidelines.

Abstract

New Heterocyclic compounds derivatives comprising 1,3-oxazole, chalcone,thiazole, pyrimidine, quinolone moieties are reported. New derivatives of Quinazolin-4 (3H)-one ring comprising Schiff’s bases,(1,3,4-Thiadiazole),(1,3,4-Oxadiazole) and (1,2,4-Triazole), Thiaurease moieties are reported. Compounds (1), (2) and (5) were synthesized by reaction of benzoyl chloride with urea , thiourea and anthranilic acid respectively , then compounds (1)and (2) were converted into(3a-c) and (4a-c) derivatives. While compound (5) reaction with urea to convert to compound (6) which was converted to (7a-c) . chalcone derivatives (9a,b ) were readily obtained by reaction of compound (8) with different aldehydes, Compounds (9a, b) were converted into (10a,b) and (11a,b) The structure of these compounds has been established on the basis of their spectral data FTIR and 1H NMR. These compounds were tested for invitro antibacterial activity against Escherichia coli, Sepidermidis, S.aureusand Klebesillastandard methods. These synthesized compounds have been shown moderate to good antibacterial activity.

Keywords: 1,3 oxazole, chalcone, thiazole, pyrimidine, quinolone, antimicrobial activity.

Introduction

Heterocyclic compounds had been receiving considerable attention due to their pharmacological and pesticidal importance1 . The heterocyclic nitrogen compounds like quinazolinone derivatives has a vital role in synthetic drugs and biological processes. A Quinazolin-4-one derivative possessing broad spectrum of biological and pharmacological activities such as antifungal 2, antimicrobial 3, bronchodilator 4,antihistaminic 5, anti-inflammatory 6,1,3-Oxazole and thiazole derivatives possess a broad spectrum ofpharmacological activities such as antibacterial 7-9, antiviral, anti-inflammatory10,11, antitumor 12. The biological significance of the pyrimidine derivatives has led to the synthesis of substituted pyrimidine and their derivatives13, pyrimidine derivatives have been important role in medical applications. One possible reason for their activity is the presence of a pyrimidine base in cytosine, thymine and uracil which are essential building of nucleic acids, RNA and DNA. Pyrimidine derivatives possess several interesting biological activities such as antimicrobial 14-15, antitumor 16, antifungal 17, antimalarial, 18, anticancer 19, antiallergic 20, antitubercular activities 21 and anti-inflammatory activities 22. Many Pyrimidinederivatives are used for thyroid drugs and leukemia 13.

Materials and Method

Apparatus

Melting point were determined in open capillary tubes and were uncorrected and the purity of the compounds were checked by TLC. The IR Spectra were recorded on a Perkin-Elmer 1600 series FTIR spectrometer, using KBr discs. 1H NMR Spectra of prepared derivatives were recorded in DMSO with TMS as internal standard on aVarian-Mercury 300 MHz Spectrometer the reaction were followed.

A mixture of benzoyl chloride (1.1 mole), and urea (1.1 mole) in dry benzene (30 ml) were mixed in round bottom flask and refluxed for 15 hrs, resulting mixture was poured in to crush ice and the solid filtered and recrystallized from appropriate solvent table 1.

Synthesis of N-(aminocarbonothioyl)-benzamide (2)

A mixture of thiourea (1 mole) and (1 mole) benzoyl chloride were dissolved in benzene (30 ml) then refluxed for (16 hrs.), the mixture was cold and filtered to obtained the solid, and purified by recrystallization table 1.

Synthesis of N-substituted acetamide (General method)

In adry and clean conical flask (0.01 mole) of substituted aromatic amine was dissolved in 15 ml dry benzene with continuous shaking and (0.015 mole) of chloro acetyl chloride was added drop wise by dropping funnel, the mixture was heated in water bath for (1 hr) after the reaction complete, the product which separated were filtered and washed with sodium bicarbonate (5%) , water, dried and recrystallized from alcohol.

Procedure for Synthesis of derivatives (3a-c)

A mixture of compound (1) (0.01 mole) and (0.01 mole) of 2-chloro-N- (substituted phenyl)acetamide in ethanol were refluxed for 24 hrs and allowed to stand undisturbed over night, the product separated on cooling was filtered and purified by recrystallization.

General Procedure for Synthesis of derivatives (4a-c)

A mixture of compound (2) (0.01 mole) and (0.01 mole) of 2-chloro-N- (substituted phenyl)acetamide in ethanol were refluxed for 24 hrs and allowed to stand undisturbed over night, the product separated on cooling was filtered and recrystallized from appropriate solvent table 1.

Synthesis of (2-phenyl)-1,3-benzoxazin-4(H)ones (5)

A mixture of benzoyl chloride (1.4 gm, 0.01 mole) and anthranilic acid (1.38 gm, 0.01 mole) in triethyl amine (30 ml) were stirred at 0-5°C for 1 hr, then further stirred for additional 1 hr at room temperature. A pasty mass obtained which was washed thoroughly with sodium carbonate (10%) to remove unreacted acid, the solid separated by cooling and was dried and purified by recrystallization.

Synthesis of (2-phenyl)-3-carboxamidequinazoline-4-(3H)ones (6)

Compound (5) (2.23, 0.02 mole) and urea (0.6 gm, 0.02 mole), in pyridine 20 ml, the reaction mixture was refluxed for (12 hrs) in oil bath at (180-200°C). Then the reaction mixture was poured in to ice cold water containing conc. HCl. The separated solid was filtered, washed and recrystallized from appropriate solvent table 1.

General Procedure for synthesis of derivatives (7a-c)

2-chloro-N-(substituted phenyl)acetamide (0.01 mole) and (2-phenyl)-3-carboxamidequinazoline-4-(3H)ones [6] (0.01 mole) of in ethanol were refluxed for 24 hrs and kept the product over night, the solid separated on cooling was filtered and purified by recrystallization.

Synthesis of N-(4-acetylphenyl) benzamide (8)

To a mixture of 4-amino acetophenone (0.01 mole, 1.39g) in 25 ml of benzene and benzoyl chloride (0.01 mole, 1.4g) was refluxed for 3 hrs according to literature procedure [12]. After that, mixture was kept overnight. The product thus obtained was recrystallized from appropriate solvent table 1.

Synthesis of N-(4-(3-(4-substituted aryl) acryloyl)phenyl)benzamide (9a9b)

A mixture of substituted benzaldehyde (0.01 mole) and compound (8) (0.01 mole) and (20%) 10 ml NaOH in ethanol (30 mL) was stirred for 24 hrs at room temperature. After that, mixture was poured onto crushed ice to get precipitate. The product thus obtained was purified by recrystallization table 1.

Synthesis of N-(4-(2 mercapto-6-(substituted aryl)-1,6-dihydropyrimidin-4-yl)phenyl) benzamide (10a,b)

A mixture of required chalcone (9a,b) (0.01 mole) and thiourea (0.01 mole) in 1,4 dioxan (10 ml) and acatalytic amount of glacial acetic acid are taken in around bottom flask and heated under reflux for about 24 hrs. The reaction mixture was poured into cold water with stirring, the product was filtered and purified by recrystallization.
Synthesis of N-(4-(2-hydroxy-6-(substituted aryl)-1,6-dihydropyrimidin-4-yl)phenyl)benzamid 

(11a,b)

A mixture of N-(4-(3-4-substituted aryl)acryloyl)phenyl)benzamide (9a,b) (0.01 mole) and urea (0.01 mole) in the presence of KOH (1 gm) in 20 ml ethanol was heated under reflux for 12 hrs, then cooled and poured in ice cold water, the solid mass was obtained by filtration, recrystallization table (1).

Results and Discussion

All compounds were prepared according to the following scheme:

The structures of prepared compounds were identified by FTIR (table 2) and $^1$H NMR spectra (table 3). All results spectral data were in correspondence to expected values. The purity of prepared compounds were checked by using TLC chromatography. The physical properties of compounds are listed in (table 1). Compound (1) was synthesized from benzoyl chloride and urea with dry benzene. The IR spectra of this compound, show the appearance of bands at 3360, 3342, 3225, 3068 and 1674 cm$^{-1}$ which could be due to $\nu$ (NH$_2$, NH), $\nu$ C-H aromatic and $\nu$ C=O amide, respectively. The $^1$H NMR spectra measured in DMSO-d$_6$ at 25 oC revealed a multiplet from 8.41 to 7.64 ppm for aromatic protons, a singlet at 11.58 ppm (N-H$_2$, NH$_2$), and 3.7 ppm (NH$_2$).

Also the reaction between benzoyl chloride and thiourea with dry benzene lead to the formation the compound (2). The spectroscopic observation of compound (2) is given by the appearance of bands at 3360, 3342, 3225, 3068 and 1674 cm$^{-1}$ which could be due to $\nu$ (NH$_2$, NH), $\nu$ C=O aromatic and $\nu$ C=O amide, respectively. The $^1$H NMR spectra measured in DMSO-d$_6$ at 25 oC revealed a multiplet from 8.41 to 7.64 ppm for aromatic protons, a singlet at 11.58 ppm (N-H$_2$, NH$_2$), and 3.7 ppm (NH$_2$). The reaction of benzoyl chloride with anthranlic acid in basic media lead to the formation of compound

Antimicrobial activity

The activity of antibacterial and antifungal were studied by using cup-plate agar diffusion method. The inhibition zones were measured in mm. Amoxilline and Mefenamic acid (500mg/ml) were used as standard drugs for antimicrobial activity. The compounds were screened for antibacterial activity against Klebsiella, Escherichiacoli, Pseudomonas aeruginosa and Staphylococcus aureus in Mullar Hinton agar. The results are shown in the tables 4a, 4b, 4c and 4d. The results obtained by antifungal activity, indicate that compounds (4b, 7a, 11b) show activity against S. aureus and Sepidermidis than E. coli and Klebseilla and compared these results with standard drugs (mefenamic acid and amoxicillin). While only the derivative 10b shows good activity against Klebsiellamoore the activity for standard drugs. The results obtained by antifungal activity, it is found that the compounds (3a, 4a, 7a and 7b) show good activity against condid fungi and these results compared with standard drugs (mefenamic acid and Amoxicillin).

Conclusion

different heterocyclic derivatives containing thiazole, quinazolin-4-one, oxazol and pyrimidine in structure were prepared and characterized using spectroscopy techniques. four route in the synthesis, the first synthesis of oxazoloderivatives 3a-3c by reaction of benzoyl chloride with urea ,after that cyclization product with (substituted phenyl) acetyl amides.in the same method prepared thiazole derivatives 4a-4c but with thiourea . the third route include preparation of quinazolin 4-one derivatives 7a-7b by reaction of benzoyl chloride with anthranilic acid and reaction product with urea ndcyclization by (substituted phenyl) acetyl amides .in the final scheme synthesis was prepared pyrimidine derivatives 10a-11b.these derivatives have been evaluated in vitro for their antimicrobial activities against several microbes like klebsilliha, Escherichia coli, Psreudomonasaeruginosa and Staphylococcus aureus, addation of antifungl activity.

Risk Factors related to Sudden infant death syndrome (SIDS)

Hussein Jassim Mohammed1, Musadaq Abdulkadhim Dohan2, Nuhad Mohammed Kassim3, Mohamed Igrish 5, R.N Kadhim Hussein Jassim6

1PhD Community Health Nursing, College of Nursing, University of Babylon, 2Diploma, Pediatric Medicine, Ministry of Health, Iraq, 3PhD Child Health, Nursing, College of Nursing, University of Babylon, 4Babylon Health directorate/Iraq, 5Babylon Health directorate/Iraq

Abstract

Sudden infant death syndrome (SIDS) is a phenomenon of unknown cause among infants between 1 month and 1 year of age”. Methodology: descriptive design conducted through September 2018 to the end of March 2019, mothers attended health centers in Al- Hilla City, who consists of (120 meters). Data were collected through using SIDS_QA-508 after doing some adjustment on the questionnaire, The questions that used in collecting data were checked out for any mistake or error and scrutinized, Data of the 120 participant’s were entered and analyzed by means of the statistical package for social sciences (SPSS) .The results indicated that the children age (65.0%) was less one year aged, (41.7%) mother’s educational attainment with primary school. (94.2%) with pre-term pregnancy, (74.2%) were married, (77.5%) from the population present their satisfaction concerning monthly income and (55.0%) had health problems through their pregnancy. Most mothers have low knowledge regarding abrupt baby death, which correlated for mother’s age, sources of knowledge as weak correlation. Recommendations: Hospital staff should instruct parents who, in turn, must emphasize to secondary caregivers that the baby must always be placed to sleep on the back and never on the tummy, since prone sleep increases the risk of SIDS.

Key words: Infant, death syndrome

Introduction

“Sudden infant death syndrome (SIDS)” is an unknown reason of death among infants within the first year, which has a critical link with abdominal sleeping since 1965. The pathophysiology of SIDS is incompletely understood, but the critical period of newborn development exposed him to triggers and unexpected death could be allied to immaturity of respiratory control which cause hypoxemia and long apnea(Coverstone, 2019, Wilson, 2017). “The philosophies of safe sleeping practices among infancy are not well recognized, however, a considerable body of evidence supports back sleep. As long as, many sudden baby death risk factors are linked to certain unexpected influences occurring during sleep, “the Amerian Academy of Pediatrics” expanded its strategy to comprehend diversity of harmless sleep performs that can diminish hazard for sleep-related infant death to endorse discouraged bed sharing and smoking, and authorized the use of the supine position and fitting surfaces for all sleep, breastfeeding, and adequate prenatal care. Risk factors of “SIDS” are complicated by social and economic factors, whereas, in United States, the young, poor, and minority women are at elevated risk for this problem 3, in addition to lack of prenatal care, low socioeconomic status, smoking, and low birth weight babies are also associated with increased risk. It was influenced by community norms and cultural practices 4, in particular infant sleep practices, moreover, multiple epidemiologic studies have shown a strong relationship between paternal smoking and SIDS 6. These unsafe issues increases the infant mortality rate in the world is 29.5 (2017) Iraq IMR is 23.3 per 1000, Iran is 12.1 per 1000, Jordan is 13.8 per 1000, Egypt is 17.5 per 1000 (2013)” — a proportion greater than most other developed countries abrupt death and suffocation account for more than half of all unexpected infant, which considered as the
leading causes of post neonatal infant death in the US. Aitken’s grandmother and other caregivers can effect on mother’s decision in selection of the sleep position and their beliefs about infant comfort and other traditions may also affect attitudes to risk reduction. Researcher’s always focuses on reassuring the non-risky behaviors, specifically focusing on supine position and sleep location. Over and above, interested in differences between grandmothers’ behavior in their own homes compared to the home of the parent, along with, whether safe sleep practices were associated with beliefs in sleep safety. So, the present study aims to assess the risk factors related to “Sudden Infant Death Syndrom” through the first year of life.

Methodology

II.1: The design and setting of the study; A descriptive study was conducted on a number of mothers who lost their babies with less than one year age in Babel province during the period from October 2018 to April 2019.

The study was conducted with mothers who visit “MCH” centers, which include Shemali, Al Huda, Meditative Model, Qasim, Hashemite.

II.2: Study sample: Mothers included were (120 mothers) who attended health centers in Al- Hilla City

II.3: Instrument of the Study: Data were collected through using “SIDS_QA-508 (NIH Pub. No. 07-7202 June 2007)”. The researchers used a standardized questionnaire to identify the risk factors for sudden and pre-programmed death syndrome for the same purpose in European and Arab countries.

The questionnaire consisted of two parts: the first related to demographic information and the second contains (40) bubbles allied to the subject of the study. The internal correlation coefficient between these paragraphs was calculated and the results were shown (0.79). Few modifications done on it, like reducing the scale from five to three scales, and delete some points from demographical (“Increasing the number of scale categories did not necessarily improve performance”).

The sample are (120) mothers, selected from more than 3000 visitors to “MCH” centers, the information was collected by interviewing mothers who lost their children under the age of the year.

The researchers interviewed mothers and explained the dimensions and importance of their participation in the research and the results of this study, in addition to helping them to understand some of the issues related to the questionnaire.

II.4: Data Collection: After the collection of information according to the questionnaire, which was approved by the “Health Directorate of Babylon”

II.5: The Statistical Analysis: The researchers collecting data construct a database on the (SPSS, version 24,2016) statistical system and analyzed; using descriptive statistics to calculate the frequencies, percentages and standard deviation.

II.6: Ethical consideration: All participants were informed fully about current study and its aims and voluntary verbal consent was obtained from the participants in order to participate in the study. Besides, it has been taken into account the confidentiality of information obtained.

This table indicated that the factors effect “RDS” are ,(65.0%) of the baby had not cry strongly after the birth, (55.8%) of the children were given oxygen after birth, while (58.3%) of the babys sharing mothers’ bed throughout feeding or sleeing, (50.0%) were fed from breast, (50.8%) feeding the baby during sleep and (59.2%) the baby were choked during feeding. The risk factors of “SIDS” are complicated by societal
and financial factors; which almost allied with lack of prenatal care, low socioeconomic status, smoking, and low birth weight. In addition to cultural practices have a great impact on infant sleep practices. “Regardless the age of a new mother, intergenerational transmission of childrearing practices is common.” Table (1) revealed that nearly half of the sample included in the study are educated primarily, (41.7%) of the mothers with poorly follow-up through pregnancy with non suitable safe practices, which effect on their babies weights to have a low birth baby which constituting (52.5%), whereas (94.2%) as preterm delivery, and (45%) of them exposed to smoking besides to other indicators could be clearly detected in same table. (35%) of the babies crying strong along the night, (50%) of them feed just from breast with more than half, despite the fact (58%) were sharing mother’s bed for the period of sleeping; which considered as a chief cause for “SIDS”. In 2015 US, more than half (61.4%) of the respondents reported in bed sharing with their infant, and(37.0%) reporting “rarely or sometimes” and 24.4% responding “often or always” bed sharing, Self-report of any bed sharing varied by state, ranging from 49.0% in West Virginia to 78.9% in Alaska. The prevalence of bed sharing varied by maternal characteristics, gestational age at birth, and breastfeeding at 8 weeks postpartum being elevated. Bed sharing prevalence was higher among respondents in American Indians/Alaska Natives, non-Hispanic blacks, or Asians/Pacific Islanders compared with non-Hispanic whites or Hispanics. The population effected by many beliefs from their mothers when mentioned that they must to share because the babies in majority (59.2%) choking through night feeding. CAPTMinn S, (2013) stated that the reasons of practicing or choosing non supine sleep positions with their sharing reported by parents in this study; were for infant preference, comfort, and fear of choking or safety on supine position. Conversely, those that chose supine sleep position did so for safety reasons, based on advice and recommendation from their health care providers and their knowledge that this position reduced the risk for “SIDS”. Similarly, The participation of nurses in the care of newborns reduces the risk of deformities in the head while lying down.

**Conclusion**

The study concludes that infants less one year aged, their weight less than two Kg, estimating equal sex between male and female, as well as, mother’s educational attainment with primary school most mothers had pre-term babies in majority, they had not health problems during pregnancy and complications occurred during childbirth, delivered by normal birth, the baby had not cried, strong after the birth and feeding the baby during sleep which get choked during feeding.

Design and Implementing System to Study Environmental Noise Pollution Using Microcontroller

Ahmed Yousif Falih1, Ali Talib Qasim2, Basma Jumaa Saleh3, Walaa Sami Tahlok4

1University of Mustansiriyah/ Engineering Faculty/ Computer Engineering Department/ Baghdad/ Iraq,
2University of Baghdad/ Science Faculty/ Computer Science Department/ Baghdad/ Iraq

Abstract

This paper proposed a system and presents its result obtained in a study on environmental noise pollution in the city of Baghdad, Iraq. The sensing system is built on Atmega128 and CC2420 platform. We designed and implemented a sensor function for wireless sensor network application using special network named (WSN) for measuring environmental acoustic noise.

Based on the readings obtained became clear that 90 % out of the locations during the peak time have equivalent sound level over 75 dBA, and 60 % out of the total number of locations measured display during the normal time equivalent sound level over 75 dBA.

Key words - Pollution, environmental monitoring, Noise, WSN, T-Test

Introduction

The effect of noise pollution on human health and his welfare is recently considered as an important and vital issue which encourages scientists and interested agencies all over the world, such as World Health Organization (WHO), to conduct more researches concerning assessment of its levels and harmful effects. Sometimes defined in common speech the environmental noise as unwanted sound. The European Environment Agency defines environmental noise as ‘unwanted or harmful outdoor sound created by human activities, including noise emitted by means of transport, road traffic, rail traffic, air traffic, and from sites of industry activity’

Noise in industries such as construction equipment, electrical machines, loudspeakers, hawkers, vehicle movement, railroad work, and airplanes in the airports which cause an increased blood pressure and an irritation decreasing the work efficiency. It is therefore of utmost importance that excessive noise is controlled. We use the term decibels (dB) to explain sound intensity. World Health Organization (WHO) has illustrated that the most appropriate noise level not bigger than 75 dBA to prevent hearing loss. Any level above 75 dBA will effect on human ear with time. World Health Organization (WHO) recommendations that required noise level over 75 dBA in streets and public places (outdoors) leads to weakness of hearing. It is undesirable to exceed noise level the permissible limit, because it is harmful to human health and causes an inability to concentrate and nervous tension, therefore government institutions must develop appropriate solutions to reduce the pollution by noise and its effects on people’s lives. The European Directive 2002/49/EC requires all Member States to provide accurate noise level mappings of inhabited areas with more than 250,000 people and make this information publicly available via web-interfaces of appropriate quality. This article aims to design a digital sound intensity measurement system capable of sensing sound-frequency controlled by microcontroller & programming in C++ language. The main application areas of sound intensity sensing include different streets in Baghdad at two different times. We chose 16 of the most important areas in Baghdad (Al-Karrada, Al-Mansour, Al-Sinak, Al-Sadr City, Bab Al-Moatham, Bab Al-Sharqi, Al-Mustansiriyah, Al-Dora, Hae Al-Khadhraa, Al-Sha‘ab) to measure sound intensity and to compare measured results with permissible parameters. It was measured in two separate periods, one at the peak time when end of the working hours (1:00 pm – 4:00 pm) and the other in the morning (9:00 am - 12:00 pm). This work focuses primarily on the establishment of wireless environmental monitoring systems proposed to measure noise pollution by sound within cities. There are many requirements that need attention when designing wireless sensor networks.
when talking about environment in cities. In 8, System designed for monitoring environment pollution should be flexible, reliable and independent. applied a test network based on the TinyNode 8 MHz platform with a XE1025 transceiver 868MHz to observe a hydrological model of the Swiss Alps. in order to monitor environment, authors In 12 proposed a WSN framework: a Distributed Signal Processing infrastructure (SbDSP) based on the sensor to deal with sound data in a distributed manner. Anyway, a detailed application did not included in the sheet. The work done in 15 may be the closest to our project. In their work, the Tmote Sky platform 16 was applied with deploying sensors to measure traffic noise on the roads. Through the measured data, the number of vehicles and the number of different species can be calculated. The authors stress that the process of measuring noise in wide-scale using the WSN solution is possible. However, the accuracy of their measurements was not illustrated, leaving the contract calibration open, and the sensor sampling rate was determined at 8 kHz due to the reduction of the CPU / ADC. Examine the effects of noise pollution in other research has been undertaken in residents of Birj and its airport. The purpose of this research is to apply the descriptive study of the group, where took data at a specific time in a cross-sectional study. The purpose is to use 144 questionnaires by Morgan table distributed to 500 peoples living in those analyzed areas. 2 These studies have been done in narrow spaces that facilitate the handling and control the physical components and human, which confirms on the importance of introducing technology and programming to collect information and obtain results.

Method of Sampling

Our objectives were about measuring noise pollution levels in different areas with different traffic flow at different periods of time. Sound levels were measured using a controller consisting of microcontroller, sound sensor, and transceiver. In each location, the device is turned on for 10 minutes as a playback time and for a continuous measurement period of 2 to 3 hours during which several sound readings are recorded, sent and automatically saved to the computer, then calculate sound intensity. Noise levels of environmental pollution were measured in two different periods of the day to study the impact of human activity and vehicular traffic on the street. The first period was during the morning (9:00am-12:00pm). This period is characterized by relatively low traffic activity for cars and pedestrians because they are present in their jobs. The second period was during which noise measurements were carried out at the test hour (1.00pm-4.00 pm). This period is characterized by the maximum traffic of vehicles and pedestrians due to continuous working hours and the momentum of cars and other industrial and commercial activities in those streets. We correlated the obtained information of WSN sensor with XD-58C sensor to declare the effect of noise pollution on heart rate. We did the test on different levels of people were documented properly and collected in an excel File.

- Body Area Network (BAN) Implementation

For implementing such network we used XD-58C Pulse Sensor for arterial pressure and heart rate was used. This module is designed to plug-and-play heart-rate sensor for Arduino, any medical equipment that are measure heart rate may use this module. It can be worn on finger. its need 5 volts & 4 mA to work. It has open-source monitoring app that graphs pulse in real time. The high levels of pollution by noise cause every year a lot of heart attacks; therefore should be monitored heart health frequently.

![Pulse Sensor Amped Visualizer v11](image)

To sketch the heartbeat waveform and check heart rate, we used software program “Pulse Sensor Amped”.

Collecting Data Method

A plan has been created to check research objectives and testing devices. The test was applied on group of 10 human; 5 males and 5 females them ages is between 25 and 40 years. They were subjected to noise level equal to 80 dB in average and for 20 minutes. The XD-58C sensor was hanged on a hand of each person during the test to measure blood oxygen saturation, and heart rate. There was a variation in the heart rate and changes in blood oxygen saturation levels when most of the people who were tested after exposing to noise. from this group,
one person had a significantly increased blood oxygen saturation and heart rate levels, felt in stress, and he had some pain in one ear. The results showed high heart rate and blood oxygen saturation levels values on the selected group which confirm the findings data published by the World Health Organization (WHO) regarding the harmful effects of noise pollution on human health. Figure (2, 3) shows changing in heart rate levels before and after exposure to noise.

We read sound levels, which wrote linearly through analog port of Arduino and then send it by WSN; at the base node receive data and recorded it to a computer automatically. WSN is a modern technology that is currently applied in a variety of fields including, the environment, natural disasters, public safety, Government, Health and intelligent buildings and machine surveillance. The sensor network contains a specific set of sensor nodes and a gateway connected to an external communications network. WSN networks are useful as well it considered low cost and low power electronic components. We had used LM386 in order to measure the sound level with a KY-038 microphone sound sensor; this design had used in order to reduce the
power consumption where the circuit works with low voltage 5V. After received a signal (the sound), converts to a
digital value in order to be dealt with by the computer.

\[
R = \frac{V_{\text{I, max}}}{N_{\text{comb}}} 
\]

Where: \(V_{\text{I, max}}\) is the maximum input voltage defined as 5V; \(R\) is the resolution; the obtained
resolution value is \(R=4.9\text{mV}\); \(N_{\text{comb}}\) is the number of combinations for 10 bits, it means \(2^{10}=1024\).

Acquisition is used for converting to analog:

\[
V_A = \frac{V_{\text{I, max}} \cdot V_S}{N_{\text{comb}}} 
\]

Where: \(V_A\) is for converting voltage from analog to digital; \(V_S\) is a pin in arduino obtained
the sound level meter voltage in analog. Because the sound level meter has a DC output where
1dB of noise represents 10mV it is obtained:

\[
V_S = \frac{S}{V_{aq}} 
\]

Table 1 - Noise Risk Zone Criteria Adopted To Be Used In This Study. 1

We have selected some residential and commercial districts to measure sound intensity in two periods of the day.
The result that we get it as below:

In general, sound intensity had obtained indicate an increase in sound intensity, which negatively effects on the
lives of people in this city, therefore its need to develop procedures to reduce this effect. By comparing the result we
obtained with the default values in table (1) we got the following table:

</tbody>
</table>

The T-test [Table 3 & 4] showed that there were strong statistical differences (\( P < 0.0001 \)) between the noise levels during the two measurement periods as shown in (Figures 3). These data confirm that the traffic activity during the period of the beginning and end of official working hours considered the main source of noise pollution in the city of Baghdad. The statistical comparison of the results with respect to the activity of some streets indicated that there is no large difference between the results of the two measured periods, as they are areas of cars and passers-by and are considered permanent crowded areas in all active hours of a day.

Conclusion

Based on the readings obtained with the use of Arduino microcontroller and voice sensor, we found the percentage of sound pollution in the different areas of Baghdad. Became clear that Based on the readings obtained that 90% out of the locations during the peak time have equivalent sound level over 75 dBA, and 60% out of the total number of locations measured display during the normal time equivalent sound level over 75 dBA, and 90% of them over 75% during peak time. The most Baghdad area in the sound pollution is Bab Al-Sharqi (86 dBA), While lowest Baghdad areas in
sound pollution level were districts with low density population such as Hay Al-Khadraa, where it reached (74 dBA). The used design have accurate readability, low cost with ease of use, which makes it easy for us to compile readings, analyze them and produce satisfactory results.

Nurses Staff Knowledge Regarding Standard Hand Hygiene Precautions in Rania City/Kurdistan Regional Government of Iraq

Blend B. Ameen
College of Nursing, University of Raparin

Abstract

Objectives: -To assess nurses staff level of knowledge regarding standard hand hygiene precaution, and to find out the association between their level of knowledge and some of socio-demographic characteristics such as (gender, and level of education).

Method: Quantitative design, a descriptive study was carried out at Rania City. To achieve the objectives of the present study, non-probability purposive sample was used. The study sample was (66) nurses who were providing nursing services at two hospitals (Rania teaching hospital and Rania maternity and pediatric hospital). 10 of samples were excluded for a pilot study.

A questionnaire was constructed by the researcher for the purpose of the study technique and it was used as a tool for data collection. The data were collected through using an interview technique (face to face) approach.. Data were analyzed through the application of descriptive statistical analysis, such as: (frequency, percentage, mean of scores), and inferential statistical analysis (Pearson’s chi-square and correlation coefficient), by using the statistical package of social sciences (SPSS) version (20).

Results: The study indicated that the most of samples aged between 32-36 years old and represents 28.6% of the study samples. In addition, the highest percentages of the nursing staffs were female 73%. Concerning of the educational level, more than half of nurses graduated from the medical institute 66 %. And the largest study sample have 6-10 years of experiences 28.5%The findings of the study reveal that the nurses have a good level of knowledge about hand hygiene (HH) and appropriate time to do HH. The majority of the stay sample routinely used HH and they disinfectant their hands either by washing hands with water and soap or use alcohol-based jell for, while some of the nurses don’t wash their hands either because they are busy, they forget to do it or even the products are not available or not easy to reach. The study also approves that there was a statistically no significant association between the knowledge of nurses and gender and years of experiences.

Keyword: Hand hygiene, Hand washing, Alcohol-based hand rub, Knowledge, Nurses

Introduction

Nurses do hand hygiene even by washing hands with water and soap or using alcohol-based hand rub to prevent spread of infection to them or even to patients. With that there are many moments that the nurses do not do it either because they are busy, they forget to do it or the products are not available or not easy to reach. In addition, they do not wash their hands correctly because of lack of knowledge about standard HH. Hand hygiene is a simple, low cost and an effective way to prevent separation of infections. Cleaning your hands can prevent the spread of germs and save the nurse and the patient lives. Hand hygiene refers to either hand washing with antimicrobial soap or hand disinfecting with an alcohol-based hand-rub. The aim of hand hygiene is to remove dirt and limit the microbial counts on the skin, to prevent cross transmission of pathogens between patients 1. The New England Journal of Medicine reports that a lack of hand-washing remains at unacceptable levels in most medical environments, with large numbers of doctors and nurses routinely forgetting to wash their hands before touching...
patients, thus transmitting microorganisms. One study done in ICUs in Michigan (2003), showed that proper hand-washing and other simple procedures can decrease the rate of catheter-related bloodstream infections by 66 percent. The World Health Organization (WHO) has issued guidelines for procedural hand washing in order to reduce the prevalence of hospital associated infections, but lack of knowledge amongst health care workers is associated with poor compliance. To reduce the spread of germs, it is better to wash the hands or use a hand antiseptic before and after tending to a sick person. All staff in hospital should deal with hand hygiene actively because this is one of the easiest ways to help keep patients as safe and healthy as possible. So there is a need to check up nurses’ knowledge and awareness toward hand hygiene periodically in order to ensure prevent spared of infection in health care setting and to stop patients and health care workers from getting infections.

Method

A quantitative design, descriptive study was carried out in the Rania city from August 2, 2018 to the end of March 2019. In order to assess nursing staff level of knowledge regarding standard precaution (Hand hygiene) in Rania city. Rania is a city located in the Slimani Governorate Kurdistan Region/Iraq. A non-probability purposive sample of (66) nurses at the Rania teaching hospital and maternity and pediatric hospital. Who were providing nursing services at hospitals, 10 of samples excluded for a pilot study. Through an extensive review of relevant literature, and previous studies a questionnaire was constructed by the researcher for the purpose of the study and it is used for data collection. The questionnaire consisted of three parts: 1st part includes socio-demographic characteristics of nurses, staff, 2nd part consists of (7) question about HCWs compliance regarding hand hygiene, and 3rd part includes (18) items, which include (2) sections. Section (1) consists of (11) items, about knowledge of study samples regarding the hand hygiene, section (2) consists of (7) items, about the most appropriate timing of hand hygiene actions that prevent transmission of germs to the patient. The data were collected through the use of interview technique (face to face). Items were measured by using two levels of (Likert) scale and rating as, the Yes answer (2), No answer (1). To content validity of the tool was established through penal of (5) experts. Reliability of the questionnaire was determined through the use of (test-retest) technique by using Pearson’s coefficient of correlation formula. This means that the questionnaire format was adequately reliable as a tool for data collection. Data were analyzed through the application of descriptive statistical analysis, such as: frequency, percentage, mean of scores, Pearson’s chi-square and correlation coefficient and independent sample test), in addition use the statistical package of social sciences (SPSS) version (20). The mean of the score (1-1.33) was considered a low level of knowledge, (1.34 - 1.67) considered a moderate level of knowledge, and (1.68 – 2) considered a good level of knowledge.

Results

Figure (1). When nurses worked with his/her colleague and he/she forgot to disinfect their hands before touching the patient.
The bar indicate when the nurses worked with his/her colleague and he/she forgot to disinfect their hands before touching the patient, in what percent he would remind him (28.57%) percentage of nurses about (75-100%) remind his colleagues, (21.43%) says they will remind them in a percentage between (25-50%). (33.93%) give a percentage between (50-75%). In addition to (8.93%) says I never be reminded him to do hand hygiene and (7.14%) give between (0-25%).

Table (1): Level of knowledge of the study sample regarding the hand hygiene action with (2) levels of scale and frequency, percentage, mean of scores, and comparative significant.

This table shows there is no significant association between knowledge of nurses regarding hand hygiene and years of employment at level of P value ≤ 0.05.

**Discussion**

Hand hygiene is one of the essential ways to prevent or reduce the spread of infection in the health care setting. Periodically assessing knowledge of nursing staff regarding hand hygiene is an important ways to provide them with update information. In relation to the sociodemographic characteristics of the nurses’ the results show more than a quarter percentages of the nurses their ages between (32-36) years old. More than two-third of the study sample were female, due to Rania city has two hospitals; (Rania teaching hospital and Rania maternity and pediatric hospital). Most of the nurses in maternity and pediatric hospital were female. Concerning the level of education, more than half percentage of the samples are graduated from the medical institute, at the
same time only a small percentage of the nurses were graduated from nursing college 12%. Regarding the years of experiences, above the quarter percentage of nurses’ has (6 - 10) years, while only five percentages of nursing staff have (16 – 20) years’ experience. The result is an agreement with the Alireza Sharif study, the result of the study shows most of the nurses (38.5%) had working experience 5-10 years 6. But another study done in Mozambique which titled (Cold chain management: Knowledge and Practice in PHC facilities) that one-third of workers had between (2 to 5) years which constituted 32 % 7. Concerning source of information, more than 70 % of nurses had a self-reading either from reading books or from internet to increase or update their knowledge about HH. In addition, more than half of nurses took the training course about HH. The hospital administration, always tried to help their nursing staff to participate in course training in order to increase the staff’s knowledge and experiences about hand hygiene. While the diagram 1 shows that the more than seventy percentage of the study sample routinely used hand hygiene either by washing hands with water and soap or use alcohol-based handrub, but nearly 30 % did not do hand hygiene routinely. This is not acceptable in hospitals because maybe they become source of transmission of infection. Healthcare workers’ hands are the source for the carrying of pathogens from patient to another and within the healthcare environment. The health care worker commitment to the highest degree of practices remains low 10. The study also shows the reason that makes the nurses did not do hand hygiene due to they are too busy, out of product or the product are way or located in an inconvenient location to get in time. In addition, they forget to do HH sometimes. Even though these excuses are not reasonable for nurses or other health care worker, they need to do hand hygiene in order to prevent or reduce the transmission of infection in healthcare facilities. Health experts say poor hand hygiene is one of element in hospital-borne infections that kill tens of thousands of Americans each year. One every 25 patients in U.S. hospitals get a hospital-acquired infection as part of his or her care despite modest progress in controlling those pathogens inside medical facilities, the Centers for Disease Control and Prevention (CDC) reported in its most comprehensive look at a stubborn and dangerous health care problem 11. The result of this study is consist with the study done in teams in eight hospitals used secret observers, to identify the causes of hand hygiene noncompliance. Data from the eight hospitals revealed 41 different causes of noncompliance, which were some of them were healthcare worker forgot, inconvenient placement of hand rub dispenser or sink, broken dispenser or sink and healthcare worker was too busy 12. The result of this study also shows depicted that no significant association between knowledge of nurses regarding hand hygiene with gender and years of experiences. The mean knowledge score was not associated with gender (p=0.82), and years of employment (p=0.63). This may back to some reasons like the small percentage of study samples, and this is out of hand of the researcher due to Rania city has only two hospitals, and only nurses includes in the study. Another reason is the most of the study samples have the same level of education (most of them graduated from the institute). There is consistent with a study done about the knowledge of hand hygiene among the healthcare workers of two teaching hospitals in Mashhad. The result shows there was no significant difference in the knowledge level of the participants who had received formal training in hand hygiene and those who had not. Also, the mean knowledge score was not associated with age, gender, department, and the profession 13.

**Conclusion**

According to the results of the study, nurse have good knowledge regarding HH, but they are not routinely aware to use HH due to they are too busy or because out of disinfect product or they forgot to do that. In addition, most of them, they did not remind other to disinfect their hands before touching the patient in case they forget to do that. Finally, the findings of the study also show there is no significant association between nurses’ knowledge regarding HH with gender, and years of experiences.

Risk Factors Increasing Prevalence of Type 2 Diabetes Under The Age of 40 Years Attending Al-Diwanyia Teaching Hospital

Hassan Raji Jallab1, Zahraa Abdul Ameer Kadhim1
1Department of Community and Family medicine, University of Al-Qadisiyah, College of Medicine, Iraq

Abstract

The present case control study of Iraqi people living in Al-Diwanyia city to identify the attributable risk factors that leads to type 2 diabetes in younger age groups and the correlation of the most prevalence risk for developing diabetes. The study was designed to be a case control study includes 315 individuals, 150 is the number of controls, and the rest of the participants are patients that have been diagnosed by diabetes mellitus type 2 before or at age of 40 years. All these participants attended outpatient clinics at Al- Aldiwanyia teaching hospital in Al-Dewaniyah province/ Iraq. The beginning of data collection was dated on the January 2019 and ended on June 2019. Mean age of patients with diabetes mellitus was significantly higher than that of control subjects. There was highly significant difference in the frequency distribution according to marital status, occupation, residency, level of education, economic status in patients and controls groups. It appears that the rate of overweight and obesity is comparable in patient and control group.

Key words: diabetes mellitus; risk factors; prevalence; Iraq; young age

Introduction

Type 2 diabetes mellitus (T2DM) is a complicated disease, the starting age of subjects is as early as 15 years old.2 Diabetes is widespread among people, ages and regions of the sphere due to changes in standard of standards of living, inheritance and environmental factors which all together in the disorder 1. Type 2 diabetes is a serious chronic disease resulting from a complex inheritance environment interaction along with different risk factors such as high BMI and sedentary lifestyle. Type 2 DM and its complications comprise a major worldwide public health trouble, affecting populations in both developed and developing countries with high rates of diabetes related morbidity and mortality. Diabetes mellitus is a clinical syndrome characterized by hyperglycemia caused by absolute or relative shortage of insulin. Lack of insulin affects the metabolism of carbohydrate, protein and fat, and can cause considerable disturbance of water and electrolyte homeostasis; fatality may result from acute metabolic decompensation. Long-standing metabolic derangement is associated with functional and structural changes in numerous organs, predominantly those of the vascular system, which guide to the clinical ‘complications’ of diabetes.

In both of the common types of diabetes, environmental factors interrelate with genetic vulnerability to establish which group develop the clinical syndrome, and its onset. However, the fundamental genes, precipitating environmental factors and path physiology vary considerably between type 1 and type 2 diabetes. The prevalence of diabetes is rising in epidemic magnitude on a global basis. In the USA alone, it has been estimated that there are around 16 million people diagnosed with DM, representing about 6% of the population. Diabetes mellitus is becoming progressively more prevalent in developing countries, possibly due in part to alter in dietary habits, diminished physical activity, and increase BMI.

The worldwide prevalence of DM has risen considerably over the Last two decades, from an estimated 30 million cases in 1985 to 415 million in 2017. Based on current trends, the IDF projects that 642 million individuals will have diabetes by the year 2040. It is estimated that the greater part of patients with diabetes obtain their care from a family doctor. The complexity and chronicity of diabetes presents special challenges for family physicians, whose chief responsibility is the screening and avoidance of diabetes-related complications.
Patient and Method

The type of the design used in this study was a case control. This study was done in the Republic of Iraq, Aldiwanya governorate, in Aldiwanya general teaching hospital. Patient selected randomly throughout their attendance to outpatient clinic of diabetes in the former hospital. The study included period from January 2019 to July 2019. The patient introduce to this study were in the age under 40 years old or has been diagnosed with diabetes below 40 of age, and the study is only for type 2 DM. An arranged questionnaire was prepared by collecting any possible risk factors and Verbal consent was obtained from participant in the study. All diabetic patient with type two who were under the age of 40 or have been diagnosed with DM before that age, we exclude patient that have been diagnosed after the age of 40 years and the patient with type 1 DM. The ethical approval of this study include the following:

- Acceptance of Scientific Committee of Community and Family medicine department in collage of medicine / university of Al-Qadisiyah and acceptance of Committee of Ethical Scientific Researches in the collage
- Verbal consent of individual participated in the study

Results

The Distribution of diabetic patients and control subjects according to age and gender is shown in table 1. Mean age of patients with diabetes mellitus was significantly higher than that of control subjects, 49.93 ±9.95 years versus 34.68 ±12.56 years, respectively ($P <0.001$). No diabetic patient was under 20, 5 (3.1 %) were between 20-29 years, 15 (9.3 %) were between 30-39 years, 51 (31.5 %) were between 40-49 years, 32 (19.8 %) were between 60-69 years and 4 (2.5 %) were between 70-79 years, table 1. The mean age at diagnosis was 36.85 ± 4.48 years with a range of 20-40 years.

$n$: number of cases; SD: standard deviation; †: independent samples t-test; ¥: Chi-square test; HS: highly significant difference at $P \leq 0.01$; NS: not significant at $P \leq 0.05$
There was also highly significant difference in the frequency distribution according to occupation between patients and control groups ($P < 0.001$) in such a way that employee was less frequent in patients than in control group, 32.2 % versus 51.7 %, respectively, whereas the frequency of housewives and retired was more in patients than in control group, 45 % versus 32.9 % and 16.8 % versus 4%, respectively.

In addition, there was highly significant difference in the frequency distribution according to residency between patients and control groups ($P = 0.005$) in such a way that rural residency is more frequent in patients than in control group, 29.5 % versus 14.1 %.

Moreover, there was highly significant difference in the frequency distribution according to level of education between patients and control groups ($P = 0.001$) in such a way that illiterate and primary and secondary levels were more in patients than in control group, 32.9 % and 28.2 % versus 16.8 % and 16.1 %, respectively. Regarding economic status, there was also highly significant difference in the frequency distribution between patients and control groups ($P < 0.001$) in such a way that very poor and poor categories were more frequent in patients than in control group, 13.4 % and 45 % versus 1.3 % and 14.8 %, respectively. The comparison of body mass index (BMI) and waste circumference between diabetic and control groups is shown in table 3. Patients and control subjects were categorized into underweight (< 18.5), normal (18.5 -24.9), Overweight (25-29.9), class I obesity (30-34.9), class II obesity (35-39.9) and class III obesity (≥40 kg/m2), as shown in table 3. It appears that the rate of overweight and obesity is comparable in patient and control group; in addition, there was no significant difference in mean BMI between patients and control groups, 27.02 ±2.83 kg/m2 and 28.01 ±6.85 kg/m2, respectively ($P = 0.091$); however, mean waste circumference was significantly higher in diabetic patients than in control group, 105.85 ±14.26 cm versus 99.21 ±16.62, respectively ($P <0.001$).

$n$: number of cases; ¥: Chi-square test; HS: highly significant difference at $P \leq 0.01$
Discussion

In the current study the mean age of patients with diabetes mellitus was significantly higher than that of control subjects. The mean age at diagnosis was 36.85 ± 4.48 years with a range of 20-40 years, which indicates a significant relationship between DM and aging. This result has been supported by many studies worldwide including study have been done in UK, which prove that type 2 diabetes is more common in the middle-aged and elderly. It affects 10% of the population over 65, and over 70% of all cases of diabetes occur after the age of 50 years. Gender differences arise from sociocultural processes, such as different behaviors of women and men, exposure to specific influences of the environment, different forms of nutrition, life styles or stress, or attitudes towards treatments and prevention. In this study there is no significant relationship between gender and DM, the result have been supported by USA study that found no difference between male and female, study done in Pakistan revealed that there’s no difference in prevalence of diabetes mellitus with the gender. In Iran the prevalence of DM 12.1, with no significant difference between male and female, while the prevalence of diabetes in Saudi Arabia as demonstrated by Al-Nozhal show a higher ratio in females than in males, with 42%, and 37.2%, respectively. There was highly significant difference in the frequency distribution according to marital status between patients and control groups in this study in such a way that the frequency of married is more in diabetic than control which may be attributed to alteration of habitual life style. Study was done throughout Iranian urban population found that marital status was not significantly related to diabetes mellitus. In our study rural residency is more frequent in patients with DM, which has a similar result conducted from a cross sectional study using data from US centers for Disease and Prevention’s (CDC’s)2008 Behavioral Risk Factor Surveillance, has found the increasing prevalence of DM in rural area more than urban that may be attributed to increasing poverty and lower education. Highly significant difference in the frequency distribution according to level of education between patients and control groups. A case-cohort study in eight Western European countries nested in the EPIC study, demonstrates the inequalities in the risk of T2DM in Western European countries, with an inverse relationship between educational level and risk of T2DM that is only partially explained by variations in BMI. Individuals within the middle socio-economic level, who are physically inactive and do not consume large amounts of fruit are at greatest risk of developing type 2 diabetes mellitus as explained by study has been done in Ghana. Individuals within the middle socio-economic level, who are physically inactive and do not consume large amounts of fruit are at greatest risk of developing type 2 diabetes mellitus as explained by study has been done in Ghana as well as in this study.

Conclusion

This study has been focused on the most important risk factors for the development of type 2 diabetes in young age patients and has assimilate other studies conducted throughout the world which puts the BMI, family history, lifestyle, hyperlipidemia, hypertension, and psychological insults in the top of these risks which necessitates the screening for diabetes in earlier ages. Other risk must have further evaluation.

Psychosocial Consequences of Children with Idiopathic Growth Hormone Deficiency in Baghdad

Adraa H. Shawq1, Zaid W. Ajil1

1Lecturer, Pediatric Nursing Department, College of Nursing, University of Baghdad, Iraq

Abstract

Study aim: to evaluate psychosocial problems of children with growth hormone deficiency.

Methodology: A cross sectional study, of (80) children from both gender, (4 – 15) years diagnosed with idiopathic growth hormone deficiency, attending endocrine clinics in Baghdad city. Consent form taken from children and their guardians to participate in the study. Pediatric Psychosocial Symptoms Inventory (mood, behavioural, somatic, learning, and personality problems) was used to evaluate children psychosocial consequences. SPSS programme version 23 used for data analyses.

Result: children with growth hormone deficiency experience moderate psychosocial problems, especially personality and behavioural problems.

Recommendation: The researchers recommended details psychological assessment for children with growth hormone deficiency during their routine physical examination and provide suitable psychological support for them and their parent.

Key words: psychosocial consequences, growth hormone deficiency

Introduction

Children with growth hormone deficiency usually followed up endocrine clinics for treated their short stature and improve their quality of life (1, 2, 3), they aware about their physical growth and feel with embarrassment about body differences from peers (4). As reported in the pediatric studies that children with health disorders may suffer from different negative psychosocial consequences (5). Those children and their parents influence by children`s short stature, in addition, to the burden of treatment regime (4, 6). In Baghdad a study conducted in 2009 showed the prevalence of short stature only was 18.7%, while with underweight and short stature was 13.5% (7). The prevalence of short stature related to growth hormone deficiency was 1/4000 child and 60-80% of them with idiopathic causes (17). Many previous literature documented adverse effects of the short stature on children`s psychologically and socially (8).

Methods and Materials:

Research design: cross sectional study used, data was collected from first of May tile the first of November 2018.

Setting: study was carried out in outpatient endocrine clinics at two pediatric teaching hospitals and two specialized centres for endocrine disorders in Baghdad city.

Instrument of the study and procedure: Pediatric Psychosocial Symptoms Inventory PEPSI, parents reported scale, Arabic and English version. It has good reliability, developed from two famous pediatric psychosocial scales: strength and difficulties scale and child behavioral checklist scale by Dr. Al -Ayed and Al-Haider in their study about screening of children`s psychosocial problems in Riyadh (9). The approval obtained from the ownerships by electronic mail. PEPSI consists of (38) items, with five subscales: Mood symptoms subscale scored from (0-24), Behavioral

Corresponding Author:
Adraa H. Shawq,
College of Nursing, University of Baghdad,
Email: adraa.hussein@gmail.com
symptoms subscale scored from (0-27), Learning problems subscale scored from (0-18), Somatic symptoms subscale scored from (0-24), and Personality characteristics subscale scored from (0-21). Rating from 0-3: no symptoms= 0, rarely= 1, occasionally= 2, and frequently= 3. The total score ranged from 0-114 (0-38 = mild, 39-76 = moderate, 77-114 = severe).

**Statistical Analysis**

SPSS programme version 23 was used, frequency, percentage, and mean used in data analysis.

This table reflects that (84.75%) of children with growth hormone deficiency experience moderate psychosocial problems when assessed by PEPSI.

**Figure (1) Child’s Age and Gender Distribution**

In these figures, the mean age of children with growth hormone deficiency is (8.41±2.7), most of them (75%) at school age (6-12) years, and mostly are boys (65%).

**Figure (2) Subscales Levels of Pediatric Psychosocial Symptoms Inventory for children with growth hormone deficiency**
Figure (2) shows the details aspects of psychosocial problems (mood, behaviour, learning, somatic, and personality problems) according to Pediatric Psychosocial Symptoms Inventory PEPSI. Generally, children with growth hormone deficiency experience moderate mood problems (46.6%); moderate behavioural problems (60.4%); moderate learning problems (43.3%) moderate somatic problems (47.6%); moderate personality problems (65%).

Discussion

The results of the present study showed that (48.75% and 22.5%) of children with short stature related to growth hormone deficiency experience moderate and severe psychosocial problems respectively. Their physical growth (height) interferes with social competence and body differences from normal peers which caused psychological disturbances. A study about psychosocial problems of children with growth hormone deficiency by using the Visual Analogue Scale for Children, support the present findings that those children showed negative self perception concerning physical appearance 6. Another longitudinal study about terminated treatment of adolescents with growth hormone deficiency showed that, their shortness affects negatively on their psychosocial status and their quality of life 6. Children with growth hormone deficiency suffer from psychosocial disturbances and their psychosocial functioning depending on various factors especially family support and school adaptation 10. Short stature associated with psychosocial distress and emotional deprivation 5. While another study about reviewing the psychosocial consequences of children with short statured that, those children showed negative social experiences but they have not psychosocial problems 5. However some studies mentioned the benefit of growth hormone treatment on their quality of life and self esteem after one year of successful treatment 5.

The present findings showed the aspects of children psychosocial problems according to pediatric psychosocial symptoms inventory PEPSI (learning, somatic, emotional, behavioural, and personality problems), in all aspects of children psychosocial problems children with growth hormone deficiency scored such problems. Mostly they scored behavioural and personality problems (60.4%, 65%). As parent reported their children have mood changes, fight with others, fidgety, tell lies, do not listen to rules, feel down, no hobbies, no friends, spend time alone, depend on others, and seem shy.

Most of children experienced teasing or juvenalization, these negative psychosocial consequences related to their shortness. Those children experienced behavioral and emotional problems, low self esteem. They exposure to bullying and could not adopt with their condition, the psychosocial burdens may also play role in developing short stature among some children 11. Short stature in children can lead to adverse psychosocial impact on those children and affects on their school performance and development of their personality 1. Children with short stature scored behavioural problems as a result of negative social relationships especially with their peers 6. Another study to measured behavioral and social problems of (195) children with short stature compared with normal children found that children with short stature experience higher score of school difficulties and behavioral problems 6. Children with short stature experienced different barriers in their personality development which affects negatively on their school and sport competence 17. Children’s psychosocial problems and school performance are the most concern of their parent 11.

As parent reported children with short stature have low social competence when compared with normal children, because of their unsatisfied appearance which affects on the social relationships and development their personality 10. Those children may face bullying in school or playing with younger children 10. A study in Japan about psychosocial problems of children with growth hormone deficiency by using Child Behaviour Checklist (CBCL) scale, the result of the study showed those children have higher scored than normal children, they also showed high scored on subscale of Child Behaviour Checklist scale such social problems, anxiety and attention 8. Previous studies showed school and psychosocial problems due to their appearance, they experience internalize problems and behavioral problems, and showed low health related quality of life 5. By using child behavior checklist scale for children with short stature, the findings showed those children scored high score of behavioral problems than normal developing children in addition to the somatic, attention, and social problems 14. In a study about reviewing children with short stature reported that those children scored lower in academic functioning, while another American study reported no differences form normal children 5. More than half of children with short stature experienced bullying and showed low quality of life 15.
Children with growth hormone deficiency scored low neuropsychological test and impaired social relation. Those children recorded poor academic level due to effects of social relationships in spite of IQ score comparing with normal children.

Kranzler and his colleague in their study about psychosocial function of children with short stature that, those children scored externalize problems and inadequate social relationships. Children with growth hormone deficiency showed aggressive behavioral problems, attention, social, emotional problems and maladaptive. Prepubertal short children developed more social, internal, and external problems than children in the same age group. Children with short stature experience behavioral problems. Children with short stature scored low self esteem, bullying, juvenilization, and stigmatization because of their shortness. Previous studies reported those children have academic, internal, external, and behavioural problems due to their shortness. Those children have low quality of life. Psychosocial assessment of children with short stature is important in diagnosis and treatment of those children and well being. Some studies reported those children experienced low quality of life, and internal problems. Child health problems affects negatively on their parents.

Early children diagnosis and treatment reduce the risk of psychosocial problems and financial burden of treatment comparing with untreated children, in addition to the psychosocial advantages. Before treatment regimen the psychological profile should be assessed. The psychosocial services should also provide during treatment of children with growth hormone deficiency, those children experience sad feelings because of their shortness and puberty development delayed the psychological assessment of short adult showed some psychological disturbances. The setting and cultural attribute play a role in developing the psychosocial problems associated with certain health problems. The psychological health services will decrease and children well-being improved. Psychosocial improvement is one of the important goals for treated children with short stature.

**Conclusion**

Children with growth hormone deficiency were experience psychosocial problems, especially behavioral and personality problems.

Prevalence of Hepatitis B and Hepatitis C Viruses in β-thalassemia Major Patient in AD-Diwaya Province, Iraq

Hassan Raji Jallab1, Zahraa Muayad Eesa1
1Family medicine specialty, College of Medicine/ University of Al-Qadisiyah

Abstract

Background: transmission of infectious agent is still the most common cause of death and disability related to blood transfusion.

Objective: to estimate the prevalence of HBV and HCV in beta thalassemic major patients in Ad-Diwayah governorate.

Method: The current study is a retrospective cross sectional study involving sample of 80 thalassemic major patients who regularly visit thalassemia center in Ad-diwuryah for treatment, data that required in the study had been collected from patients, their guardians and from the records.

Results: The prevalence rate of HBV was 2.5% (l male and 1 Female ) which was significantly associated with family history of hepatitis ; while the prevalence rate of HCV was 3.8% (1 male and 2 female) which was significantly associated with age and family history of hepatitis.

Key words: prevalence; hepatitis; thalassemia; major.

Introduction

Thalassemia syndromes are characterized by varying degrees of ineffective hematopoiesis and increased hemolysis 1. Clinical syndromes are divided into α- and β – thalassemias, each with varying numbers of their respective globin genes mutated. There is a widen array of genetic defects and a corresponding diversity of clinical syndromes. Most –thalassemias are due to point mutation usually in both of the two β-globin genes (chromosome11), which can affect every step in the pathway of β-globin expression from initiation of transcription to messenger RNA synthesis to translation and post translation modification . A mutation in a single β-globin gene inherited along with triplicated alpha genes also may cause a β-thalassemia syndrome. Autosomal dominant forms of β–thalassemia also occur rarely 1. β-Thalassemia major is caused by mutations that impair beta chain synthesis. Because of unbalanced synthesis of alpha and beta chains, alpha chains precipitate within the cells, resulting in RBC destruction either in the bone marrow or in the spleen . β -Thalassemia major is seen most commonly in individuals of Mediterranean or Asian descent. The clinical severity of the illness varies on the basis of the molecular defect. Signs and symptoms of β-thalassemia major result from the combination of chronic hemolytic disease, decreased or absent production of normal hemoglobin A, and ineffective erythropoiesis. The anemia is severe and leads to growth failure and high output heart failure. Ineffective erythropoiesis causes increased expenditure of energy and expansion of the bone marrow cavities of all bones, leading to osteopenia, pathological fractures, extra medullary erythropoiesis with resultant hepatosplenomegaly, and an increase in the rate of iron absorption. Treatment of β-thalassemia major is based on a hyper transfusion program that corrects the anemia and suppresses the patient’s own ineffective erythropoiesis, limiting the stimulus for increased iron absorption. This suppression permits the bones to heal, decreases metabolic expenditures, increases growth, and limits dietary iron absorption. Splenectomy may reduce the transfusion volume, but it adds to the risk of serious infection. Chelation therapy with deferoxamine or deferasirox should start when laboratory evidence of iron overload (hemochromatosis) is present an before there are clinical signs of iron overload (non immune diabetes mellitus, cirrhosis, heart failure, bronzing of the skin, and multiple endocrine
abnormalities)\(^2\). When it is certain that they require regular transfusion, they should be given washed red cell transfusions at monthly intervals; it is vital that the blood is screened for human immunodeficiency virus (HIV)/acquired immune deficiency syndrome, hepatitis B and C viruses\(^3\). Most death and disability related to blood transfusion worldwide is still caused by the transmission of infectious agents\(^4\). Despite the availability of a highly effective vaccine against hepatitis B, approximately 2 billion people worldwide are infected, 350 million with chronic active infection accounting for (600,000) attributable deaths annually worldwide. Hepatitis B is spread via blood and body fluid contact through heterosexual and homosexual relations, by sharing of needles by infected drug abusers, and by accidental needle sticks in the medical setting. In areas of high disease prevalence (e.g., Southeast Asia, China), transmission is primarily from mother to child during childbirth or in early childhood. The vaccination for hepatitis B uses recombinant DNA, requires three doses on a set schedule, and confers immunity in the majority of recipients. Patients with chronic infection can develop cirrhosis and end-stage liver disease. Hepatitis C affects more than 300 million people worldwide. At least six genotypes and 100 subtypes have been identified. The diagnosis is established with serum testing for HCVRNA antibodies; although an antibody is induced, it is not protective against disease contraction and progression. Transmission occurs via blood or body fluid contamination through IV and intranasal drug use, blood transfusions, and in health care workers (e.g., needle stick or skin disruption with contaminated instrument)\(^5\).

**Patients and Method**

The study has been designed as a retrospective cross-sectional study including a cohort of Iraqi patients having beta thalassemia major on regular transfusion therapy. No limitation for gender or age was proposed. An 80 patients were randomly selected in the study from the population of thalassemic patient regularly visit the thalassemia center in AD-Diwayyah for transfusion therapy (at least once monthly). Any patient had been diagnosed with HBV or HCV infection before starting the first transfusion had been excluded from the study, also family history of HBV or HCV prior to infection of thalassemic persons was one of the exclusion criteria. The study had been done at AD-Diwayyah thalassemia center in AD-Diwayyah governorate in Iraq. The study had been started from first of April 2019 and ended on the third of June 2019. The study had been approved by the committee of ethical approval at Collage of Medicine university of Al-Qadisiyah. Verbal consent had been taken from the patients who included in the study if their age was more than 18 years or from their guardians if they were younger than 18 years old. The questionnaire had been designed to involve sociodemographic informations of patients included in the study like gender, age, residency; if it was rural or urban area and occupation. Socioeconomic state also was part of the questionnaire, the patients classified as high, moderate and low socioeconomic state; taking in consideration their level of education, income, residency, number of family member comparing with number of rooms and the house size, also if the house was renting or their own.

**Results**

**Distribution of patients with beta thalassemia major according to age**

The frequency distribution of patients with beta thalassemia major according to age is shown in table 4.1. Patients less than 10 years old accounted for 29 (36.2 %), patients between 10 to 19 years old accounted for 38 (47.5 %), patients between 20 to 29 years old accounted for 8 (10.0 %) and patients between 30 to 39 years accounted for 5 (6.2 %). The mean age of all participants was 13.38 ±8.26 years with a range of 2 to 39 years, table 1. Majority of patients were between 10 to 19 years and <10 years of age, as shown in figure 1.

Correlation between HBV or HCV infection and age of patients with beta thalassemia major

Mean age of patients with HBV were older than patients who were free of HBV infection, 20.00 ±2.83 years versus 13.21 ±8.29 years, respectively; however, the difference did not reach statistical significance (P = 0.253). Mean age of patients with HCV were older than patients who were free of HCV infection, 24.33 ±12.74 years versus 12.95±7.86 years, respectively; and the difference was statistically significant (P = 0.018), as shown in table 4.

Table 4: Correlation between HBV or HCV infection and age of patients with beta thalassemia major

| Hepatitis virus | n  | Mean age (years) | SD  | P       |

Discussion

The current study had been designated in order to highlight the prevalence of HBV and HCV infection beta thalasemic patients in Ad-Diwanyah province since those patient need multi transfusion therapy for the rest of their lives, the fact that make them at higher risk to have blood transfusion transmitted infections, including HBV and HCV, and these infections can be transmitted to healthy persons by many routes other than blood transfusion and causing dangerous morbidity that reach hepatocellular carcinoma or even death. Also there is no other published study concerning about this topic in the mentioned area. Patients with beta thalassemia major had been targeted in the current study because those
patients need blood transfusion in a very early life time mostly in the first year of life so, if those patients had been infected with HBV or HCV, that would be most likely due to transfusion of contaminated blood.

Regarding age distribution in thalassemic patients who involved in the study, it was ranging from 2 to 39 years old with 83.7% of them less than 20 years old which could be due to high fatality rate of thalassemic patients comparing with general population .This result had been agreed by many other studies in the vicinity like Kamal Dumaidi and co-worker study about prevalence of hepatitis C and B viruses among patients with B thalassemia in Palestine which reveal that (75%) of patients involved in the study were aging 24 years and less 8. The mean of age in the current study was 13.38±8.26 year , this result was near but less than the mean age in the studies that done in the vicinity , as in the study that had been done in Iran by silos Mohammadi and Mazaher Khodabandehloo about the prevalence of HCV antibodies among Beta thalassemia major patients which revealed that the mean age was 18±8.05 years 7. Male to female ratio was 1.05:1 since the inheritanc of thalassemia is autosomal which was agreed by Al-Naamani study in Oman 8. 66.2 % of patients who included in the study were living in rural areas. Regarding occupations of patients who enrolled in the current study; most of patients were either so small to attend school , students or having no job apart from single patient who was a nurse. Most of patients involved in the current study was classified as low or moderate socioeconomic state (87.5%) and the other 12.5% was classified as high socioeconomic state. 85% of patients’ parents were relative since most of them live in rural areas in which there is high rate of marriage between relatives. The rate of blood transfusion was ranging from 1 to 4 times per month patients with small age and patients who had splenectomy usually need transfusion 1 - 2 times per month while patients who didn’t have splenectomy and reaching adulthood or teenage , they usually needs transfusion 3-4 times per month. The prevalence rate of hepatitis B virus infection in patients participating in this study was 2.5% (two patients out of 80) which was less than the result of similar study done by Widad Yazaji in Syria which is a neighboring country, the study involved 159 patients, the study reveal that 13.2% of patients were seropositive for hepatitis B infection (21 patients out of 159) 9. The prevalence rate of HCV infection in the current study was 3.8% (3 patients out of 80) which was slightly higher than the prevalence rate of HBV infection which might be due to the availability of HB vaccine in the national vaccine program while there is no vaccine for HCV till the current day in the entire world. The prevalence rate of HCV infection in patients with thalassaemia in Zabol city of Iran; another neighboring country, was 8.5% 12 which was higher than the current study which might be due to higher prevalence in general population in Iran (0.5%) 13 comparing with Ad-Diwanyah population (< 0.3%) 14. Regarding to relation of gender with HBV and HCV infection, there was no significant relation between them, this result going with study of Ansari et al 16. In the current study, there is no association between residency and infection with HBV and HCV. Also , no significant association between socioeconomic state and infection with HBV and HCV. This result had been agreed by Ghufranud Din’s et al study in Pakistan 17.

Conclusions

Prevalence of HBV and HCV infection is more in multitransfused beta thalassemia major patient than in the general population. Measures taken in the blood preparation and checking still not enough to prevent infections transmitted by blood transfusion. Risk of having HBV and HCV infection in multitransfused patients increase with progression of age. There was highly significant association personal and family history of HBV and HCV infection.

Deposition of TaN Film on Commercial Pure Titanium Disk by Modified Reactive Plasma Sputtering Technique

Hassan Jawad Farhan1, Raghdaa Kareem Jassim2, L. thair3

1Assistant lecturer, Department of Prosthodontics. College of dentistry. University of Karbala, 2Professor. Head of Department Of Prosthodontics. College of dentistry. University of Baghdad, 3Chief researcher. Ministry of Science and Technology, Iraq

Abstract

Background: The new trend of implants is to find materials which accelerate bone formation at bone implant interface and improve Osseo integration to provide immediate or early loading after placement and eliminate waiting period which is uncomfortable and disturbs patients. Titanium as an implant material still need some improvement of surface properties physically and chemically. Tantalum which is gaining more attention as a new metallic biomaterial. Coating layer over implant is an important way for improvement of surface properties of titanium. Plasma used for surface modification, has several advantages such as changing surface topography, increasing surface roughness and in increasing the wettability of the surface.

Aim of study: To evaluate the effect of TaN coating by modified plasma sputtering technique of commercially pure titanium disk on wettability, surface roughness, surface chemical composition in comparison to non-coated surface.

Materials and methods: Two groups were tested in this study which include non-coated commercial pure titanium disks and coated commercial pure titanium with TaN. Modified reactive plasma sputtering apparatus was used to coat CpTi with TaN at 4, 6 & 8 h. Surface characterization by x-ray diffraction (XRD) analysis, scanning electron microscope (SEM), energy dispersive spectroscopy (EDS), contact angle measurement, were carried out for coated and uncoated disks.

Results: The result of coating specimen with TaN at times (4, 6 & 8) h showed that 8 h coating time was the best time. And this was according to the results of X-ray diffraction analysis which show a new peak formation of TaN coated CpTi disk which was not present in non-coated CpTi disk. The results of wettability test for CpTi disk coated with TaN disk was more than wettability of non-coated CpTi disk. Surface Roughness was more and better distributed in CpTi coated with TaN disk than non-coated one which appear clearly in electron microscope.

Keywords: TaN film, pure titanium disk, modified reactive plasma sputtering technique

Introduction

Engineering and surface modification of dental implant material become much advanced than it was earlier 1. Titanium shows a favorable combination of intrinsic properties for the fabrication of dental implants such as low specific weight, high strength to weight ratio, low modulus of elasticity, very high corrosion resistance, easy surface coating and excellent general biocompatibility 2 enhancing the osseointegration of CpTi results in reducing the non-functional time period of the implant, increase its applicability in alveolar bone with low quality, cause minimum discomfort to patient, and minimize the failure rates. 3. Surface coating was one of the methods used in accelerating the Osseointegration process and this by increasing roughness and change surface properties physically and chemically. Chemically and physically reactive plasma discharges are widely used to modify the surface properties of materials. 5. The stable chemical element Tantalum (Ta) can exist in the surface layers of base materials. Ta is one of the promising materials used in medical and dental fields 6. The stable TAN protective film can provide better
corrosion resistance and bioactive property than that of TiO film. The Ta components offer a low modulus of elasticity, high surface frictional characteristics, and excellent Osseo integration properties (i.e. Bioactivity and biocompatibility). Surface-coated implants are reported to have less failure and can support heavier and more dynamic forces surface coating with TaN by using plasma sputtering techniques was applied in this study on Cp Ti disk. In dental field especially in dental implant, plasma coating constitutes a simple, dry technique, which does not harm the environment, of low cost and does not comprise the intrinsic properties of the biomaterial, affecting only its surface. Many types of gases can be used in such technique to modify surface properties physically and chemically. Aim of our study to coat CpTi with TAN by using coat plasma sputtering technique.

Material and Method

Sample preparation

Titanium disks were prepared (10×5mm) diameter and thickness respectively which were cut from Cp Ti rod by using Bench Nibbling machine (TAURUS 7000-W6 CNC, Italy). All specimens were abraded successively using SiC grinding paper with different grits started from 80 grit, and continued by 120, 230, 400, 600, 800 and 1000 grit to get flat and scratch free surface. These disks were polished until a smooth and mirror polished surface was obtained. After that all specimens cleaned by using ultrasonic cleaning device

Surface coating with TaN:

The procedure of sputtering was performed by using modify Dc glow discharge reactive plasma sputtering system. The total number of samples were 10 disk which divided as 1 uncoated and 9 coated disk. These coated disks were divided into 3 groups according to the time of coating (4, 6, &8) h. The procedure of sputtering started with placing the clean and polished disks on the center of anode base. Then evacuating process of chamber to high vacuum (~1x10^-5 mbar) by using high vacuum system which consist of rotary and turbo molecular vacuum pumps to ensure the complete removing of the heavy gases like hydrocarbons. After that Power supply negatively charged voltage of 3.5 kV applied. For sputtering process, the voltage was gradually applied using variac until the required energy achieved (applied voltage and current), The pressure was 2x10^-2 to 7x10^-2 mbar and this pressure was achieved by feeding the bombardment and reactive gases. The appropriate voltage and amber were adjusted precisely by regulator until intended sputtering glow (purple color, which standardized for each gas) is achieved. One of the most important modification done to convert normal plasma system to sputtering plasma system include replacement of electrode position, so the cathode placed in upper part and anode electrode placed in lower part of chamber. A Target (cathode) and anode stainless disk. The cathode faced the anode with 7 cm distance between them, which provides electric field for the gas to be discharged. The electrical electrodes and the associated dc-power supply of 5kV. The bottom of the stainless steel disk cathode electrode are covered with tantalum sheet which regarded as target. The clean and polished samples were placed on the anode in the center of base which regarded as substrate. All the samples were cleaned by argon plasma sputtering for 15 min prior to the TaN coating process by applying a bios dc voltage of 100 Von the anode. Parameters used for reactive plasma sputtering procedure: argon was used as bombardment gas and nitrogen as reactive gas. The process was carried out at various sputtering times (namely 4, 6 and 8 hours). The reactive gas nitrogen was introduced into the evacuated chamber and the flow rate was adjusted until the pressure was stabilized to the required pressure (1×10^-2 mbar), then the argon gas introduced to the chamber until the sputtering pressure of 5×10^-2 mbar achieved. After the sputtering process completed, the samples were kept until ambient temperature in the vacuum chamber was reached.

Phase Analysis by using X-Ray Diffraction

Surface analysis for Phase’s distribution was performed for non-coated CpTi, and CpTi coated with TaN. It done by using X-ray Diffraction Facilities (SHIMADZu 6000, Japan) using Cu Kα radiation. XRD analysis were performed at room temperature in the 2θ range from 30˚- 80˚ with a 0.05˚ step and counting time of 5 secs per step. The indexing of the data and the diffraction peaks were identified according to the powder diffraction files. (PDF), received from ICDD (Intimations’ Center for Diffraction Data).

Wettability test

In this test, non-coated and coated disk (10×5) mm diameter and thickness respectively were used. An equal amounts of normal saline (0.25ml) from graduated
container dropped on each disk. Then after 20 second from putting the drop on disk, surface measurement for the angle formed between titanium disk surface and drop of normal saline done by taking a picture obtained from a digital camera.  

**Scanning electron microscope examination**

All tested group were examined by using SEM (JEOL-JSM-5600). Samples were prepared as cross section and then mounted in double face metal tape (electrically conductive) to make the sample holder electrically conductive before entering the samples into the SEM Chamber. VEGA3 TESCAN, SEM HV: 20 KV, SEM MAG:7.50kx, VIEW FIELD:27.7

**Energy dispersive spectroscopy analysis**

Chemical structures and relative concentrations for non-coated CpTi and coated CpTi with TAN discs were assessed via energy dispersive spectroscopy (EDS). EDS use of the X-ray spectrum radiate a solid sample with a focused beam of electrons to obtain a localized chemical analysis. All elements from atomic number 4 (Be) to 92 (U) can be detected in principle. Qualitative analysis involves the identification of the elements in the spectrum and is fairly straightforward owing to the simplicity of X-ray spectra. Quantitative analysis determination of the concentrations of the elements.

**Atomic force microscopy examination**

Atomic force microscope able to detect both conductive and nonconductive surfaces on the atomic scale. The AFM relied on the scanning technique and provided a high-resolution 3D image from the surface of the sample. A sharp tip at the end of the cantilever is in contact with the surface of the development and the sample displaced with piezoelectric scanners. The force on the tip causes deflection to measure with tunneling capacitive or optical detectors such as interferometer laser in this technique, the standard pressure applied to the joint is zero (to prevent any surface deformation).

**Result**

**Surface characterization by using X-Ray Diffraction.**

**A: Before Heat treatment:**

XRD patterns of the non-coated Cp Ti specimen and TaN coated by modified reactive plasma sputtering after different sputtering time (namely 4, 6 and 8 hours) are demonstrated in Figure (1). and these data were indexed according to the Powder Diffraction Files (PDF) for the hexagonal αTi (JCPDS-ICDD file # 44-1294), TaN (JCPDS-ICDD file # 25-0922, 33-1391and 33-1390), and TaN (JCPDS-ICDD file # 34-0977). The diffraction peaks of the uncoated CpTi were found to be corresponding to (100), (002), (101), (102), (110), (200), (112) and (201) α-Ti at 2θ values 35.00°, 38.30°, 40.05°, 52.9°, 62.8°, 70.6°, 76.25° and 77.35° respectively. The patterns of the plasma sputtered specimen for 4 and 6 hours show wide peak in the range of 2θ 20-30° which seems to be due to the formation of not fully crystalline TaN, whereas the pattern of the specimen sputtered for 8 hours show clear and prominent TaN peaks corresponding to the reflections (111) at 2Θ 35.14 and (200) at 2Θ 41.24°. Also its very clear there are a shift in the 2θ position of the CpTi reflections towards the higher 2θ indicting the change in titanium crystal cell volume.

**B: After Heat treatment:**

The CpTi specimen’s coated with TaN for sputtering time 8 hours before and after heat treatment are shown in Figures (2). The pattern of the heat treated specimen show prominent new peaks of 111 TaN at 2θo 36.00 and developed one assigned as 200 TaN at 2θo 41.24. also The XRD pattern of the heat treated specimen shows the formation of 110 of tantalum peak TaN at 2θ 27.23.
Surface characterization using Wettability test

From the result of wettability test, 8 hr. coated disk with TaN give more hydrophilic surface feature with contact angle formed less than non-coated disk as shown in Figure (3).

Surface characterization using SEM 3.3

A: Topographic. The scanning electron microscopy images of CpTi disk before coating in (figure 4a) revealed a relatively flat and smooth surface. While the surface morphology of CpTi plasma sputtering samples with TaN for 8 h showed a fully arranged nanochips and uniformly distributed in (figure 4b).

B: chemical composition by EDS

![EDS images](image)

Regarding the analysis of the chemical structure of CpTi figure (5, A) show two titanium peaks with these values (kα 4.512 and lα 0.452), these values represent alpha phase of titanium. For coated disk with TaN, there were five peaks, two peaks for titanium which represent alpha phase, two tantalum peaks and one peak of nitrogen with following values percentage (kα 4.512 and lα 0.452) (lα 8.146 and mα 1.712) (kα 0.392) respectively as shown in figure (5, b). Elemental composition of tested group as follow in (fig a) titanium was 100%, and in (fig b) percentage of titanium was 3%, tantalum was 22% and nitrogen was 75%.

Discussion

The new trend in implant research is to increase and accelerate the osseointegration of Cp Ti. One of the methods used in accelerating the osseointegration process is to modify the surface properties of the implant. Chemically and physically reactive plasma is widely used to modify the surface properties of materials. In this research, tantalum is a material with specific properties which is used as a coat material with nitrogen gas to develop TaN surface on CpTi disk by using modified plasma sputtering technique which has several advantages such as changing surface topography, increasing surface roughness, wettability of the surface. Reactive plasma coating constitutes a simple, dry technique, which does not harm the environment, does
not comprise the intrinsic properties of the biomaterial.

The results of X-ray diffraction analysis revealed a new peaks formation towards the 2θ direction in coated disk as a result of deposition of TaN material on the surface of CpTi, these new peaks were more prominent after heat treatment in coated disk as evidence to the more crystallinity of TaN. Surface properties and roughness of uncoated CpTi and TaN coated disk for 8 h were examined by Scanning electron microscope, showed fully arranged nanochips with uniform shape in coated layers, this might be due to difference of chemical composition of coated layer of non-coated and TaN disk, this shape of nanochips due to the deposition of TaN on the surface of CpTi. Contact angle of fluid drop in 8 hr. CpTi coated disk with TaN less than non-coated CpTi disk, which mean the coated disk more hydrophilic than non-coated disk. This may be due to more affinity of tantalum and nitrogen to fluid.

Abstract

This study designed to investigate the effects of 7,12 dimethylbenz [a] anthracene (DMBA)on some blood parameters and hepatic histopathology in rats and antioxidant enzyme. twenty female Wistar albino rats, weighing 180–200 g, were randomly divided into two group 1- DMBA group (positive group) who received 20 mg DMBA/kg body weight/ (single Douse) 2-Control group (negative group) doesn’t receive any item. The animals in these groups were sacrificed at the end of the 90 days:The histological structure of the liver tissues in the control group was normal. the liver exhibited hydropic degeneration and coagulation necrosis in hepatocytes, severe dilation in the sinusoids, congestion in the central and portal regions , DMBA groups, was degenerative and necrotic changes were detected.MDA levels increased in the DMBA group, compared to the control group, Antioxidant activity CAT, SOD and GPX, the results showed increased enzyme activity in positive control compared with negative groups , ,the hematological parameter was increase in WBC, PLT, GRA, and LYM and decrease in RBC value .

Keywords: 7,12-dimethylbenz[a]anthracene (DMBA); Blood parameters; Antioxidant enzyme ; MDA ; Rat.
