of this pathogenesis is reflected in the variation of available prophylactic drugs. The most commonly used prophylactic drugs are tricyclic antidepressants (TCA), other classes of antidepressants and muscle relaxants, but benzodiazepines and vasodilator agents are also prescribed 4. To obtain effective treatment, it was conducted a study comparing valproic acid 500 mg and amitriptyline 15 mg in reducing the frequency of headache attacks in patients with tension-type headache5.

Method

Subjects in this study were tension type headache patients who were treated at the Neurological Outpatient Unit of Dr. Soetomo General Hospital Surabaya, Indonesia that have fulfilled the criteria of inclusion and exclusion 6. Inclusion criteria included chronic and frequent episodic tension type headache that fulfilled the criteria based on the National Consensus III Study Group Headache Perdossi 2010 and aged 18-50 years old. Exclusion criteria included secondary headache patients based on the National Consensus III of the Study Group of Headache Pain in 2010, patients with a history of allergy or contra indication of the administered drug, and pregnant women, mental illness or severe illness such as malignancy. Patients who were willing to participate in the research had to fill out the informed consent sheet 7.

The study protocol was approved by the Ethical Commission to conduct basic science/clinical research in Dr. Soetomo General Hospital Surabaya. Subsequently, the subjects were divided into two groups, the group receiving amitriptyline 15 mg and the group receiving valproic acid 500 mg. Both drugs were put into capsule packs of the same color and size; thus, the researchers and the study subjects could not distinguish the contents of the capsule. This drug was given to the patients for six weeks 8. The patients were given an explanation of the headache diary that must be filled by the patients every day during the study. After the examination, the patients were sent back with a headache diary, and medicine. The patients were given 14 capsules of medicine to drink 1x1 for two weeks either while experiencing headache or no. The patients were also given analgesic of 10 tablets and consumed only if there was a headache attack. The patients were asked to return for control, handed over a headache diary and took medication every two weeks for six weeks 9.

The collected data was processed by statistical tests using SPSS 16.0 software (SPSS, Inc., Chicago, IL). The statistical test used in this study was paired t-test and independent t-test if the data was distributed normal. If the data was distributed abnormal, it was examined by wilcoxon test continued with mann withney test. Furthermore, chi square test was conducted to know the success of treatment on each group with p <0.05 10.

The number of samples at the beginning of the study were 50 respondents. Most of the subjects were females of 36% in the amitriptyline group and 36% in the valproic acid group. Senior High School students were 18% in amitriptyline group and 22% in the valproic acid group. Employed subjects were 26% in the amitriptyline group and 32% in the valproic acid group. The subjects who did not consume coffee were 44% in the amitriptyline group and 46% in the valproic acid group. The subjects who did not have stressor were 46% in the amitriptyline group and 48% in the valproic acid group.

*Odds ratio of treatment success = 1.37*

The success of preventive treatment was assessed by a decrease in the frequency of headache attacks at the end of the study at week six. The improvement of the frequency of headache attacks after treatment was the difference between the frequency of headache before treatment (mean TTH1) and the frequency of attacks after-treatment (mean TTH2), reported as delta mean TTH. Improvement in pain intensity was assessed by the difference between the value of pain intensity before treatment (VAS1) with pain intensity after treatment (VAS2), reported as delta VAS.

The success rate of treatment in both groups where the drug was considered effective if it successfully reduced the frequency of headache attacks as much as ≥ 50%. The treatment success rate was higher in the amitriptyline group than in the valproic acid group.
Odds Ratio obtained 1.37 with 95% confidence interval. The results of statistical analysis showed that there was no significant difference between success rate in both groups with $p = 0.570$.

**Discussion**

The effectiveness of amitriptyline as a chronic TTH preventive therapy is quite common. A randomized study compared amitriptyline with citalopram as a chronic TTH preventive therapy. They found that amitriptyline was more effective than citalopram in reducing headache attacks. Various publications also concluded that amitriptyline significantly reduces chronic TTH attacks compared with placebo.

Meanwhile, other studies have observed that amitriptyline may also reduce pain in the palpation of the pericranial muscles. But they also found that undesirable side effects were high in the amitriptyline group compared to other drugs. Randomized controlled clinical trials on TTH management with TCA conducted stress management therapy and a combination of both 187 patients. It was revealed that 78 (80%) of 97 patients receiving amitriptyline reported unwanted side effects such as dry mouth, drowsiness, weight gain, sweating, constipation, abdominal pain, nervousness, and increased appetite.

A systematic review and meta-analysis of the use of tricyclic antidepressants and headache involving 37 studies (30 studies using amitriptyline) showed that tricyclic antidepressants reduced the number of days of headache attacks in TTH patients and the number of headache attacks in migraine patients. However, side effects that arise are also quite a lot like dry mouth, drowsiness and stomach upset. The dose of amitriptyline used varies from 10 mg-150 mg per day. Because of this side-effect profile, amitriptyline is not an appropriate therapy for patients with multiple contraindications and elderly.

Several studies have examined the use of valproic acid as a preventive therapy for headache. A research studied the efficacy and safety of sodium valproate for long-term therapy in patients with chronic headaches. The study involved 642 patients undergoing treatment with sodium valproate, in which 138 patients received only sodium valproate. The results of this study received an average improvement of 47%, 50% decrease in the frequency of headache attacks in patients who obtained only sodium valproate (93 of 138 patients). Almost 75% of patients experienced a decrease in frequency of headache attacks by 50%. Drug side effects occurred in about 35% of patients but no serious side effects, and hepatotoxicity is also not found during treatment up to 6 years.

Previous research conducted an open-label trial of 30 patients using sodium divalproate at a dose of between 1000 mg and 2000 mg per day. Based on the index of weekly headache, pain-free days and dysfunctional days, general well-being rating and physicians global assessment of patients increased significantly in two-thirds of patients. In another study, the researchers consecutively studied 75 patients with intractable headache syndrome, dividing them into 3 groups of migraine frequency, transformed migraine, TTH and treating all patients with sodium divalproate 500 mg twice daily. Thirty-six patients (48%) reported a decrease in headache frequency by 50% or more.

A randomized double blind trial with placebo controlled enrolled 70 patients with chronic headaches. Twenty-nine migraine patients and 41 chronic TTH patients were divided into groups of valproic acid and placebo. Visual Analog Scale (VAS) and frequency of pain are used as evaluation. The initial dose used in this study was 500 mg per day given for 3 months. In this study, there was a decrease in the maximum pain of VAS and frequency of pain in the valproic acid group at the end of the study ($p = 0.000$). The incidence of rare, somnolent and tremor-like side effects was found in one patient, impotence occurred in one patient and hair loss occurred in one patient. This was in line with the results of our study, which also resulted in decreased frequency of pain and pain intensity (VAS) in the valproic acid group at the end of the study ($p = 0.000$).

The use of amitriptyline and valproic acid in this study is as preventive action. With the reduced frequency of headache attacks, the less the intensity of pain was experienced by the patient. This is probably due to the high levels of neurotransmitter inhibitors such as serotonin and GABA; thus, it suppresses the acute pain impulse that appears. This explains that prevention of headache attacks on TTH and efforts to find effective preventive drugs is still a challenge in medicine and this is closely related to the many factors involved in the pathogenesis of this headache. A previously published review shows that the average preventive therapy is less effective.
Conclusion

There was no significant difference between the effectiveness of valproic acid 500 mg and amitriptyline 15 mg in reducing the frequency of headache in patients with frequent episodic and chronic TTH.

Ethical Clearance: This research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, nonmaleficence, and justice.

Conflict of Interest: The author reports no conflict of interest of this work.

Abstract

Background: Nasopharyngeal carcinoma (NPC) associated with Epstein-Barr virus (EBV) chronic infection is a common head and neck malignancy in South China and Indonesia. Although radiation and chemotheraphy is the main therapy, it requires repeated and invasive biopsy for pathological evaluation. Therefore, a marker is required for screening including the level of anti early antigen immunoglobin a serology level.

Method: Pre-pots test, longitudinal cohort design. The PTV of 18 samples were examined using CT scan, while their serum EBV anti EA IgA level were examined using pre and post three series-cisplatin-paclitaxel chemotherapy ELISA.

Results: Although there was no significant changes in the level of anti EA IgA, however we found a decrease in the mean of pre-chemotherapy anti EA IgA level from 136.49 U/ml to 124.61 U/ml. There was significant changes in the VTP in pre and post-chemotherapy (p<0.05). The mean of VTP in pre-chemotherapy was 66.26 cm³ (SD-38.61 cm³), while in post-chemotherapy was 31.64 cm³ (SD-27.5 cm³). The delta mean of changes in anti EA IgA level was 11.8 U/ml and in VTP was 34.62 cm³. No correlation was found between the changes of anti EA IgA and the changes of VTP in post-chemotherapy (p>0.05). However, decreases were found in the level of EBV EA IgA and PTV in pre and post NPC patients.

Conclusion: There were decreases of serum EBV EA IgA level and PTV in pre and post-chemotherapy NPC patients.

Keywords: Immunoglobulin A, primary tumor volume, cisplatin-paclitaxel chemotherapy, nasopharyngeal carcinoma

Introduction

Nasopharyngeal carcinoma (NPC) is a rare head and neck malignancy except in South China and Southeast Asia including Indonesia. NPC incidence in South China is between 20-40 per 100,000 population per year and in Indonesia is 6.2 per 100,000 population per year or 12,000 new cases per year.¹ In Dr. Soetomo General Hospital and Dr. Cipto Mangun Kusumo General Hospital as the main hospital in Surabaya and Jakarta, Indonesia, respectively, nasopharyngeal carcinoma ranks fourth in malignancy after carcinoma of the cervix, breast and skin.²

EBV infection will be followed by the formation of specific antibodies against EBV antigens including anti viral capsid antigen (VCA), early antigen (EA), and Epstein-Barr nuclear antigen (EBNA). Increased

levels of Immunoglobulin A (IgA) anti EA and VCA are commonly found in patients with KNF. Anti-EBV antibody levels, particularly IgA in NPC patients are higher than healthy individuals or patients with other kinds of malignant head and neck tumor, other organ tumors and even in other nasopharyngeal disorders.

Post-therapy NPC monitoring associated with EBV infection is performed with painful repeated biopsy and pathology examination. EBV serology examination can be used as screening for at-risk patients and occult primary tumors as well as to detect recurrence. A research shows that there is a significant association between serum EBV DNA levels of KNF patients with clinical staging and tumor progression. It is expected that EBV serology may replace the role of the biopsy.

Several studies have shown that the levels of IgA anti VCA and EA EBV increase with the appearance of NPC symptoms. Immunoglobulin A anti-EA is a tumor marker for the diagnosis of NPC because it exhibits high specificity compared to other tumor markers and IgA anti-EA will increase 1 - 5 years before NPC. IgA levels in pre-therapy have diagnostic and prognostic value, whereas NPC patients with higher levels of antibodies have a worse prognostic. The remaining high levels of IgA anti VCA and anti-EA after therapy are associated with poor prognostics. The increased serum immunoglobulin A (IgA) EBV serologic levels with normal histopathologic results should still be warranted for greater recurrence or higher risk of recurrence.

Serum IgA anti EA EBV serologic examination is required for post-therapy NPC evaluation. The purpose of this study was to determine the relationship between changes in IgA anti EA EBV levels in serum with primary tumor volume in post cisplatin-paclitaxel NPC patients in Dr. Soetomo General Hospital Surabaya. The results of this study are expected to be used as a basis for assessment of therapeutic response, early detection of KNF recurrence, and prognosis determination.

**Method**

This is an observational study with longitudinal cohort approach using pre-post test. The study was conducted in Department of ENT Dr. Soetomo General Hospital Surabaya in the period of August 2016 until January 2017. 24 new NPC patients were collected as the samples from a total of 25 patients that met the study criteria. Six samples were dropped-out due to changes in paclitaxel regimen, one patient due to an allergy, one patient continued the chemotherapy procedure in outside Dr. Soetomo General Hospital Surabaya, one patient refused to continue chemotherapy, two patients have undergone radiotherapy before the chemotherapy finished and one patient passed away.

The examination of serum EBV EA IgA level was conducted using. The basic data collected in this study consisted of the patients data based on age, gender and ethnicity. The examination results in the form of pre and post cisplatin-paclitaxel chemotherapy serum EBV anti EA IgA in NPC patients was assessed by Clinical Pathology Consultant. Pre and post cisplatin-paclitaxel chemotherapy primary tumor volume was assessed by radiology consultant. The data were analyzed using Wilcoxon Signed Rank Test and rho Pearson correlation test. This Research to find out the changes of serum EBV anti EA IgA and primary tumor volume (PTV).

</table>
The most NPC patients were in the age group of 40-49 years old with seven patients (38.89%). The youngest age was 19 years old and the oldest was 62 years old. Distribution of NPC patients based on gender was described in patients were male (13 patients or 72.22%) and there were 5 female patients (27.78%). The comparison between male and female was 2.6:1. Distribution of NPC patients based on ethnicity were Javanese with 14 patients (77.78%) compared to Madura 4 people (22.22%).

The result of anti-EA IgA level in pre-chemotherapy was found to be 136.49 U/ml and standard intersection of 140.38 U/ml. The results of anti-EA IgA in post 3-series cisplatin-paclitaxel chemotherapy were found to average 124.61 U/ml and standard deviation of 127.80 U/ml (Table 1). Statistic test using Wilcoxon Sign Rank Test showed p value of 0.053. This indicated no significant changes in anti-EA IgA level in pre and post cisplatin-paclitaxel chemotherapy in patients with NPC (p >0.05).

The results of PTV in pre-chemotherapy cisplatin-paclitaxel showed the mean of 66.26 cm³ and standard deviation of 38.61 cm³. The results of precisplatin-paclitaxel showed the mean of 66.26 cm³ and standard deviation of 38.61 cm³. Statistic test using Wilcoxon Sign Rank Test showed p value of 0.001. The data indicated a significant difference of PTV in pre and post cisplatin-paclitaxel chemotherapy in NPC patients (p <0.05).

Changes in pre and post cisplatin-paclitaxel anti EA IgA levels showed Δ mean of 11.88 and Δ standard deviation of 55.88. Changes of PTV in pre and post-cisplatin-paclitaxel chemotherapy had Δ mean of 34.62 and Δ standard deviation of 36.85 (Table 4). Statistical test using Pearson correlation showed correlation coefficient (r) of 0.260 and p value of 0.298, suggesting insignificant correlation between the changes in anti-EA Ig A level and primary tumor volume in post cisplatin-paclitaxel chemotherapy in NPC patients.

Discussion

Distribution of NPC patients based on gender was the 13 male patients (72.22%) and 5 female patients (27.78%). The ratio between men and women was 2.5:1. Distribution of KNF patients based on gender, most patients were male (70%) with the ratio between men and women being almost the same throughout Indonesia, i.e. 2-3:1.24 The habits such as smoking increase the risk of KNF 2-6 times and so did the exposure to steam, dust and chemical gas at the workplace also increase the same risk. Formaldehyde exposure at workplace also increase the risk of NPC to 2-4 times. Increased risk also occured in workers who inhaled firewood smoke, and the risk increased 2 times in workers exposed to industrial heat and combustion products. This led to high incidence in men due to differences in living habits and occupations that cause males to have more frequent contact with carcinogens that caused NPC.2 Testosterone hormone which was dominant in male was suspected of causing immune response and tumor surveillance decrease and thus male are more prone to EBV infection and cancer.

The results of statistical analysis of changes in the levels of serum EBV anti EA IgA in pre and post-chemotherapy cisplatin-paclitaxel patients with NOC was not significant. Nevertheless, there was a mean decrease by 136.49 U/ml in pre-chemotherapy to 124.61 U/ml in post-chemotherapy (Table 1). This was incompatible with the chemotherapy mechanisms that caused humoral and cellular immune suppression. Humoral immunity expressed by B cells and assessed on the level of immunoglobulin.27 The similar mechanism in radiotherapy was given to NPC patients which often caused immunologic cell damage which resulted in decrease of cellular humoral immune response8.

Decreased serum EBV anti EA IgA levels after cisplatin-paclitaxel chemotherapy in this study might be due to abundant EBV not only in NPC tumor cells but also from activation of T cell infiltration, B lymphocytes, and epithelial cells capable of producing antigen associated with EBV.28,29 In addition, there was a difference of individual immune responses to various antigens which made antibodies as important markers were highly dependent on the host response to the viral antigen on the tumor.10 Changes in the latent cycle into lytic cycles in NPC tumor cells could occur spontaneously or induced by cisplatin chemotherapy, γ ray radiation, phorbol ester, sodium butyrate and bortezomib.30,31

Levels of EBV EA Ig A highly increased in 2 patients with NPC i.e. 19.84 U/ml in pre-therapy to 184.31 U/ml in post-therapy and 84.07 U/ml to 113.72 U/ml and 4 patients with NPC had slight increase, i.e. around ± 2.00 U/ml. The levels of EBV EA Ig A in patients with NPC in this study decreased in 12 patients. This was consistent with the study by Gu, et al.32 (2009) obtaining fluctuation of EBV antibody reactivity during therapy and steady follow-up. Fifteen of the 35 NPC patients tested for antibodies decreased after therapy but
13 patients showed small changes. Increased levels of EBV antibody after therapy were obtained in 5 patients while 2 patients that initially decreased had increase. This might be due to the different kinetic diversity of serologic EBV for each KNF patient during therapy as well as illustration of differences in radiosensitivity and immunological reactions. 

The results of the measurement of primary tumor volume (PTV) in post-chemotherapy cisplatin-paclitaxel showed a decrease of PTV mean in post-chemotherapy cisplatin-paclitaxel. The PTV change was statistically significant and therefore it was concluded that there was a significant PTV change in pre and post chemotherapy. This corresponded to the use of cisplatin-paclitaxel chemotherapy in the management of malignant tumors, i.e., to eradicate tumor cells or for locoregional control when used in conjunction with surgery or radiotherapy. Chemotherapy was used to treat macroscopic and microscopic metastases. Microscopic metastasis that was clinically invisible and deposited in the body would turn into macroscopic if not treated.

Pearson correlation test result on serum EBV anti EA IgA level changed with primary tumor volume change (PTV) in post-cisplatin-paclitaxel chemotherapy got the value $r = 0.260$ and $p = 0.298$. The results showed a non-significant relationship ($p > 0.05$). However, in general we found a decrease in EBV EA IgV levels and decreased primary tumor volume in patients with NPC who received pre and post cisplatin-paclitaxel chemotherapy. Interaction of cancer cells with lymphocytes or chemotherapy and radiotherapy that could have a significant effect on the immune system my explained it, and also the imbalance of humoral immunity and decreased cellular immunity triggered cancer progression and treatment failure. In this study changes in serum anti-EA IgA might be due to direct effects of chemotherapy or indirect effects of viral replication associated with growth of NPC tumor. The immediate effects of chemotherapy and cytostatic drugs were known to greatly damage lymphoid as an antibody producer but some studies have found that chemotherapy did not destroy all B memory cells and memory T cells even when examination did not get humoral immune response. Increased response of various antibodies to EBV protein at a higher stage of malignancy suggested viral replication associated with NPC tumor growth.

A study showed no statistically significant association between gender, age, and distant metastases with anti-VCA IgA antibodies, anti-EA IgA, anti-RGA IgG, and anti-EBNA IgA. There was a tendency to increase the levels of anti-VCA IgA and anti-EA IgA with a classification of N, but there was no association with the classification of T. This might be related to lymphocyte infiltration in NPC which significantly contributed to increase antibody to EBV antigen lytic phase.

The results of this study were consistent with a study that various chemotherapeutic drugs such as cis-platinum, fluorouracil, and taxol trigger alteration of latent cycle into lytic EBV virus infection in tumor cells. This change occurred through the protein signal kinase C δ, phosphatidylinositol 3'-kinase, and p38 stress mitogen-activated protein kinase but not caspase activation. This study was also conducted on mice containing KNF cells and found that combination of GCV therapy with 5 FU or a combination of GCV with cis-platinum being more effective in triggering KNF cell apoptosis than single therapy. Spontaneous induction of viral replication was more determined by the intracellular plasma environment than the factors that cause plasma cell differentiation. Lit replication of infected latent cell lines might be performed by induction including anti-immunoglobulin antibody (anti-IgG), activation of transforming growth factor β (TGF β), and activation of CD4 + T cells. The transition from the latent cycle to the EBV lytic cycle could be induced by DNA destruction agents such as chemotherapy (cisplatin), γ ray radicals, phorbol ester, sodium butyrate, and bortezomib.

**Conclusion**

There was a decrease in serum EBV EA IgA level and primary tumor volume n post-chemotherapy compared to in pre-chemotherapy and therefore could be used to monitor the success of post-chemotherapy medication.

Correlation of Cardiorespiratory Fitness Levels with Functional Mobility Ability in Post Thrombotic Infarction Stroke Patient

Eny Susilowati¹, Reni Hendrarati Kusharyaningsih², Dewi Poerwandari²
¹Department of Physical Medicine and Rehabilitation, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo Teaching Hospital, Universitas Airlangga, Surabaya 60285, Indonesia

Abstract

Background: Stroke patients often experience functional ambulation difficulties and lack ability to walk independently due to the reduction cardiorespiratory fitness so that an understanding of the relationship between fitness levels cardiorespiratory with functional mobility ability is needed, especially for thrombotic infarction stroke patients.

Objectives: This study aims to assess the relationship between cardiorespiratory fitness levels with functional mobility ability in the first three months after thrombotic infarction stroke.

Method: Subjects are 38 post trombotic infarction stroke. Functional mobility is measured by the Timed Up and Go test. Subjects were asked to stand up from a chair whose seat is ± 46cm and the height of its back is 65cm, walk as far as 3 m, turn 1800, walk back and sit back. Data were analyzed and performed statistical test using SPSS 17.

Results: The study showed the average TUG test was 15.56-7.79 seconds with the longest travel time was 37.38 seconds and the fastest travel time was 8.16 seconds. The average of VO₂max was 10.62 ± 2.31mL / kg / min, with the lowest VO₂max yield of 5.78mL / kg / min and the highest was 14.54mL / kg / minute. The TUG test had a negative correlation with VO₂max the 6 minute walk test result.

Conclusion: There is a significant relationship between cardiorespiratory fitness level and functional mobility abilities in post thrombotic infarction stroke patient.

Keywords: Thrombotic Infarction Stroke, TUG, Cardiorespiratory fitness level, Functional Mobility Ability, VO₂max

Introduction

Stroke incidence approximately occurs in 15 million population per year worldwide, 5 million people died and 5 million people experiencing sequelae and permanent disability ¹-⁴. Stroke prevalence in Indonesia is 12.1 per 1,000 population ⁵. The number of stroke incidences continues to increase along with rising risk factors and elderly population and can affect quality of life ⁶ that leads to appropriate treatment ⁷,⁸. Motor impairment is the main cause of disability and limited mobility in individual with stroke ⁹. Mobility recovery is the main purpose of stroke patient during rehabilitation since it serves as the key factor to be independent in daily activities ¹⁰.

Stroke patient commonly has functional ambulation difficulties and reduced ability to walk independently due to decreased cardiorespiratory fitness, changes in neuromotor control and increased energy required

for daily activities. Other research pointed out that improved Timed Up and Go (TUG) score was obtained in the first week until 3 months after stroke, while there was no significant change after those periods, and the patterns of mobility recovery differed by age groups. The age group above 80 suffer from decreased mobility in the third until the twelfth month after stroke, while mobility in other age groups tends to be stable.

Cardiorespiratory fitness decreases significantly in post-stroke patients. It brings negative effects to walking speed, endurance and performance in daily activities and stroke patient independence. Other study obtained minimum VO$_{2\text{max}}$ (peak oxygen consumption) for age group of 85 to live independently was 17.7 mL/kg/minute for male and 15.4 mL/kg/minute for female. Minimum VO$_{2\text{max}}$ in order to perform daily activities is 15 mL/kg/minute. MacKay-Lyons and Makrides, in their study on assessing VO$_{2\text{max}}$ in post-stroke patients after 1 month with body weight supported female, found average VO$_{2\text{max}}$ was 14.4±5.1mL/kg/minute or around 60% of prediction value based on age and sex.

Stroke patient has low cardiorespiratory fitness. Average VO$_{2\text{max}}$ is an indicator of average aerobic capacity from 11.7±3.7 mL/kg/minute to 17.3±7.0 mL/kg/minute or around 50-60% of normal value based on age and sex. Low training capacity is a result of increased energy usage to walk due to paretic deficits. These deficits also cause low social participation and life quality. The study is then aimed to investigate the correlation between cardiorespiratory fitness level and functional mobility ability in the first three months after thrombotic infarct stroke, factors affecting functional mobility ability and cardiorespiratory fitness level. Previous study found a correlation between TUG score and distance achieved in 6-minute walking test.

**Method**

An observational analytic study was carried out at Medical Rehabilitation Unit of Dr. Soetomo Teaching Hospital, Surabaya, Indonesia from June 2015 using cross sectional study design. The samples were taken using consecutive sampling after fulfilling the inclusion criteria: post-thrombotic infarct stroke patients aged 21-70 (first stroke attack or recurrent attack) with unilateral or bilateral hemiparesis (leg muscle strength ≥3), onset ≥2 weeks until 3 months after thrombotic infarct stroke, subjects could walk 10 meters without aid, non-assistant, could comply with simple orders and signed informed consent. The study protocol was approved by the ethics committees of Dr. Soetomo Teaching Hospital (Surabaya, Indonesia). 38 eligible subjects’ functional mobility ability were measured using TUG test and 6-minute cardiorespiratory fitness test. The data were analyzed using SPSS 17.0 (SPSS, Inc., Chicago, IL).

**Results**

**Subjects’ characteristics**

There were 38 subjects, consisting of 26 males and 12 females. The youngest and oldest subjects were 39 and 69 years old, respectively, with subjects’ average age was 55.13±8.29. The subjects’ average body mass index (BMI) was 24.25±4.05 kg/m$^2$. The subjects’ average stroke onset was 6.60±3.20 weeks. There were 32 subjects (84.2%) with first stroke attack, 16 subjects with right right-sided hemiparesis and 22 subjects with left-side hemiparesis. There were 2 subjects used walking aids. There were 16 subjects with diabetes mellitus history, 36 with hypertension history, 11 with smoking history and 1 with alcoholic history. All subjects had lower extremity muscle strength ≥3. Male subjects’ muscle motor strength of paretic lower limb was better than female subjects after enhancement. 33 subjects (86.8%) were post-stroke patients who had first visitation to Medical Rehabilitation Unit of Dr. Soetomo Teaching Hospital, Surabaya, Indonesia and had not received rehabilitation therapy, while the rest 5 subjects (13.1%) had more than one visitations and received rehabilitation therapy.

**Results of TUG and 6-minute walking tests**

The results of functional mobility test using TUG test in 38 subjects showed average TUG time was 15.56±7.69 seconds, with longest and shortest TUG time were 37.38 seconds and 8.16 seconds, respectively (Table 1).

Association between cardiorespiratory fitness and functional mobility ability

Spearman’s correlation test showed a negative correlation between TUG time and $\text{VO}_2\text{max}$: TUG time correlated with age ($r = 0.387, p = 0.016$), while it had no correlation with onset ($r = 0.106, p = 0.525$) and BMI ($r = 0.183, p = 0.270$). $\text{VO}_2\text{max}$ did not correlate with age ($r = -0.168, p = 0.313$), onset ($r = -0.277, p = 0.092$) and BMI ($r = 0.158, p = 0.343$; Table 5).

**Discussion**

The study found that there is a correlation between cardiorespiratory fitness level and functional mobility ability in post-thrombotic infarct stroke patients. The higher the VO2\textsubscript{max} in 6-minute walking test, the lower the TUG score. Cardiorespiratory fitness decreased, VO2\textsubscript{max} <25.2 ml/kg/minute is associated with increased stroke risk and ischemic stroke, and this is a modifiable risk factor that requires training intervention for increased cardiorespiratory fitness \textsuperscript{17}. The average TUG time in subjects with average stroke onset of 6.60±3.20 weeks was 15.56±7.69 seconds, faster than the finding of Persson et al. They found TUG score of 17.0±11.0 seconds in the first-week test, slower than three-month evaluation (14.5±10.0 seconds) \textsuperscript{12}. The VO2\textsubscript{max} was measured using training test as a gold standard to assess cardiorespiratory fitness. Stroke patients have limitations in performing training test due to decreased strength and sensory impairment \textsuperscript{11}. Six-minute walking test is a submaximal test since patients determine their own walking speed. The test is performed in 100-feet track or around 30 meters in accordance with American Thoracic Society (ATS) guidelines \textsuperscript{20}. The study used 10-meter track since subjects in the study were subacute post-stroke patients who had not performed stress test. Therefore, emergency condition could be easily detected, and patients could be immediately treated. Pohl et al. in their study used 10-meter track for initial screening before conducting 6-minute walking test \textsuperscript{21}.

The average VO2\textsubscript{max} was 10.62±2.31 ml/kg/minute, a little bit lower than the finding of Tang et al. (12.3±3.1 ml/kg/minute) \textsuperscript{11}. Pohl et al. in their study in 72 subjects found average distance obtained in 6-minute walking test was 215.8±91.6 meters in 73.3±26.8 days of onset \textsuperscript{21}, a little bit higher than the result found in the study (206±78.6 meters). Normal distance obtained in the 6-minute walking test was 593±57 meters for female and 638±44 meters for male \textsuperscript{22}. The study found a slightly lower distance than Pohl et al. since subjects in their study had received training program, either strength, balance or endurance in lower and upper limbs for 12 weeks \textsuperscript{16}. On the other hand, 86.8% of our subjects were post-stroke patients who first visited medical rehabilitation unit. Pohl et al. used 30-meter track, while we used 10-meter track that required a lot of time for turning.

Cardiorespiratory fitness varies from age, sex, physical activity level, body composition and chronic or disability presence \textsuperscript{14}. In this study, VO2\textsubscript{max} obtained from 6-minute walking test was not significantly affected by age, stroke onset, hemiparesis and BMI. Subjects were relatively young (55.13±8.29), hence there was no decreased muscle mass and strength that subsequently shortened the distance. All subjects were in subacute phase. Our findings were not affected by BMI since 47.4% of all subjects had normal BMI. Subjects with obesity had a shorter distance. Nevertheless, VO2\textsubscript{max} was
significantly different by sex since male had a longer distance compared to female. Male was higher than female, therefore they had a wider stride length when walking. VO2max was significantly different due to hypertension risk factor, DM and smoking habit. In this study, blood pressure in subjects with hypertension history was controlled by drugs. Subjects in this study were dominated by non-DM patients (57.9%) and non-smokers (71.1%). Dourado et al. found arterial hypertension and smoking significantly affected distance during 6-minute walking test. The study found around 40% of post-stroke cardiorespiratory fitness decreased compared to normal people.

The study found significant TUG time and age differences between male and female subjects (p = 0.038 and p = 0.016, respectively). It might be due to male subjects (68.4%) were more than female subjects (31.6%), and male’s lower limb motoric improvement was better than female’s. Subjects aged <60 were 24 (63.2%). There was no decreased muscle mass, muscle strength and coordination in this age group. The study found no significant TUG time difference based on onset, BMI, hemiparesis side, DM history, hypertension and smoking. TUG score in the previous studies were affected by muscle strength, balance, coordination, spasticity and postural control anticipation. Ng et al. found a negative correlation between walking speed and TUG score at a comfortable pace, even though TUG test is a series of movements and commands requiring balance control of muscle strength and coordination.

In this study, post-stroke patient’s TUG time was longer than healthy subject. It indicated decreased functional mobility ability in post-stroke patients, in which subjects are still independently capable of main transfer with or without aids, but are at risk of failing. Distance in 6-minute walking test is used to calculate VO2max as it reflects a person’s cardiorespiratory fitness level. In this study, VO2max was negatively correlated with TUG time. The longer the distance, the larger the VO2max and it shows better cardiorespiratory fitness. The shorter the TUG time, the better the mobility status. Therefore, the higher the VO2max, the shorter the TUG time. It indicates that subject with better cardiorespiratory fitness level has better functional mobility.

**Conclusion**

The study showed a significant correlation between cardiorespiratory fitness level and functional mobility ability in post-thrombotic infarct stroke patients. The higher the VO2max in 6-minute walking test, the lower the TUG score.

The Early Detection in Gestational Diabetes Mellitus at Indonesia Primary Health Care

Erni Rosita Dewi1, Budi Prasetyo2, Muhammad Ardian Cahya Laksana2, Hermanto Tri Joewono2, Ivon Diah Wittiartika1

1School of Midwifery, Faculty of Medicine, Universitas Airlangga, 2 Department of Obstetric Gynecology, Faculty of Medicine, Universitas Airlangga

Abstract

Background: Gestational diabetes mellitus (GDM) is diabetes that is first diagnosed during pregnancy. Uncontrolled GDM or late found can increase mortality for both mother and baby. Not only bad medical conditions, but also it can decline the community productivity, affect socio-economic and increasing financial health. Early detection of GDM is crucial to be implemented by providers, especially in the primary health care.

Objective: to determine the framework of early detection in gestational diabetes mellitus at primary health care

Methods: The method used is a literature review, which was published in 2008-2018. The literature were collected using some keywords such as “detection”, “gestational diabetes mellitus”, and “primary health care” using PubMed and another electronic journal website. Furthermore, the findings were filtered based on our inclusion criteria and analyzed qualitatively.

Results: Early detection of GDM in primary health care with risk factor assessment (age of pregnant women ≥ 35 years, some of bad history namely GDM in previous pregnancies, anti-diabetic drug use, diabetes mellitus in the family, congenital of infants, IUFD, preeclampsia, macrosomia, blood pressure examination, calculation of body mass index and random blood sugar examination). Furthermore, early detection of GDM is carried out by examining blood glucose accompanied by the provision of appropriate glucose solution interventions (OGCT and OGTT).

Conclusion: primary health care can take more action in early detection of GDM through quality antenatal care, which can be done by applying the framework of early detection in gestational diabetes mellitus.

Keywords: Early detection, gestational diabetes mellitus, primary health care

Introduction

GDM is a glucose tolerance disorder that was first discovered during pregnancy, this condition occurs in a woman who has never been diagnosed with diabetes then shows high glucose levels during pregnancy1. GDM begins to be diagnosed at gestational age above 20 weeks2. The prevalence of GDM in Indonesia is around 14% of the total number of pregnancies, while the number of undiagnosed or diagnosed GDMs is around 10-25% of the total cases handled, this number is certainly quite large and needs to be better managed. Uncontrolled diabetes mellitus during pregnancy can increase mortality and morbidity for both mother and baby. Abortion can occur in the mother, preeclampsia, polyhydramnios, labor trauma and other complications such as diabetic retinopathy, diabetic nephropathy. In

DOI Number: 10.37506/ijfmt.v14i2.3146
infants can occur cardiac abnormalities, abnormalities of the central nervous system, premature, macrosomia, brachial nerve damage, respiratory distress syndrome, jaundice, hypoglycemia, hypocalcemia and fetal death.

At the long-term risks accepted are obesity, impaired permanent glucose tolerance (DM type 2) and low intelligence whether there are mothers or babies born. Antenatal care is one of the interventions recommended to prevent maternal and infant mortality and morbidity worldwide, including in the effort to detect and treat high risk cases. Early diagnosis and detection are the key to successful management of GDM in order to achieve improved quality of life for mothers and infants.

The implementation of antenatal care in health facilities so far refers to the minimum standard elements of 10T antenatal care, namely (1) weight measurement and height measurement (2) blood pressure measurement (3) measurement of Upper Arm Circumference (LILA) (4) height measurement uterine crest (fundus uteri) (5) determination of tetanus immunization status and administration of tetanus toxoid immunization according to immunization status (6) Administration of blood tablets at least 90 tablets during pregnancy (7) Determination of fetal presentation and fetal heart rate (FHR) (8) Implementation conversation (interpersonal communication and counseling, including family planning) (9) Simple laboratory test services, minimal blood hemoglobin (Hb) test, urine protein examination and blood type examination (if it has never been done before) (10) Case management.

In the integrated ANC program, every pregnant woman receives at least one more comprehensive service, one of which is for laboratory examinations. However, the implementation of existing laboratory tests is not effective enough for early detection of GDM. In many of the findings of the integrated ANC laboratory results, the components examined focus on hemoglobin, blood group, hepatitis B, sexual transmitted illness (HIV and syphilis), urine protein and urine reduction. On examination of urine reduction results positive or negative. When linked to the gold standard for early detection of GDM (blood glucose testing by providing glucose solution interventions to produce results in the form of numbers), then the routine antenatal implementation has not been effective enough and has not been focused on diagnosing GDM. The routine antenatal examination refers more to the efforts of early detection of preeclampsia, anemia, sexually transmitted diseases, risk of bleeding and others. Based on the description above, the aim of this study is to determine the framework of early detection in gestational diabetes mellitus at primary health care.

**Method**

The method used is a literature review through an electronic search of published literature in 2008-2018. The literatures are available in soft copies; such as PDF journals and direct reading from online journal articles scientifically proven.

The literature were collected using some keywords such as “detection”, “gestational diabetes mellitus”, and “primary health care” using PubMed and another electronic journal website. Furthermore, the findings were filtered based on our inclusion criteria and analyzed qualitatively.

The inclusion criteria of the studies consists of: (1) the definition of gestational diabetes mellitus (2) the study explained the risk factor and the management of gestational diabetes mellitus (3) the studies showed the outcome of implementation the management of gestational diabetes mellitus (4) the sampling of studies, data collection and analysis are clearly described and correlating to the research questions (5) the studies included in the review were restricted to English and Indonesia languages. The result of the studies was explained qualitatively provided in the result and discussion section.

**Result and Discussion**

Based on the regulation of the Minister of Health of the Republic of Indonesia in 2014s, routine laboratory tests must be performed on every pregnant woman, namely blood type, blood hemoglobin, and specific examination of endemic/epidemic areas (malaria, HIV, etc.). While a special laboratory examination is another laboratory examination carried out on indications. Pregnant women suspected of having diabetes mellitus should have a blood sugar check during their pregnancy at least once in the first trimester, once in the second trimester, and once in the third trimester.

Gestational Diabetes Mellitus is diabetes that first arises (first onset) or is diagnosed (first recognition) during pregnancy. More than half of women with GDM eventually develop overt diabetes within the next 20 years, and there is increasing evidence of long-term
complications including obesity and diabetes in offspring caused by GDM. At more than 26 weeks’ gestation, the body produces several hormones, such as estrogen, progesterone, cortisol and HPL (Human Placental Lactogen) which have insulin resistance effects. The function of this hormonal effect is to increase nutrition and sugar in blood circulation so that it helps the growth of the fetus. As compensation, the body produces more insulin. GDM occurs when pregnant women cannot produce enough insulin or body cells are more resistant to insulin. 

GDM has no specific signs and symptoms. Pregnant women with GDM almost never give a complaint. This disease is considered mild, without any real symptoms but has a major influence on maternal and fetal morbidity both short and long term, so early detection is needed to improve the well-being of the mother and fetus both during pregnancy and after pregnancy.

Early detection of GDM is done universally in all pregnant women, not elective screening. This means conducting an examination without looking at risk factors. If only those who have risk factors are examined, then almost 50% of GDM cases will pass undiagnosed. But in the study of Trauffer (2008) recommends screening or early detection at high risk because at low risk only 0.9% suffer from GDM, at high risk around 4-7%. However, the gold standard set is for all pregnant women aged 24-28 weeks once with a 50 gram load and if the next 1 hour plasma glucose is more or equal to 130 or 140 followed by a 100 gram TTGO.

In addition to examining glucose tolerance, another screening for GDM is the assessment of risk factors. Assessments that need to be carried out include:

a. Pregnant women age ≥ 35 years

Pregnancy at too old age is included in the criteria of high risk pregnancy, death and maternal complications increased 9-fold in pregnant women aged ≥35 years. The incidence of GDM tends to be high in old age which is expected due to the influence of the aging process and damage to vessel endothelial progressive blood.

b. History of diabetes GDM in a previous pregnancy

The risk will increase in the history of pregnant women who have been exposed to GDM in previous pregnancies.

c. History of diabetes mellitus/ use of OAD/ special diet

In the history taking, there is a history of diabetes mellitus that is being suffered by the mother or the use of certain diets or the use of anti-diabetic drugs (OAD) or routine use of insulin can lead to a diagnosis of GDM so that further referral can be made immediately.

d. Family history of diabetes mellitus

Diabetes mellitus tends to be inherited or inherited, and is not transmitted. Genetic factors provide a greater chance of suffering from diabetes mellitus compared to family members who do not suffer from diabetes mellitus. If there are parents or siblings who suffer from diabetes mellitus, then the person has a 40% risk of suffering from diabetes mellitus.

e. History of congenital defects

The incidence of major fetal malformations increased by 5% in women with diabetes. Lack of diabetes control during pregnancy increases malformations in the fetus. One of them is heart defects is that oxidative stress triggered by hyperglycemia inhibits the migration of heart-filled cysts. Women who exercise glucose control in preconception care can reduce the risk of congenital anomalies.

f. History of unborn fetus (IUFD)

This incident is related to fetal metabolic disorders. Ketoacidosis can cause fetal death. In addition, mothers with GDM can find a placenta experiencing hydrops due to chorion villus edema that is triggered by osmotic pressure which causes disruption of oxygen delivery to the fetus.

g. History of preeclampsia

The incidence of preeclampsia has a relationship with glucose control during pregnancy especially at HbA1c levels.
h. History of childbirth (> 4000 gram)

The incidence of macrosomia increases significantly if the mother’s glucose concentration exceeds 130 mg/dl. The distribution of birth weight of infants of diabetic mellitus mothers always tends to be higher than that of infants of normal pregnancy.

i. Blood pressure check: hypertension results (≥ 140/90 mmHg)

Pregnant women with diabetes mellitus can trigger hypertension and most often force labor less than 8 months17.

j. Calculation of Body Mass Index (BMI)

BMI calculation results are said to be obese if ≥30 kg/m2. Obese women have a 1.7 times higher risk of giving birth to macrosomia babies compared to women who have normal weight Gestational diabetes mellitus is found to be higher in women with a higher BMI and higher body weight before pregnancy. This shows that many groups of mothers giving birth to macrosomia have risk factors for giving birth to macrosomia babies and suffering from gestational diabetes mellitus17.

k. Random blood sugar (GDA) check

The results of blood sugar can indicate the condition of glucose intolerance. The normal value for random or temporal blood sugar examination results is <200 mg/dl. This finding can be confirmed by the discovery of the classic trias of diabetes (polyuria, polydipsia, polyphagia)17.

In the framework of early detection of gestational diabetes mellitus above starting from pregnant women making the first ANC visit to primary health care, a risk factor assessment that increases the incidence of GDM is carried out. Risk factor assessments are carried out for all visiting pregnant women, regardless of gestational age. If a midwife or other health worker discovers one of the risk factors above, the midwife needs to take further management, which is to make a referral or collaborate with other health workers who have the authority to provide care according to the needs of the pregnant woman. If the risk factor data is not obtained in the assessment, pregnant women will be given routine ANC services according to standards by the midwife.

Furthermore, at 24-28 weeks of pregnancy, midwives will conduct an OGCT (Oral Glucose Challenge Test) without prior fasting preparations. In this examination, pregnant women will be given a 50 gram glucose solution. Furthermore, after 1 hour of giving glucose solution, pregnant women will be tested for blood sugar. If the results of the examination >135 mg/dl, the mother will be advised for the next examination, namely TTGO / OGTT (Oral Glucose Tolerance Test). And if the result is <135mg/dl, pregnant women will be scheduled for routine ANC according to the schedule.

At the TTGO / OGTT (Oral Glucose Tolerance Test), pregnant women are asked to fast for 10 hours. Furthermore, the mother will be examined for fasting blood sugar (positive results, if: ≥ 95mg/dl). After checking fasting blood sugar, pregnant women are given 100 gram glucose solution. Furthermore blood sugar will be checked after administration of 100 gram glucose solution at 1 hour after administration (positive result, if: ≥ 180mg/dl), at 2 hours after administration (positive result, if: ≥ 155mg/dl) and 3 hours after administration (a positive result, if: ≥ 140mg/dl). The diagnosis of GDM is made if at least 2 of the TTGO / OGTT results are positive. If only 1 positive test results are found, then antenatal care is treated the same as GDM. If the five blood sugar tests in TTGO / OGTT are negative, pregnant women will be scheduled for routine ANC according to schedule.

The framework is expected to be a reference source for primary level health facilities in providing quality antenatal services, especially in the early detection of GDM without reducing elements or antenatal service standards set by the government (ANC 10 T program and integrated ANC).

**Conclusion**

Improving the quality of antenatal services, especially in the early detection of GDM, can be done in primary health facilities through implementing an early framework for GDM detection based on screening of risk factors and further examination management.

1Department of Radiology, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo Teaching Hospital, Universitas Airlangga, Surabaya, 60285 Indonesia

Abstract

Background: CT scan has become the imaging modality of choice in diagnosing appendicitis in unusual cases, replacing appendicogram with very little reliability. However, there is still an appendicogram demand in particular hospital in Indonesia.

Objectives: This study aimed to obtain information on lumen appendix filling pattern with multi slice Multislice computed tomography (MSCT) scan using oral contrast media in patients without clinical appendicitis. Thus, it is able to provide additional information in the appendicogram interpretation.

Method: This study was descriptive observational to 30 subjects selected by consecutive from April to June 2012. Subjects who underwent an abdominal MSCT scan using oral contrast media were analyzed descriptively by sex, age and lumen appendix filling pattern.

Results: 30% of patients were men and women by 70%. The most common age group is 51-60 years (50%). Appendix of non-filling of 56.6%, partial filling of 43.3%, and no full filling appendix was obtained.

Conclusion: Appendix filling as an indicator of the presence of appendicitis was not reliable in an abdominal MSCT scan using oral water soluble contrast, thus it needs to be considered when interpreting the appendicogram results/

Keywords: MSCT, oral contrast, appendix without clinical appendicitis

Introduction

The appendix is a dead end tubular structure that is an out pouching of the cecal tip on the posteromedial side 1. Appendicitis is one of the most common diseases in the emergency department and requires immediate surgical intervention. Typical cases have been diagnosed clinically and laboratories. Whereas, not typical cases especially in pediatric patients, parents and young women were required radiological assistance in making the diagnosis 2. Immediate and precise appendicitis treatment will reduce the risk of morbidity and mortality due to perforation and sepsis inflicted. There are various modalities in appendix imaging. Prior to the 1980s, barium appendix was still the main radiological method used for the diagnosis of acute appendicitis 3, however this modality was considered inaccurate. After 1990, CT scan was accepted as the primary imaging technology 4–6 for acute appendicitis due to visualization capabilities of the appendix, intestines and surrounding tissues 7.

Prior to 1997, surgeons agreed that 20% of appendectomy negative was still accepted because of high mortality in appendicitis coulson, however, it was unused any longer 8. Improvement in imaging technology resulted in CT scans capability to decrease negative appendectomy up to 3% 9. Therefore, Another result recommends CT scan as the diagnostic modality of choice for adult, pregnant and children. Appendix barium examination (appendicogram) is still obtained at Dr. Soetomo Teaching Hospital Surabaya. Therefore,
that is encouraging researchers to reexamine the pattern of oral contrast media fillings into the appendix lumen in patients without clinical appendicitis at Dr. Soetomo Teaching Hospital Surabaya. Observations of oral contrast media filling patterns into the appendix lumen in patients without clinical appendicitis were performed by using dilute oral water-soluble contrast and observed with Multislice Computed Tomography (MSCT) 16-slice abdominal scan. There have been no previous similar studies. Therefore, This study aimed to obtain information on lumen appendix filling pattern with multi slice Multislice Computed Tomography (MSCT) scan using oral contrast media in patients without clinical appendicitis. Thus, it is able to provide additional information in the appendicogram interpretation

**Method**

The subjects of the study were group of patients with MSCT 16 slice abdominal scans examination using oral contrast media at Radiology Unit of Integrated Diagnostic Center Building in Dr. Soetomo Teaching Hospital Surabaya from April to June 2012. The subjects were sampled using consecutive sampling that fulfilled the inclusion criteria (Patients with abdominal MSCT examinations using oral contrast media, oral contrast medium had reached cecum or ileocecal junction) and exclusion criteria (patients of post-appendectomy, patients with appendicitis (inflammatory or tumor), oral contrast media did not reach the cecum). Moreover, the subjects had signed informed consent.

This study was a descriptive research with the observational method to determine the pattern of appendix lumen filling in patients without clinical appendicitis that given oral contrast media in CT scan unit of radiology section at Dr. Soetomo Teaching Hospital Surabaya with a total sample of 30 subjects. Subjects who had fulfilled the inclusion and exclusion criteria consumed oral contrast media water soluble urography of 76% by 10 ml that diluted with 1200 ml of water, since 6-8 hours before the examination until prior to the MSCT abdominal examination. Contrast water soluble media was easier to fill the narrow lumen than barium.

**Results**

**Characteristics of Subjects**

We obtained 30 subjects consisting of 9 men (30%) and 21 women (70%). This study obtained the distribution of the most common age group; 51-60 by 15 subjects (50%), followed by the age group of 31-40 as many as 5 subjects (16.6%), age group of 11-20 years by 4 subjects (13.3%), and age group of 21-30, 41-50, and 61-70 each consisted by 2 subjects (6.6%). The observations of the 30 normal appendices showed that nothing was filled with full oral contrast media. The most common appendix was non-filled by 17 subjects (56.6%) with the distribution based on the age of the subjects. The remaining 13 subjects (43.3%) experienced partial filling with the distribution based on the age of the subjects.

**Discussion**

No full-filled appendix was found in the 30 subjects. The partial filling appendix was 43.3% (13 subjects) and the remaining of 56.6% (17 subjects) was non-filling appendix. In the non-filling appendix (17 subjects), there were 58.8% (10 subjects) in the age group of 51-60. Followed by age group of 11-20 by 11.7% (2 subjects), 31-40 by 11.7% (2 subjects), and 21-30, 41-50, and 61-70 were consisted of 1 subject (5.8%) respectively. This phenomenon showed that not all appendices were normal full-filling following by oral contrast administration. These results were in accordance with previous study that mentioned that oral contrast was not required in appendicitis diagnosis because it was unreliable to fill the normal appendix, and also non-filling appendix was not indicated an appendix obstruction. A study by Schisgall using barium swallow in children suspected of acute appendicitis reported that 92% of partial filling and 58% of non-
visualized (non-filling) were normal appendices. A study by Sakover using barium enema in the normal appendix reported that there were 5.5% of partial filling, 12.5% of non-filling, and 21.7% appeared at the spot delay from 82% of full filling. Rice et al. mentioned that 5-10% of the normal appendix was not filled by barium. The results were in accordance with the theory that normal appendix lumen may contain contrast material, air or slightly fecal material. Thirty patients who underwent MSCT abdominal scan at the CT Unit in the Integrated Diagnostic Center Building Dr. Soetomo Teaching Hospital Surabaya were consisted of 30% male and 70% female with age range from 12 to 70 years old. Most common age group was 51-60 (50%), followed by age group of 31-40 (16.6%), 11-20 (13.3%) and the rest were evenly distributed in age group 21-30 years, 41-50 years, and 61-70 years of 6.6% respectively. This suggested that other imaging modalities with low radiation exposure will be selected at the age of the child and the reproductive age.

Schey mentioned that non-filling appendices might be due to their retro scale location. Sakover reported that the non-visualization of the appendix was related to the location of a true pelvic appendix or colitis was obtained in the right-sided colon. The absence of a full filling appendix in this study might be understandable because the normal peristaltic activity of the appendix will cause contrast in and out repeatedly. Therefore, when the picture was taken, there was no contrast filling or partially filled into the appendix lumen even though the contrast was in sufficient quantity in the cecum.

The presence of a small mucous flap covering the normal appendix orifice might functionally as a valve that allowed the appendix contents to flow out and prevented the contrast of the cecum from entering the appendix. The fact that the distal portion of the appendix might become obliterated in elderly and some might have fibrosis since birth. It should be considered as one of the causes of partial filling as well as non-filling in the normal appendix, which in this study, 50% of the sample was dominated by the age group of 51-60 (15 subjects). The ability of CT scans to visualize the appendix structure in more detail also allowed appendix filling assessment to be different compared to appendicograms. Because the appendicogram inaccurately represented the tip of the appendix, thus full filling of the appendicogram might appear as partial filling on the MSCT scan. Partial filling and non-filling might occur in normal appendices as examined using MSCT scans with oral water soluble contrast in which the ability to fill the very narrow lumen better than barium. The same conditions could occur in appendicograms that were currently being performed for appendicitis diagnostics. Meanwhile, the opinion that non-visualized/non-filling appendix with mass effect description as a pathognomonic sign for appendicitis could not be used as a reference because the mass effect might cause by the other factors such as ileitis, sesitis, small bowel obstruction, and pelvic inflammatory disease.

**Conclusion**

In MSCT abdominal scan using oral water soluble contrast, normal appendices also experienced partial filling and non-filling without any signs of obstruction, therefore the appendix lumen filling as an indicator of appendicitis was not reliable. The same results could occur in barium appendix examination (appendicogram), thus it needs to be considered when interpreting the results of appendicogram.

**Ethical Clearance:** The study has been approved by ethical committee in Dr. Soetomo Teaching Hospital Surabaya, Indonesia.

Study the Biological Efficiency of an Isolated Terpenic Compound from the Ether Petroleum Extract and the Trace Elements of the Plant Tribulusterrestris

Fatima S.Sabah Eman A.Mukhaifi

Department of chemistry Department of Biology, College of Science and University of Basrah College of Science and University of Basrah

Abstract

Many different compounds with a spread of biological properties and chemical structures are known from genus Tribulusterrestris together with steroid and terpinoid. In this study we tend to indicate the preliminary phytochemical analysis for rock oil ether extract and isolated compound. The results unveiled that there was no alkaloids, supermolecule , glycosides, saponins and tannic acid in petroleum ether however contain stereo and terpinoid. The isolated compound contained solely terpinoid compound. attention procedure was last this compounds. the FTIR qualitative analysis knowledge of isolated compound showed discovered absorptions signal . ultraviolet illumination spectrum showed most absorption at 220 nm due to $\pi \rightarrow \pi^*$ transition that is taken into account as characteristic feature of the unsaturated covalent bond. The concentration of the weather analyzed during this study decrease within the order Fe>Ca>Cu>Zn>Cr. important totally different among microorganism toward T. terrestris oil with p<0.05 and LSD 15.4 ,highest MIC by E.coli about 50 mm in 100% concentration of T. terrestris oil compared with control.

Keywords: Tribulusterrestris, Petroleum ether Extract, Infrared, UV-visible spectroscopy and Antibacterial

Introduction

Puncture tracheophyte genus Tribulusterrestris a spermatophyte within the rosid dicot family, native to heat temperate and tropical regions of the southern Europe and Southern Asia. This plant contain saponins ,flavonoid, sterols fatty oils ,terpenoids and metallic element salts.T. terrestris utilized in people medicines as a tonic, aphrodisiac, palliative, astringent, stomachic, antihypertensive drug, diuretic, lithotrithic, and urinary disinfectant. The edible fruit of the herb is extremely effective in most of the gu tract disorders. it’s a significant constituent of GokshuradiGuggul, a potent Ayurvedic medication wont to support correct functioning of the gu tract and to get rid of the urinary stones[1]. T. terrestris has been used for hundreds of years in writing to treat impotence, genital diseases, and sexual infirmity. In Bulgaria, the plant is employed as a people medication for treating impotence. additionally to all or any these applications, the Ayurvedic accumulation of Republic of India attributes cardiotonic properties to the foundation and fruit. In ancient Chinese drugs, the fruits were used for treatment of eye hassle, edema, abdominal distension, emission, morbid mucus, and sexual disfunction. T. terrestris represented as a extremely valuable drug within the Shern-Nong accumulation (the oldest well-known pharmacologic add China) in restoring the depressed liver, for treatment of fullness within the chest, mastitis, flatulence, acute rubor, headache, and skin problem. In Unani drugs, T. terrestris is employed as drug, delicate laxative, and general tonic[2,3]. T. terrestris could be a yearling plant cosmopolitan within the Mediterranean and also the heat elements of Europe, Asia, USA, continent and Australia [4]. This plant is employed in ancient drugs in China, India, Iraq, Iran, etc. Studies show that T. terrestris contains steroids, saponins, flavonoids, alkaloids, unsaturated fatty acids, vitamins, tannins, resins, potassium, nitrate, aminoalkanoic acid and aminoalkanoic acid [5]. This plant has several medical effects including: antimicrobial, medicinal drug, antioxidant and anti-toxic. The plant is additionally used for the treatment of vas diseases, cancers, metabolic process diseases and joint pain [6], the utilization of T. terrestris extract will increase body’s ability to create muscle mass and strength and additionally improves circulation and gas transfer [7]. future use of T. terrestris causes dilatation
of the vessels and improves coronary arteries while not facet effects \cite{8}.

Trybstan is one in every of the T. terrestris compounds that will increase concupiscence and counteract of cold-natured physiological state and biological time disorders. T. terrestris extract will increase sexual efficiency in men by increasing level of free androgenic hormone and control the number of sex hormone, progestogen and pregnenolone\cite{9}. Further, the employment of the plant in ancient drugs in Asian country and China is to treat sexual pathology and increase concupiscence by increasing the amount of androgenic hormone and gonadotropic hormone. T. terrestris had no impact on the organs like the prostate, seminal vesicles, womb and duct that are sensitive to system \cite{10}. On the opposite hand, using T. terrestris with alternative herbs as well as ginseng, soy and berries improves erectile and sexual behavior. Finally, chemical derived from T. terrestris had a big impact in reducing liquid body substance aldohexose levels that might introduce the plant as a potent healthful plant for the treatment of polygenic disorder \cite{11}.

**Materials and Method**

**Plant Material:** Puncture vine \textit{T. terrestris} classified from the local markets \textit{\textbackslash} College of Science Basrah University, the dried fruits cleaned and blended by using (Electrical Mill blender). The powder of fruits kept until required.

**chemical and Materials** : All chemicals were of purity analytical grades : hydrochloric acid (analar), n-hexane, ethyl acetate and petroleum ether from (BDH); acetone, 95% ethanol from Baghdad factory for drugs and cosmetics (Whatmann 540) filter paper.

**Petroleum ether Extract:** 20,000 gm of \textit{T. terrestris} powder was added to a thimble and then placed in a Soxhlet extractor. Heat was applied to a round bottom flask which contain petroleum ether solvent was placed at the base of the Soxhlet extractor. The extract was concentrated using a rotary evaporator (PuchiRotavapor-Re) then dried at room temperature (12), the weight of brown oil was 3.967 gm.

**Isolation methods with Column Chromatography**

Petroleum ether extract (2,000gm) was subjected to column chromatography on silica gel (73–240mesh – Merck) packed and eluted with mixture of n-Hexane: ethyl acetate(7:3).

**Thin Layer Chromatography**

(TLC) were carried out on the petroleum ether extract and isolated compound using n-Hexane: ethyl acetate(7:3)

**Preliminary Qualitative Tests**

Preliminary tests were carried out on the petroleum ether extract and isolated compound

**Infrared and UV- visible spectroscopy**

IR spectra using PyE-UNICAM-30300S Infra red spectrophotometer and Uv-visible spectra on JASCO UV \textit{T. terrestris} was weighted and digested in (5:1) mixture of nitric acid and perchloric acid (10 ml). After digestion few drops of concentrated HCl added .The solution was diluted with distilled deionized water . The dilute filtrate solution was used for analysis of minerals by atomic absorption spectrophotometer \cite{13}.

**Antibacterial to isolated compound**

It has been getting negative and positive Cram bacteria from the Department of Life Sciences / College of Science / University of Basra

**Determination of minimum inhibition concentration of \textit{T. terrestris} oil**

1ml inoculum of bacteria was added to 100 ml of nutrient broth and then incubated at 30°C for 24h and then dilution of bacterial solution with Physiological Normal saline compared with the standard test tube McFarland for 108 cells / ml of stuck bacterial and inoculated into nutrient agar , supplemented with different concentrations of the compound chemical (100%, 75%, 50%, 25%, 12.5%), using L-shap to work hole by puller diameter 6 mm, and then incubated dishes in the incubator for 37 º. Then measured the diameter of the inhibition and compared with the control \cite{14}.

**Result and Discussion**

Herbal medication was practiced in several components of the planet, thanks to its low value and affordability. Qualitative phytochemical analysis of various components of the plants and distinguishing its compounds helps practitioners in treating diseases. It conjointly helps researchers in synthesizing new chemical substances. Puncture vascular plant T. terrestris
L. could be a healthful plant wide used as a drug provider in pharmaceutical business [15]. Table (1) indicate the preliminary phytochemical analysis for fossil oil etherextract and isolated compound. The results discovered that there was no alkaloids, sugar, glycosides, saponins and phenol in petroleum ether however contain, steroid and terpinoid. The isolated compound contained solely terpinoid compound. tender loving care procedure was endure this compounds and also the results were shown in table (2) as refer[16].

Determination of minimum inhibition concentration of *Tribulus terrestris* oil

Significant different among bacterial toward *T. terrestris* oil with *p*≤0.05 and LSD 15.4 as shown. Gram negative bacteria showed high significant difference in inhibition to *T. terrestris* oil, due to differences between gram positive and gram negative bacteria include the thickness of the cell membrane, that is just about twenty to thirty nanometers thick in gram positive and eight to twelve nanometers thick in Gram negative; the number of supermolecule within the cell walls; and also the conjugated protein content, that is low in gram positive bacterium and high in gram negative. All bacterium contain a layer of peptidoglycan in their cell membrane, however the distinction between gram positive and gram negative bacterium is that Gram negative contains a skinny layer of peptidoglycan placed between 2 supermolecule layers this is often what provides Gram negative bacteria a sensitive to matter result compared gram positive bacteria[18].

From the results in table (6) highest MIC by *E. coli* about 50 mm in 100% concentration of *T. terrestris* oil compared with control. *Staphylococcus aureus* and *Bacillus cereus* were showed simple difference in MIC compared with control and showed differential and specific MIC of chemical compound impact of the growth of bacteria used to study and this showed that the impactiveness of biological or poisonous substance plant adversely have an effect on the physiology of microorganism because it contains terpenoids vehicles have substance to the expansion of bacteria effect through its impact on the method of the article organic phenomenon and so its impact on the composition of proteins contribute to the formation of necessary enzymes within the metabolism[19].

Medico-legal Significance of Diatoms Detection in Different Organs of Drowning Victims

Haidar N. Hussein\textsuperscript{1}, Nabeel G. Hashim\textsuperscript{2}, Niran M. Ahmed\textsuperscript{3}

\textsuperscript{1}Ministry of Health, \textsuperscript{2}Medico-Legal Directorate, \textsuperscript{3}Assistant Prof. Department of Pathology and Forensic Medicine / College of Medicine / University of Baghdad, \textsuperscript{4}M.B.Ch.B., Forensic Diploma / Medico-legal Directorate in Baghdad

Abstract

Background: Drowning is a main universal community health problem & In Medico-Legal Aspect the autopsy diagnosis of drowning presents one of the major problems especially when there is delay in recovering the victim from water. This study concentrates on the significance of diatoms detection in different organs to reach more accurate diagnosis of drowning.

Objective: To determine the diagnostic features of drowning depending on detection of diatoms in deep tissues of drowning victims.

Methods: This study was performed at Medico-legal Directorate (M.L.D.) in Baghdad for (12) months within the period from 1/1/2018-31/12/2018. Full proper autopsy including external and internal examination of the body for all cases was performed, after obtaining complete medico-legal history, in addition to diatoms detection in different organs of drowning victims to determine the cause of the death as due to drowning.

Results: The study included (60) cases, (52) male and (8) female with their ages ranged between (15-44 years old) for male, while ages ranged between (1-44 years old) for females. Drowning was the cause of death in all cases. Among the most important results of this study is the presence of diatoms in the different organs of the drowning cases. The diatoms were found in the lung in all drowning cases (100%), and found in other organs in a percentage that increased with the duration of immersion.

Conclusion: Drowning is the 10\textsuperscript{th} cause of violent deaths in Baghdad. And important point in the diagnosis of drowning by detection of diatoms in different organs of drowning cases and pennate diatoms was common type in Iraqi waters and also study showed Aulacasiera granulata sp. common in Iraq.

Keywords: Medico-legal, diatoms detection, Drowning.

Introduction and Literature Review

Drowning is the process of experiencing respiratory impairment from submersion / immersion in liquid as stated by WHO. (Van, et al, 2005; Joost, et al, 2016) In Medico-legal view drowning is a type of asphyxia due to aspiration of fluid either water, milk, oil ...etc instead of air following immersion of whole body or nose and mouth under the level of fluid. (Hussein, 1999; Hassan, 1980; Ali, 1976; Al-Jabri, 2000). In drowning there is relation between liquid and air junction at the entrance of the airway prevents breathing air. (Idris, et al, 2003) Drowning could be considered as a mixture of mechanical presence of water within the respiratory system (mechanical asphyxia) with liquid and electrolyte changes depending on the medium (either sea or fresh water) in which immersion has occurred. (Simpson, 2011)
Autopsy Signs include those of immersion and drowning signs. Immersion signs are Maceration of the skin, becomes wrinkled, pale and wet so-called ‘washerwoman’s skin’. Cutis anserina is a common sign in immersed bodies but is connected to cold rather than warm water and cause a generalized pimpling of the skin. (Knight, 2004)

The hypostasis of bodies is frequently pink, this color is caused by the presence of unreduced oxyhemoglobin in the superficial blood vessels, but has no diagnostic value. (Joost, et al, 2016; Knight, 2004)

Mud, coal-slurry, oil, silt or sand present on the body, in addition to other artefacts such as seaweed, waterweed, algae. Mud may be adherent to the whole-body surface and clothing. Sand may be found deep in the respiratory passages and stomach, especially if the body has been rolled by the waves on a beach. But deep penetration is not sign of live aspiration. (Knight, 2004)

Other features include contraction of scrotum, and algae growth on the skin. (Knight, 2004; Roll, 2004; Nandy, 1996)

Drowning signs include froth in the air passages as a positive sign in fresh bodies. Froth is also seen around mouth and nostrils. (Knight, 2004)

Froth also observed in epilepsy, electrical shock, drug intoxication and cardiogenic pulmonary edema. (Simpson, 2011; Forens, et al, 1998)

The most important organ to observed the cause of death in drowning are lungs. They are distended brick red in color, with signs of emphysema. (Knight, 2004; Hallery, 2003)

Miscellaneous signs in drowning include bloody or watery fluid in the intracranial sinuses, engorgement of solid organs, reduced weight of the spleen, Tardieu spot on organ and muscular hemorrhages in the neck. (Simpson, 2011)

Cadaveric spasm is a positive sign and may be see in one or both hands. There may be grass, herbs, or gravel in the fist of the victim. (Simpson, 2011; Knight, 2004)

Diatoms are unicellular algae, eukaryotic microorganism measuring from 5 micron -3 mm (Bate, 2004), belong to the class of Bacillariophyceae which includes in excess of (15 000) species living in sea & fresh water. The skeleton of these algae is called a frustule which is constituted by two valves fitting together to enclose the cytoplasm (Ludes et al., 2003), and made of hard silica. Due to this hard smilacaceous skeleton, diatoms can be recovered from putrefied or injured tissues due to enzymatic or acid digestion. (Ludes, et al, 1999)

Diatoms are non-motile. (Crawford, et al, 1990) Diatoms are responsible for about 20–25% of global oxygen production. (Smolt, et al, 2010) Not all diatoms are able to penetrate the body organs through the lung cavity. The diatoms which can penetrate through this capillary network are called Drowning Associated Diatoms (DAD). (Modell, et al, 1999) A medicolegal & algological collaboration in lasting several years aimed at developing methods for dealing with cases found in water where the circumstances are not clear. (Lunetta, 2005) The specimens for diatom detection are taken from bone marrow, sphenoidal sinus aspirate, lung, liver, both kidneys, and brain. About 25gm of specimens to be taken without any contamination and collected in a clean glass bottle. (Pollanen, 1998) The acid resistant extracted material is isolated from specimens with some water from the drowning medium and would be examined microscopically to detect diatoms. (Lunetta, 2005)

Diatom test is used for diagnosis of drowning is based on the present diatoms in the medium where drowning had taken place. The inhaled water enters the alveolar spaces of lungs and penetrates from the alveoli into the blood circulation, thus diatoms will be transported to different organs of body. The diatoms found inside the organs of drowned victim is a conclusive evidence to support the diagnosis of death by drowning. Diatoms are classified as Class Bacillariophyceae that is divided into two Orders. The Centric (Biddulphiales) which have valve striae arranged basically in relation to a point, an annulus or a central areola and tend to appear radially symmetrical as in figure (1). The Pennates (Bacillariales), which have valve striae arranged in relation to a line and tend to appear bilaterally symmetrical as in figure (2), their silica-based skeletons do not readily decay, and they can sometimes be detected even in heavily decomposed bodies. (Kaushik, 2017)
This study is aimed to determine the diagnostic significance of diatoms detection in different internal organs of victims in drowning cases.

**Subjects and Methods:**

**Site and Duration:** Medico-legal Directorate (M.L.D.) of Baghdad for one year duration from 1/1/2018 till 31/12/2018.

**Subjects:** sixty victims of drowning. Inclusion criteria: Cases with circumstantial evidence favoring drowning death. Exclusion criteria: Decomposition.

**Method**

Full forensic autopsy consisting of external examination including that of the clothes and external signs followed by internal examination after taking history of the incident from the autopsy request form written by the police authority and from the relatives of the victims. Tissue samples were taken from different organs for detection of diatoms type and species, and this includes:

1. Taking specimens (about 1 gram) from lungs, heart, liver, kidneys and brain.
2. Putting them in a mixture of ethanol alcohol (20%) and (80%) distilled water.
3. Taking bone pieces from sternum or femurs and washing them in distilled water. Longitudinal sections to be made using a clean band saw, then taking sample of (1 g) to be placed into a mixture of ethanol alcohol (20%) and (80%) distilled water.
4. Keeping samples in a cool atmosphere (refrigerator).
5. Sending samples to the toxicology lab. to investigate them for diatoms.

**Laboratory investigation for Diatoms:**

One gram from each organs are taken and placed in glass bake. Sulphuric acid diluted with distilled water (30%, 70%) is added until the volume is twice that of the original sample. The sample then will be placed at room temperature over night to dissolve the organic matter. Sulphuric acid removes resistant dirts In this method no foaming will be produced. After that centrifugation will be done in test tube with (4000) rpm for (10) min. The supernatant will be discarded and sediment washed several times by distilled water. The previous process are repeated (3 – 4) times. From each sample (100) microliter is taken, spread on a surface of slide and dried in oven at (70 - 90°C). The slides are examined under light microscope (Novel type). The diatoms were identified according to morphology & species. Diatoms resist putrefaction, so diatom test is valuable even if the decomposition is advanced. Diatom test is negative in dead bodies thrown in water and in dry drowning. In diatom examination, the control water samples must be used for comparison purpose. Standard diatom samples can be preserved on slides and can be used as standards for comparison purpose. The test is positive if minimum of (20) diatoms are identified in each (100 µl) of sediment extracted from lung sample and if more than (5) diatoms in each (100 µl) of sediment extracted from a tissue sample.
Results

The study included (60) cases, (52) male and (8) female with their ages ranged between (15-44 years old) for males, while ages ranged between (1-44 years old) for females. Drowning was the cause of death in all cases.

This study showed the presence of diatoms in different organs of the drowning victims. The diatoms were found in the lung in (100% = 60) of cases, in the liver in (41.7% = 25) of cases, in the kidney in (40% = 15) of cases, and there were no diatoms in bone marrow and brain (if the duration of immersion is about 30 minutes). Other results were obtained in other durations of immersion as shown in figure (3).

![Figure 3: Presence of diatoms in samples of different organs according to the duration of immersion in water.](image)

This study showed that there are two types of diatom in fresh water, the first is pennate diatom in a percent of about (75%) or in (45) cases. The second type is centric diatoms in a percent of (25%) or in (15) cases as in figure (4).

![Figure 4: Diatoms type in drowning cases.](image)
The Aulacasiera granulata sp. was the most common in fresh water in this study (in about 43.3% of cases =26). While Amoeba sp. was discovered in about (3.3%) or (2) cases as in Table (1). See also figure (5) & (6).

**Figure 6:** - Centric diatom, *Cyclotella* sp. x 400
Discussion

In this study the diatoms were found in the lungs in all drowning’s victims if the period of immersion is about 30 minutes as in Figure(3) because the lungs are the first invaded by water in drowning. While in other organs, such as the liver, kidneys, brain and bone marrow the presence and percentage of diatoms varies according to the duration of immersion in water. Those results agrees with an Indian study. (Kaushik, 2017)

The study also showed the presence of diatoms in the body organs of the drowning victims in all cases due to the fact that the person was alive during drowning and he inhaled water containing diatoms that moved to various organs of the body, so diatoms detection in samples taken from different organs of victims especially those other than lung and stomach are very helpful in diagnosis of drowning as it is a challenge in forensic practice. (Robert; Stemberg, 2009)

The Pennate type of diatoms was commoner than the centric in this study. The commonest species respectively were Aulacasiera granulata sp., Cyclotella sp., Nitzschia filiforms sp., Gurosigma sp., Amoeba sp., were found to be frequent respectively in Iraqi water Table(1) in agreement with the above mentioned Indian study. (Kaushik, 2017)

The detection of diatoms in the lungs alone (Found in all cases in this study) is also helpful in the diagnosis of drowning. The result that was also found in a study from srilanka. (Gunatilake, 2010)

Conclusion

Diatoms detection in samples from lung and different other internal organs of drowning victims are very helpful in the diagnosis of drowning cases in addition to the traditional external and internal findings. Diatoms were present in the lung in all cases of drowning, while diatoms detection in other organs was in relation with the period of immersion of the victim.

Diatoms of Pennate type specially that of Aulacasiera granulata sp. was the most common in Iraq.

Evaluation of Nurses’ Knowledge and Attitudes toward Pain Management at Baghdad Teaching Hospitals

Haider M. Majeed¹, Ahmed F.Hassan¹, Raja I. Abid²
¹Assistant Instructor, ²Assistant Prof, Fundamentals of Nursing Department, College of Nursing-University of Baghdad

Abstract

Poorly managed or unmanaged pain is a problem that affects individuals, entire healthcare systems and societies throughout the world.

Objectives: To assess nurses’ knowledge and attitudes about patient’s pain management and to find out the relationship between knowledge, attitudes and their demographical characteristic.

Methodology: A descriptive cross sectional design study was carried out among 100 nurses working in male and female surgical wards, ICU, surgical ward, emergency and operating theatre of four teaching hospitals, Baghdad city. Census method was used to select the participants, in which all the nurses working in the selected wards who agreed to participate in the study were selected. Data was collected by distributing structured self-administered questionnaire which was a modified form of a standard tool, that is, Nurses’ Knowledge and Attitude Survey Regarding Pain (NKASRP) developed by Ferrel and McCaffery.

Results: The majority of the study were male who accounted for (63%) of the total participants while female constituted (37%). Most of participants (49%) were ages between (18 – 27) years old, a high percentage of them were have institute graduate (40%), (50%) of the nurses were single and the remainder was married. Majority of them (37%) were employee (1-5) years in employment in nursing. Majority of them (45%) were employee (1-5) years in intensive care unit, and finally majority of nurses (77%) have training session about patient’s pain management.

Conclusions: This study indicated that nurses’ have poor knowledge about pain management, as well as study indicated overall nurses’ have positive attitudes toward pain management.

Keywords: Evaluation, Nurses’, Knowledge, Attitudes, Pain Management

Introduction

Pain is defined as unpleasant sensory and emotional experience associated with actual or potential tissue damage or described in terms of such damage (¹). Chronic and acute pain differs in both mechanism and duration. Acute pain is a behavioral or biochemical cascade initiated by tissue injury (²). Pain is the major symptom that brings patients to the health care setting and is also the commonest symptom that hospitalized patients encounter in general and in surgical settings in particular. Pain management practices are the activities that are provided by nurses and other health care professionals to ensure that the pain is managed effectively (³). An examination of the prevalence of acute pain in hospitalized adult patients, by way of a systematic review, revealed a range of 37.7%-84.0% of patients reporting acute pain (⁴). Nurses are key contributors to inter professional pain management teams, and are involved in both the assessment and management of pain. It is important to understand pain knowledge and attitudes amongst nursing. Effective pain management is a vital component to quality patient care. Nurses play an essential role in implementing pain management.

Methodology

A descriptive cross sectional study design was applied for assessing knowledge and attitude of nurses on pain management. The study site was Baghdad teaching hospital, Kase AL- Harere teaching hospital, Al-Kindey teaching hospital and Al- Karama teaching hospital in Baghdad city. The selected wards for the study were male and female surgical wards, ICU, surgical ward, emergency and operating theatre. These wards were selected purposively as the nurses working in these areas have to deal more often with pain management. All the nurses working in the selected wards who agreed to participate in the study were selected. The total number of nurses working in the selected wards was 150. However, as few nurses refused to participate in the study, the total sample size was 100. Modified after literature review and discussion with the experts as well as considering the national context. The tool’s test-retest reliability was \( r = 0.85 \) and the internal consistency reliability was alpha \( r = 0.75 \). Each correct answer was scored 1 and there was no negative marking for wrong answer. The data was collected through distribution of self-administered questionnaire. The instrument comprised of pre-designed structured questionnaire which included demographic information, 22 multiple choice questions and 10 questions related to nurses’ attitude. The standard tool was used, that is, Nurses’ Knowledge and Attitude Survey Regarding Pain (NKASRP) by Ferrel and McCaffery (5). The data collected from 1st October 2018 to 15th July 2019. The data were analysed through statistical analysis was done using statistical package for social Sciences (SPSS v23.0).

Results

The majority of the participants were male (63%) of the total participants while female constituted (37%). (49%) of participants were ages between (18 – 27) years, majority of them were have institute graduate (40%), (50%) of the nurses were single and the remainder was married. (37%) were employee (1-5) years in nursing, (45%) were employee (1-5) years in ICU, and finally (77%) of nurses’ have training session about pain management.

Discussion

Throughout the course of the data analysis of the current study, the findings show the majority of the study were male who accounted for (63%) of the total participants while male constituted (37%). Most of the study participants (49%) were ages between 18 and 27 years old. A high percentage of them were institute graduate (40%), most of them (50%) were single, (37%) were for (1-5) years were employment in nursing, Majority of them (45%) were employee (1-5) years in surgical wards, and finally majority of nurses (77%) have training session about patient pain management.

These findings agreed with study done by Benimama, who reported that majority of participants 34 (39.5%) are aged between 31-35 years old; (22.1%) are ranged between (26-30) years and (18.6%) are aged between (36-40) years, majority of participants 37 (43%) have between (3-10) years of experience in nursing (5,6,7).

Fifty three questions assessed general knowledge of patient pain management. Overall (48.1%) of the participants answered knowledge questions correctly and (51.9%) responded “Incorrect answer”. All general question knowledge concerning method used to reduce or relieve patient pain through non-pharm logical and pharm logical intervention for patients suffering pain. The table (1) informs us that participants have scored 80% and above in only (4) questions. They scored between 50% and 79% in (5) questions and they scored less than 50% in thirteen questions. The highest score was 84%. The table also shows that (83%) knew that most accurate judge of the intensity of the patient’s pain, (84%) of nurses’ answers that pain should be assessed before and after administering drugs. Only (42%) knew...
that side effects of narcotics should be observed at least 30 minutes after administration. Ninety seven of them asked pain rating scale, is appropriate for patients to use to rate their he/she pain, low percent of participation answer A patient’s pain should be assessed at rest and during mobilization. It also show that (82%) of total population study reported that pain assessment is based on the patient’s behaviour and physiological changes. It also shows that (56%) knew the meaning of opioid addiction, (25%) knew that obstructive sleep apnea is the risk factor of opioid induced respiratory depression, only (25%) knew the analgesics for postoperative pain should initially be given around the clock on a fixed schedule. It shows that (54%) knew that then patient will request increased doses of pain medications because he/she is experiencing increased pain. (54%) knew that likely it is those pts. who develop pain already have an alcohol / drug abuse15 minute, (47%) knew the time to peak effect for morphine given orally is15 minute and (18%) knew the patients may sleep in spite although severe pain. These findings agreed with study done by Benimana who reported that the (79.1%) knew that respiratory depression can occur in patients receiving opioids, and (89.5%) knew that sedation assessment must be done during opioid pain management because of excessive sedation that precedes respiratory depression. Only 27(31.4%) knew that obstructive sleep apnea is the risk factor of opioid induced respiratory depression. It shows that (70.9%) knew that after the initial dose of opioid is given, other doses will be adjusted according to patient’s response. It also shows that 71(82.6%) knew the meaning of opioid addiction, and only (22.1%) knew the manifestations of physical dependence when there is abrupt discontinuation of an opioid (5) These findings are similar to Yosef as he found that pharmacological knowledge of anaesthetists regarding post-operative pain management in Ethiopia were poor yet being knowledgeable about pharmacology of opioid analgesics was prerequisite for all health care professionals in the effective pain management (8). Kizza, reported that most of participants had knowledge deficits and bad attitudinal beliefs which lead to ineffectual pain management among surgical patients (9). Another study done by Craig that found poor knowledge and bad attitudes of nurses towards pain management (10). The results are also supported by Shahriary et. al who found that oncology nurses lacked sufficient knowledge regarding pain management among cancer pain (11). The study was also supported by study done in Rwanda by Ufashingabire et al., who found that nurses working in ICU had poor knowledge and bad attitudes towards pain assessment and management (12).

This finding was in good agreement with that obtained by Tufekci et al. have identified knowledge deficits about pain management and health care professionals misconceptions about pain as the major challenge towards effective pain management. Among the challenges about pain management that are related to health care professionals, there is insufficient knowledge about pain assessment and management, therefore health care professionals need to have recognition of it in order to improve quality of care through pain management (13,14). The association between socio-demographic and nurses knowledge and attitudes score was explored. There are association between years of employment in nursing and studied sample knowledge at p value 0.05 and also illustrate that no relationship found with rest of studied variables. These findings are in line with study done by Irene, who reported that found no statistically significant evidence for a real difference between mean knowledge scores with respect to unit experience [6]. These findings are in line with study done by Indrah, the student t-test was employed to compare the associations between pain assessment practices and nurses demographic data namely years of experience as a registered nurse, years of experience as ICU and the qualifications (15).

Conclusions

This study demonstrate that, despite poor nurses’ knowledge regarding pain management, as well as study indicated overall nurses’ have positive attitudes toward pain management. We recommend to There is need to design and implement a continuous professional education program on pain and its assessment with special focus on methods of assessment, guidelines, how to use assessment tools, protocols and charts for proper documentation for critically ill.

The Effect of Empowerment Program on Participation of Mothers with Premature Infants Hospitalized in Neonatal Intensive Care Unit

Hania Sajadi¹, Golbahar Akhundzadeh², Hamid Hojjati³

¹Student, ²Assistant Professor, ³Assistant Professor, Department of Nursing Branch, Aliabad Katoul Islamic Azad University, Aliabad Katoul, Iran

Abstract

Introduction: The birth of a premature infant who needs to be admitted to neonatal intensive care unit from birth impedes early communication and participation of mother in her infant’s care. The purpose of this study was to determine the effect of empowerment program on the participation of mothers with premature infants admitted to neonatal intensive care unit.

Method: This study was a randomized clinical trial in 2018, which was conduct on a sample of mothers with premature infant who had randomly been divided into two intervention and control groups. The data collection tools were the Parents’ Participation Inventory designed by Melnick in 1994. Data were analyzed by descriptive statistics (tables, mean and standard deviation) and inferential statistics using SPSS-16 software.

Results: There was no significant difference in the level of mothers’ participation in the care of their infants between the two groups before the intervention (p = 0.45). But after the empowerment training program, the results showed that mothers’ participation in the intervention group (19.10 ± 3.09) was higher than the control group (16.8 ± 2.01), (p = 0.01).

Conclusion: The results of this study showed that implementation of empowerment training program increases mothers’ participation in the care of their premature infants. Early intervention and the use of written information along with the booklet will increase the mothers’ participation in the care of their infant.

Key words: Empowerment, Participation, Mothers of premature infants

Introduction

When the patient’s age is small events and various diseases threaten him(1, 2). Patient hospitalization poses challenges for the patient and the patient’s family(3). These events can cause more harm to the person. Infants who are born before 37 weeks from the last menstruation day are called premature infants that often weight less than 2500 grams(4). Premature or gestational age of less than 37 weeks is one of the most important health indicators in any society, and infant survival is directly related to gestational age and birth weight(5). Advances in technology and neonatal care have ensured the survival of pre-term infants and reduced their mortality rate(6, 7).

Admission of a newborn infant to a neonatal intensive care unit (NICU) is a frightening and stressful experience for parents (8, 9). Number of adverse outcomes including increased risk of mental problems such as anxiety, depression, traumatic stress disorder, poor parent-infant interactions, and emotional, behavioral and cognitive problems are associated with the premature birth. It has been well documented that, the presence of scary medical equipment in the neonatal intensive care

Birth of a premature infant is not only an emotional and stressful experience for parents, but also an evolutionary stage of life for infants. Understanding the process of becoming a parent is difficult due to the fast and unexpected events that unfold, and having a premature infant can be a sad experience and difficult to cope with and sometime, this emotion is so severe that makes it difficult to control the situation. Numerous studies have shown that parental roles and responsibilities will change in these situations. Mothers of premature infants are less likely to have parental roles and often have doubts about their abilities to identify and meet their infant’s needs. Parents need to be able to cope with these conditions and their new role, but this process is not always easy. Undoubtedly, the parents of premature infants require support and currently, one of the best and most effective ways to prevent injuries and harm to premature infants is to actively involve their parents in their care.

The purpose of this study was to determine the effect of empowerment program on participation of mothers with premature infants hospitalized in neonatal intensive care unit of Sayyed Shirazi hospital in Gorgan, Iran.

Materials and Method

This study is a randomized clinical trial which was conducted on the two groups of mothers with preterm infants. The setting of this study was Sayyed Shirazi Hospital at the city of Gorgan, Iran. The sample size in this study was determined based on the study of Gavami et al (2012) using G*POWER software with the effect size of 0.94, significant level 0.05, confidence interval of 0.95 and test power 0.080. The samples were randomly divided into two groups of intervention (n=20) and control (n=20). Inclusion criteria were: being over 18 years old, having the ability to read and write, having no history of neonatal intensive care unit care, having no physical or mental illness leading to drug use, having a 26 to 37 weeks old infant who weigh less than 2500 grams, and lack of life-threatening condition in the infant. The simple random sampling method was used in this study. Data collection tools were demographic information questionnaire (maternal age, education, occupation, number of children) and Parents’ Participation Inventory, which was designed by Melnick in 1997 to measure parental involvement in the neonatal intensive care unit. This questionnaire lists 25 activities that a mother can perform for her infant. Also, the mother is asked to tick every activity that she has performed. The questions in this questionnaire have two options, and the higher number of options selected by the mother indicate the greater care provided by the mother and the more involvement she has in the care of her infant. A score of less than 9 indicates low level of participation, 10-18 indicates moderate level of participation, and score of 19 or more indicates the high level of participation. In Melnick’s (1997) study, the Cronbach’s alpha of this tool was 0.85.

After explaining the purpose of study, the necessary permission was obtained from the hospital authorities. According to the inclusion criteria, purposeful sampling was done in the first step and then, the study samples were randomly divided into two intervention and control groups. The researcher, after introducing herself, explained the aims of study to the mothers, ensured them about the principles of confidentiality and anonymity, asked them to provide a written informed consent and informed them that they could withdraw from the study at any time with any reason. The first appointments were made with the participating parents and the meeting place was agreed upon. The interval between each intervention step was 4 days. Three phases of the parent empowerment program were implemented for the parents in the intervention group. The control group received no intervention other than routine care and support in the ward. At the beginning and the end of the study, pre-test and post-test questions were completed by the participants. Data were analyzed by SPSS-16 software.

After the study, audio tapes containing written information and booklets used for parents in the intervention group during the study were given to the control group, so that they could also benefit from the program. The intervention was based on the following protocol:

**Session 1:** Demographic information questionnaire was competed by mothers 4 days after the infant hospitalization and beginning of the intervention in this stage. Then, a 15-minute long audio tape containing information on the first stage along with the booklet was given to the mothers. The information on this stage was
related to the appearance and behavioral characteristics of the premature infant, the differences between a pre-term and term infant, environmental characteristics of NICU, and strategies to enhance the maximum participation of parents in the infant care.

**Session 2:** It took place 4 days after the first stage. A 15-minute long audio tape containing information on the second stage along with the booklet was given to the mothers. In addition to providing support for the first stage, information on the behavior and evolutionary growth of infant and some suggestion for maximizing the parents’ participation in the care was provided.

**Session 3:** It took place one day before the infant discharge. In addition to providing support for the last two stages, information on discharge, how to care for infant at home, how to identify the characteristics of behavior and evolutionary growth of infant and signs of distress were given to parents. After the intervention, mothers completed the post-test.

**Findings**

The results of independent t-test showed no significant difference between the two groups in terms of mothers’ age (p = 0.62) and length of hospital stay (p = 0.27). In the intervention group, 0.09 of the samples (N=18) were housewives and 0.010 (N = 2) were employed. Also, in the control group, 0.080 of the samples (N = 41) were housewives and 0.020 (N = 4) were employed. The result of chi-square test showed no significant difference between the two groups in terms of mother’s occupation (p = 0.66), history of childbirth (p = 0.25), delivery method (p=0.35), history of abortion (p = 0.26), and type of pregnancy (p = 0.36). The Fisher test showed no significant difference between the two groups in terms of education (p = 0.69), and the Mann-Whitney test also showed no significant difference between the two groups in terms of number of children (p = 0.31).

Chi-square test did not show a significant difference between the two groups before and after the intervention (p = 0.45). Also, the independent t-test showed no significant difference between the two groups in terms of the mean score of level of participation (p=0.21), (Table 1).

Chi-square test showed a significant difference between the two groups in terms of the level of participation after the intervention (p=0.01), so that the level of participation increased to 55% (N=11). Paired t-test showed a significant difference between the two groups in terms of the level of participation before and after the intervention (p=0.008), (Table 1).

**Conclusion**

Nursing interventions improve patients’ health\(^{18, 19}\). Findings of the present study showed that mothers with premature infants who had an empowerment training program were more involved in the care of their infants. In a study by Melnick et al., four stages of the “creating opportunities for parent empowerment” (COPE) were implemented in the United States\(^{6}\). In this program, parents learned about the premature infant, family’s abilities and activities that parents can perform. Also, psychological support was provided for parents and sufficient time was given to them for preparation. Consequently, the confidence of parents in caring for their premature infants increased\(^{20}\). Jaw Brown conducted a study on parents of premature infants that showed that the knowledge of mothers increased after the training. Providing information on infant behavior and interaction with infant reduce mothers’ stress and have positive effects on the level of parents’ participation in the care of their infants\(^{16}\).

Results of studies by Fatemeh Alaei Karahroudi et al. (2012) showed that COPE program had a positive effect on mothers’ participation in the care of their infant and increased it in the intervention group\(^{20}\). Therefore, empowerment model can be considered as an appropriate model for promoting health, increasing knowledge and enhancing parents’ participation in the care of their infants\(^{21}\). Study of Abdolali Zadeh et al. (2015) showed that a health promotion support program is effective in promoting the quality of life in mothers of premature infants\(^{22}\). Empowering and involving parents and families in the care and decision-making for their infants promote health and wellbeing. People who are able to control their emotions can make the right decision\(^{23}\).

**Conclusion**

Considering the results and the impact of empowerment program on the participation of parents in the care of their premature infants, it can be said that the implementation of empowerment program can facilitate active participation of parents in the care of their premature infants. Thus, we suggest to implement this program from the first day of delivery for mothers of premature infants.

Abstract

Background: Accuracy of preoperative brain tumor’s histopathologic differentiation is very important to determine preoperative staging, intraoperative management and postoperative therapy. Diffusion weighted magnetic resonance imaging is an advanced technique developed as an important method for brain tumor assessment.

Objectives: This study aimed to investigate correlation between diffusion weighted imaging (DWI) profile and apparent diffusion coefficient (ADC) value with brain tumor’s histopathology.

Methods: This study examined 86 subjects with brain tumors using magnetic resonance imaging and histopathology examination at Dr. Soetomo Teaching Hospital and evaluated DWI profile and ADC maps. The spherical ROI on ADC maps was placed on the solid part of the tumor to measure ADC value. Spearman’s correlation test was conducted to determine correlation between DWI profile and ADC values with histopathological grading and types of brain tumor.

Results: There was a significant correlation between DWI profile and ADC values (p = 0.000), as well as DWI and ADC values with histopathological grading and types of brain tumor (p = 0.000). There was an inverse correlation between ADC value and histopathological grading. The higher the ADC value, the lower the brain tumor grade, while lower ADC value resulted in high tumor grade. The average ADC value of grade-1 meningiomas was 1.061±0.257 x 10⁻³ mm²/sec, pilocytic astrocytoma was 1.301±0.107 x 10⁻³ mm²/sec, glioblastoma multiforme was 0.831±0.080 x 10⁻³ mm²/sec, and medulloblastomas was 0.600±0.078 x 10⁻³ mm²/sec.

Conclusion: Evaluation on DWI profile and ADC value could provide additional information on conventional magnetic resonance imaging examination to determine histopathological grading and types of both intra and extra-axial brain tumors.

Keywords: ADC value, brain tumor, brain tumor histopathology, DWI.

Introduction

Accurate brain tumor diagnosis has an important role in selecting an optimal therapeutic strategy due to the influence of tumor natural course and grading on therapeutic approach of preoperative, intraoperative and postoperative management. Conventional CT scan and MRI have limitations in differentiating intracranial lesions, with sensitivity, specificity, PPV and NPV of conventional MRI to determine high grade glioma. Therefore, many advanced MRI techniques are developed to improve the accuracy of preoperative brain tumor histopathologic diagnosis.

Diffusion weighted imaging (DWI) is an advanced MRI technique that is currently being developed as an
important method for assessing brain tumor. In general, malignant tumors have large cell nuclei and exhibit high cell density. A study has shown that malignant tumors have low ADC values than benign tumors. Therefore, one of the most prominent contributions of DWI is the differentiation between malignant and benign brain tumors. The sensitivity, specificity, PPV and NPV and ADC values of DWI in differentiation of high-grade brain tumors and lymphomas with low-grade glioma and non-neoplasm cases were 94.1%, 78.2%, 76.1% and 94.7%, respectively.

Recently, there has been no data on DWI profile and ADC of brain tumor which is associated with histopathology examination result, especially in Dr. Soetomo General Hospital, Surabaya, Indonesia. These data are important to show whether there is a difference with previous research. They also can be used as a reference in determining the diagnosis and characterization of preoperative brain tumor using MRI examination. Therefore, we aimed to examined correlation of DWI profiles and ADC values with histopathological outcomes in both postoperative patients with intra-axial and extra-axial brain tumors.

**Method**

A retrospective study investigated correlation of DWI profile and ADC value with histopathology grading and type of brain tumor in post-brain tumor surgery patients at Dr. Soetomo Teaching Hospital, Surabaya, Indonesia. The subjects were patients with brain tumor who visited Neurosurgery Unit for head examination, surgery and histopathology examination.

All subjects should meet the following inclusion criteria: (1) Patients with intra-axial and extra-axial brain tumors; (2) Having a complete and accessible medical record; (3) Having performed head MRI with contrast and DWI sequence; (4) Having performed surgery and histopathological examination of tumor tissue. We excluded subjects with the following criteria: (1) There was no MRI file or have not performed any DWI sequence; (2) Intratumoral bleeding; (3) Intratumoral inflammatory process.

Subjects were taken using consecutive sampling technique. We used GE Optima 360 1.5 Tesla MRI machine. MRI examination protocol used head coil, while sequences made included T1WI using fast spin echo with Time repetition (TR) 250-750 ms and Time echo (TE) 10-20 ms (SE 250-750/10-20), T1WI + C, T2WI sequence (SE 4000-8000/100). DWI with b value of 1000 mm²/sec was performed on axial pieces. ADC is a reconstruction of the DWI sequence. ADC value measurement in ROI tumors was round with size of 20-30 mm². It was placed in the denser area of the tumor that experienced signal intensity changes on DWI. ADC value measurement in normal brain parenchyma ROI had round shape of 20-30 mm², and it was placed in white matter on the counter-lateral side of the lesion. Gadolinium-DPTA (Omniscan, GE Healthcare Inc.) media contrast was administered intravenously to all patients with a dose of 0.1 mmol/kg WW.

Data processing and analysis begin with an evaluation of MRI examination results conducted by two neuroradiologists (ADS) and (WFA) who did not know of tumor tissue’s histopathological examination results. Decisions were made by means of agreement if there were any difference in MRI interpretation.

Descriptive analysis was conducted to obtain the sample’s characteristics. We conducted Kappa test to determine interobserver variation on the interpretation of MRI head examination. Spearman’s correlation test was then performed to determine the correlation between DWI profile and ADC values with grading and histopathology type in brain tumor. The confidence limit used was 95% (95% CI) with significant p value <0.05. The statistical calculations used SPSS software (SPSS. Inc. Chicago. IL).

**Results**

We obtained 97 samples aged 1-82 years old, with average age of 33.39 years. Most subjects were found in the age group of 41-50 years (n = 24, 24.74%) followed by age group of 31-40 years (n = 23, 23.71%) and age group of less than 10 years (n = 21, 21.65 %). Table 1 showed subjects’s distribution by Tumor Histopathology. Table 1 showed subjects’ distribution by tumor histopathology.

Spearman’s correlation between ADC value and brain tumor’s histopathology (r = .563; p = .000)

**Discussion**

In this study, the average value of normal brain parenchyma’s ADC white matter in age group less than 17 years was 0.865±0.045 x 10^-3 mm²/sec, while 0.820±0.057 x 10^-3 mm²/sec for age group more than 17 years. This value was higher than the normal value found in a study conducted by Thomas study (0.75±0.03 x 10^-3 mm²/sec)⁴.

We found a significant correlation between DWI profile and ADC value (p = 0.000). The average ADC value in DWI profile of facilitated and restricted diffusions in brain tumor were 1.139±0.037 x 10^-3 mm²/sec and 0.644±0.057 x 10^-3 mm²/sec, respectively. In another study, ADC value less than 1.0-1.1 x 10^-3 mm²/sec indicated a restricted diffusion of water molecules⁵. Nevertheless, we found no significant correlation between ADC value and brain tumor location. The value of facilitated and restricted diffusions in intra-
axial and extra-axial brain tumors showed no significant difference.

MRI is a highly sensitive imaging modality for evaluating brain tumors, but conventional MRI has limitations to differentiate histopathologic types of most brain tumors. In this study, we found a significant relationship between ADC value and tumor histopathology grading (p = 0.000). This finding was consistent with a study that found higher ADC value led to LGG (WHO I, II), while lower ADC value led to HGG (WHO III, IV). These findings were consistent with a study that found low ADC value led to atypical or malignant meningiomas compared with benign 6.

Increased mitotic processes, necrosis, high cytoplasmic nucleus ratios and increased disturbed cell growth patterns are found in high-grade meningiomas, causing restricted diffusion of water molecules seen in DWI. On the other hand, benign meningiomas show little representation of a coherent histological organization, because they are composed of oval-shaped neoplastic or spindle cells that form threads, fascicles, cords, or nodules, which force water molecules to move relatively isotropic 1. The location of pituitary adenoma could be affected by the air-induced susceptible artifacts in the sinuses and surrounding bones resulting in varying results on the evaluation of ADC values, but no data supporting this possibility has been obtained 7. On the other hand, PCL as a hyperseleruler tumor has been reported to have lower ADC values significantly greater than HGG and metastatic tumors1. A study reported that lymphoma and metastasis’ ADC values were lower than glioma8.

A study (n = 76) reported ADC tumor metastasis was $0.72 \times 10^{-3} \text{mm}^2/\text{sec}$ (using b-value of 1,000 mm$^2$/sec) 9. On the other hand, another study (n = 21) reported ADC tumor metastasis values ranging from 0.35 to 1.37 x $10^{-3} \text{mm}^2/\text{sec}$, with an average of $0.79\pm0.23 \times 10^{-3} \text{mm}^2/\text{sec}$ (using b-value of 1,000 mm$^2$/sec). Nevertheless, the study found no significant correlation between ADC tumor metastasis score and GBM 10. However, there is limited analysis of ADC sample values with histopathology ependymoma and heterogeneous morphology and tumors, therefore the results of this group are not fully reliable and further research is needed 12.

Brain tumor is an abnormal growth of cells in the brain. Magnetic resonance imaging (MRI) is an advanced diagnostic tools that enable us to visualize anatomical details more clearly so superior in detecting abnormalities in the soft tissues of the brain 13. Neoplasia refers to the growth of new cells that are different from the growth of cells around it 14. Image segmentation has been popularly performed for researchers in the field of Biomedical, Informatics Engineering, and Statistical Computation 15.

**Conclusion**

ADC value measurement in both extra-axial and intra-axial brain tumors was a significant predictor of grading differentiation and histopathologic types of brain tumor. Clinicians could use this diagnostic method for comprehensive action planning and management of brain tumor cases.

**Ethical Clearance:** The study protocol was approved by the ethics committees of Dr. Soetomo Teaching Hospital, Surabaya, Indonesia.

Abstract

Background: Mitochondrial DNA is an important tool for human identification and is used to differentiate between human and animal blood at the crime scene, because in extreme conditions nuclear DNA is severely destroyed while Mitochondrial DNA contains multiple copies (200-2000) in per cell as well as resists harsh and more stable conditions. Methodology: Seventy-two blood samples were collected from human (Homo sapiens), sheep (Ovis aries), goat (Capra hircus) and cow (Bos taurus) (Eighteen blood samples for each). All blood samples were withdrawn by technician and 5ml were aspirated using aseptic technique and transferred to EDTA-Na2 tube and mixed well and stored in refrigerator. The collection takes 2 weeks (15th May 2019 to 30th May 2019). All samples were collected from Al-Diwanyia city. Results: The results of PCR reveal that, the primer pairs were specific and non-specific products not appear for all samples. The amplification of Homo sapiens mitochondrial DNA with primer pairs of other (Ovis aries, Capra hircus and Bos taurus) and amplification of each with primers pair of another genus gave negative results and this a primary evidence for primer pairs specificity. The amplicon of 16S rRNA gene of Homo sapiens were 1200bp, Ovis aries were 1060bp, Capra hircus were 820bp, and Bos taurus were 1300bp. The sequencing revealed that no cross-reactivity of designed primer pairs and the PCR assay based on the designed primer pairs will be simple, fast, sensitive, specific, and cost-effective. Conclusion: Sensitivity, specificity and accuracy of the designed species specific primer pairs and applicability of the designed primer pairs in forensics to investigate blood sports or evidence belonging for human, sheep, goat and cow.

Keywords: Homo sapiens, Ovis aries, Capra hircus, Bos taurus, Forensic.

Introduction

Mitochondria have their possess small spherical genome, mtDNA, which encodes for the thirteen important subunits of the electron transport chain and ATP synthase together with 22 tRNAs and 2 rRNAs necessary for mitochondrial protein synthesis[1,2]. Mitochondrial DNA presents several characteristics valuable used for forensic studies, especially attendant to the absence of recombination, to a great copy number, and to matrilineal inheritance. Mitochondrial DNA typing founded on sequences of the control region otherwise filled genomic sequence is used to examine a variation of forensic mtDNA profiling methods used for human proof of identity and present their use in the chief cases of human identification from non-human [3-5]. Mitochondrial markers that are used for species identification are as follows: cytb gene, cytochrome c oxidase subunit I gene, 12S and 16S rRNA segment and control region in wildlife[6-8]. A short fragment of the 12S rDNA was employed for DNA amplification leading to species identification. The mitochondria DNA 16S rRNA gene is an advanced genetic marker for animal genetic diversity. Utilizing gene mitochondrial DNA 16S rRNA. Polymorphism sites, nucleotide variation, and haplotype variety were determined using whole sequences of the mitochondrion DNA 16S rDNA gene[9,10]. Animal mitochondrial DNA (mtDNA) is commonly described as a small, circular molecule that

is conserved in size, gene content, and organization \cite{11}. The aim of this study is to design valuable species specific-PCR tool to discriminate blood of human and non human Species specific- primer design.

**Methodology**

**Study Design**

The study design was experimental to design species specific primer pairs for typing the blood samples and their assignment to human (\textit{Homo sapiens}), sheep (\textit{Ovis aries}), goat (\textit{Capra hircus}) and cow (\textit{Bos taurus}).

**Blood Sample Collection:**

Seventy two blood samples were collected from human, sheep, goat and cow (Eighteen blood samples for each). All blood samples were withdrawn by technician and 5ml were aspirated using aseptic technique and transferred to EDTA-Na2 tube and mixed well and stored in refrigerator. The collection take 2 weeks (15th May 2019 to 30th May 2019). All samples were collected from Al-Diwanya city.

**Primer Design**

The gene selected for this study is mitochondrial 16S rRNA gene. the NCBI data base were used to recover the sequences chosen for primer design. The sequence ID of \textit{Homo sapiens}:(NC_012920.1); sequence ID of \textit{Ovis aries}:(NC_001941.1); sequence ID of \textit{Capra hircus} (NC_005044.2); sequence ID of \textit{Bos taurus} (NC_006853.1). Primer 3 software \cite{12} was used to design the specific primer using the sequence of above mentioned sequences ID. The generated primer were: Homo 16S-F: GCCTGGTGATAGCTGGTTGT, Homo 16S-R: ATCATTTACGGGGGAAGGCG (1200bp); Ovis 16S-F: AGGCCTAAAAGCACGCGCATCA, Ovis 16S-R: GCCCTTTCTAGGGCAGGT (1060bp); Capra 16S-F: GCCTGGTGATAGCTGGTTGT, Capra 16S-R: TCACCCCAACCAAACGCTGCT (820bp) and Bos 16S-F: CTAAGCAGCGAACCAGA, Bos 16S-R: GGGCAAGGGTGGTGGCT (1300bp).

**Mitochondrial DNA extraction**

G-spinTM Total DNA Extraction Kit(50 Preps) (REF: 17045 ) was used to extract mitochondrial DNA from blood of different species according to the manufacturer’s protocol instructions.

**Agarose gel electrophoresis**

Agarose gel was prepared by dissolving agarose powder in 1X TBE buffer. The amount of agarose which can be dissolved depending upon the purpose in which agarose sheet used. 0.7% agarose gel used for visualization the DNA after extraction while 1.5%-2% agarose sheet visualization of PCR product (amplicon). RedSafe (alternative for ethidium bromide) stock solution concentration was 10 mg/ml. Only 5μl of RedSafe stock solution were added to 100ml of melted agarose gel to get final concentration 0.5μg/ml \cite{13,14}.

**Primer pairs preparation and PCR conditions**

The primers were synthesized at (Macrogen/ Korea), were provided in a lyophilized from, which were re-dissolved with 300 nuclease-free water according to institution of manufacture company to reach to the final concentration (100 pmoles/μl). The working solution will be 10 pmoles/μl to be used directly in PCR\cite{15,16}. The PCR conditions were calculated using online Protocol Optimize writer software. The conditions were illustrated in table (1).

This study
Result and Discussion

The four sets of designed primer pairs were submitted to specificity using Primer-Blast and the results revealed that, they are specific to amplify 16S rRNA gene of Human (*Homo sapiens*), Sheep (*Ovis aries*), Goat (*Capra hircus*) and Cows (*Bos taurus*) (table 2). 16S rDNA region is highly conserved region among mtDNA[17]. mtDNA can be easier to retrieve from low-quantity and/or degraded DNA samples, as it is present at many copies per cell, thus providing a clear advantage over nuclear genome-based methods of species identification[18-20].

The results of PCR reveal that, the primer pairs were specific and non-specific products not appear for all samples. The amplification of Homo sapiens mtDNA with primer pairs of other (Ovis aries, Capra hircus and Bos taurus) and amplification of each with primers pair of another genus gave negative results and this a primary evidence for primer pairs specificity. The amplicon of 16S rRNA gene of Homo sapiens were 1200bp (Figure 1A), Ovis aries were 1060bp(Figure 1B), Capra hircus were 820bp (Figure 1C), and Bos taurus were 1300bp (Figure 1D). PCR amplification and sequence analysis of mitochondrial 16S rRNA gene for their use in differentiation/identification and subsequently evaluating their application in solving the forensic cases [21]. Mitochondrial 16S is suitable for the differentiation of 300 mammalian species. 16S rDNA gene is common mitochondrial gene for detection of blend mutton and pork at high sensitivity. The mitochondrial 16S rRNA genes have been used as molecular markers to identify mammals, birds, shrimp, and other species using species-specific primers that amplify the 12S rRNA or 16S rRNA gene regions from mtDNA[17,22]. Gene loci on the mitochondrial genome have been used in species identification. These include the 12S and 16S rRNA loci. The D-loop (displacement loop) has been used less in species identification but more in intraspecies identification. Due to the greater sequence variation at this non-coding locus, it is now being used as a tool for identifying the presence of particular species within mixture of many species [23,24].

The secondary and confirmatory assay for specificity of primer pairs used in study is sequences of PCR products. Eight amplicons from each were sent for sequencing using Sanger technique (Macrogen/Korea). The retrieved sequences firstly must be trimmed to remove unwanted sequences before submitting them for BLASTN. The trimming performed by Bioedit to get the finally processed sequences. Abbreviation of *homo sapiens* sequences were used as (HIS-1 to HIS-8), *Ovis aries* sequences be (IOA-1 to IOA-8), *Capra hircus* sequences be (IBCH-1 to IBCH-8) and *Bos taurus* sequences be (IBT-1 to IBT-8).

The identity percentage and alignment results of amplified 16S rRNA gene of *homo sapiens*, *Ovis aries*, *Capra hircus* and *Bos taurus* with database were illustrated in table (3,4,5,6) respectively.

Figure 1: Agarose gel electrophoresis 1.5% for: A: 1200bp amplicon of *Homo sapiens* 16S rRNA gene. lane H1-H18 represent samples. B: 1060bp amplicon of *Ovis aries* 16S rRNA gene. lane H1-H18 represent samples. C: 820bp amplicon of *Capra hircus* 16S rRNA gene. lane H1-H18

The sequencing of the 16S rRNA has revolutionized the study and identification of human and non-human in forensic. Many study development a simple method using universal primers for species identification based on direct PCR sequencing using primer sets were designed based on the conserved regions of the 16S rRNA loci detected by the comprehensive sequence comparison among 30 animals whole[25]. Mitochondrial DNA the method could be a dominant tool for mammalian species identification, especially in forensic cases in which many unidentified biological samples must be analyzed such as blood spots[25]. The 16S and 12S sequences

allowed identification of most species to the genus level. Faster-evolving DNA regions are required to identify closely-related species\textsuperscript{[26]}. The successfully used forensically informative nucleotide sequencing analysis of the 16S rRNA mitochondrial DNA to identify before unknown biological specimens of human and animals\textsuperscript{[27]}. The mitochondrial 12S rRNA and 16S rRNA genes, including those from fish and amphibians to mammals including human beings. Therefore, universal primers were designed to amplify sequences in the fast-evolving animal mtDNA\textsuperscript{[17]}, the PCR amplifications of mitochondrial 16S rRNA followed by sequencing and analysis showed to be very efficient for identification of species origin of species\textsuperscript{[21]}. The 12S rRNA and 16S rRNA gene sequences of animals reveal the fitting level of interspecific variation but the great level of intraspecific homogeneity\textsuperscript{[28]}. The results showed no cross-reactivity of designed primer pairs and the PCR assay based on the designed primer pairs will be simple, fast, sensitive, specific, and cost-effective.

**Registration of Sequences in GenBank:**

All the 32 sequence of 16S rRNA gene were submitted to GenBank for registration. After checking and revision the following accession numbers were donated:

**16S rRNA** *homo sapiens* (Human): MN192057, MN192058, MN192059, MN192060, MN192061, MN192062, MN192063, MN192064 (Appendix 4-69 to 4-76).

**16S rRNA** *Ovis aires* (Sheep): MN173528, MN173529, MN173530, MN173531, MN173532, MN173533, MN173534, MN173535 (Appendix 4-77 to 4-84).

**16S rRNA** *Capra hircus* (Goat): MN173285, MN173286, MN173287, MN173288, MN173289, MN173290, MN173291, MN173292 (Appendix 4-85 to 4-92).

**16S rRNA** *Bos taurus* (Cow): MN197611, MN197612, MN197613, MN197614, MN197615, MN197616, MN197617, MN197618 (Appendix 4-93 to 4-100).

**Conclusion**

Sensitivity, specificity and accuracy of the designed species specific primer pairs and applicability of the designed primer pairs in forensics to investigate blood sports or evidence belonging for human, sheep, goat and cow.

Curcumin Improves the Regulation of Ovarian Folliculogenesis in Culture Media with Peritoneal Fluid from Infertile Women with Endometriosis

Hendy Hendarto1, M Yohannes Ardianta Widyanugraha1, Widjiati2, Soehartono Darmosoekarto1
1Department of Obstetric and Gynecology, Faculty of Medicine, Universitas Airlangga, Surabaya (60131), Indonesia, 2Laboratory of Embriology, Faculty of Veterinary Medicine, Universitas Airlangga Surabaya, Indonesia

Abstract

Background: Peritoneal fluid (PF) from infertile women with endometriosis contains a variety of inflammatory mediators that may interfere with folliculogenesis. The aim of the study was to evaluate effects of curcumin on the regulation of ovarian folliculogenesis by evaluating Growth Differentiation Factor (GDF)-9, Kit Ligand (KitL) and Tumor Necrosis Factor (TNF)α expressions in bovine cumulus oocyte complexes (COC)s cultured with PF from infertile women with endometriosis.

Method: COCs were aspirated from antral follicles of bovine ovaries. PF was collected from infertile women with endometriosis undergoing laparoscopy for infertility evaluation. Curcumin, a strong anti-inflammatory turmeric, was added in Tissue Culture Media (TCM)199 and PF from infertile women with endometriosis for culture media. Bovine COCs were cultured into 3 groups of media: 1) TCM199, 2) TCM199+PF from infertile women with endometriosis, and 3) TCM199+PF from infertile women with endometriosis+curcumin. GDF-9, KitL and TNFα expressions were examined using immunohistochemistry technique.

Results: GDF-9 expression of bovine COCs cultured in PF from infertile women with endometriosis with curcumin addition (2.67±0.98) was found to increase compared to those cultured without curcumin (0.50±0.67) but reduced compared to the control. This result was similar to KitL expression of bovine COCs cultured with curcumin (2.67±1.23), in which it increased compared to those without curcumin (0.33±0.49) (p<0.05). A significant difference in TNFα expression was noted between groups with or without curcumin (p<0.05).

Conclusion: In the culture of PF from infertile women with endometriosis, curcumin addition may improve the regulation of ovarian folliculogenesis through the decrease of inflammation factor.

Keywords: endometriosis; curcumin; GDF9; kit ligand; TNFα

Background

Endometriosis is a condition characterized by the growth of endometri-alike tissue outside the uterus that subsequently induces a chronic inflammatory reaction. Numerous symptoms are associated with endometriosis, including dysmenorrhea, pelvic pain, dyspareunia and infertility, as well as reduced quality of life 1. The relationship between endometriosis and infertility remains unclear. One of the postulations of decreased fertility in women with endometriosis is the reduction of oocyte quality caused by abnormal folliculogenesis related to peritoneal fluid (PF) inflammation 2.

Folliculogenesis is a dynamic process marked by proliferation and differentiation of granulosa cells and maturation of oocyte. The regulation of ovarian folliculogenesis, determined by a number of growth factors and classic endocrine mechanism, provides optimal environment to produce fertilizable oocyte 3. There are two important growth factors that contribute to the regulation of ovarian folliculogenesis including the interactions between oocyte
and granulosa cells.

Those growth factors are Growth Differentiation Factor (GDF)-9 produced by oocyte, which is useful for granulosa cell proliferation and differentiation; and Kit Ligand (KitL) secreted by granulosa cells, which induces oocyte maturation. In women with endometriosis, ovaries are naturally bathed in PF that is rich in inflammatory mediators. This may cause abnormal folliculogenesis and subsequently results in infertility. The PF of women with endometriosis contains a variety of inflammatory mediators, including Tumor Necrosis Factor (TNF)α.

Curcumin, which is derived from Curcuma longa (turmeric), has a strong potential anti-inflammatory activity. It has been widely used both traditionally and scientifically to treat various conditions including inflammatory diseases, such as rheumatoid arthritis, chronic anterior uveitis and ulcerative colitis. Treatment with curcumin can reduce implant size and cell proliferation in rat endometriosis model, but the effects of curcumin on intraovarian growth factors in endometriosis and infertility remain controversial. The objectives of our study was to evaluate whether curcumin could improve the regulation of ovarian folliculogenesis in bovine cumulus oocyte complexes (COC)s by analyzing GDF-9, KitL and TNFα expressions in culture media with PF from infertile women with endometriosis.

Method

We evaluated the growth factors expression of folliculogenesis regulation on bovine COCs cultured in three different types of media. Tissue Culture Media (TCM) 199 only (group 1= control), TCM199 plus PF from infertile women with endometriosis (group 2=endometriosis), and TCM199 plus PF from infertile women with endometriosis added with curcumin (group 3=endometriosis+curcumin). The ethical board of Dr Sutomo Hospital approved the study.

Endometriosis peritoneal fluid

We obtained PF samples from women of 20 to 40 years old with endometriosis undergoing laparoscopy for infertility evaluation at Dr. Sutomo Hospital Surabaya. The diagnosis of endometriosis was made by visual inspection and peritoneal biopsy according to American Society for Reproductive Medicine criteria. We collected PF by aspiration from posterior cul-de-sac during the laparoscopic procedure. The samples were placed in a tube and centrifuged at 600 g for 10 min. The supernatants were stored at -80°C until analysis.

Curcumin

We obtained curcumin from Merck Schuchardt OHG (85662 Hohenbrunn, Germany). Curcumin (0.2 mg) was added and homogenized in 10 ml of TCM199 media and PF fluid infertile women with endometriosis (30 µl). BSA (3%) was added until the pH reached 7.4-7.8. The solution was then filtered through a 0.22-µm microfilter and 100 mL of solution was placed in a petridish for culture.

Bovine cumulus oocyte complex

COCs aspirated from antral follicles with a diameter of 3-8 mm were obtained from bovine ovaries in a slaughterhouse. The ovaries were washed and stored in 0.89% NaCl with penicillin-G (1000 IU/ml) and streptomycin sulfate (0.2 ug/l) at a temperature of 30-35°C. Before follicle aspiration, the diameter of the follicles was measured with a caliper. The COCs were aspirated using an 18-G needle connected to a 5-ml syringe containing 1 ml phosphate buffered saline (PBS) with 3% bovine serum albumin (BSA) and 50 µg/ml gentamycin. The COCs were washed 3 times successively in PBS media and one time in TCM199, placed in TCM199 media with 50 mIU/ml FSH and 50 mIU/ml LH, divided into three groups by placing them into media groups 1, 2 and 3, and then incubated at a temperature of 38°C in 5% CO2 for 24 hours. Subsequently, the COCs of each groups were fixated in a glass flask and subjected to immunohistochemical staining for GDF-9 (Biosis Antibodies Inc USA, catalog no. Bs-4720R), KitL (Abcam USA, catalog no. ab52603), and TNFα (Biosis Antibodies Inc USA, catalog no. Bs-2081R) expressions.

The three expressions were semi-quantitatively assessed according to the modified Remmele method which is the result of multiplication between the percentage score of immunoreactive cells (positive cells) with the color intensity score generated on the cell.

Statistical Analysis

Data analysis was performed using statistical software (SPSS version 17.0 for windows) Normality of variable was tested with Shapiro-Wilk test. Non-parametric test was used to detect significant differences of all variables. P < 0.05 was accepted as statistically significant.
Results

A total of 21 bovine COCs were cultured in 3 different types of media; each group contained 7 COCs. The GDF-9 expression in bovine COC was determined by dark color of immunoreactive cells on the immunohistochemical staining result. The semi-quantitative results of GDF-9 expression in control, endometriosis and endometriosis+curcumin groups were as follows: 5.83±1.58; 0.50±0.67; and 2.67±0.98, respectively. The mean expression of GDF-9 in bovine COC cultured in PF from infertile women with endometriosis+curcumin (2.67±0.98) increased compared to those cultured without curcumin (0.50±0.67) but reduced compared to the control (5.83±1.58). (p=0.46) (Figure 1).

The semi-quantitative results of KitL expression in bovine COC cultured in control, endometriosis, and endometriosis+curcumin groups were as follows: 3.92±2.02; 0.33±0.49; and 2.67±1.23, respectively. This result was similar to those of GDF-9 expression. The mean expression of KitL in bovine COC cultured in PF from infertile women with endometriosis (0.33±0.49) reduced compared to the control (3.92±2.02) and those in endometriosis+curcumin group (2.67±1.23) (p=0.001). There was also a significant difference between KitL expression in bovine COC cultured in PF from infertile women with endometriosis + curcumin and control group (p=0.035) (Figure 2).

The semi-quantitative results of TNFα expression in bovine COC cultured in control, endometriosis and endometriosis+curcumin groups were as follows: 0.00±0.00; 8.67±3.72; and 2.17±1.69, respectively. TNFα expression in bovine COC cultured in PF from infertile women with endometriosis (8.67±3.72) increased compared to those in control group (0.00±0.00), whereas TNFα expression in bovine COC cultured in PF from infertile women with endometriosis added with curcumin (2.17±1.69) reduced compared to those cultured without curcumin; however, the level increased compared to the control (p=0.001). (Figure 3).

Regression analysis revealed significant association among TNFα, GDF-9, and KitL expression cultured in PF from infertile women with endometriosis added with curcumin (p=0.00).
Discussion

The PF of infertile women with endometriosis contains a variety of inflammatory mediators and the PF component plays an essential role in the process of folliculogenesis, ovulation and fertilization. Communication between oocytes and granulosa cells occurs during folliculogenesis to produce mature and fertilizable oocytes. This process is impaired in infertile women with endometriosis. We previously reported abnormal GDF-9 and KitL expression in endometriosis. In our study GDF-9 and KitL expressions in bovine COC cultured with PF from infertile women with endometriosis were significantly reduced compared to control. It suggests that numerous inflammatory mediators in the PF of infertile women with endometriosis enters the bovine COC and further inhibits oocytes and granulosa cells activity. This results in abnormal folliculogenesis and subsequently infertility.
GDF-9 is an oocyte-specific member of the TGFβ superfamily. GDF-9-deficient female mice demonstrate a block in follicular development beyond the primary one-layer follicle stage which leads to complete infertility. In the transition to the antral stage, GDF-9 promotes follicular survival by suppressing granulosa cell apoptosis and follicular atresia. In this study, the addition of curcumin to culture media of PF from infertile women with endometriosis resulted in more improved GDF-9 expression than those without curcumin. It is possible that the anti-inflammatory effects of curcumin release oocyte suppression. By taking into account the fact that the expression of GDF-9 was still lower than the control, it indicates that it is necessary to adjust the dosage of curcumin. These findings indicate that the dose of curcumin plays a role in GDF-9 expression 16.

KitL produced by the granulosa cells in the oocyte acts by binding to c-Kit and may activate different signaling pathways. The KitL/c-Kit system regulates follicular viability, the initiation of primordial follicle growth, and oocyte and follicle development. In our study, KitL expression in bovine COC cultured in PF from infertile women with endometriosis added with curcumin significantly increased from those cultured without curcumin 17. It indicates that curcumin has positive effect on KitL expression. The changes on two growth factor expressions, GDF-9 and KitL suggest that curcumin has a repair effect on oocyte-granulosa cell interactions and the regulation of ovarian folliculogenesis18.

In order to evaluate that curcumin has repair effect on oocyte-granulosa cell interactions and the regulation of ovarian folliculogenesis, we assessed the effect of curcumin on bovine COC inflammation via TNFα expression 14. An increase in TNFα expression was noted in the PF from infertile women with endometriosis compared to that from normal women 19. In addition, we found a correlation between TNFα concentration and the degree of endometriosis severity. In fact, it has been reported that TNFα plays a role in the inflammatory process and angiogenesis, triggers follicular atresia and impairs oocyte maturation 20.

The findings of increased TNFα expressions in bovine COC cultured in PF from infertile women with endometriosis suggest that TNFα from PF enters the COC and is active. The addition of curcumin to the culture media results in an improvement as indicated by the reduced TNFα expression 16. Curcumin exhibits anti endometriosis activities by affecting MMP2 and TIMP2. It works by inhibiting cyclooxygenase2 and lipoxygenase and suppressing the activity of NFkB and pro-inflammatory gene expressions 21. Based on its mechanism of action, curcumin can suppress an inflammatory process in bovine COC cultured in PF from infertile women with endometriosis 15.

Ethical Clearance: This research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, nonmaleficence, and justice.

Correlation of Fugl-Meyer Assessment Score with Barthel Index and Functional Independence Measure in Patients with Stroke

Husnul Mubarak¹, Noor Idha¹, Bayu Santoso¹
¹Department of Physical Medicine and Rehabilitation Faculty of Medicine Universitas Airlangga, Dr. Soetomo Teaching Hospital, Surabaya 60285, Indonesia

Abstract

Background: The prevention of stroke morbidities that is oriented to the approach of functional performance improve is expected improve the productivity of post-stroke patients. One of the tools to measure the physical performance is Fugl-Meyer Assessment (FMA) scale, while the recommended tests to measure interpedency level are Barthel Index (BI) and Functional Independence Measure (FIM).

Method: This study was conducted on 20 outpatient stroke patients in Medical Rehabilitation Installation of Dr. Soetomo General Hospital Surabaya, Indonesia. FMA, BI and FIM examination were performed in all subjects.

Results: The authors obtained the correlation coefficient value with r=0.816 and therefore a high positive correlation was found between the total score of FMA and BI, while the correlation coefficient value between the total score of FMA and FIM showed r of 0.728. Thus, the author concluded that there was a positive correlation between the total score of FMA and FIM. The sub-domains FMA-UE, FMA-LE and FMA Balance were highly correlated with BI and FIM. This implied that physical performance measured using FMA could describe the interdependency level of stroke patients in doing ADL.

Conclusion: Physical performance (based on Fugl-Meyer Assessment) was positively correlated with the interdependency level of BI and FIM of inpatient stroke patients in Medical Rehabilitation Dr. Soetomo General Hospital Surabaya.

Keywords: Fugl-Meyer Assessment, Barthel Index, Functional Independence Measure, Stroke

Introduction

Stroke is the main cause of death and disabilities in Indonesia and the world ¹. Elderly with hypertension have a greater risk for ischemic stroke ². In America, the number of post-stroke population was predicted in three millions and this number has escalated twice as much of the number of post-stroke population 25 years ago. Stroke has enormous clinical, social, and economic implications and demands a significant effort ³, the prevention of stroke morbidity that is oriented in the approach of functional performance improve is expected to improve post-stroke patients’ productivity. Stroke rehabilitation, if conducted comprehensively and accurately, will improve post-stroke patients’ life quality and productivity ⁴.

Fugl-Meyer Assessment (FMA) was first introduced in 1975 as a method for evaluating post-stroke patients’ physical conditions. Before FMA was published, almost all methods of motor recovery and stroke output evaluation were empiric-based or based on activities of daily living (ADL) evaluation. The experts of stroke rehabilitation consider FMA as one of the most
comprehensive quantitative measuring instruments and the use of it has been recommended for stroke rehabilitation clinical observation.

Functional Independence Measure (FIM) was introduced in 1984 by Granger and the joint organization of representatives of medical rehabilitation institutions in the USA (United States America). This is a common instrument used for evaluating functional conditions in various types of disease which cause disabilities and indicate how much help is needed by a disabled person in performing daily activities. FIM has subsequently developed as an instrument for clinicians to evaluate rehabilitation programs and measure the success ratio of rehabilitation programs with the costs incurred.

In 1965, Mahoney and Barthel published a scale to measure Living/ADL. The Barthel Index initially has 10 items consisting of eating, transfer, dressing up, hygiene, bathing, toileting, walking, stair climbing, and controlling micturition and defecation. Patients with the score of 100 are considered as individuals who can eat and dress independently, walk at least one block, up and down stairs, and maintain a continuous urine/aluvi. BI checks are probably the most commonly used examination in around the world to measure daily activities. Several studies have shown that this instrument has acceptable psychometric properties, including its sensitivity in measuring changes in a person’s ADL, which is a major predictor of rehabilitation outcomes, as well as BI’s examination results that are significantly associated with the patient’s medical status.

Method

This is an observational study with cross sectional study approach. This study was conducted in Medical Rehabilitation Installation of Dr. Soetomo General Hospital from August to October 2014. There were total 20 subjects that met the inclusion criteria (patients of post-thrombotic and hemorrhagic infarction stroke in outpatient unit aged of 30-70 years with hemiparesis in dominant side, stroke occurrence in ≥3 weeks, stable cooperative cardio-respiratory functions, and able to comply with simple commands) which consisted of post-ischemic and hemorrhagic stroke inpatient. The primary parameter evaluated in the subjects were Fugl-Meyer Assessment (FMA) which was divided into 6 sub-domains: FMA-UE, FMA-LE, FMA-Sensoric, FMA-balance, FMA-ROM, and FMA-joint pain. The parameter to be compared was the subjects’ level of independence by using Barthel Index questionnaire and Functional Independence Measure. All the subjects were enrolled in motor rehabilitation programs, with each subject having different program from the others. The data were analyzed using SPSS program (SPSS, Inc., Chicago, IL).

Results

Subjects general characteristics

The number of male and female subjects were 10 respectively (50%). The mean of stroke onset in the study subjects was 10.6 ±7.728 months (3-36 months). The mean of the subjects age was 55.9 ± 10.58 years, ranged between 30 to 73 years. The majority of the subjects’ dominance were right-handed. In accordance with the inclusion criteria, i.e. hemiplegia in the dominant side, most subjects (17 subjects or 85%) had right hemiparesis. The 16 subjects (80%) were generally infarction stroke patients (Table 1).

Correlation between FMA-total score and Barthel Index score

A significant correlation was found between FMA-total score and Barthel Index score with r=0.816 using Pearson’s correlation test with p value of <0.05. The graphic in XY curve also showed a correlation between the two examination instruments, in which the higher the FMA-total score was, the higher the Barthel Index score would be.

Correlation between FMA-total score and Functional Independence Measure score

A significant correlation was found between FMA-total score and Functional Independence Measure (FMI) score with correlation coefficient of r=0.728 by using Pearson’s correlation test with p >0.05.
Pearson’s correlation analysis in each sub-domain of FMA showed a correlation with FIM score with $r=0.747$ in the sub-domain FMA-UE, $r=0.719$ in the sub-domain FMA-LE and $r=0.694$ in the sub-domain FMA-balance. Similar to FMA and Barthel Index comparison, the sub-domains FMA-sensory, FMA-joint pain and FMA-ROM did not show any significant correlation with FIM score.

Discussion

The result of this study showed that most subjects (10 subjects or 50%) had significant motor impairment, while the other subjects had slight and severe impairment with 6 (30%) and 4 (20%) subjects respectively. A study by Duncan in 1992 with the subjects consisted of 104 stroke patients reported that 37 subjects (35.6%) had slight motor impairment, 2 subjects (21.2%) had moderate motor impairment, 13 subjects (12.5%) had significant motor impairment and 32 subjects (30.8%) had severe motor impairment ⑨.

In this study, the obtained mean of FMA-UE was 43.08±18.38 (4-66), while the mean of FMA-LE score was 22.55±7.69 (6-34). The mean of FMA-sensory score was 19.9±3.21 (12-24). This was in line with the results of a study by Sullivan et al. conducted in 15 stroke patients in which the obtained mean of FMA-UE was 30.40 (5-63) and FMA-LE motor score mean was 23.10 (8-33), whereas the mean of FMA-sensory total score was 18.70 (2-24). This implied that the mean of FMA-LE motor score was higher than that of FMA-UE motor score if reviewed from each instruction item’s score and sensory total score which were not much different from
the results from Sullivan et al. 10.

The mean of FMA-balance score was 8.25±2.82 with the lowest score being 2 and the highest score 14. The score of FMA-balance was lower than that in the study by de Oliveira et al. in Physiotherapy and Occupational Therapy Ambulatory of the University Hospital-UNICAMP, Brazil, in which the obtained FMA-balance of the 20 stroke patients was 10.80±1.24 7.

The mean value of FMA-Total in this study was 167.5 ± 33.73 (110-220). The mean FMA-total value was consistent with research conducted by de Oliveira, i.e. 170.50±31.91. The mean FMA-total in this study indicated that the functional state of the subjects was in a phase where there a controlled movement occurred outside of the synergistic pattern of the limbs and the spasticity level that has begun to decline 7.

Barthel Index score mean obtained was 80.75±16.56 points and ranged between 40-100 points. This was slightly different from the results obtained by de Oliveira et al in which the authors also evaluate the correlation between FMA and Barthel Index. The mean of Barthel Index score in that study was 90.75±5.45 7.

The mean of the subjects’ FIM score was 101.45±18.38 points and ranged from between 60-126 points. This indicated the subjects’ state where they could perform daily activities although the caregivers’ supervision was still required in each FIM measurement. The mean of FIM score here was higher compared to the results from Ravaud J.F. et al who tested the FIM constructive validity as a rehabilitation instrument. The mean of Barthel Index score in that study was 90.75±5.45 7.

This study’s results suggested that FMA-total score was significantly correlated with Barthel Index with the correlation coefficient of r=0.816. The correlation coefficient indicated a strong correlation between FMA score and BI score. The results of this study showed a higher correlation coefficient value compared to that of the study conducted by Oliveira et al. who obtained a statistically significant correlation coefficient (P <0.05) of r = 0.597. This indicated that the level of physical performance measured based on the FMA value affected a person’s level of independence in performing daily activities (ADL/Activity Daily Living). The high correlation coefficient in the study implied that FMA score could be used as a reference to measure a stroke patient’s independence level 7.

The results of this study also indicate that the sub-domains FMA-UE, FMA-LE and FAM-balance had statistically strong correlation with Barthel Index score. This suggested that motor function recovery (AGA and AGB) in stroke patients along with the post-stroke balance level were correlated in improving a stroke patient’s independence. This was also similar to the study by de Oliveira where a significant correlation was found between the sub-domain motor total and Barthel Index score with r=0.597. In addition, Ferrucci et al. also reported a quite statistically significant correlation between FMA score and Barthel Index score.

AGA was known to have a bigger role in self-care while AGB affected mobility. However, the correlation coefficient in this study was higher in FMA-LE than in FMA-UE toward Barthel Index. The authors assumed that this was because in performing self-care activities, the subjects have done substitutions in the non-dominant arm that did not impacted by hemiparese. This was stated by Olsen et al. who assumed that a compensatory mechanism has occurred as a strategy in functional performance. The mobility components were considered as the components causing FMA-LE and FMA-balance to have a statistically significant correlation with Barthel Index. Correlation between balance and functional performance has often been documented in hemiparese patients, in which a posture impairment was found that was related to standing and sitting balance and this would lead to impairments in functional performance related to mobilization 7,12.

Other results showed that FMA total score had statistically correlation with FIM score with r=0.728. FIM was the more current instrument and had a rapid popularity increase. Aside of measuring ADL, this examination also had social and communication cognitive items. This instrument was considered more quantitative compared to Bathel Index since the score of each FIM item was ranged between 1-7 and thus the score of each item would be more specific.

A lot number of evidences from several validation studies confirmed that the FMA score could represent the independence level or disability level of stroke patients. In this study, the scores were found in FMA-UE, FMA-LE and FMA-balance that were significantly correlated with FIM score, with correlation coefficient of 0.728, 0.747 and 0.694 respectively. All FMA components were highly correlated with FIM. This was understandable since FIM items required functional
motor strength and balance for independent functional performance. However, the correlation coefficient of FMA-BI was higher than that of FMA-FIM. It was caused by the cognitive and communication components in FIM were not empirically correlated with motor performance or balance. However, cognitive and communication components had lower score proportion compared to self-care, sphincter control, mobility and locomosi in which then correlation between FMA-total and FIM remained found despite the correlation coefficient being lower than that of FMA-total and BI.

**Conclusion**

A high positive correlation was found between functional performances measured using Fugl-Meyer Assessment and interdependency levels in performing daily activities measured using Functional Independent Measure (FIM) score in stroke patients with dominant-side hemiparese undergoing the rehabilitation programs in Medical Rehabilitation Hospital.

Determination of Priority Elements of Vigilance in the Use of Pesticides based on Difficulty and Usefulness (A Supporting Study for Law and Policy in Health)

Ilyas Ibrahim1, I Ketut Sudiana2, H J Mukono3, Suhartono4, Heru Santoso Wahito Nugroho5

1Doctoral Student, Faculty of Public Health, Universitas Airlangga / Lecturer, Faculty of Health Science, Universitas Bumi Hijrah Tidore, 2Professor, Department of Pathological Anatomy, Faculty of Medicine, Universitas Airlangga, 3Professor, Faculty of Public Health, Universitas Airlangga, 4Associate Professor, Faculty of Public Health, Universitas Diponegoro, 5Associate Professor, Poltekkes Kemenkes Surabaya

Abstract

The use of pesticides is still a problem for public health, therefore we need a regulation by the authorities, which can lead to the behavior of using pesticides correctly. This is part of the area of law and health policy. Pesticide poisoning can cause breathing difficulties, headaches, neurological or psychological effects, and skin irritation and mucous membranes. The purpose of this study is to provide an overview of some elements of vigilance in the use of chemical pesticides for farmers. The variables studied were difficulty and usefulness with eight elements, namely the use of personal protective equipment (PPE), pesticide storage, pesticide use procedures, use of pesticide doses, duration and frequency of pesticide spraying, maintaining equipment cleanliness, pesticide spraying according to wind direction and time of pesticide spraying. The sample size of this study was 100 respondents from the community who knew about the use of pesticides throughout Indonesia. The research instrument used was a Google form questionnaire sent to respondents via Whatsapp social media. The data that has been collected is analyzed descriptively to get an idea of which elements are the priorities for improvement. Referring data analysis result, the elements with high difficulty and usefulness together were use of pesticide doses and procedures for using pesticides. Thus, the two elements selected as priority elements will be fixed first. It is suggested that the pesticide control policy makers can develop regulations by prioritizing the two main elements, without ignoring the other six elements. In addition, it is also recommended that other control efforts be made that can be recommended to related parties in the area of law and health policy, related to the prevention of health problems caused by the use of pesticides.

Keywords: health law and policy, pesticide; farmer; difficulty; usefulness

Introduction

The use of pesticides is still a problem for public health, therefore we need a regulation by the authorities, which can lead to the behavior of using pesticides correctly. This is part of the area of law and health policy. With formal regulation, efforts to control the use of pesticides can be better regulated, so that the negative impacts that occur can be minimized.

Pesticides have a major role in increasing agricultural production. Based on experience in Latin America, the use of pesticides can increase cocoa production by 40%. In Pakistan, pesticides help increase sugarcane production by 33%, and based on FAO records the use of pesticides can save cotton crops up to 50%.(1)

Many research results show a relationship between the use of pesticides with health problems in workers. According to WHO, intentional or unintentional pesticide poisoning is a serious problem in agricultural communities in poor and developing countries. It is estimated that around 250,000 deaths occur due to pesticide poisoning each year.(2)
Symptoms of poisoning arising from the use of pesticides include difficulty breathing, headaches, neurological or psychological effects, and skin irritation and mucous membranes. Manifestation of these effects depends on the type of pesticide and the level and duration of exposure.\(^3\)

Advanced health problems arising from exposure to pesticides are mutagenic, carcinogenic, endocrine disruptors, reproductive and neurotoxic disorders.\(^4\) Pesticides can enter the body through digestion, inhalation and through the surface of the skin that is not protected.\(^5\) The presence of pesticide exposure in the body can be determined by checking the activity of the cholinesterase enzyme. Organophosphate pesticides work by inhibiting the activity of the cholinesterase enzyme so that acetylchholin cannot be hydrolyzed, so that the amount becomes excessive, which in turn can result in continuous stimulation of the muscarinic and nicotinic nerves.\(^6\)

Horticultural crop farmers are one of the populations at risk for pesticide poisoning, with long-term negative impacts. The risk of this exposure is related to their involvement in activities in agriculture, such as spraying, preparing equipment for spraying, mixing pesticides, washing equipment and clothing used when spraying, removing weeds from plants, removing pests, watering plants and harvesting.

In Indonesia, the proportion of pesticide use or storage in the home is 20%. This shows the high risk of exposure to pesticides, not only in rice fields but also in the household environment.\(^7\) Farmers who use chemical pesticides in Indonesia, most do not pay attention to pesticide use standards, although many have received counseling from the agriculture and health offices in pesticide prevention and control programs. So far, risky behavior carried out by farmers in the use of pesticides has not decreased, therefore, research needs to be carried out that aims to identify and provide an overview of the selection of elements of behavior of farmers who are very risky, to prioritize which elements need to be dealt with quickly quickly and right.

**Method**

This research was a descriptive study conducted in 2019, involving the general public who know about the use of chemical pesticides in Indonesia as research respondents, with a sample size of 100 respondents.

The research variables measured were difficulty and usefulness\(^{(8),(9)}\) of 8 elements of risk behavior consisting of; 1) personal protective equipment (PPE), 2) storage of pesticides, 3) procedures for using pesticides, 4) use of pesticide doses, 5) duration and frequency of spraying pesticides, 6) maintain cleanliness of equipment, 7) spraying pesticides in the direction of the wind, 8) time spraying pesticides. The selection of these elements was based on references written by Djojosumarto, titled “Pesticides and Their Applications”\(^{(10)}\). In this questionnaire, difficulty was scored with a negative symbol (0 to -10), so the higher the difficulty of an element, the score for that element increasingly negative. Usefulness was scored with positive symbols (0 to 10), so the higher the usefulness of an element, the more positive the score for that element was.

The research instrument used was a Google form questionnaire sent to respondents via Whatsapp social media. The categorical data that has been collected was analyzed descriptively in the form of frequency\(^{(11)}\) to get an idea of which elements were the priorities for improvement.

</tbody>
</table>

Regarding usefulness, elements with a relatively high level of usefulness (score 6 to 10) were procedures for using pesticides, time spraying pesticides, and use of pesticide doses.

Referring to Table 1 and Table 2, it can be seen that the elements with high difficulty and usefulness together were use of pesticide doses and procedures for using pesticides. Thus, the two elements selected as priority elements will be fixed first.
Discussion

Based on the results of the study, it is known that there are 2 elements that are prioritized for improvement, referring to the difficulty and usefulness according to public perception. The two elements are:

1) Use of pesticide doses
2) Procedures for using pesticides

The two elements above were chosen as elements to be addressed first, but that does not mean ignoring the other six elements. Selection as an element of priority is limited to the issue of time urgency. Because these two elements have the highest level of difficulty to be changed for the better and have the highest level of benefit for the community, both of them are chosen to be addressed first.

The use of difficulty and usefulness as a priority determination refers to the findings pioneered by Nugroho et al.\(^1\)\(^2\) which was originally applied to research on the elements of e-learning in the health field, which has been realized in two studies namely the use of difficulty and usefulness without weighting and weighting. In both studies it is recommended that this priority setting method can be applied to various fields of science. Thus, in this study also applied the use of difficulty and usefulness as a method of selecting elements that are prioritized to be addressed first in the framework of the program of vigilance against the behavior of the use of wrong pesticides, which could adversely affect health.

However, in this study, only the main elements were selected with high difficulty and usefulness values together, based on descriptive data analysis in the form of frequency. Meanwhile, Nugroho et al.\(^1\)\(^2\)\(^3\) in both researches, applying in different ways using numerical data analysis in the form of mean scores for each element, and presented in the form of Difficulty-Usefulness Pyramid (DUP).

Conclusion

Based on the results of data analysis, it can be concluded that based on difficulty and usefulness, there are two main elements that are prioritized to be addressed first, namely use of pesticide doses and procedures for using pesticides.

Based on the conclusions above, it is suggested that the pesticide control policy makers can develop regulations by prioritizing the two main elements, without ignoring the other six elements. In addition, it is also recommended that other control efforts be made that can be recommended to related parties in the area of law and health policy, related to the prevention of health problems caused by the use of pesticides.

The Association Between Myoglobin, Troponin I, Hfabp and Nt-Probnp Levels with Acute Myocardial Infarction in Patients with Acute Coronary Syndrome

Ime Fransiska Adidharma1, Jusak Nugraha1, Muhammad Aminuddin1

1Department of Clinical Pathology Faculty of Medicine Universitas Airlangga Dr. Soetomo Teaching Hospital Surabaya60285, Indonesia

Abstract

Introduction: Myocardial infarction is one of the five major manifestations of coronary heart disease. Myoglobin heart markers, Isoenzyme Creatine Kinase-MB (CK-MB), cardiac Troponin I (cTnI) or Troponin T (cTnT), Heart type fatty acid-binding protein (HFABP) and NT-proBNP are currently used in assisting the diagnosis of acute myocardial infarction. The study aimed to analyze the association of cardiac marker examination results of myoglobin, cTnI, HFABP and NT-proBNP with AMI occurrence on examination I and examination II.

Method: This study enrolled 33 patients in Installation of Emergency Care with suspected acute coronary syndrome, from March to August 2013. Serum samples were taken including cTnT, myoglobin, cTnI, HFABP and NT-proBNP. Then, it was further analyzed.

Results: There was an association between myoglobin, cTnI, HFABP, and NT-proBNP with AMI events. Myoglobin and HFABP were early markers for the diagnosis of AMI, the mean levels of both markers was higher at the first examination (<1 hour admitted patients) when compared with 6 hours later after being tested. Essentially, the diagnostic value of both did not differ, only HFABP was more specific than myoglobin. Troponin I showed to be the best choice in the diagnosis of AMI because of the high sensitivity and specificity.

Conclusion: An association between myoglobin, cTnI, HFABP, and NT-proBNP with AMI events was found. Myoglobin, cTnI, HFABP can be used in diagnosing AMI patients, whereas NT-proBNP is not recommended for the diagnosis of AMI due to its low specificity.

Keywords: AMI, ACS, myoglobin, cTnI, HFABP, NT-proBNP

Introduction

Cardiovascular disease is a global public health problem, contributing to 30% of global deaths and 10% of global diseases.1

Acute myocardial infarction is part of the spectrum of acute coronary syndrome. Acute coronary syndromes include Unstable angina (UA), Non-ST-elevation myocardial infarction (NSTEMI), and ST-elevation myocardial infarction (STEMI).1,2

World Health Organization (WHO) also shows that deaths from ischemic heart disease ranked at 12.2% in 2004 and 14.2% in 2008.3 Indonesia’s health profile in 2009 expended by the Ministry of Health of Indonesia shows that in 2008 vascular system disease was highest among 11.06% of all causes of death in the hospital.4

Early diagnosis of myocardial infarction is still a problem because not all patients who later prove to be suffering from AMI come with clear diagnostic criteria, especially in the early hours. Cardiac serial examination

Corresponding Author: Jusak Nugraha
Email: Jusaknugraha153@gmail.com
is now universally accepted as an important determinant in the diagnosis of acute myocardial infarction. Appropriate and rapid method of examination for early diagnosis of myocardial infarction is essential.5-9

Myoglobin heart markers, Isoenzyme Creatine Kinase-MB (CK-MB), cardiac Troponin I (cTnI) or Troponin T (cTnT), Heart type fatty acid-binding protein (HFABP) and NT-proBNP are currently used in assisting the diagnosis of acute myocardial infarction.8

Heart type fatty acid-binding protein (HFABP) is a low-BM-dissolved protein, which is widely present in the myocardial cell cytoplasm. HFABP is a rapid biological marker in the circulation after myocardial injury.10-11 B-type natriuretic peptide is a hormone that is structurally included in the group of natriuretic peptide hormones associated with renal and cardiovascular function. Increased levels of natriuretic peptide, especially NT-proBNP, are also found in post-myocardial infarction, which may be caused by localized infarct strains and are associated with activation of the neurohormonal system.12-13 This study aimed to analyze the association of cardiac marker examination results of myoglobin, cTnI, HFABP, NT-proBNP with the incidence of AMI in patients suspected of acute coronary syndrome who came to emergency unit of Dr. Soetomo General Hospital on examination I (<1 hour on admission) and examination II (6 hours after admission), and compare the sensitivity and specificity of the heart marker.

Method

This study was an observational analytic study using a cross-sectional study design. The study was implemented in Emergency Department Dr. Soetomo Teaching Hospital, Surabaya Indonesia. The samples were 50 patients who came to emergency unit Dr. Soetomo Teaching Hospital within 1 month of suspected ACS, suspected acute myocardial infarction fulfilled the sample criteria.

The inclusion criteria in the study included patients with chest pain complaints with suspected ACS, willing to participate in the research and signed informed consent and had a complete medical record. On the other hand, the exclusion criteria included patients with serum creatinine >2mg/dL, sepsis patients, cirrhosis hepatis and acute stroke. The flow of the study began when emergency unit patients were diagnosed with acute syndrome syndrome, and matched with inclusion criteria. If it was appropriate, it was continued for the next stage of anamensis, physical examination, ECG, cTnT examination, myoglobin, cTnI, HFABP and NT-proBNP. Examination I (<1 hour of patient admission) and examination II (6 hours after admission) were conducted. The subjects were distinguished into AMI patients and non AMI patients. Afterwards, the data collection and data processing were conducted using statistical analysis.

All data was obtained and inserted into the computer, then then processed statistically. The results were presented in tables or graphs. The diagnostic test criteria included sensitivity, specificity, negative and positive predictive value calculated using 2x2 tables based on 95% CI. An association analysis between the levels of myoglobin, troponin I, HFABP and NT-proBNP with AMI events was analyzed by Chi-square test.

Results

The sample characteristics showed in table 1.

The results of cTnT examination showed that there were 3 patients who were at the beginning of the negative examination and on the 6th positive check. The mean cTnI, HFABP and NT-proBNP levels were higher in the 6 hours of patient admission. The mean myoglobin levels was higher at examination 1 (<1 hour of admission) (Table 2). HFABP levels in AMI (STEMI and NSTEMI) patients were higher than in non-IMA patients, with higher HFABP levels of STEMI patients than in NSTEMI patients.

**Analysis of associations of myoglobin, cTnI, HFABP and NT-proBNP with AMI incidence**

Based on Fisher’s exact test, in examination I, (<1 hour of MRS patient) the value of p was 0.005 which meant less than α = 0.05. It can be concluded that there was significant association between myoglobin and AMI event. Fisher’s exact test result on examination 6 hours after patient admission showed that p = 0.005 which meant less than α = 0.05. Thus, it can be concluded that there was significant association between myoglobin and AMI event. Fisher’s exact test result, on examination I
(<1 hour of patient MRS), the p value was 0.000 which meant less than α = 0.05. Thus, it can be concluded that there was a significant association between cTnI with AMI event. Fisher’s exact test result on examination 6 hours after patient admission showed that p = 0.000 which meant less than α = 0.05. Therefore, it can be concluded that there was significant association between cTnI and AMI event.

Based on Fisher’s exact test, on examination I (<1 hour of patient admission) the value of p was 0.002 which meant less than α = 0.05. Thus, it can be concluded that there was a significant association between HFABP and AMI event. Fisher’s exact test result on examination 6 hours after patient admission showed that p = 0.002 which meant less than α = 0.05. Therefore, it can be concluded that there was a significant association between HFABP and AMI event. Result of Fisher’s exact test test, on examination I (<1 hour of patient admission) the p value was 0.026 which meant less than α = 0.05. Thus, it can be concluded that there was significant association between NT-proBNP and AMI event. Fisher’s exact test result on examination 6 hours after patient admission showed that p = 0.017 which meant less than α = 0.05. Therefore, it can be concluded that there was significant association between NT-proBNP and AMI event.

Discussion

An individual is very susceptible to coronary atherosclerosis along with the aging process. The incidence of AMI increased fivefold at the age of 40 to 60 years old. It is associated with increasing age (especially in the menopausal phase), where there is a decrease in endogenous estrogen levels. Most AMI patients suffer from dyslipidemia. The study of multiple risk factor intervention trials in 356,222 subjects showed that cholesterol levels rise in proportion to the increase of AMI attacks. Increased LDL and HDL decline are important risk factors for AMI. Any decrease of 4 mg% of HDL will increase AMI risk by about 10%. The National Academy of Clinical Biochemistry (NACB) recommends serial examination and the use of 2 cardiac markers of myocardial necrosis: early and slow-emerging cardiac markers.

Myoglobin examination showed if the highest results in the STEMI group, it corresponds to several literatures that stated that the increase in myoglobin in the blood occurs 1-4 hours after damage of the heart muscle tissue or skeletal muscle, reaches peak within 6-7 hours after myocardial infarction, and returns to normal within 24 hours. Because myoglobin is an early heart marker, it is necessary to check with other cardiac markers.

Based on the results of research on the highest average cTnI examination in the STEMI group on the second examination, it is consistent with the literature which states that troponin I begins to increase 3 to 5 hours after myocardial injury, peaking at 14 to 18 hours and keep increasing for 5 to 7 days. Increased concentrations of BNP and NT-proBNP during the arrival in hospital under conditions of acute coronary syndrome are associated with poor prognosis, including increased mortality, congestive heart failure, and recurrent ischemic events.

Suitability of myoglobin, cTnI, HFAB, NT-proBNP results against gold standard in AMI patients. Troponin I is an ideal AMI biochemical marker because of its sensitivity and specificity. These biochemical markers are not affected by skeletal muscle disease, skeletal muscle trauma, renal disease or surgery. A multifaceted mobile technology-supported primary health care intervention was associated with greater use of preventive CVD medication and lower BP levels among high-risk individuals in a rural Indonesian population. Conclusions High cardiovascular risk is common among Indonesian adults aged 40 years, and rates of preventive treatment are low.

Conclusion

It can be concluded that there was an association between myoglobin, cTnI, HFAB and NT-proBNP with the incidence of AMI. The emergence of biomarkers does not occur at the same time, therefore serial cardiovascular examination and use of 2 cardiac markers in diagnosing AMI are required, considering the presence of early marker and a marker that appears more slowly, and in view of the different sensitivity and specificity of each cardiac marker.

Evaluation of Some Inflammatory Cytokines and Glycated Hemoglobin in Uncontrolled Type 2 Diabetes Mellitus with Nephropathy

Inaam Ahmed Ameen1, Eman Saadi Saleh1, Sarah Hashim Mhaibes1, Kaled Nather Taha2, Dhikra Abdul Hameed Dawood2, Hawaa Salman Kamil2

1Department of Clinical Laboratory Sciences, College of Pharmacy, University of Baghdad, Baghdad, Iraq, 2Ministry of Health / Medical City / National Center for Educational Laboratories, Baghdad, Iraq

Abstract

Background: Chronic hyperglycemia causes diabetic nephropathy (DN), which is a typical microvascular complication of type 2 diabetes mellitus. The pathogenesis of DN is not fully understanding. The inflammation may possess a significant role in the progression of DN in diabetic patients.

Method: The study accomplished at teaching laboratories of medical city, Baghdad, Iraq. It was included 50 uncontrolled diabetic type 2 patients with nephropathy, age range (40 – 78) years and 42 controlled diabetics type 2 without nephropathy, age range (35 – 52) years as a control group. The participants divided into two groups according to HbA1c measurement which is described as follows: < 7.5% of HbA1c describes controlled diabetes, and > 9% of HbA1c describes uncontrolled diabetes. The calculation of the Glomerular filtration rate (GFR) was used to determine the renal function for each participant. A venous blood sample was obtained to estimate HbA1c, fasting serum glucose (FSG), urea, creatinine, interleukin-6 (IL-6), interleukin-1 beta (IL-1β) and tumor necrosis factor – alpha (TNF-α).

Results: Significantly higher serum urea and creatinine levels in uncontrolled diabetic patients with nephropathy than controlled diabetic without nephropathy. The mean of HbA1c of DN group was higher as compare to diabetic control (DC) group. Results of IL-1β, IL-6 and TNF-α exhibits a significant raised level for diabetics with nephropathy, (p< 0.05) for IL-1β, (p< 0.05) for IL-6 and (p< 0.01) for TNF-α.

Conclusion: Raised serum levels of TNF-α, IL-1β and IL-6 in uncontrolled diabetic patients with nephropathy concurrently with raising the average HbA1c in them indicate that the inflammation may have a role in the advancement of DN in diabetic patients with poor glycemic control.

Keywords: inflammation, interleukins, type2 diabetes mellitus, HbA1c, hyperglycemia

Introduction

Diabetic nephropathy (DN) is an advanced renal disease designated by persistent albuminuria with reduction of glomerular filtration rate (GFR) due to uncontrolled hyperglycemia [1]. Metabolic changes occurred in diabetes causes deterioration of glomerular functions leading to DN that recognized by an accumulation of nitrogenous compounds like creatinine and urea with a consecutive deterioration in the GFR followed by arterial hypertension give raise to renal damage [2]. Immunological and inflammatory employ significant roles in DN and its progression, particularly IL-8, IL-6, IL-1β, and TNF-α, by modifying disease via various mechanisms. Regulation of inflammatory and immune responses by these cytokines through secondary pathways which are contributes to the pathophysiology of many diseases including diabetes mellitus (DM) [3]. Pathological alterations in DN are renal hypertrophy and hyperfiltration that are associated with inflammation processes which included release of proinflammatory and anti-inflammatory cytokines from many immune cells [4]. IL-1β is proinflammatory cytokines produced by macrophages and renal in inflammatory based diseases. It was involved in the declining of glomerular functions, leading to renal
damage in DN [5].

Interleukine-6 (IL-6) has both a pro-inflammatory cytokine and an anti-inflammatory effect in human, causes glomerular basement membrane thickening, enhances endothelial permeability and mesangial cell proliferation [6]. Tumor necrosis factor alpha (TNF-α), an inflammatory cytokine modifies glomerular functions and increased vascular endothelium permeability infiltration by inflammatory cells, grow extracellular matrix, generation of reactive oxygen species and blood flow interrupt are additional notable effects in renal structures [6]. The production of these proinflammatory cytokines, which triggered by the hyperglycemic status that happens in diabetic patients, followed in renal deterioration, either glomerulus or different structures [7].

Hyperglycemia or poor glycemic control was considered a good promotor of DN. Tightly controlled of blood glucose level is required to prevent or delay diabetic kidney disease [8]. Glycosylated hemoglobin (HbA1C) is biomarker of glycemic control in DM condition because it describes blood glucose levels in the last 60–90 days. Several studies determined that HbA1c were significantly correlated with cytokine concentrations in DN [9,10]. The purpose of this research to define the relation between glycated Hemoglobin and some inflammatory cytokines (IL-1β, IL-6 and TNF-α) in DN.

**Patients & Method**

The study accomplished at teaching laboratories of medical city, Baghdad, Iraq, a total 50 uncontrolled diabetics type 2 with stage 3-4 of nephropathy (UDN), age range (40 – 78) years and 42 controlled diabetics type 2 without nephropathy (DC), age range (35 – 52) years as a control group were enrolled in the study. The ethics committee approved the study of college of pharmacy, university of Baghdad, Baghdad, Iraq (No. UBCP-RECA 26102019). Exclusion criteria included: type 1 DM, gestational DM, multivitamin supplements, bleeding disorder, anemia, infections (e.g. hepatitis, malignant diseases). The glycemic file of the participants did evaluated by estimating HbA1c, FSG levels. The participants divided in to two groups according to HbA1c measurement which is described as follows: < 7.5% of HbA1c describes controlled diabetes, and > 9% of HbA1c describes uncontrolled diabetes [11]. Venous blood sample was collected to measure HbA1c using HPLC assay (Arkray, Germany) and fasting serum glucose (FSG) levels by enzymatic colorimetric method (Siemens USA). Serum urea nitrogen was measured by using urease/glutamate dehydrogenase coupled enzymatic technique (Dimension clinical chemistry System, DF21 Siemens, USA). Serum creatinine was measured by using modified kinetic Jaffe technique (Dimension clinical chemistry System, DF33B Siemens, USA). Enzyme linked immunosorbent assay (ELISA) technique was used for quantitative measurement of IL-1β, IL-6 and TNF-α by using human ELISA kit. Estimated Glomerular Filtration Rate (eGFR) was measured by modified diet renal disease (MDRD) equation for Creatinine and the equation adjusted for age and sex. [12], as shown in table (1). GFR measurement gives the basis for discovery and classification of chronic renal disorder. The eGFR of the UDN involved in the research classified as mild to moderate GFR reduction. The eGFR of the DC group classified as normal GFR.

**Statistical Analysis**

Statistical analysis was made employing SAS (Statistical Analysis System. Version 21). An Independent t-test sample was used to compare the serum levels of all parameters between UDN and DC groups. The variations between the groups were reflected to be significant at a p-value of ≤ 0.05.

**Results**

The laboratory and descriptive analysis for the participants were installed in table 2, which revealed the mean, standard deviation for these parameters and
p value. Calculations displays the mean of eGFR for patients group is 33.65, this value classified as moderate GFR reduction. The mean of eGFR for control group is 100.58 which classified as normal GFR values. Mean HbA1c of UDN group was 10.45±1.52% and that of DC group was 6.17±1.02%. The mean of HbA1c of UDN group was higher as compare to DC group, so the increase of HbA1c values associated with increased incidence of nephropathy in type 2 DM. Results of IL-1β, IL-6 and TNF-α displays a significant increased levels for UDN group, (p< 0.05) for IL-1β, (p< 0.05) for IL-6 and (p< 0.01) for TNF-α (table2).

**Discussion**

Chronic hyperglycemia and inflammation are the major causative agent of DN[13]. Several metabolic, biochemical and hemodynamic changes act as a promoter to inflammation in DN. DN is a critical microvascular complications of type 2 diabetes mellitus that required early diagnosis and management to prevent irreversible renal failure[14]. Therefore, adequate control of blood glucose levels is needed to delay the progression of DN. Important markers were applied to determine the renal function which are blood urea and creatinine levels. The measurements of eGFR is depend on the amount of creatinine detected in a blood specimen. Raising serum creatinine levels result in increased GFR. Renal disorders are happened when eGFR is < 60ml / min / 1.73m2. Activation of the immune system and chronic inflammation are both implicated in pathogenesis of DN, researches have demonstrated that chemokines, cytokines, as well as immune cells as monocytes, lymphocytes, and macrophages are involved in pathogenesis and complications of type 2 diabetes mellitus[15]. In the current study, it noticed that IL-6 and IL-1β serum levels are significantly higher in UDN group than the levels mentioned in DC group as correspond with other studies[16,17]. IL-1 is recognized to be implicated in the deterioration of glomerular functions. It related to the secretion of prostaglandin by mesangial cells of kidney leading to changes in renal structure which are important in the development of DN[18]. In addition to this study, Sari MI et al. determined that serum IL-6 levels raised in patients with diabetic nephropathy [19]. Also a previous study has reported a significant difference in the IL-6 levels between a group of diabetic patients and a group of healthy people[20]. IL-6 also encourages growth and proliferation of mesangial cells. It has been recognized that increase proliferation...
and action of mesangial cells producing in extracellular matrix growth, glomerular basement membrane thickening, and glomerulosclerosis, eventually lead to DN [7]. Furthermore, IL-6 has non immune mediated mechanism that influence glucose metabolism by action on skeletal muscle cells, pancreatic islet cells and adipocytes [21,22]. Additionally, this research reveals that serum TNF-α levels in UDN group are significantly more than the serum TNF-α levels in DC group. Similarly, other studies show that increase risk of diabetic kidney disease associated with the increase levels of TNF-α in patients with type 2 DM [23,24]. TNF-α exert different effects to cells including apoptotic and necrotic cell death by direct and autocrine mechanism, also changes of endothelial permeability. TNF-α lead to impairment of glomerular capillary wall barrier function, hence increasing albuminuria [7].

In this study, the average of HbA1c in UDN group was significantly more than that of DC group, thus HbA1c may be used as an indicator of prognosis in the development of DM complications. Similar results were observed by other studies which found that increase HbA1c levels above 7.0% were significantly correlated with increased prevalence of nephropathy [25,26]. Past studies pronounced that age was crucial factor linked to renal function derangement. The old age and duration of diabetes were significant risk factors for nephropathy as an deal with this study [27,28]. Poor glycemic control shown by elevated mean HbA1c, and fasting serum glucose levels were significantly connected with increased predominance of nephropathy in this study.

**Conclusion**

Raised serum levels of IL-1b, IL-6 and TNF-α in uncontrolled diabetic patients with nephropathy concurrently with raising the average HbA1c in them indicate that the inflammation may have a significant role in the progression of DN. The occurrence and risk of DN increased with advanced age and poor glycemic control, so that the incidence and worsening of DN among type 2 diabetic patients could be limited or restricted by keeping tightly controlled HbA1c. The perception of the inflammatory response in DN is urged to identify novel anti-inflammatory plans for the intensive therapy to patients with DN.

The Impact of High Cortisol Level in Increasing Incidence of Infection Cases among Acute Stroke Patients

Indah Ari Handaayani¹, Joseph Eko Wahono Rahardjo¹, Muhammad Hamdan¹, Paulus Sugianto¹, Achmad Firdaus Sani¹, Mohammad Saiful Ardhi¹

¹Department of Neurology, Faculty of Medicine, Universitas Airlangga, Surabaya (60131), Indonesia

Abstract

Background: Infection in the stroke was a treatment major problem, because it determines the prognosis. In the acute phase of stroke, high level cortisol may lead to a decreased immune system and patients tend to be more susceptible to infection. The correlation of serum cortisol level among acute stroke patients with incidence of infection was not fully investigated.

Objective: The aim of this study was to determine the relationship between initial serum cortisol levels and the incidence of infection in acute stroke patients.

Method: A prospective cohort study was conducted on 32 of acute stroke patients who admitted in RSUD Dr. Soetomo Surabaya during the period December 2015 to February 2016. Total of 2 cc to the venous blood within 48 hours in onset of stroke being examined of serum cortisol. During the 7 days of hospitalization, the patient was observed for signs of infection, both clinically and the investigation in accordance with the operational definition.

Results: In the infected group there were 8 people (50%) with high cortisol levels (p = 0.015; RR 15,000; 95% IK 1.583-143,171); 6 people were (50%) using urine catheter (p = 0.049; RR 6,667; 95% IK 1.067-30.085); And 6 people were (54.5%) using NGT (p = 0.035; RR 7,200; 95% IK 1.311 - 39,557). In multivariate analysis obtained that Odds Ratio (OR) 15,468 based on high cortisol and OR 7,469 based on NGT usage.

Conclusion: High cortisol levels and the use of NGT had the effect on the incidence of infection in acute stroke.

Keywords: Acute Stroke, Serum Cortisol Level, Infection Incidence

Introduction

Stroke was a major health problem in Indonesia. According to the National Basic Health Research data on 2013, the prevalence of stroke in Indonesia was 12.1 for each 1000 population, the number has revealed an increase in stroke prevalence when it was compared to the national data in 2007 which was 8.3 for each 1000 population. Based on Registry Stroke data 2014 infarct stroke was noted as the most frequent cases (67.1%), followed by bleeding stroke (32.9%) ².

In acute stroke, the systemic infection after the brain damage could be a symptom of the reduction competence of the immune system, that mediated by the central nervous system. The following period of stroke might be considered as a reaction to the stressful event. The red thread that links these two supersystems was the hypothalamus-pituitary-adrenal (HPA) axis ³. The main characteristics of the response to stress were the activation of the sympathetic nervous system and the HPA axis ⁴.

Corresponding author:
Joseph Eko Wahono Rahardjo

There were several hypotheses that attempt to explain the effect of stroke on the HPA axis, one of them was the structural injury in the brain regions that play a role in the regulation of HPA axis, such as the brainstem, hypothalamus, pituitary, terminal lamina, Limbic hippocampus. Additionally, the lateralization of the nervous system also helps in explaining the several locations that affect the metabolic changes post stroke. In addition, recurrent stress might increase the adrenal sensitivity to ACTH, which turn to leads to the prolonged hyper cortisol. Cortisol was the responsible of primary hormone for the responses to the stress. In the event of exposure to stress the increased of circulating cortisol were inhibits the HPA activity at the hypothalamus and pituitary levels.

Increased cortisol suggests a severe inflammatory process that will lead to increased temperature, fibrinogen, leukocyte count, β thromboglobulin and IL-6[11]. Cortisol levels remain high within 7 days post-acute stroke and return to the normal limits approximately after 3 months. The highest cortisol levels were estimated to occur in the first 48 hours marked by the highest deactivation of monocytes.

Whereas, In acute stress conditions, cortisol also facilitates the release of anti-inflammatory mediators such as IL-4 and IL-10 that have apoptotic effects on immune cells[13]. However, in chronic exposure, high levels of cortisol prevent this effect. The effect of cortisol on these cytokine signals was likely to optimize the occurrence of inflammation. Complications of infection in stroke was a major problem in the treatment of stroke patients. Reported that 5-65% of acute stroke patients with the most common types of infection were urinary tract infections (16%) and pneumonia (12%). Factors that caused the Incidence of infection in high stroke includes: (1) frequent invasive medical procedures such as surgery, catheterization, mechanical ventilation, nasogastric tubing, (2) bed rest, (3) exposure to various drug-resistant bacteria, and (4) the swallowing disorders resulting from the lesions in the central nervous system and causing aspiration. However, the correlation of serum cortisol level among acute stroke patient with incidence of infection was remain unclear.

**Materials and Method**

This study was prospective cohort with analytic observational design. Affordable populations as the sample of this study were an acute stroke patients who admitted in Department of Neurology, Dr. Soetomo hospital, Surabaya, Indoensia during the period December 2015 to February 2016. The subjects were divided into two groups, namely the subject group of acute stroke patients with high cortisol levels and acute stroke subjects group with normal cortisol levels. Of total 32 samples, 16 samples were included in the high cortisol group and 16 were included in the normal cortisol group. In this study, several variables that measured were serum cortisol levels, the incidence of infection, age, body temperature, use of urine catheter, use of nasogastric tube (NGT).

Serum cortisol level are measured by blood samples collection as much as 3 ml from the study subjects within the first 48 hours of stroke onset, at 6-8 am then being examined in laboratory. High serum cortisol levels, when the results obtained on the examination more than 22.40 μg / dL. Normal cortisol serum levels, when the results obtained on the examination between 4.30 - 22.40 μg / dL.

Statistical analysis was performed with SPSS version 22.0. The collected data was analyzed by Chi Square test for categorical data and unpaired t test for normal distributed numerical data. Differences in the proportion of infections in both groups were tested using Chi Square test.

**Results**

In the group of subjects infection, 6 (54.5%) was got NGT and 3 people (14.3%) did not use NGT. The chi square test showed statistically significant difference of proportion with $p = 0.035$ and relative risk (RR) was 7,200 (95% CI 1,311 - 39,557) (Table 3). This means that subjects with the use of NGT had a relative risk for infection 7.2 times compared to the subjects without NGT use.

</tr>
</tbody>
</table>

Based on this multivariate analysis (table 4), it revealed that the variables affecting the incidence of infection cortisol levels and the NGT use with the greatest relation strength was cortisol content with OR = 15,468.

**Discussion**

In this study, we found 20 subjects with infarct stroke and 12 subjects with intracerebral hemorrhage stroke. There was no significant difference of cortisol
content based on the stroke type with p = 0.716. This was consistent according to the results of a meta-analysis of various studies that found elevated cortisol levels were more associated with morbidity, mortality and stroke severity, compared to the stroke types. In this study, we obtained acute stroke patients with high cortisol levels of 16 subjects or 50% of the total subject. In the patients with acute stroke, there was an increase or abnormality of ACTH secretion and cortisol associated with extensive infarction, poor functional outcome and increased mortality.

In this study, 8 subjects with diabetes mellitus and 24 subjects did not suffer from the diabetes mellitus. There was no significant difference in the proportion of diabetes mellitus status between the two groups in this study (p = 0.220). Chiodini in his study also mentioned that the increase in cortisol levels was more related to the complications of diabetes mellitus and it was the degree of complication. Meanwhile in this study was not studied about the complications and degrees of complications in diabetes mellitus that occurred in the study subjects.

Glucocorticoids affect vascular tone by increasing vascular resistance and causing secondary hypertension. However, there was no significant difference in proportion between the two groups in our study (p = 0.5654). This might be due to our study, that the hypertension was thought to be primary hypertension that was more associated with vascular risk factors and not secondary to the high levels of glucocorticoids.

Urinary catheter insertion action could bring the organisms from the urethra directly into the bladder. Most strains of bacteria entering through the urinary catheter could multiply rapidly within a day and persist for up to weeks causing urinary tract infection (UTI). This was consistent with our results where in the group with infection there were 6 subjects (50%) using catheters and 3 subjects (15%) did not. From the analysis with chi square test, there was a statistically significant difference of proportion with p = 0.035 and relative risk was 7.200 (95% IK 1.311-39.557). Based on these data it could be said there was a significant relationship between the use of NGT with the incidence of infection, where subjects who use NGT have a risk of 7.2 times to experience the incidence of infection than subjects who did not use NGT. The use of NGT in this study was a significant confounding factor for the occurrence of infection.

Chen et al mention that the brain infarction could lead to the systemic immunodepression which was predisposes to the infection. Stroke induces widespread apoptosis of lymphocytes and a shift in the production of Th1 to Th2 with immune-system depression. Choi et al mentioned in his research that cortisol exposure was known to reduce the telomerase activity in human T lymphocytes. Meanwhile, Mavoungou et al found that cortisol decreased the ability of NK cells to kill target cells. Cortisol inhibits the expression of cytotoxic receptors from NK cells Transcription level of the regulating gene.

Although several studies have examined the relationship between the post-stroke and the incidence of infection, there have been no specific studies that been examining the association between serum cortisol levels and the incidence of infection in acute stroke patients. Therefore, this study was the first study to find the relationship between serum cortisol levels and the incidence of infection in patients with acute stroke. The limitations in this study were the presence of the other confounding factors that could not be controlled, such as the use of urine catheter and NGT. The advantages of this research were to use a prospective cohort research design which was the best observational research design to find the cause and the effect relationship.

Conclusions

In conclusion, this study revealed that high serum cortisol levels and the use of NGT among stroke patients
may contributed to the incidence of infection.

**Ethical Clearance:** This research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, nonmaleficence, and justice.

Time Recommendation and Alternative Parameters for Severe Maxillofacial Trauma Reconstruction

Indri Lakhsmi Putri¹, Magda Rosalina Hutagalung¹, Ida Bagus Narmada², David Sontani Perdanakusuma¹

¹Department of Plastic Reconstructive and Aesthetic Surgery Faculty of Medicine Universitas Airlangga Surabaya Indonesia, ²Department of Orthodontics Faculty of Dentistry Universitas Airlangga Surabaya Indonesia

Abstracts

Background: Severe maxillofacial trauma often associated with other injuries, therefore the delay of reconstruction often occur until the patients are stable. Early reconstruction results a better facial function and appearances.

Aim: The aim of this study to give the recommendation and alternative parameters for severe maxillofacial trauma reconstruction.

Methods: The method of this study is adult patients with bimaxillary and bilateral maxillofacial trauma were eligible for this study, while pregnant women were excluded. Nine patients with maxillofacial trauma were involved in this study and we measured 15 facial anthropometric and 41 lateral cephalometricon 7, 14, 21 days compared to 3 months post-reconstruction.

Results: The result of this study showed reconstruction can be planned 14 days after trauma for lower jaw fracture and 21 days after bimaxillary fracture. Lateral cephalometry was a reliable method to measure facial edema following surgery which combined facial anthropometry with lateral cephalometry using parameters that are not affected by edema. This can be applied as an additional guiding tool in surgical planning for maxillofacial trauma patients especially those with bimaxillary and bilateral fractures.

Conclusion: Combination of anthropometric and cephalometric parameters which are not affected by edema can be applied as an additional guiding tool in surgical planning for maxillofacial trauma patients.

Keywords: Facial Anthropometric, Lateral Cephalometry, Facial Edema, Severe Maxillofacial Trauma.

Introduction

Maxillofacial trauma patients, especially with panfacial fracture, often requires of following surgery that associated with the facial deformity which is often indicated repairing natural architecture of facial bone and leaving minimal traces as possible¹. In developing countries, almost 50-70% of traffic accidents remain the leading cause of facial trauma¹.

Anthropometry is the measurement of living subjects². Head and facial anthropometry measurements can be used together with cephalometry, Computed Tomography (CT), and Magnetic Resonance (MR) in preparation for a patient undergoing plastic and reconstructive surgery³. The lateral cephalometry may help evaluate the loss of vertical dimension and skeletal relations between the arches. Easy to access the equipment and low cost could provide a correct surgical planning when analysed appropriately⁴.

Modified techniques using anthropometric combined with cephalometric examination are easy and inexpensive. Facial edema can be assessed using cephalometric measurements, Moreover a combination between anthropometric and cephalometric for surgical planning could be used as an alternative for surgeons. Therefore, we aimed to assess the time recommendation and alternative parameters for severe maxillofacial trauma reconstruction⁵.

Method

This research uses experimental study design, posted test only group design. In other side, this study used adult patients with bimaxillary and bilateral maxillofacial trauma were eligible for this study, while pregnant women were excluded. After obtaining the informed consent of the patients underwent surgery. All of them were operated following the same procedure in the same hospital by three different surgeons at the same level of experience. Facial anthropometric and lateral cephalometric measurements were taken ON day 7, 14, 21 and 3rd month postoperatively. Facial anthropometry was measured using a standardized anthropometric tool such as spreading and sliding caliper, its showed on Figure 1 and lateral cephalometry using Vistadent software (GAC Techno Center, Birmingham, United Kingdom) on Figure 2.

Figure 1. Anthropometric measurement using spreading caliper and sliding

Figure 2. Cephalometric analysis using vistadent software, the dots which are refer to landmarks on cephalometry are being filled, and computer will calculate it.

Figure above it’s the figure that used by researcher in this study. In other side, researcher used some data. First, data from 15 facial anthropometric and 41 lateral cephalometric which measured on day 7, 14, 21 were compared to those taken within 3 months after post-operatively. It was to assess whether facial anthropometric and lateral cephalometric measurements following the surgery were affected by edema. Second, the measurements of lateral cephalometric on day 7, 14, 21 were compared to third (3) month post-operatively to assess the time resolution of facial edema after the operation. The paired samples T-test was used to compare anthropometric and cephalometric variables on day 7, 14, 21 with third (3) month postoperatively. Data were analyzed using SPSS version 11.0 for windows.

Result

Between September 2012 and March 2013, the data were collected from nine patients consisted of seven males and two females between 17 and 31 years old (median 24 years). Seven out fifteen (7/15) anthropometric parameters (zy-zy, go-go, ex-ex, sn-c, go-cdl1, go-cdl2, gn-go1) were affected by edema (p <0,05), while the remaining eight parameters remained constant throughout day 7, 14, 21 and 3rd month postoperatively. All cephalometric parameters remained constant throughout day 7, 14, 21 and 3rd month postoperatively except 4 parameters (Ls-NsPog’, A’-SS; Ls1u-Ls; Pog-Pog’). The cephalometric parameters are able to assess the time resolution of facial edema, such as basic upper lip thickness (A’-SS), thickness of vermilion of the upper lip (Ls1u-Ls), and soft tissue thickness of chin (Pog-Pog’). Basic upper lip thickness (A’-SS) and soft tissue thickness of chin (Pog-Pog’) on day 7 were significantly different compared to 3rd month postoperatively (p <0,05) while basic upper lip thickness on days 14 was significantly different compared to 3 months postoperatively (p <0,05). There was no further reduction of facial edema in the lower jaw after day 14 and in both upper and lower jaw after day 21.

This study showed that the edema of the lower jaw disappeared within two weeks after the reconstruction of maxillofacial trauma and edema of the face within three weeks. The faster resolution of edema on the lower jaw could be explained by the presence of the largest space in the fourth layer of the face, the premasseteric space, allowing greater movement leading to greater of edema reduction6 (Figure 3).

Figure 3. Soft tissue spaces of the face: upper temporal, prezygomatic, masticator and premasseter space. Adapted from Mendelson, B. ‘Facelift anatomy,
On the figure 3, we considered the surgery as the moment of trauma because the surgical trauma itself is proportional to the actual trauma that causes the fractures. The morphology of the face returned close to 90% of the baseline facial scan at 3rd month while, scanning after sixth months was used as the baseline. In our study, facial morphology returned to the baseline at week 3, while the scans recorded on the third month was used as the baseline.

The fracture of facial bone remodeling process begins in responding to an interrupted blood supply. At the end of the first week after trauma, non-perfused bone is substituted by a new bone that could be visible 2 to 3 weeks after trauma. Facial bone remodeling is faster than in long bones, because of the outstanding circulations allows faster recovery. Normally, facial bone healing takes around 4 to 6 weeks in midface region and 10 to 12 weeks in mandible region. Callus could be seen at 2 to 3 weeks after trauma, while performing reconstruction after 4-6 weeks in the midface and after 10-12 weeks in mandible probably will need osteotomy because of the bone is reunion.

The optimal results of surgery for repail of panfacial fracture can be obtained two weeks after the trauma. In some circumstances, even early surgical intervention should be avoided, such as cervical spine injury. Primary repair can be successfully completed up to 3 weeks after injury. The results of this study indicate that reconstructive surgery should be planned 14 days after trauma for lower jaw fracture and 21 days after bimaxillary fracture. The surgeons have an alternative option to immediately operate on a maxillofacial trauma patient with subsequent surgery risk if postoperative deformity occurs or wait until facial edema resolves.

Eight anthropometric parameters were not affected by edema, they remain constant for postreconstruction. This can be explained by the presence of facial ligaments cause the area to become more fixed, therefore, it is more resistant to edema (Figure 4).
Figure 4 showed that forty-one cephalometric parameters were not affected by edema. We also found that upper and lower facial height (tr-gn, n-gn, UFH, LFH) were not affected by edema. We suggest these parameters can be used when edema appears on the face.

From this study I can be showed that maxillofacial trauma caused by severe ballistic or avulsion injuries. Some of that injuries can be creates complex composite defects for the human13.

**Conclusion**

Swelling due to edema of the lower jaw disappeared within two weeks after the reconstruction while, swelling of the face disappeared within three weeks for maxillofacial trauma. Reconstruction can be planned 14 days after trauma for lower jaw fracture and 21 days after bimaxillary fracture. Lateral cephalometry was a reliable method to measure facial edema following surgery which combined facial anthropometry with lateral cephalometry using parameters that are not affected by edema. This can be applied as an additional guiding tool in surgical planning for maxillofacial trauma patients especially those with bimaxillary and bilateral fractures. This approach has the advantage of accuracy, convenience and inexpensive than other scan-based techniques.

Development of Geogebra Learning Media Based on Statistical Reasoning on Statistics Materials of Junior High School Students and its Influence for the Inteligent of Student

Intan Sari Rufiana¹, Cholis Sa’dijah², Subanji³, Hery Susanto⁴
¹Doctoral Student, Mathematics Education, Universitas Negeri Malang, East Java, Indonesia, ²Professor, Corresponding Author, Mathematics Education, Universitas Negeri Malang, East Java, Indonesia, ³Associate Professor, Mathematics Education, Universitas Negeri Malang, East Java, Indonesia, ⁴Assistant Professor, Mathematics, Universitas Negeri Malang, East Java, Indonesia

Abstract

This research aimed to develop geogebra learning media based on statistical reasoning. For the purpose of this research and development, ADDIE model by Dick & Carry was used. This research and development produced geogebra learning media based on statistical reasoning for junior high school students. Class environment that applies technology based on statistical reasoning is another variable besides genetic which is adaptive. The integration of new technologies for education is no longer an alternative; it has become an obligation and even guidance to develop these knowledge-sided. Through geogebra, students are directed to build their knowledge not just to memorize rules. The class that applies technology based on this statistical reasoning will develop students’ intelligence.

Keywords— geogebra, statistics, statistical reasoning, intelligence

Introduction

The rapid development of data in the era of big data like now makes the need for statistics not only needed in the field of mathematics (1), (2), (3), (4), (5). Given the importance of statistical reasoning, several researches related to statistics refer to statistical reasoning (6). Statistical reasoning must be output in statistical learning (7). In addition, statistical reasoning is also an input in statistical learning as a consideration of the process in statistical learning (8).

However, current statistical reasoning research is more focused on the level of statistical reasoning. Research related to learning has not had a significant impact. There are no specific learning techniques or methods to improve statistical reasoning abilities (9). It is explained further that there is no significant difference between the ability of students who are taught by using traditional learning and student-centered statistical learning (10). There are important components considered in statistical reasoning besides statistical learning methods, including the use of technology, curriculum, and assessment (11).

The integration of new technologies for education is no longer an alternative; it has become an obligation and even guidance to develop these knowledge-sided (12). One of the six principles of learning design is a technological device (13), (14). It was important for many institutions to make vast investments in such innovations with the intention of incorporating digital computer tools into their educational curricula (15),(16).

Learning media are various kinds of tools and equipment that can be used to improve or also complement the efforts of teachers in ensuring interesting learning for students (17). In learning statistical reasoning, technology-based learning media are needed. Integrating the use of appropriate technology can facilitate students to test their expectations, explore, and analyze data interactively (18).

But in reality, the use of technology for learning is still rarely done. Innovative strategy were not appear in teaching (15). Integration of information technology in reasoning is still rare (7),(8). The use of media in statistics is usually only to produce statistical measurements or to draw graphs. This is done in order to encourage educational efforts aimed at assimilating competencies
from the use of digital technology (19). One of the technology learning media that is currently being developed is GeoGebra.

GeoGebra is software that can be one of the best choices for learning media that has many benefits for geometry, algebra, and statistics to be more easily understood (20). GeoGebra empowers pupils to discover, detect patterns, make a assume, illustrate, organize data (21). The majority of current research is on the implementation of GeoGebra in learning geometry and algebra, statistical learning using GeoGebra is still very minimal to be studied. GeoGebra offers geometry, algebra and calculus features in a fully connected, compacted and easy-to-use software environment (22). In statistical learning, technology-based learning media are used not only to produce statistical measures, draw graphics, or analyze data but also to help students visualize concepts and develop the understanding of abstract ideas through simulations. It is expected that by using GeoGebra learning media, students’ statistical reasoning can be improved. The indicator of reasoning ability is to use or interpret statistical models such as formulas, graphs, tables to draw conclusions; solve problems according to the method; communicate information effectively visually, numerically and verbally; assess the accuracy of conclusions based on the quantity of information (23).

Based on the urgent need for technology-based learning media, the researchers are interested in developing GeoGebra learning media based on statistical reasoning.

**Research Methodology**

This research used development research with ADDIE development models by Dick & Carry. Some phases of the implementation of research and development of ADDIE (Analysis (A), Design (D), Development (D), Implementation and Evaluation (I&E)) model are as follows (24):

**Analysis Phase**

This phase includes analysis activities: 1) needs based on the unavailability of statistical learning media that support the implementation of learning in the classroom, where only teachers and students books are available; 2) literature, obtained from the results of studying student books and teachers books that the objective of statistical learning existing; 3) analysis of learning in the classroom obtained results that in learning, the teacher only uses technology learning media namely LCD to display ppt and students books to students.

**Design Phase**

At this phase, research planning was carried out which includes:

1) Exploring Potential and Problems

The problem that arises in the schools studied was the use of new mathematics learning media limited to the use of power points to present material and the lack of students’ abilities in statistical reasoning;

2) Literature Study and Information Collection

The competencies expected to arise in junior high school students learning statistics are related to statistical reasoning. Statistical reasoning is the way people make excuses with statistical ideas and make “sense” of statistical information which includes skills in making interpretations based on a collection of data, making statistical summaries related to data, where students need to combine ideas about data, make conclusions, and interpret results statistically (24).

**Product Development Phase**

1) Validation

At this phase, a GeoGebra learning media expert was validated by 4 validators, 2 from GeoGebra media experts and 2 material experts. The validation data were then analyzed using the following formula:

\[ P_m = \frac{\sum x_i}{32} \times 100\% \]

Note:

\[ P_m = \text{percentage of eligibility for all items} \]

\[ \sum x_i = \text{total score obtained for all valid items by validators} \]

If the value of \( P_m \geq 74\% \), the media is a valid medium, and therefore it does not need to be validated.

2) Revision

After validation, a design revision was conducted based on validators’ input. This input was used as a basis for improving learning media.
1.1 Implementation and Evaluation Phase

The initial product was then tested on a limited basis. After being tested, students were asked to provide responses related to the learning media used. The students’ response data were then analyzed using the following formula:

\[ P_a = \frac{\sum x_i}{N \sum y_i} \times 100\% \]

Note:

- \( P_a \) = percentage of eligibility for all items
- \( \sum x_i \) = total score obtained for all items by the user
- \( \sum y_i \) = the number of expected scores for all items by the user
- \( N \) = the number of students who filled out responses

If the value of \( P_a \geq 74\% \), the media is said to be practical, so there is no need to revise it.

The results of students’ responses were then used to revise product learning media 1. The results of this revision are referred to as the final product whose results are given back to students. This is done to test whether the learning media has been effective for improving students’ reasoning or not. Data analysis of the effectiveness of this media was obtained from the results of the pre-test and post-test of students’ statistical reasoning abilities. The mean values of pre-test and post-test scores were compared using paired sample t-tests on the condition that the sample must be normally distributed.

### Result and Discussion

#### Initial Product Development Results

At this phase, geogebra media was developed in junior high school statistics material. The preparation of the media was done based on the competencies that exist in the applicable curriculum.

#### Experts’ Validation Results

The results of the learning media validation are presented in Table 1 below:

From the results of the validation above, there was a value that represents that the media were valid and very valid. Input given by the media expert validators is that learning media needs revision, namely the addition of sliders to facilitate changes in the amount of data, refinement of layout, changes in writing, and hiding features that are not needed.

#### Trial Results

The next step after the media has been validated and then revised is a trial of 1 product. The test was conducted at a junior high school with 30 students. Students were given statistical learning by utilizing the learning media that had been developed. After learning, students were given students’ response questionnaire to be filled in. The students’ response data were then analyzed using formula \( P_a \) as stated in section 2.4 above. From this questionnaire, it was ascertained that learning media was very practical to use. It can be seen from the analysis of students’ responses that have a value \( P_a \) of 87.7%. The results of this study are in accordance with the function of the media, one of which is to guarantee interesting learning for students (17), their interest improved greatly and teaching efficiency boosted significantly (19). From the students’ response questionnaire, there were suggestions/inputs from students that it is necessary to get used of using the geogebra application to make it easier. This input is used for further learning.

#### Effectiveness Test Results

The effectiveness data were obtained from the scores of pre-test and post-test results of trial 2. Data were obtained from questions related to statistical reasoning. Paired t-test data analysis was performed with the help of SPSS with a significance value of 0.01. The SPSS test results showed that the pre-test and post-test score were normally distributed. It was also obtained data as follows:
Table 2. Paired Samples Test

<table>
<thead>
<tr>
<th>Paired Differences</th>
<th>t</th>
<th>df</th>
<th>Sig. (2-tailed)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mean</td>
<td>Std. Deviation</td>
<td>Std. Error Mean</td>
<td>99% Confidence Interval of the Difference</td>
</tr>
<tr>
<td>Pretest - Posttest</td>
<td>-1.79000E1</td>
<td>7.18403</td>
<td>1.31162</td>
</tr>
</tbody>
</table>

From the above data, it was obtained that $t_{\text{count}} = -13.647$. This value was then compared with the table value with $\alpha = 0.01$ and degrees of freedom $= 29$ that is equal to -2.462. Because the value of $t_{\text{count}} < t_{\text{table}}$, $H_0$ was rejected, which means the average score of post-test is bigger than the pre-test value. It can be concluded that the developed geogebra learning media met the effectiveness criteria which could improve students’ statistical reasoning abilities. This also affects the intelligence of students. One of intelligent components is reasoning. Some experts even explain that reasoning and intelligence refer to the same thing (25), (26).

The factors that influence intelligence are not only biological aspects, namely genetic. Environmental factors will also greatly affect the development of human intelligence (27), (28). Intelligence is not entirely due to biological variables. Intelligence is also influenced by other variables. Any variables can affect intelligence if this variable is related to adaptive nature (29). Class environment that applies technology based on statistical reasoning is another variable besides genetic which is adaptive. The class that applies technology based on this statistical reasoning will develop students’ intelligence.

Geogebra is software for developing mathematical ability, with the use of geogebra, students can manipulate various types of mathematical constructions from the simplest to the most complex. The impact is students will understand better and will open the way for further learning (30). It is emphasized again that geogebra can facilitate students in exploring, representing, and analyzing one concept with another concept (23). As explained in the theory that technology-based learning media is not only used to calculate statistical measures, draw graphs, and also analyze data but it can be used to help students visualize concepts and develop understanding statistics abstract ideas.

**Final Results**

The final result of this development research is the learning media of geogebra software on grade VIII SMP/ MTs statistical material. The resulting file is a ggb file format. To operate, it is necessary to install geogebra software on PC / laptop used, or by visiting the geogebra tube website so that it can operate without installing geogebra software.

**Conclusion**

From the process and results of the research stated above, it can be concluded that the geogebra learning media developed is effective which can improve students’ statistical reasoning abilities and intelligence.

The Association between Blood Glucose Control Measured with Serum HbA1c Level with Peroneal Motor Nerve Conduction Velocity in Patients with Type 2 Diabetes Mellitus with Polyneuropathy

Muhammad Hamdan, Raini Wisnujono, Mudjiani Basuki, Fidiana, Fadil, Intan Sudarmadi

1Department of Neurology, Faculty of Medicine, Universitas Airlangga, Surabaya (60131), Indonesia

Abstract

Background and Objective. The poor control of blood glucose levels in patients with diabetes mellitus is a major risk factor from various complications of diabetes mellitus, such as polyneuropathy. One of the nerves that are often affected in the case of diabetic neuropathy is the peroneal nerve. This study aimed to determine the association between blood glucose level control measured with serum hemoglobin A1c (HBA1c) levels with peroneal motor nerve conduction velocity in type 2 diabetes mellitus patients with polyneuropathy.

Methods. The study was conducted on diabetic neuropathy patients who fulfilled inclusion and exclusion criteria in neurology unit and diabetes unit Dr. Soetomo General Hospital Surabaya on a consecutive basis from February to July 2013. The serum HbA1c level and nerve conduction velocity in peroneal motor nerve were examined; then, the results were grouped into two groups which were serum HbA1c <7% and ≥7% and NCV in normal and low peroneal motor nerve

Results. There were 26 subjects, consisting of 6 subjects with serum HbA1c <7% and 20 subjects with serum HbA1c ≥ 7%. There was an association between blood glucose level control measured by serum HbA1c levels and NCV in peroneal motor nerve with statistical significance of p = 0.0018 (Odd ratio 15; 95% IK 1.397 - 161.045).

Conclusion. There was an association between blood glucose level control measured by serum HbA1c levels with NCV in peroneal motor nerve in type 2 diabetes mellitus patients with polyneuropathy.

Keywords: polyneuropathy, HbA1c, nerve conduction velocity, diabetes mellitus

Introduction

Diabetes Mellitus (DM) is a group of metabolic disorders characterized by hyperglycemia, due to damage to insulin secretion, insulin work, or both. Factors that contribute to hyperglycemia include reduced insulin secretion, decreased glucose use, and increased glucose production, and the etiology of diabetes mellitus. The number of patients with DM in the world has increased. Based on the Central Bureau of Statistics’ data in Indonesia in 2003, from Indonesia’s population above 20 years old of 133 million people, the number of DM patients in urban areas is 8.2 million and 5.5 million in rural areas. Based on the pattern of population growth, it is estimated that by 2030 the population over the age of 20 is 194 million; thus, it is estimated that there are 12 million people with diabetes mellitus in urban areas and 8.1 million in rural areas. Based on the observations in Surabaya (reported in 1993), the prevalence of symptomatic diabetic neuropathy was high (51.4%), and it will increase with the duration and severity of diabetes.
Chronic hyperglycemia in diabetes is associated with damage, dysfunction, and failure of various organs, especially the eyes, kidneys, nerves, heart, and blood vessels. Poor control of glucose levels is a major risk factor for complications of diabetes mellitus. The incidence of diabetic neuropathy is related to male gender, irregular blood sugar control and hypertension in diabetes patients. The American Diabetes Association (ADA) recommends the A1c target of less than 7%, while the American Association of Clinical Endocrinology recommends less than 6.5%. Efficient glucose control and monitoring using HbA1c can reduce complication of diabetes efficiently.

The pathogenesis of diabetic neuropathy involves many factors such as metabolic, vascular, oxidative stress, and neurohormonal growth factor deficiency. Diabetic neuropathy results from complex interactions between metabolic factors directly related to hyperglycemia and structural changes such as degeneration of axonal and demyelination caused by microangiopathy. This mechanism can involve a nerve called mononeuropathy or multiple called multifocal neuropathy. Both acute and chronic damage to peripheral nerve will result in anatomical and physiological changes in the peripheral nerve and will damage the structure consisting of myelin, axons, and buffer layers.

In the case of polyneuropathy, the longest nerve fibers have the highest risk of exposure, while the short fibers are less risky. Polyneuropathy is a length-dependent neuropathy, because the longest nerve fibers in the body are those that travel from the lower back to the legs; thus, in case of polineuropathy, the initial weakness or sensory impairment is the leg. The peroneal nerve in the limb contains motor and sensory fibers; thus, in the neuropathy of the peroneal nerve, the patient may experience both sensory weakness and impairment. This study aimed to determine the association between blood glucose level control measured with serum HbA1c levels with NCV in peroneal motor nerve in patients with type 2 diabetes mellitus with polyneuropathy.

Method

This research was a cross sectional study by using case-by-case sampling method (sampling from consecutive admission) until the samples were collected. The study was conducted in neurology unit, diabetes unit, and electromyography room of Dr. Soetomo General Hospital Surabaya on February - July 2013. The subjects were selected according to the inclusion criteria including patients with type 2 diabetes mellitus who had polyneuropathy (Toronto Score ≥ 5), aged 45-70 years old and willing to participate in the research. The exclusion criteria were anemia, history of alcohol addiction, had impaired renal function, impaired liver function, complication of diabetic ulcers in the legs which complicated the examination of NCV (Nerve Conduction Velocity) in peroneal motor nerve.

The variables of this study included independent and dependent variables. The independent variable is blood glucose level control measured by serum HbA1c levels. Meanwhile, the dependant variables was NCV in peroneal motor nerve.

The research material was a blood sample of the veins taken when the patient visited to the electromyography room in Dr. Soetomo General Hospital Surabaya before the neurophysiology examination. The research instrument used a patient data collection sheet. Examination of NCV in peroneal motor nerve was conducted with EMG tool in electromyography room of Dr. Soetomo General Hospital Surabaya with Caldwell brand and interpreted by EMG consultant neurologist. Serum HbA1c examination was performed in laboratory that has been certified internationally for HbA1c examination which was in Prodia clinic laboratory, Surabaya.

Patients with type 2 diabetic polyneuropathy were screened based on the inclusion and exclusion criteria to obtain the research samples. The samples were then examined for serum HbA1c levels and NCV in peroneal motor nerve. After obtaining the data, it was performed a statistical test to determine the association between blood glucose level control measured with serum HbA1c levels with NCV in peroneal motor nerve in patients with type 2 diabetes mellitus with polyneuropathy. The data were analyzed using a software (SPSS 17) to find out whether there was an association between two variables by using chi square test.

In this study, the normal value of NCV in peroneal motor nerve was >40 mm/sec according to the standards applied in the Electromyography room Dr. Soetomo General Hospital Surabaya by using the Caldwell tool. The analysis was divided into two groups: NCV in peroneal motor nerve >40 mm/sec (normal) and ≤40 mm/sec (slowing). Each patient in this study obtained two results of NCV in peroneal motor nerve.
the right and left side. For analysis purposes, if both sides obtained a normal result, it was considered normal. Meanwhile, if both sides or one side were slower, it was considered to experience a slowdown.  

Result

The overall subjects of the study were 26 subjects consisting of 9 males (34.6%) and 17 females (65.4%), whereas in the HbA1c ≥7% group, 7 (77.8%) males and 13 females (61.5%) (table 1). The gender difference in each group was not statistically significant (p = 0.668). Mean age of DM patients with polyneuropathy with HbA1c <7% was 56.67 ± 6.861 years old while DM patients with polyneuropathy with HbA1c ≥7% was 56.90 ± 5.486 years old (table 1). The mean age difference in each group was not statistically significant (p = 0.693).

From DM patients with polyneuropathy with HbA1c ≥7%, 9 (69.2%) were suffering from DM <10 years old and 11 subjects (84.6%) suffered from DM ≥ 10 years (table 1). The difference in percentage of long-suffering DM was not statistically significant (p = 0.645). From DM patients with polyneuropathy with HbA1c ≥7%, 11 (73.3%) had normal serum TG level and 9 (81.8%) had high serum TG level (Table 1). The percentage difference in serum TG level was not statistically significant (p = 1.000).

In low NCV in peroneal motor nerve group, 6 subjects (66.7%) were males and 10 subjects (58.8%) were females (table 2). Different percentage of gender in each group was not statistically significant (p = 0.668). The association between long-suffering DM and NCV in peroneal motor nerve was shown in Table 2. In DM subjects with polyneuropathy with low NCV in peroneal motor nerve, 8 subjects (61.5%) suffered from long-standing DM <10 years and 8 subjects(61.5%) suffered DM ≥10 years old. The difference in percentage of long-suffering DM in both groups was not statistically significant (p = 1.000).

The association between the serum triglyceride (TG) level and NCV in peroneal motor nerve was shown in Table 2. In DM patients with polyneuropathy with low NCV in peroneal motor nerve, 9 (60%) had normal serum TG levels and 7 (63.6%) had high serum TG levels. The difference in percentage of serum TG levels in both groups was not statistically significant (p = 1.000).

The association between serum HbA1c levels and NCV in peroneal motor nerve was shown in table 2. In DM patients with polyneuropathy with low NCV in peroneal motor nerve, there was 1 subject (16.7%) whose serum HbA1c levels were <7% and 15 subjects (75%) whose serum HbA1c ≥ 7%. The percentage difference was statistically significant with p = 0.018. The value of odd ratio was 15, with a confidence interval range of 1,397 - 161,045 (95% CI).

Discussion

In the basic data characteristics of research subjects, there was no significant difference in several basic variables including gender and age. It needs to be taken into account because gender and age affect HbA1c values. A study revealed that males had a greater prevalence of DM than females (7.5% males, 3.4% females, p <0.001). However, in elderly (> 66 years), it occurs in more females. Long-suffering from DM also affects HbA1c levels, as stated in the study that HbA1c levels significantly increased with duration of DM. In addition, it is stated that hypertriglyceridermia may decrease HbA1c. Age and gender can affect nerve conduction velocity, as stated that subjects with elder age have longer latency, smaller amplitude, and slower nerve conduction velocity than young subjects 12.

Females have a higher amplitude at the examination in the upper extremities, shorter latency of upper extremities, and longer latency in lower extremities than males. Long-suffering from DM also affects the velocity of the nerve conduction, as it is stated that the occurrence of a microvascular complication of DM along with the duration of DM is associated with low nerve conduction velocity 13. Triglyceride levels can also indirectly affect the velocity of nerve conduction. Hyperlipidemia is important in the development of diabetic polyneuropathy, as elevated serum triglyceride level correlates with decreased myelin fiber density which is independent of other variables such as age, DM length, DM control, and other variables. Therefore, this study attempted all subjects in relatively similar conditions, with the expectation of minimizing the influence of other factors that will affect the value of the variables studied 14.

Other factors that affect HbA1c are anemia, impaired renal function, alcohol addiction as well as factors affecting nerve conduction velocity, such as kidney function impairment and alcoholism have been attempted to be controlled by researchers through several components of exclusion criteria. The results of this study statistically obtained a significant association between serum HbA1c levels with peroneal motor nerve conduction velocity. In DM patients with polyneuropathy
with low peroneal motor nerve conduction velocity, there was 1 subject (16.7%) whose serum HbA1c levels were <7% and 15 subjects (75%) with serum HbA1c levels ≥7%. The percentage difference was statistically significant with $p = 0.018$. The results of this study also obtained the value of Odds ratio of 15 with the range of confidence interval 1.397 - 161.045; thus, it is concluded that serum HbA1c ≥ 7% is a risk factor for low peroneal motor nerve conduction velocity.\(^\text{15}\)

It is in accordance with a study by Shekharappa et al., which mentions that there is progressive neuronal damage in DM patients triggered by poor blood glucose control, in which the researchers compared the nerve conduction velocity between DM patients and non-DM patients.\(^\text{16}\) The wide range of confidence intervals in this study could be due to small sample size or basic data characteristics such as long-term suffering of DM, ranging from 1 year to 20 years, although in the analysis, the duration of DM is categorized into two groups.\(^\text{17}\)

**Conclusion**

There was an association between blood glucose level control measured by serum HbA1c levels with peroneal motor nerve conduction velocity in type 2 DM patients with polyneuropathy.

**Ethical Clearance:** This research involves participants in the survey using sampling method that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, nonmaleficeince, and justice.

**Conflict of Interest:** The authors swear that there is no conflict of interest related with this paper.

Decrease of Sensorineural Hearing Frequency and Cochlear Hair Cell Function in Malignant Head and Neck Tumor Post Cisplatin Chemotherapy Series II

Irawati1. Bakti Surarso1. Haris M. Ekorini1
1Departement of Otolaryngology, Faculty of Medicine, Universitas Airlangga-Dr. Soetomo General Hospital Surabaya. 60131 Indonesia

Abstract

Background: Malignancy in head and neck is mostly squamous cell carcinoma which are relatively radiosensitive. Giving chemotherapy combination of cisplatin-5 fluorouracil most frequently used in Lotus inpatients unit of Dr. Soetomo General Hospital Surabaya.

Purpose: This study aimed to prove the decrease of sensorineural hearing frequency and cochlear hair cells function in malignant head and neck tumors patients post-cisplatin chemotherapy series II.

Method: The samples were malignant head and neck tumor patients that would receive cisplatin chemotherapy. The inclusion criteria were aged 18 to 65 years, malignant head and neck tumors planning to get cisplatin chemotherapy, intact tympanic membrane, ANM checks within normal limits. Tympanogram type A, DPOAE examination with pass results.

Results: Pre-and post-cisplatin chemotherapy series I did not obtain any changes, those were pass on all frequencies. Mc Neymar test on DPOAE post-cisplatin chemotherapy I obtained p = 0.250 in 6 kHz frequency (p>0.05). DPOAE post-cisplatin II in 6 kHz frequency showed no significant difference (p>0.05)

Conclusion: There was no decrease of outer cochlear hair cells function in malignant head and neck tumors patients who received cisplatin chemotherapy series II.

Keywords: cisplatin-5 fluorouracil chemotherapy, sensorineural hearing, intact tympanic membrane, cochlea.

Introduction

Head and neck malignancy is a major health problem in the world. In America 2006 it is estimated about 500,000 new cases1. Head and neck malignancy (>75%) is a type of squamous cell carcinoma which is relatively radiosensitive. Approximately one-third is still in early stage that can be treated with surgery or radiotherapy. Therefore chemotherapy is an alternative choice in the treatment of malignant head and neck tumors2.

Combination chemotherapy of cisplatin-5 fluorouracil is frequently used in Lotus inpatients unit of Dr. Soetomo General Hospital Surabaya3. Along with this fact, chemotherapy toxicity is now a concern. one of them is ototoxic. Chemotherapy drugs that have ototoxic effects are cisplatin, carboplatin, nitrogen mustard, metrotrexat, vincristine, dactinomicyn, and bleomicyn4.

Cisplatin (cis-diamminedichloroplatinum-CDPP) is one of the most widely used and most potent chemotherapeutic drugs for malignant head and neck tumors treatment. Giving high doses of cisplatin 100-120 mg/m² of body surface could cause progressive sensorineural hearing loss. Irreversible, and bilateral starting at a frequency above 8000 Hz which will eventually affect the lower frequencies if therapy is continued and accompanied by tinnitus5. A research in America reported that cisplatin chemotherapy led to sensorineural hearing loss of 82.6% at a frequency of
3 kHz, 45.3% at 4 kHz, 81.0% at 6 kHz and 90.5% at 8 kHz with pure tone audiogram examination. Another study on malignant tumors patients using Distortion Product Otoacoustic Emissions (DPOAE) obtained outer hair cell damage of 63.4% (6.7% at 6-10 kHz, 56.7% at 8-10 kHz) post-first chemotherapy and 70% post-second chemotherapy (8.3% at 4-10 kHz, 31.7% at 6-10 kHz, 30% at 8-10 kHz). Hearing loss at high frequency may not cause communication disorder but continuously there will interfere conversations frequency resulting patient’s communication disorder. Cisplatin damages the cochlear outer hair cells progressively from the base to the apex therefore sensorineural hearing loss occurs starting at high frequency. Apoptosis causes death of cochlear outer hair cells resulting in sensorineural hearing loss. On the condition of outer hair cells damaged, the damage can affect the inner hair cells and supporting cells. The cisplatin ototoxicity is not limited to the cochlear outer hair cells but also reported to occur atrophy of vascular stria, collapse of reisnerr membrane and the degeneration of spiral ganglion.

Cochlear hair cells play a role in improving or sharpening the peak of traveling waves by increasing basilar cellular activity on a particular frequency. Cochlear outer hair cells damage due to cisplatin occurs from the third day in the basal to apex. An objective diagnose tool of cochlear outer hair cell damage is otoacoustic emission. Distortion product otoacoustic emission can evaluate cochlear response at high frequency which is the sensitive frequency to detect muscle ototoxicity.

**Method**

This study was an observational study with a non-comparable longitudinal approach conducting at Audiology inpatient unit of Otolaryngology Department Faculty of Medicine, Universitas Airlangga-Dr. Soetomo General Hospital Surabaya, Indonesia. The samples were malignant head and neck tumor patients who would receive cisplatin chemotherapy. The sampling technique used in this study was consecutive sampling.

The inclusion criteria were age 18 to 65 years, malignant head and neck tumors planning to receive cisplatin chemotherapy, intact tympanic membrane, ANM checks within normal limits, Tympanogram type A, and DPOAE examination with pass results. While the exclusion criteria were presence history of noise exposure, radiotherapy in the temporal bone area, previous otic drugs, hypertension and diabetes mellitus.

This research used the following tools and materials; tools for ear examination consisting of head lamp, cotton wool, cotton and otoscope. ANM checking tool consisted of Audiometer AD type 229E, a tympanometry type Inter acoustic AT 35. DPOAE examination tool used 100 mg/m^2^ body surface and data collection sheet.

The samples were patients with tympanogram A. This study used one ear sample but if both ears met the criteria, the sample used was right ear. ANM and DPOAE I (pre chemotherapy)/cisplatin chemotherapy I used 100 mg/m^2^ body surface. After 3 days, ANM and DPOAE II (post-chemotherapy I) were performed. Administration of cisplatin chemotherapy II was given 3-4 weeks after cisplatin chemotherapy I. After 3 days of cisplatin II series, ANM and DPOAE III (post cisplatin II chemotherapy) were performed.

The data were tabulated and analysed statistically using SPSS (SPSS. Inc. Chicago IL). The data obtained was then examined and processed statistically by paired sample t test to analyze high frequency sensorineural hearing loss and McNemar test to analyze the decrease of cochlear outer cell function pre and post cisplatin chemotherapy.

**Result**

Table 1 showed age, sex and diagnosis distribution.

A paired sample t test on ANM results post-cisplatin chemotherapy I and II obtained \( p = 0.339 \) at 4 kHz, \( p = 0.053 \) at 6 kHz and \( p = 0.809 \) at 8 kHz that meant ANM post cisplatin chemotherapy I and II has no significant difference (\( p > 0.05 \)). Based on statistical calculation using paired sample t test obtained \( p = 0.339 \) at 4 kHz, \( p = 0.002 \) at 6 kHz and \( p = 0.166 \) at 8 kHz that meant ANM pre and post cisplatin chemotherapy II at 4 kHz and 8 kHz had no significant difference (\( p > 0.05 \)) while at 6 kHz had a significant difference (\( p < 0.05 \)). DPOAE pre-and post-chemotherapy cisplatin I obtained pass at all frequencies, therefore the data obtained were homogeneous and could not be done a statistical test. DPOAE examinationpre-chemotherapy was 12 patients (100%) and 12 patients (100%) post-chemotherapy (Table 2).

**Discussion**

The results indicated that the most patients based on age distribution aged 35-45 years. Most patients with nasopharyngeal carcinoma were on 4-6th decade and the climax was on 5th decade that was between 41-50 years. In 2009, most sinonasal carcinoma patients in Dr. Soetomo General Hospital aged>40 years. Age over 50 years is very influential on the incidence of malignant head and neck tumor due to a decrease in physiological capacity and reduced ability to deal with environmental stress.
The ratio of male versus female was 2:1. This result was in accordance with the data of Oncology Unit of Otolaryngology Department, Dr Soetomo General Hospital that nasopharyngeal carcinoma was the most malignant head and neck tumor. The ratio of male versus female were 2:1 in nasopharyngeal carcinoma, 3:2 in sinonasal carcinoma, and 11:1 in laryngeal carcinoma12,13. Male is the most suspected gender because they often go out of the house to work therefore the risk of carcinogenic substances exposure and other environmental factors are higher1.

ANM pre and post cisplatin chemotherapy I at 4 kHz had no changes therefore the data could not tested statistically. While at 6 and 8 kHz obtained no significant different. This was different with other studies that obtained sensorineural hearing loss as much as 33% post-cisplatin chemotherapy I but it was not stated at what frequency the sensorineural hearing loss happened15. This difference could also be affected by the effects of chemotherapy combined with radiotherapy, thus increasing toxicity. This study was consistent with another study that stated the cisplatin ototoxicity with conventional ANM examination obtaining 1 person (35.7%) with sensorineural hearing loss, if with the extended high frequency (EHF) audiometry obtaining 88.1% with the range of 40-60 dB16.

The researchers have not been able to find the reason why the significance only occurred at 6 kHz while at 4 kHz and 8 kHz pre and post cisplatin chemotherapy II obtained no significance difference. This result was inconsistent with other studies suggesting sensorineural hearing loss occurring since the administration chemotherapy and being progressive with larger cumulative doses15. Based on comparative studies between audiogram and cochlear damage, cochlear outer hair cell damage caused hearing loss between 55-65 dB. Cochlear inner hair cells caused a very heavy hearing loss of 95 dB14.

There was no decrease in cochlear outer hair cell function in patients with head and neck tumor post-cisplatin chemotherapy I. This was not in accordance with the theory that cisplatin would cause disturbance after cisplatin chemotherapy I. Other studies showed the results of DPOAE post-cisplatin chemotherapy I obtaining refer at 6 kHz frequency as much as 6.7% and at 8 kHz as much as 56.7%. Another difference was the number of samples of 30 people that was more than this study7.

DPOAE post-cisplatin chemotherapy I and II obtained no significant difference. This is different from other research obtaining refer at 4 kHz frequency as much as 8.3%, 6 kHz as much as 31.7% and 8 kHz as much as 30%7. This difference could be due to the differences of sample size and the weakness of the tools used in this study. Research on Testicular Carcinoma in Hungary showed SNHL in samples receiving cumulative doses >400 mg/m² while in samples with cumulative doses <300 mg/m² obtained no significant difference17.

Pre and post cisplatin chemotherapy II results obtained no significant difference. The cisplatin ototoxicity was highly dependent on cumulative doses. Ototoxicity increased at doses >400 mg, with DPOAE examination obtained referral data at lower frequencies. In this study chemotherapy I used accumulative dose between 120-170 mg, post-chemotherapy II used cumulative dose between 240-340 mg. Research on testicle carcinoma in Hungarian obtained an impaired function of cochlear outer hair cells in samples receiving cumulative doses >400 mg/m² while in samples with cumulative doses <300 mg/m², there was no significant impaired function of cochlear hair cells17. This inadequacy of this study with other studies might be due to several factors that induce cisplatin ototoxicity. Many things could be an induced factors of cytotoxicity such as cumulative dose (>400 mg), long-term administration (>6 months), administration method, individual susceptibility variation, extreme age, previous hearing loss, anemia, radiation history, and the use of other ototoxicity drugs17. Chemotherapy affects the body cells. Continuous exposure causes damage to hair cells in the cochlea that cause cochlear dysfunction and will increase the hearing threshold18. Chemotherapy has physical and psychological side effects19. There was a correlation between the increased dose of cisplatin with the cytotoxicity effects on NPC stem cell20.

Conclusion

It was obtained sensorineural hearing loss at 6 kHz frequency, while at 4 and 8 kHz frequencies were still in normal state (no hearing loss). Malignant head and neck tumor patients who received cisplatin chemotherapy II. There was no decrease in cochlear outer hair cells in malignant head and neck tumor patients who received cisplatin chemotherapy II.

Abstract

The thiophene core is the most broadly applied constructing blocks to the production of many biomolecules, pharmaceutical drugs, vitamins, also in industrial compounds, in dyes compounds because of its high stability in environment. Thiophene derivatives were synthesized in present study from chalcone compound as a starting material from aldol reaction in first step, followed by cyclization reactions by using various conditions, and this paper involved new reaction for diazonium salts to producing (Sulfide-azo) compounds in same bond for the first time that we termed (Sulfazane) as a first and Novel preparation to this new type of compounds., the synthesized derivatives were confirmed through numerous spectral techniques (FT.IR, H.NMR, C.NMR), other physic-chemical data for synthesized thiophene derivatives, besides to studying of behavior of compounds in organic solvents and screening tests for efficiency of thiophene derivatives against microbes.

Keywords: Microbial, Sulphazane, Aldol, chalcone, thiophene, heterocyclic, phenylene diamine, coupling, Azo, new reaction of diazonium, sulfide-azo, (-S-N=N-), seven membered, five membered.

Introduction

Thiophene is a colorless liquid in a benzene-like odor., with aromatic properties involving one hetero atom (sulfur) in the formula structure(C₄H₄S), including a planar five-membered ring (four carbon atoms and one sulfur atom), it behaves in the reactions as a substitution reaction. Thiophene is stable in high temperatures and its nucleus in most natural molecules like biotin, numerous plant colors, natural dyes, besides various pharmaceuticals., some thiophene derivatives have applications in antifungal fields.

Experimental Part

The routes of reaction carried out by many steps, various conditions, different catalysts to formation heterocyclic compounds from chalcone-thiophene, all formatted derivatives followed with (TLC) in addition to iodine vapor chamber. Thiophene derivatives {1-8} were established via various apparatuses: FT-IR spectra (FT-IR 8300 Shimadzu) with the range (400-4000)cm⁻¹ using discs of KBr., ¹H.NMR–Spectra besides ¹³C.NMR with solvent (d-DMSO), besides to studying of behavior of compounds in organic solvents and microbial screening:

Routes of Preparation⁰⁻¹⁵:

Route of Preparation for Thiophene Derivatives {1, 2, 3}

P-Formal benzoic acid(0.01 mole) rotated with 2-acetothiophene (0.01 mole) at room temperature via mechanical rotation for (8 hrs) according to processes in basic medium to yield product that acts chalcone Compound{1}, the next step, drying, re crystallized
weigh (0.01 mole) cyclized with (0.01 mole) of ortho-aminophenol in refluxing step, the resulting filtered, dried followed by re-crystallized to give seven-membered ring from compound{2}, which (0.01 mole) condensed for (26 hrs) with (0.01 mole) of thiosemicarbazide in basic medium (5% NaOH) in two steps according to processes\(^{8-12}\), then filtered, dried, then recrystallized to obtain triazole derivative as a compound{3}.

The resulting compound washed in distilled water, dried, to give (S-N=N-)Sulfazane compound {4}.

Compound{3} (0.01 mole) reacted in basic medium via coupling reaction with (0.01 mole) of p-methyl phenyl diazonium salt-derivative at (0-5) C° according to approaches\(^9,15\), after (24 hrs) . The resulting compound washed in distilled water, dried, recrystallized to give (S-N=N-) Sulfazane compound {5}.
Route of Preparation for Thiophene Derivatives{6,7,8}

Thiophene Compound{2}(0.01 mole) cyclized with (0.01 mole) of ortho-phenyl diamine in refluxing step in (4N of HCl) in refluxing process according to approaches(9-12), the resulted compound filtered, dried followed by re-crystallized to produce compound {6}.

Thiophene Compound {2}(0.01 mole) cyclized with (0.01 mole) of ortho-aminophenol in refluxing step in (4N of HCl) in refluxing process according to approaches(9-12), the resulted compound filtered, dried followed by re-crystallized to produce compound {7}.

Thiophene Compound {2}(0.01 mole) cyclized with (0.01 mole) of ortho-thiol aniline in refluxing step in (4N of HCl) in refluxing process according to approaches(8-10), the resulted compound filtered, dried followed by re-crystallized to produce compound {8}.

Results and Discussion:

The products of thiophene compounds prepared via cyclization reaction of chalcone compound which prepared in previously step (aldol reaction)(14), followed by cyclization with amino derivative to yield seven membered ring, then cyclization reaction with thiosemicarbazide to yield triazole derivative with thiol (SH)- terminal that reacted with various diazonium salts–derivatives in new reaction step in this paper by (Dr. Nagham Aljamali –as a new reaction for diazonium salt) that we termed (Sulfazane) as a first and novel preparation to this new type of compounds.

All Thiophene-heterocyclic and sulfide-azo compounds examined by spectral characterization besides microbial screening:

Spectral Description:

**FT-IR- Description of Spectra** : From spectral analysis, that noted disappearance of bands while appearance of new bands to indicate to formation of Thiophene-cyclic and that improve formation of (sulfide–Azo) compounds as a new band and as evidence for new reaction:

Thiophene –Chalcone Compound {1}: bands at (-CO-O) carboxyl of carboxyl group: 1706, (CO-) carboxyl of chalcone: 1667, (C-S) thiophene: 753, (=CH-) Alkene: 3049.

Thiophene (Sulfide- Azo) Compound {4}: new bands improved formation of (sulfide–Azo) (S-N=N-).
at (1389, 1454, 1515) as a new band in new reaction .
(C-O-C): 1134, (C-S) thiophene : 779, (=CH-) Alkene :
3067, (C=N) endocycle: 1657, (NH) amine : 3273, (CH)
aliphatic : 2985.

Thiophene (Sulfide- Azo) Compound {5}: new
bands improved formation of (sulfide–Azo) (S-N=N-)
at (1384, 1467, 1509), (C-O-C): 1165, (C-S) thiophene :
786, (C=H-) Alkene: 3092, (C=N) endocycle: 1655, 
(NH) amine : 3256, (CH) aliphatic : 2976.

Thiophene –imidazole Compound {6}: bands at
(C-O-C): 1155, (C-S) thiophene : 769, (C=H-) Alkene :
3071, (C=N) endocycle: 1642, 1663, (NH) in imidazole :
3310.

Thiophene –Oxazole Compound {7}: bands at
(C-O-C): 1147, (C-S) thiophene : 791, (C=H-) Alkene :
3069, (C=N) endocycle: 1639, 1658, (C-S-) Oxazole :
1189.

Thiophene –Thiazole Compound {8}: bands at
(C-O-C): 1147, (C-S) thiophene : 791, (C=H-) Alkene :
3069, (C=N) endocycle: 1635, 1650, (C-S-) in Thiazole :
763.

Other functional groups appeared in some spectra
figure(1).

1H.NMR- Description of Spectra: From spectral
analysis, that noted disappearance of peaks while
appearance of new peaks to indicate to formation of
Thiophene-cyclic and (sulfide–Azo) compounds, all
spectra appeared signal at (2.50) due to solvent (d-
DMSO), and other signals like:

Thiophene–Chalcone Compound {1}: appearance
signals at (12.66) due to proton of carboxyl group
(COOH), (6.14, 6.33) to protons of chalcone (CO-
CH=CH-), (6.63 – 7.99) to protons of aromatic ring.

Thiophene–Seven Membered ring Compound {2}:
appearance signals at (12.20) due to proton of carboxyl
group (COOH), (2.83) to proton of alkene (-C=CH-),
(6.65 – 7.51) to protons of aromatic ring.

Thiophene–Triazole Compound {3}: appearance
signals at (8.24) due to proton of amine in Triazole ring
(NH), (13.54) due to proton of Thiol group (SH), (2.64)
to proton of alkene (-C=CH-), (6.72 – 7.67) to protons
of aromatic ring.

Thiophene (Sulfide- Azo) Compound {4}: appearance
signals at (8.19) due to proton of amine in
Triazole ring (NH), (0.98) due to protons of methyl
groups (CH3), (2.68) to proton of alkene (-C=CH-),
(6.90 – 7.74) to protons of aromatic ring.

Thiophene (Sulfide- Azo) Compound {5}: appearance
signals at (8.27) due to proton of amine in
Triazole ring (NH), (0.63) due to protons of methyl
group (CH3), (2.72) to proton of alkene (-C=CH-),
(6.85 – 7.81) to protons of aromatic ring.

Thiophene –Imidazole Compound {6}: appearance
signals at (8.11) due to proton of amine group (NH) in
Imidazole, (2.81) to proton of alkene (-C=CH-),
(6.77 – 7.67) to protons of aromatic ring.

Thiophene –Oxazole Compound {7}: appearance
signals at (2.64) to proton of alkene (C=CH-),
(6.95 – 7.87) to protons of aromatic ring.

Thiophene –Thiazole Compound {8}: appearance
signals at (2.61) to proton of alkene (C=CH-),
(6.90 – 7.73) to protons of aromatic ring.

Other protons of functional groups appeared in
some spectra figure (1).

The 13C.NMR Description of Spectra: From
spectral analysis, that noted disappearance of peaks while
appearance of new peaks to indicate to formation of
Thiophene-cyclic and signals that improve formation of
(sulfide–Azo) compounds, all spectra appeared signal
at (40.00) due to solvent (d-DMSO), and other signals
like:

Thiophene–Chalcone Compound {1}: appearance
peaks at (171.04) due to carbon atom of (COOH)
carboxyl group, (110.0, 112.1) due to carbon atoms
of chalcone (-CH=CH-), (179.7) due to carbonyl in
chalcone (-CO-), (120–132) due to carbon atoms of
aromatic ring, (136–142) due to carbon atoms of
heterocycles.

Thiophene–Seven Membered ring Compound {2}:
appearance peaks at (171.05) due to carbon atom of
(COOH) carboxyl group, (100.0, 105.7) due to carbon
atoms of alkene (-CH=CH-), (112–127) due to carbon atoms
of aromatic ring, (132–144) due to carbon atoms of
heterocycles.

Thiophene–Triazole Compound {3}: appearance
peaks at (101.22, 104.83) due to carbon atoms of alkene
(-CH=C-), (152.12) due to carbon atom of
(-C=N-), (116–130) due to carbon atoms of aromatic
ring.
Thiophene (Sulfide- Azo) Compound \{4\}: appearance peaks at (100.14, 103.92) due to carbon atoms of alkene (-CH=C-), (150.36) due to carbon atom of (-C=N-), (111.32 – 129.08) due to carbon atoms of aromatic ring, (133.8 – 148.75) due to carbon atoms of heterocycles, (17.45, 19.61, 19.92) due to carbon atoms of methyl groups.

Thiophene (Sulfide- Azo) Compound \{5\}: appearance peaks at (100.76, 102.38) due to carbon atoms of alkene (-CH=C-), (149.52) due to carbon atom of (-C=N-), (115.76 – 130.17) due to carbon atoms of aromatic ring, (134.41 – 146.27) due to carbon atoms of heterocycles, (16.96) due to carbon atom of methyl group.

Thiophene – imidazole Compound \{6\}: appearance peaks at (101.54, 103.21) due to carbon atoms of alkene (-CH=C-), (150.56) due to carbon atom of (-C=N-), (109.73–130.94) due to carbon atoms of aromatic ring, (135.87–146.89) due to carbon atoms of heterocycles.

Other carbon atoms of functional groups appeared in some spectra, figure (1).

Fig(1): Spectra of Antimicrobial Compounds\{1,2\}

Behavior of Thiophene Derivatives in Organic Solvents
Thiophene–Cyclic and Sulfide- Azo (Sulphazane compounds) screened and tested in various organic solvents, the solvents that selected have various polarities for this reason, some of prepared thiophene compounds have solubility in polar solvents while other compounds have no solubility in these solvents, Table (1).

Diagnostic test of Brief Peripheral Neuropathy Screen as Distal Sensory Polyneuropathy-HIV Diagnostic Tool

Joko Rudyono1, Mudjiani Basuki1, Erwin Astha Triyono2
1Department of Neurology, Faculty of Medicine, Dr. Soetomo Teaching Hospital, Universitas Airlangga, Surabaya 60285, Indonesia, 2Department of Internal Medicine, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo Teaching Hospital, Surabaya 60131, Indonesia

Abstract

Distal sensory polyneuropathy (DSP) is the most common human immunodeficiency virus (HIV)-associated peripheral neuropathy with a prevalence of 30-67%. Brief peripheral neuropathy screen (BPNS) examination is a non-invasive, fast, cheap, easy-to-do diagnostic method, and one of the clinical tools that can be used to diagnose HIV-DSP. This study to assess the BPNS diagnostic test as a DSP diagnostic tool in HIV patients. The cross-sectional study was conducted on HIV patients that allegedly having DSP. All subjects were examined by BPNS and nerve conduction study (NCS), then the results were analyzed by chi-square test of a 2x2 Table. There were 42 subjects enrolled in this study. The mean patients were 38.88±8.62 years and most of the male patients were 24 subjects (57.14%). Most of the patients had high school education by 20 (47.61%) subjects and did not take anti-retroviral (ARV) by 18 (42.85%) subjects. Most of the research subjects conducted BPNS disturbed examination by 27 (64.28%) subjects and examination of NCS obtained positive DSP by 30 (71.4%) subjects. The obtained sensitivity of 83% BPNS, 83% specificity, 93% positive predictive value, the negative predictive value of 67%, a positive likelihood ratio of 5.00, and a negative likelihood ratio of 0.20. BPNS examination with 83% sensitivity and 83% specificity can be used as a DSP diagnostic tool in HIV patients.

Keywords: Diagnostic testing, DSP-HIV, Brief peripheral neuropathy screen (BPNS), NCS examination

Introduction

Human immunodeficiency virus (HIV) is a retrovirus that can cause immune system failure in humans 1,2. It is estimated that 35.3 (32.2-38.8) million people are living with HIV in 2012 and annually about 2.3 (1.9-2.7) million with new infections 3. After the highly active anti retroviral therapy (HAART) era since 1996, the life expectancy of HIV patients has increased. As a consequence, patients and medical personnel will be faced with neurological complications of HIV disease from comorbidities and the drugs used 1,4,5. Peripheral neuropathy has been documented since early reports of HIV disease and HIV isolation in the human nervous system. The prevalence of peripheral neuropathy in HIV-positive individuals are high and is the most common neurologic complication of HIV infection. Although not life-threatening peripheral neuropathy will affect the quality of life in HIV patients 1,4,6–9.

Distal symmetrical polyneuropathy (DSP) is the most common form of HIV-associated peripheral neuropathy, it also called distal sensory polyneuropathy. Two potential mechanisms for the cause of neurotoxicity plays an important role in the pathogenesis of HIV DSP: viral neurotoxicity and its products and neurotoxic side effects of treatment used in the managements of HIV 1,9. Where the prevalence ranges from 30%-67% 10. Until now there is no standard for diagnosing DSP-HIV, but several clinical devices have been developed to assess this condition in both clinical and research practice. One of the most commonly used clinical devices is the brief peripheral neuropathy screen (BPNS) 1.
Brief Peripheral Neuropathy Screen is one of the clinical tools that can be used to diagnose DSP-HIV. Non-neurological clinicians such as general practitioners, trained nurses or therapists may use BPNS to diagnose peripheral neuropathy. BPNS has been validated as a screening device to determine the degree of polyneuropathy. This check includes subjective and objective information and takes only <10 minutes for its implementation. The diagnosis of sensory HIV neuropathy can be established if the patient shows ≥1 specific symptoms of BPNS and 1 other sign of decreased ankle/Achilles reflex and/or vibration perception.

The availability of electro myo graphy (EMG) tools in peripheral areas in Indonesia is limited, so research is needed to assess the usefulness of BPNS diagnostic tools in establishing the diagnosis of HIV-DSP. Based on the international research, the data showed that BPNS diagnostic tests can be used to help establish a diagnosis of HIV-DSP. Therefore the researchers tried to conduct research on the diagnostic test of BPNS examination compared to the examination of nerve conduction/NCS in HIV patients with DSP suspicion in Dr. Soetomo Teaching Hospital, Surabaya.

**Method**

The study subjects were HIV patients with allegedly of DSP who visited outpatient of UPIPI at Dr. Soetomo Teaching Hospital Surabaya, Indonesia. The subject inclusion criteria were HIV patients with DSP suspicion and aged 18 to 60 years. While, the subject exclusion criteria were, patients with type 2 Diabetes Mellitus, using neurotoxic drugs (metronidazole, chloramphenicol, vincristine, vinblastine, dapsone, isoniazid, and ethambutol), lower extremity amputations, and lower extremities contracture. The subjects who are willing to participate the research in advance fill out the form informed consent. And then, before this study the researcher conducted a test of ethics at Dr. Soetomo Teaching Hospital Surabaya Indonesia.

This study used a cross-sectional study design that conducted over 5 months. The instruments used in this study were data collecting sheets from interviews and reflect and Achilles reflex examinations, Riester reflex hammer tool for Reaction Achilles inspection, 128 Hz tuning fork tool for vibration check, NCS tool is EMG/NCV Cadwell, paper of NCS readings. The stages of this study examination of BPNS, subsequent examination of NCS, and all recording results were collected for subsequent data tabulation and statistical analysis.

The data obtained from the data collection sheet then expressed on the scale of the dichotomies, i.e., the nominal scale having 2 positive or negative values. The examination results of HIV patients suspected of having DSP with BPNS examination that was analyzed by the 2x2 table for the dichotomous values, the difference of clinical findings and BPNS positive compared to negative findings. Then, it was compared to NCS, and analyzed by diagnostic test to obtain sensitivity, specificity, positive suspicion value, negative suspicion value, positive possibility ratio, and possible negative ratio. Statistical analysis using SPSS 19 (SPSS, Inc., Chicago, IL) and paint maker program.

**Results**

The data collection were BPNS examination and NCS examination conducted within 5 months, from December 2014 to April 2015. The basic data of the patient was taken by direct interview with the patient and the BPNS examination was performed by UPIPI whereas the neural conduction examination was done in Electromyography (EMG) room at Department of Neurology Dr. Soetomo Teaching Hospital Surabaya, Indonesia.

The mean patients were 38.88±8.62 years and most of the male patients were 24 (57.14%). Most of the patients had high school education by 20 (47.61%) subjects and did not take anti retro viral (ARV) by 18 (42.85%) subjects. Most of the research subjects conducted by BPNS examination that disturbed of 27 (64.28%) subjects and examination of NCS obtained positive DSP by 30 (71.4%) subjects (Table 1).

Cross tabulation between BPNS diagnosis and NCS results in the study subjects resulted in a similar diagnosis which 27 patients diagnosed with DSP and BPNS, 25 patients (92.6%) were positively diagnosed with DSP and NCS as well. Out of the 15 patients diagnosed with DSP and BPNS, 10 patients (66.7%) were diagnosed as negative DSP and NCS (Table 2).
Discussion

Brief Peripheral Neuropathy Screen is one of the clinical tools that can be used to diagnose DSP-HIV \(^1,11\). BPNS cannot distinguish the underlying cause of neuropathy but shows its sensitivity to small nerve fibers/pain fibers, indicating the presence of DSP. This check includes subjective and objective information and takes only <10 minutes for its implementation. The HIV diagnosis of SN can be established if the patient showed ≥1 specific symptoms of BPNS and 1 other sign of decreased ankle/Achilles reflex and/or vibration sensation \(^13,14\).

The data from this study indicated that BPNS examination may be used to establish the diagnosis of HIV DSP, however, did not replace the function of NCS in identifying other conditions similar to DSP such as lumbosacral radiculopathy or another polyradiculoneuropathy. NCS is also more appropriate as a predictor of clinical severity than BPNS.

Diagnostic tests were distinguished by their usefulness as a screening tool, to ascertain and exclude disease, monitor disease course, and determine prognosis. Choosing the right diagnostic check is not easy. The ideal diagnostic test is rare, a test that gives positive results on all sick objects and gives negative results on all not sick subjects. Almost on all types of diagnostic tests it is possible to obtain positive test results on healthy subjects (false positives) and negative results on sick subjects (apparent negative) \(^15,16\).

This diagnostic test study aims to determine the sensitivity, specificity, positive predictive value, negative predictive value, positive likelihood ratio, and negative likelihood ratio of BPNS with standard nerve conduction examination/NCS. A diagnostic test can be to diagnose a disease or exclude a disease if it has a high sensitivity and specificity \(^15\). A high sensitivity diagnostic test is required to detect the presence of a disease, as more cases can be detected by the test. High specificity diagnostic tests are used to confirm the presence of a disease because the greater the specificity of a diagnostic test, the greater the likelihood that patients who do not have a disease are excluded by the test \(^16\).

The results of previous studies showed a more comparison of male patients i.e., 85% and 84% \(^17,18\). According to the data of HIV patients that undergoing treatment at outpatient UPIPI of Dr. Soetomo Teaching Hospital where the number of male patients 4-7 times more than women \(^19\). However, in other studies obtained more women 69.8%, 65.3%, and 67.5% \(^13,20,21\). The results of this study was not much different from previous studies that get an average age of 36.5 ± 9.3 years and mean age was 38.3 ± 10.8 in the HAART group and 35.5 ± 8.7 in the non-HAART group \(^17,21\).

In this study, 18 subjects (42.85%) had not received antiretroviral therapy, as most new subjects were diagnosed, no CD4 results and some research subjects were suspected of having other opportunistic infections. Type of antiretroviral drugs used research subjects using 3 kinds of combinations, namely: a. tenofovir, lamivudine, efavirenz, b. tenofovir, lamivudine, nevirapine, and c. zidovudine, lamivudine, nevirapine. This therapy is according to WHO 2006 first-line therapy for adult patients \(^19\). Among the antiretrovirals used by the study subjects, there was zidovudine which can cause peripheral neuropathy. The subjects taking antiretrovirals less than 3 months were 26.1% and 31% were taking antiretroviral drugs for more than 3 months. According to a previous study, the peak incidence of DSP HIV occurred on day 90 after the use of antiretrovirals\(^17\).

Sensitivity is the proportion of ailing subjects with positive (absolute positive) diagnostic test results overall sick subjects (false positives and apparent negative) or the possibility that the diagnostic test results are positive when performed on a group of disease subjects. Specificity is the proportion of healthy subjects who give negative (true-negative) diagnostic test results compared to all non-sick subjects (true negative and false positives) or the possibility that the diagnostic test results will be negative when performed on a group of healthy subjects \(^15\).

In previous studies, BPNS showed a sensitivity of 49% and a specificity of 88% for diagnosing HIV-DSP \(^12\). This estimated value is strongly influenced by the prevalence of disease, where the population in this study is hospital-based so that more suffer than healthy. Positive assumptions are important statistics in the diagnostic test \(^15\).

Another statistic of the diagnostic test is the likelihood ratio (LR), i.e., the likelihood of the sick subjects getting the same test result. The positive likelihood ratio is the proportion of the proportion of sick subjects who test positive with the proportion of healthy subjects who test positive. The negative likelihood ratio is the proportion between the proportion of sick subjects
who tested negative tests and healthy subjects who gave negative test results. In this study, there was a positive likelihood ratio of 5.00 (CI 95%, 1.40-17.90) and a negative likelihood ratio of 0.20 (CI 95%, 0.09-0.46). According to the literature, the ratio of probability ratios varies from 0 to infinity. The results of positive positive diagnostic tests provided a probability ratio value much greater than 1, strong negative test results will give a probability ratio value close to 0.15.

BPNS examination can be used as a diagnostic tool of DSP HIV and has an advantage if it is compared to the examination of nerve conduction/ NCS. Daily clinical use is faster, easier, cheaper, non-invasive, and can be performed by trained medical and paramedical workers.

Conclusion

In this study, the sensitivity of BPNS examination was 83% and specificity was 83%, positive predictive value 93%, and negative predictive value 67%, positive likelihood ratio 5.00 and negative likelihood ratio 0.20.

Relation of Homocysteine With Malondialdehyde and Dyslipidemia in Type 2 Diabetic Patients with Coronary Artery Diseases

Khalid Shaalan Sahab¹, Ali S. Mahmoud Al-Saadi¹

Department of Chemistry, College of Science, University of Diyala, Baquba, Diyala, Iraq

Abstract

Diabetes mellitus (DM) is one of the most common chronic disorder widely prevalent throughout the world. DM is characterized by elevation of blood glucose (hyperglycemia). Hyperglycemia, with time, led to several serious macro and microvascular complications.

The purpose of study was to investigate the relation of Homocysteine (Hcy) with oxidative stress (malondialdehyde”MDA”) and dyslipidemia in type 2 diabetic patients with coronary artery diseases in comparison to patients of coronary artery diseases (CAD) without DM.

Methods: The present study included 60 patients of coronary artery disease. Patients divided into two groups: group1 = 30 coronary artery disease patients without diabetic and group2 = 30 coronary artery disease patients with type2 diabetes. Homocysteine was estimated by competitive ELISA test using commercially available kit. MDA was estimated by colorimetric method. Lipid profiles were determined by using commercial available kits.

Results: Plasma levels of Hcy and MDA in group1 and group2 were significantly higher (p<0.05) than controls. In group1 Hcy shows significant (P<0.05) positive correlation with MDA and Total Cholesterol (TC). Hcy shows no significant (p>0.05) positive correlation with very low density lipoprotein (VLDL), low density lipoprotein (LDL), and Triglyceride(TG). Hcy shows negative significant (p<0.05) correlation with high density lipoprotein (HDL). While in group2 Hcy shows significant (P<0.05) positive correlation with MDA, TC, VLDL, LDL and TG. Hcy shows negative significant (p<0.05) correlation with HDL. Hcy, MDA, TC, TG, LDL and VLDL were higher without significant in CAD diabetic patients than non-diabetic CAD patients. HDL was lower in diabetic coronary artery disease patients than non-diabetic coronary artery disease patients but without significant importance.

Conclusion: In this study Hcy and MDA levels obtained were found to be positively correlated with dyslipidemia in patients in both groups. Hcy may be one of the cause for development and progress of macro- and microvascular disease. Hcy and dyslipidemia were higher in CAD with DM than CAD without DM this shows that hyperglycemia may be is another factor to increase atherosclerotic process.

Keywords: Diabetes mellitus, Homocysteine, Malondialdehyde, Dyslipidemia.

Introduction

Diabetes mellitus (DM) is an epidemiological disease widely prevalent throughout the world. DM is a significant cause of mortality and morbidity worldwide because of its serious complications such as micro- and macroangiopathic complications[1,2]. Globally studies shows about 300 million people will suffering from diabetes in 2025[1]. One of diabetic complication is coronary artery disease or cardiovascular diseases (CAD or CVD). CAD is the commonest cause of heart disease and the most important cause of death in the different countries of worldwide. Beside the known classical risk factors of CAD like hypertension, cigarette smoking, diabetes mellitus, low HDL, obesity and reduce physical inactivity, a few new parameters at last few years have been identified and studied as risk factors.
factors for development and progress of the CAD such as prothrombotic factor, pro-inflammatory factor and homocysteine\cite{3}. Homocysteine is sulfur containing amino acid formed as intermediate product in normal biosynthesis of methionine. In human body there are two major pathways to metabolize homocysteine, both of these pathways required vitamin B6, B12 and folic acid \cite{4}. One of the ways by which homocysteine increases the damage to the cardiovascular system is the formation of reactive oxygen species (ROS) by auto oxidation of homocysteine. The ROS produces by auto-oxidation of homocysteine including hydrogen peroxide and superoxide which enhances oxidative stress by production free radicals which causes lipid peroxidation to formation aldehydes. The most commonly measured compound produced by action of free radical is malondialdehyde (MDA)\cite{5}. The results of many clinical and epidemiological studies have been showed a positive correlation between pathogenesis of CAD and increasing homocysteine levels. Few studies have been carried out to established correlation between homocysteine and oxidative stress in diabetic patients with and without CAD\cite{6-10}. Therefore the study has been current to establish the correlation of hyperhomocysteinemia with oxidative stress as one of the risk factors for coronary artery disease in diabetic patients.

**Materials and Method**

The present study is conducted on 85 male subjects, 60 subjects were of coronary artery disease patients who visited Consultative Clinic of Baquba Teaching hospital in June-July 2017. The 60 CAD patients divided into two groups: group1 = 30 coronary artery disease patients without diabetic and group2 = 30 diabetic patients with coronary artery disease. The patients were compared with 25 healthy subjects were chosen as control group. All samples were collected in the morning after overnight (8-12 hours) of fasting. 6 ml of vein blood was drawn by venipuncture using a 10 ml disposable syringes from each subjects. 3ml of blood transferred into an EDTA containing vacutainer tube for determination of plasma MDA and homocysteine, and 3 ml of blood was transferred into a plain tube for evaluation of lipid profile. Estimation of plasma homocysteine was done by competitive Elisa test using commercially available kit. Estimation of serum TC, HDL-C and TG were done by using commercially available kits. Serum LDL-C and VLDL-C were calculated by using Friedewald’s formula. Estimation of plasma MDA malondialdehyde was done by colorimetric method.

Statistical analysis were done for tabulated results of all undertaken parameters by the Pearson correlation and t-test from which p value were obtained.

**Results**

Table 1 below represents the Mean±SD values for different parameters in group 1 as compared with control group. The patients of group1 and healthy controls were matched in age and body mass index(BMI), but fasting blood glucose was higher non-significantly in patients of group1 than control group. Plasma level of Hcy and MDA were significantly higher (p<0.05) in group 1 than controls. Levels of TC, TG, LDL-C and VLDL-C were higher in group1 than in controls, whereas level of HDL-C was lower in the group1 in comparison to controls. The difference is statistically significant only for TC, VLDL-C and HDL-C. Hcy showed significant positive correlation with TC, and significant negative correlation with HDL-C as shown in table 2.

Discussion

The statistical positive significant correlation between Hcy and MDA levels that obtained in study is agreed with some previous studies[6-11] that shows positive correlation between Hcy and MDA levels (p<0.05). The exact mechanism of toxicity by Hcy is still unknown well, but it’s believed that homocysteine or compounds liberated from its metabolize enhancing atherosclerosis by several mechanisms for example the hydrogen peroxide generated by auto oxidation of homocysteine which affect toxically on endothelial cells[11-13]. Generated hydrogen peroxide promotes oxidation of low density lipoproteins(LDL) and lipids peroxidation. The oxidized LDL causes alteration of metabolism for nitric oxide (NO) the oxidative damages also causes alteration of functions on vascular endothelial cells and platelets[5]. Auto-oxidation of homocysteine beside generation of hydrogen peroxide, it is also generates superoxide anion and hydroxyl radical, and all these compounds are factors contributing for vascular injury that is associated with hyperhomocysteinemia[11-14]. Also the auto-oxidation of Homocysteine to produce the free radicals which are the initiators of lipid peroxidation in cells. Lipid peroxidation induced by homocysteine is more occurrence in hyperlipidemic state which can increases the production of MDA through enhance oxidative stress[11-14]. As shown in table 3 diabetes mellitus increases risk factors levels of CAD. Although, the possible role of hyper Hcy in diabetes is not clear. Hyperglycemia may another risk factor with HHcy increases the oxidative stress and contributes to acceleration the atherosclerotic process in diabetes mellitus[15]. So, HHcy may accelerate vascular damage related to diabetes. Some studies re-searching the relationship between plasma Hcy and diabetes have shown that type 2 diabetic patients have a higher prevalence of HHcy than control subjects[16,17].

Conclusion

Hcy and MDA levels obtained in this study were found to be positively correlated with each other and with lipid parameters in CAD patients without diabetic and diabetic patients with CAD but the increase were higher in diabetic patients with CAD than CAD patients whom without diabetic. This indicates that Hcy enhances
the oxidative stress by lipid peroxidation, HHcy may accelerate vascular damage related to diabetes this may be one of the cause for development of coronary artery disease in diabetes rapidly, and, Hyperglycemia may another risk factor with HHcy increases the oxidative stress and contributes to acceleration the atherosclerotic process in diabetes mellitus.

Determination of Some Biomarkers that affect in Behaviors of Autism Spectrum Disorder Individuals in Iraq

L. Basim M. Ali¹, Iqbal Jasim Badr Alasadi¹, Sameerah Ahmed Zearah¹

¹Department of Chemistry, College of Science, Basra University, Iraq

Abstract

Autism is a developmental disorder characterized by troubles with social interaction and communication by restricted repetitive behavior. The parents usually notice signs in the first two or three years of their child’s life. These signs often develop gradually. Blood samples were taken for 60 people with autism and 30 healthy people as a control group. Both groups ranged age from 3 to 8 years. After completion of number, required tests were carried out on samples. The tests were three biochemical markers. The first is neurotransmitters (γABA), the other enzymes of happiness (Serotonin & Melatonin), all this biochemical markers were measured by elisa technique, the results were a decrease in level of γABA for ASD as compare with control group, A significant increases in serotonin in ASD relative to control group, and no change in level of Melatonin in both ASD and healthy group these results consistent with many research and another research inconsistent with these results have shown the reasons that led to differences in results.

Key word: Autism, GABA, Serotonin & Melatonin

Introduction

“Autism is a developmental disorder characterized by troubles with social interaction and communication by restricted repetitive behavior. Parents usually notice signs in the first two or three years of their child’s life. These signs often develop gradually, though some children with autism reach their developmental milestones at a normal pace and then worsen” ¹ ² so researchers were characterized the “Autism spectrum disorders” by vast lack of social communication skills and skill of attraction or care between the patient and society. According to recent studies carried out at one of the American centers that deal with diseases and methods of prevention ³, a statistical study showed (ASD) affects (1) child from (68) less than eight years old, ⁴ the great challenges facing developmental neuroscience is to understand how complex social interactions can shape brain development during ontogeny to affect adult functioning in social and behavioral contexts. Additionally the type of autism Spectrum Disorders (ASDs), including Autistic Disorder (AD), Asperger’s Syndrome as Childhood disintegrative disorder (CDD), Rett’s Syndrome (RS) and Pervasive Developmental Disorder Not Otherwise Specified (PDD-NOS) represent a cluster of instability in the growth of nervous which suffers from this cluster as a result is the inability to social communication at all levels, the excessive behavior repeated since the third year age ⁵.

So research was connect between (ASD) and neurotransmitter when they explain gamma-Aminobutyric acid, γ-aminobutyric acid, GABA which is the chief inhibitory neurotransmitter in the developmentally mature mammalian central nervous system. Its principal role is reducing neuronal excitability throughout the nervous system. In humans, GABA is also directly responsible for the regulation of muscle tone ⁶.

One of the factors that has revolved around the information on autism and Serotonin level in autistic children and assess the reliability of serum serotonin levels as a biomarker for diagnosis of ASD. Serotonin influences many physiological activities in the human body ⁷.

Another studies that deals with Melatonin and its relative with (ASD) This hormone is primarily produced by the pineal gland, several factors have been shown to alter circadian rhythms and melatonin levels, abnormal melatonin secretion has been implicated in circadian disturbances and neurodevelopmental abnormalities including autism spectrum disorder (ASD) ⁸.
Subjects & Method

1- Subjects

1-1- Patients: 60 Iraqi children with Autism spectrum disorder (ASD) and 30 apparently healthy Adult were selected as the control group. Their ages ranged between 3-8 years. These children (ASD) were registered in many specialized centers that care with autism in Iraq particularly in the governorates of Basra, Karbala, Babylon, Baghdad and Najaf. Where the blood sample was taken from them after the approval of their parents. The present study excluded the children (ASD) from apparent other mental disease.

1-2- Blood Samples

A Five milliliters of venous blood samples were collected from each children of (ASD) and control subject. then serum was separated and transported into new disposable tubes and freezes at (-70 °C) until assayed.

2- Methods: Measuring each of (Gama amino butyric acid (γABA), Serotonin and Melatonin) markers by ELISA ElabSciences kit.

Statistical analysis: The data collated after biochemical analysis were subjected to statistical calculation using statistical software (Megastat). The mean, standard deviation of mean, F-distribution test were obtained. Critical value or test of probability less than 0.05 (p< 0.05) was regarded significant also we use Microsoft Excel (2010), SPSS 17, and Minitab v. 14.

Results and Discussion

This study involved 60 patients with autism (42 males and 18 females) and 28 controls (17 males and 11 female).
The statistical analysis was divided into two sections, so the first was divided into three parts: the first was dealing with all samples, the second was concerned with male samples, and finally, the third part dealt with female samples. The second section dealt with the relationship between all items, which was measured in patient samples only.

Table (1) level of parameters (γABA, Serotonin, & Melatonin) for patients with ASD as comparison as control group.

The table (1) shows a high significant decrease (p value = 0.0097) in level of γABA for the case of ASD (275.3) as compare with the control group (371.9), In this paper, study γABA, serotonin and melatonin hormones. The result in table (1) shows a high significant decrease in level of γABA for the case of ASD as compare with the control group, as well the results in table (2&3) were congruous with the results of the table (1) which were a significant decrease in level of γABA as compare with their healthy group, many papers were agreement with these results, a significant reduction in the level of γABA in people with autism, the level of γABA was very low in people with autism, in addition scientists were demonstrated with all confidence that the association of autism has an inverse relationship with γABA, where the lower the level of γABA lead to increase the emergence of symptoms of autism. In a second demonstration, so the γABA level was low in those with autism at the beginning of the diagnosis.

On the other hand, there are other studies that contradict the results of current study, the research about persons suffering from autism were different groups in the ages, that the level of γABA was within the normal level, the discrepancy between current paper and the researchers’ It may be due to differences in the age of the studied cases for both studies. The age of the new research is 3-8 years, while the research whose results are opposed was about 12-16 years old. A rise in the level of γABA the attribution of reason for contrast ages of autism individuals, they said the study of autism must be for all age groups, so, the cause of different levels of γABA was attribute gap ages in people with ASD.

In contrast to γABA the level of serotonin in the table (1) shows a significant elevation (p value = 0.04) in case of ASD (160.7) as compare with their control group (124.8). Several previous studies have demonstrated a common phenomena in persons with autism is the high level of serotonin, so in this current study as shown as in table (1) a significant elevation for level of serotonin in case of ASD as compare with their control group, In a research paper on autism, Levitt P.(2011) explained the high level of serotonin in autism patients, in addition researcher was concluded that the level of serotonin increases in people with autism, so the reason for increasing the concentration of serotonin comes from a decrease in turnover of serotonin in the body and to support the results conducted experiments on a type of mice treated mice with a substance that increases the level of serotonin and found that The rate of rotation is inversely proportional to the level of serotonin in the body.

A high level of serotonin in persons with autism is one of the important signs that a good candidates for the determination of the susceptibility to autism. Many of the studies are in line with the results of the new research, serotonin plays an important role in their study of autistic patients, in the other hand the researchers found that serotonin levels were low in serum while there was a significant increase in the level of serotonin in the whole blood or platelet-rich plasma, Therefore, this study is contrary to the results found in the current study. To know why the difference in results between the current study and the opposite study is that platelets is a place for the accumulation of serotonin in its, which leads to a decrease in level of serotonin. This is what explained in their research, the relationship between the level of serotonin in people with autism in the serum and blood platelets. They also conducted a genetic study of serotonin generators.

In this study they Clarify the relationship between levels of serotonin in platelets and serum, The difference may be due to the severity of case for subjects in the study, as there is a study by Amjad where the division of cases according to severity to three classes, the serotonin levels directly proportional to the increased severity of the disease, in addition scientists were proved there is no association between low levels of serotonin and autism, while the same table (1) displays no change in level of melatonin in both ASD sample (121.1) and its control group (149.7), The result in this current research shows no significant change in level of Melatonin between autism samples and its healthy group, perhaps most of the research that deals with the study of melatonin in people of autism, shed light on the relationship of this hormone with serotonin hormone, It is a daily synchronous hormone derived from serotonin, So serotonin hormone is inversely proportional to melatonin hormone This is dependable with the results in the current search, the relationship between serotonin and melatonin is negative and the level of melatonin is low while the level of serotonin is high in people with autism compared to control group.

The level of melatonin in people with autism should be low compared with the healthy people and the time when the blood sample was drawn. They showed that melatonin levels may give abnormal levels to people with autism or may have insignificant results.
compared to Group healthy, where they attributed the abnormal results to many reasons including the situation of the ASD in a dark room or a room with a dim light, where the relationship of light with melatonin was an inverse relationship, so the lower light increased the level of melatonin in the other hand, The rise in levels of melatonin in the autistic may be caused by the use of monotherapy drugs containing a proportion of melatonin for giving them more sleep hours, leading to a higher level of autistic compared to the standard group, this search also corresponds to the current search, additionally in their research that supplements and some drugs that increase the level of melatonin in the blood of the autistic, where they conducted a search on a group of autistic people taking drugs containing melatonin and found that the level of melatonin does not differ significantly from the control group 22, these results was agreement with the current search.

### Table (2) Relationship between items for persons who are suffer from ASD.

<table>
<thead>
<tr>
<th></th>
<th>Melatonin</th>
<th>Serotonin</th>
</tr>
</thead>
<tbody>
<tr>
<td>γABA</td>
<td>0.647</td>
<td>-0.292</td>

<td>0.000</td>
<td>0.024</td>
</tr>
<tr>
<td>Serotonin</td>
<td>-0.306</td>
<td>0.017</td>
</tr>
</tbody>
</table>

The second section of biostatistical analysis which was deal about the relative among items that appear in table no. (2), so the table illustrates a highly positive significant relationship between γABA and Melatonin in persons have ASD(r = 0.647 & P value = 0.000), while in the same table demonstrates a negative significant relationship between γABA and Serotonin in same cases of ASD (r = -0.292 & P value = 0.024), additionally the table appears a negative significant relationship between Serotonin and Melatonin with individuals who suffer from ASD (r = -0.306 & P value = 0.017).

In recent years concern has risen about the increasing prevalence of developmental disorders. A striking example is Autism Spectrum Disorders (ASD). In this study which is interested in studying some of the biochemical factors and their effect on individuals who suffer from autism, neurodevelopmental disorders primarily diagnosed in childhood.

Many researchs that agree with the recent study as the individual of ASD suffers from a lack of the level of γABA, at the same time also suffers from a deficiency in the level of melatonin, since melatonin is composed of serotonin, which means that the higher the level of melatonin decreased the level of serotonin and vice versa, This is agreed upon by 23 and 24.

Abstract

Enteric-borne diarrheal illnesses are significant causes of human morbidity and mortality. Over 2 million diarrhea-related fatalities happen annually, especially among kids under the age of five. During the period extended from February 2019 to June 2019, A total of 196 stool locally specimens from diarrheal patients samples were collected from AL-Anbar city of AL-Ramadi hospital and AL-Fallujah hospital out of 196 samples diagnosis by biochemical test, morphology and selective chromogenic medium, found 80 samples of E. coli. The aim of the study detection of VT1 and VT2 genes in Escherichia coli isolated from Diarrhea patients by using PCR Sequencing. The result showed when diagnosis by PCR for Sanger Sequencing technique for VT1 and VT2 genes E. coli O157:H7, and E. coli O25b:H4 were positive for VT1 gene, and Escherichia coli O25b:H4, and Escherichia coli O18:H1 positive for VT2 gene.

Key words: *Escherichia coli*, diarrhea patients, VT1 and VT2 genes.

Introduction

Diarrheal illnesses are a significant cause of low-to-middle-income morbidity and mortality nations and are predestined to be the second most important reason from death among kids < 5 years of age, resulting in 0.5 million fatalities worldwide¹. Sub-Saharan and South-East Asian areas have the largest illness burden (> 72%). In spite of the known actuality that diarrheal illnesses are transferred by stool oral route (²). It is a complicated syndrome because it includes interaction of environmental, dietary and infectious variables (³). *Escherichia coli* is extremely multilateral bacterium that develops its commensal and pathogenic capacity in human host. Diarrheagenic E. coli (DEC) is recorded as one of the world’s major causes of gastrointestinal turmoil and is an significant public health issue⁴⁻⁷. These pathotypes likewise play a significant part in the morbidity of diarrhea in the Indian people. Remarkably, distinguish DEC pathotypes offer particular, virulence arsenal which convert the prevalent repertoire available for diagnostic and therapeutic methods. DEC is moreover cataloged into different pathotypes based upon appearance from these virulence determinants participating to specific pathophysiology⁸. Human and bovine STEC strains detailed two powerful phage-encoded cytotoxins called Shiga toxins (Stx1 and Stx2) or Verotoxin (VT1 and VT2)⁹⁻¹⁰. Moreover, Shiga-like toxin (Stx)-producing Escherichia coli (STEC) contagion is an continuing health issue that can leadership to severe complications, inclusive hemolytic uremic syndrome (HUS) and death¹¹.

Materials and Method

Subjects and specimen collection.

A total of 196 stool samples of patients with diarrhea aged among (2-60) yearsthrough the period from February 2019 to June 2019. Samples were collected from AL-Anbar city of AL-Ramadi hospital and AL-Fallujah hospital out of 196 samples diagnosis by biochemical test, morphology and selective chromogenic medium, found 80 samples of E. coli. Patients with soft stool as a major complications, furthermore reported another clinical appearance likewise dehydration, vomiting, Fever, common abdominal pain and mucus. Patients have been given written consent. To identify *E.coli*, stool specimens were plated into Differential media Sorbitol- MacConkey agar(SMAC), Chromo agar *E.coli* and Eosin methylene blue agar(EMB) Samples were cultured on differential agar and incubated aerobically at 37 C for 24-48 hours to isolate *E.coli*¹².
Extraction of total DNA

Genomic DNA of 80 Escherichia coli isolate was extracted by utilizing (DNA mini kit that was provided by G-spin DNA extraction kit, Korea) as instructed by the manufacturer’s instructions. Primers were acquired from the IDT corporation in this study.

Detection of Verotoxin (VT1 and VT2) genes by PCR

The genes of Verotoxin (VT1 and VT2) were amplified by F (5'-CGC TGA ATG TCA TTC GCT CTG C -3’) and R (5'-CGT GGT ATA GCT ACT GTC ACC -3’), sense F (5'-CTT CGG TAT CCT ATT ACC GG -3’) ,anda anti sense R (5'-CTG CTG TGA CAG TGA CAA AAC GC -3’) respectively (11). The PCR reaction mixture contains 5 μl of pre Master Mix, 1.5μl DNA, 1 μl of each forward and reverse primers, then the volume completed to 25 μl by deionized water. Thermo cycling conditions were as follows: initial denaturation at 5 min at 95 ° C, followed by 35 denaturation cycles at 95 ° C for 45 seconds, annealing at 58 ° C for 45 seconds, extension at 72 ° C for 45 seconds and final extension at 72 ° C for 7 minutes. A 70 volt/65 Amp current leaves the gel to run for 60 min. Visualization was performed with a UV transilluminator after electrophoresis. The sequencing of Verotoxin (VT1 and VT2) genes were performed at Macrogen company utilizing their ABI 3730xl genetic analyzer (Applied Biosystems, US). Online at the National Center for Biotechnology Information (NCBI) at (http://www.ncbi.nlm.nih.gov) and BioEdit, homology search was conducted utilizing the Basic Local Alignment Search Tool (BLAST) program. The outcomes were compared with information accessible online at the NCBI from the ExPASY program released by Gene Bank.

Results and Discussion

This study includes detection from the prevalence of VT1 and VT2 genes in collected samples locally from stool specimens after isolation on selective chromogenic medium and diagnosis by PCR for Sanger Sequencing technique found 1 out of 80 test samples were positive for E. coli O157:H7, 31 isolate E. coli O126:H20, 19 isolate E. coli O25b:H4, and 29 isolate for E. coli O18:H1.

In developing nations, toxigenic Escherichia coli has been acknowledged as the leading cause of diarrhea in both humans and animals (13). Such divergent pathogroups are often allocated using distinct terms such as “hybrid” “mixed virulence profiles” and “mixture of virulence” (14,15,16). Virulence genes in E. coli strains were connected with the coexisting STEC. In Germany, the United States and Slovakia, coli strains of human, animal and environmental origin have been recorded (17,18,19). Some of them related to human illness (19). Previous studies in Finland recognized hybrid STEC strains from patients and livestock. (20) Nyholm performed a comparative genomics and characterization study of such strains to determine their phylogenetic position in E. Coli and the genes they harbor to define virulence (21).

The polymerase chain reaction diagnostic techniques is rapid, easy, inexpensive protocol becoming the most commonly utilized of all molecular genetics ways for detecting important toxin genes and identifying the bacteria (22). Its elevated sensitivity, specificity methods for detect Specific sequence of nucleic acids discovered in the genome of pathogens (23). PCR products of 302bp for VT1 gene, 850bp for VT2 gene were detected in the positive and PCR product was not seen in the negative samples as seen in figure (1,2).

![Figure (1): Agarose gel electrophoresis for VT1 gene (302bp). Bands were fractionated by electrophoresis on a 1.5% agarose gel (2 h., 5V/cm, 1X TBE) and visualized under U.V. light after staining with red stain. Lane: M (M: 100bp ladder), Lane: 1,9,11,12,13 (negative PCR product).](image-url)
Figure (2):- Agarose gel electrophoresis for VT2 gene (850bp). Bands were fractionated by electrophoresis on a 1.5% agarose gel (2 h., 5V/cm, 1X TBE) and visualized under U.V. light after staining with red stain. Lane: 1 (M: 100bp ladder).

The VT1 and VT2 genes were amplified by PCR method, and sent for sequencing service to Macrogen company Korea. The sequencing result of VT1gene shows for strain Escherichia coli O25b:H4 having one Transition T>C in location (1273120 nucleotide) code TTG>CTG of amino acid Leucine>Leucine and Predicted effect nonsense , also three Transversion one in location G>C (1273126 nucleotide) code GAA>CAA amino acid change Glutamic acid to Glutamine the effect Missense , and two T>G in location (1273131 and 1273148 nucleotide respectively code GGT>GGG of the same amino acid Glycine > Glycine, that nonsense substitution , also code CTG to CGG transformation Leucine to Arginine that effect Missense. From the Gene Bank, found that part of VT1 gene having 99% compatibility with subject of VT1 gene in NCBI as seen in table (1). (24).

For the first time in Iraq, this study explored VT1 and VT2 genes using Sanger Sequencing method where few research was conducted to detect those samples through sequencing. Few studies have assessed or compared easy DNA extraction techniques to enable and improve the sensitivity of fecal samples to PCR detection of enteric pathogens (26, 27).

**Conclusions**

In the present study in stool samples of patients with diarrhea when diagnosis by PCR for Sanger Sequencing technique for VT1 and VT2 genes E. coli O157:H7, and E. coli O25b:H4 were positive for VT1 gene, and Escherichia coli O25b:H4, and Escherichia coli O18:H1 positive for VT2 gene.

**Conflict of Interest:** There is no conflict of interest among the authors.

Correlation between the Duration of Ethambutol Therapy and the Toxic Optic Neuropathy Occurrence in Patients with Multidrug-Resistance Tuberculosis

Muhammad Hamdan¹, Eko Wahono R.¹, Kurnia Kusumastuti¹, Laily Irfana¹
¹Department of Neurology Faculty of Medicine, Universitas Airlangga – Dr. Soetomo Teaching Hospital, Surabaya(60285), Indonesia

Abstract

Background: Tuberculosis affects one-third of the world’s population. Increasing number of tuberculosis cases also leads to the increase of anti-tuberculosis drugs use, such as ethambutol. Ethambutol is one of the most effective and rarely resistant tuberculosis drugs.

Objective: To determine the relationship between duration of ethambutol therapy with toxic optic neuropathy in tuberculosis patients

Method: This study enrolled MDR-TB patients who visited MDR-TB Unit of Dr. Soetomo General Hospital from July 2014 until the sufficient amount of sample was achieved. The patients enrolled are those who met the inclusion and exclusion criteria. Inclusion criteria consisted of MDR TB patients treated with ethambutol therapy, aged of 20-69 years old, and whose VEP examination results showed extension of P100 latency.

Results: The mean of <6 month duration was 3.24±1.348, while for the ≥6 months was 11.71±5.764. This difference was statistically significant with p = 0.043.

Conclusion: There is a correlation between duration of ethambutol therapy with toxic optic neuropathy in patients with MDR-TB.

Keywords: ethambutol therapy, toxic optic neuropathy, multidrug-resistance, visual evoked potentials

Introduction

Tuberculosis affects one-third of the world’s population. The increasing number of tuberculosis cases leads to the more use of anti-tuberculosis drugs, such as ethambutol. Ethambutol is one of the most effective and rarely resistant tuberculosis drugs, and therefore is often used in the case of Multidrug-Resistance Tuberculosis (MDR-TB). However, many researches reported the occurrence of optical toxic neuropathy (TON) with clinical symptoms of decreased vision until blindness.

The incidence of toxic optic neuropathy associated with ethambutol varies greatly from several studies ranging from 0.5-35% of patients. Visual Evoked Potentials (VEP) can be used to determine the toxic effects of ethambutol. Of the 14 samples, 5 were showed abnormalities in VEP, where in from the clinical findings only showed abnormal person. A study reported that 42% of patients with permanent vision impairment were dependent on the initial disorder severity. As reported in most cases, toxicity occurs at doses greater than 20mg/kgBW/day. However, not too little toxicity has occurred at a standard dose of 15mg/kgBW/day. For instance is in a case reporting optic neuropathy occurrence at a dose of 12 mg/kgBW/day. The duration of drug use that causes toxic effects is averagely one to six months. However, it has been reported that the fastest duration in which
visually impaired due to ethambutol occurs in the use duration of only three days.

Toxic optic neuropathy can provide symptoms of progressive decrease in vision, which might get worse until blindness occurs. Although the loss of vision is reversible when ethambutol is lowered or terminated, some patients experience permanent vision impairment even with standard drug doses. Some cases of progressiveness continue to run even though the drug has been stopped. Imperfect improvement was often found. Some even experienced permanent blindness. The mechanism of optic neuropathy due to ethambutol is thought to be caused by impaired function of the mitochondria. One study found a vacuole change from the cytoplasm of ganglion cells in animals injected with ethambutol. Ethambutol is a metal chelator, which can interact with zinc, copper and iron that cause damage to the mitochondria. Studies conducted on animals have demonstrated the toxic effects of ethambutol on electrophysiological visual systems as well as histopathology.

Toxicity can be detected earlier by VEP, even before the emergence of complaints from patients. This is very useful because by detecting TON earlier, can be stopped or replacement of drugs before clinical symptoms appear. In addition, knowing the occurrence of TON and drug termination will inhibit the progression of the disease and thus permanent loss of vision can be prevented. Aim to determine the relationship between duration of ethambutol therapy with toxic optic neuropathy in tuberculosis patients.

Method

This is an observational analytic study. The samples are MDR-TB patients who received ethambutol therapy who came in MDR-TB Unit of Dr. Soetomo General Hospital from July 2014 until the sufficient amount of samples was achieved. They all met the inclusion criteria consisted of MDR-TB patients who received ethambutol therapy, aged of 20-69 years old, VEP examination results obtained extension of P100 latency. The exclusion criteria consisted of the subjects with diabetic retinopathy, hypertensive retinopathy, renal failure, hepatic dysfunction, history of stroke, history of intracranial infection, multiple sclerosis history, cerebral neoplasm history, eye abnormalities, and those who were unwilling to participate in the study.

The sampling method of the study was conducted according to the consecutive case (sampling from consecutive admission) until the sample size was determined. The study instrument was visual evoked potentials. The duration of ethambutol therapy was the duration (within months) of patients taking ethambutol during the MDR program, calculated from the first day of drug use until the VEP examination with short duration of <6 months, and long duration of ≥6 months.

Toxic optic neuropathy is an abnormality in vision function due to optic nerve damage caused by toxic substances diagnosed from an extension of P100 latency from the normal limit of VEP examination with a 116 ms cutoff point. TON occurred when the obtained P100 latency is >116 ms, and it is considered normal when the normal P100 latency is ≤116 ms. VEP is the electrical potential of the visual stimulus recorded from the scalp to assess the integrity of the afferent visual path. The examination was done by Cadwell Sierra Wave in Electromyography of Dr. Soetomo General Hospital. The results will be interpreted by a neurophysiologist consultant. All subjects included in the inclusion criteria and the family responsible for the patients were given an explanation of the purpose, usefulness and risk of the study, and were asked to be involved in the study. The identity and characteristics of the subjects signing the consent were recorded in the form. Data collection of research subjects was conducted through anamnesis, careful physical examination and neurology, selection of samples for the cases according to inclusion and exclusion criteria. The eligible samples and all necessary clinical data were recorded. VEP examination was performed in the EMG of Dr. Soetomo General Hospital. All the recording results were collected for further data tabulation and statistical analysis.

The data obtained from the data collection sheets were then analyzed. The correlation between duration of ethambutol therapy and optic neuropathy was calculated and analyzed using the appropriate statistical tests. This study will be proposed as an ethical feasibility study to the Research Ethics Committee of Dr. Soetomo Teaching Hospital Surabaya.

</table>

All subjects underwent eye examination in MDR-TB and VEP units in the EMG section of Department of Neurology, Dr. Soetomo General Hospital Surabaya from July to December 2014. In this study, there were 34 subjects consisting of 17 normal subjects with normal Visual Evoked Potential (VEP) results referred to as controls and 17 subjects with VEP prolonged latency P100 results hereinafter referred to as cases. Table 1 shows the characteristics of the study subjects. In the case group there were 7 male subjects (41.2%) which were less than in control group with 13 male subjects (76.5%). There was a difference of sex proportions between each group, and this difference was statistically significant with p = 0.037. The mean of the subjects’ age in the case group was 43.29 ± 11.58 years, while in the control group was 38.82 ± 10.06 years old. However, this difference was not statistically significant with p = 0.239. in the case group, However, this difference was not statistically significant with p = 0.724. Characteristics of subjects based on dose of ethambutol ≥1200 mg / day in case group there were 10 people (58.8%) more than control group that was 7 people (41.2%). However, this difference was not statistically significant with p = 0.303. Characteristics of subjects based on history of ethambutol therapy ≤1 years showed that in the case group there were 7 people (41.2%), which was more than the control group with 4 people (23.5%). However, this difference was not statistically significant with p = 0.271.

The difference in the proportion of duration of ethambutol therapy in each group of subjects can be seen in Table 1. In the case group, there were 12 subjects (70.6%) with ethambutol therapy duration of 5 months, which is more than the control group with only 5 subjects (29.4%). Meanwhile, in group <6 months duration there were 5 subjects in case group (294%), which is less than in control group with 12 people (70.6%). This difference was statistically significant with p = 0.016. Odd ratio of...
5.76 (95% IK 1.317-25.187) was also obtained. Logistic regression of sex and duration indicated a significant correlation between duration of ethambutol therapy and TON with p value = 0.043 and an odds ratio of 4.93 (95% IK 1.053 - 23.082). Thus, subjects with duration of ethambutol therapy ≥6 months had 4.93 times higher risk of TON compared to subjects with ethambutol therapy duration of <6 months. This suggests that the study is clinically and statistically significant.

**Discussion**

The gender characteristics of a total of 34 samples 20 (58%) male and 14 (42%) female. A population-based study in Taiwan found more male with 65.8%. Similarly, in studies that linked ethambutol therapy to another TON, there were more male subjects than females 71%.

The mean age of the subject of the case group was 43.29 ± 11.58 years old while in the control group was 38.82 ± 10.06 years old, as seen in the older average age group. These demographic data were compared with studies that correlated the dose of ethambutol with TON obtained in the mean age of 55.4 ± 14.4 years old. The study of TON incident, the obtained the mean of age range was 58.23 ± 16.68 years. Characteristics of subjects based on risk factors of diabetes mellitus in case group was 7 people (41.2%) slightly more than control group 6 people (35.3%), but this difference was not statistically significant with p = 0.742.

The dose of ethambutol of ≥1200 mg/day in the case group was obtained in 10 subjects (58.8%) more than in the control group with 7 subjects (41.2%). While the dose of 800-1199 mg/day were found in case group with 7 subjects (41.2%) less than control group that was 10 subjects (58.8%), was not statistically significant. The study with 231 TON samples was 49.8% dose <800 mg, 38.1% dose 800-1199 mg, 12.1% dose ≥1200 mg/day (3). Based on the history of ethambutol therapy of ≤1 years, in case group there were 10 subjects (41.2%), which is more than control group with 4 subjects (23.5%). However, this difference was not statistically significant with p = 0.271.

The previous studies have not reported about the history of the use of ethambutol before, possibly because the previous studies involved a sample of TB patients category 1, whereas in this study the samples are MDR-TB patients who had previously received ethambutol therapy. In the case group, the number of subjects with ethambutol therapy duration of ≥6 months was 12 (70.6%), more than in control group with 5 subjects (29.4%). Meanwhile in the control group, the number of subjects with ethambutol therapy duration of <6 months is 12 (70.6%) which is more than in the case group with 5 people (29.4%). The mean of <6-month-duration was 3.24 ± 1.348, while for the ≥6-month-duration was 11.71 ± 5.764. This difference is significant statistically with p = 0.043, and clinically with odds of 4.93 (95% 95% 95%-23.082).

This study was conducted using the cut-off of >3 months. In case group, there were 143 subjects (61.9%) with 3-month duration and 88 subjects (38.1%) with ≤3-month duration, with odds ration of 1.35 (1.02-1.86). The case series performed by Griffith et al. found that the duration of ethambutol in the case group was 1-16 months (6.7 ± 5.8 months), with a tendency for longer duration using ethambutol with optical neuropathy.

Long duration of ethambutol therapy might cause TON. This can be analyzed from the following explanation: ethambutol is a metal chelator, this agent is able to strongly bind metals especially zinc required in axonal transport, and citric acid cycle. Ethambutol bonding to these metals results in calcium influx, mitochondrial dysfunction, and ultimately leads to decreased ATP, ganglion cell death, and papillomacular bundle damage. If this process lasts longer then most likely will occur more bonds causing the increased risk of TON. However, this does not occur easily. Some factors are also influential and therefore a person might develop TON while the others do not. These factors include the use of other toxic substances such as isoniazid, chloroquine, chloramphenicol, amiodarone, cyclosporine, the use of these drugs are not found in the study subjects. Isoniazid, in particular, is reported to have toxic effects as on the eyes, but the incidence is very small. When starting this MDR-TB treatment program patients are not given isoniazid therapy because MDR-TB patients are resistant to isoniazid. However, most of the patients had received isoniazid therapy previously during the DOTS program. This could have an effect but is not analyzed. In addition, systemic disorders such as kidney and liver disorders that are likely to cause drug accumulation have also been excluded. Other factors that are also influential and not examined in this study are malnutrition conditions, and zinc deficiency.
Conclusion

There is a correlation between duration of ethambutol therapy with toxic optic neuropathy in patients with MDR-TB.

Conflict of Interest: There is no conflict of interest.

Source of Funding: This study is self-funded.

Abstract

Background: Tuberculosis is a chronic infection caused by Mycobacterium tuberculosis, a facultative intracellular parasite, that can be eliminated by cellular immunity played by macrophages. It has become a debate whether the co-infection of nematodes will affect the immune response of macrophages towards mycobacterium infection.

Objective: To reveal macrophage activity and histopathological difference of lung tissue in sequential co-infection of Heligmosomoides Polygyrus towards Mycobacterium tuberculosis infection.

Method: This study used 49 mice divided into 7 treatment groups with Mycobacterium tuberculous infection by inhalation and Heligmosomoides polygyrus orally within 8 and 16 weeks, and observed by immunohistochemical staining.

Result: Infection for 8 weeks showed polarization of macrophages towards M1 macrophage, whereas in 16 weeks, the macrophage polarization more towards M2 macrophages, supported by histopathological changes of lung tissue: peribronchiolitis, perivaskulitis, alveolitis, and granuloma formation with counts of acid-resistant germs +3. There was a difference of expression of arginase1 to each group (p <0.001) and there was a difference of T CD4+ Th1 lymphocyte (p <0.001).

Conclusion: There is a difference in macrophage activity in lung tissue; however, it does not cause different levels of histopathological changes in lung tissue and does not affect the immune response to Mycobacterium tuberculosis infection.

Keywords: Heligmosomoides polygyrus, Mycobacterium tuberculosis, macrophage, Immunohistochemistry

Introduction

Tuberculosis (TB) is a chronic infection caused by Mycobacterium tuberculosis. According to WHO report in early 2012, it is estimated that 8.7 million individuals in the world suffer from TB infection especially in developing and low income countries. Most areas of the country with high TB incidence and low BCG vaccination effectiveness are also areas of high prevalence of worm infections ²-⁴. Worm infections cause changes in the immune response that harm the body’s defenses against TB infection ⁵,⁶.

Each year, there are 8.7 million new TB cases, with a mortality rate of around 1.4 million per year ¹. Mycobacterium tuberculosis is a paracitic intracellular facultative bacillus ⁷. An appropriate immune response to
eliminate TB is cellular immunity played by macrophages; CD4+ T-lymphocytes that secrete IFN-g; CD8+ T lymphocytes that eliminate infected macrophages with TB germs; as well as Tgd lymphocytes. This response requires a strong Th1 type cytokine. In contrast, worm infections stimulate the activation of eosinophil cells, mast cells, basophile cells, and IgE formation, which are Th2-type immune responses. The dominant Th2-type immune responses suppress the Th1 type immune response through suppression by IL-4.

Sequential research is certainly not ethical in human populations, because it can only be conducted with the standard model of nematode worm infection in mice that is Heligmosomoides polygyrus, and Mycobacterium tuberculosis sequentially. To describe the chronicity of a worm infection requires an interval of infection for at least 8 weeks. Chronic worm infection is known to trigger the onset of regulatory T cells (Treg) 11,12. Treg may affect the balance of Th1 and Th2 immune responses. Th1-Th2 balance will also affect macrophage function in overcoming mycobacteria infection 13,14. If it is proven that chronic infection of the worms stimulates the onset of Treg cells that are capable of altering the balance of Th1 - Th2 type immune responses and macrophage functional activity, then the debate about the effect of worm infection on histopathological changes in TB infection will be resolved. This study aimed to identify the effect of sequential co-infection of Heligmosomoides polygyrus nematodes on pulmonary histopathological changes in Mycobacterium tuberculosis infection 15.

**Method**

The research was conducted for 6 (six) months at Experimental Animal Cage of the Clinical Parasitology Division, Faculty of Medicine, Universitas Brawijaya and in Bacteriology Laboratory of Tuberculosis Infection Study Group of Tropical Diseases Institution, Universitas Airlangga, Surabaya, Indonesia. The research sample used 49 male (Mus musculus) mice of wild type aged 8-12 weeks with body weight of 30-35 grams. The sample was divided into 7 groups consisting of: a group infected with tuberculosis (TB) for 8 weeks (M.tb8), a group infected with TB (Mycobacterium tuberculosis) for 16 weeks (M.tb16), a group infected with a worm (Heligmosomoides polygyrus) for 8 weeks (H.pg8), a group infected with a worm (Heligmosomoides polygyrus) for 16 weeks (H.pg16), the group of mice treated with helminth co-infection (Heligmosomoides polygyrus) followed by TB infection (Mycobacterium tuberculosis) (H.pg + M.tb), a group of mice treated with TB co-infection (Mycobacterium tuberculosis) followed by a helminth infections (Heligmosomoides polygyrus) (M.tb + H.pg), as well as control group without infection treatment 16. Prior to conducting the research, the researchers conducted ethical test (151-KE) at the Faculty of Veterinary Medicine, Universitas Airlangga, Surabaya, Indonesia.

**Result**

The activity of alternatively activated macrophage (AAMΦ) also known as M2 macrophage was characterized by the expression of Arginase1 protein. It was explained that macrophages with brown cytoplasm and Arginase1 protein were blue (arrows) and seen with a 400x light magnification microscope. Group 1: H. polygyrus infection for 8 weeks; group 2: H. polygyrus infection for 16 weeks; group 3: H. polygyrus infection for 16 weeks + M. tuberculosis for 8 weeks; group 4: infection of M. tuberculosis for 16 weeks + H. polygyrus for 8 weeks; group 5: 16 weeks of tuberculosis infection; group 6: M. tuberculosis infection for 8 weeks (figure 2). The level of Arginase 1 expression by macrophages in lung tissue showed in Table 1.

Histopathologic features and iNOS expression rates indicated that M. tuberculosis infection for 8 weeks resulted in infiltration of large amounts of macrophages into the infected lung tissue of mice and most of the macrophages infiltrating the tissue express iNOS (macrophage M1) activated in the atmosphere of Th1 cytokine. In infection with M. tuberculosis for 16 weeks, the number of macrophages that infiltrated the lung tissue was relatively decreased, and the level of iNOS expression in the macrophage group (4) whereas, histopathological features and levels of Arginase 1 expression indicated that M2 macrophages were also present in lung tissue, either in M. tuberculosis infection for 8 weeks or for 16 weeks. However, the level of Arginase1 expression by macrophages in mice for 8 weeks of M. tuberculosis infections (Fig. 3.-D) was lower than in the 16 weeks group of M. tuberculosis infections (Figure 3.-E).

To ascertain whether the duration of M. tuberculosis infection affected the level of expression of iNOS and Arginase1 by macrophages in lung tissue, MANOVA test was performed. From the statistical calculation, Box’s Test of Equality of Covariance Matrices obtained p value = 0.148 (p >0.05) which means homogeneous
data. From the Multivariate Test table on Hotelling’s Trace, \( p = 0.00 \) (\( p < 0.05 \)) showed that the duration of M. tuberculosis infection significantly affected the level of expression of iNOS and Arginase1 by macrophages in lung tissue.

**Histopathological Changes of Lung Tissue**

The calculated percentage of T CD4\(^+\) Th1 lymphocytes in peripheral blood showed a significant difference (\( p = 0.000 \)). The percentage of CD4\(^+\) T1 T lymphocytes in the highest lung tissue was found in M. tuberculosis infection for 8 weeks (\( 4.508 \pm 0.947 \)) and then decreased in M. tuberculosis infection for 16 weeks (\( 2.058 \pm 0.845 \)). The group treated with the last co-infection in the form of M. tuberculosis infection had a significantly higher percentage of CD4\(^+\) Th1 T lymphocytes than the opposite co-infection. In addition to assessing histopathological changes in pulmonary tissue, it was also calculated the acid-resistant M. tuberculosis bacteria in the lung tissue sieves preparation stained with Ziehl Neelsen staining (Table 1).

There was a correspondence between germination scores and histopathological lung rate change scores, wherein *H. polygyrus* co-infection did not affect acid-resistant bacteria count nor the rate of histopathological changes of lung tissue. The correlations between polarization of macrophage activity in lung tissue (ie, iNOS or Arginase1 expression) with histopathologic lung tissue change rate (ie Dormans scale score and acid-resistant bacteria count) were evaluated by Spearman test (Table 2).

Discussion

In this study, we found an increase in the percentage of Th1 lymphocytes in lung tissue and in peripheral blood that correlated strongly with levels of IFN-γ cytokines in peripheral blood serum. The increase occurred in M. tuberculosis infection for 8 weeks which then ‘subside’ at the time of infection lasted up to 16 weeks. Our results are consistent with the results of several other researchers who found that elevated IFN-γ levels were primarily obtained in the early stages of the infection especially after the second week post infection. The mobilized lymphocytes accumulate at the site of infection, proliferate and secrete cytokines, especially IFN-γ. Protective immune responses to M. tuberculosis are more necessary for the role of Th1 type cytokines. Th1 type cytokines, including IFN-γ, are required not only to activate macrophages but also to assist the activity of CD8+ T lymphocytes.

Worm infection induces the emergence of T regulatory lymphocytes (CD4+ CD25+ Foxp3+) in both the intestinal tract, peripheral blood and lung tissue. T regulatory activity can be assessed from elevated levels of IL-10 and TGF-β cytokines in peripheral blood serum, as well as T regulatory lymphocyte percentage in intestinal tissue, lung tissue and peripheral blood. Similarly, the findings of the Th1 and Th2 lymphocyte immune responses, the T regulatory lymphocyte response were only found in the worms infection group for up to 8 weeks. When the infection has lasted up to 16 weeks, the activity and the role of T regulatory lymphocytes also decreased.

Activation of T regulatory lymphocytes apparently also occurs in M. tuberculosis infections, especially in infections lasting up to 8 weeks. Thus, it can be concluded that the time interval between the infection of the nematode worms and tuberculosis, as well as the observation will greatly affect the outcome of the co-infection. The success of the macrophage immune response is influenced by the balance of iNOS and Arginase expression which describes the direction of polarization of macrophage activity. Worm infections induce Th2-type immune responses, such as IL-4 and IL-13, leading to macrophage polarization into M2 macrophages expressing Arginase1. The purpose of M2 macrophage activation is to evoke an anti-parasitic response and repair tissue damage. In the group who received the last co-infection treatment of M. tuberculosis, the Arginase1 expression decreased whereas iNOS expression increased sharply.

This can be explained through several arguments that sequential infection of M. tuberculosis and H. polygyrus at intervals of 8 weeks does not affect the balance of T lymphocyte activity in lung tissue, sequential infection of M. tuberculosis and H. polygyrus at intervals of 8 weeks does not affect the ability of macrophages to generate an appropriate immune response for M. tuberculosis infection in lung tissue, and histopathological changes occurring in lung tissue due to M. tuberculosis infection are slowly changing and evolving changes that cannot be detected in the observation process for 8 or 16 weeks.

Immune responses to M. tuberculosis often fail to eliminate germs because germs are able to use several ways to circumvent the host’s immune response, among others by inhibiting the maturation and acidification of the phagosome, inhibiting the fusion of phagosome and lysosome, and escaping from the phagosome. It triggers macrophages to work together with CD4+ and CD8+ T lymphocytes to form granulomas that aim to isolate M. tuberculosis. However, M. tuberculosis can still survive in macrophages and beyond macrophages in granulomas. Thus, granulomas are retained for long periods of time through delayed-type hypersensitivity (DTH) responses requiring Th1 lymphocyte competence. If there is a significant decrease in immune response as well as in patients with HIV-AIDS macrophage, it can decay that allows dissemination of M. tuberculosis.

Conclusion

There is a difference in macrophage activity in lung tissue; however, it does not cause different levels of histopathological changes in lung tissue and does not affect the immune response to Mycobacterium tuberculosis infection.

Nurses’ Knowledge Regarding Pneumonia in Children Under Five Years of Age at Pediatric Wards in Kirkuk Teaching Hospitals

Luay Amjed Mahmood Al-Waly¹, Mohammed Ahmed Sultan Al-Wily¹, Radhwan Hussein Ibrahim²
¹M.Sc. Pediatric Nursing, ²PhD, CHN, Professor Department of Clinical Nursing Sciences, College of Nursing, University of Mosul, Mosul, Iraq

Abstract

The Objective: to identify the nurses’ knowledge regarding pneumonia in children under five years of age at pediatric wards in Kirkuk teaching hospitals.

The Methodology: A descriptive study was carried out at pediatric ward of Teaching Hospitals in Kirkuk City to Assessment of Nurses’ knowledge regarding pneumonia in children under five years of age at pediatric wards from 20 of February till 3ed of June 2019. A non-probability (purposive) sample was chosen for the current study. The sample consisted of (40) nurses working in the pediatric medical ward of selected hospital.

The Result: The socio-demographic characteristic of the study presents that 62.5% of them females, 60.0 % at age (20 – 25) years old, 40.0 % graduated from college of nursing (Bachelor of Nursing) , 80.0% of them have (1-5) years of general experience. The results of the study sample presents (50.0 %) the majority of the nurses have poor knowledge in total knowledge score of pneumonia in Children under age five years. Also the mean of total knowledge score nurses in concern to protein energy malnutrition was (1.55) with standard deviation (0.714) . Shows that there were significant differences between the age and the service in the field of nursing with nurse’s knowledge but there were no significant differences between other parts of socio- demographic characteristics with nurse’s knowledge about pneumonia in children under age five years at p≥0.05 value.

The Recommendations: A continuous extensive special programs, training course and workshops regarding pneumonia in children under age five years should be design and implement in hospital’s departments to enhance the nurse’s knowledge in regard to this major issue.

Keywords: Assessment, Nurse’s knowledge, Pneumonia in children.

Introduction

Nursing education and training is progressing remarkably and requires a high level of attention in assessment methods, such as problem solving and critical thinking.¹ Pneumonia is a major cause of childhood morbidity and mortality especially in developing countries, particularly in developing countries; many studies have been conducted using population-based or hospital-based surveillance to estimate the disease burden of pneumonia². However, globally there is substantial variability in access to hospital treatment of childhood respiratory diseases including pneumonia at national and regional levels and within the healthcare systems³. It is estimated that about 0.9 million deaths happened due to pneumonia out of the total 6.3 million under-5 deaths in this population.
in 2013.(4,5). The pneumonia in high-income countries is different than in low-income countries, including more viral and atypical organisms causes(6,7). Pneumonia is a common serious infection that afflicts children less than five years throughout the world and is considered the most important global cause of death among them. It is an acute illness caused by infection. The lungs become inflamed, congested leading to cough and breathlessness. Nurse plays an important role in providing nursing care and health education for children and their families especially if they are skilled and well cultured.

**Objectives of the Study**

1. To assess the nurses’ knowledge level regarded pneumonia in children under five years of age at pediatric wards in Kirkuk teaching hospitals.

2. To find out the relationships between the socio-demographic variables and the nurses’ knowledge level regarded pneumonia in children under five years of age at pediatric wards in Kirkuk teaching hospitals.

**Material and Method**

**Design of the study:** A descriptive study was carried out at pediatric ward of Kirkuk Teaching Hospitals to assess of nurses’ knowledge regarded pneumonia in children under five years of age from 20ed of February till 3ed of June 2019.

**Sample of the study:** A non-probability (purposive) sample was chosen for the current study. The sample consisted of (40) nurses working in the pediatric medical ward of selected hospital. This is due to shortage of nursing staff and high number of children patients in the ward.

**Study tool:** The questionnaire was constructed and provided for nurses to assess the knowledge which consists of four parts. The first part concerns the social and demographic information, while the second part was related to the nurses’ knowledge in concern to pneumonia in children less than five years of age in general. The third part of the questionnaire dealt with nurse’s knowledge in about risk factors and medical management of pneumonia in children under five years of age, while the part four put emphasis on the nurse’s knowledge about nursing care management of pneumonia in children under five years of age.

**Validity of the study:** The validity of the questionnaire tool was established through a panel of experts whom specified the content clarity, relevancy, and adequacy.

**Reliability of the study:** To evaluate statistically the reliability of instruments, a pilot study was carried out during the period from 17 till 25 of March / 2019. Randomly (5) nurses were selected from Children’s Teaching Hospital (this sample was excluded from the original study sample). The Pearson’s coefficient of correlation result are ($r= 0.671$) and are significant at $p \leq 0.000$ level was used to estimate the scale (test – retest) by using SPSS version 20.

**Data collection:**

The data were collected from the selected hospitals in Kirkuk City. The study connected at the pediatric medical ward that available in the Kirkuk General Teaching Hospital and Children’s Teaching Hospital, at the period from 1st till 22 of April / 2019.

**Result**

The results shows that the demographic characteristics of the study sample, 60.0 % at age (20 – 25) years old, 62.5% of them females, 40.0 % graduated from college of nursing (Bachelor of Nursing), 80.0% of them have (1-5) years of general experience, 97.5% of them have (1-5) years of experience inside the medical pediatric ward , and lastly 57.5 not have any participation in training courses at the pneumonia in children under five years of age. Table (1) presents the results of Nurses’ Knowledge that 50.0% of them have not acceptable knowledge about pneumonia in children under five years of age in general, 40.0 % of them have Failure knowledge in relation risk factors and medical management of pneumonia in children under five years of age, 45.0 % of them have acceptable knowledge about to nursing care management of pneumonia in children under five years of age, and at lastly 50.0% of them have not acceptable knowledge in total knowledge score for all domains. Table (2): Shows that there were no significant differences between the most of social and demographic characteristics result with nurse’s knowledge regarding pneumonia in children under five years of age except the age with nurses knowledge level about pneumonia in children under five years of age in general, and nurses knowledge level about nursing care management of pneumonia in children under five years of age. also the service in the field of nursing with nurses knowledge level about risk factors and medical management of pneumonia in children under five years of age...
of age and nurses knowledge level about nursing care management of pneumonia in children under five years of age that there were significant differences at \( p \geq 0.05 \) value.

Discussion

The demographic characteristics of the study of total sample number (40)N, presents that 60.0 % at age (20 – 25) years old, 62.5% of them females, 40.0 % graduated from college of nursing (Bachelor of Nursing), 80.0% of them have (1-5) years of general experience, 97.5% of them have (1-5) years of experience inside the medical pediatric ward, and lastly 57.5 not have any participation in training courses at the pneumonia in children under five years of age. This result agree with Eiman M. ; Oshak S., (2016) They presented that the nurses’ ages ranged between 20 - 30 years. Their education levels were varied with bachelor level (76%) and the diploma (24%) and post graduate level (0%). So there was an increase in knowledge about pneumonia with an increase educational level. also revealed that nurse’s years of experience >2 year (54%) and 2-3 year (20%) and> 4 year (26%) was not related to the quality of care. Therefore, the common worker in this hospital was less experienced as they were practicing only for 2 years(8). Nurse’s Responses Results in concerning the pneumonia in children under five years of age Knowledge. The results of nurses’ knowledge level presents that 50.0% of them have not acceptable knowledge about pneumonia in children under five years of age in general, 40.0 % of them have Failure knowledge in relation risk factors and medical management of pneumonia in children under five years of age, 45.0 % of them have acceptable knowledge about to nursing care management of pneumonia in children under five years of age , and at last  50.0% of them have not acceptable knowledge in total knowledge score for all domains Table (1). These results agree with Mogahed, (2011) his result showed that: (25.0%) was poor, (57 .0%) fair, (17 .0%) had good knowledge of participants’ regarding prevention of pneumonia. Therefore, factors such as level of qualification, and experience years, does not significantly affect level of knowledge(9). Statistical differences of social and demographic characteristics result of nurses’ knowledge level about pneumonia in
children under five years of age. The result of study shows that there were no significant differences between the most of social and demographic characteristics result with nurse’s knowledge regarding pneumonia in children under five years of age. Except the age with nurses knowledge level about pneumonia in children under five years of age in general, and nurses knowledge level about nursing care management of pneumonia in children under five years of age. Also the service in the field of nursing with nurses knowledge level about risk factors and medical management of pneumonia in children under five years of age and nurses knowledge level about nursing care management of pneumonia in children under five years of age that there were significant differences at P ≥ 0.05 value Table (2). This result agree with Tahseen A. (2015) was a significant association between nurses’ knowledge and their age and years of employment. This means that nurses’ ages and years of employment have great impact on their knowledge(10). But This result disagree with AL-Sa’idi, B.: (2006) and Shuq, A. H (2008) they showed that was a significant association between nurses’ knowledge and demographic characteristics(11,12).

**Conclusion and Recommendations**

According to the results of the present study, the researcher concludes the nurses do not have appropriate and adequate knowledge about the pneumonia in children less than five years of age. There is significance relationship between the nurse’s knowledge and age and the service in the field of nursing toward the pneumonia in children under five years of age only. But there is no significance relationship between the nurse’s knowledge and other socio-demographic characteristics toward the pneumonia in children under five years of age. According to the results and conclusion of the present study, the researchers recommend the Kirkuk Health Directorate has to conduct statistics of certified prevalence about pneumonia in children under five years of age at all pediatric hospitals at Kirkuk City on the web site. Also special programs, training course and workshops about child pneumonia in general, risk factors, medical management, nursing care management can be designed and implemented in hospital’s departments to enhance the nurse’s knowledge in regard to this major issue. Increasing the number of nurses especially those who hold Bachelor degree in nursing to work at the pediatric medical wards for their ability and background.

**Ethical Consideration:** Prior to data collection, official permission was obtained from the Ministry of Health/ Department of Planning and Health Research committee and Written approval of participants was obtained prior to the start of data collection.

**Conflicts of Interest:** Nil

The Effectiveness Comparison of Desloratadine and Loratadine in Reducing Total Nasal Symptom Score and the Level of Interleukin 4 in the Nasal Secretions of Allergic Rhinitis Patients

Luh Putu Dhena Purwaningsih¹, Dwi Reno Pawarti¹, Bakti Surarso¹

¹Department of Otolaryngology, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo Teaching Hospital, Surabaya, 60285, Indonesia

Abstract

**Background:** Allergic rhinitis (AR) is a common atopic disease; however, the available therapy has limitation in the usage and its success rate. Desloratadine has a role as an alternative allergic rhinitis therapy to eliminate the overall symptoms of AR and reduce IL-4 level in nasal secretions.

**Method:** This study was double-blind randomised clinical trial with pre-post test design. The data was analyzed by using independent sample t-test. There were 24 AR patients divided into 2 therapy groups which were study group (desloratadine) and control group (loratadine). The evaluation based on SGHT and IL-4 in nasal secretions was conducted pre and post 15 days of therapy.

**Results:** The present study that was conducted on July-October 2016 showed significant difference in the average percentage of reduced TNSS in desloratadine group compared to loratadine group (p=0.000). The comparison of reduced level of IL-4 in nasal secretions between desloratadine and loratadine group was indicated insignificantly different.

**Conclusion:** Reduced TNSS in desloratadine group was higher than in loratadine group. Also, there was no difference in decreased level of IL-4 in nasal secretions.

**Keywords:** Desloratadine, loratadine, total nasal symptom score, interleukin 4, allergic rhinitis.

Introduction

Allergic rhinitis (AR) is a common inflammatory nasal mucosal disease mediated by Immunoglobulin E (Ig E) after the exposure of allergen in nasal mucosa. The main symptoms of AR include sneezing, stuffy nose, runny nose, and itchy nose. Several cases of AR are accompanied by the occurrence of symptoms in eyes, ears, and post nasal drip in throat. The assessment of AR symptom severity is determined by total nasal symptom score (TNSS). The clinical manifestations of AR involve proinflammatory cytokines and other cytokines; one of the essential cytokines in AR is Interleukin 4 (IL-4) which has a role to form Ig E and recruit eosinophils.

Loratadine is an H1-antihistamine that has not been able to eliminate the overall symptoms of AR; therefore, the use of loratadine is often combined with other drugs. Desloratadine is an active metabolite from loratadine known to have more potent affinity towards H1 receptor than loratadine itself. It also can reduce the level of IL-4 in AR. The high severity of AR encourages researchers to reveal other AR therapies beside loratadine. However, it has not been conducted any study that compares the effectiveness of desloratadine and loratadine in reducing TNSS and IL-4 level of nasal secretions in AR patients.
The latest research proved that desloratadine was an active metabolite from loratadine and as a single therapy to eliminate AR symptoms especially stuffy nose and reduce IL-4 level in nasal secretions. Desloratadine is the main active metabolite from loratadine that can decrease either nose symptoms or other symptoms such as chronic idiopathic urticaria. Another in vitro research also showed that the affinity of desloratadine towards H1 receptor was 50-194 times bigger than loratadine, cetirizine, and fexofenadine. Another study also stated that in 2 weeks, AR patients who consumed desloratadine 5mg/day has a significant impact in decreasing stuffy nose than placebo (p<0.05).

One of the cytokines from Th2 that plays an important role in AR pathophysiology is IL-4. The role of IL-4 is to produce and differentiate B cell to be plasma cell. Afterwards, it will produce Ig E that is tied to mast cell and basophile. In addition, another role of IL-4 is to competitively impede or produce cytokines from Th1. It also has a role in recruiting eosinophil which is connected to vascular cell adhesion molecule-1 (VCAM-1). The activation of eosinophil causes chemical mediator extrication such as mayor basic protein (MBP), eosinophil cationic protein (ECP) and eosinophil peroxidase (EPO). This chemical mediator causes clinical manifestation such as sneezing, runny nose, itchy, and stuffy nose.

A particular research revealed that the total of IL-2, IL-4, IL-13 cytokines and TNF-α in nasal secretions was significantly higher (p<0.05) rather than the total number in serum. IL-4 significantly increases in AR patients compared to non AR patients. Based on the elaboration above, the researcher is intended to conduct a study to compare the effectiveness of desloratadine and loratadine to reduce TNSS and IL-4 level in nasal secretions in AR patients.

**Method**

The research subjects were moderate-severe intermittent AR patients, mild intermittent AR patients and mild persistent AR patients based on ARIA 2008 who were treated in Outpatient Otolaryngology-Head and Neck Surgery Unit, Division of Immunology-Allergy, Dr. Soetomo General Hospital Surabaya and fulfilled inclusion and exclusion criteria. The inclusion criteria were pre therapy TNSS more than or equal to 5, aged 21-60 years old, have not consumed anti allergic drugs such as: AH (1 week), systemic corticosteroids (4 weeks), topical corticosteroids (2 weeks), topical decongestants (1 week), anticholinergic and chromoline, willing to follow the research and signed the consent forms. The exclusion criteria were acute respiratory tract infections, acute and chronic paranasal sinusitis, medical rhinitis, nasal abnormalities such as tumors, rice polyps, severe deviation septum, pregnancy or lactating and a history of loratadine allergy.

This study was conducted by employing double-blind randomized controlled trial with pre-post test design. The sample collection was conducted by using the method of consecutive sampling on July-October 2016. The samples were allocated randomly based on block permutation technique which was divided into study group and control group. The study group obtained desloratadine therapy 5 mg/day while the control group obtained 10 mg/day. The samples were excluded from the study if they resigned from the research, underwent severe side-effects or dismissed by the researchers for patients’ own good, not consume the drugs for 2 (two) days in sequence, consumed sympathomimetic drugs, AH, systemic and local steroidal anti inflammatory, ketoconazole, erythromycin and cimetidine during the research, and not come to the medical control in the last evaluation on the fifteenth day.

The measurement of IL-4 level in nasal secretions was conducted by using nasal lavage. Each nasal cavity was inserted 5 ml of isotonic saline solution (it was warmed up in 37°C) by using squirt 10 cc. The supernatant was collected and stored in a refrigerator in a temperature of -80°C in Biomedical and Tissue Bank Unit Dr. Soetomo General Hospital Surabaya. The measurement and reading of IL-4 level in nasal secretion in the initial and last evaluation were conducted simultaneously. The statistical analysis on level of significance (p) of 0.05 or 5% applied 2 sample independent t-test to find out the comparison of desloratadine and loratadine therapy towards TNSS and IL-4 level in nasal secretions.

There were 26 AR patients appointed as research samples. During the study, it was found 2 drop out cases which were 1 sample from study group on the fifteenth day and 1 sample from control group because the patient suffered from sore throat and had to consume other drugs. Therefore, the samples that can be analyzed were 24 patients. They were divided into two groups: 12 patients in study group and other 12 patients in control group. The male patients were 8 subjects while female patients were 16 subjects. The youngest age of those 2 groups was 21 years old while the oldest one in control group was 52 years old and in study group was 58 years old. The number of moderate-severe intermittent AR was 18 patients; mild intermittent AR was 3 patients; and mild persistent AR was 3 patients.

The result of statistical test using independent sample t-test was $p=0.000$ that indicated a significant different in the comparison of reduced TNSS between desloratadine and loratadine group (table 2). The result of statistical test using independent sample t-test was $p=0.256$ that indicated insignificant different ($p>0.05$) in the comparison of reduced IL-4 in nasal secretions between desloratadine and loratadine group (table 3). During the study, it was reported that the most frequent side-effect in both groups was sleepy which occurred in
Discussion

The result showed that the average reduced TNSS in desloratadine group was 7.67 (SB 1.77) while in loratadine group was 2.42 (SB 1.62). The statistical test using independent sample t-test obtained the value of p=0.000. The value indicated a significant different in the comparison of reduced TNSS between desloratadine and loratadine group (p<0.05). It can be concluded that desloratadine was more effective compared to loratadine in reducing TNSS in AR patients. Desloratadine is the main active metabolite from loratadine. Seen from pharmacology, desloratadine and loratadine have similar pharmacokinetic profile which work in a quick phase and slow phase, inhibit the histamine bond with its receptor, inhibit infiltration and eosinophil activation to eliminate several mediators such as MBP, ECP, EPO, and EDN, inhibit mediator release from mast cell and basophile through direct obstacle in calcium ion canal to prevent further damage of the nasal mucosal epithelium. Based on the data of preclinical study, desloratadine was 60 times more selective towards H1 receptor than H2 receptor. Also, it had no affinity towards receptors of dopamine, monoamine oxidase, acetyl-cholinesterase, δ-amino butyric acid, and bradykinin. In addition, loratadine is a selective tricyclic antihistamine towards peripheral H1 receptor and not indicate the activity towards H2 receptor

Based on preclinical study, the desloratadine affinity towards H1 receptor is 50-194 times higher than loratadine, cetirizine and feksonadine. QingJia conducted a study on January until October 2014 in AR patients who underwent desloratadine and loratadine therapy. It revealed that desloratadine had the therapy effects such as runny nose, stuffy nose, itchy nose, sneezing and better edema inferior than loratadine. The previous study had similarity with this study which is reduced TNSS in desloratadine is better than loratadine group.

The result of this study is not in accordance with the previous study. The double blind research in PAR patients who had allergic towards dermatophagoides farinea, cat’s and dog’s fur and obtained desloratadine 5 mg and levoceterizine 5 mg showed reduced IL-4 after 4 weeks therapy towards both drugs. Another study showed that the effect of desloratadine towards reduced IL-4 level in SAR patients after 2 weeks therapy with desloratadine 5 mg/day. A study in PAR patients also revealed that desloratadine reduced IL-4 in nasal rinses during four weeks of therapy.

The technique of nasal rinse collection in the previous study was conducted by provoking the previous allergen in order to determine the proper time to measure IL-4 level. The technique of nasal rinse collection in this study was not conducted. However, it was conducted in every patient with AR in order to recognize the difference of exposure time to allergens among the patients during sample collection. This condition can impact the measurement result of IL-4 level in various nasal secretions and we are not able to recognize the proper time to measure IL-4 level in nasal secretions.

The previous study indicated that IL-13 has a role in slow phase allergy in which an increase was obtained 24 hours after allergen provocation test. IL-13 can affect chronic stuffy nose symptom in AR patients. Another study in AR patients obtained increased IL-4 and IL-13 level in nasal secretions after undergoing the provocation test of pollen and wheat powder allergen. The administration of anti IL-4 antibodies during the sensitization phase shows an inhibitory effect in the development of Th2. This suggests that IL-4 is important in fast type antigen responses. If IL-4 is given to animals that encounter sensitization, it is less affected in reducing the production of Th2 cytokines and eosinophil reflux. On the other hand, IL-13 has more roles than IL-4 after secondary antigen exposure. The therapy implementation in allergic patients who has been given IL-4, IL-5 and IL-13 does not increase disease improvement and the symptoms caused by other mediators in allergic diseases.

The hypothesis of this study was not proven that desloratadine had bigger role in reducing IL-4 level in nasal secretions than loratadine in AR patients. It was because IL-4 is not the only factor affecting the occurrence of AR symptoms. Several mediators and proinflammatory cytokines derived from mast cell degranulation play an important role in the emergence of clinical symptoms in AR. The previous research reported that there was no association between nose clinical symptoms with several signs of inflammation in perennial AR. Other researches revealed that there was no significant association between the severity of nose symptoms and nose inflammation.
Conclusion

The present study can be concluded that desloratadine is more effective than loratadine in reducing TNSS; however, the effectiveness is similar in reducing IL-4 level in nasal secretions in AR patients. It is required to conduct allergen provocation test in order to determine the proper time to collect the samples to measure IL-4 level in nasal secretions. IL-4 has similar function to IL-13; therefore, it is required to conduct a research with IL-13 variable simultaneously. The result of desloratadine therapy which was significant in reducing TNSS can be considered as an alternative of AR therapy other than loratadine.

Prevalence of Dermatophytes Fungal Infection among Different Gender

Luma T. Ahmed1, Zahraa A. Darweesh1, Wathiq M. Hussain2
1Lecturer, Branch of Microbiology, College of Medicine 2Lecturer, Diyala Health Directory Ba’aquba Teaching Hospital, University of Diyala

Abstract

The present study was designed to determine the prevalence of superficial fungal infections among the patients that were living in different circumstances in Diyala region, Iraq. From July 2018 to February 2019, there were (218) patients with ages (2-78) years were surveyed for dermatophyte fungal infections by history and clinical examination. The results revealed that (71.2%) of the patients were infected with skin lesions followed by scalp lesions (16.5%) and nail lesions (14.6%). The prevalence rates of dermatophyte fungal infections were linked to the types of tinea infections, including tinea corporis (17.4%), tinea pedis (13.7%), tinea capitis (16.5%), tinea unguium (14.6%), tinea cruris (17.4%), tinea faciale (3.6%). The proportion of fungal infection in rural area (63.6%) was more preponderant in comparison to urban areas (39.8%). Furthermore, the rate of percent infection by tinea capitis (66.6%), tinea corporis (60.5%), tinea cruris (57.8%), were higher in male whereas the percentage of tinea unguium (87.5%) and tinea faciale (62.5%) infections were highest in female. In addition, study demonstrated that indices of tinea infection has been significantly associated with age. This study suggested there has been an exigent need to ameliorate the edification of hygiene values of peoples in addition to increment the economic condition of the society.

Keywords: Dermatophytes, fungal infection, living conditions

Introduction

Fungi are typical eukaryotic cells, representing a distinct kingdom, estimate one quarter of a million species, only few are pathogens to humans, or other warm-blood animals. Fungi may be broadly divided into two basic forms, the moulds and the yeasts. The moulds are made up of long multinucleated filaments called hyphae, which can infect the skin, hairs, nails and the internal organs. The yeasts are made up of unicellular ovoid to globes cell, which usually reproduced by budding or more rarely by fission, which can infect the skin, nails, mucous membrane and the internal organs. Fungal infections of the skin may be divided into two types according to the level of skin involvement, the superficial and deep infections. The superficial infections, which are confined to the stratum corneum, hairs and the nails, which include: dermatophytosis, candidiasis and other non-dermatophyte infections. Clinical manifestations of dermatophyte infections vary depending on the site of infestation and the type of strain; therefore, accurate identification of the strain is crucial in order to facilitate rapid treatment and to prevent spread of the disease.

The prevalence of different types of superficial fungal infections of the skin is variable among different age group, gender, socio-economic levels and countries, in UK and other Western Europe countries, the prevalence is 5.1% and in USA is 8.1% and in general it is more prevalent in male’s children and 5.In Iraq two studies was done, one in Baghdad and the other in Diyala province, showed that the prevalence was 9.9% of all skin diseases. Regarding the different types of superficial fungal infections of the skin, tinea capitis and corporis are more prevalent in males children aged 3-14 years and more in African countries Dermatophytes species belonging to three genera (Trichophyton, Microsporum, and Epidermophyton). Trichophyton and Microsporum genera are the most numerous and diverse, there are over 40 species belonging to these two taxonomic groups.
**Epidermophyton** genus has only one representative – *Epidermophyton floccosum* species. Transmission of dermatophytes may occur by direct contact with infected humans or animals or indirectly by contact with contaminated fomites. Dermatophytes require keratin for growth and they can cause superficial infections of the skin, hair, and nails. Dermatophytes may spread by direct contact from other people (anthropophilic organisms), animals (zoophilic organisms), and soil (geophilic organisms) as well as indirectly from fomites. The disease is widely distributed all over the world with various degrees and more common in men than in women.

So the aim of the present study is to demonstrated the correlation of gender, age, place of residence (rural or urban), and the nature of work practiced by the patient on dermatophyte infection.

**Materials and Method**

A sample size of Two hundred eighteen were collected from patients who have attended the dermatology unit at Baquba’a teaching Hospital, Baquba’a City, Diyala Province between first July 2018 to end February 2019. The association of frequency of dermatophytoses infection to the individual were investigated in terms of following aspects: place of residence (rural or urban); health history of the individual; marital status and the nature of work practiced. Diagnosis was made according to the diagnostic criteria listed by in terms of patient’s history and clinical examination.

**Results and Discussion**

Among the 218 cases, results (table 1) showed that the dermatophyte fungal infections were comprised from the followings types: Tinea capitis (16.5%), and Tinea faciale (3.6%), Tinea cruris (17.43%), Tinea corporis (14.6%), Tinea ungium (14.6%), Tinea pedis (13.7%).

Evidences suggested that ringworm infections are quit prevalent and found to be one of the most frequent causes of dermatological complications.

This difference may be attributed to the fact that the secretion of androgen peaks during adolescence and therefore sebaceous secretion increases. for flaring up but there is no significant correlation regarding species identified and age group. The current study disagrees with which differed from other studies results .In addition to Candidasis is more prevalent in adult females, pityriasis (tinea) versicolor is more prevalent in adult males.

Distribution of dermatophyte fungal infections based on residence area

The result has shown that the highest ascendant of dermatophyte fungal infections within rural area (57.38%) compared to urban area (42.6%).

The results revealed that the highest ascendant of dermatophyte fungal infections within urban areas were Tinea cruris (68.4%), Tinea corporis (63.1%), Tinea unguium (62.5%), and Tinea pedis (63.3%), whereas in rural areas the percentage of these fungal infections were found lowest, all other types of tinea infections were substantially higher in rural areas as compared to urban areas.

Evidences additionally suggested that residential area (rural and urban) is known to markedly affect the rate of infection as the most of rural areas are inhabited by the families with animal husbandry such as canines and cattle which are the source of Tinea infections. These factors are further known to spread fungal disease in the region where health accommodations are circumscribed in comparison to urban areas and 15 and 16.

Some researchers additionally attributed the concept of self-pollination (autoinoculation) of ringworm types which have been known to be associated with climatic conditions of rural or urban area. Tinea capitis and Tinea faciale were significantly more common in rural area. In particular, Tinea capitis was more mundane in rural area as compared to urban area. One reasons for Tinea capitis infections in rural areas is associated with animal husbandry profession of the peoples. Other one due to over crowdedness in joint families which impart close contact with children and philic infectious agents 16.

Our results showed Infections of Tinea cruris were higher in urban places than in rural areas and this to be consistent with earlier findings as described by Figueroa et al., that skin diseases are the second most common cause for medical consultation for children in rural communities. It has additionally been shown that in regions with a poorer socioeconomic environment, the morbidity rates, especially with infectious diseases are found to be higher. The most significant difference is in tinea capitis (52.7%).

The education level of the patients in this study results showed that the percentage of infection by Tinea capitis (77.7%), Tinea corporis (52.6%), Tinea pedis (50%), and Tinea faciale (75%) were found to be highest in primary and secondary education, while the Tinea cruris (63.1%) had the highest rate of infection in university education (fig.1): This result comes in accordance with 19. There is an increased activity of sebaceous glands under the hormonal influence in adolescents and young adults and this explains the increased frequency of tinea infection among the student population 16.

On the other hand, 20 stated that military personnel, athletes, and those doing hard works that usually associated with hyper sweating were more vulnerable to pityriasis versicolor infection. Furthermore, sebaceous glands secretion is increased in males 15 years and older compared to females, and that may also promote, pityriasis versicolor infection in males.

![Figure (1) Distribution of patients with dermatophytes according to their education.](image-url)
The results in table (2) have revealed that the highest ascendant of dermatophyte fungal infections in child and students were Tinea capitis (100%), Tinea cruris (47.3%), while the Tinea corporis (47.3%) had the highest rate of infection in self employers and workers, and Tinea unguium (62.5%), Tinea pedis (70%) is to be highest in housewives because of using detergents. In addition, students are also more involved in sports activities which predisposes them to increased sweating and hence, pityriasis versicolor 21.

### Table (2) : tinea types distributed among different factors(study, self employed, housewife & salaried)

</table>

The nature of the work could also affect the proportion of infection as our result revealed that 39.9% of infected patients were students whereas 33% patients were house wives and rest of 28% patients belongs to others diverse range of professions. The results also suggested that the marital status positively correlated with the proportion of dermatophyte infection.

Akcaglar reached to the same conclusion that the increasing occurrence of dermatophyte fungal infections could be attributed to living circumstances with increase the number of the people that living in close contiguity in addition to the patient’s family history, lifestyle, immune status. Prevalence of different types of fungal infections varied according to geographical location, environmental conditions, and cultural factors, age, gender, socioeconomic status and predisposition to diabetes amongst others 22 and 23.

Host susceptibility may be enhanced by moisture, warmth, concrete skin chemistry, composition of sebum and perspiration, heftily ponderous exposure and genetic predisposition. The incidence of fungal infection is higher in sultry humid climates and in crowded living conditions 22. The differences in the incidence of superficial infections between the age groups and genders may be reflected the differing rates of sebum production and fluctuations of immunity with aging 21.

The results have demonstrated that the highest ascendant of dermatophyte fungal infections in oily skin 107(60.79%), while 19 (10.79%) were dry, and 50(28%) were normal fig.2):

![Figure (2) Type of skin](image)

Unfortunately, why some people suffer from excessive sebum production while others endure dry skin remains difficult to explain. Numerous factors have been proposed to play a role in the pathogenesis of oily skin. Thus, pinpointing one successful treatment is challenging. Here, we review the physiology of sebaceous glands as well as current and up-and-coming treatment options that can be offered to patients.
Concerned about oily skin.\textsuperscript{23}

Despite the pessimistic view of sebaceous glands as a result of their role in oily skin, they do play a vital role in the skin’s well being. Sebaceous glands display endocrine function (particularly androgen synthesis), compose the fetal vernix caseosa, and play a key role in the epidermal barrier and innate immunity. Here, we review current and up-and-coming treatment options that may be utilized to help patients with oily skin.\textsuperscript{24,25} High level of sebum production in such age group which offer suitable condition to lipophilic Malassezia for flaring up but there is no significant correlation regarding species identified and age group.\textsuperscript{10}

Predisposing factors for the development of \textit{Malassezia} infection include excessive production of sebum and/or decreased quality of sebum (seborrhea), accumulation of moisture, damage of epidermis, concurrent dermatoses, atopy, and bacterial skin infections\textsuperscript{26}.

\textbf{Conclusion}

The present study demonstrated that the dermatophytosis was more common in educated people and in low socio-economic regions that is because crowded and bad hygiene characteristics of such community. The types of tinea are varies between tinea corporis and tinea cruris especially with the adult age group. Also, tinea capitis record high rate which found mainly in children. Further studies are urgently required to fully understand the pathomechanisms of the doggedness of dermatophyte fungal infection in certain patient population by using more sensitive and precise methods for example polymears chain reaction with specific primers [conventional polymerase chain reaction and real time polymerase chain reaction], restriction fragment length polymorphism ,in situ hybridization of fluorinated neucleotides, nested polymerase chain reaction .

Risk Factors of the Elderly Falling in Public Hospitals: A Systematic Review Study

Masoumeh Otaghi¹, Zahra Mohammad-Niakan², Sanaz Aazami¹, Ali Khorshidi³

¹Department of Nursing, Faculty of Nursing & Midwifery, ²MSc Student, Faculty of Nursing & Midwifery, ³Department of Epidemiology, Faculty of Medicine, Ilam University of Medical Sciences, Ilam, Iran

Abstract

Background: Falls are the most common and problematic issue of old age. There is the possibility of falls among the elderly in the hospitals. The present study was conducted to determine the risk factors for falls in the elderly in hospitals through systematic review.

Method: This is a systematic review based on the PRISMA protocol. The IranMedex, SID, Magiran, IranDoc, Medlib, Pubmed, Scopus, Web of Science, Science Direct, Medline and Google Scholar databases were searched for keywords in the time frame of 1994-2017.

Results: The mean age was 64-81 years old and the number of elderly people varied from 88 to 28524 people. Of these studies, six studies were performed in the acute care unit, three studies in the elderly care unit, three studies in the surgical and clinical department, one study in the rehabilitation department, one study in the psychiatric department and other studies were performed in several parts of the hospital. The results of this study referred to individual and external factors as risk factors for the falls in the elderly in the hospital. The use of medications, physical problems, and psychological problems were the most common risk factors for falls in the elderly.

Conclusion: In acute care, chronic care, psychiatric care, and elderly care units, there are many risk factors for the falls in the elderly due to their physical and mental status. Identifying and resolving these risk factors may provide safety for the elderly.

Keywords: Risk Factors; Accidental Falls; Aged; Hospitals; Systematic Review.

Introduction

Elderly is a stage of life influencing a person’s biological, mental, and physical status (¹). Enhancing the quality of medical care is one of the main concerns on the part of healthcare professionals. A major goal of a healthcare organization can be the prevention of any harm to patients and avoiding endangering patients’ safety following providing healthcare for them (²). Diseases that threaten this group include diabetes and hemodialysis³, ⁴.

There are many types of trauma, including vascular trauma, accidents, and falls⁵-⁷. Falling often put people over 65 at risk influencing their economic, social, and psychological status such as losing the sense of independence and self-assurance. These can, in turn, ensue negative effects which may culminate in fracture or even their death⁸. Moreover, these factors can make the elderly vulnerable to various complications including fracture, destruction of soft tissues, bruises, and subdural hematoma⁹. Falling can also have different physical consequences (such as hip fracture, disablement, and inability to move) and mental consequences (including losing one’s self-confidence, self-esteem, and lowering of life expectancy)¹⁰. It ought to be noted that falling not only influences the patients’ lives, but also it may lead to the prolonging of hospitalization period as well as healthcare expenses in medical care system¹¹.

The major risk factors affecting falling are categorized into four groups: 1) biological factors such as age, gender, diseases, cognitive disabilities; 2) socio-economic factors including literacy, income, housing, public health, and social seclusion; 3) behavioral factors
such as fear of falling, life style, concomitant taking of medications, doing no exercise, and unsuitable clothing; 4) environmental factors like building planning, stairs, slippery halls and floors, carpets, floorings, fences, and bathroom (12, 13). One of the tasks of nurses is to improve patients’ health (14). The current study seeks to identify risk factors for the elderly falling in hospitals through a systematic review method.

**Material and Method**

The present study is a systematic review which attempts to examine risk factors underlying the elderly falls in hospitals around the world. In this study PRISMA protocol, which is especially designed for systematic reviews and meta-analytic studies, has been used.

In order to reach the intended studies, English data bases including Science Direct, PubMed, Scopus, Web of science, Medline along with Farsi data bases of SID, Magiran, Iranmedex, Irandoc, Medlib and Google Scholar search engine were searched within the interval of 1994 till 2017. The search was conducted drawing on key words of “Risk Factors; Accidental Falls; Aged; Hospitals; Systematic Review”. AND/OR were used to secure sensitivity of the search.

The inclusion criteria were studies which focused on risk factors for the elderly falling in hospitals. The exclusion criteria comprised studies which drew on nonrandom sampling methods, no reporting of the requisite data such as the size of the population or risk factors affecting the elderly fall, unacceptable quality of studies according to STROB Checklist, and lack of access to studies full-texts.

The international and standardized checklist of STROB was used to qualitatively evaluate the studies. This checklist comprised 22 sections covering different parts of a report. Based on this checklist, articles that had acquired the minimum score of 16 could enter the extraction stage within systematic review procedure.

Two researchers carried out data gleaning independently in order to minimize any error or bias in data gathering procedures. Data collection form was used based on the study aims. Researchers entered the elicited data to a checklist which encompassed the following: researcher’s name, title of the article, sample size, gender, age group, elderly falling risk factors, the year study conducted, and the country in which the study had been conducted. A third researcher examined the gleaned data by the two researchers looking for any inconsistencies or discrepancies. After completing the form, the resulting data were examined, summarized, and finally reported.

**Findings**

The initial search yielded 982 research papers. In the next stage, their titles were analyzed by two members of the team independently and 335 articles with content overlapping were eliminated from the study. Then, the articles abstracts were examined and 38 research papers for which their full texts were not available were removed from the study. Afterwards, the remaining articles were scrutinized in terms of the inclusion/exclusion criteria. After the meticulous and exhaustive reviewing of the articles, 590 articles that did not conform to our exclusion criteria were removed from the study. Finally, the remaining research papers were analyzed drawing upon STROB checklist which ended up in the exclusion of three more articles. In the end, 16 articles entered the systematic review process.

Characteristics of articles entered Systematic Review Process:

In the Case study Salgado, R (12) (1994) in Australia with 128 elderly (ccu word) result showed Risk Factors fall is Disorientation, Taking medicines Evidence of CVA and Poor performance in “Get-up-and-go” Test.

In the study Luukinen, H (16) (1995) in 145 elderly (Prolonged cares in hospitals / nursing homes) result showed Dizziness, evidence of CVA Consequences, high blood pressure, using walking aids, taking antidepressants, Lowering of muscular strength, Lowering of pulse in Art spot test, And lowering of walking pace.

In the Cass-control study Salgado ,R (17) (2003) in Australia with 88 elderly (ccu word) result showed Risk Factors fall is Disorientation, Taking psychiatric Drugs, Evidence of CVA and Poor performance in “Get-up-and-go” Test.

In the study Ishizuka, MA (18) (2005) in Brazil with 49 elderly (Geriatric care) result showed Risk Factors fall is Depression, history of referring to psychiatrist, Muscular Dystrophy.

In the Retrospective study Bollini, G (19) (2010) in Australia with 112 elderly (ccu word) result showed Risk Factors fall is High blood pressure, 15 or higher on Norton Scale, over 10 days of hospitalization
In the Retrospective study Freidman, SM (20) (2008) in USA with 212 elderly (ccu word) result showed Risk Factors fall is Presence of the elderly In nursing homes.

In the Case-control study Chen, YC (21) (2009) in Taiwan with 202 elderly (All Wards) result showed Risk Factors fall is Leg dystrophy, Insomnia, Blood pressure fall, History of Falling in the last year, Recent use of hypnotics.

In the study Bollini, G (19) (2010) in Italy with elderly (8 wards) result showed Risk Factors fall is Taking one or combined drugs.

In the Retrospective/ Case control study Chen, XL (22) (2010) in China with 438 elderly (Geriatric) result showed Risk Factors fall is living in dormitory/ nursing homes before hospital admission, requiring assistance for movement, cognition disorder, CVA, urinary incontinence and arthritis/ osteoporosis.

In the Retrospective study Church, S (23) (2011) in USA with 9625 elderly (Surgery Wards) result showed Risk Factors fall is Delirium 43%, Disability 34%, External factors 13%, Other factors 10%.

In the Case-control study Chen, X (24) (2011) in Australia with 399 elderly (Geriatric) result showed Risk Factors fall is History of Anemia, CVA, Ventricular Fibrillation, Over 5 weeks hospitalization.

In the Retrospective study Maxwell, CA (25) (2013) in USA with 101 elderly (Surgery Wards) result showed Risk Factors fall is Delirium 36 patients (44%) had cognition disorders and 62 patients (78%) had performance disorder prior to their fall.

In the Case-control study Chan, CH (26) (2013) in USA with 290 elderly (Psychiatry Wards) result showed Bipolar Disorder, Psychiatric disorders, Manic episode, History of health problems Or fall in last 6 months.

In the Cohort study Jorgensen, TSH (27) (2015) in Denmark with 28524 elderly (All Wards) result showed People with dementia, osteoporosis, CVA, depression, COPD, and Parkinson.

In the Retrospective study Li, IF (28) (2016) in Taiwan with 244 elderly (Clinical, Oncology, Surgery word) result showed Dizziness and Leg dystrophy, taking medications such as tranquilizers, sleeping pills, blood pressure drugs, hypoglycemic, and diuretic drugs.

In the Descriptive-cross sectional study Moura, LA (5) (2017) in Brazil with 99 elderly (Clinical, Surgery) result showed High blood pressure, taking insulin, long walks.

Discussion

Systematic review studies provide comprehensive information. This study is the first systematic review study to evaluate the Risk Factors of Elderly Falling in Public Hospitals. The findings of the present study can be summarized into two important categories of factors underlying the elderly falls in hospitals: individual factors (physical, mental, cognitive) and external factors. Following a review study in 2013 in Iran, it was found that more than 30% of people over 65 experience falling at least once a year. Lowering of consciousness, convulsion, sudden myocardial infarction, and environmental problems were among the influential risk factors for the elderly falling. In another review study on risk factors for the elderly falling in hospitals in Iran in 2013, the risk factors were mostly either individual or external. The results of another review study demonstrated that the major risk factors for the elderly fall comprised balance disorders, visual disorders, lowering of cognitive abilities especially problems of concentration and noticing along with other factors such as increasing of age, gender, dizziness, cardio-vascular diseases, dementia, depression, and taking medications.

In another study, the elderly people who used walking aids were more prone to falling than others since some of the elderly may not be able to use such aids properly. In the current study, it was mentioned that in studies by Luukinen and Aizen it had been demonstrated that the elderly who used walking aids (such as walkers, clubs, etc.) more often were more likely to fall in hospitals. Moreover, the relationship between taking drugs (especially Amphetamines, sedatives, antidepressants, diuretics, and cardio-vascular medications) and the elderly fall. It was also demonstrated that the elderly who take more than one drug are more likely to fall. It has also been claimed that antipsychotic medications, anti-arrhythmia, digoxin, diuretics, as well as tranquilizing medicines increase the risk of the elderly falling in hospitals.

Conclusion

In CCU, prolonged care, psychiatry, and geriatric wards in hospitals there are different factors contributing
to the elderly fall, depending on their physical and mental states. Thus, identifying and eliminating these risk factors can guarantee more safety for the elderly.

Conflict of Interest: There is no conflict of interest between authors.

Abstract

Background. One of the organs of the body that is lacking attention is the teeth and mouth, whereas maintaining healthy teeth and mouth is very important, because the nerves of the teeth are related and directly affect the nerves of other organs. The development of information technology that is so advanced has entered the world of health, namely to detect early dental and oral diseases by using an expert system. Making an expert system is not to replace the expert itself but can be used as a very experienced assistant. There is a need to solve this problem so that people can know how to deal with diseases related to teeth and mouth. The various information supporting factors in this study by building an expert system with three methods are Certainty Factor (CF), Dempster Shafer (DS) and Bayes Theorem to diagnosis early dental and oral disease events and determine the effect of expert systems in increasing the validity level of dentist diagnosis. Material and Method The type of research used was an observational method in a cross-sectional study design. The sampling method uses total sampling. The study was conducted in September-January 2020. The number of sampling was 200 people. This research consists of three stages are the making of an application system, application testing, and the final stage is a statistical test. The data analysis technique used in this study is Chi-square and validity test. Results. The results of the analysis of the relationship between the value of accuracy with the validity of the doctor’s diagnosis found variable diagnosis doctor have p value (0.013), DS value, CF and Bayes Value are the same p (0,000) <p (0.05). Conclusion. Applications built using the CF, DS and Bayes Theorem methods can be used by users to detect dental disease early before making further examinations to a specialist. The test results given by the system are the same as the results given by experts (dentists). The system of early diagnosis of dental and oral diseases has a very significant effect on the level of validity of the dentist final diagnosis.

Keyword: System Expert, Dental and Oral Disease, Validity, CF, DS and Bayes, diagnosis doctor

Background

One of the organs of the body that is lacking attention is the teeth and mouth, whereas maintaining healthy teeth and mouth is very important, because the nerves of the teeth are related and directly affect the nerves of other organs.¹,² The development of information technology that is so advanced has entered the world of health are to detect early dental and oral diseases by using an expert system. Making an expert system is not to replace the expert itself but can be used as a very experienced assistant. In addition, lack of knowledge and limited sources of information cause low public awareness of efforts to prevent and even treat oral and dental diseases. Public understanding of dental and mouth disease is still relatively low so that many people still rely on the knowledge of an expert in this case doctors to be able to diagnose an illness, so it requires a long time and expensive costs. Tooth and mouth disease can cause pain and tooth loss. The high prevalence of dental and mouth disease is generally caused by various

Corresponding author:

factors, including: factors of knowledge, attitudes and actions in maintaining dental health that is still low.\[^{3,4,5,6,7}\] In addition to expensive consultation fees, long queues and looming pain are also the reasons people are afraid to see a dentist.

There is a need to solve this problem so that people can know how to deal with diseases related to teeth and mouth. The various information supporting factors in this study by building an expert system with three methods are CF, DF and Bayes to diagnosis early dental and oral disease events and determine the effect of expert systems in increasing the validity level of dentist diagnosis. Based on the above background, the authors wish to discuss research on the early diagnosis of dental and oral diseases with the level of validity of the diagnosis of dentists in the Public Health Center Makassar, Indonesia.

**Material and Method**

The type of research used was an observational method in a cross-sectional study design. The sampling method uses total sampling. The study was conducted in September-January 2020. The number of sampling was 200 people. This research consists of three stages are the making of an application system, application testing, and the final stage is a statistical test. The data analysis technique used in this study is Chi-square and validity test.

**Results**

Data collection was carried out to obtain some information related to making an expert system application for diagnosis of dental and oral diseases are the form of symptom data and disease data. Data obtained during the data collection process was obtained from the results of patient interviews (200 people) with dentists, nurses, and supported by books, journals, and internet browsing related to dental and oral diseases. Data is then processed by the system so that it becomes input data and output data. The method in analyzing data using the algorithm is the CF, DS and Bayes methods.

1. **Design Form**

The screen will be used to log in by the user by entering a username and password. The design form of the login menu screen is as shown in Figures 1 and 2.
The user/admin screen has facilities for analyzing diseases. If the user as an admin, then has the facility to add user data or disease data, while the user is not allowed to add data. The shape of the design can be seen in Figure 3.
2. Relationship of Expert Diagnosis System with Validity Doctor’s diagnosis

Discussion

Expert system is one branch of artificial intelligence, which is a computerized application that tries to imitate the reasoning process of an expert in solving specific problems by making a decision. The basic of an expert system is how to transfer the knowledge which are owned by an expert in this case is dentist to a computer, and how to make decisions and draw conclusions based on that knowledge. [8], [9], [10], [11], [12]

As the times evolve, the field of dentistry has utilized technology in an effort to improve better services in diagnosing diseases, one of which is dental and oral disease. [13], [14] Teeth are one of the chewing organs that are very important in digestion process in the human body. [15], [16] If the tooth is disrupted, it will cause a variety of complaints and symptoms that can be fatal. Considering that experts and hours of practice are limited, so patients cannot consult with experts anytime and anywhere, we need an expert system that can replace the role of an expert. [17], [18]

The research results that will be discussed are the expert system designed using three methods, the number of diseases discussed in this study as many as 19 diseases with 61 symptoms observed, and the knowledge base is represented in the form of If-Then Rules. Each table of research results will be interpreted and given an accurate explanation.

Table 1 explains that the number of respondents who filled the expert system were 200 people with the most respondents, namely women (64.5%), ages 38-48 (11.5%), Doctor B (50.5%), not working (63.5%), unmarried (58.5%), Accuracy value (61%), DS Value (61.5%), CF Value (65.5%) and Bayes Value (63%). From the results of a trial of 200 cases of expert system diagnosis data with the doctor diagnosis results obtained in accordance with using the three methods. The test results can be used as a percentage that with expert knowledge that is obtained results above 60% of the truth value. This is different from the results of research conducted by Novi. AH (2014) which explains that the truth percentage of expert knowledge in diagnosing diseases is 100% using one method, the DF method. [19]

This is in accordance with DF theory which explains that a mathematical theory for proving hypotheses is based on belief functions and plausible reasoning, which is used to combine separate pieces of information (evidence) to calculate the likelihood of an event. The DF theory is based on two ideas namely the idea of obtaining a degree of trust from various subjective possibilities and the rules of the DF itself to combine the degree of trust based on the evidence obtained. DS theory is generally written in certain time intervals. [20]

Another study conducted by Jaenal Arifin using another method is CF explained that the level of trial results to determine the diagnosis of dental and oral diseases with a trial of 10 data resulted in a match rate of 9 data so that the accuracy rate was 90%. [21] Research conducted by Ingrid N, MY, etc. (2016) explains that the application of an expert system uses the CF method in early detection of dental disease before further examination to the expert physician showing the results that the results given by the system are the same as the results given by the system expert, is dentist. [22]

CF is a method to prove whether a fact is certain or uncertain in the metric form that is usually used in expert systems. CF was introduced by Short life Buchanan in making MYCIN. CF is the clinical parameter value given by MYCIN to show the magnitude of the trust. [23]

The advantage of the CF method is suitable for use in expert systems to measure whether something is certain or uncertain, calculations using this method in a single count can only process 2 data so that the accuracy of the data can be maintained. The disadvantages of the Certainty Factor method are: the general idea of modeling human uncertainty using numerical certainty factor methods is usually debated, this method can only process uncertainty or certainty in only 2 data only. Need to do several times the processing of data that is more than 2 pieces. [24]

Some of the research results conducted by previous researchers show that the method used is only one method and uses relatively little data. The data used not come from data directly from patients, while the research we used was using 3 methods at the same time. The use of three methods at the same time is used to see whether the results are different or not, but the results obtained are all the same percentage.

Table 2 explains the significant relationship between the value of accuracy with the validity of the doctor’s diagnosis results seen from the diagnosis doctor variable \( p (0.013) < p (0.05) \), DS, CF and Bayes Value each
having the same value is \( p (0.000) < p (0.05) \).

After seeing that there is a significant relationship between the diagnosis doctor variable and the expert system accuracy value then it proves there are similarities between the results of the 2 dentist examinations and the computer expert system. The similarity of the results of the diagnosis of the two doctors shows that the competency between one dentist and the other is the same so that in research it is proven that whatever or whoever is involved in the early diagnosis of the disease through an expert system, it will result in a high accuracy value.

Therefore, the expert system is designed to be able to imitate the expertise of an expert in answering questions and solving a problem. Expert system will provide a solution to a problem obtained from dialogue with users. With the help of an expert system, a person who is not an expert or expert can answer questions, solve problems and make decisions that are usually made by an expert. \[24\]

Knowledge stored on a computer is called a knowledge base. There are 2 types of knowledge are facts and procedures. One feature that must be possessed by an expert system is the ability to reason. If the skills are stored as a knowledge base and the program is able to access the database, then the computer must be programmed to make inferences. This inference process is packaged in the form of an inference engine. Most commercial expert systems are made in the form of rule-based systems, where the knowledge is stored in the form of rules. The rule is usually in the form of IF-THEN. Another feature of the expert system is the ability to recommend. This ability distinguishes expert systems from conventional systems. \[7\]

**Conclusion**

Applications built using the Certainty Factor, Dempster Shafer and Bayes methods can be used by users to detect dental disease early before making further examinations to a specialist. The test results given by the system are the same as the results given by experts (dentists). The system of early diagnosis of dental and oral diseases has a very significant effect (\( p 0.00 \)) on the level of validity of the dentist final diagnosis.

**Ethical Considerations:** Ethical clearance was obtained from Universitas Muslim Indonesia; with number “320/A/KEPK- UMI/VIII/2019. Just before the interview, written (or thumb impression) consent was obtained from each participant in Universitas Muslim Indonesia guidelines.

Association between Intelligence Level and Handicap Degree in Epilepsy Patients

Meity Meiliyanny Beslar¹, J. Eko Wahono¹, Isti Suherjanti¹, Paulus Sugianto¹, Riani Wisnujono¹
¹Department of Neurology, Faculty of Medicine, Universitas Airlangga, Surabaya (60131), Indonesia

Abstract

Background: Epilepsy correlates with high limitation value, disability and function loss which can give negative impact to patient’s quality of life. This negative impact correlates with either epileptic seizures (motoric, sensory and behavior) or effects of anti-epileptic drugs that can cause cognitive impairment, which in this case is intelligence aspect with handicap in epilepsy patients. We determined correlation between intelligence level and handicap degree in epilepsy patients.

Methods: The research was conducted in patients of Neurological Department of Dr. Soetomo General Hospital, Surabaya, Indonesia, who met inclusion and exclusion criteria, consecutively from July 2013-December 2013. Intelligence test was conducted using Standard Progressive Matrices (SPM) test, while test on handicap degree was conducted using Subjective Handicap Epilepsy (SHE) test.

Results: There were 40 research subjects (19 females and 21 males) with average age of 30.9±9.6. The average score of SHE was 70.08±16.69, while the average score of SPM was 88.53±10.34. There was a weak positive correlation and statistically significant correlation between SPM and SHE scores (r = 0.345 and p = 0.029).

Conclusion: There was a correlation between intelligence level and handicap degree in epilepsy patients.

Keywords: Epilepsy, Handicap, Intelligence

Introduction

Epilepsy is a chronic neurological disease marked by unprovoked epileptic seizures that occurs more than once a year. According to PERDOSSI (2012) there is a high prevalence of epilepsy in developing countries, with number reaching 114 per 100.000 population per year compared to that in development countries. An estimated 250.000 people per year in Indonesia suffer from epilepsy¹.

Epilepsy is caused by curse, magic, possession, mental disorders, and it is often regarded as a disease transmitted through saliva (Harsono, 2012). Limited medical personnel, service facilities, funding and society’s ability decrease epilepsy prevention. The disease can be controlled with medication and surgery².

Epilepsy can also deal with intelligence impairment, with prevalence of its occurrence being estimated to be 14% until 44% that has been reported by various studies conducted in United Kingdom. Furthermore, epilepsy patient with intelligence impairment usually has health problems, including fractures, trauma and side effects of anti-epileptic drugs³. Epilepsy also strongly correlates with intelligence level, which has important roles in handicap. The previous research has explained the correlation between intelligence level and handicap degree, thus this study aims to improve intelligence quality among disabled.

Method

The research is using cross sectional design. The study used sample of all epilepsy patients who visited Outpatient Neurological Clinic of Dr. Soetomo General Hospital, Surabaya, Indonesia from July to December of 2014. The research was conducted at the Outpatient Neurological Clinic of Mental Health Science, Dr. Soetomo General Hospital, Surabaya, Indonesia, for four months⁴.
The following are inclusion criteria that must be fulfilled in the research is epilepsy patients aged 13 – 55 years old, having minimum education of elementary school and can read and write. Being diagnosed with epilepsy at least for 1 year, patients are willing to participate in the research (informed consent). The research employed consecutive sampling method. The research variables were intelligence level as independent variable, handicap degree as dependent variable, and sickness duration, types of epileptic seizure, as well as types of therapy as confounding variables. The study protocol was approved by the ethics committees of Dr. Soetomo Teaching Hospital (Surabaya, Indonesia).

The research began with patients declaring their willingness to become the subjects of the study by signing informed consent. The sampling process continued by conducting anamnesis, physical and neurological examination based on inclusion and exclusion criteria. Afterwards, the researchers conducted handicap measurement based on SHE score issued by PPDS in Epilepsy unit. Intelligent test was then performed by a psychologist at Psychology Unit of Outpatient Clinic of Mental Health Science, before the researchers recorded all eligible samples and necessary clinical data. The records were collected to make data tabulation and statistical analysis. The study employed Spearman test to analyze the data since the data were not normally distributed; the results have strong positive correlation and statistically significant (r=0.697 and p=0.025). Statistic calculation was conducted using SPSS software (SPSS, Inc., Chicago, IL).

Results

The results of data processing on distribution of clinical data that includes types of seizure, seizure frequency and types of therapy are shown in Table 1, while frequency distribution of sickness duration, SHE and SPM scores are presented in Table 2. Based on the results of analysis on frequency distribution of seizure types, Table 1 showed 15 subjects with focal seizure (37.5%) and 25 subjects with general seizure (62.5%). On the other hand, frequency distribution of seizure frequency showed 14 subjects (35%) with frequency <1x/year and 26 subjects (65%) with frequency ≥1x/year. Frequency distribution of types of therapy showed 21 subjects were treated with monotherapy (52.5%) and 19 subjects with polytherapy (47.5%). The average SHE score was 70.08±16.69, while the average SPM score was 88.53±10.34.

The results of correlation analysis were divided into six data correlation analyses using Spearman test that are shown in Table 3. The results of data processing on correlation between intelligence level (SPM score) and handicap degree (SHE score) based on educational level showed a moderate positive correlation, but it was not statistically significant, between SHE and SPM scores in the sample group of elementary-junior high school graduates, with correlation coefficient (r) of 0.478 and p=0.137. Meanwhile for the sample group of senior high school-university graduates, there was a weak positive correlation between SHE and SPM scores (r=0.128 and p=0.508).

The results of data processing on correlation between intelligence level (SPM score) and handicap score (SHE score) based on the subjects’ occupation showed a powerful positive correlation between SPM and SHE scores in the sample group of students-college students, with correlation coefficient of (r)=0.886 and p=0.019, and the correlation was statistically significant. In the sample group of employed subjects, there was no correlation between SPM and SHE scores with correlation coefficient (r)=0.165 and it was not statistically significant with p=0.449. Meanwhile in the sample group of unemployed subjects, there was a moderate positive correlation, but it was not statistically significant, between SPM and SHE scores with r=0.425 and p=0.221.

The results of data processing on correlation between intelligence level (SPM score) and handicap degree (SHE score) based on seizure types showed a weak positive correlation between SPM and SHE scores in the subjects with focal seizures, with correlation coefficient value (r)=0.216, and it was not statistically significant with p=0.440. Meanwhile in the sample group of general seizure, there was a moderate positive correlation between SPM and SHE scores with r=0.419, and it was statistically significant with p=0.037.

The results of data processing on correlation between intelligence level (SPM score) and handicap degree (SHE score) based on seizure frequency showed a weak positive correlation between SPM and SHE scores in the sample group with frequency <1x/year, with r=0.347, and it was not statistically significant with p=0.224. Meanwhile, there was a moderate positive correlation between SPM and SHE scores in the sample group with frequency ≥1x/year, with r=0.505, and it was statistically significant with p = 0.008.
The results of data processing on correlation between intelligence level (SPM score) and handicap degree (SHE score) based on types of therapy showed no correlation between SPM and SHE scores in the sample group with monotherapy, with $r=0.098$ and $p=0.673$. Meanwhile, there was a moderate positive correlation between SPM and SHE scores in the sample group with polytherapy, with $r=0.574$, and it was statistically significant with $p=0.010$. From the results of overall analysis, there was a weak correlation between SPM and SHE scores with $r=0.345$, and it was statistically significant with $p=0.029$.

Discussion

Based on the results of data processing on epilepsy patients’ education level, there were 11 subjects (27.5%) graduated from elementary-junior high school, while there were 29 subjects (72.5%) graduated from senior high school-university. The results of data processing on the patients’ occupation showed 6 students and college students (6%), 24 subjects were employed (60%) and 10 subjects were unemployed (25%). Thomas SV (2005) explained that most subjects could complete their secondary education and have a job.

Types of anti-epileptic drugs (AEDs) administered to the research subjects were old AEDs, including carbamazepine, valproic acid, phenytoin and clobazam. The average dose used in the research, either monotherapy or combination of polytherapy, was still in the therapeutic range. The research found that monotherapy was more frequently used than polytherapy. Thus, this finding was consistent with the previous studies which stated that monotherapy was more frequently used than polytherapy for epilepsy patients, including the studies conducted by Cantey (5:1 ratio, n = 145) and Sejvar (3:1 ratio, n = 112).

The results of data correlation processing showed a powerful positive correlation and statistically significant correlation between SPM and SHE scores in the sample group of students and college students. However, this finding cannot be compared with findings from other studies since there is no journal with similar discussion. The present study divided occupational characteristics into two groups, namely students-college students and employed-unemployed. Thus, there was a possibility that students and college students have a more homogenous activity compared to employed subjects.
of employed subjects is more heterogenous because of varied types of occupation) 9.

There was a moderate positive correlation between SPM and SHE scores found in the group of subjects with seizure frequency of ≥1x/year (r=0.505 and p=0.008). This finding was consistent with studies conducted by Hawari I et al. (p=0.009) and Piperidou et al. (p=0.001). The finding of the present study is supported by a statement found in literatures that stated that the greater the physical and chronic health problems, the seizure will be more frequently occurred that can worsen epilepsy patients’ handicap. Research conducted by Dodril et al. also indicated that adult patients who suffer from episodes of general tonic clonic seizure more than 100 times tended to have worse intellectual, neuropsychological, psychosocial and emotional functioning than patients with fewer episodes of seizure 10.

Well-controlled seizure will maintain epilepsy patients’ cognitive function. Anti-epileptic drugs can control the work and also provide protection function that exceeds its side effects, they are: 1) by reducing seizure activity, where recurrent seizures can trigger neuronal damage and disrupt brain formation and circuits, 2) modulate neurotransmitters effects, reducing excitociticy by decreasing glutamate release, 3) inhibiting Ca²⁺-mediated cellular function and Ca²⁺- depended depolarization, 4) as a free radical scavenger, and 5) pleiotropic effects. The results of data correlation processing showed a moderate positive correlation (r=0.574 and p=0.010) between SPM and SHE scores in the subjects with polytherapy. This finding was consistent with studies conducted by Hawari I et al. (p=0.006) and Piperidou et al. (p<0.001)

Polytherapy have a relatively bigger effect on cognitive function compared to monotherapy, regardless the types of anti-epileptic drugs used in its combination. Combination of anti-epileptic drugs will worsen its cognitive side effects that can induce the occurrence of more serious cognitive impairments if the drugs are administered in the same time 11.

The research found a weak positive correlation between SPM and SHE scores (r=0.345), and it was statistically significant (p=0.029). This finding was consistent with a research conducted by Sabaz with p=0.000, as the finding stated that child epilepsy patients with intellectual impairment had a larger handicap (worse quality of life) compared to those with normal IQ. Gulhoto et al. in Brazil also stated that adolescents with focal seizures had a lower cognitive ability compared to normal adolescents. Epilepsy patients with intellectual impairment have higher emotional, behavioral and cognitive problems, with difficulty in socializing and having achievements, particularly in schoolchildren. The direction of a positive relation indicates that if SPM score increases, the SHE score also increases (smaller handicap) 12.

Although academic problems are the result of multifactorial, there is still a need for a more specific educational approach in order to improve the performance of these adolescents, in addition to helping them eliminate the stigma associated with epileptic seizures in society 13. Therefore, statistical analysis is true if the research hypothesis states that there is a correlation between intelligence level (SPM score) and handicap degree (SHE score) in epilepsy patients 14. The correlation can also occur due to effects of polytherapy, more seizure frequency towards handicap and worsening intelligence. Therefore, the results of this study are expected to be more clinically focused and precise in giving therapy for epilepsy patients by optimizing the monotherapy use of anti-epileptic drugs and more selective combination therapy.

**Conclusion**

There was a correlation between intelligence level and handicap degree in epilepsy patients.

**Ethical Clearance:** This research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. Abstract

Background: Increased incidence of cancer in the world also increases the use of chemotherapy agents. Cisplatin is one of the most effective chemotherapy agents, often used for the treatment of various solid tumors. The therapeutic effect of cisplatin significantly increased with increasing dosage.

Aim: The aim of the study was to investigate the role of glutamine in the prevention of apoptosis in proximal renal tubular epithelial cells administered by cisplatin chemotherapy, via an intrinsic caspase-independent apoptotic (AIF).

Methods: The study was enrolled thirty male Wistar rats. The rats were divided into three groups of treatments, group A (negative control), group B has given intraperitoneal cisplatin dose of 20 mg/KgBB, group C administered the intravenous injection of glutamine 100 mg/KgBB for 7 days.

Results: Analyzed ANOVA, mean expression of BCL-2 group B = 56.80 ± 4.39 than group A (control) = 63.7 ± 5.53 decreased not significant (p = 0.06), and mean expression of BCL-2 group C = 113.30 ± 8.92 increase significant compared to group A = 63.7 ± 5.53 (p = 0.000001) and group B = 56.80 ± 4.39 (p = 0.000001). The average AIF expression group C = 236.20 ± 17.58 decreased significantly compared to group B = 309.50 ± 8.08 (p = 0.000001). The average number of group apoptosis C = 151.80 ± 21.87 decreased significantly compared to group B = 255.20 ± 27.82 (p = 0.000001).

Conclusion: Glutamine can inhibit the expression of AIF, increase BCL-2 expression, and decrease apoptosis of epithelial cells of the renal proximal tubules given cisplatin.

Keywords: Glutamine, Cisplatin, Acute Kidney Injury

Introduction

Cancer is the second leading cause of death that contributing 13% of deaths from 22% of deaths from non-communicable diseases in the world¹. It is estimated that at least 22.2 million new cases will be diagnosed annually worldwide by 2030 with the estimated deaths from cancer worldwide will rise through 13.1 million deaths in 2030². Ministry of Health Indonesia in 2007 reported that cancer is the leading cause of death number 7 in Indonesia with cancer prevalence 4.3 per 1000 population.

Cisplatin (cis-diammine-dichloroplatinum II) is one of the most effective chemotherapy agents, often used for...
the treatment of various solid human tumors including testicular and ovarian cancers\textsuperscript{3}. This is evidenced by the use of cisplatin as a standard component in chemotherapy regimens in various types of cancer, such as head and neck cancer, ovarian cancer, testicular cancer, esophageal cancer, bladder cancer, cervical cancer, and non-small cell lung cancer\textsuperscript{4}.

The therapeutic effect of cisplatin significantly increases with increasing dosage\textsuperscript{5}. However, increased doses of cisplatin in clinical use, often limited by adverse events, such as nephrotoxicity and neurotoxicity, are side effects that limit the dose of cisplatin\textsuperscript{6}. The main side effect that limiting the dose of cisplatin is the effect of nephrotoxicity\textsuperscript{7}.

There are various percentages of nephrotoxicity effects of cisplatin, but the most serious and most frequent effect is acute kidney injury (AKI) occurring in 25-35\% of patients\textsuperscript{8}. Conceptually AKI is a rapid decline (in hours to weeks) of a generally reversible glomerular filtration rate (LFG), followed by renal failure to excrete residual nitrogen metabolism, with/without disturbance of fluid and electrolyte balance\textsuperscript{9}.

The diagnostic criteria for AKI according to acute kidney injury network (AKIN) are: abrupt decrease in renal function (within 48 hours) characterized by elevated serum creatinine levels $> 0.3$ mg/dl (26.4 μmol/l) or serum creatinine more than 1.5 times ($> 50\%$) when compared with previous levels or decreased urine output to less than 0.5 cc/h for more than 6 hours\textsuperscript{10}. The nephrotoxic effects of cisplatin most commonly occur after 10 days of cisplatin administration\textsuperscript{11}. Over the past few years, renal tubular epithelial cell apoptosis has been the focus of investigation on the mechanism of nephrotoxicity of cisplatin. There are several apoptotic pathways involved, including extrinsic pathways mediated by death receptor, mitochondrial-centered intrinsic pathways, and ER pathway reticulum (ER) stress\textsuperscript{12}.

Increased incidence of cancer in the world also increases the use of various chemotherapy agents, including cisplatin. The widespread use of cisplatin increases the side effects of cisplatin use, including the nephrotoxic effects of cisplatin. Acute Kidney Injury (AKI), caused by renal cell apoptosis. Glutamine is the most abundant amino acid found in the blood and in the storage of free amino acids from the body. One of the important characteristics of glutamine is that glutamine has a beneficial effect on critical illness, as it can increase the expression of heat shock protein (HSP)\textsuperscript{13}. HSP is a group of essential proteins for cell endurance under stress conditions\textsuperscript{14}. There is evidence that glutamine can increase HSP-70 and HSP-72 expression in pulmonary and epithelial cell macrophages\textsuperscript{15}. Increased expression of HSP-72 has the ability of antiapoptosis by stimulating Bcl 2, Bcl-XL and inhibiting damage to the mitochondrial membrane\textsuperscript{16}. Therefore, this study will examine the effect of glutamine injection as an antiapoptosis of proximal renal tubular cells treated with cisplatin chemotherapy.

**Method**

This research was a laboratory experimental research with “Randomized Post-test only control group design” design that used thirty male Wistar rats. Rats were divided into three treatment groups, group A (negative control), group B has given intraperitoneal cisplatin injection of a single dose of 20 mg/KgBB, group C given intravenous injection glutamine 100 mg/KgBB for 7 days and at day 7 were given intraperitoneal cisplatin dose of 20 mg/KgBB. After 72 hours of cisplatin injection, renal mouse tissue was processed immunohistochemically, to observe the number of proximal renal tubular cells expressing Bcl-2, AIF, and apoptotic cell counts.

The experimental animals used in this study were obtained from the Faculty of Veterinary Medicine of Airlangga University. Selection of sample for grouping and giving treatment using simple random sampling, with inclusion criteria is *Rattus novergicus* strain Wistar rats, healthy male rats, healthy-looking active, 2.5-3 months old, 150-200 gram weight.

The sample size in this study was determined based on Federer’s formula, with dropout correction (0.1), resulting in a total sample of 30 mice with details of 10 rats for each treatment group. Animal treatment was performed for 7 days, then examination of kidney preparation on the 10th day was the number of cells expressing BCL-2, the number of cells expressing Apoptotic Inducing Factor AIF and the number of apoptotic cells in male rats proximal tubule rats *Rattus novergicus* wistar strain, with a 1000X light microscope, positive rectal proximal tubular cells were calculated (located in the renal cortical region, characterized by cylindrical tube lumen), positive cell counts in 20 viewing field (HPF) in each sample.
The duration of Injectable Glutamine Intra-Vein (IGIV) administration was 7 days, because based on previous studies glutamine will increase HSP after 7 days of IGIV. Observation time at day 10 or 72 hours after intraperitoneal cisplatin injection (on day 7) because apoptosis in proximal renal tubular cells was apparent after 72 hours of cisplatin administration. Renal kidney tissue is processed immunohistochemically, to observe the number of proximal renal tubular cells expressing Bel-2, AIF, and apoptotic cell count. Data were analyzed with SPSS 17, ANOVA analysis followed by Post Hoc Tukey test, with p-value <0.05.

Results

Based on the results obtained the analysis of glutamine inhibit apoptosis proximal tubule renal cells. Increased HSP70 affects survival associated with the ability to inhibit apoptosis. Glutamine supplementation enhances HSP expression. It was concluded that in the 72-hour observation after cisplatin administration, glutamine could inhibit apoptosis of proximal renal tubule cells significantly, and was directly proportional to the glutamine effect that inhibited the expression of AIF.

The homogeneity test shown in Table 1 was performed by using one-way ANOVA test, indicating that there was no significant difference between body weight before treatment and weight after treatment (sig >0.05). Here is table 1.

Table 1: Homogeneity Test Based on Weight Loss

<table>
<thead>
<tr>
<th>GROUPS</th>
<th>F</th>
<th>p</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weight before treatment</td>
<td>1.486</td>
<td>0.222*</td>
</tr>
<tr>
<td>Weight after treatment</td>
<td>0.941</td>
<td>0.449*</td>
</tr>
</tbody>
</table>

From that table, it can suggests that animal weight data try to have a homogeneous variation. In this study, it appears that changes in epithelial cells of proximal renal tubules occur after 72 hours of observation.

Immunohistochemical renal tissue examination results showed that the control group’s renal tissue showed an average amount of BCL-2 expression of 63.7 ± 5.538752. Giving cisplatin (Group B) in animals tries to decrease mean expression BCL-2 is not significant (p = 0.066028) after 72 hours to 56.80 ± 4.391912. Administration of cisplatin and glutamine (group C) in the experimental animals significantly increased the mean expression of BCL-2 to group A (p = 0.000001) and group B (p = 0.000001) after 72 hours to 113.30 ± 8.920015. Administration of cisplatin and glutamine (Group C), BCL-2 expression was increased when compared to the control group (Group A) and the cisplatin-treated group (Group B). Addition of cisplatin (Group B) did not significantly decrease BCL-2 expression compared to the control group (Group A). Histologic representation of BCL-2 expression with Immunohistochemical staining, using Olympus BX 50 magnification 1000x.

The results of immunohistochemical renal tissue examination of the average AIF group A (control) expression amounted to 48.4 ± 3.134042. Giving cisplatin (Group B) in animals tries to significantly increase the average of AIF expression (p = 0.000001) after 72 hours to 309.50 ± 8.086340. However, administration of cisplatin and glutamine in group C in animals tended to decrease mean AIF expression significantly against group B (p = 0.000001) after 72 hours to 236.20 ± 17.586611. It can be concluded that in the administration of cisplatin and glutamine (Group C), the expression of AIF decreased significantly compared with the group given cisplatin (Group B). A histologic representation of AIF expression with immunohistochemical staining using Olympus BX 50 1000x magnification microscope.

The results of the renal tissue examination with apoptosis detection kit In Situ Cell Death Detection Kit, POD showed that the group A (control) kidney tissue showed an average number of cell apoptosis of 47.40 ± 18.572381. Giving cisplatin (Group B) in animals tries to significantly increase cell apoptosis averages (p = 0.000001) after 72 hours to 255.20 ± 27.828043. However, the administration of cisplatin and glutamine in group C in animals tended to decrease the mean cell apoptosis significantly against group B (p = 0.000001) after 72 hours to 151.80 ± 21.877436. It can be concluded that in the administration of cisplatin and glutamine (Group C), rectal proximal renal tube apoptosis decreased significantly compared to the cisplatin group (Group B). Histologic features of rectal proximal tubular apoptosis with detection kit In Situ Cell Death Detection Kit, POD, using Olympus BX 50 1000x magnification.

The results of data analysis obtained showed that cisplatin and glutamine can increase BCL-2 expression, so BCL-2/Bax ratio can be increased which will inhibit
the leakage of mitochondrial membrane, and inhibit the release of apoptogenic factors (cytochrome c, apoptosis inducing factor (AIF), Second Mitochondria-Derived Activator of Caspase (SMAC), and others)\textsuperscript{12}. Similar results were also obtained from previous studies which concluded that HSP-72 expression enhancement has anti-apoptotic ability by stimulating Bel 2, Bel-XL and inhibiting damage to mitochondrial membranes\textsuperscript{16}.

In other side cisplatin (cis-diammine-dichloroplatinum II) is one of the most effective chemotherapy agents, often used as chemotherapeutic reagents of various solid human tumors including testicular and ovarian cancers\textsuperscript{3}. This is evidenced by the use of cisplatin as a standard component in chemotherapy regimens in various types of cancer\textsuperscript{4}.

The therapeutic effect of cisplatin significantly increases with increasing dosage\textsuperscript{5}. However, increased doses of cisplatin in clinical use are often limited by adverse events, such as nephrotoxicity and neurotoxicity, which are side effects that limit the dose of the cisplatin\textsuperscript{6}. Giving glutamine to malignancy is still controversial. There are groups who argue that glutamine is the main food needed for tumor cell metabolism, so the administration of glutamine can enlarge the tumor and resistant to chemotherapy\textsuperscript{17}. Yet another group believes that glutamine intake is necessary as a nutritional intake of cancer and has antioxidant effects by increasing Glutathione (GSH) that can inhibit tumor growth otherwise it is known to reduce the side effects of chemotherapy agents Doxorubicin\textsuperscript{18}. Previous studies proving cisplatin may increase AIF expression in the renal proximal tubular cytosol, which then AIF out of the mitochondria, will accumulate in the cell nucleus that will induce apoptosis through the caspase-independent pathway\textsuperscript{19}.

Hsp 72 renal epithelial cells may decrease mitochondrial membrane injury by Hsp 72 interaction with BCL-2. Furthermore, the potential of L-glutamine to HSP 72 is associated with increased intestinal epithelial resistance to apoptotic injury, and the reduction of HSP 72 may be associated with increased caspase activity in glutamine deficiency. Thus, it is hoped that the administration of glutamine would be useful in increasing heat shock protein (HSP) 72 and BCL2 which ultimately decrease apoptosis of renal proximal tubule cells due to cisplatin.

Glutamine administration inhibits the expression of AIF so it can inhibit the occurrence of apoptosis. This result is not in accordance with previous research, the resistance of AIF expression is not due to increased expression of BCL-2, this indicates if the effect of cisplatin on decreasing expression of BCL-2 is very low. Therefore, observation for 72 hours after cisplatin administration, glutamine administration can inhibit AIF expression significantly. Administration of cisplatin may increase apoptosis of proximal renal tubular cells that are mechanically nephrotoxic of cisplatin\textsuperscript{(15)}. Apoptosis due to cisplatin administration occurs through increased AIF expression. AIF that comes out of the mitochondria, will accumulate in the cell nucleus that will induce apoptosis through the caspase independent pathway.

**Conclusion**

Based on the results of the study it can be concluded that glutamine can increase BCL-2 expression in epithelial cells of the renal proximal tubules given cisplatin.

Association between Soluble Contents CD40 Ligand (sCD40L) and Acute Coronary Syndrome (ACS)

Mirza Elita¹, Muhammad Aminuddin¹, Jusak Nugraha¹

¹Department of Clinical Pathology, Faculty of Medicine, Universitas Airlangga, Surabaya (60131), Indonesia

Abstract

Background: Acute coronary syndrome (ACS) is a manifestation of coronary heart disease (CHD), which the leading cause of death in Indonesia. CD40 ligand (CD40L) stored in alpha platelet granules will be rapidly transferred to the surface when the platelets are activated and subsequently released from the surface as a soluble CD40 ligand (sCD40L). Soluble CD40 ligand (sCD40L) acts as a bridge between the inflammatory process, atherosclerosis, and thrombosis. This study aims to study the relationship between sCD40L levels and the incidence of ACS in patients with chest pain in Dr.Soetomo General Hospital, Surabaya.

Method: Research subjects were 40 patients with chest pain who came to Emergency Room at Dr.Soetomo General Hospital, Surabaya. The patients were grouped based on the diagnosis of ACS and non-ACS with the electrocardiogram and troponin T. Serum levels of patients that examined by sCD40L with enamine-linked immunosorbent assay (ELISA) method from Quantikine®.

Results: Twenty-six (65%) were diagnosed with ACS and 14 (35%) were non ACS. The diagnosis of ACS includes ST-segment elevation myocardial infarction (STEMI), non-ST-segment elevation myocardial infarction (NSTEMI), and unstable angina (UA), with the highest proportion being STEMI at 15 (57%). Spearman correlation test of sCD40L level with ACS incidence got correlation coefficient rho (ρ) = 0.52 (p = 0.001).

Conclusion: There was a moderate positive correlation between sCD40L levels and ACS incidence in patients with chest pain.

Keywords: CD40L, Acute Coronary Syndrome, Chest Pain, Unstable Angina

Introduction

Cardiovascular disease is a global health problem responsible for 30% of death globally. Data in 2005 suggested that 17 million deaths from a total of 58 million deaths worldwide were caused by cardiovascular disease ¹. The American Heart Association (AHA) mentions that 71.3 million Americans suffer from the cardiovascular disease in 2003. Cardiovascular disease accounted for nearly 1 million deaths in 2003 with 53% of those caused by coronary heart disease (CHD) ².

The mortality rate due to cardiovascular disease in Indonesia also increases annually, reaching almost 30% in 2004 compared to only 5% in 1975. Data from the Indonesian National Health Survey conducted by the Ministry of Health of the Republic of Indonesia stated that cardiovascular disease is the leading cause of death in Indonesia with CHD as the main cause by 26.4% ³.

The manifestations of CHD are the occurrence of acute coronary syndromes (ACS), which include unstable angina/UA (angle) and acute myocardial infarction (AMI). The data from the Directorate General of Pharmaceutical and Medical Devices of the Ministry of Health of the Republic of Indonesia in 2006 stated that ACS caused a huge number of hospitalizations and a major and most frequent cause of death for CHD.

The high rate of ACS death causes the need for a proper understanding of the pathogenesis disease, thus helping to find a quick and accurate examination for diagnosis. Biological markers currently used for diagnosis of molecules released after the occurrence of myocardial necrosis, such as troponin and natriuretic peptides. The markers are clinically useful, but they have not been able to describe the pathogenesis of the early phase of atherothrombosis. An alternate marker is needed that can not only help diagnosis but may also provide an understanding of the pathogenesis of ACS.

The concepts put forward today are that inflammatory markers, endothelial dysfunction, and platelet activation that can be used to identify disease activity even before myocardial necrosis occurs. One of the concepts underlying the mechanism of atherothrombotic pathogenesis involves the interaction between CD40 and CD40 ligand (CD40L). CD40 is a transmembrane protein receptor that belongs to the group of superfamily tumor necrosis factor (TNF). CD40L is stored in the alpha platelet granule and is rapidly transferred to the surface at which platelets are activated. CD40L that has been expressed on the surface will soon be broken down and released from the surface of platelets as soluble CD40 ligand (sCD40L).

Until now the role of sCD40L in the process of ACS has not been fully understood. Several studies have shown that CD40 and CD40L are one of the mediators of vascular inflammation and act as a bridge between the inflammatory process, atherosclerosis, and thrombosis. Research on the sCD40L level and its relation to ACS incidence have not been performed, so that this study aims to know the relationship between sCD40L level with ACS incidence in Dr. Soetomo General Hospital, Surabaya.

**Method**

This research uses analytic observational research design with the cross-sectional design. The study was conducted at Emergency Room of Dr. Soetomo General Hospital, Surabaya, and Installation of Clinical Pathology Faculty of Medicine Universitas Airlangga/Dr. Soetomo General Hospital Surabaya. This research implemented in April to June 2013. All patients who become the sample of the study must meet the inclusion criteria, among others; patients with chest pain, aged ≥30 years, have complete medical records. While for exclusion criteria, among others; patients had sepsis, acute stroke, until serum creatinine>2 mg/dl.

The laboratory procedure in this study was started by examining the sCD40L level using the enzyme-linked immunosorbent assay (ELISA) method of Quantikine®. Then the inspection principle of sCD40L was an enzyme-labeled enzyme by the sandwich. The microplate coating was coated with polyclonal antibodies specific to CD40L. A number of samples were dripped with a pipette into the well so that the CD40L present in the sample would bind to the antibody. Washing was done to remove unbound substances, then polyclonal antibodies labeled with specific enzymes for CD40L are added to the well. The washing was performed again to remove the unbound enzyme-labeled antibody reagents.

The substrate was added and the color change occurs that measured after the addition of the reagent to stop the reaction. After that, the sample for serum sCD40L level examination. Serum samples were obtained from 5 ml of venous blood inserted into serum separator tube (SST). The sample was allowed to form the clot for 30 minutes before centrifugation at 1000g for 15 minutes.

The serum transferred into an aliquot tube and stored at a temperature of -20°C until examination. Serum samples were diluted 5 times by adding 50 μl samples with 200 μl diluent calibrator RD5P. Followed by preparing the reagent which the first left for some time at room temperature before use. The inspection procedure for sCD40L levels was expanded when all reagents, standards, and samples have been prepared. The microplate strip to be used as released from the intact microplate. The microplate was placed in a horizontal orbital shaker with a speed of 500 ± 50 rpm and incubated for 2 hours at room temperature.

The standard curve was made by inserting the absorbent of each standard solution on the y-axis and the level on the x-axis, then connecting the dots into a straight line. Nonlinear data can use absorbent logs and logs. The levels can be read with standard curves based on each absorbent. SCD40L sample rate was the multiplied reading result level 5.

All data on ACS patient characteristics, distribution, and frequency of ACS are presented descriptively. Diagnostic value of examination of sCD40L as the marker of ACS in Dr. Soetomo Surabaya obtained from the calculation of the formula to calculate the sensitivity, specificity, positive predictive value, and negative predictive value, using 2x2 tables. Statistical analysis to
determine the relationship between sCD40L and ACS incidence by using Pearson correlation test.11

Results

The lowest SCD40L test result of patients with chest pain was 0.07 ng/ml obtained in Stable Angina patients while the highest level was 12.39 ng/ml obtained in patients with NSTEMI diagnosis. The mean sCD40L level of chest pain patients was 4.23 ± 3.49 ng/ml. ACS patients had mean sCD40L levels of 5.45 ± 3.70 ng/ml, while non-ACS patients had mean sCD40L levels of 1.97 ± 1.33 ng/ml. The mean rate of patients with the diagnosis of ACS was significantly higher than the mean rate of patients with non-ACS diagnosis (p <0.05), whereas the mean sCD40L concentration in ACS subgroup did not find the significant difference (Table 1).

The SCD40L levels of ACS patients were 16 (61.53%) above the cut off (> 2.99 ng/ml) while 10 (38.47%) were obtained to be lower than cut off (<2.99 ng/ml). Most non ACS patients, 10 (71.42%) had sCD40L levels below cut off (<2.99 ng/ml), while the remaining 4 (0.28%) had sCD40L levels above cut off (> 2.99 ng/ml) (Table 2). The calculation of the diagnostic value of sCD40L based on 2x2 table showed 61.53% sensivitas, specificity 71.4%, predictive value 80% and 50% negative predictive value (Table 3).

Correlation analysis aims to determine the pattern and closeness of the relationship between two or more variables. Statistical analysis to determine the relationship between sCD40L level and ACS incidence using Spearman test because the sCD40L content data is not normally distributed. Result of statistical analysis got coefficient correlation rho (ρ) = 0.52 with value p = 0.001. This means that the sCD40L level was moderately correlated with the ACS incidence and this correlation was significant. The positive correlation coefficient indicates that the correlation was unidirectional, i.e., higher sCD40L levels will increase the incidence of ACS.

**Discussion**

The results of mean random blood glucose levels in ACS patients were higher than non-ACS patients. This is in accordance with previous studies that mention that acute hyperglycemia occurs in about 50% of patients with ACS. Cardiovascular stress will trigger the release of catecholamine, cortisol, and glucagon hormones resulting in increased glucose and free fatty acids increased hepatic gluconeogenesis and decreased peripheral glucose uptake. Acute hyperglycemia will worsen the prognosis and improve the mortality of ACS patients with or without previous diabetes history.

There was no difference between total cholesterol, triglyceride, and LDL cholesterol in ACS and non-ACS patients. The mean rate of HDL cholesterol in ACS patients was lower compared with non-ACS patients. This is in accordance with studies suggesting that elevated levels of HDL cholesterol are a protective factor, while low HDL cholesterol levels increase the risk of atherogenesis.

SCD40L examination results in patients with chest pain have the diagnosis of ACS was significantly higher than that of chest pain patients with a non-ACS diagnosis. It was in accordance with previous studies suggesting that elevated sCD40L may be used as a marker for thrombotic inflammatory activity in ACS patients. However, elevated sCD40L levels cannot be used to distinguish the ST elevation of myocardial infarction (STEMI), Non-ST elevation myocardial infarction (NSTEMI), or Unstable Angina (UA).

Platelet activation is an important key to the development of ACS. Subendothelial collagen exposure to platelets causes the activation and secretion of several thrombotic and proinflammatory molecules during the acute phase of myocardial infarction. sCD40L is one of the proinflammatory molecules secreted by active platelets and involved in the process of plaque destabilization and thrombus formation.

Increased sCD40L levels were also one of the causes of ACS, which allows continuous cycles in ACS patients. The occurrence of elevated sCD40L levels is due to plaque rupture. The results of the use of sCD40L levels were lower than previous studies. Previous studies have suggested that the use of sCD40L for diagnosis of ACS in patients with chest pain has a sensitivity of 90% and a specificity of 86%. The reason for the difference between this study and the previous was the number of samples used.

Risk factors that may affect the occurrence of ACS were smoking history. Smokers tend to have higher levels of sCD40L compared to nonsmokers. If the patient has a history of previous diseases such as diabetes, hypertension, and dyslipidemia may affect the patient’s sCD40L level. Patients with a history of hypertension tend to have the CD40/CD40L system become more reactive so that sCD40L levels become higher. SCD40L levels will also increase in dyslipidemia patients. Other conditions of increased levels of sCD40L were autoimmune diseases, multiple sclerosis, inflammatory bowel disease, and stroke.

 Several ACS patients in this study had a history of using drugs such as Aspirin and Simvastatin. Studies show that there is no association between aspirin use and serum sCD40L levels. Aspirin is often used in patients
with angina and may inhibit some platelet function, but inhibition of sCD40L release requires a stronger platelet inhibitor, such as GP IIb/IIIa inhibitors. The use of drugs for the treatment of dyslipidemia and hypertension such as Simvastatin, Losartan, or a combination of both for 2 months can lower sCD40L.

The result of correlation of sCD40L with ACS incidence has the moderate correlation, and the higher the sCD40L cause the higher incidence of ACS. Studies suggest that elevated levels of sCD40L are an independent risk factor for the occurrence of death and recurrent myocardial infarction in ACS patients. Other studies suggest that elevated sCD40L levels will increase the risk of follow-up cardiovascular events, such as Acute myocardial infarction (AMI), sudden death, and recurrent angina in CHD patients.

**Ethical Clearance:** This research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, nonmaleficence, and justice.

**Conflict of Interest:** The author reports no conflict of interest of this work.

**Source of Funding:** This study is done with individual funding.

**Conclusion:** Based on the results of analysis and discussion it can be concluded that sCD40L levels in patients with chest pain have diagnosed of ACS that significantly higher than patients with the non-ACS diagnosis. The use of sCD40L level for diagnosis of ACS in patients with chest pain was 61.53% sensitivity and 71.4% specificity. The correlation results obtained positive moderate correlation between sCD40L level and the incidence of ACS in patients with chest pain.

¹Armed Forces College of Medicine (AFCM), 6 Ehsan Abd El Kodous Street, Cairo 11774, Egypt, ²Department of Forensic Medicine and Clinical Toxicology, ³Department of Neurosurgery, Faculty of Medicine, Cairo University, Kasr Alainy Street, Cairo 11562, Egypt.

Abstract

Background: Radiography is traditionally used as a complement tool for forensic examination. CT applications became widely used. Traumatic cerebral hemorrhage occurs in up to 15% of patients following head injury and non-traumatic cerebral hemorrhage accounts for up to 44% of all strokes. These two disorders are therefore very common. So there is a need for accurate diagnosis of cerebral hemorrhage form medicolegal aspect. This study aims to differentiate between traumatic and non-traumatic cerebral hemorrhage by using CT.

Methods: This prospective study, was conducted on 100 patients with intracranial hemorrhage and divided in two equal groups (traumatic and non-traumatic cerebral hemorrhage) both groups were examined by CT head and the results were analyzed.

Results: There was statistically significant difference between traumatic and non-traumatic cerebral hemorrhage groups in CT finding as regard type of hemorrhage with epidural, subarachnoid and intraventricular with P value (0.001, 0.005 and 0.001) respectively. Also according to site of hemorrhage in frontal lobe and subcortical with P value (0.001) equally.

Conclusion: we conclude that equation

\[ f = -0.976 \text{ (constant)} + 2.873 \text{ (Epidural)} + 2.017 \text{ (Subarachnoid)} - 0.416 \text{ (Intraventricular)} + 0.984 \text{ (Frontal)} - 3.047 \text{ (Subcortical)} \]

If the function \( f = + \) values, it will be traumatic hemorrhage and if the function \( f = - \) values it will be pathological hemorrhage.

Keywords: CT, traumatic, non-traumatic, cerebral hemorrhage, forensic

Introduction

Radiography is traditionally used as a complement tool for forensic examination, serving primarily to document metallic bullet fragments, foreign bodies, fractures, and injury patterns¹. CT applications became widely used and had been introduced as a routine investigation in forensic medicine².

The frequency of traumatic brain injuries is high among young children and elder age groups due to road traffic accidents, work or sport accidents, firearms, and falls from height³. On the other hand, non-traumatic cerebral hemorrhage caused by hypertension (36%), aneurysm (36%), arteriovenous malformation (11%) and other causes (17%)⁴.

There is a need for accurate diagnosis of different types of cerebral hemorrhage including epidural, subdural, subarachnoid and intracerebral hemorrhage with the increasing awareness of its high prevalence⁵. Imaging methods may be capable of detecting a number of the pathoanatomical and pathophysiological consequences of focal and diffuse traumatic brain
The location of the hemorrhage is very important in the diagnosis of the nature of the hemorrhage. Subdural hemorrhage and epidural hemorrhage are mainly traumatic, while a subarachnoid hemorrhage and intracerebral hemorrhage when not accompanied with bruises and lacerations of the brain it can be non-traumatic.

Radiological imaging such as CT offering a non-invasive approach and unlimited storage and can provide as a second opinion in the court.

Material and Method

This study is a prospective, case control study conducted on 100 patients with intracranial hemorrhage selected from cases presented to the Neurosurgery department, Faculty of medicine, Cairo University, from February 2017 to January 2018.

Intracranial hemorrhage may be non-traumatic or traumatic in nature, so the patients were divided into two groups according to history of trauma as following:

♦ **Group 1 (Traumatic):** 50 patients with history of trauma.

♦ **Group 2 (Non-traumatic):** 50 patients without history of trauma.

Patients’ Inclusion Criteria:
1. Both gender was included.
2. Different age groups ( > 18, 18-54, < 55).
3. Craniocerebral hemorrhage as a primary cause of neurological deficit regardless of the etiology.

Patients’ Exclusion Criteria:
1- Cases due to thrombotic embolization.
2- Cases due to intracerebral infection.
3- Cases due to congenital anomalies (Except vascular anomalies).
4- Cases due to neoplastic lesions unless the incidence is acute due to associated hemorrhage.

Cases were analyzed with respect to:
- patients age and sex
- Presence or absence of history of head trauma to classify cerebral hemorrhage to traumatic and non-traumatic
- In traumatic group: the cause of trauma as road traffic accident (RTA), assault, fall from height or others.
- Data from application of cranial CT on Toshiba Alexon 16-slice multidetector CT scanners to detect:
  - Cause of hemorrhage in pathological group aneurysm, hypertension (HTN) or arterovenous malformation (AVM).
  - Type of hemorrhage and combined types of hemorrhages.
  - Site of hemorrhage and combined sites of hemorrhages.

Statistical analysis:
- Data were coded and entered using the statistical package SPSS version 25. The comparisons between quantitative variables were done using the non-parametric Mann-Whitney test. And for comparing categorical data, Chi square (χ²) test was performed. Exact test was used instead when the expected frequency is less than 5. P-values less than 0.05 were considered as statistically significant.

Discriminant analysis was done to discriminate between pathological and traumatic. Stepwise statistics revealed the significant predictors which were used to determine the discriminate function. Then group centroids (group means) were calculated, they represent the determinant points for discrimination between traumatic and pathological. Classification of the percentage of accurately classified cases according to the discriminate function was performed.

Finding

This study was conducted on 100 patients with intracranial hemorrhage and divided into two equal groups according to history of trauma (traumatic group and non-traumatic group).

Results showed that the mean age was (33.78) years old in (Traumatic) and (49.30) years old in (non-traumatic).
Regarding gender the majority of the cases are males which represent (68%) and female cases represent (32%).

Regarding types of trauma in traumatic group the most common cause is RTA (42%) then followed by assault (34%) then followed by fall from height (20%).

According to pathological causes in non-traumatic group, the most common cause is aneurysm (54%) then followed by HTN (38%).

Table (1): Show comparison between Traumatic group and Non-traumatic group as regard type of hemorrhage according to CT finding. It shows statistical significant difference with epidural, subarachnoid and intraventricular with P value (0.001, 0.005 and 0.001) respectively.

**Discussion**

Traumatic cerebral hemorrhage and non-traumatic cerebral hemorrhage are therefore very common\(^2\). So the accurate diagnosis of cerebral hemorrhage is important from medicolegal aspect.

The study showed that the mean age was (33.78) years old in Traumatic group and the mean age was (49.30) years old in Non-traumatic group.

These results were in agreement with those of Zhou\(^3\) who found that the incidence of acute spontaneous intracranial hemorrhage tended to increase with increasing age, the incidence of traumatic brain injury tended to decrease with decreasing age.

Regarding sex, it was found that male patients were higher which represent (68%) and female cases represent (32%).

These results were in agreement with those of Pruitt\(^4\) who found that (61.1%) of patients were males.

Also it was found in the present study that male patient are higher in Traumatic group and female patient are higher in Non-traumatic group. This result agrees with those of Al-Yessary\(^5\) who found males were more frequent among traumatic group, while females were the more frequent gender in spontaneous group and it was explained according to van Beijnum\(^6\) that the traumatic intracranial hemorrhage had mostly occurred in males because they usually expose to violence and trauma more than females. Spontaneous intracranial hemorrhage had mostly occurred in females, and that may be due to their higher reaction to emotional stress than that of males.

Regarding the type of trauma in traumatic group in the present study, it was found that the most common cause of traumatic intracranial hemorrhage is road traffic.

This disagrees with the study conducted by Pruitt\(^4\) who found the most common cause of injury was fall which represent (69.6%).

It was noticed that different of most common cause of head injury from country to another. It was explained by Odero\(^7\) as he mentioned that increasing rate head injury in developing nations due to increasing incidence of road traffic accidents.

Regarding the pathological causes in Non-traumatic group, it was found the most common cause of non-traumatic intracranial hemorrhage was aneurysm (54%) then followed by HTN (38%).

According to Van\(^8\) the majority causes of nontraumatic intracranial hemorrhage was hypertension (36 %), aneurysm (36 %) with equally percent.

Regarding type of hemorrhage, it was found that patients with epidural hemorrhage was more common in Traumatic group while patients with subarachnoid and intracerebral were more common in Non-traumatic group.

These results were in agreement with those of Suthar\(^9\) as they found in their study subarachnoid hemorrhage,
intracerebral hemorrhage and intraventricular hemorrhage were more common in spontaneous intracranial hemorrhage and epidural hemorrhage and subdural hemorrhage were more common in traumatic intracranial hemorrhage.

Regarding combined types of hemorrhage, it was found that patients without combined types of hemorrhage (one type) were (82%) in Traumatic group and (72%) in Non-traumatic group and patients with combined types of hemorrhage (18%) in Traumatic group and (28%) in Non-traumatic group.

These results were in agreement with those of Pruitt\textsuperscript{14} as they found that (74.3%) of traumatic patients had a single type of intracranial lesion versus (24%).

Regarding site of hemorrhage in the present study, it was found that Patients with hemorrhage in frontal lobe were (28%) in Traumatic group and (4%) in Non-traumatic group and patients with hemorrhage in subcortical (0%) in Traumatic group and (60%) in Non-traumatic group.

These results were in agreement with those of Suthar\textsuperscript{5} as they found in their study that the most common site of hemorrhage was basal ganglia (subcortical) (60%) in spontaneous intracranial hemorrhage.

Our results showed that most common site in traumatic intracranial hemorrhage was parietal, frontal, and temporal. These results were in agreement with those of Adekanmi\textsuperscript{19} who found that most of the bleeds were located in the parietal and frontal lobes, followed by temporal.

### Conclusion

From the present study, it was concluded that:

- Males were more commonly affected by cranial hemorrhages than females and higher in traumatic group but females were higher in non-traumatic group and the traumatic patients were younger than non-traumatic patient.
- The most common cause of traumatic intracranial hemorrhage is RTA followed by assault and the most common cause of non-traumatic intracranial hemorrhage is aneurysm then followed by HTN
- The most common type of hemorrhage in traumatic group was epidural while in non-traumatic group was subarachnoid hemorrhage.
- The most common site of hemorrhage in traumatic group was in parietal while in non-traumatic was in subcortical.
- The patients with single site of hemorrhage were higher in traumatic group while patients with combined site of hemorrhage were higher in non-traumatic group.
- We conclude the most important and significant finding in CT brain and we done discriminant function analysis model to discriminate between traumatic and non-traumatic cerebral hemorrhage and we found that equation

\[
\text{Function (f) = - 0.976 (constant) + 2.873(Epidural) + 2.017 (Subarachnoid) - 0.416 (Intraventricular) + 0.984 (Frontal) -3.047 (Subcortical)}
\]

According to function at group centroids we found non-traumatic was (-1.485) and traumatic was (1.485), so if we have the function (f) = + values (> 0) most probably it will be traumatic hemorrhage and if the function (f) = - values (< 0) most probably it will be non-traumatic hemorrhage as the accuracy of that model is 90%.

Abstract

Background: Premenstrual syndrome (PMS) is a set of physical and psychological symptoms such as mood disability, breast tenderness, food craving, fatigue, and depression. Fluoxetine and Non-Steroidal Anti-Inflammatory Drugs (NSAIDs) usually are being administered for these patients. This study aimed to evaluate the effect of saffron plant in terms of its anti-inflammatory and anti-depressant effects compared to fluoxetine.

Materials and Method: This study was a three-blind clinical trial that was carried out on working women and their relatives. Firstly, 164 patients with the premenstrual syndrome were selected, and they were randomly divided into two 82-person groups, including those who received fluoxetine and those who received saffron. Next, both groups were treated for two months. The data were collected in two stages through a self-designed questionnaire (on day 5 of menstrual cycle) and validated questionnaires of PRISM and Beck at the end of the period.

Results: It was indicated that similar to fluoxetine, the use of saffron in PMS reduced the symptoms such as abdominal bloating, depression, and mood swing, but the latter could better relieve the breast and abdominal pain than fluoxetine.

Conclusion: It was concluded that the use of medicinal herbs such as saffron could be effective in reducing the symptoms and they might cause fewer side effects than chemical drugs.

Keywords: Saffron, fluoxetine, premenstrual syndrome.

Introduction

PMS is a type of mild to moderate neuropsychological disorder. Although its mild type occurs in 90% of cases, it is argued that its severe type occurs only in 5% of cases. PMS is a collection of physical, psychological and emotional symptoms associated with the menstrual
cycle in women. The syndrome begins 7 to 10 days before the start of menstruation, and it must be recorded in 2 consecutive cycles. It is associated with a set of physical and psychological symptoms such as mood swings, sensitization of breast, food craving, fatigue, irritability and depression. It is estimated that three swings, sensitization of breast, food craving, fatigue, physical and psychological symptoms such as mood in 2 consecutive cycles. It is associated with a set of before the start of menstruation, and it must be recorded in their late 30s and 40s.

Serotonin Reuptake Inhibitors (SSRIs), including Fluoxetine (Prozac, Sarafem), Paroxetine (Paxil, Pexeva), Sertraline (Zoloft), etc usually are recommended for the treatment of PMS. These drugs have been effective in improving symptoms such as fatigue, food cravings, and sleep disorders, and they are among the first choices to treat severe types of PMS.

Moreover, the consumption of Non-Steroidal Anti-Inflammatory Drugs (NSAIDs), diuretics as well as lifestyle changes are suggested for these patients. Some herbal medicines can also be effective in treating this syndrome. Saffron plant is one of these herbal medicines that is characterized by some anti-inflammatory and anti-depressant effects and, thus, it can be useful in treating this syndrome. Since the symptoms of the syndrome disrupt everyday life, it is beneficial to identify the ways of treatment, straightforward, harmless, and accessible treatments. Saffron has known anti-nociceptive, relaxing and anti-inflammatory effects as well as anti-depressant effect on humans and animals. It was attempted to examine the impact of this Iranian traditional and valuable herb in comparison with fluoxetine as a relatively well-known drug in the treatment of psychiatric disorders and even PMS. The purpose of this study was to reduce the complications of chemical medicines and medicinal herbs.

**Materials and Method**

This study was an interventional three-blind trial). This means that the patient, physician, and statistical analyst did not know the contents of the capsules (that was carried out on women employed in Deputy of Health of Sabzevar University of Medical Sciences, Occupational Medicine Center as well as their relatives. Regarding this, 164 employees who had approved a PMS based on two previous menstrual cycles and Hamilton Test were randomly selected, and written consents were obtained from them. Treatment included 20 mg capsules of fluoxetine in the control group and 30 mg capsules of saffron in the intervention group. The capsules were identical in appearance. The treatment allocation was randomly divided into two 82-person groups, and the drug packages were provided to patients by a person who did not know the contents of the drug packages. The two groups were treated in parallel. The duration of the treatment was two months, and the forenamed drugs should be taken daily from day 14 to day 28 of the menstrual cycle (within 14 days of the follicular phase). During the last 5 days of each cycle, the researchers attempted to record the concerned data using a self-designed checklist. During the treatment period, it was attempted to make sure that each patient made use of the prescribed drugs and that no associated drugs were used accordingly and no displacement occurred between the two groups. Furthermore, patients were reminded that they could contact the researchers if they had any new drug-related problems. It was also stipulated that if severe symptoms of depression occurred, which coerced the patients to use other drugs accordingly, the patients would be excluded from the study. Besides, if patients in the intervention group were obliged to use fluoxetine for some reason, these matters would be considered when analyzing the control group. At the end of each treatment period, it was attempted to make use of Beck Anxiety Inventory in order to determine the severity of anxiety and depression among patients. This questionnaire was a 21-point scale in which the patient chose one of four options in each item, and it indicated the severity of his/her anxiety. Four options of each question were scored in a four-part range from 0 to 3. Each test item described one of the common symptoms of anxiety (mental, physical and panic symptoms). The maximum score of this questionnaire was 63, and it was indicated that scores located between 0 and 7 were normal, scores located between 8 and 15 were mild, scores located between 16 and 25 were medium, and scores located between 26 and 63 were severe thereof. In addition, Visual Analogue Scales (VAS) was used to assess the severity of abdominal and breast pain (scores less than 3 showed mild abdominal pain, scores located between 4 and 7 indicated medium abdominal pain and scores located between 8 and 10 showed severe abdominal pain). In examining the amount of abdominal bloating, the patients were asked to measure their abdominal circumference (actually, patients were trained accordingly) (0-1 cm = unchanged, 1-2 cm = mild, 2-3 cm = medium and 3-4 cm = severe). Finally, the data were analyzed through Chi-square Test using...
Results

In this study, 164 people participated (each group was 82 individuals). The mean age of the patients was 35.5 ± 13 years (Range: 26-45). After comparing the two groups, it was shown that the age distribution was similar in both groups (the age distributions in the intervention and control groups were 36.5 ± 10 and 34 ± 5.30 years old, respectively). It should be noted that all patients were married.

Having examined the abdominal pain using the Visual Analogue Scales, it was found that there was no significant difference in the improvement of abdominal pain in the two groups (P>0.05). Having compared the severe to moderate abdominal pain, there was a significant difference between the two groups at the end of the first month (p = 0.01) and the second month (p = 0.03) (Table 1).

* Given the anxiety level, it was declared that there was no significant difference in the reduction of anxiety level between the two groups (P>0.05). Having compared the severe to moderate anxiety, it was indicated that despite significant reduction in anxiety level after taking drugs, notably saffron, there was not a significant difference between the two groups at the end of the first month (p = 0.83) and the second month (p = 0.09) (Table 2).

Comparing the breast pain in saffron group with fluoxetine, it was indicated that there was a significant difference between the two groups at the end of the first month (p = 0.0001), but there was not a significant difference between the two groups at the end of the second month (p = 0.014) (Table 3).

It was shown that there was no significant difference between the two groups according to depression(P>0/05) (Table 4).

In the study of mild, medium and severe abdominal bloating, there was no significant difference between the two groups at the end of the first and second months (P>0/05) (Table 5).

The side effects of saffron were not observed during the study.

Discussion

PMS is a collection of physical, psychological and emotional symptoms associated with menstrual cycle in women. The syndrome begins 7 to 10 days before the start of menstruation, and it must be recorded in 2 consecutive cycles. Although its mild type occurs in 90% of cases, it is argued that its severe type occurs only in 5% of cases. It is associated with a set of physical and psychological symptoms such as mood swings, sensitization of breast, food craving, fatigue, irritability and depression 1. It is estimated that three women (out of 4 women) will experience this syndrome in their menstrual cycle. Some women experience this syndrome at the age of 20, but others suffer from this problem in their late 30s and 40s 2, 3. Many medicines are proposed to treat this syndrome, and some herbal medicines have been effective in treating this syndrome. Saffron plant is one of these herbal medicines that is characterized by some anti-inflammatory and anti-depressant effects and, thus, it can be effective in treating this syndrome. Since the symptoms of the syndrome disrupt everyday life, it is beneficial to identify the ways of treatment, especially simple, harmless and accessible treatments 1-7. Considering the known anti-nociceptive, relaxing and anti-inflammatory effects of saffron extract as well as its anti-depressant effect on humans and animals 10, it was attempted to examine the effect of this Iranian traditional and valuable herb in comparison with fluoxetine as a relatively well-known drug in the treatment of psychiatric disorders and even PMS.

This study was an interventional three-blind trial that was carried out on 164 women as well as their relatives. The most common age group afflicted with the PMS was those patients aged 16 to 45 years old. Compared to fluoxetine, it was indicated that if patients consumed saffron, their symptoms of abdominal and breast pain were alleviated better and more efficiently. However, there was no significant difference between the two groups in terms of reduction in anxiety level.

Mokhber et al. (2004) reported that the improvement in symptoms of depression, emotional dysfunction, appetite changes, lack of self-control, decreased interest in doing activities, concentration disorders, and sleep changes were significantly higher in fluoxetine-treated patients 13. They also evaluated the improvement of physical symptoms and tiredness and asserted that there
was no significant difference between placebo and fluoxetine.  

In our study, the intake of fluoxetine and saffron alleviated the depression and anxiety symptoms, but there was no significant difference between them. Moreover, the present study indicated that, compared to fluoxetine, saffron could better alleviate the symptoms of abdominal and breast pain.

Besides, Agha-Hosseini et al. found that, compared to placebo, saffron significantly improved the symptoms of PMS (up to 50%). Similarly, the present study showed that saffron could significantly alleviate the symptoms of PMS (i.e., depression, abdominal bloating, abdominal pain, breast pain, and anxiety).

Kashani et al. (2017) reported that saffron acted similar to fluoxetine in alleviating depression. They also found that saffron is a safe alternative medication for improving depressive symptoms of postpartum depression. Similarly, the results of the present study confirmed this anti-depressant effect of saffron.

One of the strengths of this study was to investigate the effects of saffron on patients who were all married. Inevitably, this homogenization reduced the impact of interfering factors.

Accordingly, it can be argued that the administration of saffron in the follicular phase of menstruation has a better effect on alleviating the severity of symptoms of the PMS than fluoxetine.

Considering the fact that pharmaceutical drugs and chemicals poisoning are common in Iran, considering traditional plant may be a better option in the PMS.

**Conclusion**

It was concluded that the use of medicinal herbs such as saffron could be effective in reducing the symptoms and they might cause fewer side effects than chemical drugs.

Abstract

Background: Non-steroidal analgesics are the most commonly used analgesics for pain relief in opioids induced withdrawal. One of the herbal remedies that reduce muscle pain, anxiety, and fatigue is Passiflora Incarnata (P. incarnata). In this study, we compared Piroxicam and P. incarnata in withdrawal-induced myalgia and anxiety.

Materials and Method: This was a clinical trial carried out on 43 candidate patients for maintenance treatment with methadone. The individuals were randomly divided into two groups. The control group was prescribed piroxicam capsule (10 mg every 12 hours), while the intervention group received drops of P. incarnata (10-15 drops three times a day), until symptoms of withdrawal were resolved (7 to 10 days). In the first, 3rd, sixth, and ninth days of treatment, the patient’s vital signs, myalgia (visual acuity), and anxiety (Beck test) were recorded and analyzed.

Results: The results of this study revealed that the flower drops resulted in a reduction in myalgia (mean score of 5.4± 0.79 on the first day decreased to 1.3 ±0.5 on the ninth day), but there was no significant difference in comparison with Piroxicam (p=0.705). Further, P. incarnata significantly reduced the anxiety caused by withdrawal (p =0.001).

Conclusion: P. incarnata drop can be used to reduce the pain and anxiety caused by the drug’s withdrawal.

Keywords: Passiflora Incarnata, Myalgia, Anxiety, Addiction withdrawal.

Introduction

Today, drug addiction and opioids poisoning are social, health, and political problem involving most countries of the world, especially the developing countries. Opioids use has so many direct or indirect adverse on human health. Unfortunately, drug addiction and poisoning in adolescence and youngsters also are increasing. Methadone is a proper replacement for withdrawal situation. Withdrawal is also accompanied by important consequences such as anxiety, stress, nervous seizures, and severe myalgia. Tolerating myalgia is hard and unbearable for an addicted person.

Non-steroids are one of the most commonly used analgesics to reduce the pain caused by withdrawal. While based on Iranian traditional medicine, one of the herbal remedies that reduce myalgia, anxiety, and...
grouch is *Passiflora incarnata*\(^\text{15}\).

*Passiflora incarnata* L. (Passifloraceae) is used in traditional herbal medicines, which has shown different therapeutic properties \(^\text{16, 17}\). Interestingly, in India, it is used to treat morphine’s dependence \(^\text{18}\), while in Africa, it is used for its sedative and analgesic properties \(^\text{19, 20}\). The *P. incarnata* is not narcotic or addictive, so it is used in tea, pills, and drops for treatment of sleep disorders, restlessness, irritability, and anxiety \(^\text{15, 21, 22}\). In recent years, many studies have been conducted on the effective substances of this plant as anti-anxiety and toxicity properties \(^\text{23-25}\), and as a benzodiazepine-receptor agonist \(^\text{24}\). Animal studies have also revealed that *P. incarnata* L. has been effective in controlling the pain caused by alcohol withdrawal \(^\text{20}\). Meanwhile, other studies have indicated that when the plant is used in the treatment, it reduces the need for opioids in addicts \(^\text{26}\).

Piroxicam is a potent inhibitor of the cyclooxygenase enzyme with some serious adverse effects \(^\text{27}\). Regarding the effects of analgesic drugs and very few studies on the effectiveness of *P. incarnata* plant in some common complications of drug addiction withdrawal, this study was conducted to compare the effects of Piroxicam and *P. incarnata* on myalgia and anxiety due to addiction withdrawal.

**Materials and Method**

This project was a single-blind clinical trial performed on clients of addiction treatment centers in Sabzevar city. Conscious informed consent form was obtained from all participants in the study. The project was also registered as IRCT20170404033202N6 at the Iranian Center for Clinical Record Registration. Forty-three patients who wanted to replace use of opium with methadone were included into the project with personal satisfaction. The subjects were divided into two groups using simple random method. Piroxicam (10 mg once every 12 hours) was prescribed to one group (\(n = 20\)), while the other group (\(n = 23\)) received *P. incarnata* drop (10-15 drops based on the weight three times a day) \(^\text{28, 29}\), which were consumed until the withdrawal symptoms resolved and methadone dosage stabilization (between 7 and 9 days).

The patients received methadone and analgesic every day, until resolution of withdrawal symptoms and methadone dose stabilization. Every three days (1st, 3rd, sixth and ninth), the patient’s vital signs were based on a self-designed checklist; the amount of muscle pain was completed based on the Visual analog scale (VAS) and anxiety based on the Beck test. If the visual score of pain was more than 9, then pain reliever would begin and be excluded from the study and another person would be replaced. The Beck Anxiety Questionnaire has a high validity rating \(^\text{20}\). The total score of this questionnaire lies within the range from 0 to 63 \(^\text{30}\). The pain was measured by the researcher using Visual Analog Scale (VAS), standardized for pain assessment.

Finally, the data were collected and analyzed by SPSS20 through independent T-tests, paired t-test, and repeated measurement.

**Results**

In the study of 43 individuals selected in this study, the mean age of the subjects was \(35.7 \pm 3.5\) years in the two groups, with a total of at least 28 years and a maximum of 45 years old, where most patients were 30 to 42 years old. The mean age in *P. incarnata* group was \(37 \pm 4\) years and \(34.5 \pm 3\) years in the Piroxicam group (Table 1).

All subjects were male, so in terms of the threshold of pain, there is no confounding. The frequency of drug use was between 1 and 3 times a day, with an average of \(2.4 \pm 0.2\) mg/dl in the intervention group, and in the control group \(2.3 \pm 0.2\) times a day. Most of the patients used opium three times a day. The mean amount of consumed drug (opium) was \(1.28 \pm 0.5\) in the intervention group, and \(1.21 \pm 0.5\) in the control group. The duration of opium addiction varied from 1 to 4 years, with an average of 2.68 years. The number of drug intake days (passiflora or piroxicam) was between 7 and 9 days until all the symptoms of pain were resolved. A total of 41% of people had 8 days of taking medication (pain reliever). The mean of Piroxicam and Passiflora use was \(8 \pm 0.79\) and \(7.96 \pm 0.76\), respectively (\(p = 0.85\)). The mean score of pain and anxiety before the intervention was not significantly different between the two groups (\(p > 0.05\)).

In the Piroxicam group, the mean score of the VAS on the first day was \(0.86 \pm 4.7\), and on the ninth day, it was \(0.51 \pm 0.1\), which showed a significant decrease (\(p < 0.001\)). In the *P. incarnata* group, pain intensity was \(0.79 \pm 5.4\) on the first day and decreased to \(0.5 \pm 1.3\) on the ninth day (\(p < 0.001\)).

Comparison of the two groups on the 9th day in the Piroxicam group revealed a mean pain score of 0.51 ± 1.4
and in passiflora group 0.5 ± 1.3 (p = 0.705). The mean anxiety score in the Piroxicam group on the first day was 0.5 ± 3.50 and on the ninth day in the same group, which was 0.5 ± 2.4 (p = 0.001). In the passiflora group, the average anxiety score on the first day of treatment was 0.5 ± 3.62, and on the ninth day of treatment, it was 0.34 ± 1.1 (p = 0.010). Comparing the effect of two drugs on anxiety, the results indicated that the mean anxiety score in the Piroxicam group was 0.5 ± 2.4 on the ninth day, and 0.34 ± 1.1 in the passiflora group (p = 0.001). Based on the results of repeated measurement analysis, pain and anxiety severity at different times in the \( P. \) \( \text{incarnata} \) group and piroxicam group were statistically significant (P <0.001). Further, the results of Bonferroni post hoc test showed that all the times in each group had a significant difference in two groups (P <0.05) (Table2).

* Significant difference between each day and other times

**Discussion**

The results of this study suggested that drops of \( P. \) \( \text{incarnata} \) reduce the anxiety and myalgia caused by withdrawal. There was no statistical difference in the treatment of medication between the two treatments at the end of the study. To the best of our knowledge, this study is the first clinical trial on the effect of \( P. \) \( \text{incarnata} \) in the treatment of anxiety and myalgia caused by opium withdrawal. Compared to other similar studies that had examined the effect of passiflora on other diseases, there was a similarity between our study and those articles in terms of the sample size, duration of drug use as well as the results, which are in line with the findings of this study. Other studies showed the positive effects of Passiflora drops in reducing the anxiety similar to benzodiazepines; the greatest effects of \( P. \) \( \text{incarnata} \) was from day seven onward \(^{31,33}\). Some animal studies have also suggested the agonist effects on GABA-a in creating anti-anxiety effects \(^{23,24}\). Others also argue that \( P. \) \( \text{incarnata} \) extracts may be helpful in the control of withdrawal symptoms of alcohol consumption \(^{30}\). Some studies have suggested that opioid withdrawal leads to a significant reduction in the analgesic threshold and induction of withdrawal hyperalgesia \(^{35}\). Previous studies have reported the clinical role of active ingredients of this substance synergistically \(^{17}\). It is reasonable that the pain reliever and anti-anxiety properties of this plant can be attributed to the synergistic action of GABA.
A, GABA B and its effect on opioid receptor 20, 36. A considerable part of the scientific literature has provided pre-clinical evidence of the beneficial properties of P. incarnata in the treatment of addictive behaviors related to substances such as amphetamine, nicotine, cannabis, ethanol, and benzodiazepine 34,37,38.

**Conclusion**

The results suggested that P. incarnata drops as well as Piroxicam can reduce the severity and anxiety and myalgia caused by withdrawal.

Abstract

The current study aimed at determining the effect of smoking cigarette and Narghile at some of bloody variables and Vitamin D in a sample of young smokers aged 20-35 in Ramadi. The study included complete blood count (C.B.C) tests including: Total White Blood Cell and Red Blood Cell Count, determination of the concentration of total hemoglobin and calculation of Platelet Count. Calculation of RBC Indicators: “mean corpuscular hemoglobin” (MCH), “Mean Corpuscular Hemoglobin Concentration” (“MCHC”) and Mean red blood Cell Volume (MCV). The study also evaluated the concentration of vitamin D.

Results showed that: A rise in the number of white blood cells and red blood cells, as well as a high concentration of hemoglobin and platelet count in smokers. An increase in the volume of red blood cells, mean hemoglobin concentration, and Mean Corpuscular Hemoglobin Concentration in smokers’ blood. Decreased concentration of vitamin D.

Key Words: Complete Blood Count, RBCs indices, Smokers, Cigarettes, Narghile

Introduction

Smoking is one of the leading causes of cancer throughout the body and is one of the causes of global confirmed deaths. Many studies have found that smoking is a major cause of many human diseases (1).

It is a global problem that causes 6.4 million deaths in 2015 and is expected to increase to 8.3 million by 2030 (2).

Tobacco contains organic substances such as alkaloids, nicotine, and other substances that have the same nicotine effect as arsenic, mercury, lead, cadmium, chromium, polonium and beryllium (3).

These substances negatively affect the physiological and biochemical functions of the body directly (4).

Cigarette smoking and narghile are one of the most important risk factors for heart disease and atherosclerosis, which accelerates the development of heart disease, which ends in death because of the Cigarette contained in the toxic substances whose cumulative effect appears over time (5).

Cigarette smoking is a significant proportion of myocardial infarction (MI). This is three times higher in non-smokers and the mechanism of effect is not fully known (6).

Despite the lack of knowledge of the mechanism in which smoking affects the rate of increase in the incidence of various heart diseases, but the containment of tobacco to thousands of toxic chemicals and harmful to health in general is the cause of the disease (7).

Smoking is a factor in causing neoplastic neoplasms and leads to infertility in men. Nicotine is also a substance that causes vasoconstriction, which leads to diminished blood vessels and reduced blood flow (8).

Smoking is a link between blood variables and cases of myocardial infarction (MI) as well as Coronary Heart Disease (CHD) by increasing the viscosity of the blood and associated with cases of narrowing of the blood vessels, which causes the breakdown of platelets and the release of enzymes into the bloodstream causing thrombosis (9).

Smoking causes osteoporosis, because it reduces the absorption of calcium from the small intestine as well as
increases the toxic substances of the bones and affects the metabolism of hormones and vitamins, including vitamin D.\(^{(10)}\).

The researchers note that there is a very strong association between smoking and cellular blood changes. This change leads to the stimulation of various heart diseases, including atherosclerosis and cardio-vascular disease\(^{(11)}\).

Vitamin D is known as the sun’s vitamin because the sun’s rays contain UV-B, which converts the 7-dehydroxy cholesterol into 25-dehydroxy cholesterol, known as D3 or vitamin D subcutaneously\(^{(12)}\).

Vitamin D plays an important role in bone building as well as a large cycle in many functions including immunosuppression and enzyme activation\(^{(13)}\).

In order to clarify the health effects that affect Cigarette and narghile smokers and because of the spread of the phenomenon of smoking narghile in Iraqi society, the current study aimed at studying the effect of smoking cigarettes and narghile on a number of blood variables and vitamin D. in males.

**Results**

**Concentration of vitamin D:**

The results of the current study presented a decrease in the concentration of vitamin D in the two groups of smokers of narghile and cigarette compared to the control group. The average vitamin D concentration in the serum of the three groups (30.9, 10.9, 13.3 ng / ml respectively) was significant in vitamin D concentration in the three studied groups at the probability level \(P <0.05\). Figure (1) shows the effect of smoking for Cigarette and narghile on the concentration of vitamin D in studied groups.

The least significant differences (LSD) showed significant differences in the concentration of vitamin D in the three studied groups \(P <0.05\).

**Complete Blood Count CBC**

**white blood cells WBCs count:**

The results of the current study presented an rise in the number of white blood cells in the two groups of smokers accorded to the control group. The average number of white blood cells in the control group and the group of cigarette smokers and the narghile smokers was \((7.1, 8.6, 8.9) \times 10^3\) cell / mm\(^3\).

The analysis of variance showed significant differences in WBCs count in the three studied groups at the probability level \(P <0.05\). Figure 7 shows the average number of white blood cells in the studied groups.

The LSD test showed significant differences in white blood cells count at \(P <0.05\).

**Red blood cells RBCs count:**

The results of the current study showed an increase in the number of red blood cells in the two groups of smokers accorded to the control group, with the average number of red blood cells in the control group and the group of cigarette smokers and narghile smokers \(5.3, 6.9, 7.0) \times 10^6 / \text{mm}^3\).

The results showed a significant difference in the number of red blood cells in the studied groups at the probability level \(P <0.05\). Figure 8 shows the average number of “red blood cells” in the studied groups.
Concentration of hemoglobin:

The results of the present study showed a high concentration of hemoglobin in the two groups of smokers compared to the control group with mean concentration of hemoglobin in the control group and the group of cigarette smokers and the group of narghile smokers (14.1, 15.2, 15.9) g / 100 ml, respectively.

The results of the variance analysis showed significant differences in mean hemoglobin concentration in the studied groups at the probability level (P <0.05). Figure 9 shows the average concentration of hemoglobin in the studied samples.

Mean Cell Volume (MCV).

The results of the current study showed an increase in the size of red blood cells in the two groups of smokers compared with the control group, with mean red blood cell count in the control group and the group of cigarette smokers and the group of narghile smokers (82.72, 88.56, 95.31) vimto liter respectively.

The results of the variance analysis presented significant differences in the mean values of the red blood cell volume (MCV) at the probability level (P <0.05). Figure 10 shows the average volume of the “red blood cell” in the studied groups.

Mean concentration of hemoglobin MCH:

The results of the present study showed an increase in the average concentration of hemoglobin in the two groups of smokers compared with the control group. The average concentration of hemoglobin in the control group and the group of cigarette smokers and the group of narghile smokers was 26.4, 38.6 and 40.5 pg / ml respectively.

The results of the variance analysis presented significant differences in mean hemoglobin concentration values in the studied groups at the probability level (P <0.05). Figure 11 shows the average concentration of hemoglobin in the studied groups.
Results of LSD showed significant differences in mean hemoglobin concentrations in the studied groups at the P <0.05).

Mean concentration of Hemoglobin Concentration MCHC:

The results of the current study presented significant differences in the mean values of the Hb concentration in the studied groups accorded to the control group. There was an increase in the values of the average concentration of Hb in the two groups of smokers accorded to the control group with the average concentration of Hb in the control group and the group of cigarette smokers and the group of narghile smokers was (31.5, 39.1, 38.5%) respectively.

The results of the variance analysis presented significant differences in the mean values of the serum hemoglobin concentration in the studied groups at the probability level (P <0.05). Figure 12.3 shows the average concentration of Hb in the studied groups.

Platelets Count (Plts):

The results of the current study presented an increase in the number of platelets in the group of smokers accorded to the control group. The average number of blood “platelets” in the control group and the group of cigarette smokers and the group of narghile smokers was 254000, 341000, 359000 / mm³, respectively.

The results of the variance analysis presented significant differences in mean blood platelet counts in the studied groups at the probability level (P <0.05). Figure 13-3 showed the average number of platelets in the studied groups.

Discussion

Smoking is a global problem. One of the leading causes of death is Cigarette smoking is. According to the “WHO” estimates that (2.4 billion) humans universal expended tobacco in burning, mastication, absorption or dropping. The “WHO” described that tobacco would be accountable for (10 million) deaths per year during the period 2020-2030, with 70% of deaths occurring in developing nations because of including at least 200 toxic substances and (80) known or supposed carcinogens, and large amounts of oxidants and free radicals that cause oxidative stress, lung oxidation and apoptosis14,14.

Cigarette smoking has most vital risk factors for atherosclerosis and increased deaths from chronic heart disease (CHD). Although the exact mechanism of the role of tobacco smoke in the atherosclerosis process is still not fully understood, many of the chemicals among the thousands present within tobacco smoke produce harmful and toxic effects on health (5).

There are many naturally occurring organelles in the cell that are rich in alkalis, which are tobacco and are rich in nicotine and some other toxic metals that have nicotine-like chemical activities in tobacco. These are arsenic, mercury, lead, cadmium, chromium, polonium and beryllium. The most important chemical components found in cigarettes are “tar”(3).

The most common way of “tobacco” consumption is Smoking, and the resulting vapors are inhaled. Risk substances (nicotine) are absorbed over and done with the pulmonary vesicles in the lungs and chemical reactions at the nerve endings, dopamine and epinephrine willfree, which are often associated with pleasure. Therefore, a large number of people continue to smoke in developing countries. Cigarette smoking is a known risk factor for many diseases such as the respiratory tract, heart, blood vessels and tumors, and also affects male fertility functions. Nicotine acts as a vasoconstriction, which means that the blood vessels become narrower and reduce blood flow. (15).

Smoking is a cause of cancer, heart disease, stroke and is also closely associated with stomach ulcers, (gum, sudden infant death, and metabolic) syndromes. Consumed of cigarette has a major adverse effect on various body systems especially on the “cardiovascular system”. Smoking in various forms is a major risk factor for “atherosclerosis” and “coronary heart disease”. (16).
Smoking is one of the most common and widespread addictive practices, affecting human behavior. Smoking is increasing rapidly throughout the developing global and is one of the greatest threats to present and future global health. Approximately (20%) of all “coronary heart disease” losses can be recognized to smoking. Cigarette smoking is an important risk factor for “coronary artery disease”, “arteriosclerosis” and disorders of peripheral vascular. (17).

Cigarette smoke is a risk factor for peripheral vascular disease, coronary arteries, and cerebral blood vessels. In general, a one to three-fold increase in the risk of MI was observed among current cigarette smokers.

Although smoking has a severe and chronic effect on blood standards, however, there is a lack of studies on the influence of cigarette smoking on blood in humans and animals. Over the earlier decade, it has been suggested that cigarette smoking has an effect on blood features and also leads to death. “White blood cells” has been detected nearly as high in smokers. There are some studies on the effect of smoking on platelets. In addition, data from several studies were not compared to non-smoking as control groups. Showed a high percentage of average volume of “MPV” in the smoker, which reduced after the smoker prevent from smoking. Though, no effect on “MPV” by smoking. In the light of this study, we compared the total number of “white blood cells” (WBC), “Platelets” (PLT), Platelet Crit (“PCT”), Average Platelet Size (“MPV”), Platelet Distribution (“PDW”) (P-LCR) for both smokers and non-smokers (14).

A strong correlation was found between cigarette smoking, arteriosclerosis and cardiovascular disease. Several studies have considered that endothelial injury is a major initial event in causing cardiovascular disorders. However, the exact pathophysiology of the harmful effects of smoking on the lining is not very clear. Potential mechanisms for smoking damage include increased thrombocytopenia and inflation, changes in lipid and lipoprotein levels, changes in hemostasis, increased enumeration and neutrophil activation (18).

In addition, smoking has been associated with the metabolism deformation of vitamin D. However, most studies have been conducted on the relationship between smoking and osteoporosis in postmenopausal women or elderly men after prolonged exposure to the toxic agent, and there is little information on the effect of smoking on bones in young people (10).

Vitamin D deficiency is common all over the global; even in areas close to the equator where it is assumed that exposure to sunlight is high. Furthermore to its known effects on calcium balance, “vitamin D” has a variety of functions, including immunological and anti-inflammatory effects. Many diseases have been related with “vitamin D” deficiency, including cancer and inflammatory diseases, although precise mechanisms are still under clarification. Previous epidemiological studies have shown a causal link between lung function and “vitamin D” levels. In lung-related lung diseases, lung destruction is partially mediated through inflammation, oxidative stress, and increased protease. Many of these processes are formed by “vitamin D”. Furthermore, studies in the laboratory and animal models suggest that cigarette smoke may affect with the anti-vitamin D effects, (19).

Correlation between Hyperglycemia Stress and Short-Term Memory Function in Thrombotic Stroke Patients

Muhammad Hamdan¹, Riani Wisnujono¹, Yudha Haryono¹, Abdulloh Machin¹, Dian Puspitarini¹
¹Department of Neurology, Faculty of Medicine, Universitas Airlangga, Surabaya (60131), Indonesia

Abstract

Background: Hyperglycemic stress is associated with a disorder of the entire cognitive domain in the early phase of stroke, which is memory impairment. Acute changes in blood glucose are known to affect the cerebral blood flow.

Objectives: To determine the relationship between stress hyperglycemia with short-term memory function in thrombotic stroke patients.

Method: An observational analytic research with the case-control with a patient’s of 72-hour onset thrombotic stroke that went to the Emergency Unit and was admitted to the Neurology Department of Dr. Soetomo General Hospital from January to December 2014. 42 subjects were enrolled (21 subjects in the case group and 21 subjects in the control group). The sampling of the study was conducted according to the cases that came in succession until the achievement of the subject was determined.

Results: After bivariate and multivariate analysis, hyperglycemic stress had no significant correlation to memory function (p = 0.525) and OR 0.667 (CI95% = 0.190-2.334). There was a significant correlation between educational level and cognitive function (p = 0.003) also between hypertension and cognitive function (p = 0.019).

Conclusion: Stress Hyperglycaemia has no significant relationship with memory function. Education levels and hypertension have a significant correlation with memory function.

Keywords: Memory Function, Word List Memory Task, Hyperglycemic Stress

Introduction

A stroke is an acute-onset neurological deficit syndrome, which persists for more than 24 hours. A stroke involves the focal central nervous system and is the result of cerebral circulatory disorders ¹. In acute ischemic stroke, there is a sudden decrease or the loss of blood that flow to the brain resulting in a neurological deficit. Most of the causes are atherothrombosis of the intracranial artery or large artery in the neck, as well as the embolism of the heart ². Atherosclerosis is a pathological description of the most frequent vascular obstruction that causes a thrombotic stroke. Atherosclerotic plaque exist makes the blood flow to the area will decrease, it could even stop altogether. When the decreased blood flow to the minimal needs of the brain is unfulfilled, it will arise clinical symptoms ³.

Hyperglycemia is a common manifestation of critical illness and surgery. Hyperglycemia is caused by acute metabolic and hormonal changes that correlation with response to the stress and injury. Hyperglycemia is one of the important risk factors for stroke that found in ± 43% of stroke patients, either due to the hyperglycemia stress and diabetes mellitus (25%) ⁴.

Cognitive understanding is the process whereby all the sensory input (tactile, visual, auditory) will be altered,
processed, stored, and then used for perfect interneuron correlation, thus the individual is able to sense the sensory input. The cognitive domains or modalities according to Hodges consist of three modalities, namely: attention/concentration, memory, intellectual function, social behavior and personality. Memory is an individual process for storing and retrieving information.

Acute stroke causes cognitive impairment not only in the location of infarct tissue but also in areas adjacent to inadequately perfused lesions. Global cognitive impairment might include memory impairment, attention, executive function or visuoconstruction among other cognitive domains. Hyperglycemia is associated with the increased mortality and poor functional outcomes of post-stroke and might be a predictor of cognitive function output. Acute changes in the blood glucose are known to affect regional cerebral blood flow and cause osmotic changes in brain neurons.

**Method**

An observational analytic research with the case-control design was used in this study along with a patients of 72-hour onset thrombotic stroke that went to the Emergency Unit and was admitted to the Neurology Department of Dr. Soetomo General Hospital since January to December 2014. The subjects of the study were all thrombotic stroke patients treated in Seruni A, Seruni B, and Seruni Room and fulfilled inclusion and exclusion criteria that taken with consecutive sampling. The control group is a patient with normal Word List Memory Task results, while the case group is a patient with an abnormal Word List Memory Task. Clinical Data

Demographic Characteristics

The subjects were 42 people, consisting of 24 men (57.1%) and 18 women (42.9%). In the case group, the number of male subjects was 14 people (66.7%), while in the control group 10 people (47.6%). The female subjects in the case group were 7 (33.3%), while the control group was 11 people (52.4%). Gender has no significant correlation to cognitive function with p = 0.212 (Table 1). The mean age of the subjects in the case group was almost the same (50.05 ± 6.924 years), compared to the control group (51.05 ± 7.032 years) (p = 0.645), resulting no age difference was found to cognitive function (Table 1).

The education level in the case group consisted of 11 people (52.4%) graduated from elementary school, while 2 people (9.5%) in the control group. The level of Senior High School, Vocational High School, and College in the case group consisted of 10 people (47.6%), while 19 (90.5%) people in the control group. There was a significant correlation between educational level and cognitive function (p = 0.003) (Table 1).

Clinical Data

Subjects characteristics based on hypertension in the case group found that stage 1 hypertension were 10 people (47.6%), while in the control group were 3 (14.3). Then, Hypertension stage 2 in the case group were 11 people (52.4%), while in control group were 18 (85.7%). There was a significant correlation between hypertension and cognitive function (p = 0.019). Based on the risk factor of dyslipidemia, in the case group found that 11 people (52.4%) had dyslipidemia, while in control group were 10 (47.6%). Normal lipids subjects in the case group were 10 people (47.6%), while in the control group were 11 (52.4%). There was no significant association between dyslipidemia and cognitive function (p = 0.758) (Table 2). In the case group, 7 people (33%) had hyperglycemia stress and in the control group were 9 (42.9%), while in the case group unstressed hyperglycemia were 14 (66.7%), and in the control group were 12 (57.1%). Stress hyperglycemia have no significant correlation to cognitive function (p = 0.525).
Correlation of Odds Ratio (OR) between stress hyperglycemia and cognitive function was 0.667 with Confidence Interval (95% CI = 0.190-2.334), which means hyperglycemia stress to be 0.667 times more frequent for cognitive function impairment (protective factor), where it was obtained number 1 among Confidence Interval indicating that this relationship was not clinically significant (Table 3).

Discussion

The sex ratio was 24 men (57.1%) and 18 woman (42.9%). This relevant to stroke epidemiologic data that men have more strokes experience than women. The mean age of the case group subjects was almost the same (50.05 ± 6.924 years) compared to the control group (51.05 ± 7.032 years). The mean age of the subjects was relatively young compared to the stated that the mean age was 65 ± 11.6 years. This study found a significant relationship between the level of education with cognitive function (p = 0.003). This was consistent with other studies suggest that education levels have an effect on memory.

A significant correlation was found between hypertension with cognitive function (p = 0.019). This is in accordance with research conducted by Tsao et.al that hypertension plays a role to decrease the cognitive function including memory. The changes in regional brain blood flow in hypertensive patients affect the cognitive function \(^ {11}\). Hypertension causes a direct consequence of demyelination due to hypoxia and ischemia and might lead to subcortical-cortical disconnection. There was
no significant correlation between dyslipidemia and cognitive function. This was consistent with studies suggest that there was no significant correlation between changes in plasma cholesterol levels and cognitive function 12.

Based on hyperglycemia risk factors, in the case group, fewer patients had hyperglycemia stress than the control group, but no significant relationship was found between hyperglycemia stress and cognitive function (p = 0.525). This not in accordance with the study conducted by Pan, which states that hyperglycemia stress was associated with impairment in all cognitive domains including the memory in cortical infarction, but this not found in subcortical infarction 13. This difference might due to this study that infarct stroke was not grouped based on its lesion location i.e., cortical and subcortical. Another cause was the age of the study subjects, in this study was ≤60 years whereas in other studies was <86 years old 14.

A study conducted by atkinson et,al states that 61% of patients that passed the acute period of stroke treatment and have a 1 or 0 NIHSS score encounter functional recovery well. But, the cognitive impairment was severe enough and only about 41% could return to work within 6 months after the stroke 15. However, it was found that the location of lesions and lesion sides did not affect the occurrence of cognitive function impairment, while the size of the lesions had an effect on the occurrence of cognitive dysfunction. Patients with high NIHSS scores are more likely to experience psychomotor speed disorders. In studies conducted Danovska M, the type and severity of cognitive impairment depend on the stroke picture. The location and size of the lesions also affect the occurrence of cognitive impairment in stroke 16.

Conclusion

There was no association between stress hyperglycemia with short-term memory function in patients with thrombotic stroke. Education levels and hypertension have a significant correlation with memory function. Further research using an observational analytic research method with a cohort design was needed, thus the results could be used to a better assessment of causal correlation.

The Difference between hs-CRP and Serum IL-6 Levels in Patients with Glaucoma and Non-Glaucoma

Muhammad Riduan, Endang Retnowati Kusumowidagdo, Nurwasis
1Department of Clinical Pathology, Faculty of Medicine Universitas Airlangga, Surabaya (60131), Indonesia

Abstract

Background: Glaucoma is a group of eye diseases that have the characteristic of optic nerve damage with a specific pattern and field loss of view with or without increased intraocular pressure (IOP). The objective of the study was to analyze the association between glaucoma incidence with hs-CRP and IL-6 levels.

Method: This study used patients who fulfilled the inclusion criteria. Inclusion criteria were in the form of patients with a primary closed-angle diagnosis, willing to participate in the research. The study was conducted in the period from March to August 2013. The research procedure included patient examination, hsCRP and IL-6 level examination.

Results: Mann-Whitney test result showed difference of hs-CRP with p value of 0.755 and difference of IL-6 level with p = 0.95. Thus, there was no significant difference in the levels of hs-CRP and IL-6 in patients with glaucoma and non-glaucoma.

Conclusion: Hs-CRP and serum IL-6 levels in the glaucoma group did not differ from the non-glaucoma group.

Keywords: hs-Crp, IL-6, glaucoma, intraocular

Introduction

Glaucoma is a group of eye diseases that have the characteristic of optic nerve damage with a specific pattern and field loss of view with or without increased intraocular pressure (IOP). WHO States that glaucoma is the second rank as the cause of irreversible blindness in the world. Primary closed-angle glaucoma (PCAG) is the most common form of glaucoma in Asian countries. A typical PCAG in European countries is an acute attack, unlike Asian and African countries that tend to develop gradually as chronically closed angle asymptomatic.

Glaucoma disease affects more than 66 million individuals worldwide, causing bilateral blindness at 6.8 million. It is estimated that 3.9 million individuals became blinded by PCAG in 2010. By 2020, this number is assumed to increase to 5.3 million. Eighty-six percent of PCAG patients are in Asia, with an estimated 48.0% in China, 23.9% in India and 14.1% in Southeast Asia. Indonesia has the highest number of blindness in Southeast Asia. From the 1993-1996 health survey, glaucoma caused 13.4% of blindness after cataracts. Mimiwati et al. found chronic PCAG (58.5%) was the most common form followed by subacute (26.8%) and acute group (14.6%).

Glaucoma risk factors such as old age increase the percentage of closed angle and increase the incidence of PCAG. Women are at risk 3 to 4 times compared to men because they are related to the fact that they are gonioscopy which has a shallower eye angle than men. Other risk factors for increased IOP are family history, severe myopia, systemic hypertension, cardiovascular disease, migraine headaches, peripheral vasospasm and previous neurological damage. Acute attacks of closed-angle glaucoma lead to blindness within hours or days, in contrast to primary open-angle glaucoma that is slow

and gradual loss of vision. In addition, the other most important things are the speed and the accuracy of the management. The accurate diagnosis in the form of intermittent and chronic of PCAG is also important because prophylactic treatment can protect the eyes from acute attacks and prevent damage due to repeated intermittent attacks or chronic closed angle. Loss of vision due to glaucoma is irreversible; however, it can be treated if the diagnosis is established at an early stage. Many individuals with glaucoma become blind because they have not received good help 3.

Retinal ganglion cell (RGC) apoptosis is a key of neurodegenerative glaucoma, but the detail of the underlying process remains unclear. Various mechanisms have been found such as the deprivation of neurotrophic factors, hypoperfusion or ischaemia, glial cell activation, glutamic excitotoxicity and abnormal immune responses which lead to an end result of RGC apoptosis. The in vivo study explains the role of an adaptive immune response in the pathogenesis of glaucoma. Increased IOP and ischemia is a stress that acts as an immunostimulator signal, triggering an activation of an immune response that was initially useful for repairing tissue 4.

IL-6 is a pleitropic cytokine, which both uses a common signal transduction component with other IL-6 family members. A specific IL-6 signal involves the interaction of gp130 with IL-6 alpha receptor present in the membrane (IL-6Ra). Research conducted in vivo and in vitro showed elevated levels of T helper (Th2) lymphocyte cell cytokines which are IL-6 and Th1 cytokines including interferon γ (IFN-γ), IL-1, IL-2, IL-17 and tumor necrosis factor α (TNF-α) associated with retinal damage and RGC. The increase in intraocular IL-6 levels has not been shown to affect serum IL-6 levels 5.

Serum IL-6 examination is influenced by several conditions because these cytokines are produced by various cells after stimulation of infection, trauma, immunological reactions and other systemic inflammation. In addition, IL-6 examination is still not conducted in the clinical laboratory; thus, it needs a practical examination. High-sensitivity C-reactive Protein (hs-CRP) is a solution to this problem, since it is useful in filtering out inflammatory markers such as infection, trauma, immunological reactions and systemic inflammation. Its production in the liver is induced directly by IL-6. Hs-CRP examination has grown rapidly as predicted risk of coronary heart disease, stroke and other peripheral vascular diseases; thus, it needs to be evaluated its potential for the diagnosis of glaucoma 6.

Method

This research is a laboratory analysis research with cross sectional design. The inclusion criteria of respondents were patients with a primary closed-angle diagnosis and willing to participate in the study. While the exclusion criteria were patients with coronary heart disease, systemic infections, viral conjunctivitis, and diabetes mellitus. The sampling technique used simple random sampling. The research procedure included patient examination, hsCRP examination, and examination of IL-6 levels 7.

Examination of IL-6 levels was conducted by using ELISA method. This examination used the ELISA microreader tool from R&D Systems. The venous blood sample from the cubital vein had previously been disinfected with 70% alcohol, then venous blood was inserted into a 2 ml plain vacutainer tube. Each tube was labeled (patient name, date and time of sampling, and the initials of the subjects taking the sample). Samples were incubated for 30 min and then centrifuged 3000 rpm, 15 min to separate serum. The serum was put into several microcentrifuge tubes 8. The tube was labeled and immediately shipped to the Bank Jaringan, stored in the -70°C freezer until further inspection. The retrieval time to sample storage was less than 1 hour 9. All collected data were arranged in tabular form and processed statistically. The statistical test used to determine the difference of serum hs-CRP and IL-6 levels in glaucoma and non-glaucoma patients was Mann-Whitney test with p <0.05 10.

Results

Examination of hs-CRP levels in study subjects’ serum showed that the mean value of hs-CRP in glaucoma patients was not different compared to non-glaucoma control hs-CRP values. The mean values in the control group tend to be larger and the standard deviation was also greater than the mean glaucoma group. The range of variation in hs-CRP values was also significant in the glaucoma group from 0.084 to 5.78 mg/L while in the non-glaucoma control group it was greater than 0.001 to 7.934 mg/L and the median values for each group were 1.362 and 1.710 (Table 1).

IL-6 examination results showed no significant difference in mean values in both groups of study
subjects. The mean value of IL-6 glaucoma group was greater than non glaucoma. The mean rate of IL-6 levels in the glaucoma group was greater than non glaucoma but the mean level of hs-CRP in the glaucoma group was smaller than non glaucoma. This result was not in accordance with physiological conditions, ie when the level of IL-6 increased, it will be followed by increased levels of hs-CRP. Standard deviations in both groups were also relatively large even it was larger in non glaucoma group. The range of IL-6 levels was also high in the glaucoma group from 0.21 to 9.1 pg/ml and the non-glaucoma group from 0.16 to 9.63 pg/ml with median values of 1.910 and 0.775, respectively (Table 1).

Test of normality of difference of hs-CRP level between glaucoma and non glaucoma patient has significance <0.05. Normality test with Kolmogorov-Smirnov on glaucoma group showed p value = 0.004 was in non glaucoma group p = 0.001. The situation showed abnormal data distribution (Table 3). The normality test of difference of IL-6 level between glaucoma and non glaucoma patient had significance <0.05. Test of data normality with Kolmogorov-Smirnov in glaucoma group showed p value = 0.106 was in non glaucoma group p = 0.002. Although there was a value of p >0.05, it remains statistical tests for abnormal data distribution because another p value <0.05 (Table 2).

The normal distribution curve was shown at the level of IL-6 glaucoma which was symmetrically pointed, although the median value slightly shifts toward the left of 1.910 shifts from the mean of 2.319. Non-glaucoma group distribution curve was not normal because the median value of 0.775 shifts away from the mean value of 1828; thus, the curve figure is not symmetrical. The pattern of non-glaucoma group population was more to the right of the median region. The results of normality test of hs-CRP and IL-6 results in glaucoma patients and non glaucoma patients with Kolmogorov-Smirnov showed mostly p <0.05. The value in the normality test of IL-6 data in glaucoma patients with Kolmogorov-Smirnov p >0.05 was p = 0.106 and overall data distribution remained abnormal. Mann-Whitney test result difference of hs-CRP with p value of 0.755 and difference of IL-6 level with p = 0.95. Thus, there was no significant difference in the levels of hs-CRP and IL-6 in glaucoma and non-glaucoma individuals (Table 3).

Discussion

The results of this study have stated that there was no difference in hs-CRP levels in glaucoma and non glaucoma. The results were similar to previous studies; thus, the hs-CRP examination had no clinical significance in the diagnosis of glaucoma. Serum CRP examination is routine in clinical laboratories as a marker of various acute and chronic inflammatory diseases. The production of CRP in hepatic cells are stimulated various proinflammatory cytokines such as IL-1, IL-6, TNF-α, IFN-γ and TGF-β. Small amounts are also produced locally in lymphocytes, and vascular wall muscle tissue in patients with coronary heart disease. CRP production increases in the inflammatory process. The normal range of CRP values in adult individuals ranges from 1.5 mg/L for males and 2.5 for females.

IL-6 is a single protein cytokine not only in the production of lymphoid and non-lymphoid cells. IL-6 is also expressed by normal or transformed cells such as macrophages, fibroblasts, synovial cells, endothelial cells, glial cells, keratocytes and tumor cells. IL-6 expression induced by various stimuli includes cytokines such as IL-1, TNF-α, PDGF, bacterial and viral infections and microbial components such as lipopolysaccharide. Its role has been well known in the minimal chronic inflammatory state of obesity, diabetes, cardiovascular disease as well as in infections and sepsis. In healthy individuals independent of inflammatory reactions, the IL-6 concentrations are very low from 0.2 to 7.8 pg/ml and can rise to a high of 1600 pg/ml concentrations in sepsis.

IL-6 in the systemic circulation is a pleiotropic cytokine involved in the regulation of the immune system, acute phase reaction and hematopoesis. IL-6 is associated with an acute phase reaction functionally referred to as hepatocyte stimulating factor (HSF) because it stimulates hepatocytes in producing CRP. The mean rate of IL-6 group of glaucoma was greater than non glaucoma, but the mean hs-CRP level in the glaucoma group was smaller than non glaucoma.

This result is not compatible with physiological conditions, ie when the level of IL-6 increases, it will be followed by increased levels of hs-CRP. This suggests that no significant difference in IL-6 levels in the glaucoma and non glaucoma groups needs to be analyzed further. The results of IL-6 studies on serum or systemic circulation do not coincide with IL-6 studies in aqueous humour can be influenced by various factors. Intraocular IL-6 cytokine levels are too minimal to affect levels in the systemic circulation; thus, the threshold
levels of IL-6 glaucoma and non glaucoma are very narrow. The intraocular immune privilege mechanism also limits the local inflammatory process to not spread to the circulation; thus, the levels of IL-6 in the glaucoma group are not different from that of non glaucoma 18.

**Conclusion**

Based on the results of research, it can be concluded that serum hs-CRP and IL-6 levels in the glaucoma group did not differ from the non glaucoma group. Serum hs-CRP testing can not be utilized in assisting clinical diagnosis of glaucoma, whereas serum IL-6 examination also has not been able to assist in clinical diagnosis of glaucoma.

The Risk Factors Effect of Knee Osteoarthritis Towards Postural Lateral Sway

Muhammad Siddik¹, Ratna Darjanti Haryadi¹
¹Department of Physical Medicine and Rehabilitation, Faculty of Medicine, Universitas Airlangga, Surabaya, 60286, Indonesia

Abstract

Background: Osteoarthritis (OA) is the main cause of impairment and disability in elderly. Patient with OA experience progressive functional impairment shown in increasing dependence on walking, using stairs and etc. Patients with OA experience increased static postural sway in the lateral and anteroposterior due to several factors.

Objective: This study aims to analyze the risk factors of knee osteoarthritis on postural lateral sway.

Method: This research is a cross sectional study. The severity of the respondents’ knee OA, unilateral/bilateral, dominant side, knee joint alignment, body mass index (BMI), and postural lateral sway were measured with Gait Analyzer Peak Motus 2000, and their quadriceps muscle activity was assessed with Myomed. Respondents involved in this study were 38 elderly with unilateral or bilateral knee OA stage 1 until 3 based on the criteria of Kellgren & Lawrence. The data were analyzed with multiple linear regression.

Results: The results showed that postural lateral sway was 2.23±0.59 cm. BMI, dominant side, OA types, OA severity, Quadriceps angle, and tibio-fibular angle (TFA) were found with the p value = 0.421, 0.599, 0.780, 0.913, 0.596, and 0.984 respectively. The Visual Analogue Scale (VAS) variable was R Square = 0.291, p = 0.001, Y = 0.3096 and X = 0.9393.

Conclusion: Pain is the strongest predictor factor of postural lateral sway disturbances in patients with knee OA.

Keywords: osteoarthritis, postural lateral sway, pain.

Introduction

Osteoarthritis (OA) is known as degenerative joint disease that is considered to be the most common form of arthritis. The characteristics of OA include joint and bone damage followed by the formation of new bone on the joint surface. The common types of joints that tend to experience OA are knee, pelvis, hand, and spine joint. The incidence of knee OA is 240 per 100,000 individuals per year. In Indonesia, the prevalence of osteoarthritis is 5% in individuals aged <40 years old, 30% in individuals aged 40-60 years old, and 65% in individuals aged >61 years old. The prevalence of knee OA is deemed high, which is 15.5% in males and 12.7% in females. The risk factors of OA are genetic, age, gender, ethnicity, obesity, occupation, muscle weakness, and biomechanics.

The elderly patients with OA will experience an increased postural sway if the gravitation center shifts from the center of the body. Proprioceptive suboptimal limbs cause the increase of the received force to be transmitted to the hip and knee. If it repetitively happens, the force triggers the occurrence of OA. Patients with knee OA encounter increased static postural sway in the lateral and anteroposterior, decreased knee proprioception, and decreased maximal voluntary contraction and quadriceps muscle activation.
compared to control group in the same age group. The most influential factor of OA in postural sway is the severity of pain\textsuperscript{5,6}. Other factors are age, gender, knee joint stiffness, and maximal walking speed\textsuperscript{7}.

This study intended to investigate the factors that are related to the knee OA cases such as the severity of knee OA, unilateral and bilateral knee OA, the dominant side of knee, knee joint alignment (TFA and Q angle), BMI, pain, and quadriceps muscle activity towards the incidence of postural sway in patients with knee OA.

**Method**

This study applied cross sectional and observational analytic design and was conducted on January until April 2012, in which the sample was collected using consecutive sampling. The criteria of knee osteoarthritis diagnosis are based on the guidelines set by the American College of Rheumatology (ACR). There were 38 samples that fulfilled the inclusion criteria including: (1) Patients with unilateral or bilateral knee OA stage 1 until 3 based on the criteria of Kellgren & Lawrence; (2) Aged 40-65 years old; (3) No limited range of motion of the lower limb member joints; (4) understand and follow the examination conditions; (5) Able to ambulate independently without ambulatory aids; (6) willing to participate in the study.

Measurements on the knee OA severity to decide whether it was unilateral or bilateral, dominant side of the body, knee joint alignment, and body mass index were conducted using Gait Analyzer Peak Motus 2000 to measure postural lateral sway while the quadriceps muscle activity was measured by Myomed equipment. The data were analyzed with multiple linear regression by using SPSS program for Windows (SPSS, Chicago, IL, USA).

**Results**

The result of sample measurement in this study revealed that knee OA mostly occurred in 41-65 year-old patients and the average stage was 58.03 years old and the SD was 5.635. The postural sway in the subjects was measured by using the equipment of Gait Analyzer with Peak Motus 2000 program. The measurement of postural sway was in the form of shifting center of body mass toward lateral (Table 1). The postural lateral sway was 1.25 cm until 3.37 cm with the average of 2.23 cm and SD of 0.59. The results of Kolmogorov–Smirnov test found the significance value of 0.468. The data of postural sway was considered normally distributed. Afterwards, the regression test was performed.

The result of pain and postural sway measurement based gender and OA characteristics with $p = 0.05$ showed statistically insignificant variable (Table 2). Most samples (33 individuals or 86.8%) are categorized in the overweight and obesity group based on the Asian scale of body mass index (Table 3). Another study regarding OA in Indonesia revealed that most OA patients (74.7%) had BMI more than 23, which is considered to be overweight. To add, a study conducted in Malaysia showed that people with obesity likely experience osteoarthritis.

The coefficient table (Table 4) was drawn to discern the role of each predictor (beta) and see if any predictor was significant in predicting DV (t value). Afterwards, the multiple linear regression analysis was conducted based on the method. According to pain variable, VAS had the square R value of 0.291 and the significance value of 0.0001. It can be seen that the variable was significant in predicting the postural sway (table 4).

### Discussions

From the result of the multiple linear regressions based on the enter method, it was revealed that the pain scale is the most influential factor towards the increase of postural sway in the study sample. The pain can alter the patient’s walking pattern, in which there is an unequal gait parameter between the pain in the form of a shorter stance phase. The restriction of joint motion and less muscle contraction in the location of the pain can affect the magnitude of the postural lateral sway. Another variable that was investigated in the study showed the significant result with the $p$ value of $p = 0.238$; however, it has a pivotal role in the case of postural sway.

This study found that the postural sway value ranged from 1.25-3.37 cm, with the average value of 2.23 cm. The observation in normal subjects using similar equipment and measurement method showed that postural lateral sway ranged from 1-2.5 cm with the average of 1.86 cm. In the comparison among normal individuals, there was a statistically significant difference measured by t test ($p = 0.03$). Another study in Indonesia revealed that the average postural sway in knee OA patients using posturography equipment was 2.32 cm. Despite employing different equipment, the result was quite similar with our study with the average postural lateral sway of 2.23 cm. This is due to the similarity between the basic characteristics of the study sample. Body mass index had weak positive correlation in predicting the postural sway with the correlation value of 0.112.
The femoral shaft walks slightly to the medial towards the knee. The oblique orientation occurred due to the inclination angle of 125° in femoral proximal. The joints of the proximal tibia are horizontally oriented; thus, the angle is formed (tibio-femoral angle/TFA) from the lateral side of 170 until 175°. The large angle formed by the pull of quadriceps is called a quadriceps angle or Q-angle. This angle is formed by (1) a line describing the resultant force of the quadriceps, formed by the point on the anterior superior iliac spine (SIAS) to the midpoint of the patella, and (2) the line connecting the tibia tuberosity and the center line of the patella 11. The increase of TFA and femoral anteverision angle is a predictor factor for the increase of Q-angle 12. The knee joint efficacy assessed with Q angle and TFA did not show any significant results in this study to predict the increase of postural sway with p = 0.596 for Q angle and p = 0.984 for TFA. This result is possible because of the relatively normal knee joint sessions in the study sample, in which the mean Q angle of 13.55 and the mean TFA of 172.97 are included in the normal range.

In other studies observing postural sway isometrically, it revealed that the activation and quadriceps muscle strength had significant correlation with the increased postural sway cases in patients with knee OA 13. However, different results of other studies are because most patients have obtained muscle quadriceps exercise program; thus, the activity of quadriceps muscle is improved. It can be discerned from the measurement results: the average VMO amplitude ratio towards VL was 110.02 and the average difference of VMO muscle latency towards VL was 0.037 second.

Due to the limitation of the sample with OA stage I, there is a possibility in error on the withdrawal of conclusions from the statistical analysis. Furthermore, there was no measurement in patients’ balance and questionnaire regarding the functional condition. Therefore, the effect of postural sway towards functional condition and patients’ balance in daily activity cannot be investigated.

**Conclusion**

Pain is the most influence of postural lateral sway in patients with knee OA. Other variables such as body mass index, OA types (unilateral/bilateral), dominant side of the limb with knee OA, knee joint, and quadriceps muscle activity have weak correlations and have no statistically significant effect.

**Ethical Clearance:** The study protocol was approved by the Ethical Commission to conduct basic science/clinical research in Dr. Soetomo General Hospital Surabaya, Indonesia. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice.

Microbial Risk Assessment (MRA) As a Method of Assessment for Drinking Water Refill in Pattinggaloang District of Makassar City

Alfina Baharuddin¹, Muhammad Ichsan²

¹Postgraduated of Environmental Health University Moslem of Indonesia,
²Lecturer in Departement of Environmental Health University Moslem of Indonesia

Abstract

Refill drinking water is one of the answers to meeting the needs of Indonesian drinking water that is cheap and practical. This is the reason why people choose AMIU to be consumed. The purpose of this study is to determine the risk of microbial drinking water in the community consumed in the working area of Pattinggaloang Public Health Center in Makassar in 2019.

This type of research is descriptive with Microbial Risk Assessment (MRA) assessment on refill drinking water. The sampling technique was done by a total of 6 depot drinking water refill sampling. Data processing is done by the SPPS method, the data presentation is carried out using tables accompanied by narration.

Laboratory results carried out on 6 samples of refill drinking water obtained were as many as 6 samples which were stated to be Positive (+) containing bacteria. Coli. Based on a Quantitative Risk Assessment, it was concluded that from 6 DAMIU samples had a high risk concentration, for the estimated number of bacteria E. Coli in Refill Drinking Water in the surrounding area of the Pattinggaloang Health Center in Makassar City.

It is recommended for consumers to refill drinking water in cooking first, because pollution / contamination can occur starting from the process of taking raw water, processing and packaging / filling in gallons.

Keywords: Drink water, MRA, E.coli, Microbial risk

Introduction

WHO (2015) found that 663 million people still had difficulty accessing clean water. In connection with this water crisis, it is predicted that in 2025 nearly two-thirds of the world’s population will live in areas that experience water shortages. The forecast was reported by the World Water Assessment Program (WWAP), formed by the United Nations Educational, Scientific, and Cultural Organization Regarding Indonesia, in 2012. The World Water Assessment Program (WWAP) has recorded that Indonesia was ranked the worst in the service of the availability of clean water and suitable for consumption in Southeast Asia. One of the studies in Microbiology is the material for growing and growing microorganisms from the environment, including microorganisms that have an environment, one of which is in food. Food is one of the basic needs for human life. Food functions to maintain the body’s process of growth or development and replace damaged body tissues, obtain energy to carry out daily activities, regulate metabolism and various water, mineral and other body fluids, also plays a role in the body’s defense mechanism against various diseases.

According to WHO Risk assessment is a structured process for determining risks associated with all types of hazards - biological, chemical or physical in food. It has the aim of characterizing the nature and possible dangers resulting from human exposure to agents in food. Risk characterization usually contains qualitative and quantitative information and is associated with a certain degree of scientific uncertainty.

Microbial Risk Assessment (MRA) is a methodology used to organize and analyze scientific information to estimate the probability and severity of an adverse event. Set on microbial food safety, this methodology can also help identify the stages in the manufacture, distribution, handling, and consumption of food that contribute to the increased risk of foodborne illness, and help focus resources and efforts to most effectively reduce the risk of foodborne pathogen.

Based on the Unicef Joint Monitoring report, the performance of the water and sanitation sector in Indonesia is still considered low compared to other countries in Southeast Asia. Of Indonesia’s population of around 218 million people in 2015, an estimated 103 million people (47%) did not have access to sanitation and around 47 million people (22%) did not have access to clean water. Only around 50% of the entire population of Indonesia has access to drinking water. Meeting the current needs of community drinking water varies greatly. Population needs for drinking water can be met through water served by piping systems (PAM), bottled drinking water (AMDK), and refill drinking water (AMIU). The tendency of the population to consume ready to use drinking water is very large so that the effort to replenish drinking water is growing very rapidly.

Makassar City Health Office shows the distribution of diarrhea cases according to Makassar city health centers in 2017 there were 46 health centers. The highest case of diarrhea according to the Makassar City Health Center in 2017 was the Pattingaloang Health Center with a diarrhea case of 933 cases. In the Pattingaloang Puskesmas working area there are 6 refill drinking water depots.

This is because careless disposal of human and animal feces will cause pathogens in the feces to transmit through the soil media and spread in water sources which are then used by humans. As a result, almost every year sanitation and contaminated drinking water contribute to 88% of child deaths due to diarrhea throughout the world. Based on this, the high incidence of diarrhea in infants in Indonesia can indicate poor sanitation and drinking water sources that are used by the community.

**Material and Method**

This type of research is descriptive with Microbial Risk Assessment (MRA) assessment on refill drinking water, the sampling technique is carried out in total total sampling of 6 refill drinking water depots. Collecting data using observation sheets, and using a questionnaire then carried out examination of drinking water samples in an integrated laboratory to FKM UMI. Data processing is done by the SPPS method, the data presentation is carried out using tables accompanied by narration. Inspection of Samples for drinking water that has been taken is done by checking the presence of E. coli in it. Tests are carried out three times each for the same sample of 6 samples.

**Materials and Tools**

The tools used in laboratory tests are: Incubator, Autoclaves, Weighing tools, Pipettes, Warp tubes, Tubes of dhamham, Cotton, Wire loops (ose) made of chromium-platinum, Burning bunsen Test tube racks. The materials used: Aquades, Lactose Broth (LB), Brilliant Green Lactose Broth (BGLB) 2%, Label paper, Aluminum foil, Drinking water samples.

**Result**

Based on table 1 shows the number of E. coli in the AMIU depot in the Pattinggaloan Puskesmas.

Source: Data primer

Based on table 3 that the concentration of bacteria in Refill Drinking Water in the area around the Pattingaloang Health Center in Makassar City with 6 samples stated to have a high risk of disease.

Discussion

Microbial risk assessment is a process for calculating or predicting risk in a target organism, system or subpopulation, including identification of certainty that accompanies it, after being exposed by certain microorganisms by taking into account the inherent
characteristics of the cause (microbes) that are being studied and the specific target system characteristics\textsuperscript{15}.

Microbial risk assessment can be done in two ways based on data and the methods used both qualitatively and quantitatively. Risk assessment consists of four stages of study. The four stages are hazard identification, dose-response analysis (quantitative methods) and hazard characteristics (qualitative methods), exposure analysis and risk characteristics\textsuperscript{16}.

Based on table 3 it can be seen that the concentration for high risk levels, the concentration of germs that is for sample code DP1 colony / gr with a value of $P_{\text{inf.d}} = 6.967 \times 10^{-06}$ and $P_{\text{ill}} = \geq 1.63 \times 10^{-05}$, Code sample DP2 23 colonies / gr with $P_{\text{inf.d}} = \geq 5.23 \times 10^{-05}$ and $P_{\text{ill}} = 65.365 \times 10^{-05}$, Code sample DP3 1400 colonies / gr with $P_{\text{inf.d}} = \geq 3.61 \times 10^{-06}$ and $P_{\text{ill}} = \geq 3.26 \times 10^{-05}$, Code sample DP4 sample code 28 colonies / gr with $P_{\text{inf.d}} = 85.785 \times 10^{-05}$ and $P_{\text{ill}} = 61.761 \times 10^{-05}$, Sample code DP5 7 colonies / gr with $P_{\text{inf.d}} = \geq 1.57 \times 10^{-05}$ and $P_{\text{ill}} = \geq 2.73 \times 10^{-05}$, Column DP6 sample code / gr with $P_{\text{inf.d}} = \geq 1.57 \times 10^{-05}$ and $P_{\text{ill}} = \geq 2.73 \times 10^{-05}$.

From the results of a quantitative microbial risk assessment, it can be seen that E. Coli bacteria are very pathogenic to humans. Even with the concentration of safe risk being consumed continuously for a long time, it has provided a high risk for people who consume AMIU from some of the depots\textsuperscript{4}.

The results showed that there 3 depots whose water samples did not meet the requirements in terms of the MPN Coliform parameter because the coliform content exceeds 0 in 100ml sample samples water. Whereas for inspection based on Escherichia coli parameters, all samples were fulfilled requirements because the content of Escherichia coli in the water sample is 0 in 100ml sample sample water\textsuperscript{5}.

Identification of Escherichia Coli conventionally using biochemical reactions test and inoculation, it requiring quite a long time, the biochemical tests is hard to do, and are not accurate. This is because the bacterial colony alleged Escherichia coli in selective media and deferential media is often not pure and mixed with other Enterobacteriaceae bacteria\textsuperscript{17}.

According journal in makassar All depots that were sampled in Mariso Subdistrict did not handle the containers carried by the buyer in accordance with the regulation. The most common method used by most depots now is to brush and rinse with product water afterwards, then fill it immediately.In Mariso sub-district, 38.46% of the samples were brushing and rinsing and 60% of them produced drinking water with quality according to the regulations while the rest showed positive results. While the depot only rinsed, which was 46.15%, all the drinking water produced contained coliform bacteria. The rest of the depots who do not brushing and rinsing the container of the buyer are found to have total bac teriocoliform content\textsuperscript{18}.

Risk management is often used in the fields of financial investment, military planning and public health. In the field of public health, risk management is a policy making and risk control application that can endanger health (EPA, 2012). Microbial Risk Management (MRM) aims to control risk factors that are transmitted by pathogenic microbes that can cause health problems due to consuming water from polluted water sources. Therefore, policy making in microbial risk management is the responsibility of the government and NGOs working in the health sector and related communities so that the transmission of disease through microbes can be prevented or controlled.

One of the principles of Microbial Risk Management (MRM) is that risk management analysis and risk control strategies must be based on the level of risk (risk characterization). Risk characterization is a starting point for formulating risk management and providing a basis for decision making. In addition, risk management must also be based on a risk assessment\textsuperscript{10}.

According to the WHO Drinking Water Guidelines (2008), it suggests that the risk reference standard level is 10-6. So, if the value of $P_{\text{inf.d}} / P_{\text{ill}} > 10^{-6}$ (for example 10-5) then it is stated with high risk whereas if the value of $P_{\text{inf.d}} / P_{\text{ill}} < 10^{-6}$ (for example 10-7) then the risk is declared low. As for the value of $P_{\text{inf.d}} / P_{\text{ill}} = 10^{-6}$, then it is assumed to be of moderate risk.

In the Microbial Risk Assessment Guideline the steps described to make microbial risk management are: formulating problems in a broad context (planning and scoping), risk assessment, determining risk priority choices (risk characterization), making decisions that are appropriately, take action to implement decisions and conduct evaluations related to the effectiveness of the actions taken\textsuperscript{19}. 

Aspects of concern in risk management to overcome the occurrence of diseases, namely: Reducing the risk of disease caused by pathogenic germs by means that employees can pay attention to hygiene and sanitation starting from the processing, filling to sales in accordance with established regulations.

**Conclusion**

Based on a Quantitative Risk Assessment, it was concluded that of the 6 DAMIU samples having a high concentration of risk level, for the estimated amount of E. Coli bacteria in Refill Drinking Water in the area around the Pattingaloang Health Center in Makassar City.

Association of Early Nutritional Status with the Clinical Severity in Patients with Acute Stroke

Myrna Ika Purnama¹, M. Hasan Machfoed¹, J. Eko Wahono R¹
¹Department of Neurology, Faculty of Medicine Universitas Airlangga, Dr. Soetomo General Hospital, Jalan Mayjen Prof. Dr. Moestopo 6 – 8 Surabaya 60285, Indonesia

Abstract

Background: Prevalence of malnutrition in stroke patients in Indonesia is not known for certain because the assessment of nutritional status has not been conducted optimally in all stroke patients due to the existing limitations. Early nutritional status assessment is helpful in planning the provision of nutrition for acute stroke patients. Commonly used nutritional status assessment methods are anthropometry (LOLA and TST) and biochemistry (serum albumin levels).

Objective: To analyze the association of early nutritional status with clinical severity in acute stroke patients.

Methods: The study design was a prospective cohort with consecutive sampling according to inclusion and exclusion criteria of 102 subjects. Initial nutritional status was measured in Upper Arm Circumference (LOLA), Triceps Skinfold Thickness (TST), and serum albumin level. The clinical severity was measured by calculating the NIHSS (National Institutes of Health Stroke Scale) at admission to hospital and the 7th day of stroke. Data was analyzed using chi square (p <0.05).

Results: Most subjects were males (52.00%) with mean age of clinical severity was 54.48 ± 9.634 years old. There was no significant association between initial nutritional status (p = 0.227) and serum albumin level (0.552) with clinical severity. The measurements of LOLA (p = 0.049) and TST (p = 0.481) were statistically significant (p = 0.049) but not clinically.

Conclusion: There was no association between early nutritional status that was measured with LOLA, TST and serum albumin levels with clinical severity measured with NIHSS scale in acute stroke patients.

Keywords: early nutritional status, LOLA, TST, Albumin, acute stroke, NIHSS

Introduction

The incidence of stroke is 12.1 per 1000 population and stroke is considered as the highest cause of death in Indonesia. The high number of deaths due to stroke in Indonesia is influenced by many factors, one of which is the nutritional status of the patients. Malnutrition is often undetectable and an unresolved problem in stroke patients due to the low awareness and lack of education of hospital staff; thus, only a few malnourished patients receive adequate nutritional therapy.

The incidence of malnutrition in stroke in Indonesia is not known for certain because the assessment of nutritional status has not been a routine thing conducted in the management of stroke patients. The incidence of malnutrition in acute stroke patients ranged from 8.00 to 20.00% during the first day of treatment and increased to 35.00-50.00% in the first week of treatment with a prevalence of malnutrition in acute stroke as a whole was 6.00-62.00%. The difference in prevalence of malnutrition in stroke patients is quite wide because of the variety of nutritional status assessment methods used, the measurement time and the type of stroke.

Methods of frequent assessment of nutritional status are anthropometric and biochemical parameters. Examinations of upper arm muscle antropometry...
(LOLA) and triceps skinfold thickness (TST) are quite appropriate for bed rest patients and can roughly estimate lipid storage and muscle mass. TST values will decrease significantly in acute stroke patients on day one and 7 days after treatment. Serum albumin levels are frequently used biochemical nutritional assessments. Albumin is mentioned to have a strong value in diagnosing malnutrition in stroke. Serum albumin concentration will decrease during the first day and one week after treatment in acute stroke patients.

Stroke causes a negative energy balance and increases nutritional needs, but few stroke patients can fulfill the increased need. Malnutrition is one of the poor clinical outcome indicators months post stroke and low albumin levels on the first day of treatment to be an independent predictor of poor clinical outcomes. Malnutrition can lead to high mortality in the long term. Early nutritional status assessments can greatly assist nutrition planning for patients, and given the high prevalence of malnutrition in patients with acute stroke and the magnitude of the impact, the researchers intended to examine the association of initial nutritional status assessed with TST, LOLA and serum albumin levels with clinical severity assessed with NIHSS in acute stroke patients.

Method and Materials

The subjects of the study were acute stroke patients treated in Dr. Soetomo General Hospital Surabaya from April to August 2017. The inclusion criteria were acute stroke, either infarct stroke or bleeding stroke diagnosed clinically with Computed Tomography scans (CT-scan) head without contrast, age >18 years old, and first onset stroke <48 hours. Exclusion criteria included patients with malignant tumors, symptoms and signs of sepsis when admitted to the hospital, suffering from acute and chronic kidney failure, and impaired hepatic function.

The study design was a prospective cohort. The sample collection was conducted by consecutive sampling admission technique. The major subjects of the study were determined by the sample formula for unpaired categorical analytic research, two-way hypothesis with type I error of 5.00% and type II error of 20.00%. The subjects of the study were divided into two groups, namely the acute stroke subject group with malnutrition and the stroke subject group with good nutrition. At the end of the research, we obtained a large sample of 102 subjects. Prior to the identification of the subject first, the researchers conducted a test of ethics (324/Panke.KKE/V/2017) in Dr. Soetomo General Hospital Surabaya, Indonesia.

Anamnesis was performed to collect demographic data (age and gender) as well as clinical data (type of stroke, blood pressure, random sugar levels, and smoking status). The subjects were examined for initial nutritional status measured by TST, LOLA and serum albumin levels. A good nutritional status was shown if all TST, LOLA and serum albumin levels were normal and poor nutritional status if at least one of the measurements of TST, LOLA and serum albumin levels was below normal. TST was measured with caliper skinfold. Normal TST value of male patients was 12.5 mm and female patients was 16.5 mm. LOLA was measured by a tape measure of the formula LOLA = [0.1 LLA (mm) - (0.314xTST (mm)] . The normal value of LOLA in males was 23 cm and female was 20 cm. Levels of serum albumin were examined from the blood of the subjects within <48 hours of stroke treatment. Normal albumin level was 3.5 g/dL. The clinical severity was measured by using NIHSS scale. Measurement of clinical severity with NIHSS scale was performed on the first day of admission and 7th day of onset. The data was analyzed using chi square statistic test with SPSS version. 20.0 (SPSS, Inc., Chicago, IL).

Results

Basic Data Characteristics of Research Subjects

The majority of research subjects were male patients (52.00%). In the group with clinical severity, the research subjects with male gender (69.80%) were greater than female subjects (57.10%) (table 1). The mean age of the study subjects in the group with a fixed clinical severity was 54.48 ± 9.634 years and the mean age of the study subjects in the group with improved clinical severity was 59.05 ± 11.935 years (table 2). The mean gender difference (p = 0.84) and age (p = 0.331) in both groups was not statistically significant.

Clinical Data of Research Subjects

The clinical severity in the group of subjects with bleeding stroke (64.70%) was greater than stroke infarction (63.20%). Subject groups with normotension (70.00%) were greater than hypertension (63.00%) at a constant clinical severity. The clinical severity in the subjects group with hyperglycemia (64.03%) was greater than normoglycemia (63.30%). Group of non-
smoking subjects (63.80%) was greater than smoking (63.60%) in the degree of permanent clinical severity. There was no significant difference between stroke (p = 0.884), hypertension (p = 0.744), hyperglycemia (p = 0.922) and smoking (p = 0.990) with clinical severity (table 1).

Association of Early Nutritional Status with the Clinical Severity

The degree of clinical severity subjects with malnutrition status (68.30%) was greater than in subjects with good nutritional status (56.40%) and it was not statistically significant (p = 0.227). In LOLA measurements, the clinical severity in the group of subjects with malnutrition status (73.50%) was greater than good nutritional status (54.70%).

In TST measurement, the clinical severity in the group of subjects with good nutritional status (65.40%) was greater than malnutrition status (57.10%). In measurement of serum albumin level, the clinical severity in the subjects group with malnutrition status (100%) was greater than good nutrition status (62.6%). The measurement of the fixed clinical severity towards nutritional status with LOLA (p = 0.049) and TST (p = 0.481) had statistically significant differences compared with serum albumin levels (p = 0.552). However, the measurements of LOLA (RR = 1.343, 95% CI 1.999-1.997) and TST (RR = 1.597; 95% CI 1.371-1.859) were also not clinically significant (table 3).

Discussion

The majority of research subjects were males although the percentage was not much different from female subjects. Males have a higher risk of having a stroke than females, especially in the <65 years age group. In this study, the mean age of study subjects in the group with fixed clinical severity was 54.48 ± 9.634 years and mean age in the group of subjects in the improved clinical severity group was 59.05 ± 11.935. This result was not much different from epidemiological data from 28 hospitals in Indonesia which stated that the mean age of stroke patients was 58.8 ± 13.3 years.

Confounding variables such as hypertension, stroke type, hyperglycemia and smoking do not show statistically significant proportions. Thus, these confounding factors can be neglected although in other studies stated that confounding variables have an influence with the severity of clinical stroke. There was no significant association between initial nutritional status and clinical severity. Inappropriateness with the research hypothesis may be due to the observation period for assessing clinical severity is only the first 5-7 days of acute onset of stroke. Research in China showed a poor clinical outcome (MRS scale) at 3 months post stroke. Extended observation may increase the number of clinical significance but can increase the number of drop outs for patients who undergo outpatient care.

Second, this study measured only two anthropometric parameters and one biochemical parameter as a parameter of nutritional status of acute stroke patients. The more examination of nutritional status, the value of the measurement of nutritional status is stronger, because until now there has not been one method used as a gold standard in the assessment of nutritional status.

Third, nutritional status is presumed to be only a minor risk factor in affecting the degree of clinical severity in stroke patients. Poor clinical outcomes in stroke patients are caused by age at the onset of stroke, severity at the time of stroke, disability suffered before stroke, comorbid factors and complications arising from infection.

At LOLA and TST examinations, there was a statistically significant difference in proportion but not clinically significant. The results of the analysis on both anthropometric parameters can be caused by the cut off used. This study used a cut off of LOLA and Dutch TST (Caucasian race). In Indonesia, research on cutoffs for LOLA and TST examinations on populations is still limited. Assessments of dietary intake, mobility or activity performed before illness or other factors are required to be taken that may affect the outcome of the nutritional status parameters used.

Most subjects had good nutritional status from the point of biochemical parameters. This can be seen from the low subjects with hypoalbuminemia. Hypoalbuminemia is a predictor of poor clinical outcomes as measured by MRS scales three months after stroke onset. In acute ischemic stroke is associated with mortality in the first 7 days.

Although there are studies that examine the relationship between nutritional status and hospitalization and geriatrics, there has been no research in Indonesia that specializes in nutritional status with clinical severity in acute stroke patients. This study is the first study to find the relationship between initial nutritional status.
with clinical severity in acute stroke patients. In addition, this study used a prospective cohort design study which is the best observational research design to find out the cause of a case.

**Conclusion**

The majority of subjects were male patients with the average age of more than 50 years old. The majority of subjects had a type of infarct stroke, high blood pressure, normoglycemia, and no smoking. Initial nutritional status as measured by TST, LOLA and serum albumin levels did not correlate with clinical severity measured using NIHSS scales in acute stroke patients. Factors that influenced can be a short observation time, cut off value used, the limited tool during the examination of nutritional status, and nutritional status is a minor factor that affects the clinical severity in acute stroke patients. Further research is required by measuring the degree of clinical severity over a longer period of time, increasing the parameters of nutritional status used and assessing changes in nutritional status before and after stroke treatment in relation to clinical severity of acute stroke.

The Legal Protection of Well-Known Service Trademark (The Case of Inter-Continental Vs The Intercontinental)

Nanda Riwanto¹, Agung Sujatmiko¹

¹Faculty of Law, Universitas Airlangga, Jl. Airlangga No. 4-6, Surabaya 60286, East Java, Indonesia

Abstract

The competition in the field of international services has increased the potential for copyright infringement of well-known service marks. Accordingly, it is necessary to examine the criteria for well-known service marks and legal protection to protect the trademarks’ copyright. This paper analyzes the criteria for well-known service marks according to the instruments of international law and national law. Besides, this study aims to investigate the forms of well-known service mark violations and the efforts to recover the trademarks. The method employed in this study was normative legal research. That method was used since this thesis examined the norms in the laws and regulations as well as the judgments relating to the trademarks to find the law against the issue addressed by utilizing statute approach and conceptual approach. In the case of INTER-CONTINENTAL v. the intercontinental, the trademark violation occurred was brand dilution. The parties in the INTER-CONTINENTAL v. Intercontinental case could resolve their dispute through alternative dispute resolution in the form of mediation, conciliation, or arbitration. In addition, the act of trademarks counterfeiting and piracy may be subjected to criminal sanctions according to the provisions of the applicable Trademark Law. The infringement of trademark copyrights is a detrimental act for the trademark’s legal owner. The settlement of trademark infringement can be conducted through criminal channels and alternative dispute resolution by mediation, conciliation, or arbitration.

Keywords: well-known service mark, criteria, forms of violation, and recovery efforts.

Introduction

The development of global trade causes an urgency for international brand protection. 1, 2. Nowadays, the brand forms a business strategy tool in order to win a very competitive competition. 3. The use of well-known service marks in trade has the potential to ease someone with bad intentions to market their products. It is caused by the fact that well-known brands have gained recognition and trust from consumers since they were known to have high-quality standards. To gain profits quickly, a person can imitate, profiteer, or even counterfeit the famous brands, which certainly causes harm to legitimate brand owners, consumers, and even the State 4. One of the notorious cases is the inter-continental brand plagiarism, which is the legally valid property of the INTER-CONTINENTALS HOTELS CORPORATION based in the United States. INTER-CONTINENTALS HOTELS CORPORATION as a plaintiff sued for violations committed by PT. Lippo Karawaci as a defendant for using the intercontinental trademark without the owner’s permission, as well as the Government of Indonesia, in this case, the Ministry of Law and Human Rights and the Directorate General of Intellectual Property Rights (Directorate of Trademarks) 5. This study discusses two important issues, i.e., identifying the criteria of famous service marks and analyzing the violations of famous service marks along with the recovery efforts.

Methods

The method employed in this study was normative legal research. That method was used since this thesis examined the norms in the laws and regulations as well as the judgments relating to the trademarks to find the law against the issue addressed by utilizing statute approach and conceptual approach.
Results and Discussion

Famous Service Mark Criteria According to International Law Instruments

TRIPs (Agreement on Trade-Related Aspects of Intellectual Property Right) is a more recent regulation related to brand protection. To implement the TRIPs agreement and concurrently develop national laws on IPR, Indonesia is currently preparing the regulations on IPR. The trademark law has changed several times since it was first enacted in 2001. At present, the applicable law is Law No. 20 of 2016 concerning Marks and Geographical Indications, namely the 2016 Trademark Law. TRIPs contain three main issues. First, it contains general rules and basic principles as guidance to the WTO member countries. Second, it contains the standards regarding the administration, use, and scope of each IPR mentioned in TRIPs. Third, it contains provisions relating to the WTO member countries’ obligations to carry out law enforcement on IPR and legal remedies that can be taken to protect and maintain IPR (Ramli, 2000). TRIPs as an international agreement has relevance to agreements and other international conventions on IPR (Usman, 2015).

According to Article 16 paragraph (1) of the TRIPs, the Brand Owner is obliged to register his mark in the territory of the participating country if he wants to acquire exclusive rights. Exclusive rights give rise to monopoly rights over a trademark. Thus, it can be stated that the existence of these rights emerges a legal monopoly. Trademark adheres to the territorial principle, which implies that brand protection only applies in the country where the application for the mark is submitted and granted. To obtain brand protection in the Indonesian jurisdiction, the trademark owner must submit a trademark application in Indonesia. The regulation on the famous mark stated in the TRIPs Agreement is a continuation of the regulation from the Paris Convention. The INTER-CONTINENTAL brand is a service brand that is engaged in hospitality owned by multinational companies and is registered in more than one hundred countries in the world. Legally, the INTER-CONTINENTAL brand should have fulfilled the criteria of a famous mark. Due to INTER-CONTINENTAL’s large investments in various countries in the hospitality sector since 1949, the brand should have been known by the public at large in various countries, especially in the relevant field of hospitality services.

Famous Mark Criteria According to National Legal Instruments

The registration of Intercontinental Trademark owned by the Defendant should be denied by the reasons contained in article 21 paragraph (1) of the 2016 Trademark Law because the intercontinental trademark has similarities in basics or on the whole with the Plaintiff’s trademark, i.e., the INTER-CONTINENTAL. Hence, it can give the impression that the Defendant and the Plaintiff have a relationship, attributed to the similarity. According to Rahmi Jened in Buku Hukum Merek Dalam Era Global dan Integrasi Ekonomi, the reasons for rejection in article 21 paragraph (1) of the 2016 Trademark Law are the relative grounds. Therefore, the Defendant’s trademark rejection reasons should be based on relative grounds.

The Plaintiff’s trademark has been registered at one hundred countries in the world. The Plaintiff’s trademark has been registered in one hundred countries in the world. INTERCONTINENTAL Plaintiff’s Trademark should have fulfilled the criteria of a famous mark. According to Law No. 15/2001 or 2016 Trademark Law, the definitions of famous mark are not clearly stated, but in the Elucidation chapter of Article 21 Paragraph (1) Letter b of the 2016 Trademark Law, famous mark must be considered or can be marked with a. the basis of public knowledge about the brand; b. the brand’s reputation is obtained through intensive and extensive promotion; c. trademark registration is carried out in several countries and d. the company’s investment in other countries.

Concerning the INTER-CONTINENTAL against PT. LIPPO Karawaci case, the Plaintiff’s Trademark, INTER-CONTINENTAL, has been registered in one hundred (100) countries in the world, including Indonesia, and historically the Plaintiff’s famous service mark has existed and been traded since 1949. The Plaintiff proved it with the evidence basis, i.e., a copy of the registration mark certificate from twenty-nine (29) countries, including Indonesia. In business, to create markets in various parts of the world requires capital, a very large amount of investment, and a long period. Thus, a famous mark must be protected. In this case, it is necessary to prove whether the Plaintiff’s trademark is a well-known mark or a famous mark. Famous mark is considered a higher reputation than a well-known mark since it is in a superlative form and it is the highest level of the famous brand based on the word meaning. Famous mark requires at least registration of a mark in
its own origin country.

**The Forms of Violations and Recovery Efforts for Trademark Violations**

Famous brands are prone to trademark violations, such as counterfeiting and piracy. In principle, trademark violations are based on bad faith from the violation perpetrators. Article 41 of the TRIPs states that: “Members shall ensure that enforcement procedures as specified in this Part are available under their laws so as to permit effective action against any act of infringement of intellectual property rights covered by this Agreement, including expeditious remedies to prevent infringements and remedies which constitute a deterrent to further infringements. Based on the above provisions, TRIPs requires that there is a rapid recovery effort for a trademark violation as well as a good preventive effort. Strictly stated in Article 41, TRIPs mentions the examples of violations in general, which is Trademarks Infringements.

Furthermore, brand infringement can be in the form of a Passing Off, which occurs when someone sells a product as if it were a product of the famous brand and has a good reputation, or at least allude a relationship that confuses the community, which those gives a loss to the real brand owner. The Second is Dilution. Dilution is a weakening or reducing the ability of a famous brand to distinguish goods and services without paying attention to any confounding similarities, so the consumer will not be confused in distinguishing a product even though the brand name is the same. Therefore, the distinguishing and unique characteristics of the brand are reduced by the brand similarity and likeness in principle. Dilution damages the reputation of famous brands through these actions. The Third is Counterfeiting and Brand Piracy. Counterfeiting and brand piracy can be detrimental to many parties ranging from the community, brand owners, and also the state which loses the revenue from the sales tax sector while the pirated goods are sold without tax. The consumers as users will be aggrieved due to those actions. (Agung Sujatmiko a, 2008).

**The Recovery Efforts for Famous Trademark Violations**

Concerning the INTER-CONTINENTAL against PT. LIPPO Karawaci case, the violation occurred was brand dilution. Even though dilution does not confuse because it only weakens the brand, but it is a violation of the famous brand owner’s exclusive rights. Therefore, the famous brand owner suffers a loss. Furthermore, in the Elucidation Chapter Article 76 of the 2016 Trademark Law, it is stated that the parties that can file a trademark cancellation claim are: Concerned parties are parties who legally have personal interests that are legally recognized. Anyone with interest in intellectual property, such as the right to the brand and the right to use the brand, prosecutors, foundations/agencies, religious assemblies/institutions. The trademark owner who is unregistered after submitting an application for trademark registration in good faith to the Directorate General of Intellectual Property or the owner of a well-known mark yet it is unregistered.

After taking legal action against the cancellation, the Plaintiff’s claim was rejected by the judex factie judicial panel of the Central Jakarta Commercial Court. In its decision, the judex factie assembly rejected the Plaintiff’s claim in its entirety. In its legal considerations, the judex factie panel believed that the Defendant and Defendant’s trademarks were dissimilar because of the capital letters used and writing differences. Hence, the similarity element was essentially unproven, so the Defendant’s trademark rights were legal. According to the article 78 provisions of the 2016 Trademark Law, to the Commercial Court decision, only the appeal may be submitted. Therefore, the Plaintiff filed an appeal to the Supreme Court. The Plaintiff’s appeal request was granted partially by the Supreme Court which stated emphatically that the Plaintiff’s trademark was classified as a famous mark category, so it was also protected for non-similar goods. The judex juris of Panel of Judges canceled the judex factie decision and stated that the Defendant’s trademark in the form of speech or voice said essentially resembled the Defendant’s trademark, so it had to be canceled.

Based on the provisions of article 85 of the 2016 Trademark Law, a civil action is filed with the Commercial Court, where the Defendant’s law or the offender domiciles (actor sequitur forum rei). However, if the Defendant is abroad, the lawsuit is filed in the Central Jakarta Commercial court. The provisions regarding the right to file a lawsuit by the owner and/or holders of license over mark are regulated in Article 83 of the 2016 Trademark Law that the registered Trademark Owner and/or Holders of License Over Mark can file a lawsuit for violation against another party without the right to use a Trademark that has similarities in basics or on a whole for similar goods or services in the form of
IPR criminal provisions on trademarks are in Article 61 of TRIPs. The violation of a famous service mark may be subjected to criminal sanctions if the violation is carried out by brand counterfeiting or brand piracy. Brand counterfeiting here is undertaken by faking existing brands, which can create an impression on the public as if the counterfeited goods are the same as the original goods that are using famous brands to related institutions 19. Article 100 of paragraph (1) of the 2016 Trademark Law states that any person who without the right to use the Mark as a whole in its entirety with another party’s registered Marks for similar goods and/or services that are produced and/or traded, is convicted with a maximum criminal imprisonment of 5 (five) years and/or a maximum fine with no more than Rp. 2,000,000,000.00 (two billion rupiah). This provision provides strict sanctions for the perpetrators of counterfeiting brands. Furthermore, in Article 100 of Paragraph (2) of the 2016 Trademark Law states that “Every Person who without the right to use the Mark which has the similarities in principle with a registered Mark that belongs to another party for similar goods and/or services that are produced and/or traded, is convicted to a maximum criminal imprisonment of 4 (four) years and/or a maximum fine of Rp. 2,000,000,000.00 (two billion rupiah). “ This provision provides strict sanctions for perpetrators of brand piracy. According to Rahmi Jened 72, the terminology of brand piracy in TRIPs is translated as similarity in principle in the 2016 Trademark Law, so that anyone who commits brand piracy may be subject to criminal sanctions according to the provisions of article 100 of paragraph (1) of the 2016 Trademark Law. Article 93 of the 2016 Trademark Law which regulates that in addition to taking civil actions, the parties can also settle the disputes in article 83 of the 2016 Trademark Law through Arbitration or Alternative Dispute Resolution. Based on these provisions, then in the case of INTER-CONTINENTAL v. the intercontinental, can be resolved through alternative dispute resolution (amicable settlement), where the parties voluntarily agree on a collective agreement (party autonomy principle) to settle the disputes outside the court. According to the elucidation Chapter of Article 93 of the 2016 Trademark Law, the forms of alternative dispute resolution include negotiation, mediation, conciliation, as well as other means chosen by the parties 11,20 but the regulation of domain name crimes is not regulated in the ITE Law as mandated in the academic draft of the ITE Bill. The absence of regulation of domain name norm in the ITE Law creates problems with registrant of domain name (registrant).

Conclusion

In the case of INTER-CONTINENTAL v. the intercontinental, the trademark violations occurred are brand dilution. The parties in the INTER-CONTINENTAL v. Intercontinental case can resolve their dispute through alternative dispute resolution in the form of mediation or arbitration. In addition, counterfeiting and trademark piracy may be subject to criminal sanctions according to the provisions of the applicable Trademark Law.

Determining the Quality of Services Provided in Delivery Room at Ayatollah Kashani Hospital (Jiroft, Iran) from the Perspective of Clients Using Service Quality Model (SQM) During Spring 2019

Narges Mahyapour Lori¹, Hourie Taheri Sarvetomin¹, Mahdiyeh Ahmadi², Sareh Mehnî³, Neda Dastyar³

Abstract

Background and Objective: Topnotch services provided through preserving high quality is a prerequisite to the success of service organizations including maternity hospitals. Since maternity hospitals play an important role in providing services and promoting women’s health and that of the entire society, this study attempted to assess the quality of services provided in the maternity ward of Ayatollah Kashani Hospital in Jiroft (Iran).

Method: This was a cross-sectional, descriptive study conducted on 234 women who went through vaginal delivery in Ayatollah Kashani Hospital. After 2 hours of delivery, convenience sampling was carried on the subjects in 2019. Data were collected through SERVQUAL standard questionnaire (1988), the validity and reliability of which were confirmed. Data were analyzed by SPSS using descriptive and inferential statistics.

Results: The results indicated that there is a negative gap in all dimensions of service quality. The largest gap was observed in assurance (-5.69) while the lowest gap was in the physical dimension (-3.2). There was a significant difference between women’s expectations and perceptions across all five SERVQUAL dimensions (P<0.001).

Conclusions: From the women’s perspective, the quality of services was not satisfactory and the significant difference between expected and received services indicates that managers should pay more attention to quality improvement programs in maternity hospitals so that increasing the quality of services will promote women’s health and eventually that of the entire society.

Keywords: Women, Maternity Hospital, SERVQUAL, Quality of Health Care

Introduction

Nowadays, promoting the society’s health is a key factor in economic and social development. Therefore, one of the major concerns of countries worldwide is assurance of health care quality, programs and services. Quality is a main factor in global competition, where managers have to provide quality services for successful competition (1-2-3). Quality of service is the comparison of what the client feels it should be (expectations) with what it has actually received (perceptions). If expectations are higher than perceptions, the client would perceive the quality of service to be lower, leading to dissatisfaction (4). Expectation is one of the most important determinants of client evaluation of service quality, and accurate understanding of client expectations is the most important step in defining and delivering high-quality services. In fact, one of the current challenges in the health system is how to respond to patient expectations. This has been neglected despite the importance of recognizing the needs and requirements of patients in providing care (5). The

DOI Number: 10.37506/ijfmt.v14i2.3200
results of various studies demonstrate that fulfilling patient expectations is associated with high satisfaction with services, whereas unfulfilled expectations are associated with dissatisfaction. Patient satisfaction is one of the critical goals of group therapy activities. Patients’ satisfaction with hospital services is one of the most important indicators of quality and effectiveness in service delivery and has made a major contribution in this regard. Satisfied patient is a key factor in any hospital’s success. In fact, patient satisfaction is defined as patients’ overall perception of the quality of healthcare provided (6-7). The only way for the patient to participate in caregiving is to research and seek patient satisfaction with current structures and to obtain their feedback. One of the most important groups under study in the field of satisfaction is patients in care and hospitalized in the maternity ward. That is because the delivery process during the care period is extremely stressful and it is one of the undesirable experiences of many people (8-9). According to a statement by the International Confederation of Midwives (ICM) and the International Federation of Gynecology and Obstetrics (FIGO), awareness of the disadvantages and benefits of different therapies, participation in the decision-making process and offering high quality services are among the ethical rights reserved for pregnant women (10). Observance of these rights leads to greater satisfaction with prenatal care and increased satisfaction with childbirth and, consequently, lower rate of cesarean delivery and the complications of pregnancy and childbirth on the mother and fetus (11). Accordingly, mothers can participate in their own treatment process and receive more quality therapeutic interventions (12). Deploying high-quality services saves costs, enhances the effectiveness of specialized service providers, strengthens staff morale, creates a satisfying environment, and increases patient loyalty in choosing a hospital for health care.

Conflicting perceptions of service quality have led to the adoption of different methods to assess service quality (13). For many years, researchers have been measuring quality of service using one-dimensional scales, while one-dimensional scales are not suitable for measuring a multi-dimensional concept such as quality (14). One of the best and most practical strategies to evaluate service quality involves SERVQUAL, a model designed by Parasuraman et al. (2008). SERVQUAL is a method for purposefully identifying the strengths and weaknesses of service organizations such as hospitals. It is also used to comparatively measure the perceptions and expectations of clients (patients). The SERVQUAL scale contains metrics, half of which measure the expectation level of service recipient while the second half measures the perceived level of quality provided by the organization (15). Given that patient satisfaction assessment can provide the basis for identifying the current strengths and weaknesses and pondering strategies for providing better care and improving the quality of services, SERVQUAL was adopted as a powerful tool for measuring service quality (16-17-18). Moreover, given that quality analysis of hospital services enables hospital managers to allocate funds to improve performance in areas that have a greater impact on patient satisfaction, and since our preliminary study about quality of service in Iran was more focused on primary health care without using expert opinions, we intended to conduct a research to evaluate the quality of services provided in Ayatollah Kashani Hospital in Jiroft during spring 2019. This was decided because fewer authorities have taken this into consideration despite the importance of maternity ward’s emergency department in ensuring the health of pregnant mother and her fetus, as well as the special importance of Ayatollah Kashani Hospital Maternity Hospital as the only specialized women’s hospital in southern Kerman.

The most important client will be realized through proper planning, correction of deficiencies and ultimately improvement of service quality (26).

Materials and Method

This is a cross-sectional, descriptive-analytical research project. The statistical population includes all women referred to Ayatollah Kashani Hospital in Jiroft for the period of March to June 2019. The data were collected by census method and from all qualified clients. Inclusion criteria: Informed consent to participate in the study, maximum 5th pregnancy, at least 24 hours of hospitalization, pregnant or 2 hours past parturition and transferred to gynecology ward, maximum age 45 years old, minimum literacy reading and writing, no physical or mental illness. Moreover, women in the active phase of labor who did not complete all sections of the questionnaire were excluded. Finally, the population comprised 234 subjects. After obtaining permission from the Ethics Committee and agreeing to hospital managers, the leading researcher attended the maternity ward and administered the SERVQUAL questionnaire at different labor shifts (morning, afternoon, and evening) until the end of June. The subjects returned their
written consent and were assured of the confidentiality of their information. The questionnaire consisted of two parts: demographic information and SERVQUAL items. Personal information involved 11 items (age, number of pregnancies, level of education, etc.) The second part covers SERVQUAL Multidimensional Questionnaire. The questionnaire included 28 items in 6 dimensions, namely physical (5 items), reliability (5 items), responsiveness (5 items), service assurance (5 items), empathy (4 items), and access to care (4 items), while the questionnaire was based on a five-point Likert scale: very high, high, medium, low, very low. In their study, Mousavi et al. calculated reliability and validity of the questionnaire through Cronbach’s alpha, which were 0.88, 0.87, 0.88, 88. 0, 0.91 and 0.86 in physical dimension, responsiveness, assurance, empathy, reliability and accessibility, respectively (28). In order to enhance the concentration of subjects, the questionnaire was administered without staff presence. It took about 15 minutes to complete the questionnaires. After collecting the questionnaires, data were analyzed using SPSS 20. Furthermore, the data normality assumption was evaluated by Kolmogorov-Smirnov test and, Mann-Whitney and Kruskal-Wallis nonparametric tests were used.

Results

A total of 234 subjects with a mean age of 27.0±6.44 participated in the study, of whom 80% held a diploma degree and lower, while the rest had a bachelor’s degree or higher. Of these, 87% were housewives and about 9% were occupied, 39% experienced first pregnancies and 5% were on the fifth pregnancy. There was no significant relationship between age and satisfaction (p=0.56). The mean gap score in patients with a bachelor’s degree and higher was significantly higher than those with a lower level of education (p<0.05). Interestingly, mean expectations were similar in the two groups (p=0.08) but mean perceptions in the bachelor and higher groups were significantly lower (p<0.05). The mean score of gap was significantly higher in those with a bachelor’s degree and higher (p<0.05). The mean gap score was significantly different between those who tended to be pregnant and those who did not tend to be pregnant (p=0.39).

As can be seen in the table below, physical dimension had the smallest gap (-3.2) while assurance indicated the highest gap (-5.69). Individuals expressed the highest expectations in terms of accountability and assurance while the lowest perceptions were in empathy and access. There was a significant difference (p<0.001) between mean perceptions and expectations at all dimensions.

Discussion

The main purpose of this study was to investigate the level of expectations and perceptions about the quality of services from the perspective of patients referred to Kashani Hospital in Jiroft during spring.

Similar to many researchers, we attempted to examine the gap between client expectations and perceptions of service quality. According to the findings in our study, the lowest and mean gaps and highest perceptions were found in the physical dimension which was inconsistent with the findings of Seyedi et al. (29). This reflected that the hospital cared for physical and infrastructural facilities similar to the results of a periodic survey conducted between 2000 and 2008 focusing on the provision of services at a dental service facility in Estonia. Their research results showed that the gap between patients’ perceptions and expectations of service quality widened between 2000 and 2007 and decreased during 2008 (30).

Furthermore, the low score of perception and expectation in the empathy dimension indicates that the hospital-patient interactions have weaknesses that need to be addressed. This is in contrast to the results of Gray Boshoff (31) and Sidey et al. (29). It is also noteworthy that the individual interactions that occur during the care processes have a significant impact on the recipient’s perception of the quality of service provided by the medical center.

The highest expectations and gaps were found in assurance, which is consistent with the results of the study by Mousavi et al. (32) as well as Baker (33). These results indicate that from the patients’ perspective, the proficiency and expertise of the medical staff and the protection of patient rights when providing care services are vital, and the large gap in this dimension indicates that their expectations and dissatisfaction are not met.

In this study, the mean score of expectations in patients with university and non-university education was the same, but there was a significant difference in the perception of these two groups, which resulted in a significant gap in education, so that the mean of the academic gap was higher than the others. Greater level of education increases the level of expectation and
consequently decreases the perception of quality.

In our study, the variables history of hospitalization, insurance coverage and length of hospital stay did not lead to any significant difference in the main variables.

**Conclusion**

Finally, we suggest that the gap across all items is significant, which means that the hospital has a long way to go before satisfying the patients in providing health services.

³Ministry of Health, Al- Imamain Al- Kadhimain Medical City Department of Obstruction and Gynecology, Iraq, Baghdad

Abstract

Background: Preeclampsia (PE) consider as one of the most serious complications of pregnancy, and the chief reasons of

Objectives: Study the correlation between serum & urinary placental protein (pp13) in pre-eclamptic women at their third trimester

Materials and Method: Case control study was achieved from August 2018 to January 2019. A total of 100 women involved in this research, 50 preeclampsia pregnant women and 50 apparently normal pregnant women as control, for all the subjects in the research serum and urine sample were collected for placental protein 13 (pp13) estimation by using ELISA technique.

Results: Results indicated that a highly significant decreased in serum and urine pp13 in preeclamptic women compared to healthy women pregnant

Conclusion: Maternal serum PP13 at their 3rd. Trimester has evidences to be a credible biomarker for preeclampsia risk evaluation: the specificity and sensitivity of pp13 provided the highest diagnostic for preeclampsia

Keywords: third trimester, preeclampsia, PP13.

Introduction

Preeclampsias (PE) consider as one of main pregnancy disorders that has worldwide incidence rates about 5–8% [1]. The delivery of the placenta is the only acknowledged cure. PE is the major reason of the premature birth in developed countries, generally physically shown for the assistance of the mother [2].

PE is capable of being separated into two major kinds, the early and the late onset PE. This classification is depending either on the onset period or the identification of the syndrome [3]. The late onset PE comprises the majority (>80%) of preeclamptic. In the early onset type, the clinical symptoms appear prior to 33 weeks of gestational, while regarding late onset kind they happen following 34 weeks. The early-onset type that is accountable for most of the high maternal and fetal mortality and morbidity rates [1].

The American College of Obstetrics and Gynecology defined the clinical diagnosis of PE which involves blood pressures more than 140/90 mm Hg on 2 occasions joined with excretion of protein in urine more than 300 mg/d. The word Edema, considered as a classic characteristic of this disorder, it is not yet regarded as a detection sign due to absence of validity indicators the eclampsia could be existing in 20 percent of patients without previous proteinuria or hypertension, suggestive of the presently using biomarkers for diagnosis are not ideal [4].

Placental protein 13 (PP13) is a 32 kDa dimer protein which is produced just in the placenta also it is believed to be included in maternal artery remodeling and usual placentation. It was found by Nicolaides et al. [5] that a remarkable decrease of serum PP13 values at 11 to 13
gestational weeks in the women whom consequently resulted the early type of preeclampsia, which was then validated by Spencer et al. [6].

Galectins (GAL) are many purposely controllers of primary cellular methods. They are as well included in natural and adaptive immune responsiveness and achievement aoperative role in the immune endocrine crosstalk. A number of GAL have invited interest in the reproductive knowledge for the reason that they are very much expressed at the maternal fetal line, their purposeful importance in eutherian pregnancies, and their unregulated illustration is detected in the “huge obstetrical disorders.” Those GAL; could function as significant proteins included in maternal fetal connections. The examiner of these GAL can progress the predictive, detection, and therapy of the pregnancy women difficulties [7].

Methods

A case control study was carried out on 100 pregnant women over a period of seven months from August 2018 till January 2019. The participants in this research were collected from different hospitals in Baghdad city; the Al-Elweyia, Al-Hakeem, and Al- Imamain alkadhimain medical city. The practical fraction was accomplished at Research Laboratories in the Department of Chemistry and Biochemistry, College of Medicine/Al Nahairn University.

All subjects who included in the research were subjected by their physician to physical examination, blood pressure measurement, and laboratory investigations including serum and urinary pp13.

Inclusion criteria: All pregnant women included in this study were chronic hypertension pregnant women at their third trimester, gestational hypertension, renal and liver diseases, diabetes mellitus, smokers, fetal structural anomalies, multiple pregnancy, intrauterine fetal growth restriction from other causes, heart failure, inflammatory disorders, elderly pregnant, infectious disease, endocrine disease, HELLP syndrome and collagen vascular disorder were all expelled from the study.

Five milliliters (ml) venous blood had been withdrawn from all pregnant women by the use of disposable syringes in the sitting situation. Then it was discharged gradually in disposable test tubes without anticoagulant. And waited for clotting at 37°C for 10 to15 minutes, then centrifugation at 1000 xg for about 10-15 minutes. Their serum was stored eppendorf tubes at -80°C until analysis of pp13.

Random urine sample was collected in asterilelecup for urine collection. Pregnant women who participate were informed to throw away the initial20-25ml of urine and have a collection ofapproximately60 mL urine of mid stream and stored in at -80°C until analysis of placental protein 13(pp13).

Results

The mean ± SE of maternal age for control group and PE groups (mild and severe cases) were 29.28±1.08 years, 29.84±1.70years, 29.85±1.27 respectively. No significant difference (P= 0.931) was found between them.

The mean ± standard error of mean of serum pp13 for control group and PE groups (mild and severe cases) at 3rd trimester afterbirth were 67.06± 3.296 pg/ml, 54.29± 3.129 pg/ml, 54.33 ±4.312 pg/ml, 54.25 ±4.64 pg/ml respectively.

There was highly significant increased (P=0.006) in mean of serum pp13 between control versus patient group

Also, high significant decreased (p=0.026) was found between mild preeclamptic group versus control group, while a highly significant decreased (P=0.035) was found between severe preeclamptic group versus control pregnant (Table1-2), but no significant difference (P=0.990) was found between mild against sever group.

The mean ± standard error of mean of urine pp13 for control group and PE groups mild and severe cases
at 3rd trimester after birth were 51.84±2.601 pg/ml, 38.39±2.717 pg/ml 43.44± 4.914 pg/ml, 33.34 ±1.863 pg/ml, respectively.

There was a highly significant decreased (P=0.001) in mean of serum pp13 between patient versus controls group. Also, high significant decreased (p=0.022) was found between mild preeclamptic group versus control pregnant group also, there was highly significant decreased (P=0.002) between severe preeclamptic group versus control pregnant (Table1-2). But no significant difference (P=0.062) between mild against sever group showed Table (1-2).

Table 3 showed comparison between placental protein 13 urinary and serum among preeclamptic and control women, the mean ±SE of serum levels preeclamptic and control were 54.29±3.129 pg/ml, 67.06±3.296 pg/ml respectively while the mean ±SE of urine levels for preeclamptic and control 38.39±2.717 pg /ml 51.84± 2.601 pg/ml when compared with serum pp13 between patients and control showed high significant (p=0.006). Also, patients compared urine pp13 was found with very high significant decreased (p=0.001)

Placental protein 13 urine and serum was measured in sera samples patients and healthy was presented in figure (3.2)
Table (3) Correlation of serum placental protein 13 pg/ml with all of the studied parameters in control pregnant group, mild and severe preeclamptic group.

</table>

Regarding the correlation of the serum pp13 concentration with all of the studied parameters in control, mild, and severe PE groups; in severe PE, serum pp13 values showed very high positive significant correlation (P<0.001) with pp13 ratio=r=0.806). And positive correlation with urine pp13 (r= 0.019). On the other hand, in mild PE, positive correlation with age (r=0.096) In the control group, the highest level of significance (P<0.001) were observed in correlation of PP13 with age (r=- 496), and pp13 Ratio=r= 0.694). Also it showed significant negative correlation (P<0.01) with age, urine pp13.

Discussion

Preeclampsia influences about 2 to 5 percent of women at pregnancy, causative to the fetal, neonatal and maternal mortality and morbidity, whilst the disorder noticeable at the 3rd trimester, the main placental function disturbances starts to a great extent in pregnancy earlier. Placental protein 13 (PP13) is a 32 kDa which is a dimmer protein that is present just in the placenta and is consider to be included in maternal artery remodeling and usual placentation.

Regarding ROC study between patients and control: Receiver operating characteristic curve (ROC) analyses of serum PP13 reveals the capacity of this biomarker to distinguish normal pregnancies from preeclamptic (Figure 3.5). The cut-off value = 50.43ng / ml of PP13 optimally identified patients with preeclampsia; at the sensitivity was 64% and specificity was 82.5 % and the area under curve (AUC) was 0.70 P = 0.002 .ROC study between patients and control : Receiver operating characteristic curve (ROC) analyses of serum PP13 reveal the ability of this marker to differentiate preeclamptic from normal pregnancies (Figure 3.5). The cut-off value = 50.43ng / ml of PP13 optimally identified patients with preeclampsia; at the sensitivity was 64% and specificity was 82.5 % and the area under curve (AUC) was 0.746 P = 0.002.
differences in the mean age of preeclampsia group and control normotensive.

In the current study, the maternal values of the placental protein 13 in serum were found highly significant in pre-eclamptic cases groups (mild and severe preeclampsia) as compared to controls group and showed decrease in the results of pp13 levels in preeclampsia disorder.

The result conducted by Fahmy there was low in pp13 levels in pre-eclampsia groups, this agreement with our study appeared there was decreases in pp13 levels in preeclampsia groups as compared with control pregnant group Perhaps, (Fahmy et. al. 2018).

And in agreement with Berthold Huppertz observation in patient with Preeclampsia the pp13 serum levels were increased compared with control pregnant individuals. (Berthold Huppertzetal, 2008)

And the study by Farina conclude that variations in PP13 in preeclampsia be able to be measured revealing a pathophysiological alter of PP13 in pregnancy very early. It stays to be observed if the decreased value of PP13 in pregnancy early is an essential reason or an outcome of the placentation disturbance (Farina et al., 2010).

Efficacy of Acetaminophen Plus Amitriptyline Compared to Acetaminophen to Reduce Pain Intensity in Nonspecific Chronic Lower Back Pain

Nita Kurniawati¹, Isti Suharjanti², Muhammad Hamdan², Joseph Ekowahono Rahardjo², Djohan Ardiansyah², Hanik Badriyah Hidayati²

¹Resident in Training Department of Neurology, ²Department of Neurology, Faculty of Medicine, Universitas Airlangga Dr. Soetomo Teaching Hospital, Surabaya 60285, Indonesia

Abstract

Background: There was 90% of Lower back pain (LBP) are non-specific. Acetaminophen is the first analgesic in the treatment of LBP, but some cases of chronic LBP need additional antidepressant drugs. Amitriptyline is an antidepressant drug often used in cases of pain, but the evidence research in the case of non-specific chronic LBP is still a contradiction.

Method: The study was a Double-Blind Randomized Controlled Trial using consecutive sampling admissions. The subjects were divided into 2 groups; acetaminophen plus amitriptyline group and acetaminophen plus placebo group.

Results: There was no significant difference in pain intensity of acetaminophen plus amitriptyline and acetaminophen plus placebo groups either statistically or clinically (p = 0.498; OR = 0.667; CI 95% 0.20-2.16; ARR = -0.07 or -7%). The significant improvement of pain intensity in the treatment group Acetaminophen plus Amitriptyline was 24 (72.7%), while in the control group Acetaminophen plus Placebo was 24 (80.0%). In the treatment group was 9 (27.3%) who did not experience a significant improvement in pain intensity, and in the control group was 6 (20.0%).

Conclusion: There was no difference in efficacy between acetaminophen plus amitriptyline with acetaminophen plus placebo to reduce pain intensity in non-specific chronic LBP.

Keywords: Non-specific chronic LBP, Amitriptyline, Acetaminophen, VAS

Introduction

Lower back pain (LBP) is a health problem in adults that most often occurs in developing countries around the world. Approximately 90% of LBP patients are non-specific, and one-third of them have chronic symptoms about a year after an acute episode. According to the World health organization (WHO) International classification of functioning definition, disability, and health; nonspecific LBP is an unknown LBP that underlying pathology in the absence of tissue damage to corresponding symptoms of LBP. Acetaminophen is still the first-line analgesic recommended by almost all pain guidelines in the treatment of chronic LBP, but in some cases, additional treatment is required, such as antidepressants or anti-convulsions. Amitriptyline is one of the most widely used tricyclic antidepressant drugs as an adjuvant analgesic primarily for chronic neuropathic pain and fibromyalgia. Amitriptyline 25 to 125 milligrams each could reduce neuropathically and fibromyalgia pain Relative risk (RR) 2.3, (95% CI, 1.8-3.1) with number needed to treat 4.6 (3.6-6.6), however 64% of participants in the study experienced adverse events RR = 1.5, (95% CI 1.4-1.7) with needed to harm
4.1 (95% CI 3.2-5.7). Another result mentioned that in the case of temporomandibular joint pain, amitriptyline at a dose of 10-30 milligrams/day was effective in relieving pain with pain reduction occurring within 6 weeks.

In addition, there were other objectives such as: Assessing the intensity of pain in chronic non-specific LBP patients by receiving acetaminophen 3x500 milligrams daily; Assessing pain intensity in non-specific LBP patients chronically treated by acetaminophen 3x500 milligrams plus amitriptyline 10 milligrams daily; Comparing pain intensity changes in chronic non-specific acetaminophen LBP patients by receiving acetaminophen 3x500 milligrams plus amitriptyline 10 milligrams daily with non-specific chronic LBP patients that receiving acetaminophen 3x500 milligrams. Therefore, the study aimed to prove that acetaminophen 3x500 milligrams plus amitriptyline 10 milligrams each day was better in reducing the intensity of pain than the administration of acetaminophen 3x500 milligrams each day in non-specific chronic LBP.

Method

Double-blind randomized controlled trial was used in the study. The subjects were non-specific chronic Lower back pain (LBP) patients at the Outpatient Neurology Unit of Dr. Soetomo Teaching Hospital Surabaya that fulfilled the criteria of inclusion and exclusion. The inclusion criteria were; the samples have not received treatment yet, Not treatment anti-pain drugs within a week before joining the study, Age ranges of 20-49 years, Visual analogue scale (VAS) ≥4. And willing to participating in the research by sign informed consent. Whereas, the exclusion criteria were: Depression, such as the heart is relatively unknown and noticed by radiographers and cardiologists. Objective: To analyse the image quality of 4 chamber sections of Cardiac Magnetic Resonance Imaging with and without the use of shim volume on Steady State Free Precession (SSFP. Data on the intensity change of pain was obtained from the difference between before and after the treatment, then it will be analyzed using a Chi-square test (X2). The preliminary study of 30 people was obtained 80% of the subjects that had experienced a treatment success (VAS1-VAS2 ≥2 difference) on the 14th day of treatment, so the cut point taken of treatment was 13 days.

Basic Demographic and Clinical Data of Subject

The basic characteristics of subjects by age (Table 1) showed that the median age in the treatment group Acetaminophen plus Amitriptyline was 42.00 (20-49), while in the control group Acetaminophen plus Placebo was 37.50 (20-49). The homogeneity test of the age variables in the two groups (Table 1), showed no significant difference age between treatment and control group with Mann-Whitney p = 0.345.

Characteristics of basic data of research subjects based on sex, educational level and type of job are shown in Table 2. Overall, there were 47 females and 16 males. The treatment group was 26 (55.3%) of female subjects and 7 (43.8%) of male subjects.

Clinical data of study subjects before treatment shown in Table 3. In the treatment group, the median data of initial VAS was 5.00 (4.20-8.50), whereas in the median control group the initial VAS was 5.20 (4.10-8.20). The homogeneity test of early VAS variables in both groups had no significant difference in initial VAS variable between treatment and control group, with Mann-Whitney p = 0.540.

Effect of therapy on the improvement of pain intensity Changes in pain intensity were the differences between the initial Visual analogue scale (VAS), on day 14th (VAS1-VAS2 differences). The mean of pain intensity change in the treatment group was 3.51±2.01, and in the control group was 4.08±2.05 (Table 4).

The test of variable distribution of pain intensity change in both groups showed an abnormal distribution pattern, so the comparative test used to compare the variety of pain intensity change in both groups using an unpaired t-test. The unpaired t-test of VAS1-VAS2 differences between the two groups showed no statistically significant difference, with p = 0.28 (CI 95%
Result Data based on the success of treatment

A significant improvement in pain intensity was considered successful, for example, the initial VAS value difference and the VAS day value of 14 (VAS1-VAS2 difference) was ≥2. Overall, 48 (76.2%) of the subjects who succeeded in the treatment (decreased pain intensity ≥2) and 15 subjects (23.8%) were unsuccessful in the treatment. The significant improvement of pain intensity in the treatment group Acetaminophen plus Amitriptyline was 24 (72.7%), while in the control group Acetaminophen plus Placebo was 24 (80.0%). In the treatment group was 9 (27.3%) who did not experience a significant improvement in pain intensity, and in the control group was 6 (20.0%). The result of the statistical test comparing the treatment success between the treatment group and control group was not statistically significant, with p = 0.498; Odds Ratio = 0.667 (CI 95% 0.20-2.16).

Drug Side Effects in the treatment and control group

During the study, the side effects were found in both control and treatment groups, with results as shown in Table 6. The incidence of adverse drug effects in the study subjects of treatment group was 21 people (63.6%), whereas in the control group was 15 (50.0%).

Discussion

The study, there were no significant differences in both the outcome of decreased pain intensity and treatment success, between the treatment group and the control group. It was not following previous studies suggesting that amitriptyline was more effective in the second week of treatment in reducing pain intensity (t = 4.43, p <0.001) than acetaminophen (t = 3.30, p <0.01) LBP 45. Some of the reasons that might explain the difference between our study and previous research were the inclusion criteria were non-specific LBP cases that exclude depression, did not take into account psychological factors (anxiety and coping mechanisms), and use low doses of Amitriptyline.

Another Result included both non-specific LBP and neuropathic LBP in the inclusion criteria, whereas in the study subjects were only non-specific chronic LBP. They also take into account psychological factors such as mild depression, anxiety, and coping mechanisms.
treatment and the control groups, were no significant differences. The clinical trial, ARR = -0.07, indicated that statistically and clinically, treatment in the treatment group (Acetaminophen 3x500 mg + Amitriptyline 10 mg) was no improvement in reducing pain intensity than in the control group.

The incidence of adverse events in the treatment group and the control group was also differed. Administration of acetaminophen 3x500 mg plus amitriptyline 10 mg resulted in greater adverse events compared to the control group (Odds ratio: 1.750), but the difference between the two groups was not significant. This suggests that the addition of Amitriptyline at a dose of 10 mg of acetaminophen might have a greater side effect than single acetaminophen in a case of non-specific chronic LBP.

Another study supporting the results of our study was a meta-analysis of tricyclic antidepressant drug administration compared to placebo in the case of chronic non-specific LBP. In addition, a systematic review of the use of antidepressants in chronic LBP cases suggests that tricyclic antidepressants were superior only mild to moderate when compared with placebo on pain intensity output (SMD = 0.43 and SMD = 0.69 in 2 high-quality studies). The mean superior mild to moderate decrease in pain intensity was 0.5-2 points, whereas in our study considered to be significantly improved the pain intensity that was decreased ≥2.

The work of Amitriptyline as an analgesic to strengthen the pathway of descending inhibition by increasing the number of noradrenaline and serotonin neurotransmitters in the synaptic gaps at the spinal and supraspinal levels, especially, nor-adrenaline uptake. There were several possible reasons why the administration of acetaminophen 3x500 mg plus Amitriptyline 10 mg unproven to be better than the administration of acetaminophen 3x500 mg. The first possible mechanism for the onset of pain in non-specific chronic LBP was more due to the release of excessive inflammatory mediators, and not due to reduced levels of Noradrenaline and serotonin neurotransmitters at the supraspinal level, as have excluded depression in the study. Moreover, the possibility at a dose of 10 milligrams Amitriptyline has not reached its optimal dose as an analgesic.

**Conclusion**

There was no difference in efficacy of Acetaminophen 3x500 mg plus Amitriptyline 10 mg with Acetaminophen 3x500 mg in reducing pain intensity in non-specific chronic Low back pain (LBP).

**Conflict of Interest:** There is no conflict of interest.

Society Perception of Pasung Behavior in People with Mental Disorders

Nur Khriesna Habita¹, Ahmad.Yusuf², Rr Dian Tristiana²
¹Student, ²Lecturer of Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

Abstract

Introduction: Pasung intervention of people with mental disorder still happened in the society. “Pasung Free Program” which has already designed in Indonesia since 2014 did not effective to wipe out Pasung behavior. There are still many people who are abused by Pasung behavior in Kulon Progo, Java Island, Indonesia with the various perception of society. The aims of this study examined the public perception of Pasung behavior in people with mental disorders.

Method: This study used quantitative method by using symbolism interaction approach. There were 9 people who experienced pasung in their surroundings that became samples. Data was collected by using in-depth interviewing and socio-demographic questionnaire. Method that was used to analyze was analysis method such as 6 stages of Creswell analysis that was suitable with the used method.

Result: The result of this study could become a theme. There were 8 themes came from two different perceptions. Perception of society resulted two themes namely 1) opinion about pasung behavior and 2) conclusion about pasung. External perception resulted six themes namely 1) the reason why pasung is allowed, 2) the reason why pasung is not acceptable, 3) pemasungan idea, 4) pemasungan method, 5) the society’s hope about people with mental disorder, and 6) the obstacle of health service.

Conclusion: Society perception about mental disorder still not acceptable. Pasung program planning should be in line with free people with mental disorders program. The appearance of pasung behavior related to the increase of people with mental disorders.

Keywords : Pasung, Society perception, Mental Disorders,

Introduction

Savings are still often found in people with mental disorders in several countries with a various reasons that are brought up by families and communities around¹. Society misperceptions of people with mental disorders lead to negative stigma. Negative stigma arises due to the experience of patients who cause different treatment from the society ²,³. Discrimination due to stigma is one of the triggering factors for aggressive behavior of mental disorders’ patients, but the behavior is actually one of the reasons for retention that occurs in the society.

The prevalence of mental health problems in Indonesia is 6.55% ⁴,⁵. People with severe mental disorders with age above 15 years in Indonesia reach 0.46% [4]. This means that there are more than 1 million people in Indonesia suffering from severe mental disorders. The number of people that is as many as 11.6% of Indonesia’s population experienced emotional mental disorders⁶. The prevalence of severe mental disorders based on the 2013 Basic Health Research (RiskeElementary Schoolas) which is 2.7 per mile is in Yogyakarta and Aceh.

Severe mental disorder is an individual who experiences orientation disorder, the reality of mood changes, personality, habits and habits of withdrawal. Disturbances in reality orientation trigger aggressive and dangerous behavior in the client such as harming oneself, others and damaging the environment. Stigma
on this problem has negative consequences not only for sufferers but also for family members and the surrounding community.

According to the latest data the prevalence of severe mental disorders in Indonesian population is 1.7 per mile. People with severe mental disorders are vulnerable to experience discrimination from the community, and not infrequently experience savings. Dismissal of people with mental disorders is an action taken by the society by means of being locked up, chained by their feet, put into wooden blocks so that their freedom is lost. The word pasung refers to physical restraint or confinement of perpetrators of crimes, people with mental disorders and who commit acts of violence that are considered dangerous.

Indonesia has launched the “Indonesia Pasung Free” program in 2014, however, the reality is still found pasung with various forms and reasons for mounting. The number of ODGJ experiencing savings throughout Indonesia reached more than 18 thousand people. Kulon Progo Regency with an area of 586.28 km2 and a population of 388,824 inhabitants is divided into 12 districts. Based on data from the Health Office of Kulon Progo Regency, there were 22 cases of mental disorders in Pasung in 2014, in 2015 it decreased to 8 because of outreach and pickup by related agencies. The latest data in 2016 found cases of re-embedding in people with mental disorders after getting treatment at the Kulon Progo Mental Hospital, Java Island as many as 2 people.

King Imogene’s theory of the concept model of human interaction, states human beings as a whole open system that consistently interacts with the environment with the aim of helping individuals and groups maintain their health. Human groups have an important role in the life process of society and the realization of mutual relations between individuals with one another. This study aims to determine people’s perceptions of pasung behavior in people with mental disorders. Public perception will give birth to different behaviors and stigmas for people with mental disorders that have proven to be still inherent in society today.

Method

2.1 Design of Study

Method that was used was qualitative method by investigating particular social problem. The approach of study used symbolic interaction base with qualitative approach method that was not only as a method to be a method of study, but also as a theoretical perspective conceptually. The place of study was conducted in Kulon Progo, Daerah Istimewa Yogyakarta.

2.2 Sample of Study

Sample was used constructive sample. Collecting sample data used purposive sampling technique. There is no limit to the number of samples selected to obtain data saturation, so that 9 participants are selected. These are selected according to inclusion criteria.

2.3 Instrument of Study

The instrument used in the collection process is to use in-depth interview guidelines (in-depth interview), with the method of face to face interview, field notes / field notes (recording data obtained during interviews): such as participant and other expressions and recorders or voice recorders in the form of voice recorders MP3. The validity of the recording device is carried out using a trial recording the researcher’s voice.

2.4 Procedure of Study

Data were analyzed using data using significant statement analysis, the formation of units of meaning and the development of the essence of description. This research uses Creswell’s analysis method with 6 steps of analysis.

Result

Participants in this study were 9 participants, consisting of 5 women and 4 men. The age of participants is in the range of 30 to 65 years. Characteristics of participants can be seen from the table below:
Table 1 characteristic of participants

4.1 Internal Perception

Self-perception is a statement that is directly sourced from within the participant. All participants gave answers to their opinions about pasung to people with mental disorders.

Opinion of Pasung Behavior

The first theme is pasung behavior opinion. This theme consists of two sub-themes, namely breaking the law and inhumane. The following participant statements related to sub-themes violate the law:

“If from the government, saving is not allowed ...” (P6)

«Indeed, pasung is a violation ...» (P8)

The inhuman subtheme is described as follows:

“I don’t want, so sorry. Pasung is not a good choice. It is so terrible and pity....”(P5)

Agreement with Submission Actions

The second theme is agreement with actions to protect people with mental disorders. This theme consists of two sub-themes, namely agree and disagree. The following participant’s statement on the sub-theme agrees:

Society draws conclusions about saving people with mental disorders based on what is in their minds. 7 participants argued that saving can be done, 7 participants also said they did not agree if it was done mounting. This can be seen in the following participant’s statement:

That was before; if fortunately it really raged our show as a family cannot overcome ... (P1)

“If people with mental disorders are not locked up, so it supposed to detrimental a healthy family......”(P9)

The sub-theme does not agree with the statement as follows:

“Do not agree, that’s hmm, she/he would move a lot so if put in pairs, told to be released, fortunately that, screaming continued ...” (P4)

“Yes, it is depicted, yes, we ourselves are confined in the house even though the room is saturated, doesn’t have any understanding, it can’t get out, right? It’s getting more sick .....” (P6)

4.2 External Perception

This perception is given by participants due to stimulation from outside the individual self. All participants gave answers to their opinions about pasung to people with mental disorders.

The Reason of Pemasungan

The first theme is about the reasons for saving. This theme consists of the sub-themes of violent behavior, despair, not disturbing. The following is the participant’s statement on the subtheme of violent behavior:

“It was the one who threw the stone tossing the house, hah [while his hand was drawing] ……. (P1)

“I was cheated, there is no something wrong, I was hit, I was given ashes while cooking rice. [trying to imitate] ...” (P6)

Desperate sub-themes are described in the following statements:

“So I ask that the family there is already a big little giving up (more or less give up) so, I told the children too, how?? Wow, please repent, please, please (it’s already repent, whatever), we can called it is in the sense of sincere right...... (P8)

The unobtrusive sub-theme is described in the following statement:

“I agree that’s because, what is that ... so as not to disturb the neighbors, the community can be calm. If someone is thrown by a stone then the house is thrown, if there are those children being chased ...”(P4)

The Idea of Pemasungan

The second theme is the idea of retention. This sub-theme consists of two sub-themes, namely community and family. The following statements from the community on community themes:

Yes her husband, because it damages ... (P3)

“Her husband was beaten, beaten by her husband, kept looking for people to install beams ...” (P5)

Community sub-themes are presented in the following statements:

“Straight to me, I said if I was locked up. If it goes mad, if I go on a rampage I will be beaten (hit) like that...
Pemasangan Method

The third theme is about the mounting method. This theme consists of 3 sub-themes using wooden blocks, using chains and locked in a separate room. The following statement of participants through the subtheme using wooden blocks:

“Yes, we use wooden randhu then split it to pinch the legs [while the participants’ hands are modeling] ...” (P4)

The community sub-theme uses the chain described by the participants in the following statements:

“As far as I know, I was chained, fastened (roped) and then roped in a pillar (large pole) on a pole inside the house ...” (P6)

“If you want to release the angel, right, that’s why before it is chained before the room is made. And that keeps the fatigue or goes away ... “(P9)

Community sub-themes confined in the room are described by participants in the following statements:

“Continue to build a house, use a bamboo wall spindle [smiling] ...” (P5)

Discussion

The opinion of the participants found in this study was that the response was responded to as an inhumane act for them. In accordance with the concept of Imogene King’s theory that the individual was an open system which one of the elements consists of perception. Participants observed using the five senses, experience and conclude.

In accordance with human rights, everyone has the right to receive the same treatment without discrimination. The act of retrieval will cause a person to lose his rights in various ways. Perspective on humanity perspective also causes an increase in stressors because of being locked up for a long time. The majority of acts of violence experienced by a person will be represented in the form of negative emotional experiences, so it was not uncommon for people with psychiatric disorders to be incarcerated more easily.

The social system defined the authority or authority as well as active authority in the social system the government has the authority to set policies in accordance with the applicable laws and regulations. Prohibition of people with psychiatric problems and people with mental disorders was contrary to the 1945 Constitution of the Republic of Indonesia: Article 28G paragraph (2) “Everyone has the right to be free from torture or treatment that degrading human dignity and is entitled to political asylum from other countries. From this situation caused families and communities to feel that health services do not provide a way out for mental health problems experienced.

Communication caused interpersonal systems that are formed by interactions between humans. In the process the community and family interact with each other so that a decision was made for mounting. This results in negative impacts especially for the mental as well as physical, psychological and also social patients. The physical impact caused by disruption of movement was the condition of the legs and hands will shrink, the muscles from the hips to the legs shrink because of the long time not used which will also affect the sympathetic nervous system. In addition, physical injuries also experience psychological and social impacts in the form of discrimination committed by the community.

Statements expressed by participants indicate that the health services obtained were less effective. Mental health services were still not a top priority although mental health problems continue to increase. Health workers, especially nurses as the main source of direct relations have a role in working with health institutions, consultants, resource providers, care providers, case managers, and helping with community education. The main focus in Community Mental Health Nursing (CHMN) is the importance of collaborating with families and communities.

It was hoped that there will be no more obstacles for the community and families to bring people with mental disorders to get appropriate treatment and care. For residents who do not get guarantees, the Regent Decree No.373 of 2016 concerning the participation of the poor beneficiaries of APBD contribution to the National Health Insurance Program in Kulonprogo Regency in 2017 can get free facilities (Regent’s Decree No. 373 in 2016).

Conclusion

Society perception towards mental disorders is not completely acceptable. Stigma and discrimination
towards people with mental disorders is more and more placed them as unable and isolated people. There is a big thing to be fixed by the Government than the pasung release. Pasung release is not an easy thing but prevent ODGJ could be pasung again post did a treatment is difficult. Thus, this should need another alternative as the effort to press the number of people with mental disorders.

Effects of the Use Knee-Ankle-Foot Orthosis on Proprioception Function Change in Healthy Adult Male

Nuralam Sam¹, Andriati¹, Noor Idha Handajani¹

¹Department of Physical and Rehabilitation, Faculty of Medicine - Dr.Soetomo Teaching Hospital, Universitas Airlangga Jalan Mayjen Prof Dr. Moestopo 47, Surabaya 60285 Indonesia

Abstract

Background: Proprioception includes joint position and motion. Sensory information, central processes, and neuromuscular control are important in improving joint stability. The effective use of knee joint orthosis on knee joint performance, balance and coordination is still highly controversial and has slight information on the effect of the orthotic use on proprioceptive function.

Objective: To analyze the effect of knee orthosis on proprioception function in adult male health’s subjects.

Method: This study used an experimental research with pre-post study design. The sample of this study was the male patient of Physical and Rehabilitation treatment that met inclusion criteria. The data was taken by consecutive sampling in February 2017. The subjects were 11 healthy male adults who aged of 21-40 years old that meeting the inclusion criteria. All the subjects were measured proprioception function before and at 30 minutes using knee orthosis. Joint position sense (JPS) and time to detect passive movement (TTDPM), were measured by the cybex isokinetic dynamometer tool to measure the function of proprioception.

Result: All the mean values of JPS before and at 30 minutes by using orthosis on both sides did not statistically show a significant difference (p > 0.05), except at the corner of the JPS 60° on the right-sided knee (p < 0.05). It meant TTDPM before and during 30 minutes using orthosis on both sides of the knee also did not show a significant difference (p > 0.05).

Conclusion: The use of ambulatory knee-ankle-foot orthosis caused the change in proprioception (JPS) at the right side 60° knee angle on the subject before and at 30 minutes using knee orthosis.

Keywords: Healthy Adult Male, Knee Orthosis, Proprioception.

Introduction

Knee joint is the largest joint in the human body and ginglymus-type joint (hinge joint modifications) ¹. Knee motion and stabilization is performed by the origo muscles above the hip joint, the entire shaft of the femur is also above the knee joint of the lower limb muscles. Proprioceptive comes from the position of the body, refers to the sense of knowing the position of a person’s body that is classically composed of static and dynamic components ².³. The design of orthosis is used based on the desired function. Knee orthosis is either a sleeve or has a rigid bars design on one side or both sides, nonelastic hinges and straps ⁴. Knee orthosis types which are often used including prophylactics, rehabilitative, functional, unloader/Offloader ⁵.

The integrated set of various mechanoreceptor, nociceptors and afferent muscles is known as proprioception. This information allows for feedback for motor movement control through position sensation and motion sensation (kinesthesia) and provides dynamic stability of joint. The motor movement control achieved through the feedback mechanism is realized during movement, well monitored, as well as to the appropriate response to the feedback given. The wide variability of joint position sensation has been observed in some subjects. The presence of deficits in proprioception

Corresponding Author:
Andriati

DOI Number: 10.37506/ijfmt.v14i2.3205
is associated with the increased frequency of injuries and recurrent injuries to the knee joint. Proprioception includes joint position and joint motion. Sensory information, central process, and neuromuscular control are important in improving joint stability.

The successful use of knee orthosis has been discussed over the years. Although there is evidence to suggest that orthosis can decrease the frequency of knee injury, some researchers have reported that in the use of knee orthosis there is no difference in the injury pattern. This problem is related to multifactorial epidemiological studies that are considered to be the cause of conflicting findings. These factors include the material components of the orthosis used, the different surface contact areas of each individual against the orthoses used. Researchers who tested kinematic joint and muscle activity have compared the condition without orthosis by using orthosis and observed differences in electromyographic and kinematic joint activity while performing the functional activity. Based on these findings, proprioception may be affected by the use of orthosis. Although there is still minimal information about proprioceptive testing and athletic orthoses, as well as groups of subjects with knee joint arthritis, there is an increase in proprioception function in the use of orthosis drytex economy hinged knee brace and hinge buttress orthosis. Similarly, in studies conducted, it was found that the use of orthosis can improve the function of healthy individual proprioception.

The effectiveness of the use of knee joint orthosis on knee joint performance, balance and coordination is still highly controversial and has the slight information on the effect of the orthotic use on proprioception function. At present, the proprioceptive function gets a great attention on the literature of sports medicine. In the study, the use of orthosis can improve the proprioception function, thereby increasing the mechanical stability of knee joint and the use of knee orthosis in athletes based on the factors which have implication for the proprioception function. Until now, there has been several researches on the effects of knee joint orthosis on proprioception function. This study was conducted to determine the effect of knee joint orthosis on proprioception function in healthy adult male.

**Method**

The sample of this study was a male patient of Physical and Rehabilitation treatment that meets inclusion criteria. The data were taken by consecutive sampling in February 2017. The inclusion criteria were healthy men, aged 21-40 years, the range of knee joint movement 0-135° in extension-flexion, no deformity and willing to sign informed consent. The subjects exclusion criteria were with lower extremities, pelvic and spinal injuries, underwent spinal, pelvic, knee and ankle joint surgery, with neurologic and systemic disease affecting the lower extremities, hyperlaxity, and unstable joints. The subject had informed consent and underwent a proprioception with Cybex Isokinetic Dynamometer, before and after 30 minutes using knee orthosis on both knees. This research was a pre-experimental research and posttest study design.

Joint position sense (JPS) and time to detect passive movement (TTDPM) were measured for proprioception using Cybex Isokinetic Dynamometer. The behavior examination in a sitting position with eyes closed and ears, flex knee at 90 degrees. JPS was measured at 30°, 45°, and 60°. JPS and TTDPM for both knees were measured before and after 30 min using knee orthosis. Then, an examination of JPS and TTDPM on both knees without and when using knee orthosis was collected and analyzed data by using t-pair test (Paired t-test). In this study used statistical tests SPSS V.20.0 (SPSS, Inc., Chicago, IL.) with a significance level of p <0.05.

**Results**

The total sample of characteristics subjects was 11 male. The mean age of the study subjects was 32.82 ± 2.99 years, with the lowest age of 28 years and the highest 36 years. The average height of subjects was 165.81 ± 6.03 cm and average weight were 66.18 ± 7.80 kg. The mean body mass index (BMI) was 24.25±3.11 kg/cm² (Table 1). In table 2 the JPS was explained at an angle of 30°, 45o, 60°

The mean difference of right-sided knee TTDPM without orthosis and at 30 min using orthosis was not statistically significant, as did the mean difference of TTDPM on the left side of the knee. The mean TTDPM without the use of orthosis on the right side knee and on the left side of the knee and also at 30 min using orthosis on the left side knee and right-sided knee also did not show statistically significant differences as seen in table3.

Note: the average value is the average time when the subject feels the knee passive movement. Significance level tested by paired t test (p <0.05).

Discussion

The assessed parameters were the JPS for a sense of joint position and TTDPM to assess the ability to detect passive movement of the joints. This examination was performed in one visit. Prior to the examination of JPS and TTDPM, firstly evaluated vital signs (blood pressure, pulse, and breathing) and measuring height, the weight of clinical examination of knee joint stability and knee extensor muscle strength with manual muscle test. Measurements of JPS and TTDPM were performed before the use of knee orthosis and at 30 minutes using knee orthosis. During the wait, research subjects can perform activities in the polyclinic. JPS measurements were performed at angles 30°, 45°, and 60°. TTDPM checks were done at 10/sec. The average measurement of each subject was taken from 3 times the measurement. The average JPS was calculated from the average value of the difference between the reproduction angle at a predetermined angle. The examination was performed on both knees on both the left and right sides.

Based from the results of this study, there were no significant statistically on proprioceptive differences in JPS and TTDPM in the right and left sides of the knee before using knee orthosis and at 30 minutes using knee orthosis except for right-sided knee at treatment angle 60°. On the right side of the knee at an angle of 60°, there was a statistically significant JPS. The study in this study is similar to the study of prophylactic knee orthosis conducted in the study used the prosthetic-type prosthesis knee of Mc David Knee Guard. The study was conducted on 36 healthy male subjects who performed the measurement of proprioception function before and when using knee orthosis, the result did not get a significant difference to the JPS. In the study, it was concluded that prophylactic knee orthosis had minimal influence on the proprioceptive feedback mechanism.

In the study was obtained on 24 healthy subjects (14 male and 10 female) to determine the effects of prophylactic knee orthosis on balance, proprioceptive, coordination and the strength of muscle. They use 5 different types of knee orthosis that will be used entirely by the subject. From this research, it was obtained that Drytex economy hinged knee brace has the best result for improvement of proprioceptive function compared to the other four orthosis. This type of orthosis was what we use in this study. In the study also reported that proprioceptive knee joints increased when using elastic neoprene in healthy subjects. It was believed that the use of elastic neoprene as found in prophylactic knee orthosis may stimulate the skin during joint motion and put pressure on joint muscles and capsules. Afferent feeds from a number of receptors present on the skin, muscles, ligaments and joint capsules contribute to the proprioceptive mechanism in the knee joint overall. Most cutaneous receptors will respond to changes in movement and quickly adapt. The difference in the results of this study with the findings in this study may be due to neoprene wrapping in knee orthosis is not completely appropriate around the knee joints thus reducing the increase in skin stimulation. In addition, in this study, we used healthy subjects without a history of problems in the knee joints to allow for statistically significant results.

On JPS examination of the knee joint, the target magnitude of the reliable flexion angle for the increase of the JPS in the vertical position was between the 60°-90° flexion angle. Target this knee joint position to get maximum JPS knee joint. It was also obtained in our study that between JPS angle 60° on right leg side knee without using orthosis and with 30 minutes using orthosis there was a statistically significant difference. It was said that in this position it was possible to obtain a balance of both agonist and antagonist muscles and
the required minimal complex neurological processes thereby that will causing a minimal error rate.

In this study we found a statistically significant JPS difference in the right-hand side 60° knee angle, this may be because the right knee was the dominant knee of the study subjects, but we can’t confirm it. So far we have not obtained data on the difference in the function of proprioception on the dominant and non-dominant side in healthy subjects and also still lack research on the use of knee orthosis which assessed the proprioceptive function of the knee joint.

For athletes and non-athletes who have previously suffered an ACL injury will show a worse knee joint JPS than a healthy subject. Joint Position Sense (JPS) and TTDPM without using orthoses compared to the time 30 minutes using orthosis in our study did not show the statistically significant difference, except at the right side 60° angle of the knee. The 30 minute time may be less to get a meaningful change and this still needs further research.

The TTDPM examination in this study uses Cybex isоquant dynamometer which in its use must be moved first in the direction of flexion before the machine moves toward the extension so that the subject was able to recognize when the machine starts to move and it can also be biased in the examination.

Study Limitation

In this research, we were using healthy adult male subject without any problem at the knee joint so the result was not significant statistically and the study effect when subject underwent 3 times measurement before using orthosis so the subject have experience.

Conclusion

The use of knee orthosis for 30 minutes may improve the healthy knee joint proprioception function at the right side corner of the JPS 60°. The use of knee joint orthosis cannot improve the knee proprioception function in TTDPM at 30 minutes of application.

Conflict of Interest: There is no conflict of interest.

Source of Funding: This study is self-funded.

Acknowledgment: This manuscript has been published in the repository of the Universitas Airlangga library in 2017 as the following website link (http://repository.unair.ac.id/65520/) entitled “Effects Of The Use Knee-Ankle-Foot Orthosis (Kafos) On Proprioception Function Change In Healthy Adult Male”. Further research is needed on longer period of knee orthosis application, need further study to evaluate knee orthosis effect on dominant and non-dominant side and study to minimize bias effect because “study” effect at proprioception measurement.

The effectiveness of Aqueous Extract of Grape Seeds *Vitis vinifera* as an antibiotic for some microorganisms and its Protective Role Histology for Liver, Kidney in Mice

Osama Nadhom Nijris¹, Zinah Ibrahim Khaleel¹, Swiss Yonis Hamady¹, Mohammed Ahmed Mustafa¹

¹Department of Pathological Analysis, College of Applied Sciences, University of Samarra, Iraq

Abstract

1- Among the common disease treatments and long-term use of plant extract in the treatment of bacterial infections, This research used black grape seed extract to observe its effect on some Gram negative and positive bacteria like *Escherichia coli*, *Staphylococcus aureus*, *Klebsiella pneumoniae* and *Proteus mirabilis* obtained from patients with urinary tract infection Using four specific extract concentrations (100 mm / L, 75 mm / L, 50 mm / L, 25 mm / L) to test the effect of black grape plant extract. The results showed that *E. coli* was the most resistant bacterial species to plant extract and so on with other gram negative bacterial species. In the minimum inhibition concentration test for the plant extract, showed that the highest concentration 100 mm / L had the good inhibitory activity for *Staph. aureus* and less than other strains specially for *Kleb. pneumoniae* and *Pro. mirabilis* while the 25mm / L concentration had the lowest activity against all.

2- This study used 10-day oral methionine and 30-day grape extract treatment for 16 white mice to study the histopathological effects in the liver, kidney and heart tissues, And the results showed a very good organ tissue improvement for all treated groups compared to the control group.

Keywords: bacteria, extract grape seeds aqueous, histopathological effects.

Introduction

Researchers have turned to plant extracts as natural products to tract bacterial infection and tissues damage because plants are rich with vital compounds such as volatiles oils, Tannins, Alkaloids, Phenols, Glycosides and Saponins (1).

Urinary tract infection is known as the presence of pathogenic microorganisms within the vessels of the urinary system so that they appear in the urine, *Escherichia coli* is responsible for causing about 80-90% of infections, and so on for all types of Enterobacteriaceae family, especially urethritis and bladder in Women and children, as for the positive group of gram stain, *Staphylococcus aureus* is the most common type of this type of infection (2),(3),(4).

Grape Seed Extract is one of the richest sources of powerful and beneficial component called flavonoids, the most important of which is Proanthocyanidin, which is 50 times stronger than the effect of vitamin such as C and E participate in protecting the body from the effect of oxidization by free radicals (5), and these Antimicrobial phytochemicals such as flavonoids have another functions such as Anti-inflammatory, anti-allergenic, anti-viral and anti-cancer action (6),(7). Also the Phenol which found in bear berry with an antiseptic urinary effect (8), Saponins also have anti-inflammatory, anti-microbial, anti-protozoan and immunostimulative properties (9).

As well as its effectiveness against bacteria, viruses and inflammatory diseases through the inhibition of peroxide formed by phagocytic cells (10).

For the above reasons, this research has came to study the effect of aqueous extract of grape seed on some bacterial species isolated from urinary tract infections and to study its effect of treatment for methionine treated tissues.

Materials and methods

**Bacteria diagnosis:** Samples were obtained from Samarra General Hospital’s urinary tract infections,
We have been identified through the routine procedures listed in Wise, A. (2017)\(^{11}\).

Four bacterial species were obtained: *Staph. aureus*, *E. coli*, *Kleb. pneumoniae* and *Pro. mirabillis*, which was predominant on most specimens of urinary tract infection and was subsequently taken as a test bacterial species for subsequent testing. And all its characteristics that were diagnosed as a result were identical to those mentioned in above reference\(^{11}\).

**Sterilization of the extract and preparation of fears:**

Prepare a storage solution by taking 1gm of dry plant extract powder and dissolved in 10 ml of sterile distilled water. The concentration of the storage solution is 100 mg / ml. 0.11mm filter papers were used to separate the large pieces of the extracted particles and the extract was sterilized by Millipore 0.22 mm which prevent the passage of contaminant bacteria through it to obtain a sterile storage solution of 100 mg / ml and use it as a source for preparation of fears\(^{12}\).

**Preparation of concentrations of grape seed extract:**

The four concentrations (25,50,75,100 mm/L) have been prepared through addition amount of storage solution to equal volume of distilled water as following equation:

\[
\text{Volume of storage solution/volume of distilled water.}
\]

**Assessment of antimicrobial potential:**

Neomycin (10 Mg) has been used in all media plates as a normal control for plant extracts. according to Bridson (2006)\(^{13}\), standard antibiotics and plant extracts were used in the “cylinder-plate” process to carry out the antibiotic sensitivity test. The test was performed by individually injecting extract solutions or standard antimicrobials into the media cylinders and measuring the inhibition zones by the zone reader system after incubation.

**Test for histopathological effects**

Methionine have a molecular weight of 472.09 and was dissolved in the solution to prepare a natural solution and was orally administered for a period of seven days at a concentration of 0.5 mg / kg twice a day\(^{14}\).

**Preparation of the water extract of grape seeds**

The water extract of grape seeds was prepared by method mentioned by Bayadar. N.G.\textit{et al.},\(^{15}\) by crushing a quantity of clean seeds using the Ultra-Tubax blender (Germany), Then, 50 g of dry powder was weighed and placed in a 1000 ml glass container Add the distilled water and complete the volume to 1 liter then add 3 ml of absolute ethyl alcohol to prevent fungal growth.

The samples were left for half an hour in the horizontal vibrator and at medium speed. The samples were stabilized for an hour, then filtered by three layers of gauze to separate the large plankton and then filtered to 3,000 centrifuges / min for 15 minutes to separate the small plankton. Of the extract at 40 °C using rotary evaporator and put in incubator at 37° C and then save the extract in a sealed bottle at a temperature of 8° C in wet conditions for use in the study.

![Figure 1 Black grape seeds](image)

**Laboratory Animals group:** In this study, 16 mice from Swiss white mice were used, ranging from 25 to 28 g. Obtained from Pharmacology Department / General Pharmaceutical Company for General Industries. The animals were in good health and were placed in laboratory plastic cages dedicated to the breeding of mice, and sprinkled with sawdust, with cages cleaned and sterilized twice a week. Group design: The animals were randomly divided into four groups in plastic cages. Each cage contained four mice, and treated as follows:

1- **Control group:** consists of 4 mice treated with normal saline solution, 0.1 mg/ kg

2- **Group I:** The First Group , Was composed of four mice treated orally with methionine 0.5 mg / kg for 10 days.

3- **Group II:** The Second Group , Was composed of four mice treated orally with aqueous extract of grape
4- Group III: The Third Group, Was composed of four mice treated orally with aqueous extract of grape seeds 30 % mg / kg for 30 days, as mentioned by AL.Jeboory et al., (16).

Preparation of tissue sections After dissecting the animals and placing organs in the Formalin 10% solution, the samples to be studied were converted to ethyl alcohol at 70% concentration. The following steps were taken as mentioned by Khaleel .Zinah I. et al., (17).

Result and Discussion

Assessment of antimicrobial potential:

Grape seed extract showed highest inhibitory activity on Staph. aureus, But to a lesser extent Kleb. pneumoniae and Pro. mirabillis bacteria which were 6mm at 100mm / L, 5mm at 75mm / L and 4mm at 50mm / L, But in general, the four concentrations of the extract had significant effect compared to the antibiotic Neomycin with gram positive group, whose average inhibition diameter for the four types of bacteria ranged between 10-20mm. These results were in agreement with what was stated by Jayaprakasha and. Sakariah (18), They indicated that grape seeds water extract have a greater effect on gram positive bacteria than negative, whereas 25mm / L concentration had the lowest inhibitory activity, which was 3mm for Staph. aureus, Pro. mirabillis, while it showed no effect on Kleb. pneumoniae and E.coli,

Figure 2: the effect of extraction on Pro. mirabillis

Figure 3: the effect of extraction on Kleb. pneumoniae

As for E. coli bacteria were resistant to all extract concentration, only the concentration of 100 mm / L caused inhibition of a diameter of 1 mm as shown in table 1.

Table 1 the inhibitory activity of four concentrations of black grape seed extract:

<table>
<thead>
<tr>
<th>Isolates</th>
<th>Plant extract concentrations</th>
</tr>
</thead>
<tbody>
<tr>

<td>11 mm</td>
</tr>
<tr>
<td>Kleb. pneumoniae</td>
<td>6 mm</td>
</tr>
<tr>
<td>Proteus mirabilis</td>
<td>6 mm</td>
</tr>
</tbody>
</table>
The result that showed with table 1 referred that *E. coli* was the most resistant bacterium used in the study. This shows that it has developed its ability to resist antibiotics in contrast to the other species belong to both gram positive and negative, these results agree with Zdenka Cvetni and Sanda Vladimir (19), Whom made it clear the grape seed extract less affect on Enterobacteriaceae family like Salmonella enteritidis, although Gram positive bacteria, the extract showed the efficacy of its orientation not similar to that of the Gram negative bacteria and this result is not necessarily consistent with the result of the study done by Fleming (20), In his study, *Staph. aureus* showed that the bacteria were more strongly affected than the negative bacteria of Gram.

**Liver**

Histological sections of the first group of mice treated with methionine for 10 days showed tissue changes such as necrosis, degeneration, congesting, hemolysis, sinusoidal enlargement, and hepatocyte swelling. With Infiltration Lymphocyte lymphocytes and hemorrhagic hemorrhage, as well as pyknic nuclei.

The histological examination of the liver section in the animals treated with the grape extract for the second group for 30 days showed hemorrhage and lymphocytic infiltration with intracellular necrosis of the central vein (desquamation). A few cases of Karyolitic were also found with some nuclei that suffered small size and Pyknic Nuclei intensified and also found improvements in liver cells in terms of return to normal form compared to the group of methionine. While the results of the second and third group of the same period showed a good improvement of the hepatic cells and regularity of the natural form as it was approached the normal form, although there are some cases of hemorrhage bleeding and lymphocyte Infiltration lymphocyte. and the third group was better.
The liver tissue showed a significant effect of methionine at the concentration level, with bleeding, degeneration, lymphocytic infiltration, and endogenous degeneration and decomposition. These results were consistent with the findings of Al-Saidya, Al-Shammry, and Al-Okaily. Hepatotoxic substances are hydrogen peroxide and methionine. The toxicity of substances lies in their ability to form free radicals such as O-2 and OH. These roots are characterized by their ability to interact with lipid and proteins involved in the synthesis of membranes Kink and inside cellular and Intracellular membrane and thus discourage many vital special events such as the transmission of membrane necessary for the sustainability of cell materials also interfere with the action of enzymes and thus inhibit cellular respiration which leads to a reduction of cell events.

The interaction of free radicals with lipids results in lipid peroxides, which stimulate a series of membrane interactions with a decrease in mitochondrial membrane viability and destruction of the particle membranes of the Lysosomes and thus the cell’s arrival in the necrosis.

This study also showed the reform in the liver tissue of the methionine-affected cells and the return of these changes to the natural state using the water extract of the grape plant was due to the action of the extracts in inhibiting the action of methionine by possessing many activities, especially anti-oxidation and then speeding up the repair process And stimulate the tissue cells to secrete chemical attractants to attract inflammatory cells, which was clearly visible to the region for the purpose of feeding the damaged tissue, as well as stimulate the fabric to divide to compensate the affected by methionine.

**kidneys**

The examination of tissue microscopically showed that a section of the cells lining the urinary bulb is similar to normal, but in some places there is swelling in the proximal epithelial cells of proximal and distal proxies, as well as swelling of the nuclei There is general necrosis and vacuolated necrosis with Degeneration within a section of the glomeruli within its constituent cells with dense and small nuclei observed on their way to death.

Some cases of hemorrhage, lymphocytes and lymphocytes were observed, as well as minor bleeding within the glomerulus, lymphocytic infiltration into the glomerulus, and cirrhosis in the proximal and proximal tubules.

Methionine causes a significant increase in serum creatinine, urea nitrogen in the blood and uric acid concentration in the blood, and high blood urea nitrogen is a marker of kidney disorders.
Figure 8: section of the tissue of the kidney with a dose of methionine, showing (1) congestion (2) Vacuolated, 400X H&E.

Figure 9: kidney tissue, grape extract, group I, showing (1) glomerulitis (2) lymphocytic infiltration, H&E, 400X.

Figure 10: kidney tissue, grape extract, group III, showing (1) glomerular (2) lymphocytic infiltration, H&E, 400X.
The effect of methionine on kidneys is consistent with Dever and Elfarra (26), they pointed out that high levels of uric acid have been associated with gout, high blood pressure, kidney damage, hyper homocysteine in the blood, Blood to overproduction and release of oxygen species (ROS) from the glomerulus, and then kidney damage, double glomerular filtration rate,

The excess adenosine will interact with methionine which forms S-adenosel methionine and then degrade to form uric acid as a final product leading to hyperuricemia (27).

The results of this study revealed that excess methionine caused renal injury manifested in a significant deterioration in epithelial lining cells of renal tubules. These results are consistent with Rowan (28). Where glomerular lesion was observed and the progression of glomerular sclerosis was increased after methionine dosage.

As shown in this study, a severe renal dysfunction and this renal impairment may be due to homocysteine associated with increased adenosine level associated with increased level of sclerotic changes in glomeruli (28)

Comparison of Stability And Sternum Healing Rate in Clinical and Ultrasonography (USG) between Stainless Steel Wire and Polydioxanone Yarn in Children Heart Surgery Operation

Prima Kharisma Hayuningrat¹, Heroe Soebroto¹, Paulus Rahardjo²
¹Thoracic Surgery, Cardiovascular and Vascular, ²Department of Radiology, Faculty of Medicine - Dr.Soetomo General Hospital, Universitas Airlangga, Surabaya 60285, Indonesia

Abstract

Background: The closing of the sternum bone is often used today by using stainless steel wire material and Polydioxanone yarn continuous suture. To objectives to be achieved for sternal healing after heart surgery without complications resulting from the failure of sternal healing. The bone healing process itself is influenced by mechanical stress and movement.

Objectives: To compare the effects of sternum closure techniques on surgical patients The heart of the child uses Polydioxanone and Stainless Steel Wire threads against clinical stability and rate of healing which are evaluated clinically and Ultrasonography.

Methods: Performed sternal closure of pediatric patients after cardiac surgery with sternal wire (n = 8) and PDS (n = 8). Performed sternal pain and stability evaluation with the physical examination. Further sternum ultrasonographyund was performed to assess displacement, gap and callus picture. Evaluations were performed at weeks 6, 9 and 12 postoperatively.

Results: Week 6 and 9 degrees of pain were higher in sternal wire compared with polydioxanone (p = 0.03 and p = 0.01). The 12th week of sternal wire and polydioxanone did not find any difference in pain (p = 1,000). Week 6, 9 and 12 there was no clinical stability difference between wire and PDS (p = 0.143, p = 0.264, p = 0.063). 9th, 9th and 12th Sternum ultrasonography of examination appears to be displacement in polydioxanone (p = 0.025, p = 0.009, p = 0.009). The gap increased significantly from 6th to 9th weeks in the polydioxanone group, while the addition at week 9 to 12 was statistically insignificant but it appears that polydioxanone had a wider gap addition range than the sternal wire. Week 9 and 12 callus were seen more often in sternal wire patients but not significant (P = 0.602, p = 0.333)

Conclusion: Clinically, sternal steal wire stability is proportional to polydioxanone. Radiologically, the stability of sternal wire is better than polydioxanone. The rate of sternal cure in polydioxanone is proportional to the sternal wire.

Keywords: Sternal wire, Polydioxanone, Sternum ultrasonography, Paediatrics

Introduction

Sternotomy was first introduced in 1997 by using experimental goats and human cadaver which then succeeded, then in 1957, performed sternotomy action on heart surgery patients¹². In the USA, more than 750,000 median sternotomy procedures are performed
Today, closure of the sternum bone that is often used by using stainless steel wire material (SS). The commonly used closure techniques are figure-of-8 and simple interrupted techniques. Biomechanical studies on cadavers and animals show the efficacy of several sternal closure techniques with different results 4–6. Currently, the use of synthetic polydioxanone absorbable suture after sternotomy becomes a routine procedure performed in many heart surgery centers, especially in cases of heart surgery in pediatric patients. Several studies have shown the use of polydioxanone (PDS) is effective in preventing sternal instability, assisting wound healing and is more suitable for pediatric patients 7,8. In addition, the PDS handling is easier to use, lowering the risk of bleeding at the stitching site and reducing postoperative pain 9–11.

The use of PDS in cardiovascular surgery was first performed on the sternum closure procedure for various heart operations such as correction of coarctation of the aorta, total correction Pulmonary vein drainage anomaly, arterial switches in Transposition of Great Arteries and systemic pulmonary shunts. Postoperative results obtained polydioxanone does not cause inflammatory and mediastinitis reactions, at least granulation tissue and is well-absorbed within the span of 2-6 months. The strength of fixation on the sternum is influenced by the type of fixation technique, the amount, strength and thickness of the wire used and the strength of the sternum itself 12,13.

The main goal to be achieved from the sternum closure technique is the achievement of sternal healing after heart surgery without any complications due to sternal healing failure. There are two important factors in bone healing process including mechanical stress and movement which can affect sternum technique stability in callus formation process, the formation or gap between the two sides of the split sternum and the fixation of movement between the sternal fragments 14,15.

The routine procedure performed in Dr.Soetomo General Hospital in sternal closure after childhood heart surgery is the most frequent use of continuous suture Polydioxanone yarn while the SSW of the figure of eight is rarely used. Evaluations to assess sternal healing include clinical evaluation of pain scale and physical examination scale assessing sternal stability using the scale 16. This evaluation was used in several studies of sternal stability assessment after adult heart surgery 17. But there has not been much study in patients after child’s heart surgery.

Based on, the study literature comparing the two uses of this material to a child’s heart surgical patient as well as evaluating the ratio of its cure. Until now, no research results have been found, therefore, this study intends to compare the effect of sternum closure technique on the patient’s heart surgical patients using Polydioxanone and Stainless Steel Wire threads on clinical stability and rate of healing which is evaluated clinically and Ultrasonography.

**Method**

This study used a double-blinded randomized clinical trial design in patients with cardiac surgery performed by the sternal closure. The study was conducted in the operating room of cardiac surgery, radiology ultrasonography examination room and polyclinic surgery of Toraks, Kardiak, and Vascular Dr.Soetomo General Hospital, Surabaya. The study was conducted from 2016 to 2017. The inclusion criteria included pediatric patients undergoing open and closed heart surgery with a 1-10-year-old sternotomy approach with 10-20 kg. Redo surgery, re-surgery due to postoperative hemorrhage and the patient dies or did not control during the observation period of the study was excluded.

The research procedure, covering the selection phase of the patient according to the inclusion criteria, then the research tool needed sternum closure technique using two types of material include Stainless steel wire and polydioxanone synthetic yarn. Furthermore, in the treatment stage, all patients undergoing standardized cardiac surgery procedures adhere to diagnose and prevailing protocols. The suturing process will use at least 3 SS wire fixations with the figure of -8 and 6 continuous stitching Polydioxanone for each sternum. Furthermore, the observational stage of the study, the patient was evaluated postoperatively with evaluation at the cardiac surgical polyclinic at 9th, 12th week. Sternum ultrasound examination with the transversal projection at three checkpoints (upper sternum, mid sternum, and lower sternum). Statistical data processing by using Mann Whitney Test for the non-parametric test with SPSS v23 program (SPSS, Inc., Chicago, IL.).
Results

The first group of sternal bone was fixed with sternal wire with the stitch of the figure of eight and the second group was fixed with PDS with simple continuous stitching. Patients were followed for postoperative physical and radiological examination at weeks 6, 9 and 12. The sternal closure images with PDS and sternal wire bias are seen in Figures 1 and 2.

The results of stability were obtained in the 6th-week evaluation results in patients using sternal wire, showed a higher degree of pain compared with PDS (p = 0.03) with sternal wire group pain characteristics in mild to moderate to severe degrees. While in the PDS group all patients felt a mild degree of pain. Evaluation at week 9 of patients using sternal wire still showed the higher degree of pain than PDS (p = 0.01) but with lower pain level characteristics. All patients with sternal wire experience mild pain up to moderate pain level. In the 12th week, both sternal wire and PDS were not found significant differences in pain (p = 1.000).

At the 6th-week ultrasound examination, the use of PDS showed a significant displacement compared to the use of sternal wire (p = 0.025). At 9th week ultrasound evaluation still showed significant displacement compared to sternal wire (p = 0.009) and at week 12 evaluation PDS still showed a significant displacement compared to sternal wire (p = 0.009) but no new displacement at other patients.

The results In the sixth week USG examination found a significant gap difference which obtained a wider gap in PDS in Manubrium (p = 0.021) while at mid and lowers there was no significant gap difference (p = 0.094 and p = 0.728). On the ultrasound examination also has not obtained any callus picture either in the PDS group or sternal wire.

In the 9th-week gap assessment, there was a significant difference with the wider gap of PDS in Manubrium sternum (p = 0.005) and on the sternum Corp (p = 0.001) while on the lower sternum there was no significant gap difference (p = 0.069). In the 12th week, there was a significant difference with the wider gap in the PDS group, i.e., in the Manubrium sternum (p = 0.001), the sternum Corp (p = 0.002) and the lower sternum (p = 0.029).

When compared to the number of gap additions at the 6th, 9th, and 12th-week checks, the gap size increased significantly from week 6 to 9 in the PDS group compared to the sternal wire group. The addition of a gap occurs at all points of the sternal examination. The addition of the gap at the 9th to the 12th week was not statistically significant but it appears that PDS has a wider gap addition range than the sternal wire.

In this 9th week, we have got callus picture on PDS group and sternal wire. The number of patients seen callus in the sternal wire group was more than the PDS, but not statistically significant compared to the PDS group (P = 0.602). In the 12th week of ultrasonography results, there was a callus profile of both the PDS and the sternal wire with more callus numbers obtained in sternal wire patients but not statistically significant (p = 0.333).

### Discussion

The stability and healing of the sternum in this study was stability and clinical and radiological healing evaluation at 6th week, 9th week and 12th week. The sternal stability was evaluated based on the degree of pain on clinical examination as well as the physical examination to assess sternal stability and then evaluate the presence or absence of displacement by examining ultrasonography. While the healing of the sternum was assessed through ultrasonography examination based on the evaluation of the gap on the sternum as well as the callus picture on the sternal fragment.

The stability and healing process of the sternum is influenced by the combination of daily physiological movements such as breathing, coughing and moving that create a force on the sternum. The force was the
result of a combination of transverse shear, longitudinal shear, and lateral distraction movements. In this study at weeks 6, 9 and 12 seen in ultrasound there was a significant displacement in the PDS group. This study was in accordance with the study wherein the Sternal wire group with strong material properties, proved to have a much better rigidity compared to PDS and this was indicated by a stable symmetry of the sternum.

At week 6 there was a wider gap in the Manubrium and Corpus Sternum groups of PDS than in Sternal wire. The gap differences remained significantly larger at the 9th and 12th weeks. This difference is due to the fact that the PDS uses absorbable material which will certainly be degraded over a period of time. Based on the PDS profile of ethicon® the power of the PDS at week 2 will decrease to 70% and will decrease gradually to 25% at 6th week.

At the end of the 12th week of study, the PDS gap compared to the sternal wire was 19.25 ± 1.83 vs 13.75 ± 1.58. This shows the evaluation of PDS usage by ultrasonography is seen widening and addition of bigger gap than sternal wire. Although the use of Sternal wire proves to be more confined in fixing the Sternum, PDS threads were also able to maintain the gap of Sternum with a distance below 2 mm can trigger the running of the healing process (fibrous tissue healing).

**Conclusion**

Sternal wire causes higher pain than PDS. Clinically, sternal wire stability was proportional to PDS. Radiologically, the stability of sternal wire was better than PDS. PDS produces a wider sternal gap than a sternal wire. The rate of sternal healing in the PDS was proportional to the sternal wire.

Discrimination the Gender in the Criminal Evidence at Crime Scene

Qutaiba S. H. AL-Ameedy1, Noor Salman Kadhim Al-Khafaji2

1Biologist at Babylon Health Directorate, Ministry of Health,
2Assistant professor at Biology Department, College science-University of Babylon, Iraq

Abstract

Background: An ideal method for gender identification would be accurate, simple, and cheap, enabling its use in most laboratories. In addition, it should also be able as much as possible to be used for all animals as well as tissues and/or cells. For chromosomal analysis, we need viable cells that are able to divide, and if this is not possible, these methods cannot be used. On the other hand, genetic methods are reliable and do not need living cells, and it is easy to obtain DNA for these studies even in very ancient and nonviable tissues. These methods are therefore the most accepted ones. The current study aimed to determine the gender of a given DNA samples by designed valuable specific-PCR tool.

Methodology: Thirty eight (nineteen from each male and female) human blood samples were collected using EDTA-Na2 tubes for direct DNA extraction after taken the agreement of the volunteers to give the blood sample via expert. The blood sample mixed well by rotation of EDTA tube. Two sets of species specific primer pairs targeting Homo sapiens (AMLE X and AMLE Y) genes were designed and checked. PCR and sequencing were performed and sequences were analyzed and register in GenBank. Results: The results revealed that the amplicon of AMLE X gene of Homo sapiens were 1164bp and AMLE Y were 744bp

Conclusion: The current study conclude that, validity and accuracy of designed 12S rRNA species specific primer pairs for human and nonhuman animal blood typing as a forensic tool and there is no intraspecies cross amplification.

Keywords: Homo sapiens, AMLE X and AMLE Y.

Introduction

Analysis of the gender chromosomes is important in the determination of gender and instantly excludes 50% of the population. The human gene usually analyzed to determine gender is the Amelogenin (AMEL) locus, after its amplification using PCR DNA fragments of different lengths can be generated. Amelogenin is involved in the formation of enamel, which is the hard, white material that forms the protective outer layer of each tooth[1]. Enamel is composed mainly of mineral-containing crystals. These microscopic crystals are arranged in bundles that give enamel its strength and durability[2]. Studies suggest that lesser amounts of amelogenin may also be present in tissues other than developing tooth enamel. For example, amelogenin has been found in certain bone, bone marrow, and brain cells. The function of amelogenin in these tissues is unknown. One copy of the amelogenin gene is located on each of the sex chromosomes (the X and Y chromosomes)[3]. The sequence on the X chromosome is shorter by 6 bp compared to the allele on the Y chromosome (male gender)[4]. Polymerase Chain Reaction (PCR) analysis that target regions of Amelogenin gene have become the method of choice for gender determination of biological samples[5]. The aim of this study is to determine the gender of a given DNA samples by designed valuable specific-PCR tool.

Methodology

Sampling:

Thirty eight (nineteen from each male and female) human blood samples were collected using EDTA-Na2 tubes for direct DNA extraction after taken the agreement of the volunteers to give the blood sample via expert. The blood sample mixed well by rotation of EDTA[6].
DNA Extraction Polymerase Chain Reaction:

G-spinTM Total DNA Extraction Kit (was used to extract DNA from blood according to the manufacturer’s protocol instructions (Intronbio/Korea). All extracted DNA samples were submitted for Nanodrop to ensure adequate purity and concentration required for PCR. Setting done by selection dsDNA measuring mode for 2 μl of sample. Blanking were performed using 2 μl microliter of elution buffer and then measuring the DNA samples concentration and purity[7].

The sequence of Homosapiens (AMLE X, AMLE Y) were taken from NCBI data base (AMLE X Sequence ID: AY040206.1; AMLE Y Sequence ID: NG_008011.1) were used to design primer pairs using online Primer 3 software [8,9]. The specific primer pairs: AMLEX-F: CTGGAGGGTCTTGCTGAAG, AMLEX –R: GATGTACCAAAGGGGTTGGG( 1164 bp) ; AMLEY-F: CCAGGACAGCTAGGTTCAAGTT, AMLEY –R: CACCTCCATAAAATAGCTTTGTC (744 bp). The specificity of designed primer pairs were checked using online NCBI/primer blast [9,10]. The PCR conditions were calculated using online Protocol Optimize writer software. The conditions were illustrated in table (1).

Sequence Analysis

Trimming of sequences were perform by FinchTV and then submitted to NCBI-BLASTN to see the identity of sequences with reference sequences within NCBI data base.

Results and Discussion

The results of PCR reveal that, firstly the primer pairs were specific and non-specific products not appear for all samples. The amplification of male and female Homo sapiens DNA with AMLEY primer pairs gave positive and negative results respectively while The amplification of male and female Homo sapiens DNA with AMLEX primer pairs gave positive results for all samples and this a primary evidence for primer pairs specificity The amplicon of AMLEY gene of Homo sapiens 744bp (Figure 1: A). The amplicon of AMLE X gene of Homosapiens were 1164 bp (Figure 1:B).
Figure 1: Agarose gel electrophoresis at 72 volt for 60 minutes 1.5% for A: 744bp amplicon of Homo sapiens AMLE Y gene; B: 1164bp amplicon of Homosapiens AMLE X gene. M represent 100bp DNA ladder, lane 1-19 represent male samples. lane 20-38 represent female samples.

The secondary and confirmatory assay for specificity of primer pairs used in study is sequences of PCR products. four amplicons from each were sent to South Korea for sequencing using Sanger technique (Macrogen/Korea). The retrieved sequences firstly must be trimmed to remove unwanted sequences before submitting them for BLASTN. The trimming performed by Bioedit to get the finally processed sequences. Abbreviation of AMLE Y sequences were used as IraqiAMELY-1 to IraqiAMELY-4. Same abbreviation will used as isolates name when submitting to GenBank. The identity percentage were illustrated in Table (2). The high percentage of identity of sequences confirm the specificity and validity of specific primer pairs used in current study.

The results showed no cross-reactivity of designed primer pairs and the PCR assay based on the designed primer pairs will be simple, fast, sensitive, specific, and cost-effective.

Genetic sex determination methods are not related to subjective physical examination, are accurate, require small samples, and do not necessitate the evaluation of a specific tissue, and any organ can be used. Their applicability depends on the specific methods. Successful assays are simple, need small amount of tissue, and are accurate during the entire pregnancy. Measuring the activity of X chromosome linked enzymes or RNA-based PCRs is complicated by the presence of some gene products only at certain developmental stages\(^\text{[1]}\). However, this problem is not present when the test is based on DNA. The amelogenin gene which is found on both X and Y chromosomes is in common use for sex discrimination in forensic medicine. A 6 bp deletion in intron 1 on chromosome X compared to the Y chromosome can be detected by using a pair of PCR primers. It can be used in various tissues including long-lasting remnant tissues like dental pulp\(^\text{[12]}\).

**Conclusion**

The current study concludes Sensitivity, specificity of the designed specific primer pairs; Applicability of the designed primer pairs in forensics to investigate blood sample or evidence belonging for detection of gender.

Effect of Workload and Breastfeeding Motivation of Working Mothers

Rachma Anisa Ulya1, Retnayu Pradanie1, Aria Aulia Nastiti1
1Department of Child Nursing Maternity, Faculty of Nursing, Universitas Airlangga (60115), Surabaya, Indonesia

Abstract

Background: The practice of exclusive breastfeeding in Indonesia still falls short of expectations due to working mothers’ struggle with managing both working outside and household chores. This workload results in mothers experiencing physical and emotional exhaustion and impacts on their motivation to practice exclusive breastfeeding, hence exclusive breastfeeding failure.

Objective: To shed light on the relationship between workload and exclusive breastfeeding motivation of working mothers in the working area of the Public Health Center of Bergas District, Semarang Regency.

Method: This is a cross-sectional study with a sample of working mothers in the working area of the Public Health Center of Bergas District, Semarang Regency, with babies aged 0–6 months. The sample of 32 respondents was recruited by purposive sampling technique. The data collected were analyzed by Spearman’s rho analysis. The instruments employed in this research were the modified versions of questionnaires from existing literature.

Results: The workload of nearly all of the sample (31 respondents, 96.8%) was categorized into Level 2. Besides, the vast majority of the breastfeeding, working mothers in Bergas District (30 people, 93.7%) had strong exclusive breastfeeding motivation. Last but hardly the least, a ρ-value of 0.801 (> 0.05) was obtained, suggesting no relationship between workload and exclusive breastfeeding motivation.

Conclusion: Workload bore no association with the exclusive breastfeeding motivation of working mothers. Despite the high workload, if the reinforcement system was high, individual motivation would generally remain high.

Keywords: workload, exclusive breastfeeding motivation, working mothers

Introduction

Exclusive breastmilk is human milk given to infants from birth until six months of age without the accompaniment of food or drink. Exclusive breastfeeding is followed by supplementation until the baby reaches two years of age 1. In Indonesia, the exclusive breastfeeding practice fails to live up to expectations. Exclusive breastfeeding practice failure is still prevalent, and the rate is higher in mothers working at institutional offices, government- or private-run, than in those working from home. In the case of those engaged in office work, time and rule inflexibility often sets a barrier to spending time together with their babies and takes a toll on their breastfeeding intensity 2. The government through Regulation of the Minister of Health of the Republic of Indonesia of 2014 set the exclusive breastfeeding scope target at 80%, but in parts of its territory, the percentage barely could touch as high as 50% 3.

Exclusive breastfeeding support, especially for working mothers, is manifested through global and national policies. One of such policies is Government Regulation No. 33 of 2012 on Exclusive Breastfeeding.
Another is set out in Article 2 of Joint Ministerial Regulation of the Minister of Women’s Empowerment, the Minister of Manpower and Transmigration, and the Minister of Health No. 48/MEN-PP/XII/2008/PER27/MEN/XII/2008 on Breastfeeding Promotion at Workplace. Meanwhile, global support came from UNICEF through a statement in 2013 that exclusive breastfeeding for a minimum of six months makes the lowest-cost life-saver for children.

In addition to the demand from their full-time work, mothers are also faced with household chores, including nursing their babies, after work. This phenomenon is referred to as second shift. The implications include mothers’ inability to complete their household tasks maximally due to physical and emotional fatigue. It is assumed then that this second-shift-driven physical and emotional exhaustion will influence mothers’ exclusive breastfeeding motivation.

In light of the abovementioned, this research intended to observe whether relation does exist between workload and exclusive breastfeeding motivation of working mothers. The aim of this research was to identify mothers’ workload and motivation to engage in breastfeeding practice.

Materials and method

This research is a quantitative study with a cross-sectional design, in which the relationship of independent to dependent variables was measured at one time with no follow-up.

Population and sample

The sample enrolled comprised working mothers in the working area of the Public Health Center of Bergas District, Semarang Regency. The inclusion criteria used were that respondents worked outside, had baby 0–6 months old, resided in the working area of the Public Health Center of Bergas District, and were breastfeeding. Meanwhile, the exclusion criteria were that respondents were suffering from mental disorder, were unemployed or worked at home (operating online business or operating local shop or booth at home), and resided beyond the working area of the Public Health Center of Bergas District, Semarang Regency. A sample of 32 respondents was derived from a population of 47 working mothers. This number had surpassed the minimum number of subjects for correlational studies of 30. The sampling technique employed was purposive sampling technique.

Research variables

The independent variable in the present study was workload, whereas the dependent was working mothers’ exclusive breastfeeding motivation.

Research instruments

The instruments employed in this study were questionnaires modified from existing literature. For the variable workload, the instrument adopted was the Fatigue Likelihood Scoring questionnaire by Transport Canada, consisting of five questions regarding total working hours per week, maximum working duration per shift, minimum interval between two shifts, maximum night shift duration per week, and off-day frequency. The scores generated would point to the final position in the five-level fatigue scale below.

### Table 1 Fatigue Likelihood Scoring Blueprint

<table>
<thead>
<tr>
<th>Scores</th>
<th>0</th>

<td>12.9–10</td>
<td>9.9–8</td>
<td>≤ 8</td>
</tr>
</tbody>
</table>
As for the variable exclusive breastfeeding motivation, the measurement was conducted by the Breastfeeding Motivation Instructional Measurement Scale (BMIMS) questionnaire, previously subjected to expert-based content validity test and then selected in this research based on the measurement parameters. The lowest score obtained was 12, and the highest 48. The scores obtained were then converted into percentages (%), according to which, as stated by Suadana et al. (2018) that motivation was categorized, with scores between 67–100% being strong, 34–66% medium, and 0–33% weak.

It was identified from this research that nearly all respondents scored 9 to 18 for the Fatigue Likelihood Scoring (FLS). Based on the response analysis, the workload fell into such a range owing to the fact that a great majority of the respondents worked a total of 55 hours every week (in the scoring system belonging to the score 8). In other words, they spent 10 to 11 hours a day (score 2) 5–6 days a week working, with only 8–9 hours a day for rest (score 4). Besides, they were given off-day 1–2 times weekly (score 1). When everything was added up, the final score fell to the 9–18 range. Based on the Fatigue Likelihood Scoring guide, the score range denoted Level 3 fatigue, which belonged to the yellow area of the instrument 7.

Validity test

Validity testing was run by consumer validity, that is, by distributing questionnaire to 15 respondents who were enrolled by accidental sampling technique. The respondents were chosen for sharing similarities in characteristics with the sample. The correlation coefficient from the validity testing was compared to the coefficient in the Pearson’s product moment correlation table with 5% margin of error (0.05).

Reliability test

The reliability test run against the questionnaire used Cronbach’s alpha formula. The counted $r$ alpha was compared to the table $r$ alpha. If the counted $r$ alpha was greater than the table $r$ alpha, the question item would be declared reliable and fit to be used in the research, but if the counted $r$ alpha was less than the table $r$ alpha, the question item would not be used in the research 9.

Data analysis

This research employed a bivariate analysis of Spearman’s rank correlation. Spearman’s rank correlation, or Spearman’s rho, is a test used to measure the correlation between two variables with ordinal data or with interval- or ratio-turned-ordinal data and to look at the fitness of the variables tested into equivalent group 10.

Results

Table 2 below presents the respondents’ characteristics by age, education, and occupation. The majority of the respondents were factory workers aged 31 years on average (productive age). They mostly had high school or the equivalent as their latest formal education.

The specific data presented in Table 3 were collected from the questionnaire responses. The data were comprised of six components: distribution of exclusive breastfeeding information; source of exclusive breastfeeding information; lactation facility availability at workplace; exclusive breastfeeding practice; exclusive breastfeeding motivation; and workload.

Table 3 provides a picture that the respondents mostly had strong exclusive breastfeeding motivation. It was supported by their knowledge on exclusive breastfeeding virtually all of them possessed, lactation facility availability at the workplaces at which most of them worked, and counselling from a range of parties, such as health professionals, mass, and electronic media. Despite all of the previously stated, only half of the total respondents did practice exclusive breastfeeding.

Spearman’s rho was used to analyze the relationship between workload and working mothers’ exclusive breastfeeding motivation. The results are as presented in Table 4, where it can be seen that the $p$-value was $0.801 (> 0.05)$.

Discussion

This research aimed to analyze the correlation between workload and the exclusive breastfeeding motivation of working mothers in the working area of the Public Health Center of Bergas District, Semarang Regency. As indicated by the data above, the factors included in the respondents’ workload were working hours, rest time, off-day frequency, and age, so there was an agreement between the theory and the fact 11. It was found that there was no or negligible correlation between workload and the exclusive breastfeeding motivation of working mothers as shown by the correlation coefficient of 0.046 (0.00–0.20) in Table 4. It is known that the higher the workload, the higher the level of fatigue 12. Workload has long been measured by fatigue indicator as fatigue is resulted from unreasonable workload.

The factors influencing strong motivation of their respondents, as were in this research, including possession of adequate information from health personnel, mass media, electronic media, workplace, or regular events in residential neighborhood and availability of lactation facility at workplace 13. An additional factor was the fact that most of the respondents were in their adulthood. Institution-initiated programs, activities, and campaigns pertaining to exclusive breastfeeding promotion in this context could also influence the exclusive breastfeeding motivation of working mothers 4.

The last aspect was the motivation triggered by moving information from media to do something. In this instance, bottle-feeding as well as exclusive breastfeeding promotions affected one’s decision to exclusively breastfeed. It was as found in the present study that the respondents had gained information regarding the importance of exclusive breastfeeding in the first six months in baby’s life through media, either print or electronic 14. Motivation is aroused by the desire to achieve a goal, hope, and belief that the action taken will lead to a reward. Hence, if the desire, hope, and belief are high, an individual’s motivation will also be high, and vice versa 15.

Conclusion

The results of this research indicated that workload was not related to exclusive breastfeeding motivation, although the respondents’ workload belonged to Level 3 category with an FLS score within the 9–18 score range. The strong motivation of most of the working mothers in this research was driven by strong social support from the environment. The factors involved in the respondents’ reinforcement system positively impacted their belief, desire, and hope.

Effectiveness of an Educational Program on Nurses- midwives’ Practices about Pain Management during Labor in Baghdad Maternity Hospitals

Rajaa Tareq Hasan1, Rabea Mohsen Ali2, Ekhlas A. Hussein3

1Instructor, Maternal and Neonate Nursing Department, College of Nursing/ University of Baghdad, 2Professor, Maternal and Neonate Nursing Department, College of Nursing, University of Baghdad, 3Assist. Prof. Dr. College of Medicine, Al-Iraqia University

Abstract

Objectives: To assess nurses-midwives’ practices about pain management during labor before and after implementation of educational program.

Methodology: A quasi-experimental design has been conducted during the period of (27th February 2019 through 2nd June 2019) on non-probability sample (purposive) consists of (44 Nurses/midwives’) who are work in delivery room, the sample was exposed to pretest, educational program, posttest. The study was conducted in the Baghdad Maternity Hospitals. Questionnaire has been used as a tool of data collection. Data were analyzed through the application of descriptive and inferential statistical data analysis approach through the use of (SSPS) version 22.0 and Excel system.

Results: All observations (three observations) in posttest period in the items (changing position, deep breathing, and religious and spiritual idea) appear high and moderate mean scores and relative sufficiency in the three observations after the implementation of education program for nurses- midwives’ regarding to the management taken by the midwife to reducing labor pain of pregnant women in delivery room. While other management not implemented by the nurses- midwives’ due to the lack in the resources or supplementation in delivery rooms, or due to the routine of the hospitals.

Conclusions: The study concluded that the educational program can be considered as an effective mean for improvement of the nurses-midwives’ practices about the importance pain management.

Recommendations: The study recommended to training primary health care nurses in improved pain management is important part of multi-faced approach towards improving and helping women’s to reduce pain during labor.

Keywords: Educational Program, Nurses- midwives’ Practices, Pain Management, Labor.

Introduction

Labor pain is one of the most intense pains of women. This type of pain is very common and is an inevitable part of the childbirth process. For some reasons, labor pain and its experience is quite different from other types of pains. This pain is not a symptom of tissue injury, and can spontaneously be limited and controlled. This pain gradually gets intense and eventually leads to a desirable event which is the childbirth (1)

Pain experienced during childbirth is a complex, multidimensional and subjective phenomenon that is of great concern to both the expectant mother and the maternity healthcare professional. Although the experience of pain is inherent in the childbearing process, unrelieved labor pain can result in negative consequences for the expectant mother, her family, healthcare providers and healthcare systems at large. Apart from maternal consequences such as heightened stress, fear, depression, confusion, hypertension, hyperglycemia, and constipation, unresolved labor
pain can also compromise placental perfusion leading to asphyxia, late decelerations and its resultant fetal distress. These create feelings of guilt and helplessness for the woman’s family as well as a lack of confidence in the abilities of healthcare providers and systems in general(2).

Methodology

A quasi-experimental design has been conducted during the period of (27th February 2019 through 2nd June 2019) on non-probability sample (purposive) consists of (44 Nurses/midwives’) who are work in delivery room, the sample was exposed to pretest, educational program, posttest. The study was conducted in three Directories, (Baghdad Teaching Hospital) at medical city health directorate, (Al-Elwia Maternity Teaching Hospital, Ibn Al-Zahra for Maternity and Pediatric Hospital, Fatima Al-Karckh Maternity Hospital and AL - Yarmouk Teaching Hospital - Maternity Department) at AL-Russafa/Health Directorate, and (Al -Karckh Maternity Hospital and AL - Yarmouk Teaching Hospital - Maternity Department) at Akarkh/Health Directorate. Questionnaire has been used as a tool of data collection to fulfill with objective of the study to assess nurses-midwives’ practices about pain management during labor before and after implementation of educational program and to determine the effectiveness of educational program on nurses-midwives’ practices about pain management during labor in Baghdad Maternity Hospitals. Data were analyzed through the application of descriptive and inferential statistical data analysis approach through the use of (SSPS) version 22.0 and Excel system.

Table (3) results show that there are high and moderate mean scores and relative sufficiency in the first observations in posttest period practices (2, A, B, & K); (4, C); and (8) after the implementation of education program for nurse-midwives practices taken to reducing labor pain of pregnant women in delivery room. In the second observation there are high mean scores and relative sufficiency in practices (2, & K); (4); and (8). In the third observation there are high and moderate mean scores and relative sufficiency in practices (2, & K); (4, C); and (8).

**Discussion**

Socio-demographic Characteristics of the Study Sample

Table (1) shows that the highest percentages (25%) for study sample at age group (20-24) years with mean and (SD) (33.84 ± 9.4).

These findings are agreement with cross sectional study design that assess practice of Labor pain management methods and associated factors among skilled attendants in all Tigray region general hospitals. And found that out of the total of (233) skilled attendants were included in the study, making a response rate of 100%. The mean age of the respondents was (30.2 ± 6.6), of them 152(65.3%) were in the age group of (20-29), 56(24%) were in age group (30-39) and 25(10.7%) were in age group (≥ 40) (3). Conversely, the study conducted in two medical institutions providing health care services in Moi Teaching and Referral Hospital (MTRH) and Jaramogi Oginga Odinga Teaching and Referral Hospital, Kenya. The study found that the highest percentage (48.1 %) of health care providers were in the age group of (25-34) years (4). Table (1) shows that the highest percentages (68.2%) were married. Married nurses-midwives have more perception of the labor pain than an unmarried woman, because the first woman may have experienced pregnancy and labor and felt what pain a woman feels during labor. Table (1) shows that the highest percentages (70.5%) were preparatory graduates. These findings are disagreement with a quantitative design was used to examine differences in knowledge of pain assessment and pharmacologic pain management strategies among registered nurses from a large academic medical center. Subjects were selected using type of nursing unit in which they work and a convenience sampling the study found the majority of participants had bachelor’s degrees (n = 66, 67.3%), 22 (22.4%) had associate’s degrees, and 10 (10.2%) had master’s degrees (5).

Nurses-midwives’ Clinical Practices to Reduce Labor Pains

Table (2) results was consistent with the study for nurses-midwives use in the delivery room the some non-pharmacological methods more than others for different reasons such as decrease nurses-midwives stuff in delivery room, lack of time; no have knowledge and practices about non-pharmacological methods. Inadequate staff served as an obstacle to the utilization the non-pharmacological therapies in managing labor pain. Participants perceived some of the non-pharmacologic approaches to be time consumption for the few attending maternity care providers to administer considering their heavy workload and increased client turnover. Increased workload and client turnover invariably place a lot of stress on the few practicing nurses and midwives, leading to staff exhaustion and impaired work efficiency (2).

Nurses-midwives’ practices to reduce labor pains

Table (3) results show that there are high and moderate mean scores and relative sufficiency in the first, second and third observations in posttest period practices (2, & K); (4); and (8). While other practices not implemented by the nurse-midwives due to the lack in the resources or supplementation in delivery rooms, or due to the routine of the hospitals, or neglect of the nurses-midwives’ to the practice. The results consistent with Boateng et. al, these stated in their study that nurses and midwives were more use some non-pharmacologic approaches such as sacral massage, deep breathing, and frequently use them in their practice to manage labor pain. The frequent usage of these methods has been reported in previous studies and can be attributed to the familiarity of the midwives with these approaches. While insufficient knowledge may account for the decrease frequent use of these methods, other factors such as inadequate human and material resources may have contributed to this observation; similar to what has been reported in other studies (2).
Conclusions
The study concluded that the educational program can be considered as an effective mean for improvement of the nurses-midwives’ practices about the importance pain management.

3D CBCT Analysis of Odontometric Variables for Gender Dimorphism in Saudi Arabian Subpopulation

Rakhi Issrani1, Azhar Iqbal2, Mohammad Khursheed Alam3, Namdeo Prabhu4

1Lecturer, Department of Preventive Dentistry, 2Assistant Professor and Head, Department of Conservative Dentistry, 3Associate Professor and Head, 4Lecturer, Department of Oral & Maxillofacial Surgery and Diagnostic Sciences, College of Dentistry, Jouf University, Sakaka, Kingdom of Saudi Arabia

Abstract

Background: For assessing the sex of unidentified or skeletonized individuals, the tooth crown diameters are a good and reliable source amongst the other clinical markers.

Aim and Objectives: To check the accuracy and reliability of Mandibular Canine Index (MCI) in sex determination among Saudi subpopulation using 3D Cone Beam Computerized Tomography (CBCT) images. An additional objective is to establish the norm of Standard MCI.

Methodology: A total of 400 CBCT images were studied for the measurements of mesio-distal width (MDW) and inter-canine distance (ICD) of mandibular canines. Then, the observed and Standard MCI were calculated that was statistically determined by receiver operating characteristic (ROC) analysis.

Results: Left canine showed greater sexual dimorphism. The Standard MCI was calculated as 0.239 (right mandibular canine) and 0.241 (left mandibular canine). The ability to determine gender correctly using Standard MCI (right mandibular canine) method was estimated to be 49% among males and 46.5% among females. The accuracy of the method, when applied to the combined data, was 47.8%.

Conclusion: MCI and the variables that allow MCI quantification were shown to distinguish the groups, in terms of average, suggesting the possibility that canine-related measurements may be used for sex discrimination.

Keywords: Canine; CBCT; Odontometric.

Introduction

Forensic odontology plays a vital role in the recognition of victim of mass disasters. Odontometric features used for sex identification are sometimes dependent on the gender wise comparison of tooth dimensions. Among all the teeth, mandibular canines are better-known to show the greatest sexual dimorphism, and so it is assigned as the ‘key teeth’ in human identification.

Odontometric analysis using direct measuring ways has been done using hand-held digital calipers, 2D digital model, graphical illustration to record dimensions on dental casts, digital impression model, 3D CBCT model, and laser scanned model. 3D CBCT has made it possible to conduct odontometric measurements in three-dimension and providing a lot of precise and consistent tools. It conjointly offers additional advantages like availability of images created, decrease in storage expenses and the facility to gauge the pictures by refined software. All these options strengthen the credibility and reliability of 3D CBCT method for the odontometric morphometry.
Despite conducting thorough literature review, no study could be found that has tested this methodology among Saudi population. Hence, the current study was conducted with an aim to examine the accuracy and reliability of MCI in sex determination among Saudi population by in vivo 3D CBCT. An additional objective of this study was to ascertain the norm of Standard MCI.

**Material and Method**

This cross-sectional study of secondary data was conducted between the periods of May 2017 to July 2019. Sample size was assessed using nMaster software (version 2, CMC, Vellore). Anticipating a 60% accuracy of Standard MCI method for predicting gender in the study population, an absolute precision of 5% and a 95% Confidence interval, a sample size of 369 was found to be sufficient. This sample size was rounded off as 400 with equal proportion of males and females.

The data source was CBCT volumetric data from the archives of the College of Dentistry, Jouf University and samples were selected using simple random technique. Odontometric morphometry was analyzed and recorded in 400 3D CBCT volumetric data mandibular arches. The inclusion criteria were i) age-group of 17-35 years; ii) presence and complete eruption of all morphologically normal permanent teeth with exception of third molars; and iii) high quality CBCT that have proper density and contrast with sharp outlines. The exclusion criteria were i) severe crowding; ii) excessive spacing; and iii) interproximal caries or restoration.

**Studied parameters**

**MDW**: measured as the maximum distance between the contact points of mandibular canines on the approximate surfaces of the tooth crown.\(^6\) *(Figure 1)*

**ICD**: measured between the contact points of mandibular canines.\(^7\) *(Figure 2)*

**Procedure**

The selected 400 CBCT images were analyzed using software OnDemand 3D. The readings obtained from measurement MDW and ICD were subjected to mathematical operations to calculate the observed MCI. The formula used to determine canine index was:

\[
\text{Observed MCI} = \frac{\text{MDW of mandibular canines}}{\text{ICD}}.
\]

\[
\text{Standard MCI} = \frac{(\text{mean male MCI} - \text{Standard deviation [SD]}) + (\text{mean female MCI} + \text{SD})}{2}.
\]

The Standard MCI value aided as a cut-off point to differentiate males from females. Individuals with the observed MCI values≤Standard MCI value were categorized as females; otherwise, they were grouped as males.

**Measurement of error**: The readings were repeated at two weeks interval to evaluate the systemic and random errors for 50 CBCT images that were randomly selected. Two-sample *t*-test was used for calculating systemic errors for each pair of analyses. All test and retest measurements presented an intra-class correlation of value greater than 0.91 that is acceptable as per Stirrup (1993).\(^8\) Outcomes form these variables showed that there were no random errors. All pairs of measurements showed a p-value>0.1, suggesting that there was no systemic bias in these analyses as stated by Houston (1983).\(^9\)

**Statistical analysis**

Descriptive analysis of MDW and ICD were presented as means and SD. Predictive accuracy was assessed in terms of percentage. The accuracy of the Standard MCI, to correctly identify the gender, was statistically determined by ROC analysis. Sensitivity and specificity of a diagnostic test can be interpreted by ROC curve that is created by plotting the true positive rate against the false positive rate at various threshold settings. The area under curve (AUC) determines the accuracy of the test. An AUC value of 1.0 indicates the perfect test. If the AUC is 0.9-1.0, it shows excellent test. An AUC value of 0.8-0.9 indicates a good test, whereas an AUC value of 0.7-0.8 depicts a fairly reliable test. The AUC value<0.5 indicate an unreliable test.

**Results**

The descriptive statistics for MDW, ICD and MCI are summarized in Table 1.

1. **MD dimensions**: The mean right and left MD canine dimensions among females were 6.41±0.46mm and 6.48±0.44mm respectively, while among males, the values were significantly higher. This difference was found to be statistically significant (p<0.05).

2. **ICD**: The mean ICD among males was significantly greater than among females.

3. **MCI**: The MCI were found to be higher among
females as compared to males, which was statistically insignificant.

4. Sidewise comparisons: Left canine exhibited greater sexual dimorphism when compared to right canine.

5. Standard MCI: Generally, the Standard MCI is obtained using the right mandibular canine MD dimension. But to check the suitability of left mandibular canine for sex determination, the Standard MCI using the left mandibular canine was also determined. The calculated Standard MCI was calculated as 0.239 (right mandibular canine) and 0.241 (left mandibular canine). The ability to determine sex correctly using Standard MCI (right mandibular canine) method was estimated to be 49% among males and 46.5% among females. The accuracy of the method, when applied to the combined data, was 47.8%. While, when Standard MCI (left mandibular canine) was used as cut-off value, 44.5% males and 48.5% females were correctly predicted. The overall accuracy of this Standard MCI (left mandibular canine) was calculated as 46.5%. (Table 2)

The AUC (for MCI calculated from right mandibular canine) has a value of 0.481 and 0.519 for males and females respectively. The AUC (for MCI calculated from left mandibular canine) has a value of 0.486 and 0.514 for males and females respectively (Figure 3a-d). It can be interpreted that this MCI method was not a reliable method for prediction of gender in the Saudi subpopulation.

Discriminant analysis was utilized to conduct a multivariate analysis of variance test of the hypothesis that males and females would differ significantly on a linear combination of five variables, viz, MDW of right canine, MDW of left canine, ICD, right and left MCI. The overall Chi-square test was significant (Wilks λ=0.696, Chi-square=143.56, df=5, Canonical correlation 0.552, p<0.001). Re-classification of cases based on the new canonical variables was highly successful: 72.3% of the cases were correctly reclassified into their original categories. (Table 3)

Discussion

The present study was carried out on CBCT data of 400 patients using the In-Vivo Dental program and the digital models obtained out of 3D onDemand software. The uniqueness of the current study lies upon the following statements: (1) 400 CBCT data; (2) assessment of odontometric morphometry by new approach; and (3) first time in Arabian subpopulation using this novel method.

There is no consensus on the suitability of the MCI in sex determination, as different authors have stated different conclusions. In an Indian sample, Duraiswamy et al. (2009)\(^\text{10}\) claimed 72.0% accuracy rate, while Silva et al. (2016)\(^\text{11}\) mentioned a 54.2% accuracy rate in a Portuguese population. A higher accuracy rate was reported by Yadav et al. (2002)\(^\text{12}\) but a much lower accuracy was stated by Muller et al. (2001)\(^\text{13}\). Variations can, obviously, exist in population disparities.

The present study established that the MD dimension of mandibular canines exhibited statistically significant sex variation. No statistically significant differences were found between right and left mandibular canines in both sexes suggesting that the canine measurement on any side of the jaw can also be used for the other side. This finding is in harmony with the study done by Shahid et al. (2015).\(^\text{14}\) Also a significant difference in ICD was detected between the sexes with male subjects exhibiting larger ICD. Although this finding is consistent with previous reports on the canine index but these measurements were done by digital caliper on plaster model.\(^\text{15}\)

The percentage sexual dimorphisms were also calculated by using Garn and Lewis formula.\(^\text{16}\) The present study found a definite statistically significant sexual dimorphism in mandibular canines, which is consistent with previous studies.\(^\text{17,18}\) The left mandibular canine exhibited greater dimorphism as compared to right. Thus, usage of left mandibular canine for sex determination of an individual will give more precise results. This finding is found to be in accordance with many previous studies showing the values of sexual dimorphism in this range only. Few studies had found a higher degree of sexual dimorphism in canine dimensions while few others had found a lower magnitude of sexual dimorphism. This observation is of definite significance and the discrepancy can be explained based upon the fact that tooth morphology is known to be influenced by environmental, cultural, and racial factors.\(^\text{19}\)

Nonetheless, MCI did not show any statistically significant sexual variation in the present study population. This finding was contradictory to many previous studies.\(^\text{11,18}\) Many recent similar studies on Nepalese and Indian origin population also could not found gender variation in MCI.\(^\text{20,21}\) In addition, discriminant analysis of MCI revealed poor ability to differentiate the sexes. This finding could be attributed to MCI being measured as a relative value- it is estimated as a ratio of two absolute measurements and does not reproduce sex differences that exist in the absolute measurements per se.\(^\text{22}\) Acharya et al. (2011)\(^\text{23}\) in his study have also questioned the reliability of ICD for sex assessment considering the fact that males have larger jaw dimensions with a more predilection for bilobate and square shaped chin in contrast to pointed ones in females. Moreover, MCI relies on ICD, which can be modified by orthodontic treatment or periodontal disease that can result into pathological migration of canines to different positions and despite being very resistant to hazard, teeth particularly a single rooted tooth, can be displaced from its location peri- or post-mortem. In such conditions, methods that rely on having the two mandibular canines in their alveoli cannot be used.\(^\text{24}\)

The ROC curve analyses reported poor discriminative ability values for both right and left MCI, and therefore did not support the use of dental variables for sex estimation.

Conclusion

i. CBCT provides a valuable tool in record and data management for odontometric morphometry assessment obtained directly from the digital image;

ii. MCI and the variables that allow MCI quantification were shown to distinguish the groups, in terms of average, suggesting the possibility that canine-related measurements may be used for sex discrimination; and

iii. The MCI proposed in other population sample was not found to be a reliable tool in sex determination in the present Saudi Arabian sample, and therefore its application should be confined.

Violation of Dapek Salah Customary Law in Bengkulu: Forensic Psychological Analysis Toward The Criminal Behavior of Indigenous

Rangga Jayanuwarto¹, Khudzaifah Dimyati², Absori Absori², Natangsa Surbakti²

¹Lecturer at University of Muhammadiyah Bengkulu, Indonesia

Abstract

Introduction: Every law is a system which means law bases on the unity of the mind. Customary law is understood as a law that lives in a “living law” society, legal values and a sense of justice that lives in society. All takes place after the values lived by the society under the filter of legal ideals and moral ideals prevailing in the society concerned. Without the law as an effective social control, humans potentially can lead to behavior that can bring destruction to humans. In Bengkulu, the law that lives in the community is known as the law of adat dapek salah. Violation of the law can be acts of a person or group of people who disturb the balance in the indigenous peoples. The violation of the law is an act of deviant behavior that is negative in which each culprit will be charged with various kinds of traditional sanctions. The research of forensic psychology analysis is needed to see the behavior of customary criminal crime in violation of customary law. The assessment is carried out to provide an overview of the mental state of the offender. This is in line with forensic psychology as the study of subjects in terms of cognitive, effective and behavior in relation to the legal process.

Material and Method: This research is a qualitative research which produces descriptive data in the form of written or oral words from people and observed behavior. Qualitative research is also called naturalistic research. This study departs from naturalistic inquiry whose findings are not found from statistical calculations.

Findings: Customary law of Dapek Salah in Bengkulu as a social model directs to accommodate the entire social system which includes the function of norm system. The function of norm system is to correct behavior that deviates from the relevant rules (violations). These rules are the framework of human behavior orientation (members of the social system). Norms are also often referred to as rules of conduct and blueprints for behavior in a society. This can also lead to anti-social behavior or asocial behavior which could be a factor causing criminal behavior. Criminal behavior toward the Dapek Salah law is an act that causes adverse reactions and corrections and the balance of the community. In the study of forensic psychology analysis, criminal behavior on the law depends on the perception of the respective actors. Aspects of perception consist of cognitive aspects (thoughts), affective aspects (feelings), and aspects of conation (behavior). Individual perceptions can influence and motivate subsequent behavior, if the object of perception is judged unpleasant then the behavior is negative.

Conclusion: Violation of the Dapek Salah is a phenomenon, a person or group of people who violate customary law (criminal behavior) so as disturbing the balance in indigenous peoples’ value. In the forensic psychological analysis, criminal behavior of the law depends on the perception of the respective actors. Aspects of perception consist of cognitive aspects (thoughts), affective aspects (feelings), and aspects of conation (behavior). Individual perceptions can influence and motivate subsequent behavior, if the object of perception is judged unpleasant then the behavior is negative. In the basic concept of psychology, there is something wrong with the minds of the perpetrators so that they are involved in criminal behavior. Imbalance relationship between Id, Ego and Superego makes humans weak and consequently more likely to commit deviant behavior or criminal behavior.

Keywords: Violation of Dapek Salah Customary Law, Criminal Behavior, Forensic Psychology
Introduction

Every law is a system which means its rules are unanimity based on the unity of the mind. In Indonesian legal system, there is a customary law. Customary law is understood as a law that lives in a “living law” society, legal values and a sense of justice that lives in society. The unwritten rule of law is determined by the leadership of the alliance, but it comes from habit, code of conduct, from code of conduct to customs, from customs to legal norms. All takes place after the values lived by the community under the filter of legal ideals and moral ideals prevailing in the society concerned.

Law is indeed a human necessity. Without law as an effective social control, human potentially can lead to behavior that can bring destruction to humans, as Lun Fuller said, “human is the only species that chooses its own kind as its preferred prey”. Customary law as a social control system has given its role in the framework of creating community order. Logical consequences as a means of social control, customary law is born, grew and developed in a social system.

Good law is the law in accordance with the law that lives in society. In Bengkulu, the law that lives in the community is known as customary law of Dapek Salah. Violation of the Dapek Salah is a phenomenon, a person or group of people who violate customary law (criminal behavior) so as to disturb the balance in indigenous peoples. At this point, violation of Dapek Salah as a law that lives in the community should not occur. This is because the law is an embodiment of the real legal feelings of the community, it is also a blueprint of behavior that provides guidelines and or benchmarks for community behavior.

In Bengkulu, violation of the customary law can be inevitable wrong called as criminal behavior. Criminality as an act or behavior that is detrimental to the sufferer or victim is also very detrimental to the community in the form of loss of peace and order. Criminality is also an activity which is opposed by the community because it violates the law, social and religion as well as psychological harm. If criminal behavior arises in the form of a violation of customary law, it can be concluded that something has gone wrong with the behavior of the act. Violation of the customary law is an act of deviant behavior in which each culprit will be charged with various kinds of traditional sanctions. A violator is not necessarily identical with chaotic behavior but it could be accidentally or in a desperate condition. Among deviant behaviors, some are triggered by psychiatric conditions that suffer from disorders, mental illness, and others which appear physically healthy. However, there is also based on the growth of the decision to violate the law even though he does not suffer from mental disorders and this is very closely related to the socio-psychological aspects (environment).

Therefore, the study of forensic psychology analysis is needed to see the criminal behavior of customary law in a psychological perspective. The assessment is carried out to provide an overview of the mental of the offender. This is in line with forensic psychology as the study of subjects in terms of cognitive, effective and behavior in relation to the legal process. Based on the above, it is necessary to see how violations of Dapek Salah in Bengkulu City as a study space forensic psychology analysis.

Material and Method

This research is a qualitative research which produces descriptive data in the form of written or oral words from people and observed behavior. Qualitative research is also called naturalistic research. This study departs from naturalistic inquiry whose findings are not found from statistical calculations.

Findings

A. Violations of the Dapek Salah Law in Bengkulu

Dapek Salah customary law as a social model directs to accommodate the entire social system which includes the function of norm system whose task is to correct behavior that deviates from the relevant rules (violations). These rules constitute the orientation framework of human behavior (members of the social system). Norms are one of the basic concepts to explain human behavior and causes of violations. Norms are rules that govern behavior at certain times and situations. Norms are also interpreted as behaviors that are psychologically accepted and expected by the community. Norms are also often referred to as rules of conduct, and blueprints for behavior.
Violation (Dapek Salah Customary Law) has the following principles:\textsuperscript{17}:

1. Violations of customary law or a sense of community justice.
2. The violation will cause a shock in the community’s legal balance, and
3. Customary law sentences to the criminal so that the balance happens in society.

As for the forms of violation of Dapek Salah customary law are taking or damaging other people’s belongings, beating, holding the opposite sex who is not a \textit{muhrim}, committing adultery, traveling with someone who is not a \textit{muhrim}, meeting someone who is not a \textit{muhrim}, doing something unpleasant to a neighbor, disturbing someone’s yard, damaging the environment, embarrass others, and disturb others.

In a social context, criminal behavior is a social behavior that is learned in a community group. This is based on the assumption that humans live in groups and depend on other humans. This terminology can only be applied to humans, and only humans have the capacity to enter into abstract social relations. Without the influence of society, groups of people will not be able to talk and behave socially. Therefore, punishing people in a place for a certain period can produce dramatic acts of behavior. The loss of community and group relations can be a variable that can explain why someone commits criminal behavior. This can also lead to anti-social behavior or asocial behavior which could be a factor causing criminal behavior\textsuperscript{18}.

B. Forensic Psychological Analysis Toward the Criminal Behavior of the Dapek Salah Law in Psychological Perspectives

Criminal behavior in Dapek Salah law is an act that causes adverse reactions, corrections and the imbalance of the community. Criminal behavior is not a hereditary phenomenon that is innate nor inherited biologically. Criminal behavior can be committed by anyone, both men and women, children, adults, and elder. Crimes can occur consciously, that is, think in advance, planned, and directed at a particular purpose. In addition, it can also be done in a semi-conscious, influenced by strong impulses from within a person, strong impulses (compulsions), and obsessions\textsuperscript{19}.

In the study of forensic psychology analysis, the criminal behavior of Dapek Salah law depends on the perception of each actor. Aspects of perception consist of cognitive aspects (thoughts), affective aspects (feelings), and aspects of conation (behavior). Individual perceptions can influence and motivate subsequent behavior. If the object of perception is judged unpleasant, then the behavior is negative\textsuperscript{20}.

In the basic concept of psychology, there is something wrong with the minds of the perpetrators so that they are involved in criminal behavior. The imbalance of the relationship between Id, Ego and Superego makes humans weak and consequently is more likely to commit deviant behavior or criminal behavior. That deviation results from excessive guilt as a result of excessive superego. People with excessive superego will be able to feel guilty without reason and want to be punished. The way people do to deal with guilt is precisely by committing a crime. Crimes are committed to defuse the superego because they unconsciously want a punishment to eliminate guilt. Apart from that, it also can be the principle of “pleasure”. Humans have a biological basis that is urgent and works to achieve satisfaction (pleasure principle). This includes the desire for food, sex, and survival managed by Id. This cannot be obtained legally or in accordance with social rules, so people will instinctively try to do it illegally. Actually, a moral understanding of right and wrong that has been instilled since childhood should be able to work as a superego that counterbalances and controls the Id. But if moral understanding is lacking and the superego does not develop perfectly, a person can grow into an individual who is less able to control the impulse of the Id. This stimulate people to do anything to achieve what their needs. Criminal behavior is not the result of criminal personality, but it comes from ego weakness. An ego that is unable to bridge the needs of the superego and the Id will be weak and make people prone to deviations\textsuperscript{21}.

There are two factors that cause crime (criminal behavior of Dapek Salah law\textsuperscript{22}:
1. Personal factors, including biological factors (age, sex, mental state) and psychological factors (aggressiveness, carelessness, and alienation).
2. Situational factors, including conflict situations and place and time factors.

Criminal behavior is often associated with a bad personality, for example to take revenge against others, often lie to his friends\textsuperscript{23}, narcissistic, aggressive when
their egos are threatened, and intimate relationships with a partner will tend to be problematic because of his selfish attitude and his affair. Psychopathy is also often associated with various forms of crime, including sexual violence and murder.

Naturally, some people struggle to solve social problems through appropriate ways (accepted by the community), such as trying to be individuals who are pleasant and sensitive to the people around them. However, there are also those who choose to use social hostility strategies, which are carried out by individuals with bad characters.

Conclusion

Violation of the Dapek Salah law is a phenomenon, a person or group of people who violate the law so as to disturb the balance in indigenous peoples. If criminal behavior arises in the form of a violation of Dapek Salah law, so it can be concluded that something has gone wrong with the behavior of the act. Violation of the law is an act of deviant behavior that is negative in which each culprit will be charged with various kinds of traditional sanctions. In the study of forensic psychology analysis, the criminal behavior of the law depends on the perception of the respective actors. Aspects of perception consist of cognitive aspects (thoughts), affective aspects (feelings), and aspects of conation (behavior). Individual perceptions can influence and motivate subsequent behavior, if the object of perception is judged unpleasant then the behavior is negative. In the basic concept of psychology, there is something wrong with the minds of the perpetrators so that they are involved in criminal behavior. The imbalance of the relationship between Id, Ego and Superego makes humans weak and consequently is more likely to commit deviant behavior or criminal behavior.

The Effect of Marmet Technique on Mother’s Satisfaction in Breastfeeding

Rani Dwi Sulistiawati¹, Tiyas Kusumaningrum¹, Retnayu Pradanie¹, Ni Ketut Alit Armini¹,
¹Department of Maternity and Pediatrics, Faculty of Nursing, Universitas Airlangga

Abstract

Background: The Marmet technique is a safe way to stimulate the breast to produce more milk. The administration of Marmet techniques to mothers who produced little to no amount of breast milk showed good results. Palms and fingers are recommended for breast milk milking due to them being practical, effective and efficient.

Purpose: To determine the effect of Marmet technique on maternal satisfaction in breastfeeding.

Method: This research applied quasi experiment design. There were 40 respondents, each consisting of a treatment group and a control group that met the inclusion criteria. Data were collected using questionnaires and observation sheet. The data were then analyzed using Mann Whitney and Wilcoxon’s Test (α <0.05).

Results: Statistical test results of Wilcoxon Signed Rank Test in the treatment group with the value of sig (2-tailed) obtained p = 0.000 in which p <0.05 indicates that there is a significant effect of Marmet technique on maternal satisfaction in breastfeeding. However, the control group obtained p = 0.083 in which p > α > 0.05, meaning that there is no significant effect of Marmet technique on maternal satisfaction in breastfeeding.

Conclusion: The satisfaction of the mother in breastfeeding has increased after being intervened with Marmet technique.

Keywords: Marmet technique, maternal satisfaction, breastfeeding.

Introduction

Breastfeeding is seen to be one of the solutions that may reduce infant mortality, risk of stunting, obesity, and chronic diseases. Babies who were breastfed have a fourteen times bigger chance of surviving in their first six months compared to those who are not breastfed. Failure in breastfeeding is mostly caused by the infants having difficulties in sucking, abnormalities of the breast, and the mother’s lack of knowledge about the breastfeeding. Those failures tend to cause the mothers to stop the process of breastfeeding, and start giving formula milk as a substitute for breast milk. This is due to the mothers’ limited knowledge on breast massaging, which merely revolves around the usual method, oxytocin massage.

One of the factors that cause in infants is the cessation of breast milk in less than 6 months, which is considered to early, and then continued with formula feeding. The percentage of babies who are breastfed and do not experience diarrhea is higher than those who are not. The production of breast milk can be increased by using several methods including oxytocin massage, Marmet technique, warm compresses, back massage, breast care, endorphins and oxytocin massage stimulation and suggestive provision, but due to the limited information in health services regarding the procedure of implementation-these methods are merely known and are rarely given by nurses. One way to extract milk is through Marmet technique, a combination of milking and massaging the breasts in postpartum mother. The administration of Marmet techniques to mothers who
produced little to no amount of breast milk showed good results. The Marmet technique is a safe way to stimulate the breast to produce more milk. If Marmet technique is done effectively, the milk production will be better and thus cause more satisfaction in breastfeeding8,9.

Self-satisfaction of the mother is a cognitive aspect of subjective well-being. Metnal self-satisfaction can be seen from two different approaches, first the bottom-up theory in which self-satisfaction is influenced by an individual’s assessment of important domains in herself. The second is the top-down theory in which the self-satisfaction of the mother will affect another person’s satisfaction domain. Someone who is satisfied with herself will also evaluate important domains in life more positively, although self-satisfaction in general is not only based on satisfaction with that domain alone. Mothers who are able to breastfeed their babies tend to be satisfied6.

**Method**

This study is a quasi-experimental research. The population in this study were breastfeeding mothers in the working area of the Ampenan Puskesmas (Community Health Center) located in six different integrated healthcare centers. The sample selection used inclusion criteria as follows: (1) Mothers who do not exclusively breastfeed (2) Have 3-6 months old babies (3) Able to read and write. The number of samples were divided into the control group and the treatment group. Sampling was done using probability sampling in the method of cluster sampling. The independent variable in this study is the Marmet technique, while the dependent variable is maternal satisfaction in breastfeeding. Prior to the research, both groups were pre-tested. The treatment group was treated with Marmet technique (every day for 20-30 minutes) and the control group was given a counseling about breast massage (for 30 minutes) then both were assigned for a post-test and the data were analyzed using Wilcoxon and Mann-Whitney test.

Satisfaction measurements was done based on a modification of the Breastfeeding Self Efficacy Scale - Short Form (BSES-SF) scale. BSES-SF is a questionnaire that contains 14 items statements about mothers’ confidence in breastfeeding. Validity test was carried out using Pearson product moment (r). $r$ value was calculated with the value of $r$ table at a significance level of 5% and was declared valid. The reliability test in this research was based on Alpha Cronbach, in which the basis for decision making is reliable if the value of alpha $> r$ table. Based on the questionnaire reliability test, the value of Alpha Cronbach for the satisfaction questionnaire was 0.687. This indicates that the questionnaire is reliable. This research has been declared “Ethically Feasible” with a Certificate of Ethical Feasibility from the Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia.

Discussion

Based on the results of the study, it can be from the pretest that prior to the intervention in the form of a Marmet technique, the respondents in the treatment group expressed that they were dissatisfied in every category. The majority of the respondents, or 18 respondents (45%), are either self-employed or entrepreneurs. Working mothers tend to be less focused on caring for babies and their families, causing satisfaction in breastfeeding to be reduced as well compared to mothers who are not working. Most mothers, in breastfeeding their first child, were more focused with their work in order to help their husbands in meeting their daily needs. Thus, their children were entrusted to distant relatives or neighbors and provided with formula milk\(^{10,11}\).

The pretest that prior to the intervention of Marmet technique, the respondents in the control group expressed that they were dissatisfied in every category. Most respondents were mothers with second children as much as 18 respondents (45%). Mothers with two or more children already have an experience in breastfeeding and caring for their babies compared to mothers who just gave birth the their first children or only have with one child. This is due to mothers not yet developing experience in taking care of their first children, especially in breastfeeding\(^{12}\). As seen from the posttest that after the intervention in the form of a Marmet technique, the respondents in the treatment group expressed that they were satisfied in every category. The majority of respondents in this study were in the 21-35 year age group, also known as the productive age. Age is one of the physiological factors that can directly influence the process of breastfeeding\(^{13}\).

The posttest that after the intervention of Marmet technique, the respondents in the control group expressed that they were dissatisfied in every category. The results of the study show that the maternal satisfaction in breastfeeding in the control group was influenced by the respondents’ education levels. A total of 22 respondents (55%) graduated from elementary school or junior high school. Education is one of the factors that indirectly affects the satisfaction of mothers in breastfeeding since it is related to their socio-cultural background. This factor has a correlation towards the mother’s ability to receive information that will later affect the process of breastfeeding. A mother who has an adequate knowledge will have an increased satisfaction in breastfeeding.

Statistical test results of Wilcoxon Signed Rank Test showed a significant increase in the satisfaction scores in breastfeeding. The total of respondents who experienced an increase in the satisfaction scores in the treatment group were 40 respondents. There are 9 respondents whose satisfaction in breastfeeding increased to the category
of very satisfied. While respondents whose satisfaction increased to the satisfied category were 31 respondents. The satisfaction of the mother in breastfeeding with the intervention of the Marmet technique is influenced by the technique of massaging and milking the breasts. The recommended milking technique is to use hands, palms, and fingers because it is practical, effective and efficient compared to using a pump. The process include *massaging, stroking*, and *shaking* the breast in order to stimulate the milk reflex.\(^{15}\)

The satisfaction of the mothers after the application of the Marmet technique was seen to increase drastically, especially in respondents in the treatment group. Respondents who applied the Marmet technique felt more satisfied in breastfeeding their baby. Respondents felt the impact of the intervention gradually and experienced an increase in satisfaction, such as satisfaction of the mother for successfully breastfeeding her baby, and satisfaction because the baby had received enough milk. The referred respondents were breastfeeding mothers in the treatment group who applied Marmet technique routinely and were monitored by researchers. The researcher also explained to the respondent that if there were complaints of pain in the application of Marmet technique, it was advisable to temporarily stop the technique and take immediate action such as compressing the painful area. This is done to immediately solve the problem that may arise and the evaluation process can continues to run according to a predetermined schedule, the flow of milk that increased production may meet the needs of the baby, and the use of formula milk can be reduced as early as possible.

**Conclusion**

Satisfaction in the treatment group after the intervention was seen to increase compared to the control group. Marmet technique can increase the satisfaction of mothers in breastfeeding due to the stimulation of the breast muscles from the massage and milking that is done to trigger the milk reflex, causing the mother to feel satisfied because the production of breast milk is increasing.

The Increase Level of Muscle Adductor in Idiopathic Vocal Cord Adductor Paralysis Post Biofeedback Vocal Therapy

Rani Maharyati\(^1\), Irwan Kristyono\(^1\), Muhtarum Yusuf\(^1\)

The Department of Otolaryngology, Faculty of Medicine, Universitas Airlangga, General Hospital of Dr. Soetomo Teaching Hospital, Surabaya, 60285, Indonesia

Abstract

**Background:** The Idiopathic Vocal Cord Adductor Paralysis (KAKVI) is the inability of muscle that moves the vocalist notochord to medial in phonation time with the idiopathic. This condition might has impact to the emerge of hoarse voice and other lamentations which are related to the voice production. The conventional voice therapy still show the number of the recovery of low dysphonia.

**Method:** The diagnosis of KAKVI is based on the anamnesis, physical check up, thorax photograph and laryngoscopy fiberoptic and is conducted the measurement of vocalist cord adductor muscular construction strength before the BF voice therapy with equipments. Then, the BF voice therapy is conducted twice a week for four weeks. The voice exercise is continued in home once a day by patients themselves. The measurement of the strength of vocalist cord adductor muscle contraction is conducted after the BF voice therapy.

**Results:** The result of the study revealed that there were KAKVI. The result of adductor muscular contraction strength with statistic examination in a short test is \( p = 0.044 \). The result of statistic examination of long is \( p=0.000 \). The result of statistic test of count test is \( p=0.000 \). Therefore, the change of adductor muscular contraction strength on KAKVI after the BF voice therapy is found a significant increase (\( p < 0.05 \)).

**Conclusion:** This study revealed that there are an increase of adductor muscular contraction strength in KAKVI after the BF voice therapy.

**Keywords:** The strength of adductor muscle contraction, idiopathic vocalist cord adductor paralysis, voice therapy, Biofeedback.

Introduction

The paralysis of idiopathic vocalist cord adductor (KAKVI) is a muscular inability to move the vocal cord to medial on phonation time with an idiopathic cause which is the cause is undetected or the pat physiology. This condition can lead the emerge of hoarse voice and other lamentations related with the voice production \(^1\)–\(^5\).

The KAKVI therapy consists of the nonsurgical therapy and surgical therapy. The nonsurgical therapy is the conventional voice therapy, then if it fails or there is particular indication, it can be taken into consideration with the surgical therapy \(^1\)–\(^3\). At the Otolaryngology Outpatient Unit in Dr. Soetomo hospital, the conventional voice therapy on dysphonic still show low recovery number. This low recovery number might be caused by the low self-motivation of the patients to practice and control routinely \(^4\)–\(^5\). The dysphonia research used other therapy methods which is expected to be more effective is the Biofeedback (BF) voice therapy. Biofeedback is the equipment to assist the patients to control voluntarily the strength of muscular contraction that is joined the vocal cord adduction process. However, the increase of adductor muscular contraction strength in KAKVI after the BF voice therapy is still unclear \(^6\)–\(^10\).

The KAKVI patients at the Otolaryngology Outpatient Unit of Dr. Soetomo hospital is 176 (62.4%) of 282 patients (year 1995-1999) and 73 (54.07%) form 135 patients (year 2006-2010). The KAKVI therapy at Otolaryngology Out-patient Unit of Dr. Soetomo
hospital is the conventional voice therapy, with the low recovery number of 19.6\% and 25.56\% \cite{4,5}.

The BF voice therapy requires the electronic equipments which is the *laryngeal electromyography* (LEMG) through the electrode that is put in the surface, so it is called *surface laryngeal electromyography* (sLEMG) that shows the strength of larynx muscular contraction. The patients are asked to see the computer monitor to receive information about what happened in the their skins. The patients are asked to do the various kinds of practices under the voice therapist guidance while seeing the monitor (the feedback is visual signal) or listen to the beep voice (the feedback is auditory signal) \cite{7,11,12}.

The BF voice therapy is started to be reported in the literature with a good result, that is the improvement of vocal cord deviation. According to the previous study, it was reported that 21 normal persons and 7 patients with vocal nodule who underwent the BF therapy session shows that there are a significant difference in EMG score, and the decrease level of muscle tension \cite{13}. It revealed that there were positive correlation between the EMG result with the voice quality assessment.

Another study reported that the use of sLEMG thyroarytenoid muscle in 25 patient, is an efficient and objective test to provide the prediction of the recovery after facing a vocal cord paralysis. In this study, wants to prove the increase point of adductor muscle contraction on KAKVI after the BF voice therapy.

### Material and Method

This study was conducted on June until August 2015 at the Otolaryngology Out-patient Unit and Medical Rehabilitation Instalation of Dr. Soetomo hospital, Surabaya. The study is about the change of the adductor muscle contraction strength in the idiopathic vocal cord adductor paralysis (KAKVI) after the BF voice therapy. The inclusion criteria of subject of study is KAKVI patients who diagnosed under the fiber optic laryngoscopy, attained the age of 20-60, understand the guidance and able to answer questions well, have the ability to control voluntarily, have self-movitation to coordinate well, willing to join the study, and sign the agreement letter in joining the study.

During the study period, it was obtained nine KAKVI patients who got the BF voice therapy twice a week in four weeks. The consecutive sampling is applied in this study \cite{14}. The type of the study is pre experimental with the pre post design without control group. The measurement of adductor muscle contraction strength is conducted pre and post the BF voice therapy. In the BF voice therapy, the patients is asked to breathe in first, then say a long a in one breath, then do a count test in 1,2, 3, etc. in one breath with saying a loudly (short a) as long as the patients is capable.

</tbody>
</table>

The core data of the study included the ages, gender, jobs, and the clinic characteristic of the KAKVI patients who obtained the BF voice therapy. The most age group that was 41-50 years was five patients (55,56%). The youngest age was 31 years old, and the oldest one is 59 years old (table 1). The most gender is female which was seven patients (77,78%). The comparison between male and female is 1:3,5 (table 2). The most jobs is seller that are four patients (44,45%) (table 3). The vocal cord that were mostly encountered paresis is the right vocal cord that were five patients (55,55%) (table 4).

The measurement of the adductor muscle contraction strength in KAKVI pre and post the BF voice therapy. The strength of adductor muscle is measured by electromiograph which was completed by BF. The adductor muscle contraction strength is measured when the patients did the short a test, while the adductor muscle contraction endurance is measured when the patients did the long a test and count test. The strength of adductor muscle contraction when the patients did the short a test can be seen in table 5. The minimal average of the adductor muscle contraction strength is when the patients did the short a test before the BF voice therapy is 23,44 µvolt and post therapy is 17,66 µvolt. The maximal average of the contraction strength pre therapy is 43,44 µvolt and post therapy is 55,33 µvolt. The delta average or the gap between the maximal contraction strength and minimal contraction strength is 21,11 µvolt and post therapy is 37,66 µvolt. The statistic examination with the t pairing sample test is obtained p= 0,044. It means that there is a meaningful difference between the minimal contraction strength and the maximal adductor muscle pre and post BF voice therapy (p<0,05).

The endurance of adductor muscle contraction can be seen in the long a test and count test. The endurance of adductor muscle contraction in a long a test is shown in table 6. The minimum average endurance of the adductor muscle contraction when the long a test is conducted based on seconds pre BF voice therapy is 6,22 seconds and post therapy is 18,55 seconds. The statistic examination with the t pairing sample is obtained p=0,000. It means that there is a meaningful difference between the minimal contraction endurance period and the maximal adductor muscle in the long a pre and post the BF voice therapy. The minimum average of the adductor muscle contraction endurance when the count test is conducted based on seconds the pre BF voice therapy is 7,33 seconds and post therapy is 23,77 seconds. The statistic examination with the t pairing sample examination is obtained p=0,000. It means that there is a meaningful difference between the minimal contraction endurance period and maximal adductor muscle in pre and post BF voice therapy count test (p<0,05).

Discussion

Many literatures stated that the vocal cord paralysis often encounter in the left side because the left vocal cord journey is much longer than the right side so it is easier to be affected by lesions. This condition is often caused by idiopathic, not because of inflammation, tumor, trauma, or neurological nuisance. This study revealed the number of KAKVI varied, 60% of the patients encountered the left vocal cord adductor paralysis and 40% of the patients encountered the right vocal cord adductor paralysis which cannot be known the causes.

A meaningful difference or change is better between the pre and post BF therapy; it is because the high level of the patients' self-motivation in producing a sound when seeing the practice result in the monitor. The repeated practice or muscle re-education aims to obtain the
feedback that will control the neuromuscular; increase the muscle ability or muscle ability to tense, restore the agonist action/antagonist of normal muscle, and train the postural control. The patients used to to produce a sound with the better muscle strength 10,15,16.

In six patients with excessive laryngeal tension is conducted with giving 14 BF sessions in 30 minutes each session. At the end of every therapy, three of six patients encountered the reduction of laryngeal EMG level and their voice quality are getting better. Those mentioned improvement happened because the patients are suggested to see the contraction muscle in the monitor then the therapists facilitated the contraction with electric signal in the intended muscle so that the patients can practice well. The other two patients only encountered the change in the EMG level and there is no change in the voice quality. In these two patients, it is actually revealed that there are the heavy structure damage, so it is suggested that the BF therapy might be useful in the functional dysphonia patients only 17.

To be normally voiced, not only the anatomy and cardiopulmonary are needed, but also the good physiological factor. In the KAKVI patients in this study, it is revealed that the adductor muscle that is unilateral, so that one of vocal cords cannot move to median and docked in a median line. The vocal cord paralysis is also affecting the vocal cord tension is lowered, so the vocal cord vibratio will also be disturbed 18. The long a test is actually similar with the MPT test (maximum phonation time) that is often known in THT KL. Maximum Phonation Time is mostly related with the pulmonary condition while in this study, there is no deviation in lungs (idiopathic), so the long a test is mostly used to see the maximum vocal cord contraction 16.

The other supported researches stated that 21 normal persons and seven patients with vocal nodule that undergo eight practice sessions with BF showed that there are a significant difference in LEMG score, and the reduction of muscle tension level. The reduction of muscle level happened because the chosen biofeedback for relaxation practice is high sensitivity setting, therefore that the small electricity activity is much easier to detect. When the relaxation is started to increase, the sensitivity setting is increased from low to high. This change caused the patients must relax more vocal cord muscles so that the relaxation is easier to reach. Moreover, there is a positive correlation between the LEMG result and the vocal quality assessment 19.

In the long a test, the patients were asked to say a after breathing, until the they were out of breath, while there is a respite in count test when the patients said numbers until they were out of breath. The other researches that support showed that the use of LEMG in musculus tiroaritenoid in 25 vocal cord paralysis patients, use the efficient and objective equipment can predict about the recovery after suffering from vocal cord paralysis. This is said because the biofeedback practice can increase the comprehension of how the effort in producing sound and patients can handle the vocal cord muscle relaxation response. In the initial session with biofeedback, the patients can centralize their attention to the feedback and try to handle the sound or visual. When the patients paid attention to the relaxation, they will be able and succeed to handle the sound better 20. Other suitable researches conducted the BF combination with other types of BF with targeting not only in tension and larynx muscle but also the relaxation in general. The use of BF in other voice deviation is rarely obtained, such as ventricular fold dysphonia and paradoxical vocal fold motion, is reported to give the good result 5.

The result of BF measurement can be observed, amplified, and transformed, so that it can give feedback about the condition of patients body in a form of visual signal, particularly in graphic and beep voice that can be understood. The signal is applied to be the guidance to manipulate the signal that appeared in the BF equipment. The patients can learn to control to handle their condition, and make changes, such as relaxation or strengthen the particular tonus muscle. This technique requires the patient’ willingness to conduct the signal change in order to reach their aims. The BF therapy is defined as particular therapy technique that gives the patients strengths to use their mind to control their body and practice to improve their health by using the signal form their own bodies. The mentioned improvement can be reached if the patients see the contraction muscle in a monitor, then the therapist facilitated contraction with electrical signal in the intended muscle, so that the patients can practice to tense the muscle well 7,9-12,21.

Conclusion

It can be concluded that there is an increase in adductor muscle contraction strength in the idiopathic vocal cord adductor paralysis (KAKVI) post biofeedback voice therapy.

Periodontal Evaluation of One-Piece and Two-Piece Single Implant Loaded in Esthetic Zone

Rezan Anwar¹, Ziwar Al Qasab²
¹B.D.S., Master Student, ²B.D.S., M.Sc., PhD. Assis.Prof, Department of Periodontolpgy, College of Dentistry, Hawler Medical University, Kurdistan Region, Irbil- Iraq

Abstract

Background: Soft tissue around dental implant is an important anatomical feature contributing to the long-term implant success and esthetics, different factors may influence the soft tissue-implant interface. The purposes of the current study were to evaluate the soft tissue profile around one-piece and two-piece implants loaded in esthetic zone.

Method: Totally thirty patients who had single missing tooth in premaxillary region were included in the study. Fifteen patients’ group-A were assigned to immediate loading one-piece implant and fifteen patients’ group-B were assigned to early loading two-piece implant protocol. Flapless approach was performed for both groups. In group-A, implants were loaded immediately with a temporary crown within 48h, while group-B, were loaded after two months following conventional impression for metal ceramic crown. Clinical outcomes were evaluated after two and six months in terms of success rate, papillary index, plaque index and width of keratinized mucosa.

Results: The success rate in group-A found to be 80%, which was lower than the success rate in group-B (100%). On comparison, there was no statistically significant difference in success rate between the two study groups. There was no statistically significant difference between both groups over time in clinical parameters like plaque index, width of keratinized gingiva and papillary index.

Conclusion: The results of this study indicated that using either immediately loading one-piece implants or early loaded two-piece implants protocol demonstrated the same enhancements of implant esthetics.

Keywords: One-piece implant, Two-piece implant, immediate load, Esthetic zone.

Introduction

Rehabilitation of missing teeth in the anterior maxilla with an implant-supported fixed prosthesis is a broadly accepted treatment modality¹. Many research studies have been done in implantology correlated to implant design, surgical technique, immediate implant placement and loading protocols. Traditionally, implants were subjected to delay load healing for several months, letting the implant to osseointegrate without being exposed to external forces.

Over the last few years, the concept of immediate loading or early loading flapless implant protocol has gained attention. This concept is defined as the application of a load by means of an occluding or a non-occluding restoration within 48 h for immediate loading and 48h to two months for early loading implant placement ².

Patients with a lost anterior tooth may benefit from immediate loading. Placement of the temporary crown after implant placement reduces the total treatment time, avoids a second-stage operation and offers immediate comfort during healing stage. Immediate loading, has some disadvantages, for example, might induce micromotion and instability of the implant.³,⁴

The surgical protocol for implant placement consists of both flap and flapless procedures. Reduced postoperative bleeding, fewer discomfort for the patient, shorter surgery time, and decreased healing time are reported advantages for the flapless procedure compared to flap surgery ⁵,⁶.
Lately, a new description of implant success criteria was proposed, according to which implant success should be detected by using composite outcome measures, including patient-reported outcome measures, peri-implant tissue health and functional and esthetic outcomes related to implant-supported reconstruction case-control and cohort.

An early effort to assess the esthetic aspects of dental implants was made in 1997 by Torsten Jemt who proposed a papilla index, which evaluated the size of the interproximal papilla.

Meanwhile, successively described assessment methods of esthetic results have been subjected to several studies aiming to test the accuracy and effectiveness of these methods. Nowadays, numerous factors in addition to the size of interproximal papilla including the color, form, and the level of peri-implant soft tissues have been included in evaluation of the esthetic outcomes.

The purpose of this study was to evaluate the soft tissue profile of one-piece and two-piece single loaded implant in esthetic zone.

**Materials and Methods**

**Patients and Methods**

For this randomized clinical trial, 30 patients requiring single-tooth implant in the premxillary region are going to be recruited at the periodontology department-College of Dentistry- Hawler Medical University in Erbil city. The subjects randomly assigned to one of two groups: One-piece implant -OPI- group-A (15 patients) or Two pieces implant -TPI- group-B (15 patients). Group-A had their implants loaded immediately within 48h with temporary crown which are out of occlusion, and temporary crown replaced with permanent crown two months later, while group B had implants with early loading two months after implant placement, then follow-up period started: the first assessment done at the day of permanent crown insertion and the second assessment performed six months after loading permanent crown. Informed consent obtained from all subjects, and the use of human subjects in this project was under the approval of the Ethics committee in College of Dentistry. The study period (from patient enrollment to data collection) was between November 2018 and July 2019.

**Patient selection**

Subjects who lost single tooth in premxilla at least three months of post-extraction healing were selected to participate in the study. Entry criteria includes: periodontal healthy subjects; age 18-60 years old; agreed to follow up visits for 6 months; controlled oral hygiene; absence of any lesions in the oral cavity; presence of a minimum of 1.5-2mm of vertical thickness KM at the crest of alveolar mucosa in implant zone, Adequate amount of available bone for implant placement.

Exclusion criteria: Any history of metabolic or systemic disease affecting the integration of implant or connective tissue health surrounding implant, history of head or neck radistion, smokers, pregnant or lactating women, untreated generalized periodontitis, poor oral hygiene, psychiatric disorders, acute infection (abscess) at the intended site and Under treatment or had previous treatment with bisphosphonates.

**Surgical procedure**

Before commencing surgery, surgical site is examined clinically and radiographs were taken to get the brief idea of surrounding structures. During surgical procedure all 30 patients were prepared well-informed about flapless immediately loaded OPI and TPI protocols. Local anesthesia was induced by infiltration with lignocaine (2%) and adrenaline (1:80,000) for the both groups.

Group-(A) OPI:

- Patients were instructed to rinse preoperatively for 1min with 0.12% chlorhexidine solution, to reduce total mouth bacterial load,

- An initial pilot drill with select length were used for site preparation to give needlepoint accuracy for position, angle, and depth along with the use of copious saline irrigation. The drill should pass through the cortical bone and then the cancellous bone, and then shaping drill were used to prepare the exact bed size of the implant.

- Implant was then placed using a carrier and rotated clockwise and final implant position should carry out by using a torque rachet (torque 30-40Ncm). Primary stability was mandatory.

- The provisional acrylic resin restoration (temporary crown) was fabricated and care should be taken to
achieve a smooth contour to avoid soft tissue irritation, which was temporarily cemented out of occlusion for 2 months. The patients were instructed to avoid directly biting on the provisional restoration and to consume easily chewable food and maintain good oral hygiene. Following which, permanent restoration procedures, porcelain fused to metal (PFM) crown fabricated and cemented (figure1).

Group-(B) TPI:

- Same surgical procedure was performed for TPI but it was differed in loading protocol.

- Healing cap placed for gingival growth. The patients were instructed to maintain good oral hygiene.

- Two months after healing cap was removed, permanent restoration procedures were performed using silicone impression material (open tray technique). Finally, porcelain fused to metal (PFM) crown was fabricated and cemented (figure2).

Figure1: Group-A (OPI)– (a) Pre-operative; (b)Immediate post-operative; (c)Temporary prosthesis placed; (d)Final prosthesis after 2 two months; (e)Final prosthesis after six months

Figure2: Group-A (TPI) – (a)Pre-operative; (b,c)Intera-operative; (d)healing cover placed; (e)Abutment after two months; (f) final prosthesis after two months (g)Final prosthesis after six months.

**Evaluation of treatment outcome**

Patients were evaluated with the following clinical parameters at baseline (BL) two month after implant placement (definitive prosthesis placement) and six months follow up (6M).

A. **Width of keratinized mucosa (10)**

The width of the keratinized mucosa was measured at the mid-facial aspect of each implant using Williams probe. Each measurement was made from the gingival margin to the mucogingival junction. The mucogingival junction was identified by the rolling technique, in which the mucosa was rolled until the non-movable portion of the attached keratinized tissue was identified.

B. **Papilla preservative index (8)**

Dental papilla evaluated clinically using a papilla preservative index PPI described by Jemt (8).

0 will be assigned when no papilla was present;

1 when less than half of the papilla present measured from the reference line to contact point;

2 when at least half of the papilla was present but not all the way up to the contact point;

3 Papilla filled up the entire proximal space and was in good harmony with adjacent papillae;

4 when the papilla was hyperplasic.

C. **Plaque index (11)**

The oral hygiene status was evaluated by the presence or absence of visible plaque present at soft tissue margin.

Score 0: No plaque

Score 1: Plaque recognized by running a probe across marginal surface of implant

Score 2: Plaque can be seen by naked eye

Score 3: Abundance of soft matter within the gingival pocket, gingival margin and the adjacent tooth surface.

**Data management and statistical analysis**

The data were recorded on a specially designed questionnaire, collected and entered in computer via Microsoft Excel worksheet (Excel 2010) and then analyzed using appropriate data system which is called Statistical Package for Social Sciences (SPSS) version 25 and the results were compared between patients with different variables, with a statistical significance level of < 0.05. The results presented as rates, ratio, frequencies, percentages in tables and figures and analyzed using T-test and Chi square tests.

**Results**

A total of 30 patients enrolled in this study, fifteen per each group. The surgical intervention (implantation) failed in three cases of OPI group with a success of rate 80%, while all TPI cases ended with success (success rate 100%) though this difference was not statistically significant and p-value was 0.06.

The data of Table 1 show that there were no any statistically significant differences between OPI and TPI groups in regard to PPI both mesially and distally, PI and WHK measurements at baseline and after six months of follow up. T – test was performed to compare between the average and standard deviations of both groups and p – values were more than 0.05 in all conditions as the averages were close to each other.

Discussion

The current study was performed to assess the clinical soft tissue outcomes of single-tooth implants, comparing immediately loaded OPI and early loaded TPI. All TPI were successfully integrated and in function for 6 months, leading to a 100% success rate. However, three of 15 immediately loaded OPI failed to osseointegrate, yielding 80% success rate (20% failure rate) and this result is near to previous study done by Oh et al. Previous studies reported a wide range of failure rates in immediately loaded single tooth implants, 0% to 19%. On the other hand, other studies reported no failures in immediately loaded single-tooth implants in the anterior maxilla. The differences in the failure rate between the studies might have resulted from several factors: different case selection criteria, time of functional loading (i.e., permanent crown placement) and poor bone quality. Another reason for failure in the IL group maybe due to excessive occlusal forces applied by patient.
Generally, the cause for papilla reduction after implant placement could be due to elevation of adjacent papilla during implant surgery. This was minimized by using a flapless approach in our study. The interdental papilla height slightly increased after six months of implant placement for both groups, which might have resulted from tissue remodeling after surgery and reformation of biological width. This is similar to a previous randomized controlled clinical trial by Oh et al.

The PI were recorded using the index described by Mombelli A et al. When the mean score between the groups were compared at different time points, there was no statistically significant difference. This is in accordance with other studies by Buser et al. and Oh et al. In general, the patients performed good home care and maintained good oral hygiene. Patients were informed about the subsequent consequences of plaque accumulation around implants and they were motivated to maintain oral hygiene by demonstrating oral hygiene techniques at every visit.

The WKM was measured at the mid-facial aspect of each implant using Williams probe. When the mean width of keratinized mucosa between group-A and group-B were compared at different time points, there was no statistically significant difference. This is in accordance with other studies by Oh et al. and Watzak et al. which showed results close to our findings.

The contemporary study has several limitations, including small sample size, short-term follow up, and relatively high failures in group-A. However, within the limitations of this study, it can be concluded that flapless implant surgery may provide esthetic soft tissue results in single-tooth implants either immediately loaded OPI or early loading TPI. More studies with larger sample size and long term follow up are recommended to verify the soft tissue outcomes of both groups.

**Conclusion**

From the results of this randomized clinical trial, we concluded that, after six months follow up there were no significant differences in implant esthetic between the immediately loaded OPI and early loading TPI treatment protocols regarding clinical parameters like PPI, WKM and PI.

Effect of CaCl$_2$ Crosslink Solution Concentration on the Characteristics of Gelatin Alginate Microspheres

Rizka Safitri$^1$, Tutiek Purwanti$^1$, Widji Soeratri$^1$

$^1$Graduate Student of Department of Pharmacy. Faculty of Pharmacy. Universitas Airlangga, Surabaya 60115, Indonesia, $^2$Lecturer, Department of Pharmacy. Faculty of Pharmacy. Universitas Airlangga, Surabaya 60115, Indonesia

Abstract

Alginate as a constituent of microspheres matrix has a weakness, namely the lack of ability to slow the release of drugs from the system, causing the effects of drug therapy to the body to be less than optimal. To obtain preparations with slowed release, sodium alginate needs to be combined with other polymers such as gelatin. This study aims to determine the effect of the concentration of CaCl$_2$ connection solution on the characteristics of alginate-gelatin microspheres. In this study, alginate-gelatin microspheres were prepared using ionotropic gelation aerosolization techniques. Three formulas were made, each of which was replicated three times. F1 with CaCl$_2$ concentration 0.5 M, F2 with CaCl$_2$ concentration 1.0 M, F3 with a concentration of 1.5 M. The three formulas were made in the ratio of alginate-gelatin (1.5: 1)% and a crosslinking time of 1.5 hours. Evaluation of the characteristics of microspheres includes yield percentage, organoleptic, moisture content, morphology of microspheres, size and size distribution of microspheres, and swelling index. The data of this study were analyzed using one way ANNOVA. The results reveals a loss of specific uptake of the COO-manuronate alginate group and the occurrence of wave number shifts as well as an increase in the absorption intensity of the C = O group. Organoleptic examination results of alginate-gelatinin microspheres showed that microspheres of the three formulas had the same organoleptic, and formed spherical microspheres. On the inspection of swelling index, it was found that F1 and F2 reached the peak of swelling at 2 o’clock, while F3 reaches the peak of swelling at 3 o’clock. The greater the level of CaCl$_2$, then the average diameter of microspheres will also increase, while the swelling index will decrease with increasing levels of CaCl$_2$. In the results of moisture content examination, there is no difference in different CaCl$_2$.

Keywords: alginate, gelatin, microspheres, CaCl$_2$, ionotrophic gelation, aerosolization.

Introduction

Drug delivery system is a system designed to deliver active ingredients and provide therapeutic effects on the body $^1$. The drug delivery system aims to minimize the release of drugs in unwanted areas, avoid harmful side effects, and increase effectiveness $^2$. Delivery systems for topical preparations can be aimed to provide local or systemic effects. Some delivery systems used for topical preparations include liposomes, niosomes, solid lipid nanoparticles, and microspheres (Castro et al., 2008). Microsphere is a particle that has micro size and spherical shape. The particle size of microspheres ranges from 1 µm to 1000 µm $^3$.

Microspheres can be made using a variety of methods including emulsification, coacervation and ionotropic gelation $^4$. On the method of ionotropic gelation, the formation of microspheres is based on the ability of the polymer to form a hydrogel in the presence of divalent or polyvalent cations from a cross-linking solution. Based on the literature review, CaCl$_2$ concentration that is commonly used as a cross-linking solution is 0.5 M, 1 M and 1.5 M with a cross-
connect time of 1.5 hours. Alginate as a constituent of microspheres matrix has a weakness: it lacks the capability to slow the release of drugs from the system. To obtain preparations with slowed release, sodium alginate needs to be combined with other polymers, for example gelatin.

Increasing the concentration of the crosslinking solution will increase the number of bonds between the polymer and the crosslinking solution, so that the matrix will be more compact and lower the swelling index, thus the drug release from the system will be slower. However, increasing the concentration of the crosslinking solution will result in a microsphere with large particle size. This large particle size is undesirable in topical preparations since it can cause a sandy appearance when used. In addition, a small particle size is more desirable because it will produce a wider surface area when applied since the drug release will be more optimal.

Based on the description above, this study was conducted to determine the effect of CaCl₂ crosslinking solution (0.5; 1; 1.5) M on the characteristics of microspheres with sodium alginate-gelatin matrix (1.5: 1)% which includes percent recovery, moisture content, shape and surface, particle size, and swelling index. Microspheres production is done using the ionotropic gelation aerosolization techniques with a cross-connect time of 1.5 hours. The aim of this research is that the results are expected to be used as consideration in developing microspheres as delivery systems for topical routes with local effects.

Research Method

Research Material

This research uses Low Molecular Sodium Alginate (Pharmaceutical grade), Gelatin B (Pharmaceutical grade), Calcium Chloride (Pharmaceutical grade), Maltodextrin (Food grade), HCl 0.1 N, Aquadem. microspheres production is done using ionotropic gelation aerosolization techniques. Ionotropic gelation is a simple method, does not use high temperatures, does not use organic solvents and the use of aerosolization techniques can produce smaller and more uniform particle sizes.

Alginate-gelatin solution is sprayed into the CaCl₂ solution which have been made using atomizer with nozzle size of 200 μm, under constant pressure at a distance of 8 cm from the surface of the crosslinking solution and rotated at a speed of 1000 rpm for 1.5 hours. The process will produce a suspension of microspheres which are then filtered using a Buchner funnel and washed with aquadem until it is free of CaCl₂.

Research Tools

The tools used in this study are stirrer plate (Dragon Lab MS pro), pH meter SCHOTT glass mainz type CG 842, FTIR spectrophotometer (Jasco FT-IR / 5300), aerosolization spray (nozzle size 200 μm and 40 Psi pressure), analytical scales, ovens, petri dishes, optical microscopes, moisture analyzer and other glassware.

Variable Research

This study aims to determine the characteristics of alginate-gelatin microspheres with a ratio of 1.5%: 1% and CaCl₂ crosslinking solution with concentrations of 0.5 M, 1 M, 1.5 M, made using the ionotropic gelation aerosolization technique with a cross-connect time of 1.5 hours. The independent variable is the concentration of CaCl₂ crosslinking solution, and the dependent variable is the microspheres’ characteristics. While the control variables are the viscosity of the solution, the pH of the solution, the volume of CaCl₂ and polymer solution, concentration of polymer solution, ratio of alginate-gelatin concentration, diameter of nozzle, spray pressure, and the distance of the CaCl₂ solution with nozzle.

Analysis of Data

Examination of Moisture Content

Moisture content value is expressed in percent. This value is obtained from the numbers listed on the digital screen of moisture analyzer. Replication was done three times and the results are averaged. The moisture content obtained is compared with the conditions of moisture content from the references.

Morphological Examination of Microspheres

The shape and surface of the microspheres were observed based on the results obtained from Scanning Electro Microscope (SEM). This results in the form of three-dimensional appearance of the microspheres. This three-dimensional picture can be compared in terms of surface flatness and the spherical form of the microspheres produced from the three formulas made.
From the determined size of 300 particles, they are grouped into several intervals and classes. Then the particle diameter and percentage are determined. After that, the calculation results are presented in the form of a histogram with particle diameter as abscissa, and percent of particles as ordinate.

The average diameter of microspheres of each formula is calculated by the following formula:

\[
D_{\text{average}} = \frac{\sum d \cdot n}{\sum n}
\]

Note: \(n\) = number of microspheres observed \(d\) = microsphere size

From the calculation results, average diameter of microspheres was obtained, and the results were compared between formulas. Data analysis was done using One way ANOVA.

Examination of Swelling index

Swelling index is expressed as percent swelling (Ps) in the form of a graph with the x-axis in the form of time (hours) and the y-axis in the form of % swelling (weight change) at every hour. After obtaining the graph, the parameters to be compared between formulas are time and swelling profile from the microspheres produced.

</tbody>
</table>

From table 2 it can be seen that the particle size obtained already meets the recommended size as a microsphere intended for topical use, which is less than 300µm. Yield percent of the microspheres produced were analyzed statistically using the one way ANOVA method and tested post hoc with Fisher LSD using the IBM SPSS Statistics 22.0 program with a 95% confidence level. The particle size of microspheres in each formula are F1 = F1 = 2.82 ± 0.02; F2 = 3.51 ± 0.14; F3 = 3.90 ± 0.29 respectively.

Based on the results of statistical analysis, a value is obtained; \(\text{sig} = 0.001\). Value of \(\text{sig} <0.05\) indicates a significant difference in the yield percent from microspheres produced by all three formulas. After post hoc testing it can be seen that the difference is in F1 and F2 with values of \(\text{sig} = 0.004\); F2 and F3 with values of \(\text{sig} = 0.041\) and F1 and F3 with values of \(\text{sig} = 0.000\). This means that the difference in CaCl2 concentration has an effect on yield percent of microspheres. Examination of swelling index was done with three replications using the weighing method.
Table 2: Results of Alginate-Gelatin Microspheres Swelling (1.5: 1.0)%

</tbody>
</table>

From the table above it can be seen that the high levels of CaCl₂ (1.5 M) takes longer to reach the swelling peak. Based on the results of data processing of swelling index every hour, statistical analysis was carried out using one way ANOVA with a 95% confidence interval and the LSD Hoc post test.

*: there are significant differences in the swelling value between the two formulas.
Discussion

Based on post hoc test result, it can be seen that there are differences in F1 and F2 with values of \( \text{sig} = 0.001 \); F2 and F3 with values of \( \text{sig} = 0.031 \) and F1 and F3 with values of \( \text{sig} = 0.021 \). According to a literature study, percent recovery should increase with an increase in \( \text{CaCl}_2 \) level, as long as polymer is still available to form bonds. However, in this study the highest percentage of recovery was obtained in F2 with \( \text{CaCl}_2 \) levels of 1.0 billion and decreased in \( \text{CaCl}_2 \) levels of 1.5 M. This can be caused by several factors including the calculation of percent recovery which is influenced by the addition of maltodextrin and the drying process using freeze drying which cannot be controlled by researchers.

Tables above show that the morphology of alginate-gelatin microspheres using SEM, it was found that the resulting microspheres were spherical in shape and had a flat surface. This can be seen in Figure 5.4. Whereas the particle size examination obtained particle size for F1 = 2.82 ± 0.02; F2 = 3.51 ± 0.14; F3 = 3.90 ± 0.29 respectively. Based on the results of statistical analysis, a value is obtained; \( \text{sig} = 0.001 \). Value of \( \text{sig} < 0.05 \) showed a significant difference in particle size of alginate-gelatin microspheres. Based on the post hoc test result it can be seen that the difference is in F1 and F2 with values of \( \text{sig} = 0.004 \); F2 and F3 with values of \( \text{sig} = 0.041 \) and F1 and F3 with values of \( \text{sig} = 0.000 \) (Liu & Wang, 2011).

The results of the qualitative analysis of sodium alginate organoleptically shows data in accordance with the research hypothesis. In the analysis with FTIR there are some specific uptake, namely uptake at 1599.76 cm\(^{-1}\) and 1405.42 cm\(^{-1}\) which shows the presence of carboxylic groups and uptake at 815.11 cm\(^{-1}\) which is the fingerprint area of manuronates. In addition, the results of observations of thermal analysis using DTA found a peak in the region of 233° C, this is in accordance with the data in the literature which states that on the sodium alginate thermogram peak will occur in the area of 191.15-254.6° C. From these results it can be seen that the difference in \( \text{CaCl}_2 \) level has no effect on organoleptic alginate-gelatin microspheres.

The results of organoleptic examination of maltodextrin showed that the maltodextrin used was in accordance with the data in the references, which is in the form of fine white powder, has a typical odor, and not sweet. The results of the analysis with FTIR show that there are some specific uptake that is consistent with the data in the references. Based on the references, maltodextrin will provide absorption at wave numbers between 980-1200 cm\(^{-1}\) which shows the presence of CO groups and absorption at 3400 cm wave number which indicates the presence of C = O carboxylic groups. In the results of the examination of gelatin used, an uptake was found at wave value of approximately 1021.5 and 1080 cm\(^{-1}\) which is a CO group. Uptake at around 1157.7 cm\(^{-1}\) and 3429.6 cm\(^{-1}\) which is the C=O group.

According to Mi et al. in his research (2019), microspheres as a delivery system for topical routes are expected to have a small size and homogeneous and can release the drug slowly. This is related to the acceptability and effectiveness of topical preparations. Preparations with slow release can be obtained from microspheres with algin-gelatin combination matrices using ionotropic gelation method with a \( \text{CaCl}_2 \) crosslinking solution. Sustained release in alginate-gelatin microspheres occur due to the interaction between Ca ions with the COO group guluronate in alginites and NH groups gelatin with the COO group manuronate in alginites, causing the microspheres formed to have a more compact structure.

The achievement of topical preparations with the desired criteria is influenced by the characteristics of alginate-gelatin microspheres which include morphology, size and size distribution and swelling index. The characteristics of the microspheres are influenced by several factors, including the concentration of the polymer, the cross-linking time and the concentration of the cross-linking solution. The focus of this research is to investigate the effect of different levels of \( \text{CaCl}_2 \) crosslinking on the characteristics of alginate-gelatin microspheres prepared using the ionotropic gelation aerosolization techniques. The characteristics of microspheres compared in this case include, percent recovery, size and size distribution and swelling profile.

The efficiency of the microsphering process can be seen from the recovery obtained in each formula. The results of the calculation of percent recovery are F1 = 39.77 ± 3.30; F2 = 64.69 ± 7.72; and F3 = 52.85 ± 2.72. From these results a statistical analysis was conducted using one way ANOVA and obtained the value of \( \text{sig} = 0.003 \). A value of \( \text{sig} < 0.05 \) indicates that there is a significant difference in the percent recovery results with a difference in \( \text{CaCl}_2 \) levels.
Observation on swelling index was done to seek the profile or pattern of swelling from each formula to estimate the pattern of drug release from the microsphere formula. Based on the observations it is obtained that each formula has a different swelling profile. F1 and F2 reached the swelling peak at the same hour, which is the second hour, but both have different peak swelling values. F1 reaches greater top swelling compared to F2. The peak swelling value of the two formulas in sequence are F1 = 469.33 ± 15.14, F2 = 410.67 ± 55.08.

Conclusion

Based on the results of the study, it can be concluded that an increase in CaCl2 (0.5; 1.0; 1.5)M levels in alginate-gelatin microspheres (1.5:1) had no effect on organoleptic and morphological microspheres, yet it increases microsphere particle size. Based on the observations it is obtained that each formula has a different swelling profile. F1 and F2 reached the swelling peak at the same hour, which is the second hour, but both have different peak swelling values.

Statement of Informed Consent

This study involves participants in the process using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study is carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice.

Conflict of Interest: There is no report about conflict of interest since this study has been conducted until now.

Association of Adiponectin and IgE levels with occurrence of asthma in Babylon Province

Ruwaida Wahab Salman AL-Jebory
Assist Professor. Suhayr Aesa Al- Qaysi - Assist professor. Oday Jasim AL-Salihi, Babylon University, College Of Medicine , Biochemistry Dept., Hilla, Iraq

Abstract

Background: Asthma is a health condition that affects breathing in people. Breathing comfortably is not something most of us need to think about. But if you have asthma, there are times when you have difficulty breathing. The main objectives in the current study are: Determine the role of adiponectin, a hormone that acts as an anti-inflammatory, In addition determine the concentration of immunoglobulin E (IgE) In asthma patients.

Method: This study included two groups: Group 1: 80 Patients with asthma were divided into two parts (40 samples obese and 40 samples non-obese). Group 2: 80 Group of healthy subjects with no history or clinical evidence of asthma. samples were divided into two parts (40 samples were obese and 40 were not obese). Asthma was diagnosed through a pulmonary function test (PFT) and then invited to a private clinic and measured nitric oxide gas (FeNO) to confirm the diagnosis. Enzyme-linked immunosorbent assay (ELISA) technique was used to determine the concentration of adiponectin and IgE in serum.

Results: The present study demonstrated the increase of adiponectin level with asthmatic patients compared with the control group and showed significant difference between non-obese patients group and non-obese healthy group.

Conclusion: Adiponectin related with obesity play crucial role in asthma development and inverse relationship between IgE and adiponectin.

Key words: Adiponectin, IgE, ELISA, BIM, FeNO

Introduction

Asthma is a disease of reversible airflow obstruction, bronchial hyper responsiveness, and underlying airway inflammation. In other words, it is a disease appear by effect allergic factors and non-allergic factors and result in bronchial obstruction and inflammation so it is multifactorial disease. This disease ranked 16th among the leading causes of years lived with disability and 28th among the leading causes of burden of disease. There are many reasons for asthma, but almost certainly reflect variable contributions of genetic and environmental factors in different regions. So Immunoglobulin E (IgE) is the antibody responsible for allergic reactions and is important to the pathogenesis of allergic diseases and the evolution and persistence of inflammation. IgE attaches to cell surfaces and a specific high-affinity receptor. Furthermore, there are some substance like adiponectin, it also seems influenced to the asthma. Adiponectin is a 244 amino-acid-long polypeptide. The adiponectin has four distinct regions. There are many studies on the effect of levels adiponectin on asthma. However, human data remain inconclusive and not known if may be the adiponectin affects asthma control by treatment. Shore in their study of weak mice suggests that exogenous dose from the adiponectin relieve allergen-induced airway hyperreactivity and eosinophilic influx in both sexes. Aims of this study that estimate role adiponectin in pathogenesis of asthma, estimate role IgE in pathogenesis of asthma and to find possible association between IgE with adiponectin.

Method

at the laboratory of Biochemistry Department. This study was complete some process in a College
of Medicine, University of Babylon at the laboratory of Biochemistry Department. The subjects in this prospective case-control research, include a total of 160 subjects 80 asthmatic subjects (42 females with 38 males) and 80 clinically healthy control subjects (37 females with 43 males). All samples were collected during the period from the August - 2018 till February - 2019. Patients were collected from Marjan Hospital and invited to a specialized clinic for examination by fractional exhaled nitric oxide (FeNO) device. Asthmatic subjects were categorized to (40 obese asthmatic subjects with BMI mean SE 34.5 0.52 and 40 non-obese asthmatic subjects with BMI mean 25.40.45), Also control group subdivided into two groups (40 obese control subjects with BMI mean33.7 0.56 and 40 non-obese control subjects 25.050.45). with BMI mean.

Inclusion Criteria: The inclusion criteria for the selection of the study subjects include, Asthmatic patients group (depending on pulmomologist decision according to the GINA guideline). All person accepter to participate in the current study. Age of all subjects was ≥18 years old.

Exclusion Criteria: Any person suffered from the following were excluded from this study: Patient with diabetes. Heart diseases, hypertension, malignancy, and any chronic disease. Patient with any other chronic disease (metabolic and endocrine)Smokers. Pregnancy women. Patient with chronic obstructive pulmonary disease (COPD) disease and emphysema. Another lung disease.

Body Mass Index (BMI):

Body mass index (BMI) is the ratio of a person’s weight to height in square meters; it commonly used to classify weight as healthy person or unhealthy person. BMI calculated by below equation\(^1\) as follow:

\[
BMI(Kg/m^2) = \frac{\text{Weight (Kg)}}{(\text{Height})^2 \text{ m}^2}
\]

Table 1: Demographic characteristics of the study groups.

</tbody>
</table>

P value 0.05 was significant.
BMI (body mass index)

Age:

The results were expressed as means and standard error (SE). There was no significant difference (p > 0.05) in age (as means) between control and asthmatic patients, means ±SE for the case is (34.06 ±1.28) and for control (33.45 ±1.27) as appear in Table 1. When we matching the age this is play a role to eliminate differences in results that may be due to the big variation in age 15.

Body mass index (BMI):

There was significant difference (p < 0.05) in Body mass index (BMI) (as means) between control groups and asthmatic patients, mean ±SE for the case are (30.77±0.61) and for control (28.66±0.65) as shown in table 1-1. Even though we were already taken in both groups obese and non-obese. So these results support some of the studies indicated a significant difference in the overlap between asthma and obesity, with suggesting that the association of obesity with both incidence asthma and prevalence it in women more than in men 16. So, the difference in BMI between patients and controls in this study accepted with the other studies 17,18.

Waist to Hip Ratio:

There was no significant difference (p > 0.05) in waist/hip ratio (as means) between control and asthmatic patients, means ±SE for case is (0.89 ±0.01) and for control (0.89 ±0.008), Table 1-1. Although there are many studies showed that BMI was associated with asthma as risk factor 19 but, waist/hip ratio shown independent factor than BMI 11.

Gender:

Other factor effect on the asthma it is gender.

The Figure above indicates a slight difference between male and female, and some studies can be adopted like Zein and Erzurum that shown asthma is severing and more prevalent in women especially with multiple gestation or with early menarche, offer a role for sex hormones on asthma disease 20.

Biochemical Result:

Mean differences of adiponectin level according to studied groups:

Mean differences of biochemical results including adiponectin was revealed in Table 2. The significant difference (p < 0.05) in adiponectin (as means) between control groups and asthmatic patients, means ±SE for the case is (140.50±8.46) and for control (114.27 ±7.48). The results were shown in the Table 1-2 and the concentration of adiponectin for asthmatic patients was higher than the control group.

Table 2 Mean difference SE for Adiponectin level.

P-value 0.05 was significant.

Adiponectin is a protein hormone and is 30 kDa in size; In adults it is excrete and synthesized solely by adipose cells, the levels of adiponectin in plasma are inversely proportional to percentage of fat. A little levels of adiponectin shown in Obese individuals 21. With higher adiponectin levels in animal models leads to minus airway responsiveness and inflammation as a challenge for allergens 22. Furthermore, this hormone prevents the proliferation of cultured vascular smooth muscle cells 23. Sood et al. showed that higher serum adiponectin concentrations were independently associated with adverse clinical outcomes of asthma (such as asthma-related symptoms, medications and disease activity) among men but not women 24.
Yet, poor muscle function and physical disability are linked with higher levels of adiponectin in circulating blood, which suggests a possible related between risk of falls and adiponectin.

Mean differences of IgE level according to asthmatic patient group:

Discussion

The reduction in adiponectin in obese persons possible participate to rise smooth muscle mass in asthmatic persons 29. But in this study the level of adiponectin in asthmatic patient was high so the most common risk factor for falls is muscle weakness 30. The change of the pattern in asthma therapy perhaps include weight regulation and may be change pharmacotherapeutic systems shall require special interest to that underserved populations face in the treatment of asthma. These obstructions include limited access to care and medications, cultural changes in understanding and accepting treatment options, and decreased health literacy 31,32. To manage these complexities, innovative way to therapy are needed. There is actual evidence that obesity and asthma are linked together 33.

Comparison of the Total amount of Macrophages on Full Thickness Wound Bed in The Use of Tulle, Freeze-Dried Amnion, and Microbial Cellulose

Saktrio Darmono S.1, Beta Subakti Nata‟atmadja1, David Sontani Perdanakusuma1

1 Department of Plastic Reconstructive and Aesthetic Surgery, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo Teaching Hospital, Surabaya, Indonesia

Abstract

Background: The wound is the most frequent problems faced by plastic surgeon. Many factors can affect the wound healing process. Macrophages are as one indicator of wound healing which present in the wound within 24-48 hours after injury. Currently, there is a variety of wound dressing available which can increase the levels of macrophages in the wound healing process according to previous research.

Objectives: To compare the total amount of macrophages on full thickness wound bed in the use of tulle, freeze-dried amnion, and microbial cellulose on the second day.

Material and Method: The study design was experimental, post-test only group design using 21 male rats Rattus norvegicus. The wound was closed with tulle, amnion, and microbial cellulose which was evaluated on the second day. The samples wounds were fixed by 10% formalin solution then examination of samples was conducted by Wright-Giemsa staining routine/Hemato-eosin under a microscope.

Results: Macrophages obtained at a given tulle ranges between 41-96, freeze-dried amniotic at 51-142, and the microbial cellulose at 55-96. In other hand, the mean number of macrophages in the wound by the microbial cellulose at 77.4; its 1.3 times higher than the given tulle at 59; meanwhile its 0.9 times lower than the freeze-dried amniotic given by 83.

Conclusions: There were no differences in the increase number of macrophages in the wound bed by the use of tulle, freeze-dried amnion and microbial cellulose on the second day.

Keywords: Amnion, macrophage, microbial cellulose, tulle, wound healing

Introduction

Although the etiology of an injury could be different, the healing process still remains the same. Damage to the tissue will stimulate the activation of extrinsic and intrinsic factors, acute and chronic inflammatory responses, the process of neovascularization through angiogenesis and vasculogenesis, cell proliferation, mitosis, apoptosis, and extracellular matrix deposit and remodel the matrix.

In addition to the intracellular processes, wound healing could be affected by the condition of the wound. The condition of the wound made in such way to create the appropriate atmosphere to accelerate the wound healing process. Macrophages are very important in wound healing process since they are capable of releasing cytokines and materials. They are needed to help in the healing process of wound. Macrophages present in the wound within 24-48 hours after injury...
Indian Journal of Forensic Medicine & Toxicology, April-June 2020, Vol. 14, No. 2
1923

and peaked at 48-72 hours. Moreover, macrophages are capable of producing growth factors, such as TGF-β and an epidermal growth factor that work in regulating the inflammatory response, stimulate angiogenesis, and granulation tissue formation realigned 1,3.

Macrophages play an important role as the main source of most of the active ingredient in the process of wound healing. The majority of the necessary growth factors in wound healing are produced by macrophages. Macrophages are required in the process of wound healing due to the removal of macrophages. If there is no macrophage, so it will cause wound healing to stop 4,5.

The process of wound healing occurs in three phases, namely the inflammatory phase, proliferation phase, and remodeling phase. After the injury, blood vessels constrict and retraction broke with hemostasis reaction. Furthermore, the release of histamine from mast cells that also works to increase vasodilation and capillary permeability. Inflammatory phase is characterized by increasing of vascular permeability, especially for leukocytes, neutrophils, and macrophages 1,6.

Currently, there are a variety of dressings available which according to research can increase the levels of macrophages in the wound healing process. In this study, researchers tried to observe the local response in the wound bed with tulle applications, freeze-dried amnion, and microbial cellulose associated with macrophages as one of the main components in the wound healing. It is expected that the results of the research can be used as the development of the use of freeze-dried amnion and microbial cellulose.

**Materials and Method**

This research uses experimental study design, post-test only group design. Operational variables consist of microbial cellulose, freeze-dried amnion, and tulle 7. We use Cuticell® epigraft as microbial cellulose, is a layer of pure cellulose derived from Acetobacter xylinum bacteria that has a great potential in wound healing. Microbial cellulose is proven to increase the rate of wound epithelialization. We used freeze-dried amnion which has gone through the process of freeze-dried and sterilization with gamma rays from Tissue Bank of Dr. Soetomo Hospital. Meanwhile, we used Cuticell® Classic as a tulle without any other additional ingredients (antibiotics).

Three months old of 21 mice (Rattus novergicus) were selected in this study which was randomized using providing labels. Mice were grouped into three groups consist of seven mice; tulle is applied in group 1, freeze-dried amnion is applied in group 2, while microbial cellulose is applied in group 3. Mice injected with ketamine 20mg/kg intra-muscular. Each mouse was purposely being cut in 1x1cm square-shaped size on their backs that will be disinfected with Betadine 10% and savlon 1: 30. Operation field was narrowed by dock sterile then a full-thickness wound was made by tangential excision using blade number 15. Injury in the group 1 covered with tulle, wound in the group 2 covered by the freeze-dried amnion, while in the group 3, the wound covered with microbial cellulose. After that, the wound was treated in a closed wearing thick sterile gauze and covered by stitches on the back. All mice were given the intramuscular injection of Penicillin Procaine 100mg/kg. Mice kept in different cages and fed by the same type and amount.

The wound was evaluated on the second day, where ten mice were sacrificed by injecting phenobarbital 60-100 mg/kg intraperitoneal on lateral midline area between processes hypoid and pubis. The second day was cones because macrophages infiltration in the wound bed started at 48-72 hours post-injury 2. Studies of macrophage activation showed that to look at the ability of macrophage activation should use the fastest time limit 4. Based on the data, the authors chose the fastest time which was the second day after the injury. On histologic examination, the wound dimensions of approximately 0.5 cm outside the wound edges was included as healthy tissue. Then, the tissue was removed until the muscle layer that will be folded with filter paper and fixed with 10% formalin solution. Routine examination was performed by Wright-Giemsa staining/ Hematokilin-eosin, then viewed under a microscope to count the number of macrophages with the help of graticule lens (ischak wirjatmadi).

**Results**

Normality test using the Kolmogorov-Smirnov test was performed on the number of macrophages before being tested statistically. The result of normality test for the three groups showed p value >0,05 which means all data were normally distributed.
Figure 1. The number of macrophages in the healing tissue. Macrophage cells (arrows) on the injury area with treatment using tulle (HE staining. Magnification 100x; H600L Nikon microscope; Fi2 300 Megapixel Camera DS).

Figure 2. The number of macrophages in the healing tissue. Macrophage cells (arrows) on the injury area with treatment using freeze-dried amnion (HE staining. Magnification 100x; H600L Nikon microscope; Fi2 300 Megapixel Camera DS).
Table 1. The amount of macrophages cell in each treatment

</tr>
</tbody>
</table>

It can be seen in figure 1, 2 and 3 that the number of macrophages in the healing tissue was observed histologically using 100x magnification. The calculation of macrophages was obtained by the treatment result using tulle that was about 599 by the maximum amount of 96 macrophages cells. The treatment of microbial cellulose showed the mean of 77.4 by the maximum cell of macrophages as same as tulle treatment which was about 96 cells. After that, the treatment used freeze-dried amnion resulted mean of 83.0 by maximum amount of macrophages cell was 142. Therefore, the treatment used freeze-drive amnion resulted effectively.

However, the standard deviation (SD) did not show the difference significantly and can be seen in figure 4. Macrophage of scar tissue is obtained at a certain range, for tulle at 41-96, freeze-dried amniotic at 51-142 and the microbial cellulose at 55-96.
It can be seen in table 1 that the mean number of macrophages on the wound by the microbial cellulose was 77.4 which means that it was 1.3 times higher than the tulle at 59; meanwhile it was 0.9 times lower than the freeze-dried amniotic at 83. Statistical test results obtained using ANOVA with p value >0.05 which means that there was no significant difference in the number of macrophages in the provision of microbial cellulose, tulle, and freeze-dried amniotic.

**Discussion**

In the previous studies stated that the amnion has an impact on the local immune system by giving more macrophage expression and regulate the function of macrophages 8,9. In addition, the amnion gives more influence number of macrophages in bed sores than tulle. The amnion increases the number of macrophages 2.5 times more than tulle. Microbial cellulose dressing may accelerate epithelialization while bacterial cellulose can regulate inflammation by giving effects on the formation of macrophages and lymphocytes 10,11. Those studies are different with the results of this research.

The macrophage acts as an indicator of the wound healing process that is absolutely necessary for the wound healing process. Macrophages are needed in the wound healing since they are capable of producing cytokines and growth factors such as TGF-β and the epidermal growth factor that works in regulating the inflammatory response, stimulate angiogenesis, and granulation tissue formation realigned. Macrophages present in the wound within 24-48 hours after the injury and peaked at 48-72 hours.

Other studies claimed that the use of amnion on wound gives less significant result in influencing the inflammatory phase of the healing process. Despite the significant increase seen in the process of angiogenesis in the granulation phase, it does not affect the process epithelialization, fibroplasia or fibrosis in phase significantly 12.

One of the factors that play a role and always used in the wound treatment is wound dressings (bandages). The amnion contains mesenchymal stem cells and growth factors that can accelerate the healing of a wound 13. The amnion effects on the local immune system by giving more macrophage expression and regulate the function of macrophages 8,9. Microbial cellulose dressing can accelerate epithelialization rate 10. Bacterial cellulose can regulate inflammation that effects on the formation of macrophage and lymphocyte 11,14. Bacterial cellulose stimulates macrophages to produce IL-12, p40, and TNF-α which play a role in anti-inflammatory and antigenic processes 15. This study proves that there is no difference in the number of macrophages in the wound bed given tulle, freeze-dried amnion, and microbial
cellulose.

Conclusions

There was no difference in the number of macrophages in the wound bed given tulle and microbial cellulose, given freeze-dried amnion and microbial cellulose on the second day.

Ethical Clearance: This study protocol was approved by ethical clearance Dr. Soetomo Teaching Hospital Surabaya, Indonesia.

Conflict of Interest: The author reports no conflict of interest of this work.

Evaluation of Women’s Perception toward Childbirth Experience after Utilization of Pain Management Practices at Al-Elwyia Maternity Teaching Hospital

Sarab Nasr Fadhil¹, Rabea Mohsen Ali²

¹Instructor, ²Professor, Maternal and Neonate Nursing Department, College of Nursing/ University of Baghdad

Abstract

Objectives: To evaluate the women’s perception with Childbirth Experience after utilization Pain Management Practices.

Methodology: A quasi-experimental study conducted on non-probability of (30) women whom admitted to Al-Elwyia Maternity Teaching Hospital suffering from labor pain for the period of (4th July 2018 through 24th October 2018). Descriptive & Inferential statistical analyses were used to analyze the data.

Results: show that the highest percentages of non-pharmacological methods used was frankincense oil, and related to women perception of labor pain they are assessed high as general, and they are accounted 24(96.0%).

Conclusions: The study concluded that there are a positive evaluation observed regarding women’s perception with childbirth experience after utilization pain management practices.

Recommendations: The study recommended developing structured training program and clinical practice guideline of non-pharmacological pain management methods during labor and childbirth should be made available in English and Arabic which contains information about the proper use of non-pharmacological pain management methods and its advantages to midwives working in delivery room.

Keywords: Assessment, Perception, childbirth, Pain Management.

Introduction

Labor pain is considered one of the most painful conditions in women life and these women often underestimate the pain they will experience due to several factors might influence a woman’s perception of labor pain. These factors include (cultural, ethnic, educational factors, excessive anxiety triggers “fight-or-flight” response, fear of pain may be one component of labor-related anxiety and has a high correlation with pain levels reported during first-stage labor. The environment affects the woman’s experience of pain that includes the persons present and their verbal and nonverbal communications, the philosophy of care and practice policies of the providers; the quality of support the woman perceives from those present, the degree of strangeness of the environment, including (furniture, noise, lighting, and temperature), Ability to cope all affects her ability to manage the pain of labor. (1-3)

Methodology

A quasi-experimental study design was conducted on purposive sample, of (30) women whom admitted to Al-Elwyia Maternity Teaching Hospital suffering from labor pain. Study implemented for the period of (4th July 2018 through 24th October 2018). Data collection will be gathered by application one of non-pharmacological strategies of pain relief methods include: (frankincense, jasmine, & olive oils), massage, body movement and change position (squatting, side-lying, & standing), breathing technique, and therapeutic touch) and by used questionnaire format which consisted of two parts, including non-pharmacological methods the delivering woman received during labor and delivered women’s perception toward labor pain which consisted of (25 items). A pilot study was carried out between the 25th June 2018, to 1st July 2018, on (10) women to determine the reliability of the questionnaire and content validity was carried out through the 12 experts. Descriptive and inferential statistical analyses were used to analyze the data.
Results

Figure (1) Cluster Bar Chart for the distribution types of non-pharmacological methods

Figure (1) results show that “Frankincense Oil” method has recorded the high and first ordered method, and accounted (30%), then followed with Jasmine Oil” method, and accounted (23.3%), then followed with “Squatting Position, and Side-Lying Position & Breathing” methods, and accounted (13.3%), Massage, Massage & Standing position, Therapeutic touch & Standing, Olive oil, breathing technique, & side lying position accounted (3.3%).

Table (1) shows that delivered women’s perception of their labor pain items are high as assessed generally, and they are accounted 24(96.0%), as well as only item named “I felt the nurse was more interested in her job than my needs” has a moderate assessment.

**Discussion**

**Non pharmacological methods**

The results of figure (1) show that aromatherapy are the first order used which include” frankincense oil, jasmine oil, and olive oil” then body movement and change position such as squatting position, side-lying position which used combination with breathing and recorded the second order and finally, massage, massage and standing position, therapeutic touch and standing, breathing technique, and therapeutic touch and distraction” are used in a little. In this study, it has been noted that essential oils (Frankincense, jasmine, and olive) recorded the high number of uses and accounted 17 (56.7%). The researcher attempted to use aromatherapy for participant (according to their preference) due to that the researcher noted the uses of these aromatherapy are widely in world and have many benefit such as promoting general relaxation, reduce anxiety and helpful to reduce labor pain as it used in the current study depend on wide evidence based studies\(^{(4, 5-7)}\). Relative to use of massage technique the results show that there are two women were choosing massage. The massage work as a form of pain relief by increasing the production of endorphins in the body that reduce the transmission of signals between nerve cells and thus lower the perception of pain \(^{(10)}\). Relative to use of therapeutic touch observed that there are two women chose therapeutic touch but in different way one therapeutic touch with standing position and another one use therapeutic touch with side-lying position.

**Women’s Perception of their Labor Pain Regarding Study sample**

According to the table (1), the results show that delivered women’s perception of their labor pain items concerning study group assigned that observed responses are high assessed generally, and they are accounted 24 (96.0%), as well as only item “I felt the nurse was more interested in her job than my needs” has a moderate assessed. These high assessed responses related to pivotal role that the researcher acted in care for women by using pain management practices in addition to her role as a doula (continuous labor support) in labor for all participants in study group. And these results are in agreement with evidence based studies from high

countries that have revealed that continuity of midwifery care, continuous support during labor, a good support during labor and birth are more likely to lead to less pain to women and reported higher perception of control and be more satisfied with their intra partum care\(^{(1,2)}\). In addition, another studies showed that emotional support, in holding the patient’s hands. Making a difference during labor, also Nurse’s interpersonal skills are more important than technical skills for mother and baby. Due to women’s perception to labor pain were different among women in a cultural, education, social and psychological dimensions, and the responses may be influenced by several factors that include, culture, information they have about labor pain, fear of labor process, and unfamiliar environment that can worsen the situation, therefore the emotional and physical support given to labor woman by nurse or people around her is very important \(^{(3,4)}\). Further, another study reported that having received helpful labor coping measures that were valued by participants included performing roles of emotional supported, comforters, information and advice, professional technical skills, and advocates \(^{(5)}\).

**Conclusions**

The study concluded that there are a positive evaluation observed regarding women’s perception with childbirth experience after utilization pain management practices.

**Conflict of interest:** Nil

Abstract

Background: Anger is one of the worst negative predictions in cardiac patients. Therefore, this study aimed to cure the anger of patients admitted to the Cardiac Care Unit.

Method: This quasi-experimental study was performed on 60 cardiac patients admitted to the heart care unit in a non-randomized sampling method in two groups (n = 30) and control (n = 30). In the test group, four to five times a day, the patient whispered to Allah Akbar or the prayers of Hazrat Zahra. In the control group, routine care was performed. The instrument for collecting information was anger questionnaire which was completed by self-report method before and after the intervention by the patients. The results were analyzed by inferential statistics (T-test, T-test and Independent T-test).

Result: Paired t-test showed a significant difference in the test group before and after the intervention (P <0.01). But in the control group there was no significant difference (P = 0.92). Independent t-test before intervention in the control and experimental group did not show a significant difference (P = 0.22), but this test showed a significant difference after the intervention (P = 0.006)

Conclusion: Considering the effectiveness of the therapeutic approach to reducing the rate of anger in heart patients, this non-therapeutic method can be used to reduce stress and psychological disturbances in patients and to increase the compatibility and relaxation of patients.

Keywords: cure, anger, heart disease, CCU.

Introduction

Violence has a negative impact on one’s health¹, ². Anger and stress are one of the worst prognosis in the first two hours after myocardial infarction³, ⁴. Because it increases the blood pressure and disturbs the heart rhythm⁵. Increased norepinephrine in conditions of anger and stress increases platelets, increased blood pressure, vascular stenosis and increased ischemia and atherosclerosis in the heart⁶. In such a situation, religious beliefs become more important than ever, helping the person understands the painful events of life and cause the patient to be encouraged. Therefore, spiritual experiences in difficult and critical conditions of life are considered as an adaptation⁷. Because the remembrance of God and thinking in the Lord leads to calmness and the creation of faith and the sense of security, hope and love and hope for life⁸.

A wide range of spiritual health\(^9, 10\). Among the religious and spiritual sources, the most used source is prayer\(^11\). Recall the meaning of prayer and the ways in which the presence of God and his relationship with him are experienced. Belief in God and purposefulness of life, along with a sense of thought and attention to the spiritual issues of life, reduce the anxiety and psychological weakness and its complications\(^12-14\). A great deal of research suggests that mentioning and worshiping on the soul and soul of an individual can be adapted to critical situations and create meaning in life\(^15\). Paying attention to the mental health of patients is important\(^16, 17\) and Religious spiritual intervention is effective in people’s health\(^7, 10\). According to religious beliefs in the mental and emotional state of heart patients, researchers began a study entitled “The Effect of Therapeutic Counseling on the Rate of Anger in Patients Admitted to the Heart.”

Material and Method

This quasi-experimental study was conducted on patients admitted to the Cardiac Care Unit of Golestan Social Security Hospital in 2016. The research area of the heart care unit is the two social hospitals of Gorgan and Gonbad. The inclusion criteria for patients who were hospitalized for heart problems in the cardiac intensive care unit were all Iranian and Muslim, and the physiological status was fixed at the time of the implementation of the research plan, and on average, every patient was hospitalized for three days in the cardiac intensive care unit. In this study, 60 subjects were divided into two groups (n=30) and control (n=30), based on Dehkordi et al., With a power of 80%, confidence interval of 0.95%, significant level of 0.05, and effect size of 0.86 using software. G * POWER was c calculated\(^18\). And were randomly divided into two groups of test and control. The instrument for collecting information is the standard questionnaire of anger control skill, and its score is based on Likert scale. Testers must specify their answers between 5 degrees (very opposite, disagreeing, unobjectionable, agreeing, strongly agreeing), giving each of the answers (1 to 5) respectively. The score range is from 8 to 40. The low score in this questionnaire reflects the lower ability to control the anger of the subject. The dynamics of this questionnaire with Cronbach’s alpha coefficient was confirmed in a pilot study with a coefficient of 0.80 (Solhi and Mohammadali, 2016). The questionnaire was also approved by ten faculty members from the University of Azad University and the University of Medical Sciences. In this study, the researcher did not train the therapist and did not teach the group to the group who had the conditions to enter the study, after approving the plan at the university and obtaining a license and presenting them to the hospital authorities and obtaining their consent. In the experimental group after the initial status of the patients, the purpose of the research and obtaining informed consent and ensuring the anonymity of the units in the experimental and control groups before intervention were analyzed by anger test questionnaire. Then the researcher in the test group gave a prayer and encouraged the patients to pray for the prayers of Hazrat Zahra, in which more than 100 were used by Allah, and the teaching of sublanguage readings was performed with the revelation of Hamed and the expression of the 100th mention of Rawlah and Allah Allah, and of Patients are required to do this at least 5 times a day. The researcher then carefully controlled the patient’s treatment with hospital personnel in an intangible way. In the course of the intervention, the researcher was asked by asking the section about the mention of the mention, especially the mention of the letters of Hazrat Zahra. The only control group was routine medical and nursing care. Then, at the moment of the patient’s discharge from the intensive care unit and the transfer to the department or complete discharge from the hospital, both post-test groups were taken. Data were then entered into the spss16 software. After determining the normality of the data, the data were analyzed by the Krollomogrov-Smirnov test at a significant level (alpha -0.05) by covariance test, paired t-test and independent t-test.

Findings

The mean age of the research units was 59.93 ± 41.9 years with a mean hospitalization in CCU for 3 days, which was not significantly different between the two groups (Table 1). Mean anger in the intervention group before and after the intervention was 30.56±4.26 and 29.26 ± 4.4 after the intervention, which showed a significant difference (P <0.01) in the control group as well as in the control group before intervention. The rate of anger was 3.93 ± 93.93 and the post-test score was 32.2 ± 32. There was no significant difference between t-test and paired t-test (P = 0.92). There was no significant difference between the level of anger in the two groups before and after the intervention (P = 0.22). Independent t test showed significant difference between the two groups after the intervention (006 / 0 = P). Also, covariance test showed a significant difference between the two groups (P = 0.007, P = 0.12, Et = 0.12). That is, 12% of the post-test variations are due to the

Discussion

The results of this study showed that the mentioned treatment reduces anger in patients hospitalized in the CCU. Various studies show that patients with physical injuries and injuries go to religious beliefs. Prayer in patients causes adjustment of blood pressure, adjustment of respiration, stress reduction and improvement of patients’ quality of life(19). Studies show that religious beliefs and the use of spiritual experiences reduce mortality in patients(20). Religious beliefs such as prayer and mention the protective effect against heart disease(21).

In the meantime, various studies showed the effects of spirituality on reducing anger and anxiety in the patients(22). During cardiac arrhythmia, they are more emotionally and physically relaxed, and spiritual activity such as prayer and curative therapy can control emotional stress and reduce physical illness and reduce heart rate in these patients(23). mental stress such as anger causes a negative prognosis in cardiac patients(4). That mental exercises activate the region of the brain, which causes positive emotions and beneficial effects on mental mood and symptom relief in heart patients(24).

Harvard Medical School cardiologist Herbert believes that prayer and prayer can be beneficial, such as decreasing physician visits to relieve heart pain by about 26 percent lowering blood pressure, reducing drug use in 80 percent of patients with hypertension and heart patients, and Reduces visits by healthcare organizations to patients. He showed that people, through religious and religious practices such as prayer and prayer, relaxation method is a therapeutic way to reduce stress in patients with chronic pain, heart disease, hypertension and other stress-related illnesses(23). with regard to the effectiveness of the treatment of nurses as a professional group during the period of hospitalization, patients should be accompanied with attention to the spiritual and religious needs of individuals. Provide the conditions and conditions for performing the religious and spiritual practices of the patients in the hospital(15). From the limitations of this study, the short-term hospitalization of patients in the intensive care unit as well as the lack of a heart part in social welfare hospitals in Golestan
province, which could not continue the interventions in the heart. Therefore, it is suggested that a longer study be done in this study. Also, by adding a group that is in contact with the clergy of the hospital, compare the effects of these methods.

Conclusion

Considering the effectiveness of citation therapy on decreasing the anger rate in hospitalized patients in the heart and considering the culture and persuasion of the Iranian people with religious and religious issues, this therapy can be used to improve and reduce stress, anger and mental disorders of patients. Therefore, it is imperative that nurses, as a professional care team, discover spiritual needs of the patients and use spiritual care, such as prayer and mention, to reduce anger and aggression in heart patients.

Abstract

Introduction: The stress of war has caused severe problems for the individual and family. Spouses of veterans are gradually involved in family erosion. Lack of social protection and social dysfunction decreased life satisfaction and reduce intimacy between partners.

Purpose: this study has been done in the purpose of comparing social support against the veteran’s life who are under stress.

Method: This cross-sectional study was done on 79 posttraumatic stress disorder veteran wives and it was also done on 79 ordinary wives through convenience sampling. The instrument to collect the required information was the quality of life questionnaire which contained 36 SF questions and Medical Outcomes Study Social Support Survey (MOS-SS).and the needed information was collected by self-reported method.

Results: Veteran wives social support with the mean and the standard deviation was 19.3±5.1 while it was 31.1±3.7 versus the ordinary wives and this difference was significant (P less than 0.01). It showed the veteran wives quality of life with the mean and standard deviation of 46.3±6.088 while it showed 66.9±8.5the mean and standard deviation for the ordinary wives and it showed the significant difference (P less than 0.01).

Conclusions: the obtained result showed that the quality of life related to the health and social support in veteran wives is lower in compare with the ordinary wives with the same situation, therefore educational, treatment and supporting and promoting plans for this group is necessary.

Key word: social support; life quality; veterans; PTSD

Introduction

It is important to pay attention to mental health (1,2). These effects include spinal cord injury (3). Chronic diseases threaten the physical and mental health of the patient (4). Posttraumatic stress disorder is a serious reaction and perpetual response which appears because of being exposed to serious stresses (5). Posttraumatic stress disorder was identified and recognized during the civil war in the United States (6). The prevalence of this disorder in the public population is 4-8 percent (7). But this percentage is between 9 to 25 percent among the war injured ones during the first two years (8). The prevalence of that among the Vietnamese war soldiers has been reported as much as 30.1% to 14.7% (9). It has also been reported 17.1% to 15.6% for the solders coming back from Iraq war (10,11) According to the present documents more of the Iranian veterans have posttraumatic stress disorder and this disorder which is always with the veterans has a very bad effect on they themselves, their lives and their family lives (12, 13) Living with a person who suffers PTSD can transfer some of the symptoms to their wives (14). So one of the war victims is the veteran wives who are exposed to the PTSD so the veteran wives encounter lots of problems in their lives and theses...
problems become more and more by passing the time and cause them to have mental disorder\textsuperscript{15, 16} and this continual disorder can bring trauma to the wives and can cause anxiety, depression, isolation in the veteran wives\textsuperscript{17, 18}. The veteran wives will have family erosion little by little and because of the lack of social support they lose their satisfaction with the family members especially with their husbands\textsuperscript{19}. One of the anxiety of the family suffering from PTSD is mental relationship, matrimony compatibility and sexuality satisfaction which can affect their life quality\textsuperscript{12}. Most PTSD veteran wives sometimes face challenges that force them to be compatible to life because of their children and loving their husbands and some wives who cannot tolerate this hard situation decide to divorce\textsuperscript{20}. Studies have shown that most veteran wives have lack of social communications and they cannot express themselves well and they hesitate whether to continue that life or separate their husbands and in most cases the presence of their children cause them not to do so and this causes them to accept the problems and become compatible\textsuperscript{21}. An eight-year war with Iraq and its follow-ups have made many Iranian warfare died and veterans suffer from war-related Mental disorders\textsuperscript{22}. In addition to medical and Mental disorders, this disorder decreases the sufferers’ quality of life\textsuperscript{16}. So, this study that has been based on the purpose of comparing the social support and life quality of PTSD veteran wives has been done.

Material and Method

This cross-sectional study was done on two wife groups; the first group were the veteran wives and this group contained 158 PTSD veteran wives and the second group consists of 79 ordinary wives. This study was done in the year 2016. The study setting was Aliabad city, the population of the city is 150,000 people and according to the announcement of The Foundation of Martyrs and Veteran Affair, there are 96 PTSD veterans there. The method of sampling was done by census method among the ones who had inclusion criteria which was certified by a psychologist, and those samples were the veterans with documents that proved they are veterans, and not addicted to any drug and abuse substances were chosen. All participants provided informed consent after the study purpose was explained, and assurances were made of anonymity and privacy. At most, 79 people were qualified for the study. The control group was elected among the veteran wife relatives and their close friends and they had no PTSD disorder and no chronic mental disorder rand they were not addicted to any drugs.

This study information was collected by Demographic questionnaire, Medical Outcome Study Social and supportive Survey (MOS-SS).

Demographic questionnaire: This questionnaire contains information such as age, education, number of children, the length of time living with his wife, drug using, and the chronic mental illnesses.

Short form of quality of life (QOL-SF36): This questionnaire which contains 36 questions measures and evaluates the physical, mental and eight domains of life. The physical life quality consists of physical function, limitation in having a role because of the physical lack in efficiency, physical pain and general health.; and domain of psychological, life quality, contains limitation in role because of having emotional problems, social function, happiness and vividness and healthy mental. The method of giving score to them was between zero for the worst to 100 according to the questionnaire instruction SF36, and the score obtained by the samples is between 0 and 100 and the reliability of this study has strongly been confirmed and the reliability of the native form of this questionnaire by Shahgholian\textsuperscript{2014} in all aspects has firmly been confirmed and is 0.95 – 0.91\textsuperscript{23}.

Medical Outcomes Study Social Supports Survey (MOS-SS): This questionnaire was made by Sherbourne and Stewart. These supportive social tools have 19 questions and 5 sub scales. These subscales are tangible support (4 questions), which measures the financial and behavioral, exciting support (4 questions) which evaluates the positive emotion, sympathy, encouragement to express the feelings. Informing (4 questions) which evaluates guidance, informing, kindness (3 questions) which evaluate the amount of love, and positive social compatibility (4 questions) which evaluates the people who do the amusement and fun activities. This scale is a self-report tool which is used to measure the amount of agreement or disagreement of someone to any of them in five-point Likert scale (never = 1 point, seldom= 2 points, sometimes = 3 points, often = 4 points, always = 5 points). The lowest score in this is 19 and the highest score is 95. The high point in this test shows that the test is supported by the society a lot\textsuperscript{24} The reliability of sub domain of this test was reported by Cronbach’s alpha 0.91\textsuperscript{25}. All statistical procedures were performed with SPSS 16 statistical software. Using descriptive statistics independent t-test.
Findings

The mean age of the PTSD veteran wives were 39 individuals (49%), high school and guidance school education was 24 individuals (31%) primary school education 13 individuals (6%) and three of them had university degree, among the ordinary people wife, 48 (61%) had high school and guidance school education, (31%), 5 individuals were uneducated, 5 individuals (6%) had diploma and two of them (3%) had university degree.

The amount of life quality of the veteran wives with means and standard deviation was 46.3±0.88 (P<0.01). There also was seen a significant difference between the veteran wives versus the ordinary people (Table 1).

The amount of veteran wife’s social support by mean and standard deviation was 19.3 ± 5.1 and in the ordinary people it was 31.1 ± 3.7 (P<0.1).

Discussion

Spinal cord injury affects the mental health of patients, with a prevalence of mild depression of 22.6% in the Hatefi et al(26). The result of the study shows that the PTSD veteran wives have a lower quality of life. In both the physical and mental dimensions, the veteran wives had lower quality of life in compare with the ordinary people wives. Studies have shown that the veteran wives have more excitement and it has caused them to have a lower quality of life. The results of the present study were same as Bares (2011), Brow (2010) and in all these studies the PTSD veteran wife’s life quality was low(9, 27).

Clinical experiences have shown that the veteran family, particularly their wives, suffer mental problems such as seclusion feeling, loneliness, inability, sin feeling, and depression(28), because the PTSD veteran wives are exposed to stresses and have lots of turmoil in their marriage lives(15). Lots of studies show that the PTSD veteran wives suffer a lot from mental disorder and also as the physical problems and it is known as the prevalent headache and physical complaint among the veteran wives(27) because living for a long time with someone who suffers post-traumatic stress disorder has a deep and serious influence on their family and can be a chronic stress factor for their wives and can be the source of big and serious problems their families(31).

This study showed that the social support for the veteran wives is lower than ordinary people wives. Communication disorder, physical problems and its consequence, lack of understanding the veterans by some people in the society is one of the most important things that the veterans suffer from(15). Social supports may have a very important effect on developing care health and also on mental pathology in reaction to the stressful life events(32). Social supports from the authorities and the social organizations can increase respect, can reduce blame and label and it can also form a better self-compatibility in veteran wives and it also can reduce stress in their lives(16).

Conclusion

According to the findings of this study, it can
be concluded that the martyr and veteran families are special families with special stresses and the amount of their stress increases day by day. Women are the center of these stresses, and they themselves and their children are at the risk of danger therefore the society is at danger. Therefore, in order to reduce the amount of stress and the factors that causes stress and anxiety in this group, presenting more and more suitable services and economical is an evitable necessity. Besides, in order to reduce the damage of stresses, teaching educational services, that is teaching life skills are among the communicative skills and stress management and doing actions on beliefs and their attitude towards the incidents and life meaning will be useful. It is also suggested that the veteran wife’s life compatibility is to be investigated through a quantitative research.

Risk Factors Related To Mastalgia

Suhad Kahdum Ali
Professor, Hammurabi Medical College, University of Babylon

Abstract

Background: Breast pain becomes more complicated in many humans. Various hospitals are planning for surgery in the initial stages. The main aim of this paper to find the various factors which cause mastalgia, this is mainly causing the abnormal conditions of the breast.

Method: The experiments conducted on 400 patients and this is collected from various surveys, for patients older than the age of 40 the mammography and ultrasonography (US).

Results: The mean age was 44.23 ± 9.23 years. This group consists of 300 cases, the asymptomatic group consists of 100 persons. Due to the various reasons that are related to mastalgia (p < 0.05). These are based on their breastfeeding to the child. If it is more than 4 times or more were higher in the mastalgia group (p < 0.04). The breast imaging-reporting and data system (BI-RADS 2) mammography results were associated with mastalgia (p < 0.05). These two are more common in the mastalgia group (p < 0.05) that is Fibro cysts and fibro adenomas. Based on the previous history the malignant breast disease was simultaneously higher in the mastalgia group (p < 0.05).

Conclusions: Life stress, high caffeine consumption, smoking, lactation frequency, and benign disorders were factors identified to be related with mastalgia. Though a significant relation between mastalgia and malignant breast disease was detected in our study, more studies are still necessary to investigate this relationship.

Keywords: Mastalgia · Surveys · Mammography. US findings. Pain · Surgery

Introduction

The most common factor in women is Breast pain nothing but mastalgia which causes breast tenderness, hard burning sensation or tightness in the tissue, the pain may increase or maybe constant and this will occur some other times.1 Due to the pain in the breast and tenderness, many women are fear with early symptoms of breast cancer, generally, these are not considered as disorders.2-3

Mastalgia is classified into two types such as cyclic breast pain (CBP) or non-cyclic breast pain (NCBP). CBC affects women at the age of 20 to 30 and it is up to 40 also. But still, it is menstruating. Mainly the pain occurs at the end of the menstrual cycle week or before the period occurs. At this time the breast is affected with the painful, tender, and swollen, based on the cycle the symptoms improve at another point. The pain occurs at the breast outer and upper parts of two breasts and this involve the underarm area as well. In the luteal period, the result of water increased in breast stroma produced by increasing hormone levels.3-5 Menopause is the non-cyclic mastalgia. This may like sharpness, burning, or soreness in the breast.

Causative pathophysiology of pain stays hazy however is believed to be known with secretion factors (e.g., hormone-substitution treatment, oral contraceptives, pregnancy, menses, pubescence, and menopause) these variables will modify the steroid, Lipo-Lutin and prolactin levels.6 Kind breast issue (e.g., fibrocystic changes), mind-expanding drugs, psychosocial factors and passionate stress square measure connected with breast torment.2-7 Lactation problems (e.g., engorgement, mastitis, and breast ulcer), inflammation (Tietze disorder), Postthoracotomy disorder, Spinal and paraspinal issue and Referred torment (e.g., pneumatic, heart, or vesica sickness) will likewise cause breast torment. Caffeine and vasoconstrictive utilization square measure likewise
viewed as related with pain. Cancer is a rare reason for breast torment. Breast pain associated with malignant growth is one-sided, non-cyclic, and extremely a lot of confined.

The fundamental center is to research the components of inpatient history that influences the event of breast pain, and to decide the connection among mastalgia and considerate or malignant breast utilizing a huge arrangement of members.

Method

The research was completed in an exceedingly non-public Surgery facility in Iraq, between September 2018 and August 2019. This experiment was affirmed by the local human morals committee. The patients were relegated to at least one of 2 gatherings: the pain gathering, from women, admitted to the breast surgery outpatient center with mastalgia (n = 300); and therefore the symptomless gathering (the management gathering), including patients undergoing routine breast screening (n = 100). Patients UN agency was treated with oral contraceptives, psychoactive specialists, secretion medical care, or vas operators, even as patients below 18, or over 70 older were banished from this research.

A standard summary study for all patients within the groups was performed regarding their enthusiastic anxiety, utilization of caffein and phytotoxin. AN intensive physical assessment was performed for all patients. The gap between the areola and therefore the os indent was calculable, any length surpassed 33 cm was thought of as macromastia. Breast screening was done by means that of the diagnostic procedures for patients skilled than the age of 40; imaging (US) was done once necessary for any age. Breast thickness bit by bit will increase to type D, during this manner, drop-off the affectability of the diagnostic procedure. What is more, the imaging discoveries in the diagnostic procedure were ordered accordant to the Breast Imaging-Reporting and information system (BI-RADS)? The BI-RADS classes are characterized as BI-RADS zero, fragmented; BI-RADS one, typical; BI-RADS2, thoughtful finding(s); BI-RADS three, presumptively generous; BI-RADS four, suspicious abnormality; BI-RADS five, deeply resembling harm; and BI-RADS vi, presence of biopsy-demonstrated danger.

The NCSS 2007, and PASS 2008 Statistical Software (Utah, USA) programs were used for measurable examination to perform the mean, variance, return and proportion, the Mann-Whitney U take a look at was used to affirm a normal dispersion condition. Fisher’s actual take a look at, Pearson’s chi-squared take a look at, and Yates’ progression rectification were used for the subjective evaluations of the data. Contrasts were thought of statistically vital once p < 0.05.

Results

Overall 400 females with a males period of 44.23±9.23years (approx 19-65) were enlisted. The mastalgia gathering, 300 patients, and, the well gathering, two hundred patients. Guys age was basically higher within the pain gathering (p = zero.001) (Table 1). The rate range of patients World Health Organization admitted extended gung ho feeling of tension was higher within the pain gathering (p < zero.005). alkaloid use and smoking were known with pain (p < zero.05). The lactation repeat rate disclosed associate degree on a awfully basic level higher association with bosom torment within the pain gathering (p < zero.05). The sort, shape, and laterality of bosom torment within the pain bundle area unit consolidated in Table a pair of. the speed range of patients of the pain bunch eaten soul, paracetamol, and non-steroid assuaging medicine were primarily higher (p < zero.05) (Table 3).

A total of 280 patients was given to mammographic screening, 209 patients from the pain gathering, and seventy one patients within the well gathering. The unendingly visit bosom thickness configuration was composed associate degree within the well gathering, and sort B saw as increasingly typical within the pain gathering (p < zero.01). In step with the BI-RADS categories, BI-RADS one was increasingly customary within the well occasion and BI-RADS a pair of within the commanding within the pain gathering (p < zero.05). The analysis of the U.S.A. photos disclosed the events of elementary bruises and fibro adenomas were higher within the pain gathering (p < zero.05). The assessment of the tomography discoveries between the 2 social occasions shows up in Table four.

Different sorts of six patients resolved to own BI-RADS four were within the pain gathering. Once the diagnostic assay, the psychoneurotic evaluations disclosed that 3 of those patients had a unsafe contamination, agitating cautious intervention.

Discussion

Various factors are effecting mastalgia, The author portrayed that the period of women grumbling of the pain in breast was in the range 35-55 years and that this side effect was once in a while experienced younger than 45. Present research, the male age of the all-out investigation group was 44.23±9.23years (territory 19-65 years), and the male age of the mastalgia group was higher lighting up that mastalgia happens in the perimenopausal period when the inconsistence of hormonal and menstrual beginnings. Numerous studies showed that there is a connection between breast torment and mental strain. In this paper, the patients how had an unpleasant lifestyle were essentially higher in the mastalgia gathering. Numerous concentrates uncovered a connection between caffeine utilization and smoking with breast torment. In our examination, there was a critical association between either standard caffeine utilization or substantial smoking (in excess of 10 cigarettes every day) and mastalgia.

Anomalies of the estrogen/progesterone proportion, which can happen on the off chance that one of these hormones increment, the other one will diminish, or expanded prolactin levels are identified with mastalgia. The event of breast side effects, for example, expanding, irritation, and nodularity in the menopausal period, at that point the end of these manifestations in the postmenopausal period is potential because of the impacts of the estrogen hormone.

In perspective on lactation, the level of ladies with a background marked by breast feeding or more newborn children were expanded in the mastalgia gathering. These outcomes shed light on the connection of breast torment with the expanded frequencies of lactation, which is identified with an expanded number of births, and therefore with an expanded introduction to significant levels of estrogen and prolactin. Additionally, at least 4 times of lactation may bring about anatomical changes in the breast tissue, particularly in the ductal framework, which could likewise expand the breast torment episodes.

An earlier reciprocal salpingo-oophorectomy with or without absolute stomach hysterectomy was identified with a fundamentally diminished event of mastalgia.

The mastalgia side effects which coordinate the announced investigations that found a huge connection between the asymptomatic gathering and postmenopausal state.

Macromastia or breast hypertrophy is an uncommon ailment of the breast connective tissues wherein the breasts become exorbitantly enormous. In the event that the separation between the sternal score and the areola surpassed 33 cm this means that macromastia. In our examination, the recurrence of macromastia was altogether lesser in the mastalgia gathering, recommending that macromastia probably won’t be one of the components that reason mastalgia. Mastalgia may happen attributable to greasy tissue rot, or a strain in the Cooper tendons as aftereffects of either dull or entering injury to the breast. In our investigation, higher paces of injury history found in the mastalgia gathering.

Extreme mastalgia can happen in 10–22% of patients and requires medicinal medications. As an initial step approach, analgesics In our present examination, the mastalgia bunch utilized pain-relieving specialists more than the asymptomatic gathering, and the most picked pain relieving type was NSAIDs.

As breast thickness builds, the mastalgia does. In our examination, the sort B breast design was higher in the mastalgia gathering. Different designs demonstrated immaterial contrasts between the two gatherings. Mastalgia and generous breast issue is altogether related. Our examination indicated a higher recurrence of mastalgia in patients with discoveries of benevolent issue (BI-RADS 2). The connection between breast torment and kind issue distinguished utilizing the US is likewise easily proven wrong .The author announced that fibroadenomas and basic sores were the most widely recognized existing together benevolent sores.

Furthermore, the rate of fibrocystic malady recognized by the US was essentially higher in patients with mastalgia. Since the fibrocystic ailment is a substance demonstrating a summed up inclusion of the breast parenchyma, that it prompts diffuse breast torment isn’t startling. Despite the high likelihood of the dwelling together of a dangerous breast tumor with non-cyclic breast torment, albeit uncommon, repetitive mastalgia can likewise be identified with harm.

Despite the fact that the aftereffects of our examination uncover a relationship among mastalgia and danger, this issue is as yet dubious, and there is as yet a requirement for enormous future investigations to uncover the relationship more precisely.
Conclusion

Symptoms like stress, coffee consumption, smoking, and other abnormal disorders are the key points found which is related to mastalgia. There is a relation between mastalgia and malignant breast disease is found in our research. In the future, more research is to be done.

Genetics Risk Factors and Progression of Renal Failure

Suhayr A. Alqaysi
Assist professor , Thana mohammed Juda, Assist professor Seenaa Badr Mohammed, College of Medicine, University of Babylon, Hilla, Iraq

Abstract

Objective: “MYH9 gene” is “expressed” in “kidney, platelets and liver and in lesser amounts in the thymus, spleen, and intestine”, its responsible for encoding a protein called “non muscle myosin heavy chain”. To evaluate the role of MYH9 SNP on developing of renal failure.

Method: This study depending on “methodology of Case-control study”, subjects involved were one hundred as patients and control; 50 “patients” complaining renal failure and 50 apparently healthy controls. DNA was extracted from venous blood. The “MYH9 gene polymorphisms” were recognized by applying the procedure of (“PCR-RFLP”).

Result: Genotype at rs4821480 in patients with RF: finding that obtained were TT (59%), GT (34%), and GG (6.0%) and for control TT (45%) GT (40%), GG(15%). This analysis of data indicated the TT genotype homozygote at rs4821480 convenes independently a threatening of RF than does the GT and GG genotypes. a variation in the genotype at rs3752462 was shown in patients with RF: CC (4.8%), CT (73.2%), and TT (22.0%).

Conclusion: The outcomes indicate that the CT genotype at rs3752462 confers independently a risk factor of RF than those of TT and CC genotypes. There is no significant correlation between distribution of alleles and age, sex, resident, jobs, smoking habit, family history, body mass index (BMI), and medical history (P>0.05).

Keywords: MYH9 SNP, renal failure, allele distribution and genotyping.

Introduction

The elucidation of chronic kidney disease in the last period had been simplified for assessing its proof of identity and final explanation of chronic renal failure as it is correlated with drop of glomerular filtration rate over 3 months. in adult the diagnosis of renal failure confirm when filtration of kidney drop to “less than 60 mL/min/1.73 m²” and for rate less than 60 mL/min/1.73 m² can considered renal failure with some other signs that show renal defect as abnormal of x-ray or urine sediment or biopsy of renal alongside other finding 1.

For the progression of different renal diseases with aid of final attitude of recent researches that intact “actin cytoskeleton” is a crucial to maintain the typical purpose of podocyte building and filtration 2. The ‘nonmuscle myosin heavy chain 9 (MYH9) gene” translate “nonmuscle myosin protein”, which expressed in body cells and binds to “actin cytoskeleton” to achieve specific “intracellular motor functions” 3.

Former workings were indicted a number of kidney diseases such as “(May-Hegglin, , Fechtner and Sebastiana syndromes)” linking with MYH9 mutations, also approached to identifying the link between “podocyte injury and MYH9 mutations“, which suggested that mutation in this gene that cause fluctuations of protein then diminishing of the “glomerular filtration barrier”, from this defect “proteinuria and/ or haematuria” are developing, and even “renal failure” in advanced deterioration of kidney function 4, 5. And the effort of newly works of a “genome-wide association study (GWAS)” was recognized “MYH9” as a foremost predisposition gene for ESRD, in different kinds of nephropathy as ‘idiopathic focal segmental glomerulosclerosis, HIV-associated nephropathy and hypertension” in different ethnicities ‘(African-
Americans, Europeans and Hispanic Americans)" these works suggested a link between the glomerular function and MYS gene 6–9. "MYH9 gene", comprise from 40 "exons on “chromosome 22 q12.3-13.2”, its translate of “non-muscle myosin heavy chain protein” with approximately “224,000 kDa” molecular weight, this protein dimerizes to form a chief motor protein (motor domain of non-muscle myosin IIA), that distributed in various cells 10. This gene mainly expressed in “fibroblasts, erythroblasts, and kidney cells” 11. “cytoskeleton” impairment developed in a case of irregularity in “expression, positioning, or function” and as a result of this impairment “proteinuria, haematuria, or renal failure” developed as listed in several situations12.

Anomalous in “MYH9” expression considered major predisposing factor for developing and progression in the function of kidney according to the "genome-wide association studies (GWAS)” documentations that established on numerous nephropathies, including “idiopathic focal segmental glomerulosclerosis”, “human immunodeficiency virus” (HIV)- nephropathy. The previous relation verified in different society as “African-Americans and Hispanic Americans to Europeans” 13-16.

Results

The amplification outcome of rs3752462 with selected forward and reverse primer was 421 base pair band as figure (1) reveal.
According to the restriction digestion pattern of rs3752462 polymorphism which is revealed in figure (2 and 3), genotypes of rs3752462 were divided into 3 groups:

1- Two bands (243 and 178 bp) are homozygote (CC).
2- Three bands; (243, 92 and 86) are homozygote (TT).
3- Four bands (243, 178, 92 and 86) are heterozygote (CT).

Figure (2): Restriction digestion of PCR products demonstrating the patterns of different genotypes of MYH9 on 2% agarose, 100V; bands of 243+178 bp (CC), 243+92+86 bp (TT) and 243+178+92+86 bp (CT).

Figure (3): Restriction digestion of PCR products demonstrating the patterns of different genotypes of MYH9 on polyacrylamide gel; bands of 243+178 bp (CC), 243+92+86 bp (TT) and 243+178+92+86 bp (CT).

The product of rs4821480 PCR after incubated with restrictive endonuclease revealed fragment sizes of different alleles, figure (5) which are recognized as band of different size and accordingly the alleles are classified as follow:
Figure (4). RFLP pattern of Polymorphism (rs4821480) MYSgene genotypes. Restricted fragments were electrophoresed (lane A. ladder, lane B. GT allele, lane C. TT allele) Genotyping of MYH9 of rs4821480 are representing in table

Table (2) Comparison of Alleles and Genotype Frequency of (rs4821480) of MYH9 Polymorphism in renal disease and control groups

</tbody>
</table>

Allele distributions and Genotype of the MYH9 polymorphisms rs3752462 revealed that statistical variances between control and RF subjects were non-significant in terms of genotype or allele distribution. The most common one was CT with prevalence of 69.7% in control group and 73.2% in the RF group. the genotype of CC at rs3752462 is a lower risk of CKD than TT and CT genotypes that were suggested from current results. Findings refer to that genotype (CT) at rs3752462 is independent risk factor for CKD. This finding put forward that the CC genotype may be a defending reason against renal failure than
does the TT and CT genotypes.

There is no significant correlation between alleles distribution at rs4821480 and rs3752462 and Age, sex, resident, jobs, smoking habit, family history, body mass index (BMI), medical history (P> 0.05).

**Discussion**

In recent years from the effort of scientist work, there was increasing suggestion involved the beneficial of genetic factors on development and progression of a disease as widely considered to be a “polygenic” disorder. The conclusion about developing of many diseases related to environmental and genetic cooperated these factor lead to risk of developing the disease.

This work is directed to investigate one of genetic influencing factor associated with CKD so we select MYH9 SNP and its role on developing and progression of renal failure as these difficulties are predisposing to increasing in morbidity and mortality and reflected a health problem in society.

MYH9 gene which codifies the “myosin-IIA protein” that contain an “IQ domain” which responsible on its biological function these related to role of catalytic action of enzyme present in the podocyte foot that contribute to filament movement. In animal studies, mutations in MYH9 are related to “phenotypic kidney abnormalities including albuminuria and FSGS” 21-22, as well as defects in morphogenesis 23. The “pathogenesis” of MYH9-related kidney disease is not fully assumed. In spite of establishing the role of MYH9-related disorders transformation the “podocyte cytoskeleton” and as a result lead to “glomerular filtration barrier damage that basis for developing: proteinuria, hematuria, and finally to renal failure” 24. There was no significant variances between the healthy control group and the renal failure group in terms of “genotype or allele distributions at rs3752462 of MYH9 gene” and this similar to finding of Chinese study 25, but person who have CT genotype consider risky for development of CKD and need extensive care than other with CC or TT genotype so we can search for gene therapy and avoid the bad progression.

The association between MYH9 polymorphism and developing renal failure confirmed with other study 26-29

The Diagnostic Accuracy of Phalen Test and Prayer Test in Carpal Tunnel Syndrome

Suroso Agus Widodo¹, Fatchur Rochman¹, Ratna D. Haryadi¹, Patricia Maria K¹
¹Department of Physical Medicine and Rehabilitation, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo Teaching Hospital, Surabaya 60285, Indonesia

Abstract

Background of Study: Carpal Tunnel Syndrome is a series of symptoms and signs because of pressure on the median nerve in a small space in the wrist called carpal tunnel. In diagnosing CTS, it is required anamnesis and thorough physical examination which includes CTS provocation test, for instance Phalen test, Prayer test, and Tinel sign. The aim of this study is to reveal the diagnostic accuracy of Phalen test and Prayer test in diagnosing CTS.

Methods: The samples that fulfilled inclusion criteria were 19 subjects went through Phalen test, Prayer test, and nerve conduction study using CSI in Department of Physical Medicine and Rehabilitation Dr. Soetomo General Hospital Surabaya, Indonesia. The nerve conduction study using CSI was conducted by EMG Cadwell equipment. The data analysis was conducted by using SPSS software.

Result of the Study: The sensitivity of the Phalen test and Prayer test combination in diagnosing CTS was 94.1%. The specificity of Phalen test and Prayer test combination in diagnosing CTS was 100%. The positive predictive value was 100% while the negative predictive value was 66.7%. The result of person chi-square examination was obtained asymp. Sig value of 0.001 < α 0.05.

Conclusion: There was a correlation between the combination of Phalen test and Prayer test with CTS.

Keywords: Carpal Tunnel Syndrome, Combined Sensory Index, Phalen test, Prayer test,

Introduction

Carpal Tunnel Syndrome is a series of symptoms and signs because of pressure on the median nerve in a small space in the wrist called carpal tunnel. The common symptoms include numbness, paresthesia, or the pain in distributed median nerve in the hand ¹,².

CTS has been encountered by 3% of the entire population ³. CTS is considered the most frequent cases than other entrapment neuropathy⁴,⁵. There has been no specific data which specifies the number of CTS patients in Indonesia. However, there were 173 cases of CTS in Dr. Soetomo General Hospital Surabaya on October 2011 until September 2012. Only 55% of them (95 cases) visited the Medical Rehabilitation Unit. In addition, CTS is mostly encountered by females aged 40-60 years old (70%) as from 173 cases in Dr. Soetomo General Hospital Surabaya, 151 cases (87%) of the entire cases were females. CTS usually strikes both hands, however it is more severe in the dominant side of hand ⁶. The increase of carpal tunnel compression of 30 mmHg can cause venous congestion in nerve and interruptaxonal transport ⁷. Without adequate therapy, the nerve compression can cause median nerve damage with; consequently, the function of hands will be less or lost ¹.

The electro-diagnosis examination is the only method to find out the media nerve physiology caused by CTS and eliminate other diagnosis ⁷. Electrodiagnosis examination is considered as the golden standard to diagnose CTS. In fact, there are several electro-diagnosis methods in diagnosing CTS ⁸,⁹. One of the electro-diagnosis methods is CSI (Combined Sensory Index) that compare the median sensory nerve conduction to

Correspondence:
Fatchur Rochman
fatchurrochmanf@gmail.com

DOI Number: 10.37506/ijfmt.v14i2.3224
ulnar and radial nerve. This CSI method has the highest sensitivity and specificity than other electro-diagnosis methods. However, most hospitals in Indonesia still cannot conduct such examination method due to the unavailability of EMG machine. In diagnosing CTS, it is required anamnesis and thorough physical examination which includes CTS provocation test. The CTS provocation tests that are usually conducted in the Medical Rehabilitation Unit Dr. Soetomo General Hospital Surabaya, Indonesia are Phalen test, Prayer test, and Tinel sign. The aim of this study is to reveal the diagnostic accuracy of Phalen test and Prayer test in diagnosing CTS.

Method

This study was an observational analytic study conducted using Cross Sectional approach in Department of Physical Medicine and Rehabilitation Dr. Soetomo General Hospital Surabaya, Indonesia since November 2012 until January 2013. The sample was collected on the basis of consecutive sampling. The samples of this study were CTS patients who fulfilled inclusion criteria (patients with CTS symptoms aged 20-60 years old, no movement limitations in upper limb joins, understood and followed the test rules, and fulfilled the requirements in following nerve conduction examination) and signed the informed consent forms. Nineteen subjects who fulfilled the inclusion criteria encountered Phalen test, Prayer test, and nerve conduction study using CSI on the same day. The nerve conduction study using CSI was conducted by using EMG Cadwell equipment (xx, yy, zz). The study protocol was approved by the Ethical Commission to conduct basic science/clinical research in Dr. Soetomo General Hospital Surabaya. The analysis of data was conducted by using SPSS software (SPSS, Inc., Chicago, IL).

CSI: ........
The samples were all females with the average age of 51.7, with the age range of 45–59 years old. The average BMI was 25.4, with the BMI range of 20.89-32.24.30% of samples worked as employees in particular cigarette factory in Surabaya, 20% of them worked as housemaids, 20% of them worked as housewives, and 10% of them worked as private practice midwives (Table 5.1). On the average, the subjects have encountered CTS symptoms for 19.3 months.

From 19 hands, 17 hands of them (89.5%) suffered from CTS while 2 other hands (10.5%) did not encountered CTS From 17 hands that suffered from CTS, 14 (82.4%) obtained positive Phalen test and 3 (17.6%) obtained negative Phalen test. The correct positive predictive value was 14 while the false positive value was 0. Moreover, the false negative was 3 (table 5.2).

We obtained the sensitivity value of Phalen test in CTS was 82%. The specificity value of Phalen test in CTS was 100%. The positive predictive value was 100% while the negative predictive value was 40%. The AUC value of Phalen test was 0.912 (Figure 5.1). From 17 hands that suffered from CTS, 15 (88.2%) of them were with positive Prayer test result and 2 (11.8%) of them were with negative Prayer test result. The correct positive value was 15 while the correct negative was 2. The false positive was 0 while the false negative was 2 (table 3).We obtained the sensitivity value of Prayer test in CTS was 80% while the specificity was 88%. The specificity of Prayer test in CTS was 100%. The positive predictive value was 100% while the negative predictive value was 50%. The value of AUC in Prayer test was 0.941 (Figure 5.2).

From 17 hands that suffered from CTS, 16 (94.1%) were the combination of positive Phalen test and Prayer test result and 1 (5.9%) were negative. The correct positive value was 16 and the correct negative was 2. The false positive was 0 and false negative was 1 (Table 5.4). We obtained the sensitivity value of the Phalen test and Prayer test combination in CTS 94.1 %. On the other hand, the specificity of the Phalen and Prayer test combination in CTS was 100%. The positive predictive value was 100% while the negative predictive value was 66.7%.
To examine the correlation between Phalen test and CTS was conducted through Pearson Chi Square examination. The result of person chi-square examination was obtained asymp. Sig value of 0.012 < α 0.05. It meant that there was a correlation between Phalen test and CTS.

To examine the correlation between Prayer test and CTS was conducted through Pearson Chi Square examination. The result of person chi-square examination was obtained asymp. Sig value of 0.004 < α 0.05. It meant that there was a correlation between Prayer test and CTS. To examine the correlation between Phalen and Prayer test with CTS was conducted through Pearson chi-square examination. The result of person chi-square examination was obtained asymp. Sig value of 0.001 < α 0.05. It meant that there was a correlation between the combination of Phalen test and Prayer test with CTS.

**Discussion**

All the samples were females with average age of 51.7 and with the age range between 45 – 59 years old. This demographic data was based on the result of Craig and Richardson’s study in 2011 which asserted that women are more likely to have carpal tunnel syndrome than men. They further stated that carpal tunnel syndrome is most frequently diagnosed between the ages of 40 and 60. Women are more likely to have carpal tunnel syndrome than men because the size of carpal tunnel is smaller than men’s.

The average BMI in this study was 25.4, between the ranges of BMI 20.89–32.24. Obesity is one of the factors for carpal tunnel syndrome. The risk of having CTS will increase in obesity patients. In individuals with BMI >29, the CTS risk increases 2.5 time compared to individuals with BMI <20.

All the subjects had works that required them to do repetitive motions in their wrists. 30% of the research samples worked as employees in particular cigarette factory in Surabaya. Employees of cigarette factory are much related to repetitive motions to all directions using their wrists. 20% of the samples worked as housemaids that were also related to repetitive motions. 20% of them worked as housewives and 10% worked as private practice midwives. The number of CTS risks will increase in the workers that require them repetitive and excessive hand movements.

The diagnostic test with sensitivity and specificity value of > 50 % is considered high and proved to diagnose a particular disease. The diagnostic accuracy of Phalen test and Prayer test in this study was reported in ROC (Receiver Operating Curve). The most important section in ROC is the measurement result in Area Under Curve (AUC). The vast of AUC was used to assess how accurate a diagnostic test was. A diagnostic accuracy of a test was considered high if it had the AUC value of 1.

The sensitivity value of Phalen test in CTS was 82% whereas the specificity was 100%. The value of AUC in Phalen test was 0.912 (near 1). The sensitivity in Prayer test in this study was 88% while the specificity was 100%. The AUC value of Prayer test in CTS was 0.941. It meant that Phalen test and Prayer test had high accuracy to detect the occurrence of CTS due to the value of sensitivity and specificity was each > 50% and the value of AUC was nearly 1.

The hypothesis of this study stated that Phalen test and Prayer test had high diagnostic accuracy sensitivity, and specificity in diagnosing CTS. The result of this study supported the previous study that was conducted by J. Bruske et al. about the sensitivity and specificity of Phalen and Tinel test in CTS. These samples of their study were 147 hands of 112 patients who underwent CTS operation in General and Hand Surgery, Pomeranian, Polandia from 1993 -1998. The CTS diagnosis was on the basis of electro-diagnosis with the nerve conduction study (the median sensory nerve conduction speed < 40 m/s and distal motor latency > 0.6 ms/cm). The sensitivity in Phalen test in J. Bruske et al.’s study was 85% while the specificity was 89%.

In this study, in sensitivity and specificity in Phalen test was higher than the result of J. Bruske et al. It was because, in our study, we applied electro-diagnosis examination using CSI that had higher diagnostic accuracy, sensitivity, and specificity than J. Bruske et al.’s study.

Sayeeda Bilkis, et al. in 2012 conducted a study in 66 hands of 37 patients aged more than 18 years old which found the sensitivity Phalen test of 50 %, while the specificity was 100%. Electro-diagnosis examination was considered as the golden standard. The electro-diagnosis method that was used in this study applied CSI method, in which it was the difference in peak latency between the ulnar nerve and the median nerve from the
palm of the hand to the wrist. The electro-diagnosis was considered positive if the difference in peak latency between the ulnar nerve and the median nerve from the palm of the hand to the wrist with 8 cm showing the difference of >0.3 ms\(^{15}\).

We found that the sensitivity in Phalen test was 82% which was higher than the study conducted by Sayeeda Bilkis et al.\(^{15}\). It was because we added up the comparison of the ulnar nerve and the median nerve from the palm of the hand to the forth finger, the comparison of the radialis nerve and the median nerve from the palm of the hand to the thumb, the comparison of the ulnar nerve and the median nerve from the palm of the hand to the wrist with the distance of 8 cm.

Filip Georgiew, et al.\(^{16}\) conducted a study in 215 hands from 163 CTS patients, who were confirmed by electro-diagnosis examination, stated that the sensitivity of Phalen test depends on the severity of CTS. The more severe the CTS is, it will be more sensitive. In the very mild CTS, the sensitivity in Phalen test was 63%. In the mild CTS, the sensitivity in Phalen test was 78.7%. In the medium CTS, the sensitivity in Phalen test was 97.3%, while in the heavy and very heavy CTS, the sensitivity in Phalen test was 100% (14). Because of sample limitations in our study, we did not calculate the sensitivity of Phalen and Prayer test with the CTS severity.

The result of the study stated that the sensitivity of Prayer test (88%) was higher that Phalen test (82%). It was in accordance with Denis Cerimegic et al. from Departemen Neurology of Dubrofnik, Croasia in 2010 \(^{17}\). They conducted a nerve conduction study in CTS patients in three positions: neutral position, maximum extension and maximum flexibility from the wrist. It was examined the motorist nerve conduction and sensory in median nerve in the wrist area. The electro-diagnosis result in the extension position of the wrist (Prayer position) was worse than other two positions \(^{17}\).

This study was expected in giving the benefits from scientific knowledge and enriching the information about the diagnostic accuracy, sensitivity, and specificity in Phalen and Prayer test in diagnosing CTS. In addition, it provides the contribution in the development of diagnosis management and therapy towards CTS patients. Phalen test and Prayer test had sensitivity, specificity, and diagnostic accuracy in diagnosing CTS. In the hospitals that have not provided electro-diagnosis equipments, CTS diagnosis can be conducted with thorough anamnesis, and the right combination of Phalen test and Prayer test.

**Conflict of Interest**: There is no conflict interest

**Source of Funding**: This study is self-funded

**Ethical of Clearence**: This study was approved by Ethical Commision of Health Research Faculty of Medicine University of Airlangga

**Conclusion**

1. The sensitivity of Phalen test in diagnosing CTS was 82%.
2. The specificity of Phalen test in diagnosing CTS was 100%.
3. The sensitivity of Prayer test in diagnosing CTS was 88%.
4. The specificity of Prayer test in diagnosing CTS was 100%.
5. The sensitivity of the Phalen test and Prayer test combination in diagnosing CTS was 94.1%.
6. Prayer test was more sensitive in diagnosing CTS than Phalen test was.
7. The combination of Phalen test and Prayer test in diagnosing CTS had higher sensitivity value than Phalen test itself or Prayer test itself.

Conservative & Operative Management of Tuberculous Spondylitis in Children

Teuku Arief Dian1, Komang Agung Irianto2

Department of Orthopedics And Traumatology Faculty of Medicine Universitas Airlangga. Dr. Soetomo Teaching Hospital Surabaya 60285 Indonesia,

2Department of Orthopedics And Traumatology Faculty of Medicine Universitas Airlangga. Dr. Soetomo Teaching Hospital, Jalan Mayjen Prof. Dr. Moestopo 47, Surabaya 60285, Indonesia

Abstract

Background: Tuberculosis is a deadly disease worldwide. Tuberculosis usually occurs in the lung, but there are other tuberculosis most commonly afflicted by the patient and involves the spine and is called tuberculosis of bones and joints. Management of tuberculous spondylitis is conservative and operative.

Aim: This study aimed to compare the results of conservative and operative therapy in the management of tuberculous spondylitis in children.

Methods: The sample used was teaching with tuberculous spondylitis in Dr. Soetomo General Hospital who underwent operative and conservative therapy that became group 1 and group 2. Inclusion criteria included patients aged <18 years old, suffering from tuberculous spondylitis by conservative or operative therapy in Dr. Soetomo Hospital.

Results: In patients receiving conservative therapy, the Visual analog scale (VAS) decreased significantly (p = 0.001), while frankle improved but not significantly (p = 0.157). Cobb’s angle of patients receiving conservative therapy increased significantly (p = 0.007). Patients who received operative therapy showed significant improvement of VAS and Frankle (p = 0.001 and p = 0.011). The patient’s Cobb’s angle after surgery decreased but it was not significant (p = 0.575).

Conclusion: The role of surgical action has an important role in the treatment of tuberculous spondylitis and gives better results than conservatives in patients with pain, neurological deficits and Cobb’s angle progression.

Keywords: Cobb’s angle, neurological deficits, tuberculosis, spondylitis, VAS

Introduction

Tuberculosis is still one of the most deadly diseases in the world. According to the world health organization (WHO) in November 2010, one-third of the world’s population is estimated to be infected with tuberculosis germs. Tuberculosis manifestations are usually confined to the lung. However, it can affect any organ such as bone, genitourinary tract and central nervous system known as extra-pulmonary tuberculosis 1. Tuberculosis of bones and joints accounts for 35% of all extrapulmonary tuberculosis cases and most often involves the spine of about 50% of all cases of bone tuberculosis. Spinal involvement is usually a result of hematogenous spread of the pulmonary lesion or from infection of the genitourinary system 2.

Corresponding Author:

Email: komangagungirianto@gmail.com
Spinal involvement differs in both children and adults because the adult spine is already static because it is not in the growth phase, whereas the spine in the child is dynamic which means that the child’s bones are cartilaginous. Moreover, in the growth phase, if it is exposed to tuberculous spondylitis, it will have an impact morbidity; thus, it can affect the growth of course. Both conservative and operative management actions have distinct handling and are still controversial.

The average incidence rate of tuberculous spondylitis in children is not known for certain, but it is estimated that 5%−10% of children under 5 years are infected with tuberculosis and half of it occurs in the spine as a secondary manifestation with its primary manifestation usually originating from the lung or urogenital tract. A patient’s history and clinical symptoms are important, but it was not always reliable for early diagnosis.

Neurological deficits in tuberculous spondylitis result from the formation of cold abscesses, granulation tissues, necrotic tissue and sequestrum bone or intervertebral disc tissue and occasionally vascular thrombosis of the spinal artery. Tuberculous spondylitis is a chronic disease and slow to progress with long-lasting symptoms. Management of tuberculous spondylitis is still much difference of opinion between conservative and operative. Some authors recommend the administration of drugs only, while others recommend drugs with surgical intervention. Aggressive decompression, 12 months of anti-tuberculosis drug delivery and spinal stabilization can maximize the preservation of neurological function. However, anti-tuberculosis drugs have a major role in their treatment, but surgical procedures also have their own role in the treatment of tuberculous spondylitis. Conservative treatment cannot prevent the risk of progressivity from kyphotic deformity. Surgery is indicated if there are spinal deformities, neurologic deficits, tuberculosis abscesses and conservative treatment failure. Then, the aim of this study to compared the results of conservative and operative therapy in the management of tuberculous spondylitis in children.

**Method**

This study used an observational analytic research design. The research design used was pre and posted tested controlled group design. Researchers only evaluated the results of conservative therapy and operative action in the management of tuberculous spondylitis in children performed at SMF Orthopedic Dr. Soetomo Teaching Hospital Surabaya. The study was conducted in January 2010 until December 2012.

The sample used was all patients with tuberculous spondylitis who underwent conservative or operative therapy in Dr. Soetomo Teaching Hospital. The samples were divided into two groups. Inclusion criteria included patients aged <18 years old, suffering from tuberculous spondylitis by conservative or operative therapy in Dr. Soetomo Teaching Hospital and willing to participate in this research. The exclusion criteria included no other neuromuscular disease disorders, neurological disorders both central and peripheral, and patients who refused to participate in the study.

The procedure of sampling were patients with tuberculous spondylitis visited to orthopedic unit or patients who were consulted from other inpatients to orthopedic hospitalization at Dr. Soetomo Teaching Hospital Surabaya, the patients underwent clinical, laboratory and radiological examination to diagnose tuberculous spondylitis.

All the data collected were in tabular and statistically processed using SPSS 20.0 (SPSS. Inc. Chicago IL). To compare the pain threshold value (VAS), neurological deficits (Frankle) and Cobb’s angle before and after in conservative therapy and operative action in the management of child tuberculous spondylitis used paired t-test. To compare the change of pain threshold value VAS neurological deficit (Frankle) and Cobb’s angle between conservative therapy and operative action in the management of child tuberculous spondylitis used independent sample t-test and the significance level (α) was set at 0.05. It was statistically significant if p <0.05.

**Result**

**Patient Distribution Based on Treatment Action**

The distribution of conservative and operative patients found that the number of patients was 15 cases with 54% percentage for conservative and 13 operative cases with the percentage of 46% of the total treatment of 28 patients. Its showed that operative action was conducted at one stage of operation. The most action was debridement with bracing installation of 6 cases with 46% percentage. Action with cast, fibular graft and posterior stabilization were 2 cases each with 15% percentage and debridement action with anterior stabilization was 1 case with 7% percentage on table 1.
Patient Distribution Based on Gender and Age

Gender distribution was found that the number of male patients was 16 cases with the percentage of 57% for conservative and 12 operative cases with the percentage of 43% of the total treatment of 28 patients. Then, distribution of patients by age group found that the number of age group of 6–10 years old mostly suffered from tuberculous spondylitis with the amount of 11 cases with percentage of 39%, followed by the number of age group 0–5 years old with the number of 9 cases with the percentage of 32%, age 11–15 years old of 5 cases with percentage 18% and age group 16–18 years old of 3 cases with percentage 11% from total treatment of 28 patients on the table 2.

Patient Distribution Based on Pain Scale (VAS)

Distribution of patients based on the pain scale (VAS) found that most patients with 7–8 pain scale were 12 cases with a percentage of 43%. The pain scale of 4–6 was 10 cases with percentage of 36%, 4 cases with pain scale of 9–10 with percentage of 13% and 1 case each with pain scale of 0–1 and 2–3 with percentage of 4% (Table 2). From 28 subjects, 15 cases were categorized as conservative therapy groups and 13 cases were categorized as operative group (Table 1).

From that table, it showed, distribution of patients based on neurological deficits found that patients with no neurological deficit (Frankle E) were 11 cases with a percentage of 39%. There were 17 cases with neurological deficit (Frankle A, B, C, and D) with details of 8 cases of Frankle D with percentage of 29%, 4 cases of Frankle C with percentage of 14% and 5 cases of Frankle A with percentage of 18%. From 28 cases evaluated, 15 cases were categorized as conservative therapy group and 13 cases were grouped as operative group (Table 1).
**Patient Distribution Based on Cobb’s Angle**

Distribution of patients based on neurological deficits found that patients with no neurological deficit (Frankle E) were 11 cases with a percentage of 39%. There were 17 cases with neurological deficit (Frankle A, B, C and D) with details of 8 cases of Frankle D with a percentage of 29%, 4 cases of Frankle C with a percentage of 14% and 5 cases of Frankle A with a percentage of 18%.

**Infected Vertebrae Characteristic**

Distribution of patients based on the affected vertebrae level was found that the thoracic and lumbar vertebrae sites were most affected by tuberculous spondylitis with an amount of 8 cases each with a percentage of 28.6%, followed by thoracolumbar and lumbosacral levels of each 4 cases with the percentage of 14.3%, while the cervicothoracic level area with the number of 3 cases with the percentage of 10.7% and the cervical area of 1 case with 3.6% percentage and not found one case in the sacral area of the total treatment of 28 patients (Table 1).

Characteristics of patients studied based on gender, age and level of pathological vertebrae, found that patients who received operative and conservative therapy were not significantly different in terms of gender ($p = 0.477$), age at diagnosis ($p = 0.756$), age at study ($p = 0.788$), and pathology level ($p = 0.539$). Due to the uniform sample, the analysis of the patient’s surgical or conservative results was valid for comparison (Table 2).

Correlation is significant at the 0.01 level (2-tailed)

From the table there is correlation that significant about age, location, and number. There is some segments that give outcome. Pathology affected by 2 segments upwards may make the cut of point for operative action (Table 3).

There was a significant difference in both the conservative and operative group of subjects in which subjects who underwent operative therapy experienced significant pain relief compared to subjects who underwent conservative therapy. This is consistent with several studies conducted in Indonesia. Another result stated that pain can be healed in tuberculous spondylitis which is undergoing surgery. Pain in the tuberculous spondylitis decreased at week four after undergoing operative therapy with debridement.

Comparative assessment of conservative and operative therapy in this study used a pain scale assessment with VAS, neurological deficits assessed by the Frankle classification and assessment of destruction of corpus vertebrae damage using Cobb’s angle. Assessment of the pain scale corresponds to the most frequent complaints in children who suffer from tuberculous spondylitis in daily life such as during sleep, sitting, standing and walking. Assessment of neurological deficits using the Frankle classification scale assessed by sensory and motor examination is also common in children with tuberculous spondylitis.

Not all tuberculous spondylitis has a neurological deficit. Neurological deficits can occur because of the active phase of the inflammatory edema, extra-dural compression to the posterior side of the abscess (pus, the caseous material/granulation, connective tissue granulation, sequester), the gibbus due to collapse of the infected vertebrae. Neurological deficits can’t be recovered due to spinal stenosis, direct compression of the gibbus itself or fibrosis contraction from epidural.

The pathology of tuberculous spondylitis is anterior to the destructive vertebral corpus. This destruction will cause the collapse of the anterior portion of the corpus vertebrae resulting in a sharp angle known as gibbus. Cobb’s angle assessment is important because it can be one of the prognostic factors in children. Moreover, it is appropriate to say that kyphosis is more common in children than in adults because its deformity in children is dynamic with progressive variation through growth, whereas in adults the deformity of kyphosis is static and it depends on the number of levels of the destructive vertebra. This is also supported by previous studies which suggest that conservative-treated tuberculosis spondylitis increases the deformity of kyphosis 10–150 with late kyphosis deformity.
Previous studies have suggested that the status of the posterior column and the type of fixation is a major factor in determining this kyphosis deformity. Kaplan’s classification method for assessing the severity of this Cobb’s angle is mild with angle <30°, moderate with angle of 30–60° and severe with angle >60°. Tuberculous spondylitis with severe kyphosis is very difficult to return to the normal value of kyphosis and required an operative reconstruction after healing process. Other studies suggest that at Cobb’s angle of >60°, anterior decompression action, shortening posterior and stabilization with posterior instrumentation are required. In this study, there are differences in subjects who receive conservative and operative therapy if it is evaluated based on evaluation of pain, neurological deficit and Cobb’s angle. The results of this study provide information on the importance of operative role in the treatment of tuberculous spondylitis.

**Conclusion**

The operative action gives better results than the operative actions of the assessment of visual analog scale (VAS), Frankle and Cobb’s angle. There was no correlation/difference in age, location and number of infected segments with conservative and operative action based on visual analytical scale (VAS) measurement, Frankle and Cobb’s angle.

A New Automated Approach for Early Lung Cancer Detection with Improved Diagnostic Performance – A Preliminary Analysis

Thavavel Vaiyapuri
Assistant Professor, College of Computer Engineering and Sciences, Prince Sattam bin Abdulaziz University, Alkharj, Saudi Arabia

Abstract—Lung cancer is becoming the major cause of cancer-related deaths in human worldwide and Saudi Arabia is not an exception. Therein the identification of potentially malignant lung nodules is essential for the diagnosis and clinical management of lung cancer. Unfortunately, in clinical practice, however, interpretation of Computed Tomography (CT) images is challenging for radiologists due to the large number of cases. It is therefore extremely important task to develop computer aided diagnosis (CAD) systems that can aid and enhance the radiologist to potentially reduce false positive (FP) findings. Even though numerous methodologies are proposed for CAD system in the literatures, the one proposed in this work will definitely stand out in improving the sensitivity and specificity for the detection of small nodules particularly in low dose CT images. This work attempts to employ the powerful tool, radiomics quantitative imaging features within curvelet domain to detect and characterize lung nodules with improved sensitivity and specificity. Subsequently, support vector machine (SVM) is used to learn the 2D stochastic and 3D anatomic features of curvelet coefficients and classifies suspected regions either as malignant or benign based on geometric, texture and intensity. A preliminary analysis of the proposed methodology is presented and compared against the metrics, sensitivity, specificity and accuracy on publicly available LIDC database to serve as a benchmark for future research efforts.

Keywords: Medical image Processing, Low-Dose Computed Tomography, Lung Cancer Detection, Computer-Aided Detection, Anisotropic Diffusion, Radiomic Image Features, Curvelet Transform and Support vector machine

Introduction

Lung cancer stands out among all other types of cancer with highest incidence rates and highest mortality rates in human worldwide. The prevalence is steadily escalating and alarming due to adoption of western lifestyle habits. Also, it is expected that in coming years lung cancer will represent a major public health problems. In practice, Lung cancers are reported at advanced stages and this dramatically diminishes the potential success of treatment and results in the death of around 50% of cancer patients within five years of the late diagnosis. If lung cancer is detected at its earliest stage, the five-year survival rate can reach 70%. These figures call for effective technique to detect lung cancer at early stage to reduce the mortality rate of the patient and improve their life expectancy.

In lung cancer research, CT has become the most sensitive imaging modality for the detection of pulmonary nodules, particularly since the introduction of helical multi-slice technology. In current clinical practice, Low-Dose CT is adopted for Lung Cancer screening to avoid the risks of ionizing radiation associated with CT. Unfortunately, the interpretation of Low-Dose CT images is challenging for radiologists to distinguish between benign and malignant nodules. Added to, the large number of cases and manual reading may cause error-prone and the reader may miss nodules and thus a potential cancer. Thus, there is a pressing need for the use of CAD systems that can aid/enhance radiologist workflow and potentially improve nodules detection.

Current CAD systems often only allow radiologists to visually describe the tumors or lesions and thus are limited to subjective and qualitative characterizations of
the tumors. This is because the algorithms employed in current CAD have high sensitivity that some non-nodule structures (e.g., blood vessels) are labelled as nodules inevitably in the initial nodule identification step. Since the radiologists must examine each identified object, it is highly desirable to eliminate these FPs as much as possible while retaining the true positives (TPs). Thus, it is very time-consuming for radiologists to perform extensive review of all available imaging data. As such, there is significant potential for improving diagnostic accuracy and efficiency through the use of more objective and quantitative approaches for tumor characterization.

One of the biggest emerging areas in recent years related to quantitative cancer screening and diagnosis is radiomics, which involves the high-throughput extraction and analysis of a large number of imaging-based features for quantitative characterization and analysis of tumor. The use of radiomics-driven approaches allows for a more objective and quantitative evaluation and diagnosis of cancer, which can significantly reduce inter-observer and intra-observer variability and improve diagnostic accuracy and efficiency compared to current qualitative cancer assessment strategies. A number of studies have shown that radiomics can be used to characterize tumors and can have clinical significance towards diagnosis.

Despite its potential for huge clinical impact, the current state-of-the-art radiomics techniques make use of pre-defined, hand-engineered imaging-based feature models based on texture, shape, and intensity, which can limit its potential for fully characterizing the unique traits and characteristics of lung cancer lesions as they are still largely based on specific visual traits that radiologists use for subjective interpretation. Therefore, an effective way that can identify and extract imaging features automatically compared to pre-defined and hand-engineered imaging feature models is expected to have potential in capturing tumor phenotype and improve lung cancer detection. Recently, Shen et al. and Kumar et al. have shown the feasibility of discovering radiomics using a deep convolutional neural network learning rather than using predefined, hand-engineered feature models. The main disadvantage of neural network methods lies in training process to adjust the network weights by supervised learning with standard training data. Secondly, the model performance is based on the large dataset employed for training process. Not only that, for each image in the training set, nodule structure needs to be precisely marked by a radiologist is mandatory process.

In this essence, the proposed work first investigates the association between radiomic features based on curvelet transform and lung tumor characterization. Next it employs machine-learning method, SVM to build radiomics-based multivariate classifiers for tumor characterization. Non-invasive and cost-effective radiomic data is expected to improve the histological classification and hence the treatment/thrapy, which in general could have a large impact in cancer care. Thus, the work here will serve as a promising prognostic tool for informing treatment choice and fostering therapy for lung cancer patients.

Proposed Methodology

Proposed Methodology

Considering and keeping in mind the detail survey review reported, the research methods for the proposed CAD system are devised with new efforts to utilize the effectiveness of radiomic feature model approach within curvelet domain as follows:

A. Image Processing

In practice, noise is the common problem in CT imaging under low dose protocol. Lot of studies have shown that noise on CT images is found to be Gaussian. Such degradations have a significant impact on the image quality and as a result, it affects the accuracy of CAD system even the experts with sufficient experience are not be able to draw correct and useful information from the images. Additionally, feature extraction, analysis, recognition and quantitative measurements become difficult and unreliable due to poor quality of images. Thus, the denoising and enhancement of the medical images become prime requirements for many practical applications.

From literature studies, it was clear that though several studies are based on noise filtering in the wavelet domain, they fail to give better results in edgy region because of generation of large wavelet coefficients even at fine scales and repeated at scale after scale, for the edges in the image. On the other hand, the anisotropic feature having the expertise particularly in preservation of edgy region in the denoising process will be considered to suppress noise and lung image enhancement. To improve the speed, the iterations of the diffusion filters are kept small but the diffusion factor is optimized with the trade-off between noise reduction and feature preservation.
B. ROI Extraction

Many of the earlier works employs predetermined threshold value to separate the lung from the surrounding anatomy. Nevertheless, there are also some works that employ optimal thresholding for this task. For example, Otsu’s thresholding method is based on the idea of finding a threshold value that minimizes the within-class variance of resulting foreground and background classes\(^{15}\). The method is robust, and it gives reasonable thresholding results in a vast variety of cases. However, this method has been shown to break down for a certain range of object-to-background pixel population ratios. With respect to this point, the current work refined Otsu’s thresholding employing fuzzy membership function. Subsequently, the edges of lung are restored to prevent the exclusion of peripheral nodules by applying rolling ball technique described by Silva Sousa et al\(^{16}\).

C. Pattern Recognition

Feature extraction is a significant step in the development of an automated characterization of lung nodules. Therefore, in this work, radiomic features are extracted using curvelets proposed by E. Candes and D. Donoho\(^{17}\). Curvelets are waveforms designed as an alternative to the widespread wavelet transforms. Unlike wavelets, has varying degree of localization in orientation with respect to the scale. This property makes curvelet transform capable of multi-scale representation in many directions and positions at each length scale. Also, curvelet takes less number of coefficients for handling discontinuities\(^{18}\). These features of curvelets motivate the usage of curvelet in this work with an objective to efficiently capture the finest curves within the textured medical image with respect to different scales and orientations. In the proposed system, radiomics features includes tumor intensity histogram (e.g., high or low contrast), tumor shape (e.g., round or spiculated), texture patterns (e.g., homogeneous or heterogeneous), as well as descriptors of tumor location and relations with the surrounding tissues (e.g., near the heart). Each of these features will be calculated for three levels of resolution and for each curvelet matrix based on each radial ‘wedge’ (16 angles).

To reduce the dimensionality of the feature space and further reduce the FP rates, SVM is applied in this work to analyze the feature variance and select the relevant features. The SVM finds hyperplane that separates various classes of nodules using Support Vectors\(^{19}\). These support vectors are transformed to a feature space with a nonlinear transformation. The non-linear transformations are represented with kernel function. The kernel function is used to map the input space to feature space. Here, the Morlet Wavelet kernel\(^{19}\) given below, is used as kernel of SVM Classifier

\[
K(x) = \cos(1.75x) \cdot e^{\left(\frac{x^2}{2}\right)}
\]

D. Evaluation Metrics

The accuracy, sensitivity, specificity, and area under the receiver operating characteristic (ROC) curve\(^{22}\) will be employed to as validation metrics to evaluate the performance of the classifier. Here, the sensitivity (true positive rate, TPR) represents the number of true positives divided by the total number of positive cases. The specificity to measure the number of false positive rate. The accuracy (ACC) is the proportion of true results in the population. Finally, the ROC curve to visually illustrate the sensitivity and FP rate for different threshold values.
Figure 1 Illustrates lung nodule detection process on slice number 45 of patient ID LIDC-IDRI-0191. (a) Original DCOM Image (b) Enhanced Image using diffusion filter domain (c) Segmented Binary Lung Image using Fuzzy K-means (d) Binary Image with lung boundary corrected using Rolling ball technique (e) boundary delineating the lung in Original Image (f) Segmented Lung Image (g) Lung Nodule

Experimental Design for Preliminary Study

A preliminary study was conducted to validate the feasibility of the proposed system adopting the publicly available LIDC database at in the National Biomedical Imaging Archive (NBIA)20. This database contains a greater number of subtle and irregularly shaped nodules. Also, the database contains ground truth information obtained from multiple radiologists. This dataset is composed of 1010 patients CT exams with 1500 nodules. LIDC case LIDC-IDRI-0001 through LIDC case LIDC-IDRI-0150 was considered to train the proposed CAD system. LIDC case LIDC-IDRI-0175 through LIDC case LIDC-IDRI-0200 was considered to test the proposed CAD system. During the experiments, the selected training images were also included in the testing stage for the proposed system. The ground truth information annotated by multiple radiologists was used to verify the correctness of the proposed system.

As, reduction of the feature vector is imperative to avoid SVM over-fitting and to obtain a manageable feature space, the preliminary experiments validated the system for several resolution levels and support vector kernels. Initially, three levels of resolution were investigated. A feature vector averaged over co-occurrence directions (99 total features) was compared
with a feature vector averaged over both co-occurrence directions and curvelet details (33 descriptors). The feature vector averaged over both co-occurrence directions and curvelet details was discovered to be ideal. The following sets of descriptors were calculated: features on individual levels of resolution (1, 2, or 3, each with only 11 descriptors), features based on two levels.

**Results and Discussion**

The results obtained from preliminary experimental settings are shown in Fig. 1 for the patient-id LIDC-IDRI-0191 and slice number 45. Although the preliminary results of our proposed system are encouraging and is expected to improve the specificity and sensitivity in Lung cancer diagnosis, we need more cases to test for generality. We will continue to perform additional testing and training with CT cases comprising nodules of various sizes and shapes available in the image database I-ELCAP. More importantly, extensive performance comparison between proposed system and radiologists will performed to evaluate the role of this system in clinical practice.

Next, since the nodules detected with the proposed CAD system were included in the reference standard, the study results could be potentially biased toward making the proposed CAD appear more accurate than it really is. But at this point, we are unable to confirm or reject the influence of this potential bias based on our preliminary study results. Therein, CT cases with complex nodule structures will be identified and considered for testing. The detection of such abnormal nodules may require a modification of current CAD implementation or an introduction of new algorithms or fine-tuning of parameters for the current system.

In future work, focus of attention will be put to improve the clinically relevant performance measures, sensitivity-specificity calculus of the proposed CAD systems. In this regard, systematic study will be performed to assess the relative weights and valid ranges of parameter values on the detection performance of the proposed system. We have planned to evaluate the ability of the classifier in the task of differentiating nodule candidates that correspond to actual nodules from false-positive candidates.

**Ethical Clearance:** The proposed work is a retrospective study that uses images from the public database archives. Therefore, there was no requirement to obtain any Informed consent from the institutional review boards.

Validity of Star Excursion Balance Test as Dynamic Balance Test In Subjects with Non-Operative Anterior Cruciate Ligament Injury

Yudith Dian Prawitri¹, Imam Subadi¹, Bayu Santoso¹*
¹Department of Physical Medicine and Rehabilitation, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo Teaching Hospital, Universitas Airlangga, Surabaya, 60285 Indonesia

Abstract

Background: The anterior cruciate ligament (ACL) injury is the most common knee injury that might occur during exercise. An ACL causes a balance disorder that can be considered as a risk factor for recurring injury. Identification of balance disturbances in subjects with ACL injury should be conducted to minimize the risk of re-injury.

Objectives: this study aims to determine the validity of star excursion balance test with biodex balance system SD as a gold standard

Method: This study is a diagnostic test with cross-sectional study approach. The number of research sample was 20 respondents selected as control group, five people with ACL injury as the case group. All subjects were examined with the biodex balance system SD (Overall Stability Index) and star excursion balance test (% MAXD).

Results: The result of the correlation analysis between the overall stability index and %MAXD was not significant with r = -0.316; p = 0.175. Hence, the cut-off point could not be determined due to the insignificant correlation, thus the sensitivity, specificity, positive predictive value, and negative predictive value of the star excursion balance test could not be determined.

Conclusion: Star excursion balance test was invalid as a dynamic balance test if the Biodex Balance Test SD was used as a gold standard.

Keywords: validity, overal stability index, %MAXD, anterior cruciate ligament injury

Introduction

Sports injuries are the most common type of injury. Researches have stated that the number of sports injuries make up about 21% of the injury cases in the world. Sports injuries can lead to long-term disability or dysfunction especially in patients with knee injuries. The most often structures involved are the anterior cruciate ligament (ACL) injuries in 20% of the knee injury incident, and 46% of the knee ligament injury incidences. An anterior cruciate ligament injury results in knee instability, which inhibits an athlete from playing in the field and can lead to early retirement ¹,².

The anterior cruciate ligament injury causes a proprioceptive disorder and it is suspected to be caused by mechanocarpeptic damage to the joints and ligaments. Sensory input from proprioceptive, vestibular, and visual plays a role in maintaining static or dynamic balance. Proprioceptive, vestibular, and visually impairment can lead to a imbalance in the body. Identification of a balance disorder in subjects with ACL injury should be performed to minimize the risk of re-injury ¹–³.

Dynamic balance plays a pivotal role as the athlete moves and reacts quickly to the conditions...
that occur in a sports game. Athletes often experience a perturbation that disturbs his balance either from an opposing player or from himself as he changes position and direction. The perturbation is strong and requires stability. Athletes with a good balance have superior performance compared to ordinary people. Dynamic balance disturbances have been reported as a result of injury to athletes. Standardized assessment to measure and evaluate balance is needed to determine an athlete’s readiness to return in the field 4,5.

The identification of balance disorders can be assessed in various ways, i.e., clinically, by tools, or by using a valid and reliable scale. Objective examination to determine the condition of balance can be done by using biodex balance system SD. This tool can be used to assess the balance in static format and semi-dynamic. Stability index (SI) is obtained from the dynamic balance test to determine how well the patient controls their balance in both anterior/posterior (A/P) and medial/lateral (M/L) directions. Balance assessment is expressed by overall stability index (OSI). Biodex balance system SD is a valid and reliable tool for assessing dynamic balance6,7.

The most common test used for balancing in athletes is the star excursion balance test (SEBT). This test requires balance on one foot of support (single leg stance) to achieve the maximum range that can be reached by the opposite leg. The distance that can be reached by the participants is an index of dynamic balance. The further the distance, then the balance control is also better. The mean value of the reach distance (% MAXD) is a description of the dynamic balance value. Star excursion balance sensitive test identifies a reach distance deficit as a dynamic balance in subjects with chronic ankle stability, patellofemoral pain syndrome, and anterior cruciate ligament deficiency. Implementation of this test uses a simple tool, thus it can be done anywhere. SEBT is a potential option as a cost-effective tool and reliable to assess the balance deficit in various pathological conditions of the lower limbs 8. A study to assess the validity of SEBT in assessing dynamic balance has never been conducted before. Thus the researchers aim to determine the validity of star excursion balance test with biodex balance system SD as a gold standard.

**Method**

This research is an observational analytic study with cross-sectional study approach. The study was performed at the Rehabilitation Installation Unit of Universitas Airlangga Hospital Surabaya from July to October 2014. The sample unit was subjects with ACL injury that fulfilled the inclusion criteria (male patients with unilateral ACL injury for >6 weeks at the age of 17-30 years, having a minimum exercise routine of three times a week, able to understand and follow the instructions, and willing to participate in this research by signing an informed consent).

The subjects consisted of five patients with unilateral anterior ACL injuries and five healthy people as the control group, thus we obtained 20 respondents for the sample units. The balance assessment was performed with the biodex balance system SD and star excursion balance test. The examination was finished in a day. The protocol of this study was approved by Dr. Soetomo Teaching Hospital, Surabaya, Indonesia. Data analysis was performed using Pearson correlation test with SPSS for Windows version 17 (SPSS, Inc., Chicago, IL).

**Results**

**General Characteristics of Subjects**

The general characteristics of the subjects were shown in Table 1. The average age of the subjects in the control group was 26.60±3.24 years, and 23.20±3.73 years in the case group. The average height of the controls was 173.60±5.72 centimeters, and the average height of the subject with ACL injury was 169.40±5.27. The average weight of the control group was 70.40±11.17 kilograms and 65.00±5.37 kilogram on the subjects with ACL injury. The mean body mass index of the controls was 23.26±2.67 kg/m² and 22.74±2.56 kg/m² on subjects with ACL injury.

The Results of Overall Stability Index and %MAXD

The balance of the subjects that was measured using the biodex balance system SD produced the overall stability index (OSI) on both limbs of control and case groups. The results of OSI and %MAXD are shown in table 2.

OSI: overall stability index

MAXD: maximum distance

The mean of OSI in the control group was 0.55±0.097, with an OSI. The mean OSI on the injured subjects was 0.786±0.286. The balance of the subjects measured using the Star excursion balance test on both limbs of control and case groups resulted in %MAXD. The mean of %MAXD in the control group was 0.863±0.901 with a %MAXD. The mean of %MAXD in the case group was 0.772±0.076.

The Association of Overall Stability Index with %MAXD

The association of OSI with %MAXD was assessed using Pearson correlation test. Correlation analysis of OSI with %MAXD was not significant with r = -0.316, p = 0.175 (table 3.).

Table 3. Association of OSI with % MAXD

The cut-off point could not be determined due to the insignificant correlation, thus the sensitivity, specificity, positive predictive value, and negative predictive value of the star excursion balance test could not be determined.
The Difference of Overall Stability Index and %MAXD in Subjects with Anterior Cruciate Ligament Injury and Control Group

Overall Stability Index in control and case groups was tested using T-test, the difference was significant with \( p = 0.031 \). The% MAXD score in the control and case groups was analyzed using T-test, thus a significant difference was found with \( p = 0.025 \).

Discussion

This study applied the postural stability test protocol and a single leg stance. The normal value of OSI on subjects with the age of 17-35 years was 0.82-2.26. The OSI range below the upper limit of normal values in healthy subjects ranged from 0.4 to 0.7 and from 0.5 to 1.2 in the subjects with an injury. These findings showed that the normal range of values that was used could not distinguish the presence of a balance disorder in the case group. This was likely to occur because the normal values used were determined by the normal population at the age of 17-35 years. The subjects of the study were physically trained people, thus the physical performance was better than normal people who did not practice any regular physical exercise. Therefore, the OSI values obtained were smaller than the normal range of values that already existed. Determination of the OSI normal range in the physically trained subjects as in the athlete was necessary in order to detect balance disorders using BBS.

The balance of the subjects was measured using the star excursion balance test on both limbs of control and case groups that resulted in %MAXD. The %MAXD range in the control group ranged from 0.76 to 0.98, while it ranged from 0.66 to 0.83 in the case group. The cut-off point of %MAXD could be determined if there was a significant correlation with the value of the gold standard. The reference value of the overall stability index (OSI) as measured by the current biodex balance system could not be used to set subjects with high activity levels or athletes as the gold standard of balance. This is due to the absence of a normal range of OSI values in the athlete population or subjects with high activity level. Thus, this study could not determine the cut-off point of % MAXD. Studies to determine the normal range of OSI values in a population of physically trained subjects such as athletes were required to be used as a reference in terms of the balance value in the population. The study to determine the normal value of %MAXD has never been performed, however, the assessment of the normal range of %MAXD component has been done previously, covering the distance assessment on anterior, anterolateral, anteroposterior, posterior, posteromedial, medial, and anteromedial. Research to determine the reliability needs to be performed before the study to determine the normal value of %MAXD in the athlete population was performed.

There was no significant correlation between OSI with %MAXD; OSI showed semi/dynamic balance, meanwhile, MAXD showed dynamic balance. The results of this study differed from the research by Bakhtiari (2012) that a significant correlation was found between static balance as assessed by flamingo balance test and dynamic balance assessed by SEBT.

The OSI assessment was obtained from an examination with the biodex balance system SD (BBS), the subjects were asked to stand on one foot on a fixed platform then maintained a single-leg stance while adjusting the position of the balance point drawn on the screen. There was no change in the center of gravity and in a base of support, thus the balance assessed using BBS was a static balance. In contrast to SEBT, subjects were required to stand on the limbs, while the contralateral limbs tried to reach the range as far as possible in the prescribed direction and then returned to the starting point by maintaining a balance on the limb of the pedestal. The test described the dynamic balance of the ability to maintain a balance when the body performed a functional movement.

Static balance control is required to maintain anti-gravity positions such as standing or sitting whereas dynamic balance is necessary to stabilize the body when the surface while the body rests or when the body moves on a stable surface. There might be sudden changes (perturbation) of balance when a person is currently conducting an activity, thus a balance disorders occurs. When a perturbation happens in healthy people, then the body reacts with a variety of mechanisms in order to maintain the balance, it depends on the direction and magnitude of perturbation experienced by the person. If the perturbation is small or occurs slowly or when standing still, then the ankle creates a movement in an effort to center the mass in a stable position. If the perturbation occurs suddenly and strong or while performing the movement, thus the hip is used to maintain the balance. Previous research reported that inappropriate static balance assessments were used...
to assess dynamic balance in the absence of movement at the center of gravity due to the response of muscular activity 12. However, this study found no significant correlation between OSI and %MAXD. The absence of significant correlation caused the cut-off point of SEBT to not be able to be determined. Therefore, the sensitivity, specificity, positive predictive value, and negative predictive value of star excursion balance test could not be determined.

The star excursion balance test is considered sensitive in detecting deficits of dynamic balance in patients with leg injuries such as chronic ankle instability (CAI), ACL injury, and patellofemoral pain syndrome 8. There was no significant difference between the normalized reach distance between the control and case groups. The %MAXD score describing the dynamic balance in the subjects with ACL injury was lower than the control group in this study, there was a significant difference with p = 0.025. Significant differences of balance index in subjects with ACL injury were obtained from the research by Herrington (2009) 2 compared to the control group.

The study by Chen et al (2011) 13 compared the balance of 15 patients with CAI with the control group using SEBT. The reach distance of the control group was greater than the subjects with CAI. Another study found that subjects with CAI achieved a significantly smaller reach distance when resting on injured limbs compared to non-injured limbs as well as other subjects without CAI 2,13,14.

Significant differences were also found in the overall stability index score using the Biodex Balance System SD, where the OSI values of subjects with ACL injury were higher than the control group. This illustrates that the balance deficit in subjects with ACL injury could be identified with the biodex balance system SD tool and could be determined by star excursion balance scale.

**Conclusion**

Star excursion balance test is invalid to be used as a dynamic balance test when biodex balance system SD is set as the gold standard, in which star excursion balance test cannot be used to replace the biodex balance system SD.

**Ethical Clearance:** The study protocol was approved by the Ethical Commission to conduct basic science/clinical research in Dr. Soetomo General Hospital Surabaya, Indonesia. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice.

Abstract

Background: Adolescence is a transitional phase that causes biological, cognitive, social-emotional, and behavioral changes. One of the issues of concern is aggressive behavior in adolescents. Parenting styles and peer attachment are one of the factors that have an influence on potential aggressive behavior in adolescent boys.

Objectives To analyze the relationship between parenting styles and peer attachment to the potential aggressive behavior of adolescent boys.

Method: The subjects were junior high school male students who are cared for by both biological parents and can follow all of the research procedures. The research design was cross-sectional with total sampling technique. Subjects performed anamnesis related data self, parent demographic data, and peers. (PAQ), (IPPA) (BPAQ). The analyzes used were Pearson, Spearman, and Anova.

Results: The majority of parenting styles was permissive (34.06%; 48.00%). Parenting styles and peer attachments did not have a significant relationship with potential aggressive behavior (p = 0.798; p = 0.071; p = 0.695). There was a negative correlation of peer attachment with alienation dimension (p = 0.001). Other significant dimensions with potential dimensions of aggressive behavior were trust (p = 0.018; 0.022) and communication (p = 0.029; p = 0.000).

Conclusion: Parenting styles and peer attachments did not have a meaningful relationship with potential aggressive behavior in adolescent boys. However, there were some significant correlations between the dimensions of parenting and peer attachment with potential dimensions of aggressive behavior.

Keywords: Peer attachment, Parenting styles, Aggressive behavior potential, Adolescents.

Introduction

Adolescence is a transitional phase from child to adult. This transition leads to biological, cognitive, social-emotional, and behavioral changes. One of the issues of concern is aggressive behavior. Fighting behavior of male students in a year period of about 22.00% in Sweden, 44.00% in the United States, and 76.00% in Israel. In Indonesia, acts of violence and crime committed by adolescents increased from 3 thousand cases (2007) to 4 thousand cases (2009). The level of fights among students also increased from 108 cases (2008) to 327 cases (2014).

Aggressive behavior is one of the external behaviors of adolescents. Adolescent boys are 2.5 times higher in aggressive behavior than girl. Factors related to the emergence of aggressive behavior include the interaction between nature (heredity, biological) and...
nurture (experience with the environment, such as parenting and peer attachment). The interactions of both run continuously and influence each other causing an adjustment or adaptation. Parenting styles is one of the major predictors of child behavior, but there is no definitive and comprehensive theory of how parents shaped child development.

Social attachment with peers also contributes to the emergence of aggressive behavior. There is a positive correlation between peer attachment in the group with intentions of aggressive action in adolescents aged 13-16 years, determined by peer influence and self-selection, i.e., if the adolescent wants to take aggressive action then he will look for peer group which facilitates his actions or so should be. Peer attachment affects life satisfaction and well-being of adolescent.

**Method**

The subjects were the 8th-grade male students in SMP Negeri 1 Yosowilangun and SMP Negeri 1 Randuagung Lumajang Regency that meets the inclusion and exclusion criteria. The study design was cross sectional in May-June 2017. The sampling technique was total sampling with 127 students. To demographic data collection such as age, ethnicity, entering puberty or not, sex education source, presence/absence of abuse history, a form of abusive behavior, substance or drug use and never or not committing a crime. Prior to the identification of the subject first, the researchers conducted a test of ethics (No.135/EC/KEPK/FKUA/2017) in Dr.Soetomo Surabaya, Indonesia.

In the parenting styles variables, the subject will fill in the Parenting Authority Questionnaire (PAQ). This instrument consists of 10 statements measured by 5 points Likert (strongly disagree, disagree, neutral, agree, strongly agree). In his judgment, the total number of points for each type of parenting and mother’s parenting (authoritative, authoritarian, permissive, and combination) will be calculated.

The subjects will also conduct peer attachment examination using Inventory of Parent and Peer Attachment-Peer Version (IPPA) questionnaires. IPPA was a self-report questionnaire with 25 statements and the Likert 5-point answer format was almost never, rarely, sometimes, often, almost always.

*p value<0.05
Characteristics of Parents’s Basic Data

The majority of parent education was primary school with the father of 44.10% and the mother of 52.80%. As for the job, the majority of father was more as farmer (33.10%) and mother as housewives (52.00%). The largest parent’s income was Rp. 1,000,000, - up to less than Rp. 3,000,000, - (55.10%). Then, 26.80% of subjects said to have a family with violent behavior (table 1).

The relationship between Parenting styles with the Potential of Aggressive Behavior

The majority of parenting styles were permissive in the father (34.06%) and mother (48.00%) and other authoritative successive parenting (25.20%; 18.9%), authoritarian (22.00%; 21.3%), and combination (18.1%; 11.8%). The type of parenting in the father (p = 0.798) and the mother (p = 0.071) did not have a significant correlation with the total aggressive behavior potential level. In contrast to the pattern of foster parenting, maternal upbringing has a significant correlation with anger dimensions (p = 0.024) with combined parenting patterns showing higher anger levels than other parenting (Table 2).

The relationship between Peer Attachment and Aggressive Behavior Potential

Peer attachment has no significant correlation with potential aggressive behavior (p = 0.695). Only the alienation dimension has a negative correlation with potential aggressive behavior (p = 0.001). The dimensions of trust and communication have a significant correlation with verbal aggression (p = 0.018; p = 0.029) and hostility (p = 0.022; p = 0.000). The alienation dimension has significant negative correlation with anger (p = 0.006) and hostility (p = 0.001), with weak correlation strength (table 3).

Discussion

Father and mother’s parenting styles do not have a meaningful relationship with potential aggressive behavior. Other studies also have similar conclusions. The role of parenting is only marginal. Sometimes, the child is more easily affected by the mother than by the father. A low affection level in permissive parenting is also a predictor of declining external behavior problems, but increases the risk of internal behavioral problems later on 12.

Peer attachment is not related to potential aggressive behavior. This is in contrast to research in Malaysia, but the same conclusion is that there is a negative correlation between the alienation dimension and the potential for aggressive behavior 6. The dimensions of trust and communication are related to the dimensions of verbal aggression and hostility. This condition can also be explained by the child’s efforts to meet the needs of companionship with peers 13. Thus, although there are trust and communication but aggressive behavior can still occur 14. On the dimensions of verbal aggression associated with teen communication with peers. Although verbal, but the psychological effects on people who experience worse than physical aggression 15. While the alienation dimension is negatively related to anger and hostility. Children with withdrawal have a higher risk for internal behavioral problems that may lead to anxiety and depression 16.

Most of the subjects aged 14 years with Javanese, have been puberty and get sex education via the internet. At the age of 13-15 years was a puberty of men with information media also influential convey information about sex in adolescents 17. The educational and socioeconomic level of the subject’s parents was largely in the lower middle class which is one of the factors to the child’s aggressive behavior 18. Parents who give physical punishment/aggression to children become predictors of aggressive behavior in the future through the formation of aggressive fantasy. The majority of subjects have close friends with between 1-3 people, have a group of friends. The subjects mentioned that the behaviors that followed include involving brawl, damaging goods, violating the rules, and using alcohol/drugs together. The influence of peer groups or peers was very strong in adolescence. Teenagers who are part of a peer group were signs of adaptation and separation with parents as well as replacing the focus of loyalty to friends 19.

Foster parenting for most fathers and mothers is a permissive parenting pattern, which has a pattern of parenting with low responsiveness and demandingness. Permissive parenting patterns can make teenagers grow up as impulsive people, act at will, and relate to other less responsible behaviors 20. The average peer attachment value of the study subjects can be classified at moderate levels almost the same as in previous studies 9. The old attachment theory suggests that there was parental influence in the relationship of a child, but attachment to peers was known to have an effect when the child is in
adolescence \(^{21}\).

The old attachment theory suggests that there was parental influence in the relationship of a child, but attachment to peers was known to have an effect when the child is in adolescence \(^{6}\). Physical aggression is caused by several predictor factors such as gender, low family economic status, low maternal education, and a pattern of abusive care \(^{22}\).

**Conclusion**

Parenting styles and peer attachments did not have a meaningful relationship with potential aggressive behavior in adolescent boys. However, there were some significant correlations between the dimensions of parenting and peer attachment with potential dimensions of aggressive behavior.

**Conflict of Interest:** There is no conflict of interest.

Bacteriological Study of *Klebsiella pneumoniae* Isolated from Burn Patient in Al-Najaf City

Zahraa Hameed Oda Alquraishi¹, Basaad Abdzaid Al-Fatlawi²

¹College of health & Medical tech. / Kufa, Al-Furat Al-Awsat Technical University, 31003 Al-Kufa, Iraq, ²Department of Biology, Faculty of Science, Kufa University, Iraq

**Abstract**

A total of (60) clinical specimens were collected from patients suffering from various burns during the period from November 2018 to January, 2019. These specimens were collected from patients attending to Al-Furat Al-Awsat burn center during the studied period. All specimens were cultured on the MacConkey agar plates and incubated at 37°C under aerobic condition for 18 - 24 hour. In 60 patients, 36 (60%) were female and 24 (40%) were male. Several morphological, physiological and biochemical tests were made to identify bacterial isolates. Results showed that *K. pneumoniae* constitute 15 isolates (25%) of these isolates.

A collection of 15 *K. pneumoniae* isolates diagnosed by the morphological, cultural and biochemical characters, the identification was confirmed by molecular method for the presence of *magA*. The results showed that only 10 (66.6%) isolates was carrying *magA* which are diagnosed as *K. pneumoniae*. The results of antibiotic sensitivity screening test revealed that the isolates of *K. pneumoniae* exhibited highly sensitivity to Azithromycin, moderate sensitivity for Gentamicin and Imipenem while the findings showed absolute resistant to Erythromycin, highly resistant to Ciprofloxacin, Trimthoprime. According to this result it can considered that Azithromycin as best treatment against *K. pneumoniae*.

**Keyword:** Bacteriological, *Klebsiella pneumonia*, burn patient, clinical specimens and Al-Najaf City

---

**Introduction**

Burn wound infections are one of the most important and potentially serious complications that occur in the acute period following injury(1). These wounds are subsequently colonized with microorganisms, including gram-positive bacteria, gram-negative bacteria and yeasts, which derived from the host’s normal flora (gastrointestinal flora, upper respiratory flora) and from the hospital environment (2, 3). The risk of invasive burn wound infection is influenced by the extent and depth of the burn injury, various host factors, and the quantity and virulence of the microbial flora colonizing the wound(4). The common burn wound pathogens are, *Klebsiella spp.*, *Pseudomonas aeruginosa* and *Staphylococcus aureus*, which produce a number of virulence factors that are important in the pathogenesis of invasive infection(5,6). *Klebsiella pneumoniae* is widely distributed in the gastrointestinal, urinary, and respiratory tracts of healthy people. It cause opportunistic infections mainly nosocomial infections, it is a common hospital-acquired pathogen causing severe respiratory infections such as pneumonia. Other infections caused by this organism include urinary tract infection, wound infection, abscesses, sepsis, inflammation and diarrhea, most *K. pneumoniae* are hospital associated with a high fatality rate if incorrectly treated. Treatment of *Klebsiella* infections is complicated(7). *K. pneumoniae* have different virulence factors which give the bacteria the ability to invade the host, such as capsular polysaccharide, lipopolysaccharide, serum resistance, siderophore production, fimbriae and other factors such as the production of urea and enterotoxin(8). However, antibiotic resistance properties are the major factor in its pathogenicity that it resists for wide spectrum of antibiotics and specially β-lactam antibiotics. This is due to the prevalence of infections acquired in hospital which led to the orientation of the research on alternative therapies (9). Due to the common occurrence of *Klebsiella spp*. And high virulence that cause in the absence of accurate and early detection them, severe damage may lead to the death of the patient. The aim of this study was to determine the causative microorganisms of burn wound infection and antibiotic sensitivity.
2-Materials & Methods

-Specimens Collection:

A total of (60) clinical specimens were collected from patients suffering from various burns during the period from November 2018 to January, 2019). These specimens were collected from patients attending to middle Euphrates burn center during the studied period. All specimens were cultured on the MacConkey agar plates and incubated at 37°C under aerobic condition for 18 - 24 hour.

-Isolation and Identification of Klebsiella pneumoniae

All specimens were initially cultured on isolation media including MacConkey agar. After incubation of agar media for 24 hr. at 37°C, the suspected colonies of pure cultures were investigated. Then the bacteria were confirmed by an additional biochemical test with VITEK-2 compact system and P.C.R technique.

-Antibiotic Susceptibility Test

The detection of the susceptibility of Klebsiella pneumoniae to a group of antibiotics Kirby-Bauer discs diffusion method was carried out according to (11). A pure culture of previously identified bacteria was prepared by adding a growth from isolated colony to 5 ml of sterile normal saline in a cell density equivalent to turbidity of McFarland tube No. (0.5) which approximately equal to bacterial cells density of 1.5x10⁸ cells/ml. A sterile cotton swab was used to obtain inoculums to be streaked on Blood Muller Hinton Agar medium. The antibiotic discs were placed on the surface of the medium at evenly spaced intervals with flaming sterile forceps. Incubate the plate for 18 hr at 37°C. Antibiotic inhibition zone was measured by using ruler. Zone diameter was compared to standard results being recommended by clinical laboratory standards institute documentations.

-Molecular Study of Klebsiella pneumoniae

-Isolation of Bacterial Chromosomal DNA

Total DNA was extracted from colonies grown on agar plates by boiling method according to (12) with some modifications. One bacterial colony was scraped using sterile toothpick from surface of agar plates and suspended in 40 μl Tris-EDTA buffer. The suspension was heated for 15 min at 100°C followed by 5 min on ice rapidly. The suspension containing DNA was stored at -20°C until used as template for PCR.

-Primers Selection:

All primers in this study were synthesized by Bioneer company (Korea). The sequences of this primer were magA: F5'- CGC CGC AAA TAC GAG AAG TG 3'; R5'- GCA ATC GAA GTG AAG AGT GC -3', the product of this gene 540bp (13).

-The PCR conditions of the magA gene: were the initial denaturation temperature of 94°C for 2min. three thermo-cycler condition (1- denaturation of 94°C for 45sec. 2-an annealing temperature of 52°C for 45sec .3- extension of 72°C for 45sec. The final extension of 5 min at 72°C. This condition used for 35 cycles.

-Agarose Preparation

Agarose was weighted 1g, boiled in 100ml (1X) TBE buffer, left to cool at 50°C and 5 µl of ethidium bromide is added to agarose and poured on preparing tray. Comb was removed after hardening of agarose leaving wells.

TBE (1X) buffer was added to the electrophoresis tank, tray with agarose was immersed in electrophoresis tank. Each well is loaded with 7µl of DNA sample and standard molecular weight of DNA ladder (marker) is loaded in a first well. Electrophoreses run at 80 volt/cm for 1hr. Gel was visualized with UV transilluminator and photographed by using digital Camera (14).

3. The results

-Bacterial Isolation

A total of (60) clinical specimens were collected from patients suffering from various burns during the period from November 2018 to January, 2019). These specimens were collected from patients attending to middle Euphrates burn center during the studied period. All specimens were cultured on the MacConkey agar plates and incubated at 37°C under aerobic condition for 18 - 24 hour.

In 60 patients, 36 (60%) were female and 24 (40%) were male as in figure(1). However, (15) stated that female infection was higher (54.5 %) than male (45.6 %). In addition, (16) viewed that 209 cases were males and 995 cases females, patients were mainly of the group ≥ 60 years. They referred that male patients above the age of 60 years were subjected to greater frequency
of *K. pneumoniae* infection.

![Figure 1: Distribution of infected patients according to sex](image)

*Klebsiella pneumoniae* Isolation and Identification

Clinical and environmental hospital samples were cultured on to MacConkey agar and incubated for 18-24 h at 37°C. All lactose-fermenting isolates were tested by morphologic characteristics and standard biochemical tests according to (10). Confirmation of *K. pneumoniae* was conducted using P.C.R system. Several morphological, physiological and biochemical tests were made to identify bacterial isolates. Results showed that *Klebsiella pneumoniae* constitute 15 isolates (25%) of these isolates, The other bacterial isolates were *Pseudomonas spp.* (6 isolates), *E.coli* (3 isolates) and *Staphylococcus spp.* (1 isolates) . Bacterial isolates were identified according to their cultural, microscopical and biochemical characteristics that were in agreement with (17).

**-Antibiotic Susceptibility Test**

Table (2) showed the antibiotic sensitivity screening test to a number of antibiotics on *Klebsiella pneumoniae* isolates by using Kirby-Bauer disk diffusion method .The results were interpreted according to the diameter of inhibition zones and compared with inhibition zones
determined by CLSI, and to decide the susceptibility of bacteria to antimicrobial agent whether being resistant.

The results revealed that the isolates of *Klebsiella pneumoniae* exhibited highly sensitivity to Azithromycin, moderate sensitivity for Gentamicin and Imipenem while The findings showed absolute resistant to Erythromycin, highly resistant to Ciprofloxacin, Gentamicin and Imipenem.

Erythromycin has been regarded for many years as possessing a good spectrum of activity and safety record for the treatment of respiratory, skin, and soft tissue infections in both adults and children. Azithromycin which differs from erythromycin chemically by a methyl-substituted nitrogen in the macrolide ring This difference produces improvements in spectrum and potency compared with erythromycin\(^{(18)}\).

Results showed also that the resistance of *K. pneumoniae* isolates to the aminoglycosids group included gentamicin were 50 %. \(^{(19)}\) was rather different from the data. They reported that about 79 % of *Klebsiella* isolates were resistance to gentamicin. In addition, \(^{(20)}\) found that all the *Klebsiella* strains in their studies were resistant to gentamicin. In this regard, \(^{(21)}\) found that *Klebsiella* isolates producing extended spectrum \(\beta\)-lactamase enzymes were resistant to aminoglycosids.

Resistance of *Klebsiella* isolates to ciprofloxacin which belongs to the quinolones group was 20 %, \(^{(22)}\) reported that the resistance to quinolones is related to change in antibiotic-enzyme (GyrA) binding site.

\(^{(23)}\) reported that carbapenem (imipenem) antibiotics have strong activity against ESBLs from *Klebsiella spp*. \(^{(23)}\) observed that *K. pneumoniae* isolated from respiratory tract was sensitive against imipenem. In another study *K. pneumoniae* isolated from different clinical specimens was susceptible to imipenem \(^{(24)}\). The result of the susceptibility of *K. pneumoniae* to the imipenem correlated with results of \(^{(25)}\) and \(^{(26)}\) who revealed that only one isolate was resistant to the imipenem.

While resistance to Sulfonamide group included Trimethoprim + Sulphamethoxazole) was 77.5 %, This blocks two consecutive steps in bacterial biosynthesis of essential nucleic acids and proteins and is usually bactericidal \(^{(26)}\). According to this result it can considered that Azithromycin as best treatment against *K. pneumoniae*.

3. Molecular Study (Genotypic Detection of *K. pneumoniae*)

A collection of 15 *Klebsiella pneumoniae* isolates diagnosed by the morphological, cultural and biochemical characters, the identification was confirmed by molecular method for the presence of *magA*. The results showed that only 10 (66.6%) isolates were carrying *magA* which are diagnosed as *Klebsiella pneumoniae*, these results were correlate with (27) who found that out of 10² *Klebsiella* isolates, 96.2% was identified as *K. pneumoniae* as in the figure (3).

Immunomodulation of Iraqi Lyciumbarbarium Carotene

**in vitro**

Zainab Yaseen Mohammed Hasan¹; Najwa Sh Ahmed¹; Raghad K. Al-Lihaibi²

¹Biotechnology Research center Al-Nahrain University, Iraq Baghdad, ²College of Pharmacy Al-Nahrain University, Iraq Baghdad

Abstract

The contents of Lyciumbarbarum active constituents as wild Iraqi plant was extracted then estimated qualitatively and quantitatively by HPLC method. Effect of the extracted carotene was employed in the current study on the normal human blood lymphocytes to estimate the extract effect on IL-6 and IL-8 levels as immune modulating agent. L.barbarum considered as a good source for carotenes it’s containedwas 0.287mg/g dried fruits. The current study results about the effect of extracted carotene on normal human lymphocytes and interleukins 6 and 8 levels showed that the compound can enhance cell-mediated immune responses through enhance lymphocytes proliferation with increasing in IL-8 and decrease IL-6 level.

**Keywords:** Lyciumbarbarum active, lymphocytes, L.barbarum considered, proliferation, carotenes.

**Introduction**

Wild Iraqi Lyciumbarbarumis rich with carotenoids that make the fruit possessed a beautiful orang color(1). Lycium was very important medicinal plant that possessed several biological activities, among them; hepatic protection from being damage, immune boosting agent, and can reduce the harmful effects of the chemotherapy drugs and radiotherapy treatment(2), also the regular carotene intake with daily foods as rich carotene vegetables diets might play important rule in reduction of different types of cancer(3). Due to the potent antioxidant properties of such compounds, many researches correlated between their importance in curing several several chronic disease as well as a potent biological effects on human(2). Moreover the immune modulation effects of beta carotene were suggested to be a major factor in fighting cancer, by boosting the immune system(4). This study projected on extraction of total carotene from Wild L.barbarum to insure the immune boosting activity for this components and declare how it can regulate some interleukin levels of a normal human blood lymphocytes culture.

**Material and Method**

**Extraction the total carotene from the fruit**(5): 

Ripe L.barbarumfruits were dried and powdered by blender. A quantity of one gram dried fruit powdered was homogenized well with 3ml distilled water, to be mixed then with 2ml absolute ethanol with continues agitation. After filtration, total carotene was extracted by 10 ml n-hexane using separator fennel. The organic hexane layer was objected to HPLC assay.

**Immunomodulation Determination (in vitro)**(6).

In this study about five ml blood samples was taken from peripheral vein of healthy volunteers with age of (25-35) year’s old whom never using any drugs before 2 weeks. Each blood sample was suspended onto 3ml lymphocyte separation fluid(sp.gr.1.077g/L) in vacuumed tubes separately to be centrifuged then for half an hour at2000 rpm. The isolated cell of lymphocytes were collected by sterile Pasteur pipette and transfer each sample into separated vacuumed tubes after washing the pellets, then suspended in with 5ml RPMI -1640 containing 10% fetal calf serum. All tubes were incubated over night at37°C in 5% CO₂ incubator.

**i-Measurement of the Viable Lymphocytes by MTT Assay**(7).
According to Freshney 2012 protocol, the effect of extracted carotene on normal lymphocyte culture was determined by preparing different carotene concentrations (500, 250, 125, 62.5, 31.25, 15.625, and 7.8125) µg/ml, then sterilized with disposable millipore filter. Aliquot of 100 µl lymphocyte cell culture was treated with each carotene concentrations in triplicate with control positive that employed as 0.1% PHA solution (phytohemagglutinin), and control negative represented by cells suspended in medium without any treatment. The 96 well plate was incubated for 20 hours, then centrifuged for 5 minutes at 1500 rpm. The medium was gently aspirated and MTT dye (2 mg/ml) to all wells was added. The microtiterplate was incubated again for about 3-4 hours. Crystals were formed by living lymphocytes might dissolved with 100 µl DMSO and the intensity of purple color for each well was read at 620 nm and recorded within short period by ELISA reader.

- Percentage of viable Lymphocytes can be calculated with the following equation:

\[ \text{Percentage of viable Lymphocytes} = \frac{\text{Absorbance of the test}}{\text{Absorbance of negative control}} \times 100. \]

Determination of the Cytokine Level by ELISA Technique

For this assay two tissue culture plates of 24 wells, were seeded with 1 ml of isolated lymphocytes suspended cells (1 x 10^6 cells/well). One plate was treated with 1 ml from the extracted carotene in three selected concentrations (100, 500, 250) µg/ml in triplicate to be incubated for two hours, while the other plate incubated for four hours after treatment. Lymphocyte cells in growth medium alone was represented the negative control.

All wells content were pooled at the end of exposure time the end of each interval times into sterile tubes and centrifuged for 10 minutes at 2000 rpm to separate the pellets from the supernatant of each tube and kept at -20°C to be estimated by ELISA kits for IL6 and IL-8 assy.

The Cytokine IL-6 and IL-8 Levels

The kit work was done according to protocol of United State Biological and Biochemical Reagents Trade Company specific for (IL-6 and IL-8) level, that can be calculated through plotting standard curve between concentration versus absorbance read by ELISA microplate reader (Olympus/Japan) at 450 nm were plotted, then IL-6 and IL-8 levels for each sample was calculated and then evaluated statistically.

Results

Content of Total Carotene Determination by HPLC

The retention time for the β-carotene standard was (6.647 minutes) as shown in figure (1). HPLC chromatogram of the *Lycium barbarum* extracted carotene showed a presence of sharp peak with retention time (6.638) minutes, figure (2).

Levels of IL-6 from lymphocytes treated with three concentrations of extracted carotene were shown in table(2) after two intervals 2 and 4 hours of exposure.

Interleukin 6 (IL-6) encoded by the IL6 gene is produced from different cells such as smooth cells in blood vessels. The IL-6 main action was indicated as a pro-inflammatory cytokine and myokine\(^9\), which mediated by inhibition the secretion of TNF-\(\alpha\) and IL-1 with activation of IL-10\(^{10}\). A decrease in IL-6 level secreted from treated lymphocytes with carotene in different concentration and 2 or 4 hours exposure, were shown in the current study. Dietary carotenoids and retinoids played an obvious role in boosting human’s innate and acquired immunity against inflammation\(^{11}\). The current research could be a preliminary in vitro study involve the beneficial effect of *L. barbarum* carotene, in spite that in a study concluded that the carotene decrease IL-6 level due to its suppression of transcription of this interleukin\(^{12}\).

\[ Y = 0.2044X + 0.1475 \]

Results showed that IL-8 level elevated for blood lymphocytes treated with different concentrations and two intervals time of exposure. Interleukin 8 secreted by macrophages and epithelial orendothelial cells, is an important mediator of the innate immune system (9). IL-8 acted as neutrophil chemotactic factor by induction of chemo-taxis for neutrophils and granulocytes, in order to migrate toward infection. Moreover, it acted to stimulate phagocytosis at site of inflammation as in bronchitis and respiratory viral diseases (13). *Lyciumbarbaum* carotene play important role in treating different diseases via improvement of body immunity(14).
The current results were agreed with a study by Lin and co about the effect of edible carotene on normal peripheral blood lymphocytes(15).

Conclusion

The contents of *Lycium barbarum* active constituents as wild Iraqi plant was considered a good source for carotene which contained 0.287mg/g dried fruits. The current study focused on the effect of extracted carotene on normal human lymphocytes and interleukin 6 and 8 levels. The study general conclusion insured that this compound can enhance cell-mediated response for immune system. *Lycium barbarum* carotene possess major role in boosting human immunity that highlighted their importance as food as well as a promise medical component.

Abstract

The effect of Bacterially Reduced Graphene Oxide (BRGO) as inhibitory agent alone and in combination with antibiotics against some multidrug resistant (MDR) uropathogenic bacterial isolates as well as the antibiofilm activity was investigated. BRGO nanosheets were synthesized biologically by Escherichia coli strain E-NO.7 (accession no. MK685205). Different concentrations 0.1, 0.5, 1 and 10 mg/ml of BRGO nanosheets showed potent inhibitory effects of all concentrations against tested MDR uropathogenic Escherichia coli, Klebsiella pneumonia, Pseudomonas aeruginosa, and Methicillin-Resistant S. aureus (MRSA) isolates. Results showed that the growth inhibition zones increased with increasing in BRGO concentration. The combinations of BRGO (0.5 mg/ml) and different broad spectrum antibiotics exhibited enhanced antibacterial activity against all the studied isolates in comparison with the effects of antibiotics alone. It has been observed that BRGO effectively restricted biofilm formation, and the antibiofilm effect was dose- dependent, since the biofilm inhibition gradually increased with increasing in BRGO concentration.

Key words: Uropathogenic bacteria, Bacterially Reduced Graphene Oxide, Antibacterial activity, Antibiofilm effect.

Introduction

Urinary tract infections (UTIs) are among the most common types of bacterial infections occurring in both the community and hospital settings (1) Gram-negative bacteria, specifically Enterobacteriaceae, are common causes of both community and hospital associated UTIs. The most common pathogenic organism is uropathogenic Escherichia coli (UPEC), responsible for 80% or more of the cases, while other Gram- negative rods and Gram- positive cocci, such as Staphylococcus saprophyticus and enterococci, are responsible for the remaining cases (2).

In spite of the availability and use of the antimicrobial drugs, UTIs caused by bacteria have been showing increasing trends. Much of this increase has been related to the emergence of antibiotic resistance among urinary tract pathogens. The widespread use of broad-spectrum antibiotics has led to the appearance of MDR isolates (3). Biofilms are considered an important virulence factor that causes persistent chronic and recurrent infections. They are highly resistant to antibiotics and host immune defenses (4). Bacteria protected within biofilms are up to 1,000 fold more resistant to antibiotics than their planktonic counterparts, which generates serious consequences for therapy and complicates treatment options (5) Unfortunately, antimicrobial resistance is still a major cause of morbidity and mortality. Each year more than 700,000 people die due to antimicrobial resistant infections worldwide. Antibiotic resistance is estimated to cause around 10 million deaths by 2050 (6).

Nanomaterials (NMs) have emerged as a novel alternative to defeat MDR bacteria because of their microbicidal nature and the development of bacterial resistance to NMs are less likely when compared to antibiotics (7). The physical structure of the NM itself may have inherent antibacterial properties due to its membrane damaging abrasiveness, as seen in graphene nanosheets (8). Graphene materials have potent broad-spectrum antibacterial activities against both Gram-
positive and Gram-negative bacteria and biofilm forming microorganisms. The unique properties of graphene provide surfaces with anti-adhesive properties and it is particularly effective to inhibit bacterial attachment and the biofilm formation (9).

**Experimental part**

**Bacterial isolates**

Four uropathogenic isolates *E. coli*, *K. pneumonia*, *P. aeruginosa*, and MRSA were identified according to morphological, biochemical and VITEK2 System as MDR after screening their antibiotic sensitivity against 12 selected antimicrobials of different classes using disc diffusion method. MDR uropathogens were also identified as biofilm producers by Congo Red Agar (CRA) according to the method described by (10) and by Tissue culture plate (TCP) method according to (11, 12). The interpretation of biofilm production was done according to (13).

**Antibacterial activity of BRGO**

The antibacterial activity of BRGO nanosheets was tested against the MDR uropathogens by agar well diffusion method (14).

**Combination of antibiotics and BRGO**

The combination between BRGO nanosheets and antibiotics against uropathogens was done using the Kirby- Bauer disk diffusion method. Each standard antibiotic disc was impregnated with 30μl of BRGO solution (0.5 mg/ml) and used against indicated bacterial isolates to assay their antibacterial activity. The plates were incubated at 37°C for 24 hr. After incubation, the plates were checked for the zones of growth inhibition.

The combination effect of antibiotics and BRGO was evaluated by calculating the increase in the zones of inhibition (15).

**Antibiofilm activity of BRGO**

Tissue culture plate method (TCP) was also used with some modifications to detect the antibiofilm activity of BRGO solution against biofilm producers in vitro. Three concentrations 1, 0.5, and 0.1 mg/ml of BRGO solution were prepared. Bacterial suspensions were prepared for each isolate as, 150μl of the bacterial suspensions were added to each polystyrene 96-well microtiter plate wells. Then an amount of 50μl of each 4X concentration was added to the corresponding wells to get the final concentrations. An amount of 200μl of autoclaved distilled water was added in peripheral wells to decrease loss of water. Microtiter plates were incubated in 37°C for overnight. After incubation, contents of each well of microtiter plates were treated and the OD values were measured.

**Results**

**Antibacterial activity of BRGO**

Results showed that BRGO had potent inhibitory effects against all the tested MDR uropathogenic isolates with higher activity against MRSA. The growth inhibition zones clearly revealed that BRGO inhibited the growth of tested isolates where the highest concentration of BRGO has the strongest antibacterial activity (Figure 1, Table 1). Treatment with different concentrations of BRGO nanosheets showed higher antibacterial activity against *E. coli* compared to other Gram-negative (*K. pneumonia* and *P. aeruginosa*), the growth inhibition zones increased in a concentration dependent manner.

BRGO, Bacterially Reduced Graphene Oxide; MDR, Multi Drug Resistance

Combination effect of antibiotics and BRGO

The selected antibiotics were divided into two groups, the first group included four different β-lactam antibiotics (cefepime, ceftriaxone, cefazolin, and cefotaxim) that were not effective against the studied isolates, while the second group included imipenem and gentamicin that were highly active against these isolates. Results revealed that antibiotic-BRGO combinations exhibited enhanced antibacterial activities against all the studied isolates as compared to the effect of antibiotics alone with higher activity against MRSA (Table 2 Figure 2 and Figure 3).

Biofilm formation by uropathogens

Multidrug resistant uropathogens (E. coli, K. pneumoniae, P. aeruginosa, and MRSA) were identified as biofilm producers by CRA method, it was observed that all isolates produced black colonies which is indication for the production of biofilm. The experiment of TCP was performed in triplicate. The OD values of stained adherent biofilm was determined with an ELISA reader at wavelength of 590 nm. The average of OD values obtained for individual isolate were considered as an index of bacterial adherence to surface and biofilm formation. Results revealed that all the studied uropathogens were strong biofilm producers by TCP method [Table 3]. The average OD value (2.034) for P. aeruginosa indicated the strongest biofilm production, followed by 1.930, 1.575, and 1.537 for K. pneumoniae, MRSA, and E. coli, respectively.

**Evaluation of antibiofilm activity of BRGO**

The OD values showed that BRGO effectively restricted biofilm formation of the studied uropathogens. It has been observed that the antibiofilm effect was dose-dependent, since the biofilm inhibition gradually increased with increasing in BRGO concentration (Table 3). Three different concentrations (1, 0.5, and 0.1 mg/ml) of BRGO nanosheets exhibited higher antibiofilm effect against MRSA than Gram-negative isolates. The effect of concentrations corresponding to 0.5mg/ml and 1mg/ml of BRGO caused notable reduction of the biofilm formation of MRSA from approximately 1.572 to levels of 0.619 and 0.124, respectively. The OD values also revealed that concentrations of BRGO caused notable reduction in the biofilm formation of E. coli and K. pneumoniae and the best biofilm inhibition activity was observed in higher concentration. The effect of concentrations corresponding to 1, 0.5 and 1mg/ml of BRGO caused reduction of the biofilm formation of E. coli from approximately 1.537 to levels of 1.220, 0.620 and 0.153, respectively. Similarly, these concentrations showed reduction in biofilm formation of K. pneumoniae from approximately 1.930 levels of 1.238, 0.621, and 0.191, respectively. Against P. aeruginosa, treatment with BRGO showed relatively lower antibiofilm effects compared to the other isolates. The biofilm formation reduced from 2.034 to levels of 1.304, 0.720, and 0.215 corresponding to 1, 0.5 and 1mg/ml concentrations of BRGO respectively.

**Discussion**

Graphene nanosheets can cover on the external surface of cells, which might lead to indirect toxicity by biologically isolating them from growth medium, and consequently the bacterial cells can neither proliferate nor consume the nutrients (16). In addition, the direct contact between the sharp edges of RGO nanosheets with cells can physically damage cell membrane, resulting in leakage of intracellular material and negatively affecting cell metabolism (17). Many researchers have investigated the potential toxicity of GNMs against several bacterial species (18, 19). The increase in graphene concentration led to a continuous increase in its antibacterial activity (20). The antimicrobial effectiveness of biosynthesized RGO is enhanced at higher concentrations due to the rupture of cell membrane (21).

The inhibition ability of antibiotics combined with BRGO may be attributed to “carrier effect” (22). Namely, the coating of BRGO on bacteria can cause the cell membrane damage and will facilitate the release of the deposited antibiotic on BRGO surface in high quantity. The cell entrapment property of graphene ensures high local concentrations of antibiotic molecules in the immediate proximity of the cell membrane. It is also possible that RGO contributed to increased permeation of antibiotic into the bacterial cells (23).

Bacterial biofilms play an important role in UTIs, being responsible for both acute and persistent infections in which biofilm can become a serious problem (24). Many
studies documented a higher proportion of antibiotic resistance in biofilm producers in comparison to non-producers (25, 26). The EPS matrix confers antibiotic resistance through expression of chromosomally encoded resistant genes, restricted penetration of antibiotics, and decreased growth rate (27, 28). On the other hand, it is possible that the biofilm can facilitate the accumulation of antibiotic degrading enzymes such as β-lactamases (29).

The penetration and deposition of NMs within the biofilms are key components for the design of biofilm therapeutics. The bioavailability of NMs allows them to penetrate a mature biofilm and target bacterial cells not only at the surface but also within the deep layers of biofilm (30). The antimicrobial and antibiofilm effect of graphene can be attributed to different mechanisms originated by the direct interaction between graphene and bacteria cells (31). Graphene nanosheets possess biocidal properties based on their ability to act as nano-knives, penetrating and disrupting the cell membrane (32). Additionally, their basal planes which are free of functional groups possesses anti-adhesion properties against biofilm and it is particularly effective in preventing biofilm formation (9).

The BRGO nanosheets exhibited remarkable antibacterial and antibiofilm activities against the tested MDR uropathogenic E. coli, K. pneumonia, P. aeruginosa, and MRSA isolates. The activity increased with increasing in BRGO concentration. The combination of BRGO and broad-spectrum antibiotics showed enhanced antibacterial activity against uropathogens as compared to effects of antibiotics alone.

Legal Protection Against Women in Sexual Violence

Absori Absori1, Fitriani Nur Damayanti2, Kelik Wardiono1, Sri Rejeki2
1Lecturer at Universitas Muhammadiyah Surakarta, 2Lecturer at Universitas Muhammadiyah Semarang

Abstract

Introduction: Sexual violence is one of the morbidities and mortality factors in women. Sexual violence of women causes physical and physiological sequences that make them vulnerable to health problems.

Material and method: It was normative legal research with a literature study and document study as a method to collect the research data.

Findings: Marital sexual abuse or the highest personal relation was incest with 1,071 cases followed by raping with 818 cases, and molestation with 321 cases. Meanwhile, marital rape reached 195 cases. The forms of sexual violence consist of sexual harassment, sexual exploitation, coercion of contraceptive use, compulsion in abortion, rape, marital compulsion, prostitution, sexual bondage, and sexual torture. The protection against victims of sexual violence was considered to be not optimal due to a lack of public understanding of the causes and effects of sexual violence.

Conclusion: So far, the legal protection against women in sexual violence cases have not been optimally implemented. The minimum legal protection triggered impunity, reoccurrence, and even the victims’ frustration to accept justice and recovery.

Keywords: Legal Protection, Sexual Violence, Women

Introduction

Sexual violence is considered a serious human right violation with a huge impact, especially for women1. Sexual violence is also a form of violence frequently experienced by women related to the stereotype that put women as an object of sexuality2. It can be stated as violence against women, gender-based violence, and gender violence3. Any form of sexual violence can be categorized as violence against morality and domestic violence. This act is characterized by some indicators such as carried out in the house, behind the closed door, involves physical violence, performed by people with a close relationship to the victim, and reoccurring. The victims are usually women and children, with men (father or husband) mostly as the subject of the act. However, in some kinds of literature, domestic violence refers to violence performed by a husband to his wife or also known as wife beating4.

In Indonesia, sexual violence is divided into three categories, which are molestation (911 cases), sexual harassment (704 cases), and rape (699 cases). The high rate of sexual harassment leads to weak legal protection against women5. It is more difficult to reveal and handle sexual violence compared to the other forms of violence as it is frequently correlated to society’s concept of morality. Women are considered as the symbol of purity and dignity. Therefore, it is such a shame to be the object of sexual violence. It makes women tend to be silent when they are involved in sexual violence6. Sexual violence is the main factor of morbidities and mortality in women. Sexual violence of women causes physical and physiological sequences that make them vulnerable to health problem7. Women face significant risks such as genital and extragenital trauma, an unexpected pregnancy, sexual dysfunction, and sexually transmitted disease (STD)8.

The draft of the law about sexual violence is aimed to prevent sexual violence, act against the subject of sexual violence (includes rehabilitation), victim’s recovery, implement the duty of a country to remove violence against women9. Victim protection during the judicial process strongly relates to the applied legal provisions. Today, the law about sexual violence already exists,
but it has not been optimally implemented. The scope of sexual violence is mentioned in Law No. 23 of 2004 about the elimination of domestic violence and Law No. 39 of 1999 about human rights mentions the limited scope of criminal justice for sexual violence which limits the criminal act and forms of sexual violence experienced by victims. According to the law, the victim of sexual violence can only get protection by following the legal process. Therefore, legal protection is needed for women as victims of sexual violence.

Method

It was normative legal research, which is research about legal principles. The research focused on the material of primary and secondary law. It was descriptive research that gave a detailed and systematic description of legal protection against women in sexual violence. The data was collected through literature and document study. The literature study was done by analyzing the law and regulations, books, literature, and other research papers. The research data was qualitatively, completely, and comprehensively analyzed to produce empiric-normative legal research. The data collected from the research was analyzed and systematically outlined to conclude.

Results and Discussion

The sexual violence mostly experienced by victims within their family in a form of domestic violence or their private are. The form of domestic violence was dominated by incest (1,071 cases), followed by rape (818 cases) and molestation with 321 cases. In 2017, a surprising finding mentioned 1,210 cases of incest. Meanwhile, in this year, the incest case was reduced to 1,071 cases. The level of marital rape was quite high with 195 cases; meanwhile, marital rape in 2017 was 172 cases. It meant that the marital rape report was increased from 172 to 195 reports and needed to be taken seriously. The courage to report the marital rape cases showed that the victims were more aware of the coercion of sexual intercourse was considered as marital rape which can be sued.

There was no comprehensive protection mechanism as the scope of the cases was wider than the related regulation. The impact of the minimum legal protection triggered impunity, reoccurrence, and even victims’ frustration of justice and recovery. On the other hand, the existed law and judgment were not able to prevent and handle the case using due diligence principles. Here are the forms of sexual violence reported based on the victims’ experience and complaint.

1. Sexual harassment

Sexual harassment was not identified in the Criminal Code of Indonesia; the section of morality violence only mentioned adultery, molestation, and rape which the criminal act was in the form of physical activity. On the other hand, in the real situation, sexual harassment may in a form of non-physical contact such as verbal insult and attack that made someone feel humiliated and insulted. The draft of the law about sexual harassment mentioned sexual harassment involves physical and non-physical harassment. Some examples of sexual harassment cases were: A non-physical and insulting sexual harassment experienced by BN, an administration employee in a state school in Mataram, NTB. It was said that the school principals said about his sexual fantasy of BN and pursued BN to fulfill his sexual need either on the phone or when they went face to face. It insulted BN and made her uncomfortable. Meanwhile, the local cop of NTB considered the criminal act as molestation as there was no physical contact. Besides, he also showed some sexual content either from social media or from his document to the victim.

Physical sexual harassment in affirmative law is also known as molestation, of which the definition ranges very wide as it also includes sexual intercourse. Meanwhile, the mentioned sexual harassment above didn’t include sexual intercourse and categorized as a morality violation. The National Committee on Violence against Women (Komnas Perempuan) found many forms of physical sexual harassment. The physical sexual harassment frequently aimed women’s breasts as the target in some situations including the act done by a medical practitioner or employees in any asylum or social orphanage when they cleaned their patients’ bodies in an open space in which people can see the patients easily. The employees thought that the patients would feel ashamed of their bodies. Besides, in 2018 a physical sexual harassment was experienced by a commuter line train passenger. A male passenger rubbed his sexual organ on her body. She tried to move, but the man did the same thing again. However, despite the shock and anger, the female passenger could not do anything. She then felt so much regret to be angry but could not fight against it.
2. **Sexual exploitation**

Sexual exploitation is attached in Law No. 21 of 2007 about human trafficking eradication as the objectives, and also in Law No 35 of 2014 as the revision of Law No 23 of 2002 about protection for children. Sexual exploitation includes a sexual activity that tends to take benefit from the object and mainly for the subject’s benefit only. Sexual exploitation had not been included in the Criminal Code and Law as a form of sexual violence. Therefore, any cases related to sexual exploitation rarely forwarded into the legal court. The modus of this case usually happened when women were promised to work abroad with a high salary, but they ended up being trafficked or raped by a foreigner. As an example, SF was promised to work abroad. Although she canceled her intention after experiencing sexual violation, the agent asked her to pay a huge amount of money as the substitution of administration fee the agency was spent for her during the training. SF forced to do the sexual activity for the agency benefit, or she would be fined. It was a clear form of sexual exploitation.

3. **Rape**

Rape commonly involves coercion, manipulation, violence, and threat. Sometimes, sexual intercourse does not only involve sexual organ penetration but other things besides the sexual organs such as finger or other kinds of stuff. The act also includes sexual activity with children, also take benefits from the powerlessness, inability, and disability of the victim. Those activities are mentioned as rape in the bill of sexual violence elimination. The National Committee of Violence Against Women identified a rape case back in 2018 which was experienced by AG, a college student of UGM in her internship from June – August 2017 in Maluku. Her fellow member, HS raped AG in her sleep. AG went through a long way to get justice. However, the compensation was not equal to what she expected. Instead, the university tended to blame AG with a statement that cornered AG as a woman who pursued the man to get into the sexual activity, of which no man would not deny accepting that. The case was then closed on February 4th, 2019 through the non-litigation process. No legal process was applied for this case. Both HS and AG were allowed to finish their studies and gave them counseling. HS was asked to apologize in front of the UGM commissionaires and HS parents. Meanwhile, AG was compensated with a scholarship until she finished her degree. the other case was experienced by NA, a woman who was raped by her neighbor named Marhon.

4. **Sexual bondage**

Sexual bondage is a form of sexual violence which is aimed to give sexual service under the control of the subject in a certain period until the victim got helped. An example of sexual bondage found by National Committee on Violence against Women was in 2018 which was experienced by CT (27 years old). She was the only victim who was brave enough to report the sexual bondage done by Gatot Brajamusti, ex-chief of PARFI, a spiritual guru, and a leader of a hermitage. The case attracted public attention as the subject was a public figure added with the assumption that there were many women that might be involved in that case (although most of them were not brave enough to report the case) and most of the victims were very young women which were promised to be an actress or singer.

5. **Sexual torture**

Sexual torture is a form of sexual violence that was not regulated in any law and Criminal Codes. The bill of law about sexual violence elimination tries to include sexual torture in the law as a form of effort by anti-torture convention to comprehensively handle sexual torture. Sexual torture involves some acts to intentionally attack sexual organs for certain reasons so that it can cause terrible physical, spiritual, and sexual pain. A Malaysian citizen reported that she was a victim of sexual torture during the body checking in Adisucipto Airport Yogyakarta. ML arrived at Adisucipto Airport on December 31st, 2017 at 10.30. just like the other passenger, she went through the x-ray scanning, dog screening, and document checking. However, her baggage was arrested, and she was required to went for another checking. She was placed in a special room. In that room, the officers checked her belonging but did not find any forbidden stuff. However, the officers kept on asking about a package of food and her private stuff. Instead of being released, she was asked to enter another room for body checking. In that room, a female officer asked her to take off all of her clothes without any further explanation. When she was naked, she was asked to stand in front of a big mirror. She didn’t know if that mirror was only a common mirror or a two-way mirror. At that time ML was not able to do anything other than following the officers’ instruction as she did not want to be claimed as a rebel foreigner. In the end, there was no further explanation about all the security checking, and
she left with a stressed, ashamed, and humiliated feeling. It was categorized as sexual torture as it was done by those who owned the authority to do all the checking which was aimed to satisfy their assumption that ML carried drugs17.

Based on the data about sexual violence cases, the protection for women as the victims of sexual violence was considered to be not optimal due to the lack of understanding of the cause and effect of sexual violence. Besides, the legal institution in Indonesia was not able to properly protect the victims due to the limitation of regulating law18. In the affirmative law about sexual violence did not comprehensively understand the cases. The limited scope of sexual violence criminal act limited the form of sexual violence experienced by victims19. For example, sexual harassment, sexual exploitation, coercion of contraceptive use, compulsion in abortion, rape, marital compulsion, prostitution, sexual bondage, and sexual torture did not clearly state in the law. Legal protection only protected those who were brave enough to bring the case to the court20.

Sexual violence also affected both the victim and her family as they suffered from the threat, restriction, exclusion, also social, political, and economic discrimination. Further example of the impact was when the victim was blamed by the society and family, denied by the family, expelled and excluded by her society, workplace or school, forced to marry the perpetrator, got some difficulty to access citizenship documents. They also did not get any social security, economically dependent on family and close relatives, lost her beneficiary, did not get any medical and psychological treatment by considering the victim as the wrongdoer21.

To give optimum service for sexual violence victims, collaboration and coordination are needed to evenly distribute the jobs of each related institution, including the agreed mechanism, policy support, and the availability of the resource. A country should have protected its citizens from the fear, as free from fear is a basic human right.

**Conclusion**

Sexual violence case on women was considered very high and psychological mental trauma, fear, shame, anxiety, and even a suicide trial. The legal protection of women has not been well implemented. The protection mechanism was not comprehensively available due to the case complexity that surpassed the availability of the cases in the established regulation or law. The minimum legal protection triggered impunity, reoccurrence, and frustration of the victims to get justice and recovery.

The Clinical Function Comparison of Post Operative Nerve Grafting and Nerve Transfer in Patients with Brachial Plexus Injury

Agung Tristyanto¹, Heri Suroto²

Department of Orthopedics And Traumatology Faculty of Medicine Universitas Airlangga Surabaya Indonesia,
²Department of Orthopedics And Traumatology Faculty of Medicine Universitas Airlangga. Jalan Mayjen Prof. Dr. Moestopo 47 Surabaya Indonesia 60285

Abstract

Background: Brachial plexus injury is most commonly caused by motorcycle accidents and leads to a deficit of motor strength, pain and disability of the upper limb. The main purpose of reconstructive action of brachial plexus injury is to restore the function of the shoulder and elbow. Aim: This study aimed to compare the clinical function of post-operative nerve grafting with nerve transfer in patients with brachial plexus injury.

Methods: This study enrolled a sample of patients who had surgery and evaluated the range of active movement of shoulder abduction and elbow flexion; motor strength using the scale of the British Medical Research Council (BMRC); neuropathic pain using Visual Analog Scale (VAS); and upper extremity disability using the Quick Disability of the Arm, Shoulder, and Hand (Quick DASH) questionnaire.

Results: 30 patients were divided into groups of nerve grafting and nerve transfer with each group consisting of 15 patients. 13 patients (87%) of each group had motor strength of functional shoulder abduction (>M3) (p = 0.874). 13 patients (87%) had better functional elbow flexion motor strength (>M3) in the nerve transfer group than 11 patients (73%) of the nerve grafting group (p = 0.036).

Conclusion: The postoperative nerve transfered clinical function showed a better elbow flexion function with a lower severity of upper limb disability.

Keywords: brachial plexus injury, nerve grafting, nerve transfer.

Introduction

Brachial plexus injury is a peripheral nerve injury in the upper limb which is often diagnosed and neglected by medical practitioners because of waiting for a functional recovery, resulting in motor and sensory deficits, accompanied by pain and limitation of limb function which are mutually debilitating. Consequently, it results in a decreased life quality of patients and more negative impacts in terms of psycho-socio-economic.

As the number of survivors increases from high-speed motorcycle cidents, the number of brachial plexus injuries also increases. From several epidemiological studies in the United States and Europe, 10-20% of peripheral nerve injuries are brachial plexus injuries with a prevalence of 1.2%, in which 80-90% of such injuries are caused by motor vehicle accidents. Brachial plexus injury is found in the 15-25 year-old male patients.

The management of brachial plexus injury is still considered a futile attempt by some peripheral neurologists until the 1960s. However, it changes drastically along with the development of physiology...
knowledge and peripheral nerve reconstruction techniques. The nerve grafting technique is quite effective in bridging the gap that is too wide after the excision of the nerve segment of the brachial plexus that is damaged and contains fibrotic tissue, compared to the previous action of shortening the collarbone to perform end-to-end coaptation of the neural stump proximal to distal.

Nerve graft acts as a source of the endoneurial tube in which the axonal regeneration occurs. Autogenous nerve graft has another advantage, which is capable of providing a viable source of Schwann cells. Neurotization techniques are published in the form of direct connection of functional donor nerves to the injured recipient nerves. It has provided a major advance in the technique of brachial plexus injury neural reconstruction.

The main purpose of neural reconstruction in brachial plexus injury is to restore clinical function and achieve optimal patients’ quality of life. The success of nerve reconstruction with micro surgical techniques should be followed by the assessment of patients’ clinical function as postoperative follow-up both oriented to surgeons such as range of movement (ROM) measurement of joint activation and motor strength recovery, as well as patient-oriented assessment such as neuropathic pain severity and upper limb dysfunction. From that statement, the aim of this study to compare the clinical function of post-operative nerve grafting with nerve transfer in patients with brachial plexus injury.

Method

This study used an observational analytic study, with a retrospective cohort design, in which the researchers performed a comparative analysis of current postoperative clinical function in two groups of patients who had performed different surgical actions in the past.

The sample of the study was patients with brachial plexus injury post-operative nerve grafting and nerve transfer, and conducted on January 1, 2009 until September 30, 2014 in Dr. Soetomo Teaching Hospital Surabaya. The sampling technique applied consecutive sampling, in which each patient who fulfilled the inclusion and exclusion criteria was included in the study sample until the required sample number was obtained.

The inclusion criteria were nerve grafting and nerve transfer performed by one operator, the surgery was conducted minimal and maximum within 9 months after the trauma event, and the clinical function evaluation was conducted at least 6 months after the surgery. On the other hand, the exclusion criteria included brachial plexus injury patients who have performed reconstructive actions other than nerve grafting and nerve transfer (eg. tendon transfer, free functioning muscle transfer, arthrodesis), obstetrical brachial plexus injury and patients who were not willing to participate in the research. The procedure of data collection started from collecting medical record database of inpatient and medical record of Orthopedics and Traumatology Outpatient Dr. Soetomo Teaching Hospital Surabaya to record the population of patients with brachial plexus injury that have been encountered nerve reconstruction. The sample was grouped into two groups, post-operative nerve grafting group and nerve transfer group. Further measurements of postoperative clinical function were conducted by using Data Collection Sheet and QuickDASH questionnaire, either by meeting patients at Orthopedics and Traumatology Outpatient Dr. Soetomo Teaching Hospital or conducted home-visite.

The demographic distribution of sex, age, diagnosis, incidence time to operation (in months), and time difference of surgery until evaluation (in months) was presented using descriptive statistics of mean value, standard deviation, minimum value, maximum value, median or the value of a number in percentage. On the other hand, the normality data test was conducted by using Kolmogorov-Smirnov test. If the data was normally distributed, Independent t-test was applied. However, if the distribution of data was not normal, it assessed by using Mann-Whitney test. The results were statistically significant if $p < 0.05$. The computer program used to perform statistical analysis was SPSS program version 16.0 (SPSS Inc., Chicago, Illinois, USA).

Result

This study used a sample of 15 patients in the nerve grafting group and 15 patients in the nerve transfer group. A total 15 patients (50%) with brachial plexus injury were aged 21-30 years old (7 patients in postoperative nerve grafting group and 8 patients in postoperative nerve transfer group). On the other hand, the second most age range was 11-20 years old of 6 patients (4 patients in postoperative nerve grafting group and 2 patients in postoperative nerve transfer group). The mean age of nerve grafting group was 27.2 years old and the nerve transfer group was 29.93 years old. The
independent t-test was performed because of the normal data distribution with $p = 0.510$.

In sex distribution, brachial plexus patients were dominated by male patients as many as 24 patients (11 in post-operative nerve grafting group and 13 patients in postoperative nerve transfer group). Female patients were 6 patients (4 patients in post-operative nerve grafting group and 2 patients in postoperative nerve transfer group). In nerve grafting group, there were 11 male patients (73.3%) and 4 female patients (26.7%). The nerve transfer group obtained 13 male patients (86.7%) and 2 female patients (13.3%). The gender variable was tested with Fisher’s exact test with $p = 0.651$. There was no significant difference in gender variables.

The diagnosis of patients with major brachial plexus injury was found complete postganglionic type (C5-6-7), preganglionic type (C8-T1) of 15 patients in postoperative nerve grafting group. The rest were postoperative nerve transfer patients: 9 patients with incomplete upper injury type (C5-6) and 6 patients with incomplete upper injury type (C5-6-7). From 15 patients in nerve grafting group, the patients were complete injury type (100%). The result of Chi-square test was conducted with $p = 0.000$. There was a significant difference. The result of statistical test using independent t-test (normal data distribution) showed that there was no significant difference between the two groups, either from the time incidence until the surgery ($p = 0.052$), and from time difference of surgery until the evaluation ($p = 0.959$). Overall, the sample characteristics between the nerve grafting and nerve transfer group were homogeneous.

The result of ROM comparison of shoulder abduction showed no significant difference between nerve grafting group ($71.33° ± 32.87°$) and nerve transfer group ($61.67° ± 34.52°$). The statistical test was conducted by using independent t-test normal with $p = 0.439$. However, in contrast to elbow flexion ROM results, the nerve transfer group ($102.67° ± 36.35°$) was better than nerve grafting ($86.67° ± 48.32°$) (Table 1).

### Table 1. Comparison of Post-operative Clinical Functions

<table>
<thead>
<tr>
<th>Variable</th>
<th>Nerve Grafting (n = 15)</th>
<th>Nerve Transfer (n = 15)</th>
<th>p</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shoulder abduction ROM*</td>
<td>71.330 ± 32.870</td>
<td>61.670 ± 34.520</td>
<td>0.439</td>
</tr>
<tr>
<td>Elbow flexion ROM*</td>
<td>86.670 ± 48.320</td>
<td>102.670 ± 36.350</td>
<td>0.031</td>
</tr>
<tr>
<td>Shoulder Abduction Motor (BMRC)**</td>
<td>3(2-4)</td>
<td>3(2-5)</td>
<td>0.0874</td>
</tr>
<tr>
<td>Functional Motor M &gt;3***</td>
<td>13 (87%)</td>
<td>13 (87%)</td>
<td></td>
</tr>
<tr>
<td>Elbow Flexion Motor (BMRC)**</td>
<td>3 (1-4)</td>
<td>4 (1-5)</td>

<td>0.236</td>
</tr>
<tr>
<td>Upper extremity disability (QuickDASH score)*</td>
<td>42.67 ± 21.92</td>
<td>24.60 ± 14.83</td>
<td>0.014</td>
</tr>
</tbody>
</table>
From that table the difference was statistically significant, since the independent t-test result had $p = 0.031$. The minimum motor strength of shoulder abduction on the motor scale of BMRC in the nerve grafting group was $M_2$, the maximum value was $M_4$, and the median value was $M_3$. On the other hand, the nerve transfer group obtained the minimum value of $M_2$, the maximum value of $M_5$, and the median value of $M_3$. To compare the motor strength of shoulder abduction, statistical test was assessed with Mann-Whitney test because the normality test (Kolmogorov-Smirnov test) obtained abnormal data distribution. The results obtained $p = 0.874$, where there was no significant difference between the nerve grafting group and the nerve transfer group. It corresponds to the number of samples with the motor strength of functional shoulder abduction with a value of $>M_3$ (useful motor recovery). Between the nerve grafting group and the nerve transfer was the same, i.e. 13 patients each (87%) (on table 1).

The comparison of elbow flexion motor strength showed that nerve transfer group was better than nerve grafting group. The difference was statistically significant since the results of statistical tests with Mann-Whitney test (abnormal data distribution) had $p = 0.036$. This is consistent with the number of samples with functional elbow motor strength with a value of $>M_3$ (useful motor recovery) in the nerve transfer group of 13 patients (87%), more than the nerve grafting group of 11 patients (73%) (Table 2). Based on the VAS scale in the nerve grafting group, the minimum value was 0, the maximum value was 7 and the median value was 2 (Table 2). The statistical test used was Mann-Whitney test because the distribution of data was not normal with $p = 0.236$. There was no significant difference between nerve grafting with nerve transfer group. This is in accordance with previous studies. Meanwhile, other researchers have published a recovery of motor strength $>M_3$ in 80% (total 577 patients) and 73.7% (total 19 patients) postoperative nerve transfer. The significant difference showed that nerve transfer group was better than nerve grafting. It corresponds to the number of samples with a functional elbow flexion motor strength with a value of $>M_3$ (useful motor recovery) in the nerve transfer group, more than in the nerve grafting group.

Brachial plexus injury often occurs as a result of trauma resulting in a paralysis of clinical function in the upper limb. Almost 50 years ago, there have been many reconstructive actions in patients with brachial plexus injury. The main purpose of reconstructive action on brachial plexus injury is to restore clinical function and achieve optimal patients’ quality of life.

The success of nerve reconstruction with micro surgical techniques should be followed by assessment of patients’ clinical function as postoperative follow-up (surgeon-oriented such as ROM measurements of joint active and motor strength recovery, or patient-oriented such as the severity assessment of neuropathic pain and upper limb dysfunction). In this study, there was no significant difference in shoulder abduction ROM between the nerve grafting group and nerve transfer group. The results of this study are still better than previous studies, which only obtained shoulder abduction ROM of 57$^\circ$12. Previous studies had better shoulder abduction ROM of postoperative nerve grafting results than this study of 120$^\circ$13. However, the better shoulder abduction ROM of postoperative nerve transfer result was obtained in previous studies14.

This result was also supported the operation of elbow flexion function reconstruction. It shows that all samples of nerve grafting group use sural nerve as nerve graft interposition, whereas nerve transfer group used double-fascicular nerve transfer technique published by Mackinnon. Motor power postoperative nerve transfer may be better than nerve grafting. It may be due to the occurrence of nerve re-innervation to target muscles to
The percentage of patients with functional elbow flexion motor restoration with value >M3 postoperative nerve grafting in this study was not much different from previous research results. While in patients with post-operative nerve transfer, the results of this study is also not much different from the results of research conducted by previous researchers. There was no significant difference between the nerve grafting group and the nerve transfer. However, in the nerve transfer group, it has a larger number of samples at a lower VAS scale than the nerve grafting group.

The results are consistent with previous studies that demonstrate the presence of axons undergoing regeneration via cable nerve graft, resulting in neuropathic pain postoperative nerve grafting. Other results indicate if the mean VAS value decreases postoperative nerve transfer. Then, the severity of upper limb disability based on the QuickDASH score in the nerve transfer group is lower than that of nerve grafting, resulting in significant differences. It is similar with the results of previous studies showing a lower mean score post operative nerve transfer.

**Conclusion**

Based on the result of the research, it can be concluded that elbow flexion ROM post-operative nerve transfer is greater than nerve grafting, motor elbow flexion strength post operative nerve transfer is better than nerve grafting and the upper limb disability severity postoperative nerve transfer is lower than nerve grafting.

Combination Use of Aloe Vera and VEGF Promotes Osseointegration and Stability of Titanium Implants

Athraa Y Al-Hijazi1; Zaid M.Akram2; Emad H Abdulla3

1Prof. Dr. In Al-Mustaqbal University College/Dentistry Department, Babel, Iraq. 2 Lecturer Dr. In Al-Rafidain university college, Baghdad, Iraq. Board in Oral And Maxillofacial Surgery. 3 Ass. Prof. In College of Dentistry, IbnSina University of medical and pharmaceutical sciences, Baghdad, Iraq. M.Sc. in Oral And Maxillofacial Surgery

Abstract

Background: Aloe vera was used to enhance defense mechanisms, and it has a variety of components that affected on periodontal healing and other oral condition. It was used also around dental implants to control inflammation from bacteria contamination. Vascular endothelial growth factor (VEGF) is of particular interest because of its ability to induce neovascularization (angiogenesis), VEGF also acts to recruit and activate osteoclasts as well as stimulate osteoblast chemotaxis, differentiation, and matrix mineralization.

Aim of study: The objective of this research was to illustrate the biological actions of topical application of aloe vera and growth factor VEGF on implant tissue contact surface which is involved in osseointegration.

Materials and Method: Commercially pure Titanium (cpTi) implants with aloe vera and VEGF, were placed in the tibia of (24) New Zealand white rabbits, Mechanical test (torque removal test) was performed as an indicator for the presence of osseointegration and bone implant contact (BIC) measurement as a test for the property of bone-implant interface. Histological investigation was performed on all the implants of both control and experimental groups at (1, 2, and 6 weeks) healing intervals.

Results: Findings illustrated that removal torque mean and BIC values in experimental implant showed high value in comparison to control. Histological results show an early bone deposition and early maturation in combination group.

Conclusions: Bone formation & maturation was accelerated by adding biological materials and using a combination of Aloe Vera and VEGF is a powerful tool for enhancement of osseointegration.

Keywords: Aloe Vera, Titanium implant, Vascular endothelial growth factor, Osseointegration, Implant surface, Bone

Introduction

Osseointegration refers to a structural and functional fusion of the implant surface with the surrounding bone tissue [1,2]. Many factors may include and affect osseointegration [3] such as surgical technique [4], healthfulness of host bed [5], implant design [6], implant surface and its modification [7], material biocompatibility and loading conditions [8,9].

Aloe Vera is really quite an incredible plant, has used therapeutically for over 5000 years. [10]. The bulk of the Aloe Vera leaf is filled with a clear gel-like substance, which is approximately 99% water. Aloe Vera contains over 200 active components including vitamins, minerals, amino acids, enzymes, polysaccharide, and fatty acids. The vitamins including A, C, E, folic acid, choline, B1, B2, B3 (niacin), B6 [11]. It is also one of the few plants that contains vitamin B12, while the minerals include: calcium, magnesium, zinc, chromium, selenium, sodium,
iron, potassium, copper, manganese, and important fatty acids include HCL cholesterol (which lowers fats in the blood), campesterol, and B-sitosterol\cite{12}.

Aloe vera has been used as a popular herbal medicine since ancient times for many conditions including burns, wound healing, and in dental treatment it illustrates bone, cementum and periodontal ligament regeneration\cite{13,14}.

Vascular endothelial growth factor (VEGF) is endothelial cell-specific mitogen that suggested a regulator of naturally occurring physiologic and pathologic angiogenesis. It stimulates endothelial cell growth, angiogenesis, and capillary permeability that accelerate healing events\cite{15}.

The present study was planned to use an external local application of Aloe Vera and VEGF with implantation of screw and study their effect on healing and osseointegration process.

**Materials and Method**

**Animals**

A total of 24 male New Zealand White rabbits, weighing (2.5-3 kg), aged (10-12 months) were used in this study, and kept in the animal department of (National Center of Drug Control and Research /Iraq) at a constant humidity and temperature of 23°C according to the National Council’s guide for the care of laboratory animals.

**Materials**

- Commercially pure titanium (CpTi) rods
- Aloe vera Gel 87.399%, Phyto care company.
- VEGF165, human recombinant, Bio Vision company

**Methods**

Commercially pure titanium (CpTi) rods (30 cm in length and 5 mm in diameter) were used to form (96) screw-shaped implants by using lathe machine. Each screw was 8 mm in length (5 mm threaded and 3 mm smooth) and the diameter was 3.5 mm in the threaded part and 4mm in the smooth part. The bottom of the screw was made flat but the head of the screw had a slit with 1.5 mm in depth to fit the screw driver of the torque meter during insertion and removal of the implant. Then the implants were cleaned by using ultrasonic cleaning bath (Sonomatic/170-2-T80, Germany) with ethanol and acetone of 75:25 wt% ratio was carried out to removing debris and contamination from the fabricated samples. Implants were rinsed with distilled water and then dried in the oven at temperature of 100 °C. Then the implants were sterilized by using gamma radiation with a CO\textsuperscript{60} source.

Ninety six Implants were divided as follows:

- Group I : Control : 24 Ti implant inserted in rabbit tibia
- Group II: Experimental consists 3 subgroups
  - A: 24 implant inserted in rabbit tibia with local application of 0.1µl of VEGF
  - B: 24 implant inserted in rabbit tibia with local application of 0.1µl of Aloe Vera
  - C: 24 implant inserted in rabbit tibia with local application of combination of 0.1µl VEGF and 0.1µl Aloe Vera

**Surgical procedure:**

Animals were anaesthetized generally with a mixture of ketamine (50 mg/kg) with xylazine(2.5 mg/kg). Surgical technique was performed to prepare holes, two holes in the left tibia in which control was inserted in one hole, & experimental (VEGF) was placed in the second one with a space 2 cm. In the right tibia one hole was prepared for the insertion of implant with experimental (AV), and other one for combination of (VEGF and AV) with a space 2 cm.

Each hole was washed by normal saline and dried gently by air. For the experimental group; 0.1µl of VEGF was applied in socket hole by using a micro-pipette and was left for one minute, while hole with 0.1µl of AV was left for two minute. Application of a combination was done by using VEGF firstly, allow one minute followed by adding Aloe Vera and give two minutes, then insert the implant.

Eighteen animals were sacrificed after 1, 2, and 8 weeks (6 animals for each period) for histological examination.

Bone implant contact (BIC), as histomorphometry at the light microscopic level was done for the period of 8th week.
The rest sixth animals were subjected to mechanical test (torque removal test). The torque was measured with the torque wrench device (OstitelTM; Savedalen, Sweden)[16].

**Radiographic evaluation**

X-ray was done prior to surgery, to ensure that the bone of the tibia was sufficient to accept the implants, and immediately after the operation to ensure that the implants were properly inserted in their positions. After each healing period, both tibiae were examined radiographically again to assess bone healing around each implant.

**Specimen retrieval**

The implants along with their surrounding bone were excised with a surgical saw right away following the euthanasia. The excess tissue was dissected and the specimens were removed with a margin of surrounding bone of about 5–10 mm. The specimens were immediately put into the 10% formaldehyde solution.

**Sample preparation for embedding**

The specimens were decalcified, washed and then dehydrated in the ascending graded ethanol solution. Specimens were embedded in wax block and trimmed, the first undefined slice was removed from the saw blade and the desired section thickness was selected. Mounting and staining of slides by hematoxylin and Eosin (H&E).

**Statistical methods**

Mean values and standard deviations were calculated for Removal Torque test and bone implant contact (BIC) in different studied groups at sixth week measured period. ANOVA test was used to analyze the differences between the implant groups. P value <0.05 was considered significant.

**Results**

**Radiographical evaluation** The results appeared that there were no gross changes in the tibial architecture with no areas of radiolucency between implant and adjacent cortical bone in all specimens, figure(1)

Figure(1) Conventional radiographic view for implant in rabbit tibia

**Mechanical test finding with BIC value.**

Statistics analysis of the removal torque value and bone implant contact (BIC) value for cpTi implants for study groups at eighth week interval were recorded, the torque value that needed to remove all the experimental implant was higher than the control, BIC value records same results. Findings also illustrate a significant difference in measurements for combination (VEGF & AV) in comparison to AV/VEGF group. While a non significant difference value was recorded for the comparison of VEGF with AV. The real domain of the expected torque force and BIC that needed in this period was shown in maximum and minimum value with 95% confidence interval for means and ANOVA test (tables 1,2,3).

**Histological findings**

In control group and at 1st week, osteoid tissue formation was detected at the apex of threads, then bone trabeculae was illustrated at the 2nd week. At eighth week a new lamellated bone showed in the base of implant bed that coalesce with bone thread.

Histological features for experimental group (VEGF) at 1st week showed osteoid deposition on the apex of the threads, then bone trabeculae mostly filled the threads at the 2nd week. At the eighth week an immature bone with osteon was observed.

In experimental group (AV) and at 1st week, osteoid tissue formation was detected at the apex of threads, then bone trabeculae filled most of implant bed was illustrated at the 2nd week. At eighth week an immature bone was observed.
Experimental group (combination VEGF&AV), at 1st week, showed an early formation of bone trabeculae on the apex thread, then it filled all the apex at the 2nd week. A mature bone with haversian system was illustrated at eighth week. Figure(2)

Figure(2) Implant views for studied groups shows developing threads at periods (1, 2 & 6 weeks)

1A: Shows threads (arrows) for control 1 week. H&Ex10

1B: Shows thread (arrow) with bone apposition for control 2 week. H&Ex10

1C: Shows thread (pink arrow) with bone formation extend to implant bed (green arrow) for control 8 week. H&Ex20

2A: Shows threads (pink arrows) with developing blood vessels (green arrow heads) at implant bed for VEGF group, at 1 week. H&Ex4

2B: Trabeculated bone (TB) fill most of thread for VEGF group, at 2 week. H&Ex10
2C : Immature bony threads for VEGF group, at 8week. H&Ex10

3A: Shows threads for AV group, at 1week. H&Ex10

3B: Bone trabecule (BT) mostly filled bed thread for AV group, at 2week. H&Ex10

3C: Immature bony threads for AV group, at 8week. H&Ex10

4A: Shows threads for combination group, at 1week. H&Ex10

4B: Bone trabecule (BT) fill most of thread for combination group, at 2week. H&Ex10

4C: Mature bony threads for combination group, at 8week. H&Ex20

Discussion

Aloe Vera is a well known plant in Iraq. Because of its use in folk medicine as a wound-healing agent, and in cosmetic preparation, and even widely used by public Iraqi people as mask face and in burn condition. On other hand using of VEGF was documented to enhance healing. Therefore we involved using of Aloe Vera with VEGF with implantation and study their effect on bone healing activity and osseointegration.

The present study shows an early osteoid deposition in VEGF group as osteoid tissue formation. These results could be attributed to, that the traumatic site includes, stem cells differentiate into osteoblasts (Catharino et al., 2014)[17] that enhanced by exogenous vascular endothelial growth factor (VEGF) which has been implicated in angiogenesis, and the proliferative osteoblast and active osteocyte were included in deposition of collagen fiber. Same results was illustrated for AV group.

We found also an advance osseointegration sign with early bone maturation in experimental group and specifically combination group, moreover removal torque and BIC values were higher in combination group in comparison to AV, VEGF and control groups at the studied period.

These results may due to the followings

1. Action of Aloe Vera include: anti-inflammation, antimicrobials, healing promotion, and biological/ immunological modulation [12,18,19]

2. Aloe Vera stimulate hard tissue formation include bone [20,21].

3. Aloe Vera act as a bioactive molecule and scaffold for implant bed regeneration.[22,23]
4. Angiogenic potential of VEGF is effective to constitute an enhancement effect for developing bone. [24,25,26]

5. The present findings establish proof that the angiogenic activity of VEGF or the stimulation enhancement of AV is insufficiently potent as compared to combination of AV with VEGF to achieve therapeutic benefit.

Conclusions

Our data suggest that Aloe Vera could be a candidate biomolecule for osseointegration that affect on bone -implant interface tissue regeneration. And a combination of AV with VEGF represent a such a new strategy that might ultimately be applicable to enhance implant stability and integration.

Abstract

Background and Purpose: The human nose has been reported to differ in its anatomy and morphology between different racial and ethnic groups. Nasal anthropometric features when studied can provide useful information for reconstruction or esthetic surgical procedures and personal identification for forensic purposes. Method: A total of 311 subjects with age (19-23) years were divided according to gender, race (Arabic or Kurdish), and residence regions in Iraq (north, middle and south). Different nose parameters were measured for the subjects using digital Vernier caliper. Results: Comparing races, the nose height and nose length were significant between Arab and Kurds, nasal index showed (60, 60.6) for Arabic vs. Kurdish, respectively. Sexual dimorphism was significant in all the parameters obtained. The fine nose was the commonest among all subjects. Parameters analysis revealed high positive significant correlation among various parameters except the nasal index that showed negative correlation with nasal height and length. Conclusions: Nasal morphometric parameters were unique for each person and have variations between different race (Arabic and Kurdish), gender variation and the correlation among various parameters been recorded for Iraqi people. These morphometric evaluations are the key for standardization among Iraqis, and in comparison with different countries, this have great values in anatomical, surgical (aesthetic) and forensic aspects regarding personal identification.

Keywords: anthropometry, nasal dimension, nasal index, personal identification, Rhinoplasty

Introduction

Morphometric variations are noticed in facial features among different races [¹]. The human nose has been reported to differ in its anatomy and morphology between different racial and ethnic groups [²]. Measurements of different parameters of nose became very worthy in procedures related to nasal surgery and cosmetology [³]. Nasal anthropometric features when studied can provide useful information to the rhinoplastic surgeon especially when nasal reconstruction is performed for individuals who desire to change their nasal morphology [³, ⁴]. The nasal shape differs in human populations like various facial structures. For example, the interval between nasal wings had higher significant values in Asian and African when compared to European race [⁵]. The nasal index is one of the morphometric variables among individuals. It defined as the ratio of nasal width divided to nasal height multiplied by 100. It was revealed that the nasal index was the best index for distinguishing the different human ethnicities [⁶, ⁷].

Material and Method

In this present study, a total of 311 pharmacy students were recruited for the study, having age 18-22years, at Al-Rafidain University College, Baghdad and approved by ethical committee in the university. All the subjects were normal healthy residents of Iraq, 156 male and 155 female, the study was conducted during the period from September 2018 to February 2019. The study purposes were explained to all subjects and a written informed consent was obtained from each subject. Medical history and clinical examination were obtained, none of those enrolled for the study have history of craniofacial trauma, nose diseases, congenital anomalies or surgery of the nose. Subjects are classified according to race into Kurdish race and Arabic race. In addition, subjects are also classified into their different origin; from North, middle and south of Iraq. Measurements of parameters were obtained directly from the nose by a single investigator (to eliminate error), by using a digital Vernier’s caliper. Measurements were recorded
Anthropometric measurements were performed depending on the following anatomical landmarks: nasion (n), it is the midline point nasofrontal suture and the nasal root; subnasale (sn), it is the point just at middle of columella base; alar curvature (ac), the most lateral point that could be seen at curved base line of each ala; and pronasale (prn), the most protruding point at the nasal tip. The Anthropometric parameters that were measured include the following, and are illustrated in Figure 1:

1. Nose height (NH): distance from subnasale to nasion
2. Nose length (NL): from pronasale to nasion
3. Width of nose (WN): span from right curve of nasal alae to left one.
4. Right nostril diameter (RND) where maximum diameter of right nostril measured
5. Left nostril diameter where (LND) maximum diameter measurement was done.
6. Right alar curve pronasale (RACP) distance from right curve of ala to nasal tip
7. Left alar curve pronasale (LACP) distance from left curve of nasal ala to nasal tip
8. Nasal index was measured by calculating the nasal width divided by nasal height multiplied by 100.

Nose shape had been classified into five types according to nasal indices \[^{10}\]: 1. Very fine nose with nasal index <54.9 (Hyperleptorrhine), 2. Fine nose with nasal index =55.0-69.9 (Leptorrhine), 3. Medium nose when nasal index had a value between 70.0-84.9 (Mesorrhine), 4. Broad nose with nasal index = 85.0-99.9 (Platyrrhine) and 5. Very broad nose when nasal index >100 (Hyperplatyrrhine).

The collected data was statistically analyzed using SPSS software v.20. Values were expressed as mean ± standard deviation (SD). T test, one way ANOVA followed by post hoc test, chi square Fisher Exact and Pearson correlation test were used to compare the differences of parameters with significance value P<0.05.

Results

All different nasal parameters were recorded in Table 1. The parameters were recorded as mean ± SD, comparing the two races Arabic and Kurdish in one hand and comparing males and females on other hand. Sexual dimorphism was noted with male having higher values than their female counterparts, which were significant in all obtained parameters and nasal index (Table 1).

</table>
Comparison of anthropometric nasal measurements between the two races, Arabic and Kurdish Iraqis, a statistically significant difference was found for only four parameters; nose height, nose length, LACP and LND. On the other hand, nasal index shows no significance between the two races (Table 1). Furthermore, the correlations of different parameters among Arabic, Kurdish and total subjects were analyzed and presented in Table 2.

Table 2: Pearson correlation for different parameters of nose among Arabic, Kurdish and total subjects.

</table>
Pearson correlation of various parameters revealed positive correlation among many parameters. The highest score was 0.9 and it noticed between Right and Left Nostril Diameter. In contrast, negative correlations were seen in nasal index with nasal height (-0.4, -0.4 and -0.6) for total, Arabic and Kurdish respectively. Another negative correlation was observed between nasal index and nasal length with same value for total, Arabic and Kurdish (-0.3) (Table 2). Nose shapes were calculated based on the number and percentage of nose shape by race (Arabic and Kurdish) and presented in Table 3. The most common shape in both races was the fine nose (68%) while the least frequency was the broad type (1%). No significant difference was observed between races and shape, indicating that the race does not have any effect on nose shape.

The results of the anthropometric analysis obtained among different regions of Iraq (north, middle, and south) are shown in Table 4. The middle region shows the highest parameters of all regions. One-way ANOVA test was performed to compare parameters among the three regions. A significant difference was seen only in nose height and nose length. Tukey post hoc test revealed the significance was only between the middle and north group and in both nose height and nose length (Table 4).

Table 4: Nose morphometry among different regions, north, middle and south (measurements in mm). The results were expressed as mean ±SD. One way ANOVA followed by post hoc Tukey analysis were used to compare the differences between groups. a, b, and c represent significantly different as compared to South, middle and north (P<0.05) respectively.

**Discussion**

The nasal morphometry is one of the significant features that characterize different races because it is at the center of the face. Different anthropological findings have described the nose as a signature indicating the ethnicity, race, age, and sex of an individual \cite{11, 12}. Morphometric assessments of parameters have clinical importance for nasal reconstruction after injury or for esthetic causes in addition to its importance in personal identification. Arabs had different race from Kurdish people that might help us to evaluate different race. Moreover there is variation in climate between north, middle and south of Iraq. According to our knowledge, the study of nose morphometry among Iraqis is the first study that carried out among our population, including the racial difference between Arabic and Kurdish. As presented above significant differences were noticed regarding nasal length and nasal height in both races. The dominant shape among subjects was the fine nose in both races. In addition, differences were noticed among nasal length, nasal height and nasal index. Some of the distinctive parameters that were carried out in this study are RACP and LACP. These two parameters assess distance of nasal tip and the nasal curve that provide indirect way to appreciate nasal deviation or not and the shorter distance means Ipsilateral nasal tip deviation. RND and LND parameters obtained above revealed RND and LND showed the high positive correlation only with NW and should be taken in consideration in reconstruction surgery.

Comparing our results with other results obtained from different studies, for instance among Nigerian populations \cite{13, 14}, there were lower values of nasal height and nasal length (44.1±3.7mm and 39.8±2.8mm) respectively, compared to our findings (53.8±5.7mm and 47.5±5.8 mm). However, nasal width and nasal index showed higher values (37.7±2mm and 86.1±8mm) compared to ours (32.2±4.1mm and 60.2±7.7mm) respectively. Both Nigerian studies showed similar findings to ours concerning sexual dimorphism, specifically there was significant difference in both gender regarding nasal height, nasal width and nasal index. Although, our results showed lower values of nasal width and nasal index compared to their results and higher values of nasal height. Conversely, on a recent Nigerian study, it stated lower values for nasal height, nasal length and nasal width compared to our results. Furthermore, it represented higher nasal indices for female and male (92.9, 98.9) respectively, and therefore broad nose is the dominant type, in contrast to ours, where the nasal indices for females and males were (59.2, 61.2) respectively, and fine nose is most common type. On the other hand, among Italian subjects nasal height, nasal length, nasal width and nasal index were 57.6±4mm, 49.3±4.8mm, 37.1±2.5mm and 64.9±6.9 respectively for adult male, while for females the same parameters were 54.3±4.2mm, 46.3±4.0mm, 35.3±2.6mm and 65.3±6.5 respectively \cite{15}. Our findings showed lower values for nasal height, nasal width and nasal index, with close values for nasal length.

**Conclusions**

Nasal morphometric parameters had different values for each parameter in different countries and had variations in regions within same country. Our results between Arabic and Kurdish, gender variation and the correlation among various parameters were recorded for Iraqi people subsequently these morphometric evaluations are the key for standardization among Iraqis, which have important impact for anthropologists, forensic and surgical procedures, by depending on values obtained from same community. In general, our study and many studies showed different nose parameters that emphasize the effects of race, sexual dimorphism, genetic and climate conditions on parameters.

Subjective Work Fatigue Due to Hot Work Climate  
(A Study on Indoor Production Workers of Ud King Rack  
Surabaya Indonesia)

Putri Arianto1, Endang Dwiyanti1
1Department of Occupational Health and Safety, Public Health Faculty, Airlangga University, 60115, Surabaya,  
East Java, Indonesia

Abstract

One of physical factors contributing to the increasing number of work accidents and deaths is the hot working climate. One of the effects of hot working climate is work fatigue. The purpose of this study is to analyze the strength and direction of the relationship between the hot work climate and work fatigue in indoor production workers. This is an observational descriptive study using a cross sectional design. The sample was 33 workers. This study collected data of workers weight, workers height, pulse rate, Wet Bulb Globe Temperature, reaction timer and Subjective Self Rating Test. Data was analyzed using univariate and bivariate analysis.

The result showed that only working area of Oven 1 and Oven 2 that have the hot work climate exceeding the threshold limit value. All of 6 workers in those areas reported to experience subjective work fatigue. This study found that hot work climate and work fatigue has fairly strong and unidimensional relationship.

Keywords: hot work climate, work fatigue, subjective

Introduction

Hot work climate is one of the physical factors that are the cause of work-related illnesses, workplace accidents, and even death of workers. Work climate potentially causes health problems such as Prickly Heat, heat exhaustion, an increase of body temperature, heat stroke, heat cramps, increasing pulse rate, and dehydration1. Those health problems are because the body is not able to adapt to the work environment.

The hot working climate in Indonesia is regulated by the Threshold Limit Value (TLV) in the Minister of Manpower Regulation No. 5 of 2018 concerning Occupational Safety and Health, detailed at the Appendix point 1.

The work climate that exceeds the TLV will potentially disrupt workers health and comfort, and even can lead to death. An evidence of such cases was shown from the case found by NIOSH in 1992 to 2006. During those years, it found 423 workers death due to excessive exposure to the hot environment2. In addition, according to USA Bureau of Labor Statistics Report of 2015, there were 37 deaths and 2830 occupational injuries and diseases caused by exposure to hot environments 3.

One of the health problems that can occur is work fatigue. This is supported by the theory of “The Bucket Model” which explains that one of fatigue causes is climate4. According to Grandjean, in Setyawati’s book (2010), fatigue cannot be clearly explained or defined, but it can only be felt, however Grandjean (1995) defined fatigue as the feeling of tired and decreasing alertness. Therefore, this study focuses on the state of feeling tired. Feeling of fatigue is a subjective symptom in the form of...
uncomfortable and unpleasant feelings experienced by workers at work and after work.

Other than by climate, work fatigue are also caused by mental workload and physical workload, length of work, noise, ergonomics, emotional and organizational demands and personal factor.

There are researches that support the theory that subjective work fatigue is associated with a hot work climate. Research by Yuli Suryaningtyas and Noeroel Widajati (2017) on Work Climate and Nutritional Status with Work Fatigue on Workers in Ballast Tanks at Ship Repair Section PT. X Surabaya found that there is a moderate relationship with a positive direction between work climate and fatigue. The measurement of fatigue of their research was carried out using a subjective method, namely the KAUPK2 questionnaire. In this study, it found that the WBGT index in Ballast Tanks exceeded the TLV of the permissible work climate. It also found that most of workers felt very tired.

Based on the background above, it was encouraging to conduct a scientific study and research on the relationship of hot work climate and subjective work fatigue in Indoor Production workers UD King Rack Surabaya Indonesia.

**Material and Method**

This study is an observational study as the researchers did not provide special treatment and intervention to workers. The research was carried out with a cross sectional method, namely a one-time approach, where identification of causes and effects was carried out at the same time. This study was descriptive research in accordance with the nature of the problem and analysis of the data. This study used total population sample. Therefore, subjects of this research were all workers (33 workers) who worked in the indoor production section of UD King Rack Surabaya Indonesia.

This study aimed to determine the strength and direction of the relationship of hot work climate and subjective work fatigue. The independent variable in this study is the hot work climate and the dependent variable is subjective work fatigue. To determine the relationship strength relationship between the two variables, the theory of Sarwono (2006) was used. It categorized the strength into six categories based on the analysis results:

1. 0 = no correlation
2. 0-0,25 = weak
3. 0,25- 0,5 = moderate
4. 0,5-0,75 = strong
5. 0,75-0,99 = very strong
6. 1 = perfect.

The direction was concluded by the positive and negative sign of the correlation coefficient.

Air flow speed : 0.1 - 1 (m/dt)

Table 2 shows that the highest WBGT index was in the oven 2 area of 30.7°C and the lowest was in the friction welding area of 28.8°C.

C. Measurement Results of Workload for Indoor Production Workers UD King Rack Surabaya Indonesia

To assess whether work climate meet the TLV is not only from the WBGT index in each area, but also from the workload and working time arrangements for every hour. Heavy workload will affect to the declining resilience of the worker’s body in facing the hot work environment. Therefore, if the workload is heavy, it is necessary to have a comfortable work climate for workers. The workload measurement used in this study was a 10-pulse method workload measurement. The measurement of pulse rate included the Resting Pulse Rate (RPR) and Working Pulse Rate (WPR).

Table 3. Workload Measurement Result of Workers in Indoor Production Section of UD King Rack Surabaya Indonesia

</table>
Table 3 shows that 6 workers (18.2%) in the Indoor Production Area of UD King Rack Surabaya have very heavy workload with a pulse rate of 125-150 per minute from 10 pulse rate measurements. Most of the workers (81.81%) experienced light workload with a pulse rate of 75-100 per minute.

D. Determination of Suitability of Hot Work Climate in Indoor Production UD King Rack Surabaya Indonesia 2019 with Threshold Limit Value

Based on the measurement of work climate (WBGT), workload and working time arrangements, it can be concluded that hot work climate in each area is in accordance with or did not exceed the Threshold Limit Value determined by the Minister of Manpower Regulation No. 5 of 2018 concerning Occupational Safety and Health at the Work Environment. The following table shows the suitability of hot work climate in Indoor Production of Surabaya Indonesia UD King Rack in 2019 with Threshold Limit Value of the above regulation:

Table 4. The Suitability of Hot Work Climate in Indoor Production UD King Rack Surabaya Indonesia 2019 with the TLV

Table 4 shows that there were 2 areas that have a work climate that is not in accordance with the Threshold Limit Value in terms of the WBGT index, workload and working time arrangements for each hour. The two areas were oven area 1 with WBGT of 30.2°C and oven area 2 with WBGT of 30.7°C.

E. Result of Subjective Work Fatigue Measurement

In this study, work fatigue data was obtained from a subjective method measurements in the form of Subjective Self Rating Test questionnaire, consisting of 30 questions. The fatigue category is divided into 4 categories: not tired, mild fatigue, moderate fatigue, and severe fatigue. The following table shows the results of the work fatigue measurements:
Table 5. Result of Subjective Work Fatigue Measurement of Indoor Production Workers UD King Rack Surabaya Indonesia 2019

</table>
Table 6 shows that workers who are exposed to hot work climate exceeding the TLV experienced moderate fatigue. The fatigue was 2.07 times greater than the moderate fatigue experienced by workers with a hot work climate within the TLV. The result of data analysis shows that there was a moderate relationship between hot work climate and subjective work fatigue in the indoor area of UD King Rack Surabaya Indonesia. The correlation was positive and can be seen from the correlation coefficient of 0.375.

**Discussion**

Based on the analysis results, there were only 2 areas that have hot work climate index exceeding the Threshold Limit Value. It was area of oven 1 and oven 2. The relationship between hot work climate and subjective fatigue is quite strong. It was shown by the fact that workers of area oven 1 and oven 2 reported complaints both physically and motivationally, especially those who often experienced dizziness and dehydration. The complaint was caused by very high temperatures released by the oven with a temperature of 75°C to 90°C.

Direct exposure to the heat from the oven adds the heat burden felt by workers. Workers were often seen to stop working in order to drink and take a break while waiting for oven to process which takes 5 minutes. This indicates that the occurrence of worker fatigue. As the consequences, the fatigue can decrease worker work speed, make them to be more prone to errors and less productive, which lead to the increasing risk of negative safety or incidents. In fact, one study estimates work fatigue contributes to 13% of workplace injuries. During the interview, complaints to be most of workers reported were dizziness and thirst. Dizziness and dehydration are among the physical symptoms of fatigue.

Subjective work fatigue indicates that there is no worker experiencing severe fatigue. This is because workers have acclimatized to the existing temperature. They feel accustomed and report small number of complaints of continuous fatigue symptoms. This is in line with their working period in the oven area. Most of them have been working for more than 1 month while the acclimatization process only needs 5-7 days for workers to adapt the hot work climate with the longest of 12-14 days.

The relationship between hot work climate and subjective fatigue has a positive direction. This means that if the hot work climate increases, subjective work fatigue also increases.

This result is in line with research from Ridha Ramayanti (2018) entitled “Analysis of the Relationship between Nutritional Status and Work Climate with Fatigue in Catering in Surabaya Food Wisdom”. Ramayanti found that there is a moderate positive relationship between the work climate and work fatigue. The hot work climate at Catering Surabaya’s Food exceeded the TLV. Their workers experienced severe, moderate, and mild fatigue. Ramayanti (2018) also used the same subjective method, the Subjective Self Rating Test questionnaire from Japan’s Industrial Fatigue Research Committee (IFRC).

**Conclusion**

1. Workers in the Indoor Production Section of the UD King Rack Surabaya are all male. Most workers are 20-30 years old, with work periods of less than 5 years, have smoking habits, and have a normal MBI.

2. The highest WBGT index value is in the oven 2 area of 30.7°C and the lowest is in the friction welding area of 28.8°C. Hot work climate that is not in accordance with the Threshold Limir Value set by PERMENAKER No. 5 of 2018 is in the oven area 1 with WBGT of 30.2°C and oven area 2 with WBGT of 30.7°C. All workers in the areas where the hot work climate exceeded the TLV reported to have heavy workloads and to set the working time 75% -100% for every hour.

3. The result of subjective work fatigue indicates that all workers (100%) in the area exceeded the TLV of work climate reported moderate fatigue.

4. There is a positive moderate relationship between the hot work climate and subjective work fatigue

**Recommendation**

1. Control of heat sources or oven by isolation or limiting heat source exposure to other areas.

2. To manage the hot work climate with the addition supply of air conditioning devices such as fans

3. To provide quite cool rooms for body cooling equipped with drinking water supply for workers of oven 1 and 2.

4. To educate worker on the importance of
drinking 150-200 cc of water or equivalent to a glass of water for every 15 minutes -20 minutes.

5. To set working time 25% - 50% for oven 1 workers every hour, equivalent to 15 to 30 minutes working for every hour, and 20% - 25% for oven 2 workers, equivalent to a maximum of 15 minutes working time for every hour.

Conflict of Interest: All authors have no conflicts of interest to declare.

Abstract

Background: Copper nanoparticles (CNPs) have unique physical and chemical properties for this reason it was widely used in various medical and non-medical applications. This study aimed to study the toxic effect of copper nanoparticles on liver and kidney through histopathological examination of liver and kidney tissues and if there is improvement of hepato-nephrotoxicity after cessation of exposure and to study the potential protective effect of alpha lipoic acid (ALA) against hepato-nephrotoxicity induced by copper nanoparticles.

Finding: Histopathological examination of liver and kidney tissues in rats received CNPs showed significant alteration, cessation of exposure can cause slight improvement and ALA can cause significant improvement.

Conclusion: Copper Nanoparticles have hepato-nephrotoxic effect and ALA can be safely used as a protective agent against CNPs toxicity.

Keywords: Copper nanoparticles, Nanotoxicity, Hepatotoxicity, Nephrotoxicity, Histopathology.

Background

Nanotechnology is highly promising technology that is concerned with understanding the behavior of nanoparticles and its properties and how to control particles at nanoscale range.1

Copper nanoparticles have unique physical and chemical properties such as high electrical conductivity, high melting point, low electrochemical migration behavior.2

The increasing production and use of metal nanoparticles for different applications lead to many adverse effects on health.3

The main target organs for toxicity with CNPs are kidney, liver and blood. Liver is the main damaged organ.4

Alpha lipoic acid is a potent antioxidant. It has antioxidant activity in both fat and water-soluble mediums.5

There for the aim of this study is to identify the toxic effect of CNPs on liver and kidney through histopathological examination and to study the potential protective effect of ALA against hepato-nephrotoxicity induced by CNPs.
Methodology

Chemicals

1. Copper Nanoparticles

Copper Nano Particles (CNPs) 25 nm at 99.5% purity, mineral in nature and spherical in shape, was purchased from Sigma Aldrich, co. (St. Louis, Missouri, USA).

2. ALPHA LIPOIC ACID

Alpha lipoic acid (ALA) at 99% purity, was purchased from Sigma Aldrich, co. (St. Louis, Missouri, USA).

Study Design

The study design was approved from the local ethical committee of faculty of medicine, Cairo university and from Cairo University Institutional Animal Care and Use Committee (CU- IACUC), Medical Science Sector.

Animal grouping:

100 adult male albino rats of body weight 150–170 g was supplied and housed by the National Instituted of Ophthalmology. All animals have free access to water and food and exposed to 12 hours light/dark cycle. After acclimatization for 2 weeks, 100 adult male albino rats were randomized into four main groups and were treated daily for 90 consecutive days as follows:

Group I act as controls (30 rats):

Group I-A (negative control group of 10 rats),

Group I-B (10 rats): receive deionized water (2 ml) daily,

Group I-C (10 rats): receive olive oil (2 ml) daily.

Group II (30 rats):

Group II-A (20 rats): receive Copper Nano Particles (40 mg/kg bw) for 90 days,

Group II-B (follow up group of 10 rats): receive Copper Nano Particles (40 mg/kg bw) for 90 days then no treatment for the following 4 weeks.

Group III (20 rats): receive ALA (100 mg/kg bw) daily.

Group IV (20 rats): receive Copper Nano Particles (40 mg/kg bw) and ALA (100 mg/kg bw) as a prophylactic agent.

After 90 consecutive days following the last dose administration, rats were anaesthetized and sacrificed by decapitation. The follow up group were allowed for recovery with no treatment for 30 days then scarified as before.

Dose Selection and Preparation of Oral Suspension

• Copper Nanoparticles Dose:

LD50 for CNPs is 413 mg/kg body weight. The selected dose of CNPs was 1/10 LD50 which induce biochemical alteration in rats without morbidity. Stock suspension of CNPs was prepared by dispersing CNP powder in deionized water followed by vigorous vertexing and sonication.

• Alpha lipoic Acid Dose:

The selected dose for ALA is (100 mg/kg bw) was reported to be hepatoprotective in rats. Stock of ALA oral suspension was prepared by dissolving ALA in olive oil to improve its absorption by vigorous vertexing and sonication.

At the End of the Study Period:

After 90 consecutive days following the last dose administration, rats were sacrificed. The follow up group were allowed for recovery with no treatment for 30 days then scarified.

Histopathological Observation:

liver and kidney from each rat were cut rapidly, fixed in neutral purified formalin (10%), then dehydrated with grades of ethanol (70,80,90,95 and 100%). Dehydration is then followed by clearing the samples with 2 cycles of xylene. Samples were then impregnated with 2 changes of molten paraffin wax, then embedded and blocked out. Paraffin sections (4-5 μm) were stained in hematoxylin and eosin and get examined under light microscope under high power (X100).

Stained sections of all groups were examined for:

1- Liver: alteration of architecture, portal inflammation, hepatocytes and for the presence of degeneration, necrosis and portal fibrosis.
2- **Kidney**: alteration of architecture of the cortex and medullary segments and the structure of glomeruli as well as proximal and distal tubules.

**Statistical Analysis**

Data were coded and entered using the statistical package of Social Sciences (SPSS). Comparisons between groups were done using analysis of variance (ANOVA) with multiple comparisons post hoc test.\(^8\) For comparing categorical data, Chi square \((\chi^2)\) test was performed.\(^9\)

**Finding**

Liver Histopathological Examination of the Studied Groups:

1. **Histopathological Examination of Group 1 & Group 3:**
   
   Histopathological examination of sections of liver from rats of group 1 and group 3 showed normal hepatic parenchyma with preserved lobular architecture, normal arrangement and structure of the hepatocytes. The portal tract showed no inflammatory cells. No congestion was seen, and central vein was within normal (figures 1).

2. **Histopathological Examination of Group 2A:**
   
   Histopathological examination of sections of liver from rats of group 2A showed severe histopathological alterations characterized by dilatation of central vein with disruption of lobular architecture and disorganization of hepatic cords as well as necrobiotic changes in the form of vacuolar degeneration with vesicular nuclei of the hepatocyte and fat accumulation; steatosis. The portal tract is dilated with inflammatory exudate. Periportal fibrosis was detected and the central vein was dilated (figure 1).

3. **Histopathological Examination of Group 2B:**
   
   Histopathological examination of sections of liver from rats of group 2B revealed mild ballooning of the hepatocytes, however the portal area is dilated and showed inflammatory cell infiltrate, the central vein was dilated congested. The hepatocytes showed some disorganization (figure 2).

4. **Histopathological Examination of Group 4:**
   
   Histopathological examination of sections of liver from rats of group 4 revealed that portal tracks appeared normal in some sections other sections showed minimal to mild inflammation in occasional portal tracts, the central vein is of normal caliber and is not congested. The hepatocytes showed minimal to absent vacuolar changes (figure 2).

**Comparison Between Studied Groups using Chi-Square Tests:**

Regarding severity of lesion in the four main studied group it was found that, 35% of liver sections of group 2A showed severe lesion and 54% of sections showed moderate lesion while 10% of liver sections of group 2B showed sever lesion and 40% was moderately affected compared to the three control groups 1A,1B & 1C as well as group 3 which were normal. While 65% of group 4 liver section were normal and 35% showed mild lesion with statistically significant difference between the 4 main groups (p value <0.001) (figure 3).

Renal Histopathological Examination of the Studied Groups:

1. **Histopathological Examination of Group 1 & Group 3:**
   
   Histopathological examination of group 1 & group 3 showed normal appearance of the glomeruli with normal cellularity. The tubules are not dilated with the lining cells are of normal appearance and the interstitial tissues showed no inflammation or congested blood vessels (figure 4).

2. **Histopathological Examination of Group 2A:**
   
   Histopathological examination of group 2A showed swollen glomeruli with thickened basement membrane. Both the glomeruli and the interstitial blood vessels are congested. Foci of fibrosis are seen. The tubular lining showed degenerative changes (figure 4).

3. **Histopathological Examination of Group 2B:**
   
   Histopathological examination of group 2B showed swollen glomeruli with thickened basement membrane with congested both glomerular and interstitial blood vessels however, the tubular lining showed no degenerative changes and there was no fibrosis seen (figure 4).
4. Histopathological Examination of Group 4:

Histopathological examination of group 4 showed thin basement membrane of the glomeruli. Both the tubules and interstitial tissues showed no pathological changes apart from minimal degenerative changes of the tubular lining (figure 4).

Comparison Between Studied Groups using Chi-Square Tests:

Regarding severity of lesion in the four main studied group it was found that, 40% of renal sections of both members of group 2 (2A & 2B) showed moderate lesion and 60% of sections showed mild lesion compared to the three control groups 1A, 1B & 1C as well as group 3 which were normal. While 75% of group 4 liver section were normal and 25% showed mild lesion with statistically significant difference between the 4 main groups (p value <0.001) (figure 5).

Pairwise Comparison Between Studied Groups

Using Post hoc Pairwise Comparisons between group 1, group 2A, 2B, group 3 and group 4 in histopathological examination of liver sections there was statistically significant difference between group 2 with groups 1, 3, 4 (p value <0.001) and group 4 with groups 2A & 2B (p value <0.001) while there was no statistical significant difference between groups 2A and 2B.

Using Post hoc Pairwise Comparisons between group 1, group 2A, 2B, group 3 and group 4 in histopathological examination of renal sections there is statistical significant difference between group 2 with groups 1, 3, 4 (p value <0.001) and group 4 with groups 2A & 2B (p value <0.001) while there was no statistical significant difference between groups 2A and 2B.

Figure 1: Sections of liver a) group 3 with normal appearance, central vein (the star) within normal b) group 2A showed vesicular nuclei of the hepatocyte with the portal tract is dilated showed inflammatory exudate (the arrow), c) group 2A showed dilated central vein (the star). d) group 2A showed mildly dilated congested central vein (the star). The hepatocytes showed disorganization, with hydropic changes and ballooning (the circle) and steatosis (the empty arrow). X100 H&E.
Figure 2: Sections from the liver: a) group 2B showed mild ballooning of the hepatocytes, the portal area is dilated and showed inflammatory cell infiltrate (the arrow), b) group 2B with dilated blood vessel (the star), with the portal tract is dilated with inflammatory exudate (the black arrow). The hepatocytes showed some vascular degeneration, c) group 4 showed minimal to mild inflammation in occasional portal tracts (the black arrow), the central vein is of normal caliber and is not congested. The hepatocytes showed minimal to absent vacuolar changes, d) group 4 showed within normal portal tracts (the black arrow), the hepatocytes showed no hydropic degeneration (the circle), the central vein is of normal caliber and is not congested (the star) x100 H&E.

Figure 3: Histopathological grading of liver sections in the 4 studied groups.
Figure 4: Section from kidney a) group 3; showed normal appearance of the glomeruli with normal cellularity (the arrow). The tubules and the lining cells are of normal appearance, b) group 2A showed swollen glomeruli with thickened basement membrane (the black arrow). Both the glomerular and the interstitial blood vessels are congested (the star). Foci of fibrosis are seen (empty arrow). The tubular lining showed degenerative changes, c) group 2B showed swollen glomeruli with thickened basement membrane (the arrow) with congested both glomerular and interstitial blood vessels, d) group 4 showed thin basement membrane of the glomeruli (the black arrow). Both the tubules and interstitial tissues showed no pathological changes apart from minimal degenerative changes of the tubular lining. X100 H&E.

Figure 5: Histopathological grading of renal sections in the 4 studied groups.
**Discussion**

Histopathological alteration of liver tissue could be explained by accumulation of CNPs in the liver which can cause discontinuous endothelia that allow the passage of NPs from the blood into the liver parenchyma. This accumulation is responsible for the sever histopathological alterations.10

In accordance with our study, CNPs caused various histopathological alterations in the liver tissues and the hepatocytes.6,11

The protective effect of ALA against liver toxicity could be explained as ALA was considered as chelator compound as it can chelate metals ions.12 ALA has a protective effect of on kidney and the histopathological result showed marked improvement in the group of rats received ALA.13

CNPs caused severe damage to the kidney tissues as the strong ionization potential of copper ions lead to its accumulation in the renal tissue which lead to inflammation in the renal tissues.14 In accordance, CNPs caused widespread tubular necrosis15 and can cause damage to the renal tissue14.

**Conclusion and Recommendations**

- CNPs caused histopathological alterations in liver and kidney tissues.
- Discontinuation of CNPs exposure in the follow up group caused non-significant improvement in liver tissues and did not improve the kidney tissues.
- Alpha lipoic acid can cause improvement in the histopathological changes caused by CNPs toxicity.
- Results of this study recommend periodic medical examination as well as Liver and kidney function tests in case of continuous exposure to CNPs.
- In case of deterioration of liver functions due to continuous exposure to CNPs; a period of cessation of exposure for at least 4 weeks is recommended.
- Alpha lipoic acid can be safely used as a prophylactic agent in case of Nano copper exposure.
- Confirmation of this study results regarding the period of cessation of exposure to CNPs is needed with prolongation of the follow up period.

1Department of Occupational Health and Safety, Public Health Faculty, Airlangga University, Surabaya

Abstract

Benzene is one of the aromatic hydrocarbon compounds that are widely used in the industrial sector. Benzene exposure in the work environment has been set a threshold value. Benzene exposure in humans can provide health effects especially disrupting the central nervous system, hematopoietic system, and immune system. Acute effects can include laryngeal irritation, dizziness, pallor, shortness of breath, headache, fatigue, drowsiness, and fainting. While the chronic effects can be cancer.

This research is a study with an environmental health risk analysis approach with the aim to assess and make predictions that will occur due to exposure to benzene in public fuel station (SPBU) officers around the area of Diponegoro University, Semarang. The Environmental Health Risk Analysis (ARKL) approach consists of several steps, namely hazard identification, response dose analysis, exposure analysis, and risk characteristics.

The results of the measurement of benzene concentrations in gas stations around the Diponegoro University in Semarang at point 1 were 0.38 ppm and at point 2 was 0.51 ppm. So that the concentration is still below the Threshold Value (NAB) according to the Minister of Manpower Regulation Number 5 of 2018. Based on manual calculations for safe limits benzene concentration is obtained 0.08538 mg / m³ or 0.02672 ppm. This means that the highest concentration of benzene in the work environment is 0.51 ppm, with an average body weight of 55.67 kg, height of 159 cm with a working time of 8 hours, and safe concentration so as not to cause a non-carcinogenic risk is 0.08538 mg / m³ or 0.02672 ppm.

Keyword: Benzene, Safe Concentration, Gas Station

Introduction

Besides being used in industry, benzene is found to be widely available in our daily lives. Benzene is produced by distillation of coal or crude oil. This material is used as one of the raw materials in the production of many aromatic compounds such as styrene, phenol, cyclohexane, and nitrobenzen, also in drugs, pesticides, and detergents. Sometimes benzene is also used as an extraction solvent. This material can also be found in solvents for wax, resin, rubber, plastics, film, and glue paint. In recent years the use of solvents has been restricted or banned in many countries due to its toxicity. Benzene is present in gasoline (petroleum), toluene and xylene in impure form.1

Around 1990 benzene was used as an indicator of exposure to gasoline fuel, especially for workers at gas stations. The volume of benzene in gasoline fuels ranges from 2 - 6% in the Nordic country. The allowed working time is 8 hours a day, the gas station staff in the Nordic are exposed to benzene around 0.5-1 mg / m³. Exposure to gasoline vapor at gas stations, especially when refueling gasoline into the car tank. Filling 30 liters containing 5% volume of benzene into the car, there is around 700 mg of benzene inhaled. The total concentration of hydrocarbons in the air during the
process of refueling gasoline is 10 to 100 times benzene. Gas station staff can also be exposed to vehicle gas emissions, including polycyclic aromatic hydrocarbons, aldehydes, and 1,3-butadiene.

According to WHO, one of the sources of benzene in ambient air comes from benzene evaporation in fueling stations. Benzene concentrations in ambient air are estimated to be inhaled and exposed to fuel station workers of 0.12 ppm. Benzene exposure in humans can provide health effects especially disrupting the central nervous system, hematopoietic system, and immune system. Acute effects can include laryngeal irritation, dizziness, pallor, shortness of breath, headache, fatigue, drowsiness, and fainting. While the chronic effects can be cancer.

According to the Agency for Toxic Substances and Disease Register (ATSDR), hazardous and toxic chemicals contained in oil content are benzene, toluene, xylene, ethylene, TPH (Total Petroleum Hydrocarbon), and Polycyclic Aromatic Hydrocarbon (PAHs). Of the six chemicals, benzene exposure has a very serious impact on health.

Population growth in the city of Semarang has increased in accordance with data from the Central Statistics Agency (BPS) in 2013 of 1,672,999 people. This was also due to population growth in each sub-district in Semarang City, especially Tembalang and Banyumanik Districts. Where the two sub-districts are several universities, one of which is Diponegoro University. This made the attraction of migrants from various regions to come to the two sub-districts. As in the 2013 Central Bureau of Statistics (BPS) data, the population in Tembalang and Banyumanik Subdistricts was 147,564 people and 130,494 inhabitants.

Every day the gas station around the area of Diponegoro University fills 24,000 liters of fuel. The fuel in the Gas Station causes a strong odor that can be inhaled and entered into the human body, one of them is a gas station officer who maintains fuel installations. The smell of these fuels contains benzene organic compounds. Other studies show that the results of benzene exposure in the air to the refueling station staff are 0.23 ppm or 0.73 mg / m3.

Benzene exposure in the work environment has been set a threshold value. In Indonesia the AMbang Limit (NAV) of benzene is 0.5 ppm. Use the Regulation of the Minister of Manpower and Transmigration number PER / 13 / MEN / X / 2011 concerning the Physical and Chemical Factor Threshold Values in the workplace and according to NIOSH, the threshold value of benzene is 0.1 ppm.

Fuel oil is a mixture of more than 500 volatile hydrocarbon compounds and benzene is a hydrocarbon compound which is a major concern in studies that explain health problems due to benzene exposure. The population of workers who work in industries that produce or use benzene can be exposed to the highest exposure levels. ATSDR (2007) states that the main exposure route occurs through inhalation, although dermal exposure and oral exposure may also occur.

Material and Method
This research is a research with an environmental health risk analysis approach with the aim of assessing and making predictions that will occur due to benzene exposure in gas station officers around the Diponegoro University Semarang area. The Environmental Health Risk Analysis (ARKL) approach consists of several steps, namely hazard identification, response dose analysis, exposure analysis, and risk characteristics.

The population of this study were all officers at four gas stations around the area of Diponegoro University. The number of officers at the four gas station around the Diponegoro University area is 78 people and the study sample was calculated using the Slovin formula.

The sampling technique used purposive sampling based on certain considerations made by researchers with the inclusion criteria was officers who had direct contact with benzene sources, male and/or female, worked on the morning and afternoon shifts and worked ≥ 1 year. Measurement of benzene concentrations in ambient air that is inhaled directly by gas station officers using a personal dust sampler and coconut shell charcoal. Secondary data consists of workplace administrative data, such as number of workers, length of service, type of fuel, work shift schedule. Study of intake calculations, non carcinogenic, carcinogenic, dose response values, and technical methods of Environmental Health Risk Analysis (ARKL).

Findings
A. Worker Characteristics, Worker’s Body Surface Area and Worker’s Respiratory Rate
The characteristics of the workers in this study included the body weight and working time of 27 workers.
in the Ciputat area gas station area. Based on Table 1, it is known that the highest body weight of workers in the Ciputat area gas station area is 80 kg, the lowest weight is 44 kg, and the average body weight is 57.73 kg. The duration of work in a day is 8 hours. Whereas for height use the average value of Indonesian adult male height which is 159 cm.

Based on data on worker weight and height of workers, the body surface area and the rate of respiration of workers can be calculated using the following formula.

1. The surface area of the worker’s body

\[ BSA = \sqrt{\frac{W \cdot h}{3600}} \]

2. Worker breathing rate:

\[ BR = \frac{5.3 \ln - 6.9}{24} \]

</table>
The results of the analysis of the calculation of body surface area and worker respiratory rate according to Table 1 show that the average body surface area of workers is 1.56 m² and the average respiration rate of workers is 0.59 m³/hour.

B. Benzene Concentration

The results of the measurement of benzene concentration at both points in the Ciputat region gas station environment showed the same results, which was equal to 0.58 mg/m³ (0.18 ppm).

Table 2. Distribution of Benzene Concentration in Gas Station Around the Area of Diponegoro University, Semarang

Based on the results of measurements made, the concentration of benzene in the work environment at the gas stations around the Diponegoro University Semarang area is 0.44 ppm. This benzene concentration is below the threshold value (NAB) of 0.5 ppm in accordance with the provisions of the Minister of Manpower Regulation Number 5 of 2018 concerning Occupational Safety and Health at the Work Environment. However, the benzene concentration was above the Minimum Risk Level (MRL), the level of exposure to inhalation benzene determined by ATSDR, namely for acute exposure (≤14 days) = 0.009 ppm, moderate exposure (15-364 days) = 0.006 ppm, and chronic exposure (≥365 days) = 0.003 ppm.

C. Calculation of Human Km

The results of the Human Km calculation are shown in Table 3. Based on table 3, the average Human Km at the Gas Station Around the Area of Diponegoro University Semarang is 35.37.

D. Noael

One of the objectives of research activities in the field of toxicology is to be able to evaluate the safety of a substance. To determine the safe limit of the concentration of a chemical begins with the toxicity test determining the highest dose without causing effects on experimental animals or No Observed Adverse Effect Level (NOAEL).

Swaen et al. (2010) ’s research states that NOAEL benzene is 3.0 mg / m3 or equivalent to 0.022 mg / kg which is permitted from the calculation of formulations as follows.10

\[
NOAEL\ benzene = \frac{3 \times 0.00013 \times 8}{0.1405} = 0.022\ mg/kg
\]

E. Safe Human Dose

\[
SHD = NOAEL \frac{W \text{ human}}{\text{Human km}}
\]

Based on the formula, the calculation of SHD obtained from the NOAEL value, the average animal Km, and the average human Km are:

F. Limits on Safe Benzene Concentration

Determining the safe limits of benzene concentration in gas stations around the area of Diponegoro University in Semarang uses the following formula (Soemirat, 2003).11

\[
C_{safe} = \frac{\text{SHD} \times W}{\delta \times BR \times t} \text{mg/m}^3
\]

To convert units of mg / m3 to ppm the following formula is used.

\[
C_{safe} = \frac{\# \text{ mg/m}^3}{(MW)} \times 24.5 \text{ ppm}
\]

Information:

- \( C_{safe} \): concentration of toxin in the air that is safe for workers (mg / m3)
- \( \text{SHD} \): Safe Human Dose (mg/kg)
- \( W \): Weight (kg)
- \( \delta \): % of substances absorbed by the lungs
- \( BR \): Human respiratory rate (m3 / hour)
- \( t \): Working time (hours)
- \( MW \): Molecular Weight
Based on the above formula, the results of calculating the safe concentration of benzene at the Around Regional Gas Station in Diponegoro University Semarang were obtained from the SHD value, average worker weight, percentage of substance absorption, average respiration rate of workers and average length of work time:

\[
C_{\text{safe}} = \frac{(0.00362)(55,67)}{(50\%)(0.59)(8)} = 0.08538 \text{ mg/m}^3
\]

\[
C_{\text{safe}} = \frac{0.08538 \times 24.45}{78.11} = 0.02672 \text{ ppm}
\]

The results of calculating safe limits in the air for upper workers can be used to predict toxins in the air in a safe work environment for workers if there is no determination of the Threshold value (William, 1985 in Tualeka, 2013)\(^{12}\), and to compare with the NAV that has Defined by various institutions both by the Ministry of Manpower and Transmigration, the National Standardization Agency, ACGIH, NIOSH and OSHA.

**Conclusion**

The results of the measurement of benzene concentrations in gas stations around the area of Diponegoro University in Semarang at point 1 were 0.38 ppm and at point 2 was 0.51 ppm. So that the concentration is still below the Threshold Value (NAB) according to the Minister of Manpower Regulation Number 5 of 2018. Based on manual calculations for safe limits benzene concentration is obtained 0.08538 mg / m3 or 0.02672 ppm.

This means that the highest concentration of benzene in the work environment is 0.51 ppm, with an average body weight of 55.67 kg, height of 159 cm with a working time of 8 hours, and safe concentration so as not to cause non-carcinogenic risk is 0.08538 mg / m3 or 0.02672 ppm.

Effect of Local Anesthesia and Extraction on Mouth Opening

Ali Falah Hassan
Assistant lecturer, Department of oral and maxillofacial Surgery College of Dentistry ,Babylon University, Iraq

Abstract
Background: Trismus is defined as painful limitation in mouth opening due to a muscle spasm. Trismus, also called lockjaw, (restricted jaw range of motion). There are various causes of trismus, one is spasm of the muscles of mastication. Assessment of the effect of local anesthesia and extraction on mouth opening ability.
Methodology: Total sample of 40 patients included both genders (27 male and 13 female) participated in this study, all Patients were healthy with no allergy to local anesthesia, don’t use alcohol or any drug therapy. Lidocaine HCL 2% with epinephrine 1:80,000 is used to anesthetize the inferior alveolar nerve using IAN block technique, while surgical tools were used for extraction in the usual way. Baseline mouth opening was evaluated pre-operatively, during the effect of local anesthesia and post-operatively by using digital Vernier caliper. Results: significant difference in mouth opening between the measurements (pre-operative, during anesthesia, post-operative) is found, mouth opening decreases when measurement is directed toward postoperatively.

Keywords: local Anesthesia , Extraction , Mouth opening

Introduction
Trismus is defined as painful limitation in mouth opening due to a muscle spasm\[1]. Trismus, also called lockjaw, (restricted jaw range of motion). There are various causes of trismus, one is spasm of the muscles of mastication \[2]. Permanent trismus occurs less frequently than temporary trismus, in the majority of cases trismus is temporary, and typically resolves in less than two weeks \[3]. Many problems can arise as a result of restricted mouth’s opening movement, these include difficulties in eating and swallowing, oral hygiene issues, and even speaking problems. Although trismus is not prevalent in the population, it can be commonly seen in specific groups, particularly in those who have had oral surgery to extract their wisdom teeth and those who had cancer involving structures that affect mouth movement\[4]. Maximum mouth opening in the majority of people is beyond 35 millimeters (mm) wide, which is little more than the width of two fingers \[5]. There are many causes implicated in the development of trismus. One classification depends upon the involvement of the temporomandibular joint (TMJ) or intra articular versus extra articular etiologies\[6]. Others have classified the causes into broad groups such as infectious, traumatic, and neoplastic sources \[5]. As trismus can occur due to disease entity, otherwise, it may also be iatrogenic, caused by prescribed interventions and treatments\[7]. Patients suffering from trismus, appears with many manifestations such as limited ability for mouth opening and deviation of jaw to the affected side, prevalent facial swelling and fever, sensation of muscle stiffness and sever pain in acute condition \[8]. Fibrosis of the TMJ may be the result of prolonged trismus, necessitating directed therapy\[9]. Management of trismus is commonly directed toward relieving symptoms. Symptom-directed interventions such as heat therapy, analgesics and muscle relaxants may be prescribed in the acute phase of uncomplicated transient trismus. In addition, stretching exercises is another treatment protocol that may also be considered for patients with post-traumatic and post-operative trismus, particularly when persisting longer than one week. Intensive physiotherapy and microcurrent therapy may be the treatment of choice for chronic trismus especially those cases resistant to more conservative approaches. Xanthine derivatives such as pentoxifylline also prescribed for trismus\[5,9].

SUBJECTS, MATERIALS and METHODS
This study was conducted on a total sample of 40 patients included both genders (27 male and 13 female) reporting to the Department of Oral and Maxillofacial Surgery, Babylon University/ College of Dentistry for extraction of their mandibular posterior teeth. Patients were coming to college between January 2019 and March 2019 with asymptomatic bilateral mandibular posterior teeth, patients’ age was between 26 to 52 years regardless of their gender.

All Patients were healthy, with no allergy to local anesthesia, don’t use alcohol or any drug therapy that may interfere with local anesthesia. Those with poor vital signs (hypoxia, hypotension, hypertension, heart rate, respiratory rate), untreated hypertension, severe cardiac failure, glaucoma, hyperthyroidism, raised intracranial pressure, neurotic traits or psychiatric illness or those with a history of cerebrovascular accident were excluded from the sample. Pregnant or lactating mothers were also excluded.

Lidocaine HCL 2% with epinephrine 1:80,000 is the type of local anesthesia that was used. The inferior alveolar nerve was anesthetized with one carpule of local anesthesia by using IAN block technique. surgical tools like straight elevator and lower posterior teeth forceps were used for extraction in the usual way (figure 1).

Baseline mouth opening was evaluated pre-operatively, during the effect of local anesthesia and post-operatively by measuring the distance between the mesio-incisal corners of the upper and lower right central incisors at maximum opening of the jaws (Figure 3) by using digital Vernier caliper (Figure 2).
Results

Due to the use of local anesthesia, and extraction, a decrease in mouth opening was occur to all patients who participated in this study. When the mean value of all measurements (preoperative, during anesthesia, postoperative) were calculated, results show different in the measurements: where pre-op mean value is 47.07, during anesthesia is 46.05 and post-op is 45.47. As a result the scores of mouth opening decreased when patients were subjected to anesthetic agent and extraction. Regarding to ANOVA test: when we compared between Group A (pre-op mean value) and Group B (after anesthesia), we found a significant difference in their values. Same results were found when comparing Group B and Group C (post-op). Whereas a highly significant difference was found between Group A and Group C.

It is observed that there is a significant difference between group A and group B values, also significant difference is found between group B and group C While highly significant difference is found between group A and group C.

Discussion

In this study, in order to know the effect of local anesthesia and extraction on mouth opening, measurement of mouth opening in three stages (pre-operative, during anesthesia, and post-operative) is necessary. After that comparison of the values is done. There are many difficulties in this study that affect the accuracy of measurements, weakness of muscles due to trauma is one of these difficulties, trauma may be due to needle breakage as it is bent or otherwise used incorrectly \(^{[10]}\). Also, forceful insertion can cause sudden movement of the patient so may harm the muscles of mastication causing weakness which affect on mouth opening \(^{[10-12]}\).

On the other hand Intramuscular injections can lead to hematoma formation and consequently fibrosis, which lead to trismus \(^{[5]}\). Hematoma is a blood-filled swelling. It can form when the injection needle strike a blood vessel \(^{[13,14]}\). After anesthesia, trismus is usually caused by intramuscular injection of the anesthetic agent into the pterygomandibular space, usually affecting either the lateral pterygoid muscle or the temporal muscle. Inflammation of these muscles usually occur and it is the result of the cytotoxic effect of the anesthetic solutions, eventually, the inflammation leads to contraction of the muscles leading to trismus \(^{[15]}\). Naturally, these cytotoxic reactions are commonly seen in block anesthesia more than in infiltration anesthesia \(^{[16]}\). Trismus can occur even 2 – 5 days after inferior alveolar block anesthesia \(^{[15]}\). The concentration and dose of local anesthesia may affect on mouth opening. When local anesthesia is injected into a highly vascular area, there is an increased risk of intravenous injection and this increases the concentration of local anesthesia in the circulation too rapidly, lastly a toxic reaction can occur. In addition, over dosage can lead to intoxication which result in an impairment in muscle movement eventually trismus results \(^{[15]}\). Kai Sundquist found that patients may experience difficulties in opening their mouth especially after the extraction of mandibular teeth and nerve block anesthesia to the lower jaw. These problems may continue for several months and are treated mainly by mouth opening exercises in order to stretch the related muscles \(^{[17]}\). Also Donna Christiano explained how trismus can arise after oral surgery, particularly after lower wisdom teeth extraction. Trismus can happen due to the inflammation the surgery creates or due to the hyperextension of the jaw during the procedure. It can also occur when a needle delivering the anesthetic solution damages the surrounding tissues \(^{[4]}\). Therefore these findings are both in an agreement with the findings of our study. It has been suggested that increased difficulty of third molar surgery may be attributed to patient factors; such as age, gender, size and ethnic background. Patient age, in particular, has been linked with increased surgical time and complications \(^{[18]}\), so increases muscular tone that result in trismus. Therefore, there was a significant difference in mouth opening between the measurements (pre-operative, during anesthesia, post-operative), mouth opening decreases when measurement is directed toward postoperatively.

Conclusion

Various studies regarding the effect of local anesthesia and extraction on mouth opening have been done over the years, based on this study, the following conclusions are drawn: when local anesthesia is administered to patients it will cause several effects, one of them is decreased mouth opening by their anesthetic effect on inferior alveolar nerve which has branch that supply mylohyoid muscle and anterior digastric muscles which assist lateral pterygoid muscle in mouth opening. Also, extraction of mandibular posterior teeth leads to decrease mouth opening due to increased muscular tone during extraction so patients will suffer from decreased muscular movement that affect on ability to open their mouth in normal width.

Physiological and Gen Study for Animals Exposed to Leaves of Plant (Eucalyptus) from Selected Locations at, Al-Nassiriy/ Iraq

Sabah H. Enayah1, Mohanned A. Gati1
1Biology Department, University Of Thi-Qar

Abstract

Our study was carried out during the period from November 2018 to May 2019. 24 rats were used assigned and divided into three groups. The first group was the control group and a second group were injected with aqueous extraction of Eucalyptus leaves extract at concentrations of 100 and 150 mg /Kg experiment lasted 30 days.

Zn, Pb, Cd, and Cu were measured in the leaves of plant and after confirming the presence of these heavy metals, we exposed the laboratory animals to the Eucalyptus aqueous extract and after the end of the period rats were sacrifice and blood collected. Blood were used to measure study parameters and relative gene expression of (SOD and catalase). Moreover, antioxidants and enzymes AST and AL were measured from serum.

Results showed that the concentration of Pb in the plant was 0.19μg/g. The highest mean Zn was 14.23μg/g. The Cd concentration was 0.35μg/g and the copper concentration were 2.31μg/g from previous data we can find out that the amount of heavy metals is not really high. we would be expected low impact on animals since not high concentration found. The results of blood parameters of rats showed different outcome where it has been noticed that a significant increase in Hb, PLT and RBC at the 100mg/kg exposure and an increase in WBC in both concentrations. In addition, our results showed a significant decrease in RBC and Hb at the 150mg/Kg decrease MDA, MCV and MCH levels are decreased at both concentrations. A significant decrease in AST at 150mg/kg while the results showed a significant increase in lower concentration.

Keywords: Eucalyptus, heavy metals, blood parameters.

Introduction

Plants are considered the oldest friends of mankind and always play a major role in the living of human and animal, and it’s important to live organisms. They are not just provided shelter and food, but they are also used in treatment of various diseases [1].

Environmental pollution has been a major area of concern worldwide. Environmental pollution, especially by heavy metals is one of the most important factors in the destruction of biosphere components[2]. Heavy metals remain in the soil for a long time and have a residence time ranging from a few to several hundred years [3]. Human exposure to heavy metals has increased due to excessive use of daily life and has increased in most parts of the world, particularly industrialized countries. Therefore, pollution from industrial activities is a major environmental problem requiring attention[4].

Heavy metals are pervasive environmental toxicants that have been shown to exert oxidative stress on living systems through the production of reactive oxygen species which overwhelm the cell’s capacity to maintain a reduced state. Metal-induced ROS cause damage to cellular proteins, nucleic acids and lipids, It has been clearly demonstrated that ROS interfere with the expression of a number of genes and signal transform pathways [5, 6].

This study aimed was measuring heavy metals in plant Eucalyptus taken from power station and the extent of the impact of the polluted plant on laboratory animals to reveal the influence of this plant on blood parameters,
liver enzyme and gene alternation.

**Method**

The plant leaves Eucalyptus samples were collected from Power station in the city of Al-Nasiriyah, Thi-Qar province, Iraq. The plant brought to the lab and washed with distilled water then dried in air. After complete dryness, the plant collected in a glass container at room temperature. Heavy metals were measured in the plant extract using a FAAS. Aqueous extract of the plant was prepared, and then laboratory rats of Rattus norvegicus species exposed to aqueous extracts of the Eucalyptus leaves that are taken from the power station at 2 concentration 100 and 150mg/kg once daily for 30 days. Blood parameters for rats were measured using hematological analyzer (Nihon Kohden). Lipid peroxidation (LPO) is determined by using the thiobarbituric acid method [7]. The activity of the enzymes alanine transaminase (ALT) and aspartate transaminase (AST) in the serum was measured through the processed kit from the company Biolabo (France). The heavy metals were determined in the liver and blood rats by using FAAS. Genomic RNA was extracted from blood isolates by using RNA Extraction (Direct-zol RNA MiniPrep Zymo RNA Purification Kit (USA) and done according to company instructions in many steps. All isolates of blood were detected by Real-Time polymerase chain reaction (RT-PCR assay) [2]

**Results**

Figure 1 showed heavy metals in Plant extract that are taken of Power Station. Lead (Pb) concentration was (0.19 µg/g) in the plant of the power station, while Zinc (Zn) have shown the higher levels in plant (14.23 µg/g). Other heavy metals are arranged according to the increase to Cu > Cd.

![Fig (1): heavy metals in Eucalyptus (µg/gm dry wt.)](image)

The results of the current study showed in Table (1) showed that the highest value of RBCs was in group 3 and lowest in group 2. As well as, showed that there is a significant increase in the level of RBC for group 2. While there was a non-significant difference in group 3 comparing to the control.

Group 3 was recorded the highest value with Hb than another group, while the lowest was group 2. As results appeared a significant rise in hemoglobin (Hb) levels in group 2 comparing to the control, as observed a non-significant difference in group 3 comparing to control group 1. The highest value of WBCs was in group 3 compared with the other group, the lowest was group 2.

Interestingly, the results of the study showed that the highest value of MCV was in group 2 and the lowest value was in group 3. Moreover, the results indicated non-significant different in MCV in the groups 2 and 3.

Likewise, the results presented the highest value of MCH was in group 2 compared with the other groups. It also exhibited results a non-significant difference in the MCH in groups 2 and 3. Group 3 was the highest value of PLT.

♦ Values refer to mean ± SD and P value.
Group 3 was recorded the highest value with MDA than another group. MDA level a non-significant different in the groups 2 and 3 comparing to the control group1.

The present study showed that the highest value of ALT was in group 3. It also showed the highest value of AST was in group 2 table 3.

it also observed significant differences in the enzyme AST and non-significant differences in the enzyme ALT were observed in group 2. Moreover, we found that non-significant differences in group 3 in both enzymes comparing to the control group table 3.

Table (2): Effect of Eucalyptus extract on liver enzymes.

Level of mean Zn in liver of animals that drank plant extraction higher than its values in the control group. The highest values of Zn were in group 3.

Table (3): Heavy metal concentrations in liver.

The results of the present study showed that the higher values of Zn in the group 2. The results also showed non-significant differences in groups 2 and 3.

The statistical analysis shows non-significant difference in groups 2 and 3.

The present study showed that the highest values of relative expression of SOD and catalase in group 3,

Table (4): Heavy metal in rat’s blood.

Plants are considered for a long time as the most sensitive to environmental biodiversity because of their high sensitivity to the toxicity of heavy metals, and effective as the first phase in the food chain that collects pollutants compared to other organisms [3]. Over decades, plant contamination would give a clearer picture of pollution than in other measurements. [8].
The current study revealed that all the metals were accumulated to less concentrations by the plant studied in power station, except that of Zn. The outcome of the study come along with previous studies [9, 10]. According to Alloway (2013) the presence of heavy metals in the plant is due to plant growth in polluted soil containing heavy metal. exposing to extract of Eucalyptus showed that there was a significant increase in the RBC level in the group (2) of the power station. These outcomes may be due to medicinal plants which are rich in nutrients including minerals such as calcium, zinc and potassium [11]. Extract from the same plant exhibited a significant decrease in the RBC level in blood of animals that drank high concentration of these plants (150mg/kg). These interesting results would be due to the thyroid dysfunction and hormones that are produced from effect of toxins produced in the animal body after giving the animals a polluted plant extract. Animals hormones are playing a major influence in the direction of metabolism within body and have an indirect effect on the production of blood cells in the bone marrow [12].

As well as, exposing to Eucalyptus increased in the Hb levels in the group 2. According to Smith et al (2006) increased RBC cause increased hemoglobin [13]. Another logical reason to increase level of Hb may be because of a defect in the kidneys result of heavy metals resulting in an increase in hemoglobin [14]. 150mg/kg of same plant extract taken from power station influenced differently on Hb level when significant reduction noticed after 30 days’ exposure. To explain this different would be because of reactive oxygen species (ROS) that cause hemoglobin damage. It produces deposits inside the red blood cell and thus decomposes red blood cells. Likewise, it may play role in reduction of the hormone Erythropoietin and malnutrition resulting from loss of appetite causes these hemoglobin deficiency and anemia [15].

Not only that, level of WBC also influenced by Eucalyptus where level is increased. According to researchers finding, plant is content active compounds which have proven pharmaceutical effectiveness such as flavonoids, Coumarin, Glycosides and saponins [16]. These compounds are capable to activate immune system and thus be able to increase WBC. In contrast, our results showed that there are a significant decrease in levels of MCV and MCH in groups (2 and 3 ) from Eucalyptus extract. It has been proved that the reduction of MCV and MCH in blood are return to high blood lead level and low iron (because of bowel perturbation) this decrease causes a defect in the production of hemoglobin, resulting in oxygen deficiency [17].

A study done by Saidana and his colleague who reported that there is direct impact of the active compounds extracted from Suaeda plant on bone marrow of animals to generate a large number of platelets. Whereas, the reduction in PLT levels that have been noticed in the group ( 5 ) of the power station, may be due to metals ability that can
induce abnormal responses in the immune system.

Malondialdehyde (MDA) is a final product of lipid peroxidation after exposure to ROS and many studies have used it as a marker of oxidative stress evaluation [18]. In this investigation, a non-significant in the MDA levels in the Eucalyptus aqueous extracts. These results are in agreement with other studies which reported [19]. The influence of back to plant curcumin contains which decreases the oxidative stress [20]. In the present study, ALT and AST levels Eucalyptus that are collected from power station act differently where we noticed a significant increase AST level and decrease ALT in Group 4. Increasing the enzyme synthesis of liver cells to remove the toxic effect of metals. Customarily, the rise of ALT refers to liver damage and this disorder may occur in other organs that secrete this enzyme such as heart and muscles. Chavan and Muley (2014) explained that exposure to lead and cadmium increases the level of AST and do not affect ALT. for this reason, here we think the impact of lead and cadmium was clear on animals[21]. The accumulation of minerals in the blood this can probably be attributed to various factors including in general, metabolic processes, water and food contamination, and the nature of lipid concentration in tissues[22]. This variation may be due to plant extracts contaminated with heavy metals taken from the power station.

The results of the current study showed that increases in the rate of relative expression SOD and catalase. The induction of SOD and catalase expression would be because of exposure to heavy metals. Activation of SOD and catalase in response to stress signals to result from a disruption of this association, releasing SOD and catalase [23]. The current study was the first study that aimed to find the connection between contaminated plant from contaminated area that placed around the power station and animals’ health. Highly comminuted plant that are approved before by several of environmental scientists’ group around are.

Effect of Metronidazole on Clopidogrel Bisulphate Efficacy in Male Albino Rats

Saddam Jumaa Nasser¹, Muhammed M. Al-Ani², Mohammad Sinjar Farhan³
¹Assistant lecturer, Department of Pharmaceutics, College of Pharmacy, University of Anbar, ²Assistant lecturer, Department of Pharmacology and Toxicology, College of Pharmacy-University of Anbar, ³Assistant lecturer, Department of Pharmaceutical Chemistry, College of Pharmacy, University of Anbar

Abstract

The data about this combination effect on platelet function and hematological parameters are sparse, but there is only mention in many medical science websites such as Medscape, there are possible interaction between it, in which metronidazole cause inhibition to cytochrome CYP3A4 which responsible on clopidogrel metabolism, this may put the patients that on clopidogrel bisulphate therapy at risk of clot formation and may be progress, this may occur because clopidogrel is at inactive form and need to activation by cytochrome mention above, so this study was performed in order to achieve the following aims: studying the efficacy of clopidogrel bisulphate on coagulation process by measuring bleeding time when giving clopidogrel alone and in combination with metronidazole and studying the possible effect of two drug alone and in combination on hematological parameters in male albino rats.

Keywords: Clopidogrel bisulphate, metronidazole, cytochrome CYP3A4, bleeding time

Introduction

Clopidogrel, a thienopyridine derivative, binds precisely also permanently to the platelet P2RY12 purinergic receptor, constraining ADP-mediated platelet motivation and aggregation (¹). Next oral taking of clopidogrel is promptly absorbed owned to more metabolism, clopidogrel is one of prodrug that is absorbed in the intestine and activated in the liver, then it converted to its active metabolite needs dual sequential oxidative steps, at the first time result in formation of 2-oxo-clopidogrel, followed by the conversion of 2-oxoclopidogrel to the active metabolite. CYP2C9 and CYP3A4/5 are connected to cytochrome P450 enzymes involved in the metabolism of clopidogrel (²). CYP2C9 is most important hepatic enzymes involved in the formation of clopidogrel’s active metabolite. Genetic polymorphisms of CYP2C9 are associated with impaired clopidogrel metabolism in healthy volunteers and also in patients (³). Metronidazole is antibiotic and antiprotozoal medication. it is one type for a first event of mild-to-moderate Clostridium difficile colitis if vancomycin or fidaxomicin is unavailable (⁴). It has been suggested possible inhibition of cytochrome P450 especially CYP2C9 and CY3A4, this enzyme is responsible for several drugs metabolism such as S-warfarin, etc.⁵. And this may appear in revers effect when combined with clopidogrel when compared with warfarin because the difference between two drugs chemically (warfarin is active drug and this combination cause abnormal bleeding).

Materials and Mthod

Experimental animals: A total number of twenty male Albino Wistar rats weighed (200-250 g) were utilized in this research. Their ages ranged between 4-5 months. Rats in all time of the experiment were housed in plastic cages in conditioned room (22-25°C) in the animal house of College of pharmacy – University Of Anbar with manually controlled lightening supplying daily light of 12 hours (7.00 AM to 19.00 PM) and 12 hours night cycle. They were left for 7 days for adaptation with the research conditions. Rats had free access to water and diet along the experimental period.

Experimental Design: Rats were randomly divided into four equal groups (5rat/group) and administered orally for 28 days by using special gavage needle as the following: C group rats that received ordinary distilled water and served as control, T1 group rats were treated
1.25 mg/kg B.W of clopidogril bisulphate, T2 group Rats were treated 35 mg/kg B.W of metronidazole and T3 group rats were treated 1.25 mg/kg B.W of clopidogril bisulphate + 35mg/kg B.W of metronidazole.

**Bleeding time test performance:** Bleeding time was measured via rat tail transection method according to the prescription of The tail of the rat was warmed for 60 seconds in water at 40°C then dried (8). A slight cut was made in the mid of the tail with a blade. Account started when the 1st drop touched the circular filter paper. It was tested at 30 s intervals till bleeding cosseted

*Total number of spot on filter paper/2= BT /minute.

**Hematological Analysis:** All animals in experiment comparing with the normal values of blood parameters as control and zero time. The blood collected from heart puncture after general anesthesia by using (Ketamine and xylazine). By using Uto-analyzer (setting on vet mode) Platelet count, RBC, WBC, and HB level were estimated. The procedure done according to manufactured instruction.

**Statistical Analysis:** The data was accomplished by using SAS (Statistical Analysis System - version 9.1). One-way ANOVA, two-way ANOVA and Least significant differences (LSD) post hoc test were complete to assess significant differences among means. P < 0.05 was considered statistically significant.

**Results**

Before beginning of dosage of experiment (at zero time), Bleeding time and other hematological parameters was determined and there was no significance different (P < 0.05) in all groups.

1. **Bleeding time:** A statistical analysis indicated that the mean value of bleeding time was non-significantly (P<0.05) differed in all experimental groups at zero time when compared to each other. The final results showed significant (P>0.05) increased after oral intubation of clopidogrel bisulphate, metronidazole and combination in T1, T2 and T3 groups comparing to the control group and zero time. The T1 group that receive 75 mg/Kg/day of clopidogrel bisulphate was more potent in increasing of bleeding time comparing to 35 mg/kg/day of metronidazole and in combination treated group (T2, T3) respectively.

- Table 1: Effect of oral intubation for 28 days with Clopidogrel bisulphat, metronidazole and their combination on bleeding time (by tail method as prescribed previously) of treated adult male rats. (min)

- Table 2: Effect of oral intubation for 28 days with Clopidogrel bisulphat, metronidazole and their combination on platelet count of treated adult male rats (X10^9/µl)
- Different Capital letters denote differences between groups, (P<0.05).

- Different Small letters denote differences within group, (P<0.05).

3. Red blood cells count: A statistical analysis indicated that the mean value of RBCs count was non-significantly (P<0.05) differed in all experimental groups at zero time when compared to each other. At the end of experimental RBCs count was significantly (P>0.05) decreased after oral intubation of clopidogrel bisulphate, metronidazole and combination (clopidogrel bisulphate plus metronidazole) in T1, T2 and T3 groups comparing to the control group. The extent of decrement was higher in T1 group, where as in T3 group (combination therapy) the change was at little degree when compared with T1 group.

Table 3: Effect of oral intubation for 28 days with Clopidogrel bisulphat, metronidazole and their combination on RBC count of treated adult male rats (X10^6/µl).

Discussion

It was reported that clopidogrel bisulphate cause a significant change in bleeding time in 36 human volunteer after giving a 75 mg of Plavix (7). Also another study indicated that clopidogrel bisulphate associated with significantly increased risk for postoperative wound complications especially increasing of bleeding time in tested patient (8). These normally cause increasing of bleeding in T1 group. In T2 group treated with metronidazole alone, it was reported a partial inhibition platelet aggregation with dose and time dependent in guinea pig and human platelet-rich plasma and this may cause a mild increasing in bleeding time according to dose that we give in comparison with previous study (9).

In T3 the combination of clopidogrel bisulphate and metronidazole which sharing same metabolic enzyme or cytochrome that may lead to inhibition or slowing the process of clopidogrel bisulphate converting to its active form (10), this mention why the combination of two drugs causing less bleeding time than clopidogrel bisulphate alone treated group. Many of case report indicates that in addition to the increased risk of bleeding with the use of Clopidogrel, some of its additional serious side effects include agranulocytosis, aplastic anemia/pancytopenia, thrombotic thrombocytopenic purpura, acquired hemophilia A, and neutropenia, neutrophils make up

Figure (1): showed the steps of experiment performance starting from housing of animals (A), dosing of the drugs (B), (C) anesthetizing animals, (D) bleeding time test, and (E&F) blood collection for hematological test parameters.
a significant portion of the WBCs (11). With regard to metronidazole there was reported that metronidazole can cause bone marrow depression (12). And normally this can affect all type of blood cells especially in chronic use.

**Conclusion**

The efficacy of clopidogrel bisulfate as blood thinner agent may be reduced when combined with metronidazole despite of the second have characteristic of antiplatelet agent, this were obvious in bleeding time test results and other hematological parameters, may be due to the inhibition of metronidazole to cytochrome that responsible for clopidogrel metabolism, in addition to possibility of compete the two drugs and/or inhibition of each other. This still need to more clearing by check the platelet activity in presence of this combination by more specific tests and apparatus. more attention should be paid when use the metronidazole in patient who take clopidogrel bisulfate especially critical cases by putting the patient under close monitoring or use alternative drugs.

Abstract

Polycystic ovary syndrome (PCOS) is a status that impact a woman’s hormone levels. A total of (128) samples was divided into four groups (Obese with PCOS, low weight with PCOS, Obese without PCOS, and Healthy control) collected from Kamal Al-Samarraie hospital, Ministry of Health in Baghdad-Iraq during the period of April 2017- August 2017. The aim of the study to evaluation from Serum Adiponectin Irisin and Apelin in Iraqi obese women patients with PCOS. The result shows The BMI of obese with PCOS patients and obese without PCOS was significantly higher (P<0.05) when compared to the values of the control group. No significant with other groups, also Significant increase of Prolactin (p<0.05) in Obese with PCOS and low weight with PCOS groups in relation to Obese without PCOS and control groups. A non- significant elevation (p>0.05) when comparing between Obese without PCOS, and control groups. The levels of FSH, LH and Testosterone showed significantly change (p<0.05) in Obese with PCOS and low weight with PCOS groups when comparing with Obese without PCOS and control groups. Followed by no-significant with other groups, also shows significant change (p<0.05) when comparing between Obese without PCOS and control group, showed that adiponectin level showed a significant higher level in the control group, Obese without PCOS group, low weight with PCOS patients, and Obese with PCOS patients. Oppositely, the results of the Irisin showed a significant higher level in the Obese with PCOS patients then the low weight with PCOS group followed by the Obese without PCOS and control group. While Apelin level recorded the highest level Obese with PCOS group.

Key Words: Polycystic ovary syndrome, Prolactin, FSH, LH, Testosterone, Body mass index, Adiponectin, Irisin, Apelin.

Introduction

Polycystic ovary syndrome is a popular endocrine condition related With hyperandrogenism, infertility and metabolic dysfunction. The syndrome was officially recognized in the 1930’s by Stein and Leventhal, who associated polycystic ovaries (PCO) to the clinical features of menstrual dysfunction, infertility, hirsutism and obesity (1). Androgen overabundance and insulin impedance, the two of which have powerful genetic components, underlie a great part of the clinical display. Specifically, a few studies have demonstrated that the raise androgen levels may influence adipokine produce and, increment perversiveness and cardiovascular impacts from metabolic syndrome (2). A major proportion from women with PCOS have boosted levels of LH and natural/diminished levels from FSH (3). The excess in LH is explained by an increment of the hypothalamic gonadotropin-releasing hormone (GnRH) (4). In the Granulosa cells (GCs), FSH invigorates the expression from enzymes that metabolize androstenedione to estradiol. Studies from follicular liquids and in vitro investigations of (GCs) from anovulatory PCOS ladies show that GCs, generally, remain steroidogenically dynamic with expanded aromatase movement, comparably from non-PCOS ladies. So, expanded estradiol production in PCOS is subordinate on the ovulatory condition of the patient, yet in addition on body weight (5, 6). Adiponectin is a 244-amino-acid-long polypeptide. There are four distinct areas in adiponectin with molecular weight of 30 Kilo Dalton (30KD) (7) In Female: Adiponectin, AMPK and PPARc work in show to organize ability homeostasis in the ovary and guarantee appropriate development of ovarian follicles and oocyte.
Adiponectin is involved in endometrial changes in anticipation of embryo implantation and assume a potential role in fetal upgrowth and improvement (8).

**Materials and Method**

**Samples collection**

The current study carried out at the Kamal Al-Samarraie hospital, Ministry of Health in Baghdad-Iraq during the period from April 2017- August 2017. The study was conducted on normal Weight (50) and obese (78) with polycystic ovarian syndrome, as following groups:

- **Group (1):** Includes 50 patients. The patients were obese with polycystic ovarian syndrome.

- **Group (2):** Includes 27 patients were normal weight with polycystic ovarian syndrome.

Normal, healthy individuals: For the purpose of rapprochement, 50 healthy individuals (Control) were enrolled in this study. The individuals were recruited into the following groups:

- **Group (3):** Includes 25 individuals. The individuals were obese.

- **Group (2):** Includes 25 individuals were normal weight.

All patients must be fastened overnight [10-12 hours] when they attended at the morning of 2nd-3rd day of their menstrual cycle. Five milliliters of blood was collected from each patient and control into gel tube to obtained of serum centrifuged the tube at 3000 rpm for 5 min.

**Measurements**

Enzyme-linked immunosorbent assay (ELISA) were used to estimate the serum level of Adiponectin according to the manufacturer’s instructions (bioaim scientific) and Hormonal analysis for LH, FSH, Testosterone, and prolactin was performed by using the Automated Immune Assay (AIA) by the VIDAS auto analyzer, (BioMérieux Company, France).

**Results**

The results illustrated in table (1) showed BMI within first group was 32.2 Kg/m², while the second group recorded 21.09 Kg/m², and third group were 32.8 Kg/m² compared to control group 21.12 Kg/m². The obese subjects who suffered from PCOS and obese that not suffered from PCOS recorded BMI values significantly higher (P<0.05) in comparison to control group. In addition the comparison between the BMI of low weight subjects with PCOS with control group were insignificant (P>0.05), and a non-significant differences in obese with PCOS patients as compared to obese without PCOS.

The results in table (2) can be summarized as follow. The prolactin level showed a significant increase (p<0.05) in Obese with PCOS and low weight with PCOS groups in contrast to Obese without PCOS and control groups. While a non-significant increment (p>0.05) appeared when comparing Obese without PCOS and control groups. The hormones FSH, LH and Testosterone levels were changed significantly (p<0.05) in both group of PCOS (Obese and low weight) when comparing with Obese without PCOS and control groups, while comparing between those groups of the PCOS obese and low weight showed non-significant change (p>0.05) while significant change (p<0.05) shown when comparing between Obese without PCOS and control group.

Discussion

Numerous studies have proved that polycystic ovary syndrome (PCOS) have involved in obesity, as the insulin resistance increase the body mass and dyslipidemia which in turn lead to an increased chance for cardiovascular disease and diabetes (9). Numerous studies proved that that abdominal obesity increased in PCOS women of fertile age compared with healthy subjects (9,10). Obesity the last decades are considered as major chronic diseases all around the world. As previously mentioned PCOS is associated with excess weight. So for that reasons the obesity treatment should be based editing the lifestyle by diet, exercise and behavior modification. It has been reported that, that ovulation increased after losing as minimum 5 % of the initial body weight in obese women (11).

In usual, women with PCOS are usually described by increased circulating LH levels in addition decreased FSH levels (12). While some other PCOS patients with hyper-androgenism and especially to those have obesity, shown non-elevated basal or stimulated LH levels and those may lead to heterogeneity of presentations of the syndrome. The using of LH level as biomarker of GnRH so negative correlation between the levels of GnRH and LH has also been shown in studies (13,14) proved that gonadotropin releasing may increase by hypothalamus which may lead to increased release of follicle stimulating hormone (FSH) from the pituitary gland in PCOS. In addition Shibli-Rahhal and Schlechtesuggested that prolactin modulate the body weight as there is an association between prolactin level and weight gain, but still uncertain the mechanism whether obesity associated with hyper-prolactin due to stimulation of lipogenesis or due to disruption of central nervous system (CNS) (15). While, Hernandez (16) added that a decreased level of dopamine (DA) could cause the raise in prolactin level which usually present in women with PCOS. In our study, patients with PCOS had significantly higher (P<0.05) levels of testosterone compared to controls. And those results agreed with previous studies the average level of testosterone increased in the most of PCOS patients. In addition androgen action declining with aging. but also in controls, androgen levels gradually decrease through time, as has been shown in several studies (17,18). Numerous research have examined adiponectin levels in women with PCOS, and our present results agreed with who proved the lower adiponectin levels in the obese PCOS group than in the non-obese control group. The other parameter Irisin, was discovered for factors secreted by muscle in response to exercise in 2012 (19). And because of its activity in reducing body weight so still hypothesized that circulating irisin is increased in a compensatory manner to overcome or counteract the increasingly aggravated IR, and such condition can be found in metabolic disorders disease such as PCOS (20). Our results agreement with (21) who reported irisin level higher in patients with PCOS than that in the healthy controls. That could be similar to apelin level which also showed increased levels in patients and its related with the occurrence of obesity. Those results disagreed with (22) who reported lower apelin level in normal-weight PCOS women than in control subjects. In contrast, our results were in agreement with (23,24,25) who reported that the average level of apelin is higher in PCOS.

Antibacterial and Antifungal Activities of
Centaureabruguierana (Asteraceae) from Iraq

Shaima H. A. ALAbbasi1, Talib O.H. Al-Khesraji2, Sirwan H.Salih3

Education for Pure Sciences, TikritUniversity, Iraq, 3Department of Biology, College of Education, University of
Garmian, Iraq

Abstract

The methanol and aqueous extracts of Centaureabruguierana. (Asteraceae) from Iraq were tested for their
biological activity against two Gram positive , two Gram negative bacteria and four fungal species by using
agar well diffusion method . The crude methanol extract (100mg/ml) and its dilutions and the crude aqueous
extract( 100mg/ml) showed biological activity against all bacteria and fungi studied. Compared with the
aqueous extracts , methanol extracts, particularly the crude one, were more bioactive against bacteria and
fungi studied . Among the studied microbes, E.coli, Staphylococcus aureusand Microsporumcanis were the
most sensitive species to C.bruguierana extracts tested. Methanol extract at all concentrations and aqueous
extract at high concentrations showed close or more antibacterial activity( except in case of P.auruginosa)
than that of the bacterial control ( tetracycline) . The crude methanol extract was more bioactive against all
fungi studied than the fungal control ( nystatin ).This is the first report on the antibacterial and antifungal
activities of C. bruguierana extracts from Iraq and its bordering countries.

Kew words : Antibacterial, Antifungal , Asteraceae, Centaurea , Iraq.

Introduction

Centaurea is the fourth largest genus in the Asteraceae
family , including 300 -700 species[1][2][3][4] with annual,
biennial and perennial plants [5] that distributed all
around the world especially in Mediterranean sea region
and west Asia [1][4]. In Iraq, this genus was represented
by more than 30 species [6]. Species of this genus have
been used in folk medicine as diuretic , stomachic
, tonic, astringent, antimalarial, antirheumatic,
antidandruff, hypoglycemic and antipyretic [2][7][8][9][10].
Many investigations have been indicated the presence
of different classes of active compounds in this genus
which in many cases are responsible for its biological
activity[10][11]. C. bruguierana (DC.)Hand.-Mazz. was
reported for the first time from Iraq [12]. Our previous
study [13] showed a high flavonoid content in this species.
However, there is no reports on the antimicrobial activity
of C. bruguierana in the literature .Therefore, this study

was conducted to evaluate the effects of the methanol
and aqueous extracts of this species in four bacterial
species ( two Gram positive and two Gram negative )
and four fungal species .

Materials and Method

Plant materials and extraction method

C.bruguierana samples were collected from Tikrit
province/ Salahadin Governorate (north central Iraq )in
March 2018 . Plant samples were identified according
[14] and confirmed by the Iraqi National Herbarium .Identified
samples were kept in the Department of Biology, College
of Education for Pure Sciences,TikritUniversity,Iraq .
Aerial flowering parts of C.bruguierana were oven dried
at 40°C and then grinded with electrical mill. 40 g of
the powdered samples were extracted with 160ml of
95% methanol or hot distilled water for 24 hours, then
the liquid was filtered through gauze colth and filter
paper Whatman No.1 and the filtrate was concentrated
at 40°C. The solid residue was stored in the fridge until
subsequent use . For in vitro assay ,1g of the solid
residue were dissolved in 10ml of the same solvents
(methanol or distilled water) and tested at concentrations 25,50,100mg/ml. These concentrations were evaluated in triplicate for bacteria or fungi tested. Before use, the crude extracts (100mg/ml) were filtered by using Millipore filter with Whatman filter paper No. 0.22 [15][16].

Microorganisms and antimicrobial assay

Two Gram positive(Staphylococcus aureus, Bacillus pumilus) and two Gram negative( Escherichia coli, Pseudomonas aeruginosa) bacterial species, three fungal species(Microsporum canis, Trichophyton rubrum, Aspergillus terreus) and one yeast (Candida albicans) were used in this study. All bacteria and molds were obtained from the Biology Department, College of Science, Baghdad University and the yeast was supplied from the Department of Biology, College of Science, Tikrit University. Nutritive media used included nutrient agar and MacConkey agar for bacteria and Sabouraud dextrose agar and potato dextrose agar for fungi(all media from Bekasi, Indonesia). Antibacterial and antifungal activities were studied by agar well diffusion method [16][17]. For the antibacterial and antifungal tests, tetracycline and nystatin (100µg/ml for each) were used as positive control while methanol and sterilized distilled water were used as negative control.

Results and Discussion

The biological activities of the methanol and aqueous extracts of C.bruguierana against bacterial and fungal species tested in this study are presented in Table 1; Fig.s.1,2. The results showed that all C. bruguierana extracts exhibited inhibitory activity against all bacterial species studied while these extracts showed some activity on fungi tested. Methanol extracts revealed strong activity against both bacterial and fungal species studied compared with the aqueous extracts. The activity of the studied extracts was directly proportional with their concentrations. As shown in Table 1, S. aureus, E. coli and M. canis were the most sensitive to the extracts tested especially at high concentrations. In case of bacteria(Table 1 and Fig.1), methanol extract of C.bruguierana at all concentrations showed inhibition zone diameters (16.1-25mm) very close or greater than the standard antibiotic tetracycline (16.4mm). Methanol extract only at high concentration (100mg/ml) gave inhibition zones diameter(17-20mm) greater than the antifungal nystatin(15mm). Aqueous extracts except few cases (B.pumilus and P.aeruginosa) showed inhibition zones close or greater (15.1-25.4 mm) than the control tetracycline (Table 1 and Fig.2). Aqueous extracts at all concentrations showed lower inhibition zones diameter than the antifungal nystatin. Table 1 revealed that the mean inhibition zone diameters exhibited by the methanol extracts(19.1-23.6mm for bacteria and 14.2-16.7mm for fungi) were greater than those exhibited by the aqueous extracts (3.0-22.6mm). The high flavonoid contents previously reported in C. bruguierana [13] may be responsible for the antimicrobial activity of this species [10][11]. According to the literatures, this is the first report on the antimicrobial activity of the C. bruguierana. The present study was in agreement with the previous studies on the antimicrobial activity of the other Centaurea species particularly their methanol extracts [3][6][7][8][10][18][19]. However, further studies are needed to evaluate the biological activity of methanol extracts of C. bruguierana against other pathogenic bacteria and fungi because their antimicrobial activities are more than that of the of the standard antibiotic tetracycline and antifungal nystatin.

**Fig. 1.** Antimicrobial activity of the methanol extracts of *C. bruguierana*.
St: standard
Conclusion

This is the first study on the antimicrobial activities of C. bruguierana extracts. This study showed a promising antimicrobial activities of C. bruguierana extracts, particularly methanol extracts. Methanol extracts exhibited stronger antibacterial and antifungal activities than the standard antibiotic tetracycline and the antifungal nystatin. This plant species could be a source for antimicrobial drug against pathogenic microorganisms, particularly multiresistant bacteria.

Effects of Laparoscopic Ovarian Drilling on Restoration of Menstrual Cycles, Hormonal Profiles and Pregnancy Rate in Women with Polycystic Ovary Syndrome

Shelan Omar Jaafar¹, Ghada Saadulla Alsakkal²
¹PhD student, ²Assistant professor in Gynecology, Department of Obstetrics and Gynecology, College of Medicine, Hawler Medical University, Erbil, Iraq

Abstract

One of the major cause of an ovulatory infertility is polycystic ovary syndrome with a multifactorial etiology. Laparoscopic ovarian drilling (LOD) is regarded as the method of choice for inducing ovulation in those not responding to oral ovulation induction with PCOS.

A prospective study was carried out for assessment of effects of LOD on menstruation, serum levels of hormones, and reproductive outcome including ovulation and pregnancy rate.

A total of 169 patients with an ovulatory infertility underwent LOD over a period of about two years. All patients assessed three times for clinical characteristics and serum hormone levels LH, FSH, testosterone, SHBG, prolactin and AMH. FAI and LH/FSH ratio calculated, first before the procedure, second within one week after and the last one after three months with the ovulation and pregnancy outcome follow up until six month.

The prevalence of irregular menstrual pattern was 89.3%, significantly (P< 0.001) decreased to 19.5% after the procedure with improvement of hirsutism, acne and scalp hair loss, there was a highly significant decrease in the serum levels of LH, testosterone, AMH, FAI and LH/FSH ratio (P ˂ 0.001) and a highly significant elevation of serum SHBG and prolactin post-operatively, resumption of spontaneous ovulation of 56.2%, and the pregnancy rate of all the study group was 26%. In conclusion, LOD regarded as a method for improvement of the hormones, restoration of menstruation and increasing ovulation and pregnancy rate.

Keywords: PCOS: Polycystic ovary syndrome; LOD: Laparoscopic ovarian drilling,

Introduction

PCOS is defined as one of the most common female endocrinopathy affecting reproductive aged women around the world and a major cause of anovulatory infertility¹. Has been defined using various criteria including menstrual irregularity, hyperandrogenism, and polycystic ovary morphology². Until recently no universally accepted clinical definition existed for this condition³. The prevalence of PCOS, like that of any other complex multifactorial disorder, depends on which criteria are used for definition. Affecting 6-21%of reproductive aged women, depending on population studied and diagnostic criteria applied⁴. Gonadotrophin abnormalities in PCOS include LH hypersecretion due to increased LH pulse amplitude in 30-90% of women with PCOS⁵. FSH levels tend to be normal or reduced compared to regularly ovulating women, resulting in an increased LH/FSH ratio⁶. Laparoscopic ovarian drilling was first described by Gjonnaess in 1984⁷ as an alternative to ovarian wedge resection to treat PCOS, to destroy the tissues that produce androgen and decrease conversion of androgens to estrogens peripherally. Specifically, serum levels of androgens and LH fall and level of FSH have been demonstrated to increase after LOD⁸. These changes in hormones thought to convert the adverse androgen dominant intra follicular environment to estrogenic and
normal ovarian pituitary feedback mechanism. The aim of this study was to define the effectiveness of LOD on menstrual cycle regulation, normalization of the hormones after the surgery and the rate of ovulation and pregnancy in an ovulatory infertility PCOS patients who failed to respond to medical treatment.

Patients and Method

This was a prospective, cross sectional study carried out on 169 women confirmed to have PCOS based on Rotterdam criteria (at least two of the following criteria were present: oligo-anovulation, clinical or biochemical hyperandrogenism, and polycystic ovaries on ultrasonography who were clomiphene-resistant (failed to ovulate after maximum dose of clomiphene for 3-6 cycles), allocated to undergo LOD, attending outpatient fertility clinic in Maternity Teaching Hospital, public maternity hospital in Erbil, Iraq. Patients were recruited from September, 2016 to November, 2018. All women enrolled were informed about the study with informed consent and they were subjected to detailed history and examination.

The age of the included subjects was between 20-39 years with no male or tubal factor infertility. Those with other etiologies of hyperandrogenism, AMH<4 ng/ml and FSH >12.5 mIU/ml were excluded from the study.

Blood analyses were conducted three times first at the second to fourth day of the cycle without ovulation induction before, second within one week and the third one three months after the procedure for serum hormones including LH, FSH, total testosterone, SHBG, prolactin and AMH. Serum hormone levels were measured by Elecsys machine (Roche Diagnostics, Hitachi, Switzerland) which was used for determination of human LH, FSH, total testosterone, prolactin and SHBG levels. AMH was measured by Enzyme linked immunosorbent assay (ELISA) kit. LOD performed for both ovaries by or in the presence of the first author, using mono polar diathermy at 40 watts making 4 punctures in both ovaries for 4 seconds each, with follow up for ovulation and pregnancy rate up to 6 months

Statistical Analysis

Data were analyzed using the Statistical Package for Social Sciences (SPSS, version 22). Numerical variables were summarized as means and standard deviations. Categorical variables were presented in form of frequencies and percentages. Paired t test was used to compare the means before and after laparoscopy. McNemar test was used to compare the percentages before and after the laparoscopy. A p value of < 0.05 was considered statistically significant.

Results

The study included 169 infertile women with polycystic ovary syndrome (PCOS) not responding to medical treatment under went LOD we didn’t observe any intraoperative or postoperative complications. The mean age±SD of the women was 29.63±4.5 years, ranging from 20 to 39 years, and the median was 29 years as presented in Table 1 which shows that the largest proportion (45.6%) of the sample lies in the age group 25-29 years. The duration of infertility of 65.7% of the sample was five or more years. The majority of the women(76.9%) had primary infertility. Regarding the menstrual pattern, it was irregular in 89.3% of the sample (mostly as oligomenorrhea) and more than half (59.2%) of the women were obese.

It is evident in Table 2 that the prevalence of the medical conditions mentioned in the table had significantly decreased after LOD except for acanthosis nigricans (p=0.238). It is worth to mention that the prevalence of irregular menstrual pattern was 89.3% before laparoscopy, which significantly(p<0.001) decreased after laparoscopy to 19.5%.

Table 3 shows that the means of the following hormone had significantly (p<0.001) increased after one week of laparoscopy: LH, FSH, SHBG and prolactin, while there was a significant decrease in the means of the following: testosterone(p<0.001), AMH(p<0.001), FAI(p<0.001), and LH/FSH ratio (p=0.005). The same pattern can be observed after three months except for the LH where it is evident that its mean decreased to 7.17(p<0.001).Table 4 shows a significant decrease in the means of the following hormones three months after laparoscopy compared with the means of one week after laparoscopy: LH(p<0.001), testosterone (p=0.001), AMH(p<0.001), FAI (p<0.001), and LH/FSH ratio(p<0.001), while there was significant increase in the following means: FSH (p=0.001), SHBG(p<0.001), and prolactin (p=0.029).Finally, results showed that the ovulation rate was 56.2%, and the total pregnancy rate within six months was 26%.

Discussion

LOD regarded as one of the mode of PCOS treatment and this surgical treatment renovated by assumption of different surgical technique with use of different energy modalities to increase the success rate and minimize the complications\(^{11}\).

In the current study menstrual cycle after LOD reported improvement from 89.3% to 19.5% this is in agreement with result of Seyam et al\(^{12}\) and other studies\(^{13,14}\). Also hair suite, has a significant change and improvement in our study these results are in agreement with the study of Ashrafinia et al \(^{13}\). In another study prevalence of hair suite from 60% after intervention become 40%. Also acne improvement from 50.9% to 12.4% these findings similar to results in many other previous studies \(^{13,15}\), although many authors in their studies with laparoscopic surgery not reporting on this outcome and other clinical characteristics like acanthosis nigricans, greasy skin and scalp hair loss in our study\(^{2}=0.238, p<0.001, p=0.001\) respectively, more studies required to know about them after this modality of treatment.

Improvement in the endocrine data in our work is a remarkable observation are comparable with those previously reported showing a significant decrease in LH, testosterone, LH/FSH ratio\(^{11,16,17}\), significant increase of LH\(^{p<0.001}\) few days post operatively in our study confirming report of the same phenomena by\(^{16}\), this finding is against those found in previous studies\(^{9,18}\)showed no change in the level of LH and testosterone weeks and months after operation. Significant increase in SHBG in the current work confirmed by study \(^{19}\), furthermore another study demonstrated no change in this hormone\(^9\). The obtained result in the present study confirmed previous report\(^{17,20}\) of significant reduction of FAI.

Elevation of FSH is observed in the current and different studies\(^{16,17}\), secondary increase in FSH is controversial, studies reported no change\(^{11,13,21}\) although one study done by Elgafor demonstrated reduced FSH in his results\(^{22}\) this variability in the results may be due to different age groups, sample size and technique in their study. Hormones produced by ovaries immediately after intervention restores feedback to the hypothalamus and pituitary lead to increased pituitary sensitivity and temporarily higher LH and particularly FSH levels.
Folliculogenesis initiation is induced by the increased FSH levels, in combination with decrease number of follicle and reduced intra-ovarian androgen levels\(^\text{23}\).

As mentioned by Farzadi et al risk of ovarian tissue damage may not be significant statistically and decrease in AMH to the level of normality without any effects on the ovarian reserve\(^\text{18}\). In our study decrease in AMH to a significant level but within normal range from mean of (7.45 before to 4.75 after the drilling) may be due to the significant increase in FSH and this may affect the negative feedback of the AMH secretion and also in the present study the mean AMH pretreatment was higher compared to the mean of AMH in\(^\text{18}\).

The ovulation and pregnancy rate in the present study were the two main outcome measures (56.2\% and 26\%) respectively near to the results observed in the study\(^\text{12}\), were (60\% and 27.5\%) respectively, these results in agreement with other studies\(^\text{15,18}\). In several other studies described ovulation and pregnancy success results ranging from 26.5\%-94\%\(^\text{9,11,24}\) and 20\%-84\%\(^\text{9,16,25}\) respectively. In the present study despite of 56.2\% ovulation rate but the conception rate was not high during the six months follow up compared to the most other studies may be related to the duration of follow up after the operation reaching up to 12-18 months and this explain the long term effects of LOD, number of punctures used in each study and the last may be due to hyper prolactinemia observed in our study in some of the patients and this is in accordance to the previous finding\(^\text{26}\) while another study observed no change in this hormone\(^\text{17}\), so follow up of prolactin level after ovarian surgery is important.

Conclusions

Thus LOD not only helps in regulating ovulation and enhancing conception rates but also helps much in regulation of menstruation and hormone level improvement for future steps of infertility management for those failed to conceive a period after LOD.

Association between Breast Feeding And Breast Cancer: A Case Control Study in Erbil

Sherwan Aziz¹, Abdulqadir Zangana²

¹MBChB, MSc. lecturer in the Department of surgery, College of Medicine, Hawler Medical University, Erbil, Kurdistan Region, Iraq. ²MBChB, CABS-FICS. Professor of surgery, Erbil Teaching Hospital, Erbil, Kurdistan Region, Iraq

Abstract

Background and Objective: Breast cancer is the most common cancer that threatens life of women all over the world. In Iraq it is the most common cancer; 5141 new cases of breast cancer registered in 2018 comprising 36.7% of all women cancers and 20.3% of all cancers in both sexes. Breast cancer is a multifactorial disease many of the risk factors are modifiable, one of these factors is breastfeeding.

The aim of the study is investigating the association of duration of breastfeeding with breast cancer development, and comparing the risk in premenopausal and postmenopausal women.

Patients and methods: This study is a prospective case control study conducted in Erbil Breast Clinic and Erbil teaching hospital in Erbil city from January 31, 2016 to June 31, 2016.

140 women with histopathologically proved breast cancer compared with 160 women with no breast cancer in regard to total duration of breastfeeding.

Results: Among the 140 women with breast cancer; 66.4% women were pre-menopausal, and 33.6% women were postmenopausal, among the 160 women in the control group; 73.1% women were pre-menopausal, and 26.9% were postmenopausal.

Among postmenopausal women; 19.15% of women with breast cancer never practiced breastfeeding, while only 2.33% of women in the control group never practiced breastfeeding which was statistically different.

Conclusion: Postmenopausal women who did not practice breastfeeding and parous women who breastfed their children less than 12 months are at increased risk of breast cancer.

Key words: women, breast cancer, breastfeeding, risk.

Introduction

Breast cancer is the most commonly occurring cancer in women and the second most common cancer after lung cancer overall, there were over 2 million new cases all over the world in 2018 ¹. In Iraq it is the most common cancer; 5141 new cases of breast cancer registered in 2018 comprising 36.7% of all women cancers and 20.3% of all cancers in both sexes².

The incidence of breast cancer greatly varies among different populations, up to a 10-fold difference in incidence have been observed between low rates in rural African and Asian populations and high rates in North American and Western European populations ³. This great variation in the incidence is related to the risk factors which may contribute to the development of breast cancer; genetic factors contribute only to 5-10% of cases, the rest 80-85% of breast cancer causes are related to behavior and endocrine risk factors, which vary according to the culture, education and income of these populations, most of these risk factors are modifiable and avoidable⁴, therefore preventing or modifying these factors can prevent or lessens the development of the disease, one of these modifiable endocrine risk factors is breastfeeding. Breastfeeding not only reduces breast cancer risk but also provides other health benefits to...
the mother including reduced risk for endometrial and ovarian cancers5, and reduced risk for chronic medical diseases that are also risk factors for cancer, such as hypertension and diabetes6.

Controversies exist in the researches about the protective role of breastfeeding against the risk of breast cancer development in the mother as general and in pre and postmenopausal women.

The aim of the study is to assess the risk of breast cancer development in pre and postmenopausal women who never breastfed and parous women who practiced breastfeeding.

**Patient and Methods**

A prospective case control study conducted in Erbil Breast Clinic and Erbil teaching hospital in Erbil city, Iraq from January 31, 2016 to July 15, 2017. Erbil Breast Clinic is the only governamental clinic specialized for management of breast problems, it daily receives 50-70 women with breast problems, it provides necessary investigations.

After taking informed consent, physical examination and necessary investigations performed for both breast cancer ad control women.

152 breast cancer women enrolled in the study, 13 women were excluded from the study because they declined to continue with the study and only 139 women with proved breast cancer continued with the study, 175 control women attending to the surgical consultation unit in Erbil teaching hospital for non-breast complaints enrolled in the study, one of these women incidentally found to have breast cancer and included in the breast cancer group, 14 other women declined from the study, and 160 women continued with the study.

The study is a part of an ongoing PhD research was approved by the ethical committee of the college of medicine/ Hawler Medical University.

The recorded information analyzed by SPSS software version 22 using student t test and Chi square test.

**Results**

This study compared 140 histopathologically proved breast cancer women with 160 control women, Among the 140 women with breast cancer; the women age range from 25 to 91 years with the mean of 46.06 years age, 93 women were pre-menopausal (66.43%), and 47 women were postmenopausal (33.57%), among the 160 women in the control group; the women age range from 25 to 70 years with the mean of 42.76 years, 117 women were pre-menopausal(73.1%), and 43 were postmenopausal (26.9%), with no significant statistical difference between the two groups: tables 1, 2 and 3.

Table 4 compares the practice of breastfeeding whether never or ever breastfed, regarding the premenopausal women; 25 women with breast cancer and 21 women from the control side never used their breasts for feeding which was not statistically significant different. While more postmenopausal women in the control group had breastfed their children, which is statistically significant.

**Discussion**

Breast cancer is a multifactorial disease with many risk factors, some of them are modifiable, breastfeeding is one of the important modifiable risk factor which may have protective role against breast cancer, though there is a large debate about its role especially when related to the menopausal state.

This study concluded that breastfeeding has protective role against breast cancer in postmenopausal women; postmenopausal women who ever breastfed their babies are less susceptible to breast cancer compared with women who never practiced breastfeeding, more ever among parous women who practiced breastfeeding; at least 12 months of total duration of breastfeeding needed to have a protective role against breast cancer development but this protective role was only found for postmenopausal women, while no significant difference found in susceptibility for breast cancer among premenopausal women who never breastfed and those who breastfed less than 12 months.

A number of studies reported the protective effect of breastfeeding against breast cancer only for premenopausal women. A number of studies reported the protective effect of breastfeeding against breast cancer only for premenopausal women. Many review articles and meta-analytic articles support the protective role of breast cancer in both pre and postmenopausal women:

- A meta-analysis on four cohort studies concluded that breastfeeding protects against breast cancer, a 2% reduction in breast cancer risk for each 5 months increase of lifetime breastfeeding. The longer women breastfeed, the more they are protected against breast cancer. The 4th edition of the European Code against Cancer in 2014 recommends: “Breastfeeding reduces the mother’s cancer risk. If you can, breastfeed your baby.”

- Research by the international Collaborative Group on Hormonal Factors in Breast Cancer – based on individual data from over 50,000 women with breast cancer in 30 different countries – has shown that breastfeeding has a protective effect estimated at a 4.3% risk reduction for every 12 months of cumulative breastfeeding (in addition to an estimated 7.0% reduction in risk for each birth. The same study showed that breast cancer risk was reduced in both...
premenopausal and postmenopausal women, with no significant difference in the effect estimated according to menopausal status 27.

The hypotheses which may explain the protective effect of breast-feeding against breast cancer are:

1. Breastfeeding induces long-term endogenous hormonal changes; increased prolactin production and decreased estrogen level, which may decrease a woman’s total exposure to estrogen, thereby preventing the carcinogenesis or growth of breast cancer cells 28.

2. Most lactating women will be amenorrhic as long as they lactate, so less exposure to the cyclical elevated estrogens which enhance mitotic activity of the mammary cells during the luteal phase of the menstrual cycle 29.

3. The estrogen levels in breast fluid of lactating premenopausal women is lower compared with nulliparous women and parous women who did not practice breast-feeding30.

4. Pregnancy and subsequent breastfeeding induces differentiation of the mammary gland lobules from lobule 1 of nulliparous women to fully differentiated lobule type 4 during breastfeeding which is more resistant to carcinogenesis 29, 31.

6. Breastfeeding milk excretes some potential chemical carcinogens, hence provides temporary protection of the mammary tissue from these carcinogens 32.

7. During breastfeeding Oxytocin hormone increases which inhibits proliferation and growth of tumor cells 33.

8. Breastfeeding may decrease cancer risk by excreting DNA damaged cells 34.

**Conclusion**

Breastfeeding for at least 12 months is protective against breast cancer in postmenopausal women. It is worthwhile to encourage women to breastfeed their children to increase the protection against breast cancer.

Anthropometric Study of Nose Parameters in Iraqi Arabic and Kurdish Subjects (Possible Personal Identification Tool)

Sinan S. Farhan¹, Watheq M Al-Jewari¹, Aiman Q. Afar², Aiman Al-Qtaitat²
¹Faculty of Pharmacy, Department of Basic sciences, Al-Rafidain University College, Baghdad, Iraq,
²Faculty of Medicine, Department of Anatomy and Histology, Mu’tah University, Al-Karak, Jordan

Abstract

Background and Purpose: The human nose has been reported to differ in its anatomy and morphology between different racial and ethnic groups. Nasal anthropometric features when studied can provide useful information for reconstruction or esthetic surgical procedures and personal identification for forensic purposes. Method: A total of 311 subjects with age (19-23) years were divided according to gender, race (Arabic or Kurdish), and residence regions in Iraq (north, middle and south). Different nose parameters were measured for the subjects using digital Vernier caliper. Results: Comparing races, the nose height and nose length were significant between Arab and Kurds, nasal index showed (60, 60.6) for Arabic vs. Kurdish, respectively. Sexual dimorphism was significant in all the parameters obtained. The fine nose was the commonest among all subjects. Parameters analysis revealed high positive significant correlation among various parameters except the nasal index that showed negative correlation with nasal height and length. Conclusions: Nasal morphometric parameters were unique for each person and have variations between different race (Arabic and Kurdish), gender variation and the correlation among various parameters been recorded for Iraqi people. These morphometric evaluations are the key for standardization among Iraqis, and in comparison with different countries, this have great values in anatomical, surgical (aesthetic) and forensic aspects regarding personal identification.

Keywords: anthropology, nasal dimension, nasal index, personal identification, Rhinoplasty

Introduction

Morphometric variations are noticed in facial features among different races [1]. The human nose has been reported to differ in its anatomy and morphology between different racial and ethnic groups [2]. Measurements of different parameters of nose became very worthy in procedures related to nasal surgery and cosmetology [3]. Nasal anthropometric features when studied can provide useful information to the rhinoplasty surgeon especially when nasal reconstruction is performed for individuals who desire to change their nasal morphology [3, 4]. The nasal shape differs in human populations like various facial structures. For example, the interval between nasal wings had higher significant values in Asian and African when compared to European race [5]. The nasal index is one of the morphometric variables among individuals. It defined as the ratio of nasal width divided to nasal height multiplied by 100. It was revealed that the nasal index was the best index for distinguishing the different human ethnicities [6, 7].

Material and Method

In this present study, a total of 311 pharmacy students were recruited for the study, having age 18-22years, at Al-Rafidain University College, Baghdad and approved by ethical committee in the university. All the subjects were normal healthy residents of Iraq, 156 male and 155 female, the study was conducted during the period from September 2018 to February 2019. The study purposes were explained to all subjects and a written informed consent was obtained from each subject. Medical history and clinical examination were obtained, none of those enrolled for the study have history of craniofacial trauma, nose diseases, congenital anomalies or surgery of the nose. Subjects are classified according to race into Kurdish race and Arabic race. In addition, subjects are also classified into their different origin; from North, middle and south of Iraq. Measurements of parameters were obtained directly from the nose by a single investigator (to eliminate error), by using a digital Vernier’s caliper. Measurements were recorded in
millimeter, to the nearest 0.1mm. Each subject measured twice for accuracy and to each dimension.

Anthropometric measurements were performed depending on the following anatomical landmarks [8,9]: nasion (n), it is the midline point nasofrontal suture and the nasal root; subnasale (sn), it is the point just at middle of columella base; alar curvature (ac), the most lateral point that could be seen at curved base line of each ala ; and pronasale (prn), the most protruding point at the nasal tip. The Anthropometric parameters that were measured include the following, and are illustrated in Figure 1:

1. Nose height (NH): distance from subnasale to nasion
2. Nose length (NL): from pronasale to nasion
3. Width of nose (WN): span from right curve of nasal alae to left one.
4. Right nostril diameter (RND) where maximum diameter of right nostril measured
5. Left nostril diameter where (LND) maximum diameter measurement was done.
6. Right alar curve pronasale (RACP) distance from right curve of ala to nasal tip
7. Left alar curve pronasale (LACP) distance from left curve of nasal ala to nasal tip
8. Nasal index was measured by calculating the nasal width divided to nasal height multiplied by 100.

Nose shape had been classified into five types according to nasal indices [10]: 1. Very fine nose with nasal index <54.9 (Hyperleptorrhine), 2. Fine nose with nasal index =55.0-69.9 (Leptorrhine), 3. Medium nose when nasal index had a value between 70.0-84.9 (Mesorrhine), 4. broad nose with nasal index = 85.0-99.9 (Platyrrhine) and 5. very broad nose when nasal index >100 (Hyperplatyrrhine).

The collected data was statistically analyzed using SPSS software v.20. Values were expressed as mean ± standard deviation (SD). T test, one way ANOVA followed by post hoc test, chi square Fisher Exact and Pearson correlation test were used to compare the differences of parameters with significance value P<0.05.

**Results**

All different nasal parameters were recorded in Table 1. The parameters were recorded as mean ± SD, comparing the two races Arabic and Kurdish in one hand and comparing males and females on other hand. Sexual dimorphism was noted with male having higher values than their female counterparts, which were significant in all obtained parameters and nasal index (Table 1).

Comparison of anthropometric nasal measurements between the two races, Arabic and Kurdish Iraqis, a statistically significant difference was found for only four parameters; nose height, nose length, LACP and LND. On the other hand, nasal index shows no significance between the two races (Table 1). Furthermore, the correlations of different parameters among Arabic, Kurdish and total subjects were analyzed and presented in Table 2.

Pearson correlation of various parameters revealed positive correlation among many parameters. The highest score was 0.9 and it noticed between Right and Left Nostril Diameter. In contrast, negative correlations were seen in nasal index with nasal height (-0.4, -0.4 and -0.6) for total, Arabic and Kurdish respectively. Another negative correlation was observed between nasal index and nasal length with same value for total, Arabic and Kurdish (-0.3) (Table 2). Nose shapes were calculated based on the number and percentage of nose shape by race (Arabic and Kurdish) and presented in Table 3. The most common shape in both races was the fine nose (68%) while the least frequency was the broad type (1%). No significant difference was observed between races and shape, indicating that the race does not have any effect on nose shape.

The results of the anthropometric analysis obtained among different regions of Iraq (north, middle, and south) are shown in Table 4. The middle region shows the highest parameters of all regions. One-way ANOVA test was performed to compare parameters among the three regions. A significant difference was seen only in nose height and nose length. Tukey post hoc test revealed the significance was only between the middle and north group and in both nose height and nose length (Table 4).

Table 4: Nose morphometry among different regions, north, middle and south (measurements in mm). The results were expressed as mean ±SD. One way ANOVA followed by post hoc Tukey analysis were used to compare the differences between groups. a, b and c represent significantly difference as compared to South, middle and north (P<0.05) respectively

Discussion

The nasal morphometry is one of the significant features that characterize different races because it is at the center of the face. Different anthropological findings have described the nose as a signature indicating the ethnicity, race, age, and sex of an individual [11,12]. Morphometric assessments of parameters have clinical importance for nasal reconstruction after injury or for esthetic causes in addition to its importance in personal identification. Arabs had different race from Kurdish people that might help us to evaluate different race. Moreover there is variation in climate between north, middle and south of Iraq. According to our knowledge, the study of nose morphometry among Iraqis is the first study that carried out among our population, including the racial difference between Arabic and Kurdish. As presented above significant differences were noticed regarding nasal length and nasal height in both races. The dominant shape among subjects was the fine nose in both races. In addition, differences were noticed among nasal length, nasal height and nasal index. Some of the distinctive parameters that were carried out in this study are RACP and LACP. These two parameters assess distance of nasal tip and the nasal curve that provide indirect way to appreciate nasal deviation or not and the shorter distance means Ipsilateral nasal tip deviation. RND and LND parameters obtained above revealed RND and LND showed the high positive correlation only with NW and should be taken in consideration in reconstruction surgery.

Comparing our results with other results obtained from different studies, for instance among Nigerian populations [13, 14], there were lower values of nasal height and nasal length (44.1±3.7mm and 39.8±2.8mm) respectively, compared to our findings (53.8±5.7mm and 47.5±5.8 mm). However, nasal width and nasal index showed higher values (37.7±2mm and 86.1±8mm) compared to ours (32.2±4.1mm and 60.2±7.7mm) respectively. Both Nigerian studies showed similar findings to ours concerning sexual dimorphism, specifically there was significant difference in both gender regarding nasal height, nasal width and nasal index. Although, our results showed lower values of nasal width and nasal index compared to their results and higher values of nasal height. Conversely, on a recent Nigerian study, it stated lower values for nasal height, nasal length and nasal width compared to our results. Furthermore, it represented higher nasal indices for female and male (92.9, 98.9) respectively, and therefore broad nose is the dominant type, in contrast to ours, where the nasal indices for females and males were (59.2, 61.2) respectively, and fine nose is most common type. On the other hand, among Italian subjects nasal height, nasal length, nasal width and nasal index were 57.6±4mm, 49.3±4.8mm, 37.1±2.5mm and 64.9±6.9 respectively for adult male, while for females the same parameters were 54.3±4.2mm, 46.3±4.0mm, 35.3±2.6mm and 65.3±6.5 respectively [15]. Our findings showed lower values for nasal height, nasal width and nasal index, with close values for nasal length.

Conclusions

Nasal morphometric parameters had different values for each parameter in different countries and had variations in regions within same country. Our results between Arabic and Kurdish, gender variation and the correlation among various parameters were recorded for Iraqi people subsequently these morphometric evaluations are the key for standardization among Iraqis, which have important impact for anthropologists, forensic and surgical procedures, by depending on values obtained from same community. In general, our study and many studies showed different nose parameters that emphasize the effects of race, sexual dimorphism, genetic and climate conditions on parameters.

The Comparison of Social Support Against the Life Quality of the Spinal Cord Injury Under Stress

Soudabeh Aloustani 1, Karvan Bekmaz2, Adeleh Sadeghloo3, Hamid Hojjati4
1 Lecturer, Department of Nursing, Aliabad Katoul Branch, Islamic Azad University, Aliabad Katoul, Iran, 2 Lecturer, Department of Nursing, Khoy Branch, Islamic Azad University, Khoy, Iran, 3 Lecturer, Young Researchers and Elite Club, Aliabad Katoul branch, Islamic Azad University, Aliabad Katoul, Iran, Lecturer, Department of Nursing, Aliabad Katoul Branch, Islamic Azad University, Aliabad Katoul, Iran

Abstract

Introduction: The stress of war has caused severe problems for the individual and family. Spouses of veterans are gradually involved in family erosion. Lack of social protection and social dysfunction decreased life satisfaction and reduce intimacy between partners.

Purpose: This study has been done in the purpose of comparing social support against the veteran’s life who are under stress.

Method: This cross-sectional study was done on 79 posttraumatic stress disorder veteran wives and it was also done on 79 ordinary wives through convenience sampling. The instrument to collect the required information was the quality of life questionnaire which contained 36 SF questions and Medical Outcomes Study Social Support Survey (MOS-SS).and the needed information was collected by self-reported method.

Results: Veteran wives social support with the mean and the standard deviation was 19.3±5.1 while it was 31.1±3.7 versus the ordinary wives and this difference was significant (P less than 0.01). It showed the veteran wives quality of life with the mean and standard deviation of 46.3±.088 while it showed 66.9±8.5 the mean and standard deviation for the ordinary wives and it showed the significant difference (P less than 0.01).

Conclusions: the obtained result showed that the quality of life related to the health and social support in veteran wives is lower in compare with the ordinary wives with the same situation, therefore educational, treatment and supporting and promoting plans for this group is necessary.

Key word: social support; life quality; veterans; PTSD

Introduction

Trauma has many devastating effects on the patient1, 2). These effects include spinal cord injury. Social support, PTSD veteran wives, life quality. Posttraumatic stress disorder is a serious reaction and perpetual response which appears because of being exposed to serious stresses3). Posttraumatic stress disorder was identified and recognized during the civil war in the United States4). The prevalence of this disorder in the public population is 4-8 percent5). But this percentage is between 9 to 25 percent among the war injured ones during the first two years6). The prevalence of that among the Vietnamese war soldiers has been reported as much as 30.1% to 14.7%7). It has also been reported 17.1% to 15.6% for the solders coming back from Iraq war8, 9). According to the present documents more of the Iranian veterans have posttraumatic stress disorder and this disorder which is always with the veterans has a very bad effect on they themselves, their lives and their family lives10, 11). Living with a person who suffers PTSD can transfer some of the symptoms to their wives12).
so one of the war victims is the veteran wives who are exposed to the PTSD so the veteran wives encounter lots of problems in their lives and these problems become more and more by passing the time and cause them to have mental disorders and this continual disorder can bring trauma to the wives and can cause anxiety, depression, isolation in the veteran wives. The veteran wives will have family erosion little by little and because of the lack of social support they lose their satisfaction with the family members especially with their husbands. One of the anxiety of the family suffering from PTSD is mental relationship, matrimony compatibility and sexuality satisfaction which can affect their life quality. Most PTSD veteran wives sometimes face challenges that force them to be compatible to life because of their children and loving their husbands and some wives who cannot tolerate this hard situation decide to divorce. Studies have shown that most veteran wives have lack of social communications and they cannot express themselves well and they hesitate whether to continue that life or separate their husbands and in most cases the presence of their children cause them not to do so and this causes them to accept the problems and become compatible. An eight-year war with Iraq and its follow-ups have made many Iranian warfare Died and veterans suffer from war-related Mental disorders. In addition to medical and Mental disorders, this disorder decreases the sufferers’ quality of life. So, this study that has been based on the purpose of comparing the social support and life quality of PSTD veteran wives has been done.

Material and Method

This cross-sectional study was done on two wife groups; the first group were the veteran wives and this group contained 158 PSTD veteran wives and the second group consists of 79 ordinary wives. This study was done in the year 2016. The study setting was Aliabad city, the population of the city is 150,000 people and according to the announcement of The Foundation of Martyrs and Veteran Affair, there are 96 PSTD veterans there. The method of sampling was done by census method among the ones who had inclusion criteria which was certified by a psychologist, and those samples were the veterans with documents that proved they are veterans, and not addicted to any drug and abuse substances were chosen. All participants provided informed consent after the study purpose was explained, and assurances were made of anonymity and privacy. At most, 79 people were qualified for the study. The control group was elected among the veteran wife relatives and their close friends and they had no PTSD disorder and no chronic mental disorder rand they were not addicted to any drugs.

This study information was collected by Demographic questionnaire, Medical Outcome Study Social and supportive Survey (MOS-SS).

Demographic questionnaire: This questionnaire contains information such as age, education, number of children, the length of time living with his wife, drug using, and the chronic mental illnesses.

Short form of quality of life (QOL-SF36): This questionnaire which contains 36 questions measures and evaluates the physical, mental and eight domains of life. The physical life quality consists of physical function, limitation in having a role because of the physical lack in efficiency, physical pain and general health.; and domain of psychological, life quality, contains limitation in role because of having emotional problems, social function, happiness and vividness and healthy mental. The method of giving score to them was between zero for the worst to 100 according to the questionnaire instruction SF36, and the score obtained by the samples is between 0 and 100 and the reliability of this study has strongly been confirmed and the reliability of the native form of this questionnaire by Shahgholian(2014) in all aspects has firmly been confirmed and is 0.95 – 0.91.

Medical Outcomes Study Social Supports Survey (MOS-SS): This questionnaire was made by Sherbourne and Stewart. These supportive social tools have 19 questions and 5 sub scales. These subscales are tangible support (4 questions), which measures the financial and behavioral, exciting support (4 questions) which evaluates the positive emotion, sympathy, encouragement to express the feelings. Informing (4 questions) which evaluates guidance, informing, kindness (3 questions) which evaluate the amount of love, and positive social compatibility (4 questions) which evaluates the people who do the amusement and fun activities. This scale is a self-report tool which is used to measure the amount of agreement or disagreement of someone to any of them in five-point Likert scale (never = 1 point, seldom= 2 points, sometimes = 3 points, often = 4 points, always = 5 points). The lowest score in this is 19 and the highest score is 95. The high point in this test shows that the test is supported by the society a lot. The reliability of sub domain of this test was reported by Cronbach’s alpha 0.91. All statistical procedures were performed with
SPSS 16 statistical software. Using descriptive statistics independent t-test.

**Findings**

The mean age of the PTSD veteran wives were 39 individuals (49%), high school and guidance school education was 24 individuals (31%) primary school education 13 individuals (6%) and three of them had university degree, among the ordinary people wife, 48 (61%) had high school and guidance school education, (31%), 5 individuals were uneducated, 5 individuals (6%) had diploma and two of them (3%) had university degree.

The amount of life quality of the veteran wives with means and standard deviation was 46.3±0.88 (P<0.01). There also was seen a significant difference between the veteran wives versus the ordinary people (Table 1).

The amount of veteran wife’s social support by mean and standard deviation was 19.3 ± 5.1 and in the ordinary people it was 31.1 ± 3.7 (P<0.1).

**Discussion**

Spinal cord injury affects the mental health of patients, with a prevalence of mild depression of 22.6% in the Hatefi et al(24).The result of the study shows that the PTSD veteran wives have a lower quality of life. In both the physical and mental dimensions, the veteran wives had lower quality of life in compare with the ordinary people wives. Studies have shown that the veteran wives have more excitement and it has caused them to have a lower quality of life. The results of the present study were same as Bares (2011), Brow (2010) and in all these studies the PTSD veteran wife’s life quality was low(7, 25).

Clinical experiences have shown that the veteran family, particularly their wives, suffer mental problems such as seclusion feeling, loneliness, inability, sin feeling, and depression(26). because the PTSD veteran wives are exposed to stresses and have lots of turmoil in their marriage lives(13). Lots of studies show that the PTSD veteran wives suffer a lot from mental disorder in compare with the ordinary people or the wives of the veteran who have no stress(14, 27, 28). shows the surveys of this toll in the form of depression, anxiety and mental disorder and also as the physical problems and it is known as the prevalent headache and physical complaint among the veteran wives,27 because living for a long time with someone who suffers post-traumatic stress disorder has a deep and serious influence on their family and can be a chronic stress factor for their wives and can be the source of big and serious problems their families(29).

This study showed that the social support for the veteran wives is lower than ordinary people wives. Communication disorder, physical problems and its consequence, lack of understanding the veterans by some people in the society is one of the most important things that the veterans suffer from(13). Social supports may have a very important effect on developing care health and also on mental pathology in reaction to the stressful life events(30). Social supports from the authorities and the social organizations can increase respect, can reduce blame and label and it can also form a better self-compatibility in veteran wives and it also can reduce stress in their lives(14).
Conclusion

According to the findings of this study, it can be concluded that the martyr and veteran families are special families with special stresses and the amount of their stress increases day by day. Women are the center of these stresses, and they themselves and their children are at the risk of danger therefore the society is at danger. Therefore, in order to reduce the amount of stress and the factors that causes stress and anxiety in this group, presenting more and more suitable services and economical is an evitable necessity. Besides, in order to reduce the damage of stresses, teaching educational services, that is teaching life skills are among the communicative skills and stress management and doing actions on beliefs and their attitude towards the incidents and life meaning will be useful. It is also suggested that the veteran wife’s life compatibility is to be investigated through a quantitative research.

Conflict of Interest: There is no conflict of interest between authors.

Burning Mouth Syndrome and Salivary Brain Derived Neurotrophic Factor Level in Type 2 Diabetes Mellitus Patients on Metformin Monotherapy and on Combination of Metformin and Glibenclamide (A Comparative Study)

Suhair A. Hussain1 · Enas F. Kadhim2
1M.Sc.student, 2Assistant professor, Department of Oral Diagnosis, College of Dentistry, University of Baghdad

Abstract

Background: Diabetes mellitus is a chronic, progressive, incompletely understood metabolic condition chiefly characterized by hyperglycemia. Impaired insulin secretion, resistance to tissue actions of insulin, or a combination of both are thought to be the commonest reasons contributing to the pathophysiology of type 2 diabetes mellitus.

Objectives: The objectives of this study were to estimate the salivary Brain Derived Neurotrophic Factor level in type 2 diabetes mellitus patients on treatment of metformin as a monotherapy and those on combination treatment of metformin and glibenclamide. Also to evaluate the burning mouth syndrome in patients with diabetes mellitus under hypoglycemic agents.

Method: In this study 80 male subjects divided into 3 groups: Group 1: 30 subjects as healthy control group, Group 2: 25 subjects with type 2 diabetes under treatment of metformin as a monotherapy 500 mg twice/day and duration 12- 18 months, and Group 3: 25 subjects with type 2 diabetes treated with combination of metformin 500 mg twice/day and glibenclamide 5mg twice/day and duration 12- 18 months. Oral examination was done for each participant and the oral manifestations were recorded. Unstimulated whole saliva samples were collected to measure the brain derived neurotrophic factor level and comparing the results with each group. Body mass index for all participants was recorded. Salivary Brain derived neurotrophic factor concentrations were measured by enzyme linked immunosorbent assay ELIZA.

Results: The results showed that the burning mouth syndrome was seen in both patients groups. Statistical analysis showed a significant increase in burning mouth syndrome among the study groups. Regarding salivary brain derived neurotrophic factor, results revealed that there was a significant higher in combination group as compared to control and metformin monotherapy group.

Conclusion: Both monotherapy and combination therapy was affect salivary level of brain derived neurotrophic factor. Burning mouth syndrome was seen secondarily to diabetes and poor glycemic control and seen in both patients groups.

Keywords: Burning mouth syndrome, metformin, glibenclamide, salivary brain derived neurotrophic factor, Diabetes Mellitus.

Introduction

Diabetes mellitus is a group of metabolic diseases characterized by chronic hyperglycemia resulting from defects in insulin secretion, insulin action, or both. Low levels of insulin to achieve adequate response and/or insulin resistance of target tissues, mainly skeletal...
muscles, adipose tissue, and to a lesser extent, liver, at the level of insulin receptors, signal transduction system, and/or effector enzymes or genes are responsible for these metabolic abnormalities. Type 2 diabetes mellitus (T2DM) is a complex condition and serious health problem worldwide. In net terms, T2DM is a group of metabolic diseases characterized by chronic hyperglycemia followed by the abnormal secretion and actions of insulin. Genetic and environmental factors are thought to be responsible for the development of T2DM. Besides these, it has been noticed that T2DM is associated with inflammation. Brain-derived neurotrophic factor (BDNF) is a neurotrophin (NT) that plays an important role in maturation, synaptic connection, neuronal repair, and plasticity of the central nervous system (CNS); also it has an influence on the pathology and the treatment of neurological diseases. Besides the fundamental impact on the nervous system, several reports documented an association between plasma BDNF and systemic or peripheral inflammatory conditions, such as acute coronary syndrome and T2DM. One medication that has proved effective in treatment of type 2 diabetes and is considered the first choice for oral management, as recommended by the American Diabetes Association, is a drug in the biguanide class, metformin. Most side effects of metformin are mild and can include gastrointestinal distress, soft stools, and diarrhea. It is well documented that these gastrointestinal side effects can lead to malabsorption of vitamin B12 in a dose- and time-dependent manner. Another medication used in the treatment of type 2 diabetes mellitus is sulfonylurea for example glibenclamide. Glibenclamide: Also known as glyburide is a medication used to treat diabetes mellitus type 2. Several soft tissue abnormalities have been reported to be associated with diabetes mellitus in the oral cavity. Burning mouth syndrome (BMS) affects 1.3 million Americans. Burning painful sensation in the mouth is often linked with dysgeusia and xerostomia. Classically, its symptoms improve in the morning, worsen during the day, and diminish at night.

**Aim and Objectives**

The aim of this study was to investigate the oral changes in salivary brain-derived neurotrophic factor (BDNF) in male patients with type 2 diabetes taking antidiabetic metformin as a monotherapy and comparing results with type 2 diabetic patients taking combination of metformin and glibenclamide. In addition to Clinical evaluation of the effect of the anti-diabetic medication in type 2 diabetes mellitus on burning mouth syndrome.

## Materials and Method

This case control study was conducted in the period from February 2019 to May 2019 after approval from Ministry of Health and College of Dentistry University of Baghdad by the scientific committee. The samples collection was done in the Endocrine center/ Merjan Teaching Hospital in Al- Hillah city/ Iraq during the period from December 2018 to the end of March 2019. Laboratory work was done by Al- Nasih clinical laboratory/ Baghdad- Iraq. After explaining the aims and the objectives of the study, written informed consent was obtained from all participants. Unstimulated saliva collected by draining method. The brain derived neurotrophic factor was estimated in saliva samples by using Human Brain derived neurotrophic factor (BDNF) ELISA kit.

Exclusion criteria: Excluded from this study female patient, Patient with systemic disease other than type 2 diabetes mellitus, and Patients take any medications other than metformin or the combination of metformin and glibenclamide.

Inclusion criteria: 80 male subjects Age >\= 40 years old included in this study divided in to three groups: 30 control healthy male without any systemic disease, 25 male patients with type 2 diabetes mellitus under metformin monotherapy 500 mg twice/day for at least 6 months ago, and 25 male patients under the combination of metformin 500 mg twice/day and glibenclamide 5 mg twice/day for at least 6 months ago.

Statistical analysis: Data were written in computerized database using Microsoft Excel (2016). Statistical analysis was performed with SPSS (Statistical Package for Social Sciences; Version 24) and Sigma Stat 4.0 software. Descriptive statistical analysis including: mean, standard deviation and standard error was extracted for each group, Analysis of Variance One Way-ANOVA on rank was done to identify differences among the study groups, and Post- hoc tests Bonferroni (multiple comparisons).

Results Regarding patients on metformin monotherapy treatment, the burning mouth syndrome seen in 6 (24 %) while in combination group seen in 5 (20%). Statistical analysis using ANOVA test showed that there is highly significant difference among study groups in relation to BMS, table (1).

Discussion

Diabetes mellitus is a wide spread complex disease with high morbidity and health care costs. Both diabetes mellitus and drugs used in the treatment of this disease can affect the mouth and salivary glands\textsuperscript{13}. The current study is the first study carried regarding salivary BDNF and burning mouth syndrome in type 2 diabetes mellitus under metformin as a monotherapy and combination of metformin and glibenclamide (comparative study). Burning mouth syndrome was seen in 24% of those patients with monotherapy and 20% in combination group and there is significant increase in the BMS in metformin monotherapy group as compared to control group and no significant difference between the monotherapy and the combination group. This study agreed with previous study of [Moore et al., 2007] that showed BMS or related discomforts occurred slightly more frequently than in the control group. Burning mouth syndrome (BMS) has been attributed secondarily to diabetes, poor glycemic control, and diabetic neuropathy. The correlation between diabetes mellitus and BMS is still controversial. It has been suggested that type II diabetes mellitus plays a role in BMS development and a link between the type of insulin used for the diabetes treatment and BMS has also been proposed. In contrast, other studies report a lack of association between these two conditions\textsuperscript{14}. A possible explanation for this controversy may be that these diabetic patients were erroneously classified as BMS. In fact, at the time of the above studies, a lack of strict criteria for BMS diagnosis could have affected the selection of the patients. For instance, burning oral complaints in diabetic subjects, who are more prone to oral infections, are probably caused by oral candidiasis. Although a large variety of drugs, medications, and miscellaneous treatments has been proposed in BMS, the treatment management of this syndrome is still not satisfactory, and there is no definitive cure. BMS patients have shown a good response to long-term therapy with systemic regimens of anti-depressants and anxiolytics\textsuperscript{15}. In the current study, there was a significant difference among studied groups regarding BMI. A significant increase in the BMI in the combination group as compared to control group was seen and there is non-significant difference between the two patients groups. This study showed that there is significant difference among the studied groups. Also there is significant
difference in combination group compared to metformin group. A significant increase in the mean of salivary BDNF in combination group as compared to metformin group was seen and there is no previous study regarding salivary BDNF in type 2 diabetic patient under therapy. In order to understand the impact of metformin on BDNF levels, [Ma et al. 2015] investigated the effect of metformin on Schwann cells under hypoxia condition and they found that the mRNA levels of BDNF were significantly decreased. However, this detrimental effect of hypoxia on gene expression in Schwann cells was partially reversed by metformin. The mRNA level of BDNF in metformin-treated Schwann cells was higher than those without metformin under hypoxia condition. This beneficial effect of metformin on gene expression under hypoxia condition was significantly inhibited by compound C, which is an inhibitor of AMP-activated protein kinase (AMPK) and an important cellular regulator of lipid and glucose metabolism16. Taken all together, these findings suggest that the correlation between BDNF and metformin may be the reason of metformin-induced insulin action by insulin receptor binding, metformin-induced high BDNF levels due to increasing AMPK, and enhanced tyrosine kinase receptor activity which may amplify BDNF signaling. BDNF inhibited during hyperglycemic clamp conditions in humans. This may explain the concomitant finding of low circulating levels of BDNF in individuals with type 2 diabetes17. Significant increase in the level of BDNF in combination group as compared to metformin group may explained by good glycemic control of combination treatment as compared to metformin mono-therapy treatment18.

**Conclusion**

Both monotherapy and combination therapy was affect salivary level of brain derived neurotrophic factor. Burning mouth syndrome was seen secondarily to diabetes and poor glycemic control and seen in both patients groups.

Efficacy of Chitosan Immune Response Against

Listeria Monocytogenes Infection in Mice

Sura Ayed Radam1, Inam Badr Faleh1; Osama Faid allah Atshan2, Mustafa Salah Hasan3

1Department of pathology, 2Department Microbiology, College of Veterinary Medicine, University of Baghdad, 3Department of Internal and Preventive Medicine, College of veterinary medicine, university of Fallujah

Abstract

The present research aimed to study the effect of dietary chitosan supplementation against murine experimentally infection by Listeria monocytogenes.

forty mice were divided equally into 4 groups. The 1st and 2nd groups fed on diet supplement with chitosan (1mg/kg diet) and (1.5mg /kg diet) for (4) weeks respectively, While 3rd and 4th groups considered as control positive and negative groups. At (4) weeks the first three groups were inoculated intraperitoneally i/P with (0.2) ml (1×10^9) CFU/ml, while the 4th group (control negative) inoculated with (0.2) sterile normal saline.

At (7) days post infection, the result revealed diet one of mice in each control positive and treated group at (24hrs.) post infection with heavy bacterial isolation from brain, spleen and liver of infected positive group and mild to absent bacterial isolation in the 1st and 2nd group respectively.

Grossly presence of severe congestion in the internal organs with necrotic foci seen on the splenic surface of infected positive control while the characteristic feature in the treated infected group was hepatosplenomegaly.

Sever pathological changes were noticed in the infected positive control group characterized by suppurative inflammation with necrosis accompanied with lymphoid depletion and amyloid like substance deposition while the main lesion in treated infected groups showed granulomatous lesion, lymphoid hyperplasia and mononuclear cells infiltration with heavy bacterial isolation from brain, spleen and liver of infected positive group and mild to absent bacterial isolation in the first and second group respectively, We concluded that chitosan stimulated and improve the immune responses in mice against Listeria monocytogenes infection.

Key word: chitosan, Listeria monocytogenes, immunized, mice, pathology.

Introduction

Listeria monocytogenes is regular Gram-positive motile from, rod with rounded ends, its cells found as single units or short chains or may be arranged in V, L and Y forms or in palisades (1). Listeria monocytogenes does not produce spores and capsules are not formed (2). Spread in nature where, exists largely in decaying vegetation, soil, animal feces, feed and water as make it one of the major pollutants of food and play essential role in transmitted of infection between humans and animals (3) also infection by Listeria monocytogenes can be haematogenous spread directly from the mother to fetus (4, 5)

Chitosan is a modified natural carbohydrate polymer derived from chitin, it have many medical uses because their ability to reduce bleeding also help deliver drugs through the skin also in limiting of fat absorption(6), also has been bio adhesive property for that used as a safe excipient formulations of drug, it has been used in dentistry because adhere ability to hard and soft tissues also uses in orthopedics, ophthalmology and in surgical procedures, it adheres to epithelial tissues and mucus coat present on tissues surface also has a antifungal or antibacterial, antineoplastic and anticholestermic action(7).

Material and Method

Chitosan was obtained from university of Al-
Bahasa, collage of veterinary medicine. Commercial assorted pellets were grinded by food grinder and weighed (1) gm and (1.5) gm of Chitosan was added to each kilogram of grinded pellets mixed well and converted into paste which passed through meat grinder to mould the paste into the original pellets from, left exposed to dry in room temperature. The *Listeria monocytogenes* isolate was obtained from the unit of Zoonotic diseases in the College of Veterinary Medicine, the isolate confirmed by some biochemical tests and gram stain according to (9).

A total number (n=40) male white Swiss BALB/C mice which obtain from the (National Center of Researches and Drugs Monitor in Baghdad); then divided into fourth groups. The 1st group (n=5) mice were fed on diet supplement with chitosan (1mg/kg diet) and (1.5mg/kg diet) for (4) weeks respectively, While 3rd and 4th groups considered as control positive and negative groups. At (4) weeks the first three groups were inoculated intraperitoneally i/P with (0.2) ml (1×10^9) CFU/ml, while the 4th group (control negative) inoculated with (0.2) sterile normal saline, histopathological examination of internal organs (liver, spleen and brain) were taken from both control and infected groups about (1cm^3) was taken and fixed in 10% formalin saline for histopathological section which was done according to (10).

**Result and Discussion**

1) Gross pathological changes:

The main gross feature in control group was severe congestion in the visceral organs specially in the liver, spleen and kidney with presences necrotic foci at the edge of spleen, while treated groups show hepato-splenomegalgy was the characteristic gross lesion in the treated groups.

2) Bacterial isolate and clinical signs:

No clear clinical signs noticed on experimental animals specially the treated groups were appeared healthy and well feeding. The result showed heavy bacterial isolation mainly from brain, spleen and liver of control positive groups, while mild growth to absences in other treated groups. Also the isolate was confirmed again on blood agar then we made smear from isolate and stained with grams stain.

3) Histopathological examination:

The characteristic lesion in hepatic tissue of control positive show aggregation of PMNCs cells in liver parenchyma (suppurative foci) mainly in portal area accompanied with atrophy of some hepatic cords together with sinusoidal dilation and cellular infiltration in their lumen, The splenic tissue showed destructive changed with variable degree of lymphoid depletion in the white pulp, other section showed formation of multiple cystic cavities containing cellular debris together with focal amyloid like substances deposition, The brain tissue expresses sever neuronal degeneration and apoptosis accompanied with nuclear pyknosis and appearance of hypertrophic swelling astrocytes (gamistocyte), another section showed irregular cystic cavities with neuronal vaculation.

While the characteristic lesion in the liver of treated 1st group (fed on diet with 1gm/kg of chitosan) were development of early small granulomatous lesion seen in dilated sinusoids together with proliferation of kupffer cells (figure:1), the microscopic examination in the spleen revealed mild white pulp hyperplasia with proliferation of megakaryocyte (figure:2), together with slight vacuolar changes in some neurons also the results showed moderate gliosis (figure:3).

The pathological lesion in liver of treated 2nd group (fed on diet with 1.5gm/kg of chitosan) characterized by focal mononuclear cells (MNCs) aggregation mainly around central vein (figure:4) while presence of follicular hyperplasia in the white pulp was the main lesion observed in splenic tissue (figure:5), while the main brain lesion in the treated infected mice characterized by focal aggregation of MNCs in brain tissue, associated with no clear lesion in the neurons seen mainly in the brain section.

The present study shown sever pathological lesion in the internal organs (liver, spleen and kidney) of the control positive groups these results indicate that exposed to highly virulent microorganisms overcome the innate immune system and disseminates to internal organs induce tissue damage, these observation were in consistent with (11) who explained that virulent *Listeria monocytogenes* was one of intracellular bacteria disseminated via blood stream to internal organs and induce nonspecific inflammatory reaction by production listeriolysin O which destroyed the endothelial cells of blood vessels to induce necrosis and supplicative inflammation (12). In addition, survival and proliferation of microorganisms in the hepatic and splenic cells will
lead to the formation of infection foci that result the infiltration of a large number of WBCs and activate neutrophil phagocytic cells to work on other resist the invading germs (13). We also recorded depletion of white pulp of spleen of control positive group these observations may indicate that Listeria monocytogenes induced reduction in acquired immune response via depletion of lymphocytic cells (14). Neuronal necrosis and microcavities formation may due to excess of nitric oxide generation literal infection which is important for intracellular signaling of new transmission both inducible and constitute nitric oxide synthase (NoS) are expressed in brain cells include neural lesion, further more inflammatory cells include neutrophils, macrophages express both (NoS and iNoS) may play an important role in elimination Listeria monocytogenes (15). Also the present study explain that feeding infected mice showed mild to moderate pathological lesion in the spleen, liver and brain tissue post challenge with Listeria monocytogenes and these lesion characterized by appearance of granulomatous lesion mainly in liver tissue this evidence was agreement with (16) Where noted that the granulomatous reaction was considered the strongest body defense against virulent microorganism’s infection, furthermore there are numerous response indicate that chitosan improve the immune response (17). Our results showed lymphoid hyperplasia in splenic tissue mainly in mice feeding with (1.5gm/kg) chitosan this indicate that chitosan elicited both humeral and cell mediated immunity and activated immune cells to secret cytokines that play essential role in initiated mature granuloma in the liver and this evidence was in agreement with (18) Who demonstrated that feeding of chitosan increase OX62+ percentage and DCs which up regulate the major histocompatibility complex class-II Ags. without expression changing of co-stimulatory (CD80 or CD86) molecules and Ag presenting cells produced TNFα and IL-12 and activation T-lymphocytes, lymphoid tissue hyperplasia in animals fed diet supplement with chitosan may due to chitosan stimulated proliferation of lymphocytic cells.

Fatal Drowning in Delta State, Nigeria: A Retrospective Study of Cases in this Region

Uchendu O J,1 Ijomone E A,2 Nwachokor F N3

1Senior lecturer, Department of Morbid Anatomy, Delta State University, Abraka, Delta State, 2Hospital Consultant, Department of Pathology, Central Hospital, Warri, Delta State, 3Senior lecturer, Department of Morbid Anatomy, Iginedion University, Okada, Edo State

Abstract

Introduction: Drowning death is a preventable, under-reported public health problem resulting from respiratory insufficiency secondary to immersion or submersion in liquid.

Aim: To study the sex, age, and place of death of victims of fatal drowning in Warri, Delta state, Nigeria.

Material and Method: This is a descriptive, retrospective study of cases of fatal drowning reported to the coroner and subjected to postmortem examination by the authors in Delta State from 1st January 2003 to 31th December 2016. Basic information such as the age, sex and place of death were extracted and analyzed using Microsoft Office Excel, version 2007.

Results: Thirty-seven victims comprising of 34 males and 3 females were examined during this study, giving a mean incidence of about 2.5 cases per annum. Their ages ranged from 1.5 to 59 years with a mean of 28.53 years and a dual peak in the 3rd and 4th decades. All the deaths were of accidental causes, with most the of them (70%) occurring within natural water bodies.

Conclusion: The study showed that drowning death is relatively common and usually of accidental etiology. Young males in their thirties and forties are the most vulnerable victims, with the natural water bodies being the most common site of drowning. Being a preventable cause of death, adopting and enforcing preventive safety measures by the individuals, community and government will invariably reverse this trend.

Key word: Drowning, Medicolegal, Preventable death

Introduction

According to statistics from WHO, unintentional injuries account for 3.9 million deaths annually with about 90% of these cases occurring in low and middle income countries (LMIC). These are attributed mostly to road traffic accident (RTA), fall, drowning, poisoning and burn.1

Drowning is currently defined as “the process of experiencing respiratory impairment from partial or complete submersion/immersion in liquid”. Its outcome may be fatal (death) or non-fatal, the latter of which may be with or without morbidity.2

Though preventable, fatal drowning has become a serious public health issue globally ranking among the three leading causes of injury related death in most countries.3 According to WHO report, drowning accounted for about 372,000 deaths in 2012, with 91% of these deaths occurring in LMIC.4 Children have been shown to be particularly susceptible with about 450 dying daily from drowning, and a significant number suffering from varying grades of morbidities.5 Sadly, the African continent accounts for the highest drowning mortality with a rate 13.1 per 100,000 population.6

Delta State of Nigeria is unique because of numerous unprotected natural water bodies with 35% of its 16,842 square kilometers total land area being riverine. It also has a high density of streams, ponds, lakes, creeks as well as the large body of ocean waters.7
Despite the burden of drowning death, there is paucity of research on this subject matter in this region. This study is aimed at analyzing the age, sex and death-place of victims of fatal drowning, examined by the authors during the study period. Being the earliest of such study in this part of the world, we hope the findings will increase public and government awareness of magnitude of the problem, guide government policy formulation, contribute to literature and lastly suggest direction for subsequent research.

**Materials and Method**

This is a 14-year descriptive retrospective study of drowning deaths recorded by the authors in Warri, Delta State from January 2003 to December 2016.

All medicolegal autopsies performed in this region by the authors were reviewed and confirmed cases of drowning identified for this study. The information used for this study includes the age, sex, circumstance and site of death of the victims. This information was subsequently analyzed using excel spread sheet and presented in tables.

Exclusion criteria: All cases of post-mortem drowning as well as cases of doubtful history were excluded from the study.

**Result**

In this retrospective study, 1121 medicolegal autopsies were analyzed, out of which 37 (3.3%) of the cases were as a result of drowning.

The age distribution of victims is shown in table 1, ranging from 1.5 years to 59 years, with a mean age of 28.53 years and two unimodal peaks occurring in the 3rd and 4th decade.

The sex distribution of the victims is shown in table II, with males and females accounting for 34 (91.9%) and 3 (8.1%) of the cases respectively.

Table III showed the places where the drowning occurred. Natural waters (Oceans, creeks, rivers, streams and lakes) were the site of occurrence in 26 cases (70.3%). Interestingly, two of these deaths took place during immersion baptism. Three cases (8.1%) occurred in water well. Coincidentally, two cases each (5.4%) were recorded in four different setting during the study namely: fish pond, pipeline excavation pits, gas tanks and swimming pools.

Discussion

Thirty seven (3.3%) of the medicolegal deaths in the study population were drowning death. This figure is intermediate between 2.2% reported by Nwafor and Akhiwu in Benin City, Nigeria and 4.3% reported by Ngbea et al in Makurdi, Nigeria.

We are of the opinion that this is a gross underestimation of its burden because of endemic inefficiency at data collection often seen in developing countries, and the poor attitude towards reporting accidental deaths to the police. The trend of practice where relatives of the deceased are made to pay for the autopsy has also not encouraged these relatives to report such cases to the police.

This study showed that males were found to be 11.3 times at higher risk, than the females. The high male to female ratio observed in this study concurs with reports from 62 articles in English literature reviewed on this subject matter in which a mean male-female ration (MFR) of 3:1 was observed. This male predominance may be attributed to their greater involvement in boat-driving and other boat-centric jobs, including fishing and trading. Inherently, the males are more aggressive, competitive, and take on to riskier activities and behaviors some of which include alcohol, drug abuses and swimming alone, all of which may further increase the risk of drowning. Activities in the water bodies such as crude oil theft and sea piracy which are common activities in this region may also doubt contribute to this ugly trend.

A double unimodal peak was observed in the 3rd and 4th decade, with each peak representing 32.5% of the cases. This is most likely as a result of the active lifestyle of this age group. Our observation compares favorably with those from Benin City, Nigeria, where the highest number of victims were in their 3rd decade, but contrasts with report from an earlier study in the Niger Delta region which recorded the highest number of cases in the 6th decade of life. Drowning death risk is highest among children globally. In the index study, 18.9% of the victims were children, majority of which were in their 2nd decade of life. This is lower than earlier report among children in Benin City and Niger Delta region. Lapses in supervision especially from parents has always been the major explanation to drowning among children. The lower incidence of childhood drowning death in Nigerian series, relative to the global trend, may be attributed to case underreporting as natives in the study population attach less significance to death of children than that of adults.

Environmental factors, culture, behavior of the people as well as the geography of the environment play remarkable roles in the setting of drowning death. Delta state has a rich network of natural body waters, with a lot of transportation, recreational, fishing and trading activities. This may explain the occurrence of most cases of drowning death in these natural water bodies. Our report is similar to findings in Bangladesh with 95% of cases reported in a similar setting. Likewise, Sheikhaazadi in Iran, and Pal et al in India reported 83% and 81.8% cases respectively in fresh water setting.
Our study also concurs with an earlier report by Seleye-Fubara in Niger Delta region.\textsuperscript{12} On the contrary, Nwafor et al reported lower frequency of drowning death in natural water bodies in Benin, a city that has fewer rivers within its geographic boundaries.\textsuperscript{11}

The two cases of drowning during baptism recorded in this study is a cautionary call to the church as it underscores the imminent danger of such activities. There is need to re-orient the church to avoid such practices where possible and if unavoidable, to adopt preventive measures including use of protective devices and employing divers to avert grave consequences. Arresting and prosecuting church leaders will act as a deterrent to others.

Public swimming pools were the second most common site (8.1\%) of drowning death in this study. This is a reflection of proliferation of swimming pools in modern hotels and bars, probably an influence of westernization of our culture. We think this is mainly as a result of misadventure and recklessness of the victims, who are predominantly young. It is a general observation that these setting encourage alcohol and drug use, the role of these substances in the risk of drowning may not be overemphasized. Earlier reports have shown that swimming under the influence of alcohol is associated with increased risk of drowning death.\textsuperscript{13} In USA, the highest rate of drowning occurred in swimming pools, which disagrees with our report.\textsuperscript{15} In Japan, the highest drowning death occurred in bathtubs, mostly affecting the elderly persons.\textsuperscript{16} Enforcement of fencing of Public swimming pools and use of personal floating devices routinely are worthwhile preventive measures.

Wells, fish ponds, pits and gas tanks accounted for the remaining settings for drowning death in this study. These settings are all products of man’s activities and interference with the natural environment. Therefore, using barrier fencing, caution signs, early filling up of ditches and pits, especially at sites of road construction will no doubt prevent such accidents.

With respect to forensic etiology, accidental drowning accounted for all the cases. Sheikhazadi in Iran,\textsuperscript{13} Nwafor in Benin, Nigeria,\textsuperscript{8} and Seleye-Fubara in Niger Delta region, Nigeria\textsuperscript{12} observed that most cases were of accidental causes. The rarity of homicidal drowning may not be unconnected with the difficulty in drowning a healthy conscious adult. As in our study, suicidal drowning was not reported in other Nigerian studies.\textsuperscript{8,12,13} Though there has not been any study on suicide in this region, earlier studies among Nigerian Yorubas (a major ethnic group in Southern Nigeria) showed a strong negative attitude towards Suicide.\textsuperscript{17}

In conclusion, the study showed that drowning death is relatively uncommon and all of accidental etiology in this study. Young males in their thirties and forties are the most vulnerable victims, with the natural water bodies being the most common site of drowning. Being a preventable cause of death, adopting and enforcing preventive safety measures by the individuals, community and government will invariably reverse this trend.

**Limitation of the study:**

The relatively small sample size, under-reporting of the cases, the effect of co-morbid conditions, drugs and alcohol may interfere with the outcome of this report.

**Conflict of Interest:** Nil

**Source of Funding:** Self

**Ethical Clearance:** Ethical approval was obtained from the ethical clearance committee of Delta State Hospital management Board/Central Hospital, Warri (reference CHW/ECC VOL1/124).

Measurement of Effective Dose Detox for Workers Exposed to Benzene Toxins in Sidoarjo Paint Industry

Vivi Budiarti1, Charles Kimura1, Ayu Prima Kartika1, Achmat Kuncoro1, Abdul Rohim Tualeka1
1Department Of Occupational Health And Safety, Public Health Faculty, Airlangga University, Surabaya, Indonesia

Abstract

One of the aromatic hydrocarbon compounds, namely benzene. Benzene is a colorless liquid with a sweet odor (sweet odor), volatile in the air, soluble in water and flammable. Today the use of benzene used by the paint manufacturing industry. However, the concentration of benzene that exceed standards required threshold value will negatively impact the health of workers in Sidoarjo Paint Industry. Benzene can threaten the safety and human health if inhaled because it can damage the blood forming system profile in humans. The purpose of this research is to reduce the exposure of benzene by determining the effective dose of toxin detox benzene in the paint industry, Sidoarjo, East Java. This study was an observational study with cross-sectional approach. Result the average concentration of benzene in the workplace respondents was 3.28 mg/m³. The average effective dose should be consumed by the respondent for the avocado intake is 0.011 mg/day, chicken intake 0.026 mg/day, intake of grapefruit 0.033 mg/day, and carrot intake was 0.063 mg/day.

Keywords: Benzene, an effective dose of detox, paint factory worker

Introduction

One of the aromatic hydrocarbon compounds, namely benzene which has many uses for human life, especially in the industrial sector14. Epidemiological studies prove benzene as a carcinogen substance, have toxic effects on the blood and bone marrow. The International Agency for Research on Cancer (IARC) classifies benzene into the group-1A carcinogen material, a material that proved to be carcinogenic to humans. Contained toxic levels of benzene contained in the human circulatory system can cause leukemia2. NIOSH (National Institute of Occupational Safety and Health) said that workers exposed to organic solvents, it is estimated to reach 9.8 million people, mainly workers who work on the production of paints, adhesives, glues, coatings, grease solvent / cleaning materials, production dyes, polymers, plastics, textiles, printing inks, agricultural products, and pharmaceuticals12. NIOSH estimates that more than 2 million workers in the United States the possibility of exposure to benzene.1 In Indonesia, definitive data regarding the effects of benzene on workers association has not been found14.

Benzene includes components of gasoline and toxins commonly regarded as the work16. Benzene is a toxic chemical that can lead to acute myeloid leukemia10,12. Benzene when oxidized in Phase 1 will produce benzene quinone, which is a source of increased toxicity. To complete benzene required in Phase 2 detoxification enzymes CYP2E111. metabolic enzymes play an important role in the activation or detoxification benzene15. Benzene is initially oxidized to benzene oxide by the liver cytochrome P450 2E1 (CYP2E1) in the liver14.

BO detoxification in vivo occurs by reaction with glutathione, some metabolites of benzene aromatic rings opened or catalyzed by enzymes II metabolites such as glutathione-S-transferase (GSTs) or to form the derivative is less toxic or non-toxic and excreted through the urine17. To reduce or even eliminate toxins in the chemical, diperlukan4 biotransformation process. High levels of antioxidants needed to neutralize these substances, compensate for the damage caused by free radicals and protects the liver and cells of the CYP2E111. Foods rich in beef liver, brain, and salmon; Sulfation

Corresponding Author: Abdul Rohim Tualeka,
Department of Occupational Health and Safety, Faculty of Public Health, Airlangga University, 60115 Surabaya, East Java, Indonesia. E-mail: abdul-r-t@fkm.unair; Handphone: +6281333519732
rich foods are eggs, sulfation of chicken, beef and tuna, and foods rich in glutathione are avocado, asparagus, carrots, tomatoes, oranges, and broccoli.

Research using food to detoxify benzene is still very limited. Therefore, this study aimed to determine the CYP2E1 enzyme-rich food intake, sulfation, and glutathione required to detoxify benzene in every worker in Sidoarjo Paint Industry.

Benzene is one of the aromatic hydrocarbon compounds are widely used in the rubber industry, oil refining, chemical plants, shoe factories, and oil-related industries. Benzene is also found in public facilities such as cigarette smoke, gas stations, fuel burning cars, and so on. According to the Agency for Toxic Substances and Disease Registry (ATSDR), hazardous and toxic chemicals contained in oil content, namely benzene, toluene, xylene, ethylene, TPH (Total Petroleum Hydrocarbon) and Polycyclic Aromatic Hydrocarbon (PAHs). Of the six chemicals benzene exposure are very serious impact on health.

American Conference of Government Industrial Hygienists (ACGIH) in 2006 set the Threshold Limit Value (NAV) of the chemical benzene in the workplace that is the maximum value allowed is 0.5 ppm and certainly belonged carcinogenic to humans (A1 = Confirmed Human carcinogen) 14. National Institute for Occupational Health and Safety (NIOSH) set the recommended exposure limit or REL (recommended exposure Limit) for 8 hours of work that is equal to 0.1 ppm. In Indonesia alone, according Permenakertrans 13 / MEN / X / 2011, 2011, NAB allowable benzene is 0.5 ppm.6 While based on the Minimum Risk Level (MRL) set for the ATSDR 2007 was 0.009 ppm benzene every day to give effect acute and 0.003 ppm every day cause chronic effects 2.

Areas of the paint industry as a working environment that has a high exposure to benzene, supposedly necessary efforts to reduce the negative effects of exposure to benzene so as not to cause health problems for workers. Based on previous studies of benzene in the workplace, has not done research on effective dose detok toxic benzene in the workplace that have exposure to benzene. Therefore, the authors are interested in discussing the size of an effective dose of toxic benzene in the area detok paint industry.

Material and Method

The subjects are workers in the paint industry Sidoarjo. Criteria for inclusion in this study were male workers who had worked in the paint industry and are willing to be used as respondents. The sample was 24 people.

The variables that need to be calculated first is the effective dose intake needed by each individual to calculate the weight, length of employment (years), worked on average each day (hour), and the working time in a week (days) of the respondents, as well as the measurement of the concentration, benzene at five points in the industry. Weight measurement using the scale body weight. Working length measurement, the average work every day, and time workweek obtained through in-depth interviews with respondents. Then, the measurement of the concentration of benzene in the workplace by using the NIOSH 1501 method of measurement with activated charcoal carbon pipe using the technique of gas chromatography (NIOSH 1501, 2003). The study was approved by the Ethics Committee of the Faculty of Public Health.

Then, look for the intake (formula) with the following formula:

\[
\text{intake non carcinogen} = \frac{C \times R \times tE \times fE \times Dt}{Wb \times 30 \times 365}
\]
C = concentration of benzene (mg / ml)
R = benzene reaction rate (m3 / h)
te = working time / day (hours)
Fe = working time / week (day)
Dt = working time (years)
Wb = weight (kg)

Calculate the effective dose per day with the calculation results noncarcinogen intake (intake) above, using the formula below:

\[
effective
dose
dead
= \frac{intake}{days}
= \frac{intake}{\text{toxin day}} \times \frac{Mr
enzym
detox}{Mr\ toxin}
\]

Findings

Benzene concentration (n = 24)

In Figure 1, shows that the benzene concentration maximum of 6.7508 mg / m3 and the lowest of 1.1975 mg / m3. So that the average benzene in Sidoarjo paint industry was 3.28 mg / m3.

Comparison of Predicted Benzene intake Detox

</table>
In Table 1 and Figure 2, shows that the highest benzene concentration of 6.7508 mg / m3 and the lowest of 1.1975 mg / m3. So that the average benzene in Sidoarjo paint industry was 3.28 mg / m3. The average effective dose should be consumed by the respondents to the intake of avocado is0,011 mg / hr, chicken intake of 0,026 mg / day, The intake of citrus 0,033 mg / hr, and carrot intake was 0.063 mg / hr.

**Discussion**

Detoxification is the process that is toxic to less toxic compounds. The detoxification process to be non-toxic eliminated through urine and bile. Food-based nutrition continues to be investigated for its role in modulating the metabolic pathways involved in the detoxification process. Some of the publications that have used the cell, animal and clinical studies indicate that the component-based foods and nutrients can modulate the process of conversion and excretion of toxins from the body.

YP2E1, Sulfation, and glutathione are enzymes that work on phase 2 of the biotransformation 9. CYP2E1 are involved in detoxification reactions-activation of a variety of endogenous and exogenous compounds. Rat hearts showed that the effect of the amount of protein in CYP2E1 activity increased CYP2E1 enzyme activity increased 2.6. Sulphation is one of a number of liver detoxification pathway, particularly the phase II detoxification. The sulphation detoxification of toxins, it is an antioxidant and detoxification compound produced a powerful agent in the cytoplasm of every cell of the human body 13.

Related glutathione antioxidant enzyme involved in the metabolism and detoxification of cytotoxic and carcinogenic compounds as well as reactive oxygen species.

The generation of reactive oxygen species occur in relatively prolonged hypoperfusion conditions such as aging. The etiology of presbycusis is much less certain; However, the genetic cause is most likely complex. The effects of aging shows a variety of inter-wide.

The results showed that each individual has a different cost. This is because each individual has a different effective dose of food. The effective dose can also depending on the amount of inhaled benzene concentration, weight, and length of employment. The higher the concentration of benzene in the body, the greater the mass of food needed detox. This is in
accordance with the formula that has been made in previous studies suggesting that he has a synergistic relationship with the concentration of weight, length of employment, and the concentration of benzene can affect the intake of non-carcinogens in each individual that can influence the effective dose of food. This is consistent with previous research that says that the genetic variance, sex, and weight may play a role in the biotransformation enzymes.

By knowing the foods that can be used to detoxify benzene exposure of the body, in the paint industry Sidoarjo who have a high risk of exposure to benzene can prevent this is through food. In addition, knowing the estimated costs to be incurred in order to prevent exposure to benzene through this food, workers can choose foods that can detoxify benzene in the body with the food that is in line with workers’ earnings in the paint industry Sidoarjo.

Sulphation is one of a number of liver detoxification pathways, particularly the phase II detoxification. Sulphation system is important in detoxification of several drugs, food additives and especially the gut bacteria and toxins from environmental contaminants. Glutathione is an antioxidant and detoxification compound produced a powerful agent in the cytoplasm of every cell of the human body. In broad terms, these studies have found glutathione to protect against oxidative stress, detoxification of chemicals and toxins, improve immune function, and support healthy aging. One of the toxins that can be detoxified is benzene.

The results showed that each individual has different needs detoxification intake. This is because each individual has a different effective dose of food. The effective dose can also depend on the amount of inhaled benzene concentration, weight, and length of employment. The higher the concentration of benzene in the body, the greater the mass of food needed detox. This is in accordance with the formula that has been made in previous studies suggesting that he has a synergistic relationship with the concentration of a substance. Weight, length of employment, and the concentration of benzene can affect the intake of non-carcinogens in each individual that can influence the effective dose of food. This is consistent with previous research that says that the genetic variation, sex.

By knowing which foods can be used to detoxify the body’s exposure to benzene from, shoe workers who have a high risk of exposure to benzene can prevent this is through food. In addition, knowing the estimated costs to be incurred in order to prevent exposure to benzene through this food, workers can choose foods that can detoxify benzene in the body with the food that is in line with workers’ earnings in the paint industry Sidoarjo.

Conclusion

To complete the detoxification benzene required in Phase II enzyme CYP2E1 enzyme necessary, sulfation, and glutathione. CYP2E1-rich foods are beef liver, brain, and salmon; Sulphation rich foods are eggs, chicken sulfation, beef and tuna, and foods rich in glutathione are avocado, asparagus, carrots, tomatoes, oranges, and broccoli. Weight, length of employment, and the concentration of benzene can affect the intake of non-carcinogens in each individual that can influence the effective dose of food. By knowing the estimated costs to be incurred in order to prevent exposure to benzene through this food, workers can choose foods that can detoxify benzene in the body with the food that is in line with workers’ earnings in the Paint Industry Sidoarjo.

Consequences of benzene exposure in workers obtained from the use of benzene which is very much needed and important role in many industrial processes. This can negatively impact the health of workers if efforts to control or reduce the exposure is not done well. Karsinogenen effect is one of the harmful effects resulting from exposure to benzene in the workplace, especially in the paint industry.

Therefore, the average benzene in Sidoarjo paint industry was 3.28 mg/m3, the average effective dose should be consumed by the respondents to the intake of avocado is 0.011 mg/hr, chicken intake of 0.026 mg/day, The intake of citrus 0.033 mg/hr, and carrot intake was 0.063 mg/hr. So that to reduce the impact of exposure to benzene into the body of the workers in the paint industry needed feeding benzene detoxification. Feeding is different in each individual adjusted to the concentration of benzene, weight, and duration of action.

Salivary Zinc level and Taste Detection Thresholds in Hypertensive Patients on Amlodipine and on Losartan (A Comparative Study)

Yosor M. Akram¹, Taghreed F. Zaidan², Zaid M Akram³, Omar A. Abed Alsattar⁴
¹M.Sc.student, ²Professor, Department of Oral Diagnosis, College of Dentistry, University of Baghdad, ³Lecturer, Al-Rafiddain University College, ⁴High Diploma Degree in Periodontics, Al-Ameriya Specialized Center for Dentistry, Baghdad Medical Department /AlKarkh , Ministry of health.

Abstract

High blood pressure (hypertension) is one of greatest risk factors for cardiovascular disease, which is a remarkable cause of morbidity and mortality worldwide. The outcome of hypertension (HTN) and cardiovascular disease (CVD) is influenced by a wide variation of risk factors like use of tobacco; excessive alcohol consumption; unhealthy diet, few physical activity, overweight and obesity; high blood glucose, and abnormal blood lipids. The objectives of this study were to evaluate taste detection thresholds (of four basic tastes) of hypertensive patients on Amlodipine 5 mg and on Losartan 50 mg. And to estimate Zinc level in saliva of those patients and compare it with control subjects. A total of 90 subjects were incorporated in this study they were divided into three groups: 1-Thirty patients on Amlodipine (5mg) 2-Thirty patients on Losartan (50mg) and 3- Thirty healthy control subjects. Unstimulated whole saliva was collected from all subjects including in this study. Volume of 5 ml of each taste gradient solution was offered to the participants. The samples were subjected to biomechanical analysis to estimate zinc level by using the atomic absorption spectrophotometer. The result showed that the taste detection threshold of sucrose and salt were significantly higher in patients on Amlodipine and on Losartan treatment than in control subjects. While the taste detection threshold of sour and bitter showed no significant differences between the study groups. Also there is a alteration in salivary Zinc, Zinc in patients on Amlodipine and on Losartan was significantly lower compared to control group.

Keywords: Taste Detection Thresholds, Hypertensive, Amlodipine, Losartan, Zinc

Introduction

Hypertension is often called a silent killer since frequently there are no clear symptoms. Initial signs of hypertension may be non-specific (headaches, excessive irritability, insomnia, decreased tolerance to exercise, palpitations and flushing of the head, neck and chest) and thus confusing¹. Hypertension has lately been reaffirmed as the major single risk factor contributing to world death rates². Besides, control of hypertension is one of the most cost-effective process to decrease early cardiovascular morbidity and mortality³. The national institute for health and care excellence(NICE) recommended that management of high blood pressure with any of many classes of common medication is cost saving compared with providing of no medication. The aims of management of hypertension is to control arterial pressure, prevent end-organ damage (cardiovascular, cerebrovascular, and renal), and to decrease the chance of premature death⁴.

Classification of drugs may be done by mechanism or site of action (therapeutic british hypertension society, 2014). In each class, there are numerous drugs with variation in structure and pharmacology resulting in alteration in therapeutic and side-effects⁵.

Amlodipine is an oral dihydropyridine calcium channel blocker. Compared to nifedipine and other medications in the dihydropyridine class, amlodipine
has the longest half-life at 30 to 50 hours. The advantage of such a long half-life is the ability to have once-daily dosing. Amlodipine (dihydropyridines) has been described to be an efficient antihypertensive medication related with regression of left ventricular hypertrophy and vascular hypertrophy, the antiatherogenic and the remodeling effects.\(^6\)

Losartan is an angiotensin II receptor antagonist (AIIRA) with antihypertensive action due mainly to selective blockade of (AT1) receptors and as the consequence reduced the effect of angiotensin II in elevation of blood pressure. Losartan use in the management of hypertension and heart failure, especially in patients who develop cough with the use of Angiotensin converting enzyme (ACE) inhibitors, additionally it is used in patients with left ventricular hypertrophy to reduce the risk of stroke, and also used in the management of diabetic nephropathy, and has been tried in management of myocardial infarction.\(^7\) Peak plasma concentrations of losartan are achieved within one hour of oral administration the half-life of Losartan 1.5–2.5 hours.\(^8\)

Taste is an important protective sense, progressed to manage the intake of food and help in the avoidance of poison. Genetic considered as the principal determinants of taste threshold, and taste thresholds do not differ significantly from day to day. This has lead to the idea of “non-tasters” and “supertasters”\(^9\), in which the taste threshold is linked to the haplotype (a combination of alleles for different genes and tend to be inherited together) of specific receptors.\(^10\) Taste disturbances may arise secondary to autoimmune disease, inflammation, imbalance of hormone, nerve-related damage, psychological problems like in anorexia, medication therapy or malignancy; they may also occur as a consequence of natural aging.\(^11\) Zinc is an essential trace element and is found in tissues throughout the body, reaching iron in its relative abundance.\(^12\) The body of human carry about 2g of zinc, approximately 60% of which is found in muscle tissue, 30% in bone and 5% in skin.\(^13\)

**Aims and Objectives**

1- To Evaluate taste detection thresholds (of four basic tastes) of hypertensive patients on Amlodipine (5 mg) and on Losartan (50 mg).

2- To estimate Zinc level in saliva of those patients and compare it with control subjects.

**Materials and Method**

This case control study was conducted in the period from February 2019 to May 2019. After approval from Ministry of Health and College of Dentistry University of Baghdad by the scientific committee. A total of 90 subjects were incorporated in this study, they were divided into three groups: 1- Thirty patients on Amlodipine 5mg. 2- Thirty patients on Losartan 50 mg. 3- thirty healthy control subjects.

**Inclusion criteria:** All patients presented with hypertension and they were under antihypertensive monotherapy for at least 8 months. The antihypertensive medications that used by the patients are: Amlodipine and Losartan.

**Exclusion criteria:** hypertensive patient taking combination of antihypertensive medications, Diabetes mellitus, Renal failure, smoking, patients with history of radiotherapy in the head and neck region, and history of chemotherapeutic treatment in the last 3 months.

Each taste gradient consisted of 15 solution, from 1.5 to 15.5 mmol (in 1 mmol increments) for sucrose, from 1-78 mmol (in 5.5 mmol increments) for sodium chloride, from 48-720 µmol (in 48 µmol increments) for citric acid, and from 89-117 mmol (in 2mmol increments) for urea. \(^14\) Taste solution were Prepared by calculation the amount of taste substance in grams dissolved in deionized water for recommended concentration according to weight (g)= molecular weight(g/mole) x concentration(M) x volume(ml)/1000. \(^15\) The concentrations of solutions used are shown in table (1). The sip and spit method was used, the taste solution were swirled around in the mouth briefly and expectorated into an empty cup. \(^16\)

**Statistical Analysis**

The statistical package for the social sciences (SPSS) was used for data input and analysis. The statistical significance of difference in mean between more than two groups was assessed using the ANOVA model. When statistically significant difference was shown by the use of ANOVA, further exploration of the statistical significance of difference in mean between each two groups was assessed by post-hoc multiple comparison Least Significant Difference (LSD) test.

**Results**

This study showed that the mean and standard deviation of the taste detection threshold of sucrose (sweetness) of patients on Amlodipine was 14.16±2.48 mmol/l, and those on Losartan treatment was 12.76±3.20 mmol/l. For the control subjects was 8.16±2.48 mmol/l. It has been found that the taste detection threshold of sweet showed significant difference (p<0.01) using ANOVA test and was highest among patients on Amlodipine (Table 2). Continuing analysis with (LSD) test showed that the taste detection thresholds of sweetness was significantly higher in patients on Amlodipine and on Losartan treatment than in control
subjects (p<0.00 1) but no significant difference has been found between patients on Losartan and patients on Amlodipine (Table 3).

The mean and standard deviation of the detection threshold of salty taste of patients on Amlodipine patients was 52.90± 12.03 mmol/l , and on Losartan treatment was 55.83± 14.94 mmol/l , while in control subjects was 32.11±21.66 mmol/l. It has been shown that the detection threshold of salt was significantly higher in patients on Amlodipine and Losartan treatment than that in the control subjects (Table 2). Continuing analysis with (LSD) test, showed that the taste detection thresholds of salt in patients on Amlodipine was significantly higher than that of control subjects. And the taste detection thresholds of salt in patients on Losartan was significantly higher than that of control subjects , but no significant differences was found between patients on Amlodipine and patients on Losartan (Table 3).

For the sour taste, the results showed that the mean and standard deviation of the detection threshold for citric acid in Amlodipine patients was 473.43±183.91 μmol/l and of patients on Losartan treatment was 453.23 ±175.59 μmol/l, while in control subjects the detection threshold for citric acid (sourness) was 515.46±192.34 μmol/l (Table 2). Statistical analysis showed no significant differences between the study groups.

For the bitter taste, it has been shown that the mean and standard deviation of urea (bitterness) in patients on Amlodipine patients was 91.75± 21.09 mmol/l, and for Losartan treatment was 85.00 ± 26.32 mmol/l, while for control subjects was 92.20±17.51 mmol/l (Table 2). No significant differences was found between the study groups.

**Discussion**

Hypertension (HTN or HT), also known as high blood pressure, is define as a long-term medical condition in which arterial blood pressure is elevated persistently.

Sweet detection thresholds of sucrose (sweetness) of patients on Amlodipine and those on Losartan treatment were significantly higher than that of control subjects. Salt detection threshold in patients on Amlodipine and on Losartan treatment which were significantly higher than that of control subjects. For the sour detection threshold, it was lower in patients on Amlodipine and Losartan treatments than the control subjects but it did not reach the significant level. For the bitter detection thresholds it showed no significant differences between the study groups. This result was agree with Tsuruoka et al., 2005, who found that Losartan induced taste disturbances and they found that the taste disturbance by the Losartan and Perindopril (ACI-groups) medications at the dosages used was similar in quality and quantity. But disagree with Tsuruoka et al., (2005) who stated that Losartan-induced taste disturbances appear to be larger for “bitterness” and “sourness” than “salt” and “sweetness”. It has been hypothesized that a prominent underlying pharmacological mechanism, may explain taste disorders as a class effect of Angiotensin receptor blocker (ARBs). Taste receptors are seven-transmembrane domain G protein-coupled receptors. Angiotensin II receptors belong to the same type of receptor. The sweet and bitter receptors on taste cells are coupled with G-proteins, where G-protein coupling and uncoupling results in taste on and off, respectively ARBs are secreted into saliva, binding receptors of taste and thereby distorting the tastes of sweet and bitter. Salt and sour tastes may be disrupted by ARBs ion channels plugging or obstructing (salt taste via amiloride-sensitive epithelial Na channels, and sour taste via amiloride-sensitive epithelial Na channels and H+-activated cation channels) found on taste cells. This result was disagree with Kim et al., (2017) who reported that salt-taste thresholds did not significantly differ between the control and hypertension groups.

The result showed that salivary Zinc of patients on Amlodipine and for patients on Losartan treatment were highly significantly decreased than that of control subjects. This result agree with (Korean et al., 2005) who found that Losartan treatment result in Zn depletion, mediated by an increase in urinary Zinc excretion.
This result was also agree with (Ifor, 1989) who found that there is a decrease in the level of salivary Zinc level in hypertensive patient\textsuperscript{22}.

**Conclusions**

Amlodipine and Losartan can affect taste detection thresholds of sweet, salt in such a way that they were detected taste with high concentrations of taste solutions, but sour and bitter taste was not affected. And Zinc in saliva was decreased significantly by treatment with these medication.

**Conflict of Interest** We declare that we have no conflicts of interest.

**Human and Animal Rights** All procedures performed in this study involving human participants were in accordance with the ethical standards of the institutional research committee.

**Informed consent** Informed consent was obtained from all individual patients ,including in this study.

Analysis of Relationship between Work Attitudes and Repetitive Activities with Subjective Complaints on Musculoskeletal Disorder in Circular Loom Division workers PT. Kerta Rajasa Raya Sidoarjo Indonesia

Yuly Eka Saputri¹, Y. Denny Ardyanto W²

¹Department of Occupational Health and Safety, Public Health Faculty, Airlangga, University, 60115, Surabaya, East Java, Indonesia; ²Department of Occupational Health and Safety, Public Health Faculty, Airlangga, University, 60115, Surabaya, East Java, Indonesia

Abstract

The Musculoskeletal System Disorders (MSDs) are one of the most common occupational diseases experienced by workers. This disorder is influenced by several factors, such as repetitive activity factor and unnatural work attitude factor. The purpose of this study was to analyze the strong relationship between work attitude and repetitive activity with subjective complaints of musculoskeletal disorder in the circular loom division of PT. Kerta Rajasa Raya Sidoarjo, Indonesia.

This study used observational techniques with cross-sectional design. Respondents in this study were workers in the circular loom division of PT. Kerta Rajasa Raya, Sidoarjo, that consisted of 14 people based on the researchers’ inclusion criteria. The data were obtained from the results of questionnaires and field observations. Work attitude data were analyzed using OWAS; MSDs subjective complaint data were investigated using NBM checklist sheets; and repetitive activity data were analyzed based on the results of questionnaires, interviews, and observations.

The results showed that the majority of respondents have subjective complaints of musculoskeletal disorder with high severity. The work attitude variable has a very strong correlation with subjective complaints of MSDs, and repetitive activity variable has a strong correlation with subjective complaints of MSDs.

The company are advised to provide training related to safe lifting method, provide information related to MSDs in the form of posters or providing specific material. Companies are also advised to add the expedition personnel to reduce the repetition of lifting activities.

Keywords: Subjective complaints of MSDs, Work Attitudes, and Repetitive Activities

Introduction

The Musculoskeletal System Disorders are one of the most common occupational diseases experienced by workers. According to Tarwaka, Musculoskeletal disorder is a complaint in the part of the skeletal muscle that is felt by a person ranging from very mild to very painful complaints(¹). MSDs are the biggest cause of absence in almost all parts of Europe(²). According to the Labor Force Survey (LFS), the prevalence of musculoskeletal cases (MSDs) in the year 2016/2017 amounted to 507,000(³).

NIOSH worker health chartbook of musculoskeletal cases (MSDs) shows that manufacturing industry ranks second after the service industry(⁴). The manufacturing industry is an industry that converts raw materials into a
product. In the manufacturing industry, there are many manual handling activities that can cause the emergence of MSDs subjective complaints. Evadarianto found that the majority of manual handling workers as much as 73.34% in the rolling mill section experienced MSDs complaints\(^5\). Peter Vi in Tarwaka explained that the emergence of MSDs subjective complaints are influenced by several factors such as excessive muscle stretching, repetitive activity, unnatural work attitudes; secondary factors, the combination causes and individual factors\(^1\).

PT. Kerta Rajasa Raya Sidoarjo, Indonesia, is one of the manufacturing industries concerned in producing packaging that still has a lot of manual handling activities such as lifting, pushing, moving, or pulling heavy loads. One division with the most lifting activities is the circular loom division. Workers of the circular loom division regularly lift as much as 40-160 baskets per day. The weight of each basket is 17 kg. In addition, the work attitudes in lifting activities are often unnatural.

Based on the explanation, it means that workers who carry out manual handling activities have the potential to experience MSDs subjective complaints. Therefore the researcher is interested in conducting research related to the analysis of the strong relationship between work attitudes and repetitive activities with subjective complaints of musculoskeletal disorder in the circular loom division workers of PT. Kerta Rajasa Raya Sidoarjo, Indonesia.

The purpose of this study is to analyze the strong relationship between work attitude and repetitive activity with subjective complaints of musculoskeletal disorder in circular loom division workers of PT. Kerta Rajasa Raya Sidoarjo, Indonesia.

**Material and Method**

The type of research was observational with a cross-sectional approach. The study population is 14 workers, with the inclusion criteria of workers aged \( \geq 35 \) years, doing manual handling activities, and do not have a medical history of back pain, pain in the waist, sprains, and HNP (Hernia Nucleus Pulposus). The sample in this study is the total population.

Research variables are work attitudes, repetitive activities and subjective complaints of MSDs. The instruments used in the study are questionnaires, OWAS observation sheet (Ovako Working-Postur Analysis System), and NBM (Nordic Body Map) checklist sheets.

Analysis of the data used in this study is an analysis of the contingency coefficient for nominal scale data and correlation analysis of Spearman’s rho’s for ordinal scale data. The relationship between the dependent and independent variables will be classified according to Sarwono (2006)\(^6\):

<table>
<thead>
<tr>
<th>Contingency Value</th>
<th>Level of Relationship</th>
</tr>
</thead>
<tbody>
<tr>
<td>(0)</td>
<td>There Is No Correlation Between The Two Variables</td>
</tr>
<tr>
<td>(&gt;0,00 ) – (0,25)</td>
<td>Very Weak Correlation</td>
</tr>
<tr>
<td>(&gt;0,26 ) – (0,50)</td>
<td>Medium Correlation</td>
</tr>
<tr>
<td>(&gt;0,51 ) – (0,75)</td>
<td>Strong Correlation</td>
</tr>
<tr>
<td>(&gt;0,75 ) – (0,99)</td>
<td>Very Strong Correlation</td>
</tr>
<tr>
<td>(1)</td>
<td>Perfect Correlation</td>
</tr>
</tbody>
</table>

**Findings**

The circular loom division has three job sections, namely the expedition section which lifts a basket weighing 17 kg as much as 100-160 times, then the operator section of the circular loom that must lift and move the basket weighing 17 kg which is done 30-50 times in a working day, and the maintenance section of the equipment that is responsible for checking and repairing the machine.

**Table 2. Distribution of Frequency of**

<table>
<thead>
<tr>
<th>Severity of MSDs Subjective Complaints to Workers in the Circular Loom Division of PT Kerta Rajasa Raya Sidoarjo in 2019</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSDs Complaints</td>
</tr>
<tr>
<td>-----------------</td>
</tr>
<tr>
<td>Medium</td>
</tr>
<tr>
<td>High</td>
</tr>
<tr>
<td>Total</td>
</tr>
</tbody>
</table>

The data above shows that all respondents experienced MSDs subjective complaints. As many as 57.1% experienced musculoskeletal subjective complaints with a high category and 42.9% of...
respondents in the medium category.

Table 3. Frequency Distribution of Risk level of work attitude and repetitive activity in Workers of the Circular Loom Division of PT Kerta Rajasa Raya Sidoarjo in 2019

<table>
<thead>
<tr>
<th>Variable</th>
<th>Category</th>
<th>n</th>
<th>(%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>work attitude</td>

<td>6</td>
<td>42.9</td>
</tr>
<tr>
<td></td>
<td>40 - &lt;200</td>
<td>8</td>
<td>57.1</td>
</tr>
</tbody>
</table>

Based on table 3, it was found that 50.0% of workers in the circular loom division had a very high-risk work attitude. The most repetitive activities carried out are 40 - ≤ 200 times every working day or 8 hours with a percentage of 57.1%.

The results of the analysis carried out between work attitude variables with MSDs subjective complaints give the Spearman Correlation value of 0.876. So, it can be concluded that there is a very strong correlation between work attitudes and subjective complaints of MSDs. The relationship direction is positive, which means that the relationship goes in the same direction or the higher the risk level of the workers’ attitude in doing their work, the higher the severity of subjective complaints of MSDs.

On analysis of repetitive activity variables, the closeness value of the relationship is 0.708 which is between the numbers 0.51-0.75. Thus, it can be interpreted that the relationship that occurs is strong. These values also provide information that the relationship between the variables of repetitive activity with subjective complaints of MSDs run in line for positive values. So that, the more repetitive lifting activities performed by workers in a day, then the severity of MSDs subjective complaints will also be higher.

Discussion

Musculoskeletal Disorders (MSDs) are a type of pain complaint that is felt in the skeletal muscle system. The pain is usually emerged in the joints, ligaments, or tendons. Complaints in the musculoskeletal system are usually in the form of chronic complaints that are often felt sometime after the worker does his activities and often leaves traces or residues that continue to be felt the next day. MSDs can be caused or aggravated by various risk factors in the workplace such as work attitudes, repetitive activity, vibration, and temperature (1).

Based on the results of research conducted at the circular loom division of PT. Kerta Rajasa Raya Sidoarjo, it was found that the majority of respondents experienced MSDs subjective complaints in the high category. All workers who experienced MSDs subjective complaints were operator workers and expedition workers who both carried out manual handling activities in the form of lifting baskets containing plastic thread rolls. The results of interviews conducted further found that the complaints felt by workers were spread almost throughout the body parts of workers. The location of complaints on the body felt by all workers respondents is the left and right shoulder, left and right upper arm, left and right forearm, and both legs.

Based on the results of the research and data processing of attitude variables with the OWAS method, it is known that all expedition workers have very high category of work attitudes whereas for the operator section 3 people have a medium risk, 4 people have a high risk, and 4 people have a very high risk. This is because the work of lifting in the expedition section is carried out with the body bent and twisted aside forming flexion. Moreover, the position of the hand when taking the basket is above shoulder height with a weight of 17 kg. So that, the value obtained by all expeditions is 4 (very high). This is different from the 3 operator workers who have a medium work attitude, even though the burden to be lifted is the same yet the lifting method is different. As many as 3 operators who have medium category of work attitudes are carrying out lifting activities without twisting their bodies so that for the back side get to point 2. Besides, the position of the two arms of the operator is also below the shoulder height so that his working attitude is in the medium category.

The results of the analysis get a very strong relationship between work attitude variables and MSDs subjective complaints experienced by workers. Therefore, the higher the risk of work attitude, MSDs subjective complaints will also increase. The results of interviews and observations were made found that all workers did not know about MSDs and workattitudes
matters. This was due to the education of workers who were mostly only up to high school. In addition, workers had never received information regarding good and correct work attitudes when doing work from the company. This research is in line with the research conducted by Purwosusilo (2015) which states that there is a significant relationship between work attitudes and subjective complaints of MSDs in traditional sand miners in Srumbug district, Magelang regency.(7).

Repetitive activity or repetitive movement is an activity carried out continuously(1). In the circular loom division of PT. Kerta Rajasa Raya Sidoarjo, the effect of repetitive activity is extremely felt in the expedition section. This is due to the expedition workers who are on average lifting 100-160 baskets daily. Expedition workers complain of pain in the shoulder, upper arm, forearm, calf, leg, and waist. The expedition section also did a basket arrangement on pallet truck as 5 tall stacks with a twisting body position that caused complaints on the workers’ waist.

Muscles complaints can occur when the muscles receiving pressure due to lifting the load continuously without obtaining sufficient relaxation time(1). This theory is in line with the results of research which state that there is a strong correlation between repetitive activity variables and MSDs subjective complaints. hence, the higher number of repetitions carried out, the subjective complaints MSDs will also increase. This study is not in line with the research conducted by Purwosusilo (2015) in traditional sand miners in Srumbug district, Magelang regency, which states that there is no relationship between the frequency of swinging with complaints on upper limbs; or in other words, there is no relationship between repetitive activity and musculoskeletal disorders.(7)

Conclusion

Based on the explanation above, it can be concluded that:

1. The majority of respondents have subjective complaints of musculoskeletal disorder with high severity.

2. There is a very strong relationship between work attitude variables with subjective complaints of musculoskeletal disorder.

3. There is a strong relationship between repetitive activity variables with subjective complaints of musculoskeletal disorder.

Recommendation

1. The company is advised to provide training regarding how to lift in the right position or attitude to reduce the risk of unnatural work attitudes.

2. The company is advised to provide information in the form of posters or work instruction procedures as a workers reminder related to the dangers of MSDs and safe lifting method to reduce the level of MSDs subjective complaints and risk of unnatural work attitude.

3. The company is advised to increase the number of expedition personnel by assisting operator section to reduce repetitive movements by expedition workers.

Conflict of Interest: All authors have no conflicts of interest to declare.

Application of Infection Control Rules by Iraqi Orthodontists

Rehab adil Al-Rawi1 Noor Nourie Abbass Abdulla1, Fudhla Sadoon Al-Zubaydi2, Bassam Alsheekhly1
1College of Dentistry/ Al –Iraqia University/ Iraq, 2Baghdad University\ Health Center

Abstract
Orthodontics represent an important dental speciality which deals different situations of patients malocclusion, they use many kinds of sharps and cutting instruments, making them liable to different types of infections which could be transmitted from either the patients or the instruments if they don’t follow the infection control principles. The data were collected by answering a questionnaire by 101 orthodontists, the results showed different responses of the participants to the variables used by the questionnaire leading to a conclusion that more efforts are needed to improve the application of infection control guidelines between Iraqi orthodontists.

Keywords: orthodontics, infection control, health, patients; infection.

Introduction
Orthodontists facing various types of microorganisms during practicing dentistry by contaminated instruments, inhalation of aerosols or through percutaneous injuries with different wires such as ligature or arch wires also banding and bonding materials and other sharp instruments(1).

Studies found that Orthodontists have the second highest occurrence among dental workers concerning hepatitis—B infections (2). People receiving treatment in dental clinic could be undetected hepatitis-B carriers and patients secreting herpes simplex viruses in saliva may be asymptomatic, those patients have the potential for transmitting diseases. Diseases such as hepatitis-B, HIV and tuberculosis have long incubation period and therefore, it is very difficult to detect the origin of such infections to the dental workers and other patients (3).

Before beginning with work the orthodontist should be clear about his or her goals in infection control criteria and it is mandatory to apply the most progressed method of disinfection and sterilization to get good results(4).

Sterilization kills all types of microorganisms including viruses, bacterial and mycotic spores.

Disinfection is the technique used for destruction or inhabition of the most pathogenic microorganisms and inactivating some viruses, therefore, reduction of microbial contamination to a safety level(5).

Hepatitis B virus can be spreaded by as little as 0.0004 ml blood while HIV by 0.1 ml blood(6). 1 ml of gingival crevicular fluid contains 150 billion microorganisms and 6 billion microorganisms can be found in 1 ml of saliva(7).

Many studies in literature reveals that emphasize on the effect of sterilization in orthodontics practice however there is no comprehensive research that evaluate the compliance of Iraqi orthodontist to infection control procedures.

Aim of the Study
In this study we will evaluate sterilization and disinfection methods employed in orthodontic practice in Iraq.

Material and Method
In the present study, data collection gained by an 17 items questionnaire was delivered to a total of 101 Iraqi orthodontists / general practitioners(GP) (who attended intensive orthodontic course), these question covered some infection control guide line(8).

Statistical analysis was performed by using SPSS version which includes descriptive statistic (frequency
and percent chi square test was used to find association between related variables, \( P>0.05 \) was considered significant.

The questionnaire deals with the following variables:
- Educational degree
- Place of work.
- Daily patient volume
- The way in performance of instruments cleaning
- Sterilization devices used
- Soaking instruments in disinfectant solution.
- Packaging method of instruments to be sterilized.
- Method used to sterile hand piece, hand instruments and orthodontic pliers.
- Does the practitioner sterilize molar bands after purchase?
- Sterilization of molar bands after trail inside patient mouth.
- Disposal of brackets, bands and arch wires removed from the patients
- Recycling brackets or other orthodontic materials.
- Disinfectios of the impressions and orthodontic appliances delivered to the lab.
- Place of sharp objects disposal container.
- Type of gloves used during cleaning instruments, and environmental cleaning.
- Hepatitis B vaccination

### Result

The result of this study shown in the frequency table explained as the following: table 1 describes the percent of GP and specialist who are alligated to the questioner, (22.8\% and 77.2\%)for GP & specialist respectivlly.

Table 2 showed that (45.5\%, 38\% and 15.8 \%) of the total participate work in private clinic, hospital and at university clinic, those participate have daily patients volume explained in table 3.

Table 4 show (57.4\%) of orthodontist who use manual cleaning significantly higher than ultrasonic cleaner (42.6 \%), while highly significant (87\%) with autoclave rather than oven and glass bead sterilizer, also highly significant regarding presoaked instrument and wrapping the instrument, while sterilization of dental hand piece in autoclave (41.6\%) was significantly lower than wiping the outer surfaces with (57.4\%).

Table 5 show highly significant rate of sterilize pliers (80.2\%) than dry heat, while non-significant sterilize band after purchase in comper with highly significant (67.3\%) for band after trial in patient’s mouth. The disposing of band, bracket and arch wire was highly significant with (49.5\%) regarding waste basket.

Table 6 show high rate of significantly for orthodontist who don’t recycled bracket while non-significant difference between orthodontist who disinfect impression or appliances. The rate for placing sharp bins at clinic was significant (74.3\%) and (21.8\%) for placing sharp bins in sterilization room. Highly significant rate for orthodontists who use examination gloves during cleaning of the instrument, and how recive hepatitis B vaccine.

### Discussion

Spaulding system classifies instrument into three categories which are critical, semicritical and least critical\(^{(9)}\), the semicritical considered the most important one that should be highlighted in order to prevent disease transmission \(^{(10)}\). Orthodontic instruments, orthodontic supplies and accessories considered as the semicritical since they touch mucous membrane and non-intact skin \(^{(11,12)}\).

This study mainly depended on experience, place of work as well as, daily patient capacity of the GP and orthodontist. The sterilization process is important to orthodontists as well as, dentists, even though they do not perform surgical procedures \(^{(13-14)}\).

On the other hand Starnbach & Akçam \(^{(15-16)}\) indicate, sterilization is less abidance to orthodontists than dentists since they usually deal with children, with loss of time, money and the corrosion of orthodontic instruments in addition they did not deal substitute the word (with) by ( may lead to) deep tissues.\(^{(8)}\)

Professional agencies like Center of Disease Control (CDC) and Occupational Safety and Health Administration (OSHA), have a specific recommendations representing standard infection control which considered as keywords to be followed in order to prevent cross infection \(^{(17)}\).

Despite of these rules, this study showed that \((57.4\%)\) of participate orthodontists depends on the manual cleaning procedure more significantly than the ultra-sonic devises. This may be due to the lack of knowledge about advantage of ultra-sonic devises in the granting the proper removing of debris from the orthodontic instrument \(^{(18-19)}\), the manual cleaning is also an important step in ensuring the debris removal after mechanical cleaning and before autoclaving \(^{(20)}\).

In this study \((85.1\%)\) of participated presoaked the instrument in disinfected solution before starting the sterilization process. This prevents the dryness and adherence of bioburden to instruments that protect microorganism from sterilization \(^{(21)}\).

In addition to that it begins to dissolve organic debris and in some instances begin microbial kill. This solution should discard at least once a day \(^{(17)}\).

This study showed high percentage of participates who used autoclave whether used for orthodontic pliers, band purches and molar bands after trying in patient mouth \(^{(22)}\). This concurred with the significant findings of participates who pouch their instruments.
This could be explained by the high education level and interest in sterilization of orthodontists and according to recommendations of Iraqi Dental Association (IDA).

Although most of orthodontist (87%) using autoclave but the result showed that high percentage of them only wipes the hand piece which is not recommended as the hand piece represents a hallow instrument that may contain blood drops contamination inside the internal lumen and this can be only sterilize by using autoclave class B (23, 24-25-26). This could be the result of old believes that heat could ruin the hand piece leading to a financial lost.

As a matter of fact the hand piece sterilization is obligatory according to the CDC guidelines. This can be achieved either by providing clinics with an enough number of hand piece in order to match the number of patients who daily visit the clinics, or by applying advanced sterilization programs (27). Since hand pieces are available in the Iraqi market with an affordable cost.

Bracket, wire and bands represents a dangerous source since they are removed from oral cavity in which they had been contaminated with body fluid (saliva and blood) also wire’s end considered as a sharp end that may prick the orthodontist, so the sharp pin represent the better choice for disposing (28,29).

This study showed that (74.3%) of participant have sharp bin in their clinics, despite of the importance value of having it in the clinics, only (26.7%) who are really using it while (49.5%) of the participant use waste basket. This approved a week point in disposal.

This study showed a highly significant percentage (90.1%) of the participant who do not use recycle brackets and orthodontic materials since the process of recycling altars the mechanical and physical properties also it is nor granted that they are not contaminated(30,31) also, the brackets and orthodontic materials are available in the Iraqi market with a reasonable cost.

In this study, a non-significant value (50.5% -47.5%) have been shown between the participates who disinfected their impression or appliances to be delivered to an outer laboratory. Standers showed that all impression and model must be disinfected before delivering to the laboratory and vice versa (32). Now a day, this complicated issue has been solved by introducing the digital scan in the dental filed (33).

Kitchen gloves considered as a heavy duty gloves that protect the operator from accidental puncher by sharp dental tools and cross infection (17). Unfortunately, this study showed a high rating of (96%) who use examination gloves which considered a thinner and easy tearing gloves as compared to the kitchen gloves (8).

Dentists and assistances are always mandatory to be vaccinated against hepatitis B virus (34), this coincide with the result of this study which revealed the highly significant rating (82.2%) who had been vaccinated.

Conclusion

The result of this study reveals good behaviours by Iraqi orthodontist for most of infection control steps although some behaviors need to be improved following world wide infection control guide lines.

Mast cell, IL-1 Beta and IL-6 for Wound timing and Vitality in Forensic Practice

Mohammad Abdul Mohsin Jebur, Nabeel Ghazi Hashim, Salim R. Hamoudi Al-Obeidi

Abstract

the application of immunohistochemistry has opened a new era for examining the age of the wound by forensic specialists, The aim of our study was to illustrate the use of immunohistochemical marker of mast cells activation (mast cell tryptase “MCT”) as a reliable and promising factor of wounds vitality and to Identify the role of pro-inflammatory cytokines: IL 1 beta and IL 6 as parameters of wound age determination. The study was done in the Medico-Legal Directorate of Forensic Medicine (MLD) in Baghdad. The specimens were sera and skin tissues for immunohistochemistry examination, and staining procedures and immunohistochemistry (MCT) ELISA sandwich plate will measure the levels of interleukins. Total autopsy cases were 88 and divided into study group (SG) and control group (CG). We found that density of Mast cells in sample group was significantly high and higher infiltration that correlates with time passing in the study group as compared by other group in dermis of the sample and control lesions and positive relationship between levels of IL 1-beta & IL-6 level and time progress of wound..

Key words: forensic, pathology, wound, vitality, IL 1 beta, IL-6 level, Mast cells

Introduction

During the inflammatory phase, a variety of chemicals are released at the affected site, leading to the recruitment of inflammatory cells, such as neutrophils and plaques Forensic scientists, unlike general pathologists, tend to focus on chronic mapping of the appearance and disappearance of inflammatory cells or substances produced during the inflammatory process[1]. These phenomena - for example, the proportion of positive cells, the level of tissue fibrosis, the distance between inflammatory cells and the free vessels that affected by the degree of injury, which affect the accuracy of the determination of the age of the wound. It is therefore necessary to establish models with varying degrees of injury and to evaluate the parameters involved in wound healing to determine the time of injury[2].

Thus, MCs have been involved in causing many chronic allergic / inflammatory disorders, autoimmune diseases, and cancers. The contributions of MCs in these conditions are the subject of continuous assessment[3]. Acute direct events, the allergic process involves subsequent stages characterized by leukocytes infiltration and initiation of an acquired immune response, followed by a chronic phase involving persistent inflammation, tissue reformation and fibrosis. Thus, the role of MCs at these different stages has gained increasing importance. The dissociation of MCs, in addition to their well-established and widely studied role in IgE-mediated interactions, has been the focus of MCs research in the past decades. However, the determination of the functions of MCs may progress slowly due to difficulties in accessing these cells in vivo and the obstacles encountered when obtained through enzymatic dispersion of tissues or by culture of predators of MCs isolated from the bone marrow or cord or peripheral blood. The culture of predators of mast cells produces a small number of MCs that are often expensive and time-consuming and lead to the emergence of changing phenotypes due to cultural conditions[4].

Several studies reported high levels of IL-1β production by nuclear monocyte, platelet and nuclei cells from active colon lesions in IBD (inflammatory bowel disease) patients. Since IL-1RA levels are only moderately controlled in the colon in patients with IBD, the IL-1RA ratio to IL-1β decreases significantly,
enhancing intestinal inflammation\textsuperscript{[5]}. IL-1\(\beta\) is initially produced as zymogen, but pro-IL-1\(\beta\) does not contain any known functional properties. IL-1\(\beta\) copies are tightly regulated, stimulated by stimulation by TIR or IL-1R stimulation (the first signal required to produce IL-1\(\beta\)). As previously described, IL-1\(\beta\) precursors are bisection in its active form by caspase-1, after inflammatory activation with the NLR (NOD like receptor: NOD for nucleotide-binding domain, Lucien rich repeat containing receptors) pathway (signal 2) \textsuperscript{[6]}. The secretion mechanisms of IL-1\(\beta\) and IL-18 in extracellular space are unclear, but proposed pathways include exocytosis of secretory lysosomes, shedding of membrane micro-vesicles or exosomes, or transfer by membrane vectors, such as ASC (alanine serine cysteine amino-acids transport system) transporters\textsuperscript{[7]}.

IL-1\(\beta\) practices a wide range of systemic and local effects. Once in circulation, IL-1\(\beta\) can promote the synthesis of ring-2 oxidation enzymes (COX2) in the vascular network, which stimulates the production of prostaglandin E2 in the brain and fever-mediated. IL-1\(\beta\) also promotes the synthesis of acute phase proteins by liver cells, derives differentiation of macrophages, differentiation of neutrophils and mobilization in bone marrow. Furthermore, IL-1\(\beta\) promotes the recruitment of immune cells to inflammatory sites, by stimulating the expression of adhesion molecules and chemical attractors via endothelial cells\textsuperscript{[8]}.

On the other hand, given the IL-6 behavior of restoring the host to the parity state, it is clear that IL-6 acts to control the response of tissue inflammation. In chronic diseases, which are usually manifested by immune stress factors such as intracellular infection and chronic tumors, IL-6 acts not only as a catalyst for acute phase reactions but also as an important player in cellular immune responses to infected cells and mucosal- The inflammatory reaction is acute, resulting in the destruction of a harmful agent within a short period of time and in a localized area, stimulating an immune response.[8]

IL-6 not only stimulates acute phase reactions but also develops cellular immune responses, including end-stage B cell differentiation, immune globulin secretion and T-cell activation. The main key from acute inflammation to chronic inflammation is the recruitment of monsters to the inflammation area. IL-6 is important for the transition between acute and chronic inflammation. IL-6 plays a somewhat unexpected role in recruiting white cells in vivo. The IL-6 and sIL-6Ra compounds can activate endothelial cells to secrete IL-8 protein and MCP -1, and urge the expression of adhesion molecules\textsuperscript{[9]}.

The aim of the study is to illustrate the use of immunohistochemical marker of mast cells activation (mast cell tryptase “MCT”) as a reliable and promising factor of wounds vitality and to identify the role of pro-inflammatory cytokines: IL 1 beta and IL 6 as parameters of wound age determination.

**Methodology**

The study was done in the Medico-Legal Directorate of Forensic Medicine (MLD) in Baghdad. Lacerated skin wounds with a known timing since injury less than 12 hours, regarding time of autopsy all cases were underwent autopsy as soon as possible within a maximum time of 3 hours since arrival to mortality. Only frank lacerated non-contaminated skin wounds were taken in account and the autopsy was done immediately on arrival to MLD. Total autopsy cases were 88 and divided into study group (SG) and control group (CG) [stab-wounds injuries with immediate death]. The specimens are sera and skin tissues for MCT immunohistochemistry.

ELISA sandwich plate will measure the levels of interleukins and specimens for histopathology will be taken from the periphery of wounds for SG and an intact healthy skin from same cadaver (internal control) and some tissue specimens from deaths due immediate death by bullet injury as (external control), stored in 10% formalin for staining procedures and immunohistochemistry (MCT) and the results was analyzed statistically.

Strict exclusion criteria for cases of study include mixed wounds, wounds with unknown timing since injury, contaminated lacerated wounds, wounds with expected timing less than 12 hours, firearm deaths, cases with a known documented history of chronic illnesses, age less than 15 and more than 35 years, pregnant, decomposed cadavers (delayed autopsy), major medical interventions like surgery.

The Quantikine® Human IL-1\(\beta\)/IL-1F2 Immunoassay is a 3.5-4.5 hour solid phase ELISA designed to measure human IL-1\(\beta\) in cell culture supernates, serum, and plasma. The Quantikine® Human IL-6 Immunoassay is a 4.5 hour solid phase. Both contain E. coli-expressed recombinant human IL-1\(\beta\) and IL 6...
and antibodies raised against the recombinant factors.

TB staining was used for presence of “Mast cells” and MCT immunohistochemistry by Elabsceince® is the preferable way for detecting mast cells activation.

Results

The number of wounds in the study sample was determined; most of the bodies had three wounds, 44% of the total study, where 6% of the cases had only one wound. The study group of 156 laceration skin wounds was classified into compression laceration (50%), grinding laceration (20.5%), cut laceration (6.5%), tearing (15.3%) and crush injuries (7.7%).

Mast cells by toluidine blue stain

Mast cells are found in connective tissue and the cytoplasm contains (heterogeneous) granules consisting of heparin and histamine. Toluidine blue stains mast cells with red-purple color (metachromatic staining) and blue background (orthochromatic staining). Metachromasia and tissue color staining elements differ according to the features of the dye solution due to the pH, dye concentration and temperature of the underlying dye. Blue or purple dyes will show a red shift while red dyes will show a yellow shift with contrasting tissue elements.

Depending on the number of mast cells stained by toluidine blue, three classes of were estimated, from 2 to 5 cells on 10 HPF the number of mast cells stained was regarded normal finding, from 6-8 cells on 10 HPF (+1) and from 9-10 cells on 10 HPF and (+2) and > 10 cells on 10 HPF (+3) The specimens included in the study did not have any histologic abnormality. Using light microscopy, all the mast cells (MC) in the specimens (however fixed) had meta-chromatically stained purple with toluidine blue. The nuclei of all the cells were round or oval. MC were scattered in the dermis, especially along the blood vessels and in the peri-glandular stroma. In the dermis of the Sample and control lesions, Mast cell density in the Sample group was significantly higher (P<0.001) when compared with the other group.

Table 1: Distribution of mast cells

Immunohistochemistry (Mast cells tryptase) for both samples and control

Immunohistochemistry of Mast Cell Tryptase results were recognized and classified into 4 classes according to the mast cells in both control and samples through the period of 6 hours after injury. Tryptase immune reactivity was detected in all of the cells stained by fluorescent avidin fixed either with Bouin or Carnoy’s fluid. Some MC, in the dermis of all the examined groups, was immune stained for chymase upon fixation with Carnoy’s fluid.

Table 2 correlation between test group and control group number of mast cells

ELISA levels of IL-1 beta and IL-6 in the human model

IL-1 beta standard of the kit measures at 3.9 pg/ml and minimum detectable dose (MDD) of human IL-1 beta is less than 1 pg/ml. The levels of IL-1 beta in the human model shows a significant decrease in relation to the time of the test (1 to 6 hours AMI), as showed in table 2 that the levels of IL-1 beta in the human model samples shows a maximum mean difference of 40.727 at 1 hour of AMI while the control group mean difference was 284.584. The mean difference decreased by the increasing of time after AMI to reach 3.49 after six hours. The study results suggested a reverse relationship between AMI time and the levels of IL-1 beta in the human model.

Table 3: The levels of IL-1 beta in the human model

H1, after one hour AMI H4, after four hours AMI
H2, after two hours AMI H5, after five hours AMI
H3, after three hours AMI H6, after six hours AMI

IL-6:

IL-6 standard of the kit measures at 3.13 pg/ml and the MDD of human IL-6 is typically less than 0.70 pg/ml. The IL-6 levels show increase with the time of AMI progress. The control samples show mean difference of .57436. The sample group shows maximum mean difference of IL-6 level of 353 at five hours of AMI.

H1, after one hour AMI  H4, after four hours AMI  c, control

H2, after two hours AMI  H5, after five hours AMI

H3, after three hours AMI  H6, after six hours AMI

Discussion

In this study we found that density of Mast cells in sample group was significantly high (P<0.001) as compared by other group in dermis of the sample and control lesions. This result goes with the results found by Bonilli et al. [10] in the contrary to[11] who noted no significantly different mast cells’ number of in normal cutaneous tissue & those in wounds of the sampling which could be explained partly by different techniques & morph-metrical methodology.

In this study we found higher infiltration with mast cells that correlates with time passing in the study group which agrees with the results found by [10] who utilized anti-trypase & chymase antibodies or avidin to assess density of mast cells in skin wounds through immunofluoresences And found that the MC number in the dermis showed progressive increase within little hours after injury (top at 1 to 3 hours) Matching results was found by [12] who noted a powerful extra-expression of trypase located in interstitium.

Levels of IL-1 beta in the human model samples show a maximum mean difference of 40.727 at 1 hour of AMI while in control group, the mean difference was 284.584. The mean difference decreased by the increasing of time after AMI to reach 3.49 after six hours .The study results suggested a reverse relationship between AMI time and the levels of IL-1 beta in the human model. This results matches with [13] who found IL-1β, expressed in normal human skin modified in a significant way in vital injuries in epidermal strata, sub-epidermal cellular, vascular and glandular (sweat) and had promoted expression after fifteen and twenty minutes at early increase of reactivity of the epidermis & following thirty to sixty minutes, marked expression was noted, remained many hours & later decreased to a base level again. He commented that it can help as a beneficial method to estimate vitality and aging of wounds, especially during early post-traumatic period before the leukocytic reactions. On another hand this is against what was found by [14] who stated that no wound groups showed a high increase in IL-1β level in comparison to control group. The difference was not significant from statistical view.

In our study the IL-6 levels shows increase with the time of AMI progress which matches with what was found by [15] and the same results was obtained by [16]
Conclusion

Mast cells by toluidine blue stain density in the sample group was significantly higher when compared with the other group in the dermis of the sample and control lesions. The same was shown by Immunohistochemistry (Mast cells tryptase) as there were higher infiltration with mast cells that correlates with time passing in the study group. Regarding ELISA levels of IL-1 beta and IL-6 in the human model the study found a reverse relationship between AMI time and the levels of IL-1 beta in the human model while the IL-6 levels shows increase with the time of AMI progress.

Association between Genetic Polymorphism of 5-HTTLPR, and SGOT, SGPT and Catalase with Alcoholism of Iraqi People

Anwar A. Abdulla
Department of Biology, College of Sciences, University of Babylon, Iraq

Abstract

A case-control study on the relationship of 5-HTTLPR gene polymorphism with alcohol abuse among Iraqi individuals was conducted during period from December 2018 to June 2019. DNA was extracted from the blood samples of the study subjects. The genetic polymorphism analysis was conducted by Restriction Fragment Length Polymorphism (RFLP-PCR) for SLC6A4 gene. The results raveled that the odd ratio for the LL genotype was 1.697 indicating that homo mutant genotype were at higher risk for alcoholism than the wild type SS. This result showed that L allele frequency was (0.78) in alcoholism group and (0.53) in control group whereas S allele frequency was (0.22) in the alcoholism group and (0.47) in the control group. So, the results showed there was a significant difference in allele frequencies of SLC6A4 gene between case and control (P<0.01; OR=1.697; 95% CI=0.86-1.64). There was a significant positive correlation between the SGOT activity and the genotype of 5-HTTLPR (SS, SL, LL). Additionally, there was a significantly increased level of liver enzymes (GOT and GPT) and catalase in serum samples of alcoholic males compared with non-alcoholic males.

Key Words: SLC6A4, 5-HTTLPR, SGOT, SGPT, catalase.

Introduction

Alcohol dependence and alcohol abuse are chronic disorders comprising a wide range of clinical symptoms. Given that drinking behaviors are jointly determined by genetic and environmental risk factors, alcohol consumption and alcohol use disorders are appropriate phenotypes for investigating gene-environment interactions (1). Alcohol consumption is a common, complex trait, and heavy alcohol use increases the risk of alcohol use disorders, and is recognized as, a problematic global problem threatening both individual development, family life and social life of a person (2). There is an evidence of a causal relationship between alcohol and at least 200 diseases including gastritis, pancreatitis, cardiovascular disease, liver cirrhosis, hepato cellular carcinoma, and gastric cancer (3). Ethanol is not stored in the body after ingestion because it is fully ingested oxidized during metabolism in the liver (4). The rate of ethanol metabolism determines the concentration of ethanol and its metabolite acetaldehyde in the different tissues, which in turn influences the effects of ethanol consumption on liver and the other organs. Serotonin is a signaling molecule with a widespread effect in the CNS, and has a very important role in different aspects of mammalian life, like food intake, emotion, mood, respiration, pain sensitivity, cardiovascular regulation, sexual behavior, learning and memory, circadian rhythm, sensorimotor activity, and cognition (5).

The human serotonin transporter (SETR) is a monoamine transporter protein, encoded by a single gene (SLC6A4, solute carrier family 6, member 4) located on the long arm of chromosome 17 (17q11.2). The serotonin transporter (5-HTT) is an important protein responsible for the active transport of serotonin into neurons, enterochromaffin cells and platelets (6). Twin studies have shown alcohol dependence (AD) to have a heritability of ~50–60% (7, 8). Among the genetic components, many of the genes that may contribute to the risk of alcohol phenotypes encode components of the dopamine, serotonin (5-HT), and acetylcholine neurotransmitter systems.
Material and Method

Study Subjects

A case-control study on the relationship of 5-HTTLPR polymorphism with alcohol abuse among Iraqi individuals was conducted during period from December 2018 to June 2019. Fifty blood samples of alcoholic male Iraqi people (with a history of alcohol abuse for more than seven years) were collected from the Institute of forensic medicine, Al-Yarmouk Teaching Hospital, Shaikh Zayed Hospital, and Ibn-Rushed Teaching Hospital/Baghdad, Iraq. The study subjects were men of ages mean of 35.04 years ± 10.89 SD. Additionally, 50 samples were collected from non-alcoholic subjects, as control group, with mean age of 34.30 years ± 10.86.

Blood Sampling

Five milliliters of blood were collected by vein puncture, two ml was put into EDTA tubes for molecular analysis and three ml put in separating gel tube, then was allowed to clot at room temperature for 30 minutes and then centrifuged at 2000 rpm/15 minutes. The sera were collected and stored at -20°C until analysis.

Enzymatic Assay

The liver enzymes (GOT and GPT) and catalase in serum samples of alcoholic and non-alcoholic males were measured by Reflontron/Germany in this study.

Genotyping of SLC6A4 Polymorphism

Preparation of Genomic DNA

The DNA from genome was prepared from blood samples (gSYNC™ DNA Extraction Kit) according to the instructions of the manufactured. Concentrations and purity of DNA were measured by Nano drop spectrophotometer (Apel/Germany).

PCR condition and Restriction Fragment Length Polymorphism (RFLP)

Two primers were selected (F-5’- GGC GTT GCC GCT CTG AAT GC -3 ) and (R-5’- GAG GGA CTG AGC TGG ACA ACC AC -3 ′) (9) to amplify fragments of (469 &512) bp for the detection of alleles. The specific designed primers were provided by AccuOligo/ Bioneer/ Korea. The PCR reaction was performed in a total volume 20 µl containing 10 p mole/µl of each primer, 1x Master mix(AccuPower® ProFiTaq PCR PreMix/ Bioneer/ Korea), and 0.15µg/µl genomic DNA. The reaction mixture was amplified in thermal cycler (Cleaver Scientific, UK). Initial denaturation was carried out at 95°C for 5 min and the target DNA was amplified in 40 cycles. Subsequently, each cycle consisted of denaturation at 95°C for 30 sec; followed by annealing at 63°C for 30 sec. Elongation was carried out at 72°C for 1 min. The final extension step was performed at 72°C for 10 min. Aliquots of products of amplified DNA were treated with MspI (restriction enzyme, SibEnzyme/ Russia). The PCR product (5-HTTLPR) was digested with restriction endonucleases in a total volume of 20µl containing 10 units of enzyme with buffers supplied by the manufacturer’s instructions. The amplified PCR products were checked for the expected size on 2% (w/v) agarose gel and visualized after staining with ethidium bromide under ultraviolet. A 100bp DNA molecular weight marker (BioNeer/Korea) was used to measure the weight of the fragments (10).

Biostatistical consideration

The (11) program was used to analyze the difference factors in study variables. Chi-square test was used to compare differences among percentage at P-values of 0.05 and 0.01 probability. Odd ratio and 95% CI were estimated.

Results and Discussion

The study subjects were men of ages mean of 35.04 years ± 10.89 SD. Additionally, 50 samples were collected from non-alcoholic subjects, as control group, with mean age of 34.30 years ± 10.86, table (1).

Table (1): Distribution of ages of alcoholic male among cases and control

Results listed in table (1) indicated that the most common age group of cases(alcohol consumption) was
of 30-40 years (40.00%) followed by the group less than 30 years (32.00%), and more than 40 years (28.00%).

**Blood Chemistry Analysis**

The results of testing for GPT and GOT in serum from the cases as compared to the controls are presented in figure (1: A, B).

![Figure 1: Comparison of liver enzymes; A (GOT) and B (GPT) in serum samples of alcoholic and non-alcoholic males](image1)

The results in the present study indicated that parameters measured (GPT and GOT), which are markers liver functions revealed significant differences between cases and controls, \((42.46 \pm 23.39 \text{ vs. } 19.89 \pm 11.31)\) \((48.69 \pm 21.31 \text{ vs. } 15.93 \pm 9.27)\) at \((P<0.01)\) for GPT and GOT, respectively. Measurement of SGOT and SGPT becomes very important because these liver enzymes are the most important liver enzymes to represent groups or transaminase aminotransferase enzyme, which catalyze the keto acids into amino acids by transfer of amino groups. Serum enzymes are the most commonly used and sensitive biochemical markers for the assessment of liver disease. \((12)\), who reported that alcohol is a toxin that is harmful to the liver and alcoholic liver disease and it is one of the leading causes of alcohol-related death. While \((13)\), found consumption of alcohol causes several pathological changes in the liver. In respect to catalase there was significant difference between case and control group \((363.42 \pm 214.61 \text{ vs. } 101.51 \pm 51.64)\) at \((P<0.01)\) respectively as show in figure 2.

![Figure 2: Comparison of catalase in serum samples of alcoholic and non-alcoholic males](image2)
The enzyme catalase has also been shown to oxidize ethanol into acetaldehyde within the peroxisomes. This process is hydrogen peroxide dependent. However, under normal physiological conditions, catalase plays only a minor role in ethanol metabolism, but its contribution might be enhanced in the presence of higher amounts of hydrogen peroxide. Furthermore, catalase may be an alternative metabolic pathway for ethanol oxidation within the brain, where ADH and CYP2E1 appear to be of minor importance for ethanol metabolism.

reported that the catalase activity increased in lower concentration of alcohol exposure, but in higher concentration of alcohol exposure catalase activity decreased compared to control groups. This finding suggested that catalase activity in the liver is changeable.

80-90% of alcohol breakdown in the liver results in the formation of acetaldehyde whose further metabolism in the cells leads to reactive oxygen species production (ROS). Acetaldehyde itself is a mutagenic and carcinogenic byproduct. It binds with DNA and interferes with DNA synthesis and repair mechanism. Furthermore, it results in tumor development.

Distributions of Genotypes and Allele Frequency of the 5-HTTLPR Polymorphisms in the SLC6A4 Gene

The distribution of the observed SLC6A4 gene genotypes and alleles frequencies in the control and cases individuals are shown in table (2). The highest genotype in the case group was homozygous LL(74.00%), while(18.00%) for homozygous SS genotype, and LS (8.00%).

* (P<0.05), ** (P<0.01).

The results from table (2) show significant differences in the frequencies of SLC6A4 gene (LL) in the control and case groups (at P-value 0.01). The results raveled that the odd ratio for the LL genotype was 1.697 indicating that homo mutant genotype were a higher risk of alcoholism than the wild type SS. This result showed that L
allele frequency was (0.78) in alcoholism group and (0.53) in control group whereas S allele frequency was (0.22) in the alcoholism group and (0.47) in the control group as shown in table (2). So, the results showed there was a significant difference in allele frequencies of \( SLC6A4 \) gene between case and control (\( P<0.01; \) OR=1.697; 95% CI=0.86-1.64).

Alleles of the 5-HTTTLPR promoter have either a short (S) or long (L) copy of an imperfect repeat. The short or ‘S’ allele with 14 repeats was shown to have lower transcriptional activity than the long or ‘L’ allele with 16 repeats (20, 21). (22) reported that the ‘L’ allele is associated with a predisposition to lower level of response to alcohol, which is in turn associated with the onset of alcoholism. While several previous studies that suggested an association of the S allele with alcohol and drug dependence (23, 24, 25). (26) found out that there is an association between the 5-HTTLPR ‘L’ allele and the increased serotonin and platelet uptake pharmacologically; the serotonin transporter spans the plasma membrane 12 times.

### Association between genotype of 5-HTTLPR and parameters

The association between 5-HTTLPR and SGOT, SGPT and catalase were investigated. The current study shows that the presence of an SGOT was significantly associated with genotype of 5-HTTLPR (SS, SL, LL) among cases at \( (p < 0.05) \), while SGPT was significantly among control at \( (p < 0.05) \). Regarding the association between genotype of 5-HTTLPR and catalase, there were no differences among case and control groups, table (3).

The results in the present study indicated that genetic polymorphisms of the 5-HTTLPR and SGOP in humans are linked to alcohol consumption and the incident of alcohol abuse.

Regarding the association between genotype of 5-HTTLPR and catalase, may be, duration of ethanol exposure and genetic background appear to be important variables in considering whether or not catalase changes as a response to ethanol.

Several studies have examined whether the 5-HTTLPR polymorphism (L and S variants, LL, LS and SS genotypes) interacts with environmental risk factors to predict drinking outcomes (27, 28).

A repeat length polymorphism (5-HTTLPR) in the promoter of this gene has been shown to affect the rate of serotonin uptake and may play a role in drug dependence and other chronic neurological diseases (20, 21).

Some studies have suggested a possible involvement of the 5-HTTLPR genotype with alcoholism (22), smoking (29), suicidal behavior (30), and depression (31).

### Conclusion

Researchers worldwide reported that there are several underlying genetic factors that influence the development of alcoholism among individuals. However, to date there is only few published reports on this matter in alcoholism among Iraqi individuals.
In this study there was a significant positive correlation between the SGOT activity and genotypes of 5-HTTLPR (SS, SL, LL). There was a significantly increased levels of liver enzymes (GOT and GPT) and catalase in serum samples of alcoholic compared to non-alcoholic males. The results in the present study indicated that genetic polymorphisms of the 5-HTTLPR and SGOT in humans are linked to alcohol consumption and conditions of alcohol abuse.

Sensitive Simultaneous Estimation of Atorvastatin. Ca in Pure and Dosage Forms Via Developed CFIA Using 1,2 Naphthoquinone-4-Sulfonate as a Suitable Organic Agent

Bushra B. Qassim¹, Asmaa A. Zydan²

¹Department of Chemistry, College of Science, University of Baghdad, Iraq

Abstract

Objectives: A sensitive visible spectrophotometric method and FIA/merging zones technique was developed for the determination of atorvastatin calcium in pure material and tablet dosage form.

Method: Atorvastatin calcium has a free carboxylic moiety in its structure, which when being deprotonated in basic medium facilitates the association of the reagent with the drug. This method was based on the formation of red colored chromogen of drug with 1,2-Naphthaquinone-4-sulfonate(NQS) in basic medium (NaOH). The absorbance of the chromogens was measured at their respective wavelengths of maximum absorbance against the corresponding reagent blank.

Results: The red colored product is directly completed in basic medium and exhibits maximum absorption at 525 nm. Different factors affecting the formation of the product and optimized in order to obtain the best conditions for the experiment and its stability were studied. Method validation was done over a concentration range of 2-10 and 1-20 μg/mL for batch and FIA method respectively.

Keywords: Atorvastatin calcium; 1,2-Naphthoquinone-4-sulfonate, sodium hydroxide; Pharmaceutical formulation; CFIA/merging zones technique.

Introduction

ATRV.Ca [R-(R, R*)]-2-(4-flurophenyl)-β,δ-dihydroxy- 5(1-methylethyl)-3-phenyl-4-[phenylamino]carbonyl]-1H-pyrrole-1-heptanoic acid, calcium salt (2:1) is the most commonly occurring drug in commercially available pharmaceutical formulations used for the clinical treatment of hypercholesterolemia (¹). Several methods have been described for the determination of ATRV.Ca HPTLC (²), (HPLC) in different pharmaceutical preparations, either alone (³-⁸) or with other active ingredients (⁹-¹⁷), electrochemical (¹⁸,¹⁹), spectrofluorimetric (²⁰) and capillary electrophoresis (²¹) methods have been developed for the analysis of ATRV.Ca in pharmaceutical preparations. Various spectrophotometric methods have been reported for the determination of ATRV (⁹,¹⁵,²²-²⁶) from its individual and combined formulations with other active ingredients. The official procedures in pharmaceutical preparations utilize non-aqueous titration method (²⁷). Kinetic methods have certain advantages in pharmaceutical analysis regarding selectivity and elimination of additive interferences, which affect direct spectrophotometric methods. Some specific advantages that the spectrophotometric FIA methods possess are as follows (²⁸).

- High selectivity since they involve the measurement of the absorbance as a function of reaction time instead of measuring the concrete absorbance value.

- Simple and fast methods because some experimental steps such as filtration, extraction, etc.

-Other active compounds present in the commercial dosage forms may not interfere if they are resisting the chemical reaction conditions established for the proposed method.

- Colored and/or turbid sample background may possibly not interfere with the determination process.

Materials and reagent

A standard solution of ATRV.Ca (C_{66}H_{68}CaF_{2}N_{4}O_{10}= 1155.34 g mol^{-1}, Sigma Aldrich). A 0.05 g of pure ATOR was dissolved in 100 mL methanol to prepare 500 μg/mL of standard ATRV.Ca. A standard stock solution of NQS (C_{6}H_{4}COCOCH:CSO_{3} Na = 260.20 g mol^{-1}, Fluke) A 0.05 M of Reagent was prepared by weighing a 1.3 g of reagent and dissolving in distilled water and made up to 100 mL with it. A stock solution of NaOH (40 g mol^{-1}, BDH) A NaOH 1M was prepared by weighing a 4g of oxidant and dissolving in distilled water and made up to 100 mL with it.

Instrumentation

A Optima, Photomech 301-D^{+}, UV-Visible Spectrophotometer single beam recording spectrophotometer (Japan) was used for performed all absorbance and spectral measurements of FIA procedures, for the absorbance measurements as peak height through Kompensograph C1032, Siemens or absorbance with digital multimeter (DT9205A, China). Inside the detection unit, there is a flow cell (quartz silica (QS), 1 cm) with 80 μL internal volume. A Shimadzu UV-1800 (Japan) double-beam spectrophotometer were used for batch procedure, and quartz cuvette with an optical path length of 1 cm. A one channel manifold was employed for the FIA/merging zones system. A peristaltic pump of four channels (Shenchen, LabM1) used for pumping the distilled water as a carrier stream of through the valve (homemade, six-three injection valve (merging zone version)), which moves at 90° and three Teflon loops were loaded with the sample solutions and reagent. Mixing coil that was manufactured from glass with 2 mm (I.D). A single channel manifold system in FIA was shown in Figure.1.

Assay procedure for tablets

The solutions of pharmaceutical preparations by appropriate amount equivalent 0.02 g of the each sample was weighting that be equal to 200 μg mL^{-1} of resulting powder were dissolved in 100 ml volumetric flask with 25 mL of methanol for and then shaken and filtered into a volumetric flask of 100 mL. The residue was washed and diluted to volume with distilled water to gain 200 μg/mL of statin drugs.

Mechanism of the Reaction

The suggested mechanism of this reaction of ATRV.Ca with (NQS) in basic medium to form a red complex directly as shown in scheme (I). The stoichiometry of the reaction between ATRV.Ca and NQS was investigated (22).
Result and Discussion

Batch spectrophotometric determination: In the subsequent experiments, 4 µg mL⁻¹ of ATRV.Ca was taken in 10 mL final volume and performed by changed one factors at a time and keeping the other parameters fixed and observing the effects of the product on the absorbance.

Concentration of NQS:

The effect of various concentration of NQS was investigated using different concentration ranging from (0.001-0.01 M). A concentration of 0.005 M reagent gave the highest absorbance and was chosen for further experiments.

Concentration of sodium hydroxide: The effect of concentration of sodium hydroxide was investigated by carrying out the reaction using different volumes of NaOH ranging (0.005-0.2 M). The maximum absorbance was obtained upon 0.05 M.

Calibration curve of classical method:

The impact of using different concentration of ATRV.Ca (1, 2, 2.3, 2.5, 3, 4, 5, 6, 7, 8, 10, 12) µg mL⁻¹ were examined with stabilized the other parameters. Transfer set of volumetric (10 ml) contain 2.5 mL of (NQS) (0.02 M) followed by 1 mL of NaOH (0.5 M) then an increasing volumes from standard solutions (100 µg.ml⁻¹). The solutions had been diluted to the marked using distilled water. The reaction mixture measured the maximum absorption of the colored product at 525 nm. The standard curve was constructed and linear range (2-8) µg.mL⁻¹ for the determination of ATRV.Ca, as shown in Figure (2).
Calculations of stability constant:

\[ K = 1 - \alpha / \alpha^2 \]  

(1), \( \alpha \) (degree of dissociation) can be written as follows:

\[ \alpha = A_m - A_s / A_m \]  

(2), \( A_m \); \( A_s \) are the values of absorbance of the aqueous solution including a more than enough and stoichiometric amount of the reagent.

**Optimization of the FIA system conditions**

Initial studies were directed towards the optimization of the experimental conditions for FIA system.

**Effect of reagent and basic medium:** Optimum concentration of the reagent was studied by injecting different concentrations (0.005-0.08) M using IV. The results indicated that the 0.05 M gave the good repeatability with highest value of absorbance.

NaOH found to be a useful basic medium for this reaction, different concentrations of NaOH were also studied in the range of 0.01 to 0.08 M. The result referred to increase the value of absorbance with increasing the concentrations of basic medium up to 0.02 M and after this concentration the value of absorbance decreased. As a result, 0.02 M was chosen for the subsequent experiments.

**Effect of physical parameters**

**Effect of optimum total flow rate**

Optimum flow rate was studied using a range changed flow rates (1.2-2.6) mL min\(^{-1}\). The result demonstrates that a flow rate of 2.16 mL min\(^{-1}\) gave the highest absorbance value.

**Effect reaction coil length and injection volume**

Optimum length of reaction coil was studied in range of 85-250 cm. A best absorbance with acceptable repeatability was gained from the length of 85 cm. Absorbance decreased upon using a coil length of more than 85 cm.

Various volumes of injector loop were tested in this study. Effect of injected sample volume (L\(_1\)) was changed (58.875, 68.687, 88.312 and 127.562) µL and the volume of injection reagent (L\(_2\)) also studies was in deferent volume (68.687-127.562) µL. a 58.875, 68.687
µL for L₁, L₂ respectively was used in the next experiments.

Method validation

The linearity of the calibration graph for FIA method was obtained by injecting a series of solutions of ATRV. Ca (1-20 µg mL⁻¹) prepared from stock solution (100 µg mL⁻¹) with 0.02 M of basic medium as shown in figure (3). A portion of NQS (0.005 M) was injected as summarized in Table 1. These small points were referred to high reproducibility and repeatability of the developed FIA contrasted with the batch procedure.

Application of the proposed method using pharmaceutical:

The proposed batch and FIA method was successfully applied for estimation ATRV.Ca in tablets by the analysis of three types in two different concentrations of ATRV.Ca tablets and the results are listed in Table 2. In the direction of assessing the proficiency of the method. The statistical comparison between proposed and official methods using the student t- and F-test \(^{(27)}\) indicated that the calculated values for F-test were (2.57) and (1.22), t-test values were (2.08) and (1.13) for the FIA and batch methods, respectively, were less than the theoretical one of F-test = 6.388 \((n1 + n2 – 2 = 6)\) and t-test = 2.31.

**Conclusion**

The developed methods were selective, rapid, simple and inexpensive and exhibits a fair degree of accuracy and precision. The method does not involve any critical reaction conditions. The proposed method can serve as an alternative method for the routine analysis of ATRV.Ca in pure drug and in pharmaceutical formulations. The methods is based on formation of a red condensation adduct upon reaction of ATRV.Ca and NQS in (NaOH). The method has low detection limit and high sample throughput. The proposed methods that followed Beer’s law and give a good application for the pharmaceutical preparation. The wide applicability of the FIA method for daily quality control is well proven by analyzing the assay of ATRV.Ca at effect concentration level in dosage forms.

Gall Bladder Wall Thickness: Sonographic Accuracy and Laparoscopic Cholecystectomy Conversion Rate, Evaluated by Histopathology

Mohammad Faraj Dawod Al Jafary 1, Ammar Fouad Abdulrazaq1, Ayman Nadeem Kadum3

1Surgeon/ M.B.Ch.B, F.I.C.M.S (GS), F.I.C.M.S (GIT)/ Department of Surgery, Al-Yarmouk Teaching Hospital, Baghdad, Iraq

Abstract

Background: Preoperative prediction of a difficult laparoscopic cholecystectomy can help the patient as well as the surgeon to prepare better for intraoperative risk and the risk of conversion to open Cholecystectomy.

Aim of study: Evaluation the impact of gall bladder wall thickness, on the outcome of laparoscopic cholecystectomy and conversion rate to open cholecystectomy assessed by sonography preoperative and postoperative measurement of gall bladder wall thickness by histopathology.

Patients and Methods: A prospective study conducted in the surgical unit, Department of surgery, Baghdad Teaching Hospital between November 2010 and November 2011. Abdominal Sonography performed in 110 consecutive patients before laparoscopic cholecystectomy. The surgeon re-verified sonographic finding in operative room, and postoperatively, the gall bladder specimens were sent for histopathological measurement of wall thickness.

Results: Out of 110 patients with cholecystolithiasis on sonography, we encountered easy laparoscopic cholecystectomy in 80 patients (72.7%), difficult laparoscopic cholecystectomy in 24 (21.8%) and the procedure was converted to open cholecystectomy in six patients (5.5%). The difference between Sonographic and histological measurement was within 1 mm in 102 patients (92.7%), and the other 8 patients was with 1.5 mm (7.3%) with sensitivity of (100%), specificity of (83.3%) and accuracy of (97%).

Conclusion: An accurate preoperative diagnostic sonography is mandatory for planned laparoscopic gall bladder surgery to provide information for the selection of the most appropriate approach and avoid intraoperative difficulties and surprises. On sonography gall bladder wall thickening is the most sensitive indicator of technical difficulties during laparoscopic cholecystectomy. Such difficulties may require conversion to laparotomy.

Keywords: Laparoscopic cholecystectomy, gall bladder wall thickness, sonography, Iraq.

Introduction

Cholelithiasis has a high prevalence. Although cholelithiasis only becomes symptomatic in about 50% of patients, cholecystectomy is a common surgical procedure (1). Gallstones are one of the major causes of morbidity in Western society. Prevalence of people with gallstones, whether symptomatic or asymptomatic, varies from 5 to 22% (2). In Iraq, operations of gallbladder (GB) represent a considerable fraction of total operations conducted in hospitals. This indicates that the disease is relatively important in Iraq (3). Recently, laparoscopic cholecystectomy (LC) has become the gold standard for treatment of symptomatic gallstones, due to lower morbidity, shorter hospital stay, earlier return to regular daily activities, less postoperative pain and a significant reduction in the incidence of wound complications and postoperative ileus has been documented in patients undergoing LC (4, 5). In addition to numerous advantages, also technical limitations of laparoscopy should be mentioned, which - in the presence of chronic inflammation resulting in
pericystic adhesions and conglutination – increase the risk of undesirable conversion from LC to open surgery (6). The severity of acute inflammatory change influences the degree of surgical difficulty. GB wall thickening and pericholecystic fluid are indicators of inflammation in patients with acute cholecystitis (7). The most common risk factors for conversion include a thickened GB wall, past acute cholecystitis, diabetes mellitus, past upper gastrointestinal tract surgeries, age > 65 years and male gender (8, 9). The selection of the patient who will undergo LC is important, and the most frequently used method other than the clinical evaluation, is radiological examination (ultrasonography) (2). Preoperative classification of patients into a high risk group would be an objective factor facilitating the surgeon’s decision on possible conversion (9). A preoperative GB ultrasound, which documents a thick GB wall (> or = 3 mm) with calculi, is a clinical warning for a difficult LC which may require conversion to an open surgery. In a study, it was found that the rate of conversion was 60% in case of thickened GB wall while 12% in case of normal GB wall (10). Variable results have been reported in the past about the sensitivity, specificity, positive predictive value, and accuracy of GB wall thickening as an indicator of surgical conversion (7).

The success of any laparoscopic operation depends on both proper patient selection, and the technical skill and experience of the laparoscopist (11). The aim of the study was to evaluate the impact of GB wall thickness on the outcome of LC and the conversion rate to open cholecystectomy assessed by preoperative sonography and postoperative measurement of GB wall thickness by histopathology.

Patients and Methods

Study Design and Setting: This was a prospective study that was conducted in the surgical unit, Department of Surgery, Baghdad Teaching Hospital during a period of one year from Nov, 2010 – Nov, 2011.

Study Population and sample size: The study included patients with feature of chronic calculus cholecystitis who were prepared for LC, so the total number was 110. Patients who had previous abdominal surgery and features of acute cholecystitis (clinically and by investigation) were excluded.

Workup: All patients were evaluated by sonography after fasting at least six hours, the wall of GB was carefully evaluated and consider as thick when it is (> 3mm), size and capacity of GB, pericystic fluid collection and biliary system status was evaluated as well as number of GB stones also recorded. Hematological and biochemistry investigation were done. GB wall thickness was measured postoperatively by histopathology; grossly and microscopically as. Initial Procedure of histopathological examination done by.

Measurements:

- GB: length × maximum diameter (cm).
- Cystic duct: length × maximum diameter (cm).
- Lymph node: number and maximum diameter (cm).
- Open longitudinally from the fundus towards the cystic duct with blunt-ended scissors, draining off the bile and noting any contents.
- Photograph if appropriate.
- Paint the external serosal and adventitial aspects if there is any suspicion of tumor.
- Fixation by immersion in 10% formalin for 36 – 48 hours.

The difficulty of procedure was evaluated by:

1. Clarity of calot’s triangle (peritoneal adhesion) length and width of cystic duct.
2. Handling of GB during procedure and ability to perforate it.
3. Dissection of GB from its liver bed and bleeding from it.
4. Extraction of GB to outside.

All patients were undergoing surgery which was done by senior general surgery and resident using closed methods with four ports. Histopathological examination done by senior histopathology. LC considered easy when there is minimal adhesion involving the omentum, only attaches to the fundus and body of GB, and easily separated. Difficult LC when there is sever adhesion involving calot’s triangle.

Statistical analysis: The data analyzed using Statistical Package for Social Sciences (SPSS) version 25. The data presented as mean, standard deviation
and ranges. Categorical data presented by frequencies and percentages. Chi–square test was used to assess statistical association between certain variables and GB Wall thickness. A level of p–value less than 0.05 was considered significant.

Results

In this study, mean age of patients was 42.7 ± 8.4 years; and 82.6% were females. By U/S, 64.5% of patients had GB with wall thickness ≤ 3 mm. We noticed that LC was easy in 72.7% of cases, difficult in 21.8%, and converted to open surgery in 5.5% of cases as shown in table (1).

Discussion

Since the Introduction in 1985, LC had been the procedure of choice in treatment of symptomatic gall stone (12). But some of the planned LC needs conversion due to various factors, it would be useful in advance to know which one would require conversion, so that experienced laparoscopic surgeon could be scheduled to minimize conversion rate. And since the 1970s, ultrasound has become known as a quick, non-invasive and reliable tool to diagnose GB disease (13, 14). Ultrasound is very sensitive for the diagnosis of gall stones, but few data are available to assess its diagnostic value for the GB wall thickness (15). We assessed the value of sonography for patients with gall stone disease prior to LC. This study corroborates the well-established high accuracy (97%) of sonography for assessing the thickness of GB wall thickness.

In this study, we found that increase GB wall thickness on preoperative ultrasound which encountered in 39 patients out of 110 patients (35.5%) were associated with increase operative difficulty in 18 patients out of 39 patients, and our conversion rate to open surgery in six patients out of 110 patients (5.5%) was within the range reported by several other studies (1 – 10%) as in Indian one conducted in 2017 with a report of conversion rate of 10% (16), in USA in 2010 were the rate was 9% (17), and a local study in Iraq in 2007 (18) where the rate was 5%. In this study, GB wall thickness significantly determines the difficulty during surgery. We found that increase GB wall thickness (> 3 mm) on preoperative ultrasound which encountered in 39 patients (35.5%) in comparison to those with thin GB wall thickness (≤ 3 mm) 71 patients (64.5%) was associated with increase operative difficulty and this result was in consistent with a result found by Adwan MK et al study in 2015 (3) and with a study conducted by Sharma N et al in 2015 (19) when reported that gall bladder wall thickening can predict difficulty during cholecystectomy, we found that thickened gall bladder wall are the most accurate predictors of potential operative difficulty. GB wall thickening was a sensitive indicator of technical difficulties and the risk of conversion to open cholecystectomy. GB wall thickness is related to the inflammation and fibrosis that follow previous attach of cholecystitis and thus may reflect difficulty in delineation of the anatomy during surgery (20). In conclusion, LC can be accomplished successfully with low morbidity in most patients with cholecystitis, those patients with increased GB wall thickness on preoperative ultrasonography are at high risk for conversion to open surgery. An accurate preoperative diagnostic tool is mandatory for planned laparoscopic GB surgery to provide information for the selection of the most appropriate approach and to avoid intraoperative difficulties and surprises.

Evaluating the Effect of Addition of Titanium Dioxide Nanoparticle on Some Physical Properties of Flowable Composite Resin

Sazgar Srbast Qasim¹, Diyar Khalid Bakr¹, Dara H. Rasheed
¹Hawler Medical University, College of Dentistry, conservative dentistry department/Iraq

Abstract

Objective: The flowable dental composite resins were introduced to the dental specialty because of the advantages they possess over the conventional composite resins. The use of nanotechnology in the dentistry field is one of the growing innovations in recent years. The aim of the present study was to evaluate certain physical properties of flowable dental composite after incorporation of titanium dioxide nanoparticles (TiO2NPs).

Materials and Method: In the present study, TiO2NPs at 1.25 % and 2.5% concentrations were added to flowable composite, while the unmodified composite was used as control. Then the physical properties of the control and modified composite resins, including flowability, radiopacity and water sorption and solubility were tested. Data were analyzed with One way ANOVA, using SPSS 20.

Results: The results showed that there was statistically significant difference among the tested groups regarding flowability and radiopacity (P<0.05). In addition, there was no significant difference among control group and TiO2 modified groups regarding water sorption and solubility.

Conclusion: Based on the results of the present study, a flowable dental composite was successfully reinforced with TiO2. Incorporation of small weight percentages of this nanofiller exhibited properties similar to the control material regarding water sorption and solubility. The flowability was slightly reduced and radiopacity of the reinforced composites was increased, these changes were acceptable for clinical applications and below ISO standards limits.

Keywords: Flowable Composites, Titanium Dioxide nanoparticles, flowability, radiopacity, water sorption and solubility.

Introduction

Currently composite resins are materials used in restorative dentistry, since there are many revolution and improvements such as use of different novel particles, flowable composite resin because of their advantages over the conventional composite resins were introduced to the dental specialty. These advantages includes, simple application technique, easy handling properties, increased flowability, better adaptation to the internal cavity wall and higher elasticity, in addition, the use of flowable composites resins reduces the amount of the cavity preparation and is recommended for minimal invasive dentistry (¹).

One of the most important innovations in the dentistry field in recent years is the use of nanotechnology. The mechanical, physical and optical properties of conventional composite resins have been improved by addition of inorganic nanoparticles such as silver, zinc, titanium dioxide and silica (²).

Flowability is used to describe how quickly materials flow in a certain period of time, whereas viscosity is the material’s resistance to flow. Dental composites are viscoelastic materials. They share criteria of both viscous materials (e.g., oils) and elastic materials (e.g., metals).
Radiopacity of dental restorative materials is an important indicator for accurate diagnosis and treatment planning. It is essential to use materials with adequate radiopacity in order to distinguish them from the natural tooth structures. Moreover, dental restorations should be radiopaque enough to detect overhanging margins, recurrent caries, restoration contour, proximal contacts (3).

The sorption and solubility properties are critical properties regarding biocompatibility concerns of releasing monomer and in relation to the stability of the composites due to degradation from the uptake of solvents and the wash-out of ingredients of materials (4).

Most of the studies involving addition of nanoparticles to dental composites resins have mainly focused on their anti-bacterial effects and the information regarding their physico-mechanical properties are limited. TiO2 are fine, non-toxic, chemically stable, and exhibits a high photocatalytic effect in addition to their high biocompatibility and pleasant color. TiO2NPs have large surface area that facilitates load transfer from resin matrix to nanoparticles thereby resulting in better mechanical properties of the reinforced composites (5).

Mohammed et al (2019) studied the effect of TiO2NPs on physico-mechanical properties of flowable dental composite resins by adding TiO2NPs at 1%, 2% and 3% to Tetric N Flow composite, while the unmodified composite was used as control. The developed composite was studied for functional and structural properties using FTIR, which indicated no change in the functional and structural characteristics (6).

The aim of the present study was to evaluate the effect of TiO2NPs, on some physical properties of flowable composite resins.

Method

In this study, the flowability, radiopacity and water sorption and solubility of a conventional flowable composite resin and composite resins reinforced with TiO2NPs were evaluated. For each test a total of 18 samples were evaluated. Commercially available flowable microhybrid composite resin (as control group) was used shade (A2). This material is based on dimethacrylate paste (Bis-GMA and Triethylene glycol dimethacrylate TEGDMA), without inorganic fillers. mixed with TiO2NPs 98% Purity and particle size of 50 nm at concentrations of 1.25% and 2.5 %.

Mixing was done by using a dental Micro motor, with a lentulo spiral-paste carrier #4 attached. The lentulo spiral was immersed in composite resin material – TiO2NPs, poured into a 2 ml pre-darkened syringe tube.

Such mixing was performed directly before preparation of samples for each test. Electronic balance was used to weight the percentage of nanoparticles, after one hour mixing; the mixture was injected into metal molds Curing was done by exposure to LED at 1,650 mW/cm2 for 40 seconds with a light guide held perpendicularly and within 2 mm of the material surface. Control samples were prepared and compared with two sets of samples with TiO2NPs at 1.25% and 2.5%.

The flowability testing method used in this study was according to ADA guidelines for evaluation of endodontic sealing materials (7). To evaluate the flowability of the reinforced composites, a simple test using the Gillmore needle apparatus was used. The quantity of 0.1 mL of control and each reinforced composite was dispensed between two thin glass coverslips 50 x 50 mm and 1mm thick. Flowability was evaluated by comparing the composite disc diameters after they have been sandwiched between two glass coverslips, subjected to constant weight (454 g) for 30 s and light cured for 40 s.

For radiopacity test 6 discs 15±1mm in diameter and 1± 0.1mm thick were prepared for each group. The specimens and the aluminum stepwedge were placed in the center of the film and irradiated with X-rays at (65±5) kV at a target film distance of 400 mm for 0.4 seconds at 10 mA. After developing and fixing the film, the density of the image of the specimen was compared with that of the aluminum standard using the densitometer. For Water sorption and solubility test 6 discs 15±1mm in diameter and 0.5± 0.1mm thick samples were prepared for each group using a metal molds and tested according to ADA specification (8).

Statistical Analysis

The statistical analysis was performed on SPSS program version 20.0, the descriptive statistic was done for tested groups, for verification the difference among groups analysis of variance (One-way ANOVA) with Tukey post-test.
Results

Flowability test

Table 1 presents the means and standard deviations of flowability values in conventional composite resin and composite resins reinforced with TiO2NPs at different percentages.

Based on Table 1, the Flowability of control group and 1.25% and 2.5% groups were 2.6933 cm, 2.6083 cm and 2.5067 cm respectively. The results of Table 1 revealed significant differences among the tested groups. But the difference is acceptable within the ISO standard.

**Discussion**

The flowability of floweble composite resin decreased slightly with addition of TiO2NPs at 1.25% and 2.5% and the results are within the ISO standards, these results are in agreement with previous study reported that it is possible to increase the nanofiller content due to their small particle sizes. This will result in minimum reduction in flowability as well as improvement in the physical properties of the nano-composites (10).

In the present study the most commonly used monomer) BisGMA and TEGDMA were used. The advantages of using BisGMA over other monomers are less shrinkage, higher modulus and reduce toxicity due to its lower volatility and diffusivity into tissue. Although, BisGMA possesses high strength and hardness, the drawback of this monomer is its high viscosity (low flow), because of hydrogen bonding interaction that occur between hydroxyl groups, which limits the incorporation of inorganic fillers and hence a low degree of conversion, Thus BisGMA diluted with other low-viscosity (high flow) monomer such as trimethylene-glycol-dimethacrylate (TEGDMA) (11) to enhance flowability of the used composite that allow incorporation of TiO2NPs that resulted in a little reduction of flowability of the tested flowable composite resin and the changes are within accepted range of ISO standards.

The radiopacity of a restorative material is an important parameter for accurate diagnosis and treatment planning. Success or failure of the restorative material is highly dependent on radiographs. Radiopacity of composite restorations has an important role in detecting recurrent caries and distinguishing the restorations from the tooth structures (12).

The 2.5% composite showed a higher value of radiopacity. Followed by 1.25% group Al, and control group with statistical significant difference among the tested groups and met the ISO standard for dental materials radiopacity. All of them had radiopacity greater than enamel (1.77 – 2 mm Al). These results agree with previous studies that recommended that the composite radiopacity should be equal to or greater than that of the enamel (13).

The atomic number of the elements is the most important factor affecting the radiopacity of dental materials (14). Radiopacity of dental composites can be increased by incorporating a higher percentage of fillers with high atomic numbers (15), TiO2NPs atomic number is 22 and density of 4.506 g/cm³ which is considered as a high atomic number and this explains the results of this study in which radiopacity of tested material increased with increasing percentage of TiO2NPs from 0% control group to 1.25% and 2.5 %..

The sorption and solubility properties are important regarding biocompatibility concerns of releasing monomer and in relation to the stability of the composites by avoiding degradation from the uptake of solvents and the wash-out of ingredients of materials (16). According to ISO standard (17), the maximum acceptable values of sorption and solubility for polymer-based restorative materials are 40 µg/mm³ and 7.5 µg/mm³ respectively. Sorption and solubility values for all samples were below the ISO standards limits so all investigated materials met the requirements of the ISO standard. The decreasing sorption and solubility with TiO2 content was not statistically significant. These results are in agreement with Robert et al (18) study who studied the effect of nanofillers on water sorption and solubility and concluded that the addition of nanofillers at low concentrations not change water sorption and solubility significantly since at lower concentrations there is no agglomeration of 50 nm TiO2NPs.

The improvement of both water sorption and solubility after addition of TiO2NPs might be attributed to numerous explanations such as nanofillers are insoluble in water so that the addition of TiO2NPs to the microhybrid flowable composite resin declines the solubility of composite resin (19).

Furthermore, titanium coupling agent incorporated in salinized TiO2NPs expands the adhesion between both resin matrix and filler particles which enhances composite resin properties and declines its water sorption and solubility (20).

Moreover, the reaction between resin (polar nature) and nanofillers certainly induce replacing the hydrophilic resin and minimizing the water uptake by decreasing this polarity through utilizing most active sites in the molecules of monomers, so the diffusivity of water particles through this material is greatly declined (21).

**Conclusion**

Based on the results, it appears incorporation of low concentration of nanofillers into conventional composite resins did not result in any changes in their water sorption...
and solubility; however, flowability and radiopacity of flowable were changed but the results are acceptable within ISO standards. Therefore, it is suggested to add small amount of nano-fillers to composite resins to prevent problems such as discoloration of composite resin or other possible changes in other physical and chemical properties.

Antimicrobial Activities of Green Biosynthesized Iron Oxide Nanoparticles Using F. Carica Fruit Extract

Nada Khudair Abbas¹, Azhar A. F. Al- Attaqchi², tutor Jenan Hussien Taha³
¹Department of Physics, College of Science, University of Baghdad, Baghdad, Iraq, ²Department of Microbiology, College of Medicine, University of Al- Nahrain, Baghdad, Iraq, ³Physiology and Medical Physics Department, College of Medicine, University of Al- Nahrain, Baghdad, Iraq

Abstract

In the current study, iron oxide nanoparticles (IO NPs) were synthesized via modified green synthesis technique using F. carica fig extract as reducing agent. Furthermore, the microstructural properties of the synthesized IO NPs have been thoroughly elucidated. In details, the acquired NPs diameter was found to be in the range of 11-29 nm and of root mean square (RMS) of 0.64 nm using TEM and AFM techniques, respectively. Consequently, the antifungal and antibacterial activities of the synthesized IO NPs were screened against Candida and Aspergillus species as well as Gram-positive Staphylococcus aureus and Gram-negative Acinetobacter species, respectively. The presented IO NPs play an active role in the antimicrobial activities evidencing the well-organized materials system for biomedical applications.

Keywords: Iron oxide NPs, antifungal, antibacterial, F. carica extract

Introduction

Metal oxide NPs are of great importance due to a number of unique properties such as high surface-to-volume ratio, easy separation features, and low toxicity (1). IO NPs have attracted a great significance in the field of nanoscience and nanotechnology (2, 3). In conjunction with IO NPs, several applications have been proposed in the area of optoelectronics, catalysis, self-powered smart window, lithium ion batteries and diagnostic biological probes (4-8). IO NPs are extensively applied in the biomedicine field due to their low toxicity and biocompatibility. Due to the electrostatic feature of the IO NPs, they are easily interact with fungal, and bacterial living-cell membranes (9). This property allows IO NPs to harms the cell membranes of fungi or bacteria as well as inducing the toxic oxidative stress via free radical formation (10). Antimicrobial activities of IO NPs are, therefore, dependent on three essential features namely concentration of the culture media and most importantly stability (9, 10).

In this attempt, variety of approaches have been anticipated for the synthesis of IO NPs. Among these are the well-known physical and chemical methods in which preferred NPs properties can be acquired. Particularly, these methods are electrodeposition (11), conventional heating (12), hydrothermal (13, 14), wet oxidation (15), laser ablation (16), co-precipitation (17, 18), and anodization (19). However, these techniques are presented with several draw-backs such as the use of non-biodegradable stabilizing agents and toxic chemicals, and hypothetically harmful to the well-being organisms and the surrounding environment. The green synthesis technique, which is utilized in the current study, has revealed considerable advances such as environmentally friendly, unpresented toxic chemicals, and low energy and temperature conditions (20). Green synthesis technique evolves the use of naturally existing resources such as plants extracts as reducing fuel (21). Therefore, this manuscript reports a modified green synthesis technique of IO NPs in which F. carica fig extract is used as a reducing agent. Additionally, the antifungal activity against Candida and Aspergillus species and antibacterial activity against Gram-positive S. aureus and Gram-negative Acinetobacter species were thoroughly investigated.
Materials and Method

Plant collection and extraction

Dried *F. carica* (common fig) was purchased from local market in Baghdad, Iraq. Consequently, the collected fruit was washed thoroughly; afterward, 10 gm of the washed fruit was blended alongside 150 mL of deionized-distilled water (DDW). The resultant mixture was subjected to heating process at 100 °C in a ventilation oven and then cooled down to room temperature. Finally, the solution mixture was filtered using chromatography paper (Whatman No.1) and incubated at room temperature for further use.

Synthesis of IO NPs

In a typical laboratory route, specific amount (0.1, 0.14 and 0.18 molar) of iron(III) chloride hexahydrate (*F₂Cl₃.6H₂O*) was liquefied in 100 mL of DDW under stirring rate of 800 r.p.m. for 15 minutes at RT. The consequential mixture was then mixed with fig extract (1:1) under stirring rate of 600 r.p.m. for 2 h at 50 °C (1). The first indication of the NPs occurring was observed upon color changing of the solution, whereby a light brown color was noticed, as presented in figure (1). The acquired solution was then washed and centrifuged at 4000 r.p.m. for 20 minutes. Hereinafter, the attained residual was dried for 6 h at 60 °C and later grinded using mortar and pestle to obtain a fine NPs powder.

Figure (1): Color changing process of IO NPs.

Characterization

The microstructural properties of the prepared NPs were examined using Shimadzu X-ray Diffractometer (XRD-6000) with wavelength of 1.541 Å and Cu-Kα radiation. In the meanwhile, compact char surface was investigated using Fourier Transform Infrared Spectroscopy (FT-IR, Thermo Nicolet Nexus) ranging from 400 to 4000 cm⁻¹. Furthermore, the optical properties of the prepared NPs were recorded on Shimadzu UV-1800 UV-Vis spectrophotometer. Atomic Force Microscopy (SPM AA3000-AFM) and TECNAI F-30 TEM were engaged for the morphological and nanoparticle size investigations.

Evaluation of antifungal and antibacterial activities

The antifungal activity of the synthesized NPs was monitored using agar well diffusion procedure against two fungal species which are *Candida* and *Aspergillus* species (22). Agar petri dish, which was used in this study as a culture media holder, was systematically swabbed with sterile cotton swab in which a 30 ml of 24 h Sabouraud’s dextrose was used for each fungal species. Continuously, wells were made in the pre-solidified agar plates with the help of 5 mm cork bor-er. Variety of the synthesized NPs concentrations (0.75, 1.5, 3, 6, 12 and 24 mg/ml) were sonicated with DDW and then used to evaluate the antifungal activity. Concurrently, Negative and positive control against the fungal pathogens was exhibited using DDW and antibiotics. Hereinafter, the cultured agar plates were incubated at 35 °C for 48 h, while the inhibition zones were measured in millimeter.

As for the IO NPs antibacterial activity, similar route to the aforementioned antifungal was repeated. However, the antibacterial activity was screened against Gram-positive *S. aureus* and Gram-negative *Acinetobacter* species using 30 ml of 24 h Blood agar culture media. In
this experiment, the positive and negative controls used were antibiotics and DDW and the antibacterial activity was later proceeded to an incubation procedure for 24 h at 35°C. It is worth mentioning that the concentrations of IO NPs utilized for the antibacterial activity are 0.5, 1, 2, 4, and 8 mg/ml.

**Results and Discussion**

The XRD patterns of the synthesized NPs are presented in figure (2, a). Generally, the intensity of the diffraction peaks augmented with increasing IO NPs concentrations which in turn indicates higher crystallinity at high concentrations. As depicted in the figure, eight different pronounced peaks were acquired corresponding to (110), (120), (211), (10-1), (202), (211), (312), and (310) planes and diffraction angle of 2θ = 21.9°, 26.6°, 33.2°, 35.6°, 49.5°, 50.4°, 54°, and 62.4°, respectively (Card No. 96-901-1413) (1). The (110), (120), and (211) planes mainly belong to FeO phase, while other planes, (211), (10-1), (202), (312), and (310), are corresponded to Fe₂O₃ phase (Card No. 96-900-9783) (9).

Figure (2, b) illustrates the FT-IR curve of the synthesized NPs with concentration of 0.14 M. It is clear to be noticed that characteristic peaks at 3848, 3737, and 3416 cm⁻¹ are mainly attributed to the O-H stretching bonds. In the meanwhile, peak at around 2925, cm⁻¹ is corresponded to C-H stretching characteristic. Two pronounced peaks at 2381, and 2310 cm⁻¹ are designated to O=C=O stretching. Furthermore, additional peaks at 1737, and 1638 cm⁻¹ were observed which are due to C=O stretching, while peak at 1542 cm-1 is found to be in accordance with C=C stretching (1, 23). Finally, Fe-O vibrations namely 1098, 795, 506 and 463 cm⁻¹ are assigned to the IO NPs (23).

The UV-vis spectra of the synthesized IO NPs are demonstrated in figure (2, c), which exhibited broad bands and cut-off phenomenon at 360 nm. Furthermore, as illustrated in the figure, there is a decrease in the mentioned phenomenon cut-off towards higher wavelength as the concentration enlarged; this could be attributed to the lattice defects in the prepared NPs matrix (9).

Figure (2, d) demonstrates two dimensions and three dimensions AFM images of the synthesized NPs with a concentration of 0.14 M and scanning area of 2 µm. In general, the formed NPs exhibited a vertically aligned NPs with regular spherical shape and homogenous distribution. The average diameter and RMS were found to be 84.4 and 0.64 nm, respectively. In the meanwhile, the average surface roughness was found to be 0.54 nm; this indicates a pronounced rough surface which in turn reveals high electrochemical performance (24).
The TEM image of IO NPs is presented in figure (3, a and b). Generally, the synthesized NPs revealed almost a spherical structure with average diameter of 19 nm. From the figure, it also can be observed that a uniform IO NPs distribution which found to be in good agreement with the AFM findings. Furthermore, figure (3, b) shows the NPs diameter distribution which was found to be in the range of 11-29 nm.

Figure (3): IO NPs with 0.14 M concentration (a) TEM image (b) diameter range distribution.

The antifungal activity of the green synthesized NPs against *Candida* and *Aspergillus* species are shown in figure (4, a). As presented in the figure, an observable inhibition zone increment in both kind of fungi species can be clearly seen as the concentration of the IO NPs increased, this indicates the active role of the synthesized NPs as an antifungal. This can be explained by the superior features of IO NPs such as large surface area, and small particle size as compared to their bulk nature. Although, the inhibition zones in the case of *Candida* demonstrated larger inhibition diameter, lower concentrations of the used NPs were found to be active in the case of *Aspergillus*. The maximum inhibition zone diameters were found by the highest IO NPs concentration 24 (mg/ml) against *Candida* (35 mm) followed by *Aspergillus* (33 mm). In contrast, inhibition zone diameters of 10 and 15 mm against *Candida* and *Aspergillus* with IO NPs concentration of 3 mg/ml, respectively. Similarly, at concentration of 1.5 mg/ml, the antifungal activity was only exhibited against *Aspergillus*. This may be due the differences in the *Candida* species’ cell wall structure which consists of high chitin as a yeast as compared to the moldy in *Aspergillus* species, this in turn leads to different sub-capability of each towards the tested nanoparticles.

Figure (4, b) presents the antibacterial activity of IO NPs against Gram-positive *S. aureus* and Gram-negative *Acinetobacter* species. Generally, increasing the concentration of IO NPs exhibited higher antibacterial activity. This could be attributed to the metallic NPs accumulation in the living cell-membranes which in turn releases cellular compounds as previously reported by other researchers. It is a necessity to be stated that concentration as low as 0.5 mg/ml exhibited null activity against both species. However, higher concentrations of IO NPs displayed advanced inhibition zones in both species cases. Continuously, the acquired inhibition zones against Gram-negative *Acinetobacter* bring about more diameter range as compared to Gram-positive *S. aureus* at all concentrations. Inhibition zones of 25 and 19 mm in diameter against Gram-negative *Acinetobacter* and Gram-positive *S. aureus* were screened with IO NPs concentration of 8 mg/ml, respectively. This may be due to the difference in susceptibilities property of each bacterial species towards IO nanoparticles comes from the differences in the structure of cell wall of each bacteria. In details, the Gram-positive *S. aureus* species has thicker peptidoglycan and thus demonstrate higher resistance in contrast to Gram-negative *Acinetobacter*. As observed in table (1 and 2), the synthesized NPs demonstrated higher antibacterial and antifungal effects than standard antibiotics.

**Conclusion**

IO NPs were successfully synthesized using *F. carica* fig extract. Additionally, the microstructural properties of the prepared NPs were illustrated using XRD, FT-IR, UV-vis, AFM and TEM techniques. Simultaneously, the synthesized NPs were evaluated for their antifungal and antibacterial activities against *Candida* and *Aspergillus* species as well as *S. aureus* and *Acinetobacter* species, respectively. It was found that *Aspergillus* species is more sensitive to the synthesized NPs rather than *S. aureus*, shedding the light towards this technique which may be useful for the treatment of this aggressive multidrug resistant bacteria.

Molecular Detection of Antibiotics Resistance Genes in *Burkholderia Cepecia* Isolated From Diabetic Foot Infection

Maryam Riyadh Al-Muhanna¹, Mahdi Al-Ammar¹

¹University of Kufa-Faculty of Science-Department of Biology/Iraq

**Summary**

This study aimed to isolate and diagnose *Burkholderia cepacia* from clinical specimens of diabetic foot and study the resistance of bacteria to antimicrobial agent in Najaf governorate from August 2019 to November 2019, which includes 120 clinical specimens for both sexes with an age ranged between (35-70) years old. The diagnosis of bacteria isolates was based on microscopy, as well as the culture and biochemical characteristics as an initial diagnosis. The final diagnosis by the Vitek-2 compact system.

*Burkholderia cepacia* 8 (6.6%). Antibiotic sensitivity test was examined by dick diffusion method, *Burkholderia cepacia* isolates showed high level of resistance almost for all β-lactam antibiotic classes under study which included; ceftriaxone, cefoxitin and Cefepime, with percentage of (100%); ticarcllin with clavulalnic acide, piperacillin, ceftazidimne, tobramycine, ciproflaxcin and levofloxacin with percentage of (87.5%); aztreonam and amikacine with percentage (62.5%); meropenem, imipenem and gentiamycin with percentage of (37.5%).

At molecular study, the investigated the presence of antibiotic-resistant genes (blaImp, blaOxa, blaKpc,blaCTX-M) using PCR technique and electrophoresis systems. 6/8 *Burkholderia cepacia* isolates were with *blaOXA* and (6/8) of isolates carry *blaCTX-M* gene, all isolates of *Burkholderia cepacia* gave negative result of *blaIMP* and *blaKPC* gene. Finally PCR analysis showed that the integron gene was (3/8 %).

**Keyword:** Bcc, *Burkholderia cepacia* ; Antibiotics Resistance; Diabetic

**Introduction**

The *Burkholderia cepacia* complex (Bcc) organisms are opportunistic nosocomial pathogens capable of causing severe disease in immunocompromised individuals. Bacteria frequently employ disparate mechanisms that act synergistically to achieve elevated resistance (1).

However, these data may overestimate the occurrence of resistance in *Burkholderia cepacia* organisms as the study was carried out on patient isolates solicited because they were in fact multidrug resistant. Despite this caveat, resistance patterns, both intrinsic and acquired, must not be discounted in these organisms. The often high-level acquired or intrinsic resistance of non-enteric bacteria such as *P. aeruginosa* and *Burkholderia* species is in no small part attributable to synergy between reduced penetration into and efflux from the cell (2).

Diabetes mellitus (DM) is a chronic disease caused by inherited and/or acquired deficiency in production of insulin by the pancreas, or by the ineffectiveness of the insulin produced. Such a deficiency results in increased concentrations of glucose in the blood, which in turn damage many of the body’s systems, in particular the blood vessels and nerve and constitutes the most frequent diabetes-related cause of hospitalization (3).

Diabetic foot ulcers is one of the main causes of mortality and morbidity among people with diabetes. Its include an injury to all layers of skin, necrosis or gangrene that usually occur on the soles of the feet, as a result of peripheral neuropathy or peripheral arterial disease (PAD) in diabetes patients (4).

**Materials and Method**

specimens collection and bacterial identification
A total of 120 samples were collected from diabetic foot ulcer who attended different hospitals during the period from August 2019 to November 2019 in Al-Najaf provenance, sample collection include, collection 120 pus samples swab specimens from diabetic foot infection ulcer. The specimens were transported by sterile transport swabs to the department of bacteriology laboratory. Each specimen was inoculated using direct method of inoculation on culture of selective media namely MacConkey, Blood , Mannitol agar then inoculated at 37°C for 18-24 hours.

**DNA Extraction**

Genomic DNA was extracted by using a commercial extraction system (Genomic DNA promega Kit). Molecular Identification

Gel electrophoresis was used for detection of DNA by UV transilluminator. The PCR assay was performed to detect the antibiotic resistance gene for *Burkholderia cepacia* shown in table (2). This primer was designed by Alpha DNA company, Canada as in table (1). Amplified products were confirmed using 1% agarose gel electrophoresis to estimate the PCR products size. The gel was stained with 4 µL of 10mg/mL ethidium bromide (Sigma, USA) and it run at 80V for 1.5h. A single band was observed at the desired position on ultraviolet light transillumintor (Cleaver, UK); bands were photographed using gel documentation system (Cleaver, UK). A 100bp ladder (Bioneer, Korea) was used to measure the molecular weights of amplified products.

Results and Discussion

This study was conducted on 120 specimens from diabetic foot suspected patients during the period from September 2019 to December 2019.

4.9.1.2 Molecular identification of antimicrobial drug resistance of *Pseudomonas aeruginosa* and *Burkholderia cepacia*

4.9.3.2.1 *blaOXA*

The result showed that the *blaOXA* resistance gene was detected in 6/8 *Burkholderia cepacia* as in figure (1).

![Figure](image)

(1): PCR amplification products of *Burkholderia cepacia* isolates that amplified with *blaOXA* gene primers with product 564bp. Lane (L), DNA molecular size marker (100-bp ladder), Lanes (1,2,3,5,6,7) show positive results with *blaOXA* gene.

Carbapenemases are the main mechanism by which resistance to carbapenems occurs and they belong to three of the four β-lactamase classes A, B and D. Class D carbapenemases are the OXA-β-lactamases, further subdivided into various sub-groups mainly *blaOXA-23, blaOXA-24/40, blaOXA-58, blaOXA-48, blaOXA-51* and *blaOXA-143*. These OXA-type β-lactamases occur widely in Acinetobacter with the most abundant being *blaOXA-51*, which is chromosomally encoded hence intrinsic to these species but it may confer resistance to carbapenems when its expression is up-regulated by genetic re-organization. Class B carbapenemases are also known as the metallo-β-lactamases (MBLs), they are mostly encoded by integronborne mobile gene cassettes and hence, they are transferable amongst various bacteria via horizontal gene transfer mechanisms notably conjugation. Class A carbapenemases include the Klebsiella pneumoniae carbapenemase (KPC) family that can be plasmid encoded or chromosomal.

4.9.3.2.2 *blaIMP*

The result showed negative with *blaIMP* gene of *Burkholderia cepacia* isolates. Based on recent reports, there are two major families of imported metallo-β-lactamases, IMP and VIM, that are carried on mobile gene cassettes inserted into integrons. Including those in this report, there are 18 variants of IMP metallo-β-lactamases and 11 variants of VIM metallo-β-lactamases.

The only two published reports on metallo-B-lactamases from the United States identified VIM-2 and VIM-7. Metallo-B-lactamases hydrolyze most β-lactam antibiotics except aztreonam. Therefore, many pathogens that produce these enzymes at high levels are resistant to the majority of β-lactam antibiotics, including the carbapenems. The first report of an imported metallo-B-lactamase described a *Pseudomonas aeruginosa* isolate obtained from a Japanese patient in 1988.

Since then, the occurrence of mobile genetic elements encoding metallo-B-lactamases has extended beyond *P. aeruginosa* to include many types of gram-negative organisms distributed throughout the world. Areas which have reported these types of isolates include several countries in Asia and Europe; the Americas, including Brazil, Canada, and the United States; and Australia.

4.9.3.2.3 *blaKPC*

All *Burkholderia cepacia* isolates give negative result with *blaKPC* gene.

The *blaKPC* genes that encode KPCs are present on transferable plasmids and are flanked by transposable elements, thus allowing for the gene to move from plasmid to the bacterial chromosome and back. All the carbapenem resistant isolates showed 100%
resistance to ampicillin, cotrimoxazole, all 4 generations of cefalosporins and piperacillin tazobactam. The resistance to aminoglycoside antibiotics varied from 33% for amikacin to 94% to tobramycin. In the present study, *Klebsiella* showed a 77% resistance to imipenem and 96% resistance to meropenem, while *E coli* showed 67% resistance to imipenem and 95% resistance to meropenem, blaKPC gene Detection in Clinical Isolates of Carbapenem Resistant Enterobacteriaceae were MHT negative. They may have developed a different resistant mechanism other than carbapenemase production. Resistant to both imipenem and meropenem is a strong indicator of carbapenemase production rather than resistance to either one of the carbapenems, as this may imply a different resistance mechanism (14).

4.9.3.2.4. **blaCTX-M** gene

The result showed that the blaCTX-M resistance gene was detected in and 6/8 *Burkholderia cepacia* as in figure (2).

Figure (2): PCR amplification products of *Burkholderia cepacia* isolates that amplified with **blaCTX-M** gene primers with product 554bp. Lane (L), DNA molecular size marker (100-bp ladder), Lanes (1,2,3,4,6,7) show positive results with **blaCTX-M** gene.

ESBLs are one of the main leading causes of resistance to β-lactam antibiotics among Gram-negative bacteria. These enzymes are plasmid-encoded β-lactamases that mediate resistance to penicillins, first-, second- and third- generation cephalosporins, such as cefotaxime, ceftriaxone, and ceftazidime. TEM, SHV, and CTX-M are the major genetic groups of ESBLs amongst clinically important Gram-negative bacteria. These enzymes are most commonly found in *Klebsiella pneumoniae* (K. pneumoniae) and Escherichia coli (E. coli) and are also observed in other clinical isolates of Enterobacteriaceae and Pseudomonas (15). The first TEM-type β-lactamase, produced by a clinical E. coli strain, was reported in 1965. The TEM-type ESBLs are derivatives of TEM-1 and TEM-2. The SHV-type ESBLs may be found in clinical isolates more frequently than any other types of ESBLs and have been reported from several countries in Europe, such as Austria, France, Italy, and Greece, as well as in the United States and Australia. The CTX-M-type ESBLs developed from TEM and SHV and can be divided into five subgroups according to their amino acid sequence simi-larities, including CTX-M-I, CTX-M-II, CTX-M-III, CTX-M-IV, and CTX-M-V (16).

Evaluation the Antimicrobial Effect of Glycerin Magnesia on Some Bacteria, in-Vitro Study

Maher Saber Owain¹, Khalid Ismael Oleiwi², Ali Ghazi Atiyah¹, Mustafa Salah Hasan¹
¹Department of Internal and Preventive Veterinary Medicine, College of Veterinary Medicine, University of Tikrit/Iraq, ²College of Veterinary Medicine, University of Fallujah

Abstract

This study was aimed to assess the efficacy of glycerin magnesia on some bacteria. A thirty percent of glycerin magnesia were prepared as explained below. Many types of bacteria including Proteus spp., Staphylococcus aureus, Staphylococcus epidermidis, Acinetobacter, E. coli, Pseudomonas aeruginosa, Salmonella spp. were selected for this study and obtained from university of Tikrit, college of veterinary medicine. A bacterial broth were prepared, a then a sterile swab were emulsify in these broth and streaked on muller hinton agar plate and allowed till dry, then a holes were filled with a given glycerin magnesia and incubated for 24hrs. at 37°C. The results showed that a higher antibacterial effects of glycerin magnesia against Staphylococcus aureus followed by Proteus spp., Pseudomonas aeruginosa, Salmonella spp., Acinetobacter, E. coli, Staphylococcus epidermidis respectively.

In conclusion, the glycerin magnesia have a wide range antibacterial effect and can be used in future in wound healing.

Key words: glycerin magnesia, bacteria, in-vitro.

Introduction

Magnesium (Mg) is an important ion found in the body human and animals, and may be observed as a drug with numerous clinical uses (1). The total magnesium in human and animal body were 53 % stores in the bones, 27 % in muscle, 19 % in other soft tissues, about 0.5 % in the RBCs and about 0.3 % in the serum (2). About half of Magnesium are existing as free and doesn’t bound with albumin or other ion (3).

Magnesium sulfate (MgSO4) is a solid, odorless material that present as crystal powders or as colorless crystals needle like or as a crystalline powder with white color (4).

Magnesium sulfate have a wide uses in building, industrial/processing, agriculture, special care products, medicine, food processing (5).

Ismail & Shaker (7) reported that MgSO4 with glycerin have an antibacterial effects when used on wound. The addition of glycerin as a vehicle for MgSO4, some reported that glycerin increase the antimicrobial activity of material that emulsify in it (8).

The most pathogenic bacteria for human and animals were reported including Salmonella (9-13), E. coli (14-17), Staphylococcus spp. (18), Proteus spp. (19).

The current study aimed to assess the efficacy of glycerin magnesia against some bacteria.

Materials and Method

Glycerin Magnesia (30%): The mixture was
prepared by dissolved a 30 g of MgSO4 in 30 ml heated distilled water and mixing thoroughly. After a complete dissolving of MgSO4, the glycerin was added slowly to the mixture till a final volume of 100ml and using heat and continual stirring.

Many types of bacteria including Proteus spp., Staphylococcus aureus, Staphylococcus epidermidis, Acinetobacter, E. coli, Pseudomonas aeruginosa, Salmonella spp. were selected for this study and obtained from university of Tikrit, college of veterinary medicine. Each type of these bacteria were inoculated in 5 ml nutrient broth and incubated for 24hrs., then a sterile swab were emulsify in these broth and streaked on muller hinton agar plate with a central hole (which made in each of the plate with a sterile 2.0 mm diameter cork borers) and allowed till dry, then a holes were filled with a given glycerin magnesia and incubated for 24hrs. at 37°C.

Results and Discussion

The current results obtained were showed a higher antibacterial effects of glycerin magnesia against Staphylococcus aureus followed by proteus spp., Pseudomonas aeruginosa, Salmonella spp., Acinitobacter, E. coli, Staphylococcus epidermidis respectively (Table 1) (figures 1, 2).

It has been reported that Mg alone has an antibacterial effect invitro by reduction the bacterial growth and prevent the formation of biofilm by increasing of local alkalinity (20). Robinson et al. (21) suggested that the alkaline pH was liable for the significance decreasing of CFU/ml1.

Another researcher reported that the pH and the graded charge were significant in prokaryotic physiology in production the proton motion force that used to do the useful work for bacteria, also reported that a pH is important for extra and intracellular environments favored for growth of organisms (22). Also, other researcher reported that some biomaterial have an ability to yield the alkaline pH which give rise the antibacterial mechanism (23, 24).

Li et al. (20) reported that pure magnesium when added to medium has a full effect on MRSA when tested in-vitro.
Also, Crisler et al. (25) found that the increasing medium salinity to 10% MgSO4 reduced the number of *Pseudomonas*. However, a report of Marnocha et al. (26) suggested that MgSO4 at 10% reduce the growth of most tested bacteria.

Many studies have been suggested that there was an association amongst the cell membrane fluidity and the stress tolerance. The structure of cell membrane fatty acids is liable for preservation of cell membrane fluidity. The most consequences of altering in fatty acid of cell membrane in most microorganisms are inflection the action of cells intrinsic proteins which achieve many purposes for example uptake of nutrient and ion pumping (27). The treatment by using alkaline material resulted in alterations in fatty acid composition of the cell membrane for some bacteria especially *E. coli* and *Salmonella Spp.* which leading to reduction in number of these bacterial types (28).

**Conclusion**

Glycerin magnesia have a wide range antibacterial effect on many bacteria especially *S. aureus*, *Pseudomonas* and other, the future study will use this preparation in wound healing.

The Role of CTX-II, Dyslipidemia, Vitamin D in Polycystic Ovary Syndrome

Samah Amer Hammood1 Alaauldeen S. M. AL-Sallami2

1Lecturer: Laboratory Investigation department / Science Faculty / Kufa University, Iraq, 2Prof: Department of Biology, Science Faculty / Kufa University, Iraq

Abstract

This study aimed to study the serum measurement of clinical value of type II collagen (CTX-II) in syndrome of polycystic ovary in women and indicter as osteoarthritis disease marker analyzed in future levels with a recent available immune enzyme-linked sorbent assay (ELISA) kit. For increasing sensitivity test, the protocol was modified. Levels of CTX-II increased significantly as well total protein, while decrease vitamin D and difference in lipid profile were practical between the patients compared with healthy women’s. The obtained results suggested the monitoring interest of the serum CTX-II for the OA development in patients of polycystic ovary syndrome in women and the relevance of the analysis of multiple time point for this biomarker.

Keyword: CTX-II- Biomarkers- OA Osteoarthritis- Polycystic ovary syndrome- Dyslipidemia.

Introduction

Syndrome of polycystic ovary (PCOS) is a hard condition with characteristics of prominent levels of androgen, irregularities of menstrual and/or small cysts on either ovaries or both (1). This disorder might be of ovaries morphological polycystic or hyper androgenemia predominantly biochemical. Hyper androgenism, is a PCOS clinical hallmark result of inhibition of follicular progression, ovaries microcysts, , changes in menstrual and ovulation (2). Investigations proposed that (5% to 10%) females of age 18 - 44 years are PCOS affected, rendering it the most well-known abnormality of endocrine among females of reproductive age in U.S.A. (3). Women looking for assistance from professionals in health care to address issues of excessive hair growth, obesity, acne, infertility, and amenorrhea most of the times receive a PCOS diagnosis and have cancer of endometrial at higher rates, TIIDM, dyslipidemia and cardiovascular disease (4).

PCOS pathophysiology involves defects primary in insulin secretion and action, ovarian function, and the hypothalamic–pituitary axis. Although the unknown cause of PCOS, PCOS has been connected to obesity and insulin resistance (5). There are 3 most well-known elements with PCOS associated i.e. irregularities of ovulation, androgen levels enhancement, and problems of cystic ovaries with elevated androgen levels and ovulation take place in most PCOS women (24, 26). Furthermore, alopecia, hirsutism, and acne are directly associated with elevation levels of androgen and the ovaries prevalence of polycystic on pelvic ultrasound more than 70% in PCOS patients (6).

After diagnosing PCOS, investigations prove that patients over 50% have diabetes or pre-diabetes, and there is risk increasing of hypertension, myocardial infarction (MI), dyslipidemia, osteoarthritis sleep apnea, anxiety, depression, and endometrial cancer. Furthermore, PCOS pregnant women should be noticed for increasing miscarriage rates, pre-eclampsia, premature delivery, and gestational diabetes (7). Osteoarthritis defined as a disease with developing articulate cartilage destruction and by changes pathologically in the subchondral bone and synovial membrane OA, the destruction will result in losing the 2 major components, type II collagen and proteoglycans, rendering them choice markers in determining metabolism of cartilage (8). Peptide of C-telo of collagen type II (CTX-II) is marker most studied (9). Increasing levels were documented in OA patients.
in comparison to subjects of asymptomatic or without OA signs (10). A significant association have shown between CTXII concentration and OA radiographic development (11). The goal of this investigation was to study the serum measurement of clinical value of CTX-II in polycystic ovary syndrome patients and correlated with physiological assessment that give indicator to development of Osteoarthritis in future.

**Methodology**

Serum specimen was collected from patient with infertile Polycystic Ovary patients (n = 45) and healthy patient (n=45) at AL-Sader laboratory of Medical city in Najaf Province, AL-Najaf Health Directorate / Ministry of Health /Iraq. The average of the patient’s age was (32.81±51) years. All reagents and specimens should be at a temperature of room before use. Reagents mixed in soft way with no foaming. No interruption should take place once the protocol started Tests of biochemical were performed at Biology laboratories. in this study was CTX-II protein (MBS2507692), vitamin D3 (MBS773966) , HDL (MBS170439) , VLDL(MBS265004), total protein (MBS2540455) and LDL (MBS162140) My Bio Source Company USA in Origin.

**Statistical Analysis**

Statistical analyses of all result were carried out by the help of Graphpad prism version 5) software statistical package using t-test (with p value at level of significant less than 0.05) to compare values of result between groups.

**Results**

The result show an increase of significant for protein of collagen matrix Type II figure( 1) in patient with Polycystic Ovary(mean± Std. Error 3.98±0.67) compare control group (mean± Std. Error 2.62±0.71) which that may be cause by the extracellular adhesion molecule is soluble from the cartilage surface component. Enable the binding of cartilage cells to type II collagen in the absence of serum, thereby increasing protein externally, we conclude that direct interaction between cartilage cells and type II collagen occurs through other adhesion mechanisms of cell surface proteoglycans such as membrane-bound heparin sulfate in progressive age (12). Few studies revealed a significant relation between concentration of CTXII and OA radiographic development (13). Recently, urinary levels predictive value of CTX-II for cartilage losing was assessed through MRI (14).

![Figure 1: levels of Type II protein collagen matrix protein in patients comparison to Healthy group](image)

These results was show a decrease of vitamin D3 in patient with Polycystic Ovary (mean± Std. Error 12.5±0.17) compare control group (mean± Std. Error 24.4±0.91) figure (2), Probably Vitamin D deficiency may be associated with populations with extensive skin coverage, especially in women in Iraq. There is a large body of proof the importance of vitamin D in reproductive function because VDRs have been detected in placenta, the endometrium and ovary (15). Deficiency of Vitamin D is associated with deregulation of Ca, which participates in the follicular arrest development in PCOS women resulting in dysfunction fertility and menstrual (16). Some study on PCOS women with and undergoing fertilization in vitro (IVF), they found that the women who achieved pregnancy exhibited significantly higher levels of follicular fluid of 25(OH) D and each ng/ml elevate in follicular fluid 25(OH)D elevated the likelihood for pregnancy achievement by 7% (17). Moreover, deficiency of 25(OH)D was related with rates of lower development for pregnancy and follicle after clomiphene-citrate stimulation in PCOS women, suggesting a possible vitamin D supplementation role in PCOS infertile women who undergo stimulation of ovarian (18).
The results revealed an increasing levels of significant in LDL level in patient with polycystic (mean± Std. Error 118±0.64) ; control group (mean± Std. Error 44.4±0.26) figure(4), also The result show decrease significant level in HDL level in patient polycystic (mean± Std. Error 39.4±1.14) ; control group (mean± Std. Error 49.4±2.41) figure (5),suggests that the level of LDL, HDL, insulin, glucose, apolipo protein A1, and lipoprotein a, in female with and without PCOS do not show any significant differences (20). Similarly, Jahanfar et al., in a study aimed at evaluating the genetic and environmental factors affecting lipids among twins, found no significant difference (21). The research concluded that the serum CTX-II in women with PCOS may appear to have symptoms of Osteoarthritis and thus it is considered to be a vital reliable evidence in the news of the occurrence of this disease in PCOS women.
Results proved a significant enhancement of VLDL level in patient (mean± Std. Error 29±2.34) ; control group (mean± Std. Error 20±2.64) figure(6) . Disturbances in metabolic are famous clinical syndrome characters, especially, dyslipidemia which is very well-known abnormality metabolic in PCOS female with a prevalence of up to 70% (22,23). Resistance of insulin is a key PCOS pathophysiology and dyslipidemia in PCOS women may be therefore in accordance with that detected in the insulin resistant case: decreasing levels of apolipoprotein (Apo) A-I, and high-density lipoprotein-cholesterol (HDL-C), and increased levels of ApoB, triglycerides (TG) and very low-density lipoprotein(24, 25, 26).

**Figure 6: levels of VLDL in patients comparison to Healthy group**

**Conclusion**

The research has a goal of examining the clinical value of the serum which was measured type II collagen (CTX-II) in the Polycystic ovary syndrome in the women and indictor as a marker of the (OA)disease of future levels. An important percentage increased in CTX-II levels, and the total protein but a decrease occurred in vitamin D and with a change in lipid profile which was in practical status between the patients compared with healthy women.

Abstract

Introduction: Breast cancer (BC) is a common form of cancer among women globally. It is considered 5th cause of death in females with equally to 522,000 patients / year (1). Nowadays it is considered 15.4% of death in developed countries after lung cancer. In developing nations, breast cancer considered the 1st cause of death for females 324,000 cases of deaths (14.3%) for total deaths. Method: One hundred and six female patients with breast lesion were collected from the Al-Hussein Teaching Hospital Laboratory/Histopathology department –Al-Muthanna province, during the period from January 2018 to January 2020. The data for cases were collected to study the age, type of breast lesion whether benign or malignant. Haematoxylin/Eosin staining done in Al-Hussein Teaching Hospital Laboratory / Histopathology department. Results: Cross sectional study for 106 patients done in Al- Muthanna proven for assessment breast mass and identify malignant and benign lesion, mean age of patients was (39.4 ± 15.8) years old, with min age 13 years and max age was 81 years old. Types of biopsy taken from surgeon were 71% excisional biopsy, 21% mastectomy and 8% true cut biopsy. After pathological assessment of biopsies showed 51% malignant and 49% benign. In addition, this assessment distributed as following: fibroadenoma 31.1%, IDC/ grade II 29.2%, IDC/ grade III 9.4%, ILC and fibrocystic changes 5.7% and IDC grade I 3.8% and other types of malignant and benign after pathological assessment. Significant association between age groups and cancer of breast. Conclusion: After pathological assessment of biopsies, malignant breast cancer (IDC/ grade II, IDC/ grade III, ILC and fibrocystic changes) most common changes, significant association between age group and breast cancer development more age group 41- 50 years old and then (31– 40), (51– 60) years old respectively.

Key words: Prevalence, histopathological diagnosis, breast lesions, Al-muthanna province

Introduction

Breast cancer (BC) is a common form of cancer among women globally. It is considered 5th cause of death in females with equally to 522,000 patients / year (1). Nowadays it is considered 15.4% of death in developed countries after lung cancer (2). In developing nations, breast cancer considered the 1st cause of death for females 324,000 cases of deaths (14.3%) for total deaths (2,3). This rate changes from 6 – 20 / 100.000 in West Africa and East Asia (4). The incidence in 2012 in females reach to 1.7 million (25% of entirely cancers), 883,000 patients in developed country in contradiction of 794,000 in developing nations (4,5).

The incidence was increase in age after 35 years old and peaking in 60 years old (6).

Mortality rate depend on age of females, staging of malignancy, treatment respond, metastasis of malignancy, main reasons of breast cancer is hormonal factors, genetic tendencies, behaviors and ecological reasons (7).
Benign Breast Diseases (BBDs) is not cancer. Most usual reason of breast difficulty in women and more usual than malignancy (8, 9). It is more usual than malignancy in western countries (10). More than 30% of women with BBD need treatment where survive (11). A three-ways for evaluation done by clinical assessment: US and mammogram, pathological assessment, central needle biopsy. Most women with BBD not have risk of development of breast cancer, so early diagnosis and treatment is important to remove the anxiety especially women with family history of breast cancer and must follow up annually. Most common BBD is fibro adenoma (12). Two types of breast cancer (cancer in situ): Ductal carcinoma in situ. (DCIS) 83% of all cases 2010-2014 unusual cells substitute usual epithelial cells around ducts of breast and metastasis to the lobules in addition to the ducts; it is can or can not developed to the aggressive malignancy it is grow slowly without any management it is misdiagnosis with benign 20%-53% diagnosed with an invasive breast malignance for 10 years or more. Lobular carcinoma in situ.: 13 % of patients, atypical cells developing inside and growing about some of breast lobules. It is not precursor of invasive cancer, but considered one of strong cause of invasive cancer. The aim of study is to show proportion of benign and malignant breast lesions and types of malignancy tissues by pathological assessment and relation of malignancy with increase age of females (13-15).

**Method**

One hundred and six female patients with breast lesion were collected from the Al-Hussein Teaching Hospital Laboratory/Histopathology department –Al-Muthanna province, during the period from January 2018 to January 2020. The data for cases were collected to study the age, type of breast lesion whether benign or malignant. Haematoxylin/Eosin staining done in Al-Hussein Teaching Hospital Laboratory / Histopathology department.

**Specimens:**

The one hundred and six cases classified into benign and malignant breast lesions. From each formalin fixed paraffin embedded tissue, one section of 5-micron thickness was obtained and stained by haematoxylin and eosin staining method for evaluation of morphology.

Methods of staining procedures:

The following steps were applied for (H&E) staining method.

a) Deparaffinization: This done by adding the following:

1. 5 min. period adding Xylene.
2. 5 min. period adding Xylene.
3. 5 min. period adding 99 % ethanol
4. 5 min. period adding 99 % ethanol
5. 5 min. period adding 99 % ethanol
6. 5 min. period adding 99 % ethanol
7. 5 min. period adding 99 % ethanol
8. 5 min. period adding 95 % ethanol
9. 5 min. period adding 70 % ethanol
10. Purified water.

b) Hematoxyline and eosin staining method:

1. Dewax sections (deparaffinization as above).
2. Stain in hematoxyline for 3-10 minutes.
3. Wash well in running tap water.
4. Remove excess stain by differentiating the sections in 1% acid alcohol (1% in HCL 70% alcohol) for 5-10 seconds.
5. Wash well with in tap water until sections regain their blue color.
6. Stain in eosin for 2-5 minutes.
7. Dehydrate slowly through increasing grades of alcohol (i.e.70%, 90% and 100%).
8. Clearing by xylene.
9. Mount wit DPX.

Statistical analysis done by SPSS 22 calculated mean and SD with percentage and frequency. Chi square use for revealed association between age groups and behavior of tumor, significant association when P-value less than 0.05.

**Results**

Cross sectional study for 106 patients done in Al-
Muthanna proven for assessment breast mass and identify malignant and benign lesion, mean age of patients was 
(39.4 ± 15.8) years old, with min age 13 years and max age was 81 years old. Types of biopsy taken from surgeon 
were 71% excisional biopsy, 21% mastectomy and 8% true cut biopsy as showed in fig (1). After pathological 
assessment of biopsies showed 51% malignant and 49% benign as in fig (2). In addition, this assessment distributed 
as following: fibroadenoma 31.1%, IDC/ grade II 29.2%, IDC/ grade III 9.4%, ILC and fibrocystic changes 5.7% and 
IDC grade I 3.8% and other types of malignant and benign after pathological assessment showed in fig (3).

Fig (1): distribution of types of biopsy.

Fig (2): distribution of behavior of biopsy after pathological assessment.
According to association between ages groups and behavior of lesion either benign or malignant, there is significant association between age groups and cancer of breast, 37% of females in age group 41-50 years old with malignant breast cancer, while 20% of malignancy in age group (31-40) and (51-60) years old. 13% of malignancy in age group 61-70 years old and only 6% in female over 71 years old age. As show in table (1).

Discussion

Cancer is illnesses that lead the cells in body loss of control and change. All types of cancer cells finally changes to lump or mass that named cancer, and this malignant tumor called according to the site form it the tumor originate. Breast cancer start from gland of breast tissue that lead to production of milk called (terminal duct lobular unit). Other parts of breast tissue consist of connective, fatty and lymphatic tissues (16).

According to our study, mean age of patients was (39.4 ± 15.8) years old, with min. age 13 years and max. age was 81 years old. These results similar to study done by Augustin et al. showed the age extended since 16 - 90 years by a mean of 45.83± 13.5 years old (17). Zhi-Gang Yu et.al. Also, have the same results that mean age of patients was (44 ± 11.6) years old (18)characteristics and related factors of breast cancer among women in Eastern China. A total of 122,058 female subjects completed the study, with 320 confirmed cases of breast cancer (crude prevalence: 262.5/100,000; standardized prevalence: 207.7/100,000.

In our study the types of biopsy taken from surgeon were 71% excisional biopsy, 21% mastectomy and 8% true cut biopsy this is similar to Augustin et al. that showed, the total of cases that take and examine by pathologist contain of 69% of lumpectomy then 30% biopsy of breast.

After pathological assessment of biopsies in our study showed 51% malignant and 49% benign while in another study the proportion was around 4:1 or 5:1 (19), this different is due to sample collection or may be due to high no. of malignancy of breast in al-muthanna province.

In addition, this assessment distributed as following: fibroadenoma 31.1%, IDC/ grade II 29.2%, IDC/ grade III 9.4%, ILC and fibrocystic changes 5.7% and IDC grade I 3.8% and other types of malignant and benign after pathological assessment this results similar to Augustin et al. that showed he predominant tumor histological designs IDC 113 (64.9%), ILC 17 (9.8%) then histological designs were invasive ductal carcinoma 113 (64.9%), invasive lobular carcinoma 17 ductal carcinoma in situ 10 (5.7%) and medullary ca. 5 (2.8%) (17). Similar features diagnosed by Ohene et al. (20); detailed that 53.7% of grade III, 31.5% of grade II and 14.8% of grade I. Essiben et al. showed a propensity in the following course of incidence: grades II, I besides III to the Yaoundé Gynecological Obstetric and Pediatric Hospital (21)which is a referral centre for gynecological malignancies. METHODS: It was a retrospective descriptive study over a period of four years, from June 1(st. Koffi et al. presented that tumor grade II exemplified 58.4% of females, however grade I in addition II were in the comparable amount (20.8%) (22)which is a referral centre for gynecological malignancies. METHODS: It was a retrospective descriptive study over a period of
four years, from June 1st. These results are conflicting to those reported by Meye et al. that, the grade II detained the past location after grade I and III (23) which is a referral centre for gynecological malignancies.

METHODS: It was a retrospective descriptive study over a period of four years, from June 1st.

According to association between ages groups and behavior of lesion either benign or malignant, there is significant association between age groups and cancer of breast, 37% of females in age group 41-50 years old with malignant breast cancer, while 20% of malignancy in age group (31-40) and (51-60) years old. 13% of malignancy in age group 61-70 years old and only 6% in female over 71 years old age. Augustin et al. stated the same results that most patients in ages of 35 to 44 and 45 to 54 with 28.2% and 29.3% correspondingly. We can roughly that the major people found is dependable with some preceding studies approved globally (24, 25).

Another study done by Hai-long Chen et al. showed that age groups from 50-59 years old was most group with breast cancer (26.4%), less than 30 years old and less than 40 years old represented low mount of patients (6.4%) (26). In another study stated that 6.4% of patients with breast cancer younger than 40 years old while 93.6% of them more than 40 years old, so the incidence of females to developed breast ca. was more in age group more than 40 years old so all women must do routinely breast cancer screening (27).

Conclusion

After pathological assessment of biopsies, malignant breast cancer (IDC/ grade II, IDC/ grade III, ILC and fibrocystic changes) most common changes, significant association between age group and breast cancer development more age group 41-50 years old and then (31-40), (51-60) years old respectively.

A Histological and Histochemical Study on Olfactory Bulbs to Detection Amyloid Protein Depositions by Congo-Red and Routine Staining Techniques

Rajaa Ali Moheiseen Al- Taei, Muna Hussain Al-Aameli, Yarub Modhar Al-Qazwini

Abstract

In this study, histological and histochemical techniques were used to examine olfactory bulbs in the albino rat male. Thirty male albino rats were split into three age groups (10 animals each) in the current research: Group I: consider as a control group, including adult animals aged 3 months. Group II: include animals aged 6 months. Group III: include animals aged 12 months. The histological architecture of the layers of olfactory bulbs and their main cells was identified by using H & E staining techniques, meanwhile the composition of each layer in albino rat was evident. In the glomerular and mitral cell layer of group III, olfactory bulbs showed reduced neural density. Modified staining with Congo - red was conducted for histochemical studies. Compacted amyloid cores were found in group III animals’ olfactory bulbs, while dispersed amyloid cores were found in group II&III olfactory bulbs’ cortex. The present study adds to our knowledge of the impact of amyloid protein on olfactory bulbs and their prospective neurodegeneration involvement.

Key words: Histology, Histochemistry, Congo red, Amyloid, Granular cells, Mitral cells and olfactory bulbs.

Introduction

In the olfactory signal conductive path, the olfactory bulbs are the station of relay. The OBs are the first chief relay in the processing of odor data process: it provides afferent input from olfactory sensory neurons (OSN) in the olfactory epithelium of the nasal cavity and responsible for the identification of odors in it: which is the only relay between the peripheral and central nervous system, it also processed the olfactory data. The olfactory bulb’s main histological architecture involve: olfactory nerve layer, glomerular olfactory layer, external plexiform layer, mitral cell layer, inner plexiform layer and granular cell layer. The superficial olfactory nerve layer contains afferent axons from OSNs. OSN axons synapse with OB projections of neurons dendrites, mitral / cells, and sub aggregations of regional periglomerular cells (Pgm). These layers are arranged in the olfactory bulbs very obviously and regularly. The characteristics of olfactory bulbs structure facilitate the processing of data and also provide a scaffold for olfactory data spatial encoding.

The olfactory bulb consists of four types of cells: mitral cells, granular cells, tufted cells and short axon cells according to classical studies. One of these neurons, granular cells, have long been known to be morphologically uncommon because they don’t have a standard axons, and recent studies in electron microscope have demonstrated that it participate in special reciprocal synaptic connections with mitral cells. Mitral cells are the biggest cells in the olfactory bulbs and as stated by electron and light microscope researches, moreover they are the main olfactory bulb efferent neuron. The dendritic structures of mitral cells can be subdivided into primary and secondary dendrites, and both primary and secondary smooth dendrites pass through the surface of the outer plexiform layer and only the primary dendrites extend down to the olfactory glomerular layer. Within the glomerular layer the dendrites of mitral cells are in synaptic communication with olfactory nerves and periglomerular cells, but the only synapses on mitral cells elsewhere are the “reciprocal synapses” with the granule cells. Mitral cells, as the main olfactory bulbs efferent neurons, play a significant role in olfactory signal conduction and modification.
Amyloids β (AB) are little pieces of a bigger proteins named “amyloid precursors protein” APP. While the ordinary function of APP has not yet been determined by researchers, they understand a lot about how it appears to operate (16). In its full shape APP ranges from the inside of the brain cells to the outside through the fatty membrane around the cells. As APP is activated to perform its normal activities, other protein can cut it into different and smaller parts inside and outside cells. APP can be cut in several aspects: under some conditions, β-amyloid is one of the parts generated (3).

According to the hypothesis of amyloid, phases of beta-amyloid aggregations interrupt cell-to-cell communication and activate immune cells, these cells of immune system cause inflammation (12).

The process of neurodegeneration in diseases of cognition (Alzheimer’s and Parkinson’s diseases) may involve toxicity of β-amyloid (Aβ) that could be demonstrated in vitro and seems to be involving oxidative stress, this underlie the progression of neurodegeneration that consider as characteristic feature of AD (2).

It has been shown that the amyloid induces neuronal death, reduced plasticity of synapses, aberrant axons growth, tau hyper phosphorylation and chronic inflammation (7). Aβ accumulation in the pathogenesis of AD is an early and essential case. First formation of temporal cortical regions, including the hippocampus, a memory-creating zone. Aβ aggregates have been indicated to form neurotoxic plaques that contribute to neurodegeneration accompanied by dementia (15).

Similarly, (11) showed that capillaries, venioles and arterioles in the cerebral cortex also often have amyloid deposits. Congo red staining was considered as an approved histochemical marker for amyloid β-pleated-sheet (14). Congo red: amyloid detection in tissue parts is significantly improved and verified by favorable Congo red staining. Thioflavin S and Congo red are represented the main histological stains that used for any type of amyloid (17).

Red stain is red-pink on its own. Under both light and polarized light microscopy, examination of tissue segments suspected of participation by amyloidosis must be carried out. Amyloidosis has a distinctive green apple birefringence when polarized (11).

In this study we analyzed the histological structure and histochemical (Congo red for amyloid protein) characteristics of OBs in order to evaluate the presence of amyloid depositions in the olfactory bulb layers. The aim of this research is to clarify the amyloid-histochemical and histological characteristics of olfactory bulbs in the rats of albino male in relation with aging.

Material and Method

Experimental Animals:

Male albino rats aged between (3, 6, 12) months were obtained from the Animal House, Collage of Science, University of Babylon. The rats were housed in wire mess cages under standard condition with 12 hrs. Light and 12 hrs. dark cycle throughout the entire experimental period. Food and tap water supplied with libitum.

In the current research, thirty male albino rats will be split into three age groups (10 animals each), they are: Group I: considered as a control group, including adult animals aged 3 months. Group II: include animals aged 6 months. Group III: include animals aged 12 months.

Histological study:

The specimens of olfactory bulbs were taken from the brain of the albino rats, the samples were immersed in the solution of Bouins for two days. Tissue was dehydrated in graded ethanol and embedded in paraffin. 7μm horizontal sections of paraffin blocks were cut on a revolving microtome and installed on glass slides then, the following staining processes were completed (1).

Histochemical Study:

Selected sections have also been processed for histochemical amyloid protein demonstration. Sections have been deparaffinized through xylene and alcohol into tap water. Thereafter, slides are immersed in alkaline sodium chloride. Twenty minutes later, they were immersed in alkaline solution of Congo red and then marked with alcoholic potassium. Thereafter, slides are countered with alum hematoxylin and dehydrated by xylene and ethanol (6).

Results

Histological Study:

In light microscopy, the main olfactory bulbs of the adult rat consisted of six concentrated layers: 1-The olfactory nerve layer (ONL), (fig.1A, and 1B). 2- The glomerular layer (GML). There were observation of
periglomerular cell (Pgm) around the glomeruli (fig.1D, 1E). 3- The layer of the external plexiform layer (EPL), consists of fine nerve fibers and few granule cells, (fig.1A, 1B). 4- A layer of mitral cells (MCL) contained stomata of mitral cells in single row (fig.1A, 1B). They had an ovoid nuclei with single nucleolus deeply stained. Their cytoplasm include darkly stained basophilic granules (fig. 1C, 1E). 5-The inner plexiform layer (IPL), a thin layer of fine nerve fibers and some cells of granules (fig. 1A, 1B). 6- The layer of granule cells (GCL), contained a large amount of granule cells (fig. 1A, 1B).

Fig.1: photomicrograph of histological section demonstrated to the concentric laminar organization of olfactory bulbs, H&E staining.4x, 10x, 40x.

The olfactory nerve fibers have been loosely segregated in group III rats. With a marked decrease in size, glomeruli were distorted in form (fig. 1). The EPL included a number of misplaced mitral cells’ soma (fig.1B, 1E). Most mitral cells in MCL were decreased in size and generally present in a rounded, darkly stained nuclei with undefined nucleolus (fig.1C).

Histochemical Study:

Two forms of plaque of amyloid protein deposition were seen in the cortex of olfactory bulbs: diffuse plaques were shown in all layers of OBs of group III (fig. 2B). Compact amyloid plaques were found in the ONL, GML, MCL, and EPL layers of OBs of group III (fig. 2A, 2B). Amyloid angiophathy were detected in the different layers of OBs of group II and III, (fig.3).

Fig.2: Photomicrograph of histological section showing plaque & diffuse staining for amyloid (AB, blue row) with Congo red–stain in olfactory tissue (2A, 2B), 10 x. Fig.3 (A,B): Photomicrograph of histological section illustrated the Congo red stain highlighted the vascular amyloid depositions, note the staining of vessels walls (black & blue arrow), 40 x.
Fig.3 (A,B): Photomicrograph of histological section illustrated the Congo red stain highlighted the vascular amyloid depositions, note the staining of vessels walls (black & blue arrow), 40 x.

Discussion

In the pathway of the olfactory system, the olfactory bulbs are the essential components of olfactory system and relay station. We studied the histological architecture of the olfactory bulbs, according to the outcomes of our research, surveys were done to the structure of each layer of bulbs. The histological characteristics features of OBs constitute with the prior studies by Golgi (10). Many periglomerular (Pgm) cells were found in the layer of glomeruli of olfactory bulbs. Two groups of neuronal cells are dispersed in the layer of mitral cells of olfactory bulbs, the cells with large cell bodies and cells with small cell bodies. The cells that characterized by large cell bodies seem to be correspond to the mitral cells as output neuronal cells, and the cells with small cell bodies may relate to the tufted cells, that are well known as other kind of neurons of OBs of mammals, or the interneurons in the layer of mitral cells, but the correspondence could not be determined (5).

According to the finding of the present work, the histological characters among the bulbs of olfactory of albino rat are comparable in all groups (I, II, III), but the density of cells in each group was different. The complexity of the olfactory bulbs layers organization proportional to the olfactory bulbs information-processing capacity and represents the degree of olfactory bulb development. The results of our outcomes showed that the morphology and amount of mitral cells in the group I &III were differed (18).

The results of this research are complementary and consistent with prior human OBs tissue reports that prevalent layers (NFL, GML, EPL, MCL, IPL, and GL) constitute the construction of all layers in the olfactory bulbs of albino rats. There was no distinction in olfactory bulb composition between group (I, II, III), except for cell density variations. In group I, in each layer, the density of cells was higher than in group II and III. No mechanism exited to explain this decline. The amount of granulated cells and mitral cells decreased but increased in size (11; 9). The mitral cells considered as the largest neuronal cells in the olfactory bulbs, have primary and secondary dendrites, these processes oriented vertically or parallel to their soma, glial cells formed these dendrites of mitral cells. Axons of mitral cells converge in bundles of fibers and pass through the layer of granular cells (11).

Demonstrated a “substantial layer-specific loose” of synapses ultra-structurally: synaptic density is decreased in the layer of glomerular cells but not the internal plexiform layer, leading to unbalance in circuitry of OBs. Our findings showed a decrease in GML and MCL density, consistent with (10) findings, these results indicate that decreased afferent synaptic input and local modulatory circuit synapses in OB glomeruli may contribute to particular age related changes in olfactory function.
In the current research, we showed diffusing and plaques of compact amyloid nuclei in the cortex of OBs by using modified Congo red staining. We also showed the enhanced amount of plaques and reduced neuronal populations in group III OBs compared to the olfactory cortex of group I & II, that showed typical dark orange colored patches under light microscope. It is well known that there are plenty of extracellular plaques of amyloid β peptide (Aβ) in the pathological marks of AD in the brain (16). Amyloid has been discovered to be more localized in the neuronal processes in the current research, this finding was in agreement with the outcomes of other researchers who noted that in elderly people with and without Alzheimer’s disease abnormality amyloid accumulate as neuropil threads (11). The method of neurodegeneration in AD may involve toxicity of β-amyloid (Aβ). Aβ’s neurotoxicity can be shown in vitro and seems to involve oxidative stress (2).

Our finding demonstrated that the blood vessels within the cortex of olfactory bulbs also lades depositions of amyloid that constitutes with the results of (14). Congophilic amyloid in blood vessels is called cerebral amyloid antipathy (CAA) (17).

Many researchers have shown that the deposition of Aβ peptide in the cerebral cortex leads in neural and morphological degeneration, cognitive loss, and modulation of enzyme markers such as acetylcholine esterase and choline acetyltransferase; all of which are well-known symptoms of AD (19; 4).

2Department of Pharmacology, College of Medicine, Wasit University, Iraq

Abstract

The current-focused study was carried out to generate a data profile about expected changes that could be induced in the kidneys of rats due to the use of intraperitoneal ketoprofen (KP). The study involved using 24 adult male Wistar rats sorted randomly into four groups (six animals per group). One group was treated as a control group, C, which was supplied with distilled water (DW) only. The remaining animals were presented as (50KP), (25KP), or (12.5KP) groups that received 50mg/kg.b.w., 25mg/kg.b.w., or 12.5mg/kg.b.w., respectively, of KP. The experiment was continued for 70 days, and the kidney tissue samples were collected from the scarified animals at the end of day 70 of that experiment. The kidney tissues of the 50KP animals revealed dilation of the tubules throughout the outer strip of the outer medulla with necrosis and sloughing of the epithelial cells of the proximal convoluted tubules (PCTs). However, the 25KP group suffered lesser grades of epithelial-cell sloughing of the PCTs with lower levels of dilation of tubules than those recorded in the 50KP group. On the other hand, the kidney tissues of the 12.5KP group showed only dilation in the PCTs. The present experimental data unveil the side effects generated by the use of the intraperitoneal KP in the examined rat kidneys which should be used as a launching set of information for better use or further study this drug and its side effects in human patients.

Keywords: Ketoprofen, renal failure, side effects.

Introduction

KP is an anti-inflammatory, anti-pyretic, analgesic derivative of propionic acid with non-steroidal anti-inflammatory (NSAID) therapeutic properties. KP reduces cyclooxygenase I and II enzyme activity, which contributes to a reduction in prostaglandin and thromboxan precursor production. As a consequence, the decline in prostaglandin production triggers the therapeutic potential of ibuprofen via the enhancement of prostaglandin synthase. The production of A2 thromboxane by thromboxane synthasises, which prevent the accumulation of platelets, is also decreased with KP (1). KP is the 11th most popular in Italy with 206 records for 2008, of which some 30 percent is extreme, based on a survey of random cases of adverse outcomes. A maximum of 13 percent of reported data were in the aspect of pediatric patients (under 18 years of age), even in the age group (under six years old) of off-label medication use. The 2012 evidence is not fully accessible; however, unofficial statistics show that KP was implicated in 560 adverse drug reactions, of which 31 percent were seriously affected (2,3).

KP records are that because of the unwise consumption of KP in the world countries despite multiple warnings about hepatotoxicity compared to other NSAIDs such as nimesulide. The KP's reported adverse events contain peripheral edema as a cardiovascular response, central responses such as drowsiness, headache, etc., dermatological responses including skin sensitiveness and photosensitization, blood based responses e.g. edema, platelet malfunction, etc., kidney, elevation of enzymes in the liver, gastrointestinal reactions for example vomiting, diarrhea, gastric ulcer and bleeding, etc. Additional studies have shown at least intermittent serum aminotransferase elevations ranging between one percent and two percent of the patients receiving KP. Even with product continuity, these can be

Corresponding author:
Samer Riyadh fadhil
Email: Sfadhil@uowasit.edu.iq
overcome. For less than one percent of cases, reported elevations of aminotransferase (more than threefold increased) exist. It is very unusual that liver damage with KP jaundice is clinically evident and only few cases have been recorded. The latency to onset of the symptoms is a quick process, sometimes appear within a few days. The trends of enzyme changes differ between hepatocellular and cholestatic. In some instances, immunoallergic symptoms (low level fever, rash) are observed, but are not usually prevalent and self-antibody development is uncommon (4,5).

The performance of adverse KP effects on the kidney have not been comprehensively studied from the prospective of tissue damages. According to that, the current-focused study was carried out to generate a data profile about expected changes that could be induced in the kidneys of rats due to the use of intraperitoneal KP.

**Materials and Method**

**Animals and experimental design**

The study involved using 24 adult male Wistar rats, weighed at 175-250gm with 10-14 weeks of age, sorted randomly into four groups (six animals per group) that lived in a housing under 22-25°C. One group was treated as a control group, C, which was supplied with distilled water (DW) only. The remaining animals were presented as (50KP), (25KP), or (12.5KP) groups that received 50mg/kg.b.w., 25mg/kg.b.w., or 12.5mg/kg.b.w., respectively, of KP. The experiment was continued for 70 days, and the kidney tissue samples were collected from the scarified animals at the end of day 70 of that experiment.

**Kidney tissue preparation**

Ten percent formalin was used for fixing the tissue specimens for two hours that was followed by a 30-minute-DW based removal step of the fixative. Then, a series of alcohol concentrations at (70% for 30mins, 90% for 60mins, and 100% as two cycles for 60mins per cycle) was used to dehydrate the tissues followed by a 50%:50% of alcohol to xylene immersing step for clearing the tissues for 60mins. After that, the tissues were immersed in a pure xylene for 90mins. Later, molten paraffin wax was used to impregnate the tissues followed by embedding and blocking out those tissues. Paraffin based sections at 4 to 5um were hematoxylin- and eosin-stained. The tissue sections were prepared according to (6–8).

**Results**

The kidney tissues of the 50KP animals revealed dilation of the tubules throughout the outer strip of the outer medulla with necrosis and sloughing of the epithelial cells of the PCTs, figure 1.

![Figure 1: Rat kidney histopathological changes after intraperitoneal ketoprofen treatment at 50mg/kg.b.w. for 70 days. A. Dilation of the tubules throughout the outer strip of the outer medulla. (H&E) Stain.400X. B. Necrosis and sloughing of the epithelial cells of the proximal convoluted tubules. (H&E) Stain.200X.](image-url)
However, the 25KP group suffered lesser grades of epithelial-cell sloughing of the PCTs with lower levels of dilation of tubules than those recorded in the 50KP group, figure 2.

![Image](https://example.com/image1)

**Figure 2:** Rat kidney histopathological changes after intraperitoneal ketoprofen treatment at 25mg/kg.b.w. for 70 days. Changes are shown, here, as lesser grades of epithelial-cell sloughing of the proximal convoluted tubules and lower levels of dilation of tubules than those recorded in the 50KP group. (H&E) Stain.200X.

On the other hand, the kidney tissues of the 12.5KP group showed only dilation in the PCTs, figure 3. The KP group kidney tissues were compared to each other and with the control group, figure 4.

![Image](https://example.com/image2)

**Figure 3:** Rat kidney histopathological changes after intraperitoneal ketoprofen treatment at 12.5mg/kg.b.w. for 70 days. Only dilation in the proximal convoluted tubules is shown. (H&E) Stain.200X.
Discussion

Ketoprofen is a NSAID agent that is used for treating cases mediated by an inflammatory, fever, and/or pain process. The use of the drug as a therapeutic compound has been faced with a wide range of difficulties presented by the appearance of various adverse effects such as peripheral edema and platelet malfunction, drowsiness and headache, skin sensitiveness and photosensitization, and gastric ulcer and bleeding due to cardiovascular, central, dermatological, and gastrointestinal reactions, respectively, (9–13). The adverse KP changes occurred in the kidney have not been fully sorted out. Therefore, the current work was conducted to characterized any histopathological alterations that could happen as responses to the use of KP in three concentrations.

The outcomes of the study unveiled that intraperitoneal ketoprofen treatment at 50mg/kg.b.w. for 70 days demonstrated dilation of the tubules throughout the outer strip of the outer medulla and necrosis and sloughing of the epithelial cells of the PCTs. Ingrasciotta et al., (14) has found that using NSAID drugs such as oxicams, ketorolac, meloxicam, and piroxicam was positively correlated with the increased risk of developing chronic kidney disease (CKD). It has been suggested that utilizing ketorolac may induce CKD with a subclinical property due to acute renal damages (14). This indicates an agreement with current findings that revealed the adverse effects encouraged by the use of the NSAID, KP, in the studied rats. The adverse effects of the KP use in humans can be inferred from a case report of a Turkish woman who received a topical treatment of KP as two times daily for five days who revealed increases in the levels of serum creatinine and urea which suggested an acute renal failure condition in this women (15). The use of KP in pregnant women especially a short time before delivery has been found to increase the risk of renal dysfunction in the neonates (3). The systemic-NSAID based kidney damages can be induced via acute interstitial nephritis due to a dose-independent allergic mechanism with cyclooxygenases 1- and 2-non-selective disruption causing an acute renal failure with reversed functions of the affected tissues (15).

However, those damages in the rat kidneys were correlatively decreased as the KP concentration was reduced. This was completely seen with groups 25KP and 12.5KP that showed lower grades of kidney tissue changes suggesting safer use of the KP with reduced concentrations. It has been recognized that using low doses of KP in children had led to the development of low rates of intense adverse effects with only nausea and vomiting (3).
The present experimental data unveil the side effects generated by the use of the intraperitoneal KP in the examined rat kidneys which should be used as a launching set of information for better use or further study this drug and its side effects in human patients.

Association between IL12A Gene of G/A genotype Polymorphism and Pulmonary Tuberculosis Risk in Baghdad Population

Anwar Abed Nasser Dhabaan¹, Mayes Abdul-Hadi Mahdi²
¹Assit prof Dr., ¹Post graduate. AL-Iraqia University/ Collage of Education/department of biology, Baghdad, Iraq

Abstract
The study included eighty samples. This cases-controlled study was performed including fifty Pulmonary tuberculosis patients, their ages ranged from 12 to 77 year (27 female and 23 male) and thirty controls (healthy), their ages ranged from 19 to 58 year (15 female and 15 male). We confined the frequency of IL12A gene (G/A rs568408 genotype) polymorphism by Tetra-ARMS PCR (Tetra amplification refractory mutation system-polymerase chain reaction) technology. Also, we determined the association of IL12A Gene (G/A rs568408 genotype) polymorphism with Pulmonary tuberculosis patients in Baghdad. Statistical results showed significant difference in genotype frequency of IL12A Gene (G/A rs568408 genotype) polymorphism between Pulmonary tuberculosis patients and control (healthy). The G allele shows high frequency in Pulmonary tuberculosis patients comparison with control (healthy) and present related with etiological fraction risk of Pulmonary tuberculosis patients and its ratio 62% in patients and 51.67% in control (healthy), While A allele shows high frequency in control (healthy) comparison with Pulmonary tuberculosis patients and present related with protective fraction of Pulmonary tuberculosis patients and its ratio 48.33% in control and 38% in Pulmonary tuberculosis patients. The genotypes of GG and AA homozygotes shows high frequency in Pulmonary tuberculosis patients comparison with control (healthy), and its ratio 42% and 18% respectively in Pulmonary tuberculosis patients, while its ratio 3.33% and 0% respectively in control (healthy), also GG and AA genotypes appear related with etiological fraction risk of Pulmonary tuberculosis patients, while the GA heterozygote show high frequency in control (healthy) and its ratio 96%, GA genotypes related with preventive fraction of Pulmonary tuberculosis patients. Our findings demonstrate that the IL12A Gene (G/A rs568408 genotype) polymorphism may represent a significant risk factor for pulmonary tuberculosis patients in Baghdad population.

Keywords: IL12A Gene, Pulmonary Tuberculosis, Polymorphisms, Tetra-ARMS PCR

Introduction
The Pulmonary tuberculosis (TB) is a major cause of morbidity and mortality throughout the world, especially in Asia. The statistical data showed 9.6 million new cases and 1.5 million deaths, based on the WHO (World health organization) of 2015 year¹. TB caused by Mycobacterium tuberculosis is an aerobic rode and intracellular pathogenic bacteria which have target the lungs and causative agent of tuberculosis ². Cytokines are pivotal in activation of the cell mediated immunity required for controlling of intracellular growth and eliminating of pathogens ³. Interlukin-12 cytokine play an important role in immune response of Mycobacterium tuberculosis ⁴, and mainly produced by immune cells (macrophages and dendritic cells) ⁵. IL-12 induces T lymphocyte cells and Natural Killer cells to produce pro-inflammatory cytokines such as TNF-α and IFN-γ in the immune response of pulmonary tuberculosis ⁶. IL12A gene is located on chromosome 3 of short arm in region 12 (3p12) ⁷. There is an association of IL-12A gene polymorphism with the risk of pulmonary tuberculosis ⁸. The variability in the IL-12A gene circuit association studies probably confirm of the genetic heterogeneity underlying susceptibility to pulmonary tuberculosis ⁹. The study present association between IL-12 gene and pulmonary tuberculosis risk, by using a panel of single
nucleotide polymorphism providing comprehensive coverage of these genes (10). IL12A gene is hypothesized to be involved in the progression and development of Pulmonary Tuberculosis. Genetic polymorphisms of IL12A gene, was found that genetic variants G/A rs568408 genotype associated with an increased risk of Pulmonary Tuberculosis. The results of this study demonstrate that genetic polymorphism of IL12 pathway may individually or jointly contribute to the sensibility to and prognosis of Pulmonary Tuberculosis TB (3). The study aimed to the finding association between IL12A gene polymorphism in position G/A rs568408 genotype and risk of pulmonary tuberculosis development in Baghdad population.

**Materials and Method**

**Population samples Study**

The population samples Study consisted of 50 patients with pulmonary tuberculosis (27 female and 23 male), there ages range from 12 to 77 years, and 30 control healthy individuals, (15 female and 15 male), and there ages range from 19 to 58 years. All the samples of pulmonary tuberculosis patients were collected from The National Center for Chest and Respiratory Diseases/ Medical City in Baghdad. They had an established diagnosis of pulmonary tuberculosis by the clinical examination and laboratory test.

Genotyping of IL12A gene (G/A rs568408 genotype)

Genomic DNA was extracted by take five ml of blood from each patient and healthy control by venipuncture, later, 2.5 ml was added in to EDTA tubes then DNA was extracted by DNA isolation kit (Promega, USA) and according to manufacture instructions manual. DNA purity was qualified by Nano drop and it was about 1.6 ±1.8. All samples were kept at 20 ºC for further study. Polymorphism of IL12A gene (G/A rs568408 genotype) was examined by using Tetra-ARMS-PCR technology. The PCR reaction was carried out on a DNA template with a pair of specific primers (Alpha DNA, Canada) that designed according to (11). Table (1), 20 μl was the total volume of reaction mix (PioNeer, Korea), and the molecular marker size (Promega, USA) 100-2000 base pair. Tetra-ARMS-PCR programs were summarized in table (2). The genotypes were established by analyzing electrophoresed 2.5% agarose gel stained with diamond dye (Promega).

Statistics

Differences in the frequencies of of IL12A gene (G/A rs568408 genotype) for pulmonary tuberculosis patient in this study with control groups were analyzed with a value P<0.05 by Fisher’s exact test. Odds ratios (OR) and confidence intervals (CI) were calculated using Compare 2 Ver.3.04 software J. H. Abramson (2003-2013). Preventive Fraction (PF) and Etiologic Fraction (EF) results were compared with Hardy-Weinberg equilibrium and according to the software within the following website www.had2know.com.

Results

The genetic polymorphisms of IL12A gene (G/A rs568408) in fifty pulmonary tuberculosis patients with mean age 34.95±1.4 year, and thirty of healthy individuals as a control samples with mean age 26.7±1.9 year. Notably, the two alleles G/A are more present for IL12A gene (G/A rs568408) with GG, GA and AA genotypes in pulmonary tuberculosis group and control (figure 1), use of tetra-ARMS PCR technology in study. The allelic frequency and genotypes distribution for each tested polymorphisms for healthy control and pulmonary tuberculosis patient are presented in table (3). With respect to the IL12A gene (G/A rs568408) polymorphisms, there was a significance in pulmonary tuberculosis patient in compare with control group (P>0.05), and the G and A alleles were different in frequency, so allele G frequency was 62% for pulmonary tuberculosis patient while allele A frequency was 38%, as compared with G and A alleles in control group that it’s frequency was 51.7% and 48.3% (figure 2). The odds ratio (OR) for G allele was 1.53 with confidence intervals (CI) 0.80 to 2.90 at 95 % (Table 3), and it was 0.21 as an etiological fraction (EF), while for allele A there is no significance in pulmonary tuberculosis patient comparison with control and OR was 0.6 with CI 0.34 to 1.25 at 95%, and the value of allele A as preventive fraction (PF) was 0.17 (Table 3). The previous report on polymorphisms of IL12A gene (G/A rs568408) show that may G allele be an etiological fraction and also, it’s describe that the A allele may be a preventive fraction that correlated with the risk of pulmonary tuberculosis patients. The genotyping polymorphisms for IL12A gene (G/A rs568408) by tetra-ARMS PCR technology, there are a genotypes frequency significance in pulmonary tuberculosis patients, so GG and AA genotypes showed the high frequency in pulmonary tuberculosis patients as compared with control (health) group, and it was 42 % and 18 % respectively (Figure 3), also the OR for GG and AA genotypes was 21 and 14 respectively, with CI 2.74 to 161.1 and 0.82 to 238.1 respectively. The GG and AA genotypes presented of association with etiological fraction for risk pulmonary tuberculosis, while for GA genotype the frequency was 40% and 96% for pulmonary tuberculosis patients and control (health) group respectively (Figure3), also the OR was 0.02 and CI was 0.00 to 0.18 and the value for GA genotype as protective fraction was 0.94. Briefly, the result showed that GG and AA genotypes were correlated with the risk of pulmonary tuberculosis, while GA genotype was correlated with the protective fraction of pulmonary tuberculosis in Baghdad Population. The results are
consistent with (8, 10 and 12).

Discussion

Interleukine-12 is an immuno-regulatory cytokine, which linked innate and acquired immune responses to mycobacterium through induction of IFN-γ production (13). A series of recent reports in the cytokine pathway suggest that more subtle variants of relevant genes may contribute to susceptibility to tuberculosis at the general population level. To investigate whether polymorphism in the interleukin-12 (IL-12) gene predispose individuals to tuberculosis, we studied these genes by single-strand conformational polymorphism analysis and direct sequencing (6). The most potent enhancer of reactivated T-cells and interferon production which is necessary for killing intracellular bacteria like mycobacteria is interleukin-12 (IL-12), and confirms to be an effective and successful adjuvant to a standard anti-tuberculotic medication in patients suffering from progressive pulmonary tuberculosis (TB) (14). IL-12, produced mainly by macrophages and dendritic cells, has an important role in the immune response to Mycobacterium tuberculosis, also, IL-12 induces T cells and NK cells to produce pro-inflammatory cytokines such as Interferon-γ and Tumor necrosis factor-α while also regulate the production of IL-17 in immunity response for Mycobacterium tuberculosis (6). The genetic polymorphisms of the IL-12 pathway may individually contribute to the susceptibility to and prognosis of pulmonary tuberculosis TB (12). We investigated the impact of IL12A rs568408 gene polymorphisms on risk pulmonary tuberculosis in a sample was living in southeast (13). The IL12A rs568408 variant was not a risk factor for susceptibility to pulmonary tuberculosis in codominant, dominant and recessive tested inheritance models (11), but another study showed association between IL12A rs568408 polymorphisms and risk of pulmonary tuberculosis in Chinese population and It was found that genetic variants AG/GG of rs2243115 (IL12A) were associated with a decreased risk of pulmonary tuberculosis (12).

Conclusion

The statistical data of current study proved the association between of IL12A gene (G/A rs568408) polymorphism and Pulmonary tuberculosis risk in Baghdad Population.

The Effect of Allogenic Bone Marrow on Integration Dev-Mesenchymal Stem Cell And Vascular Endothelial Growth Factor

Ferdiansis
Departement of Orthopaedi and Traumatology Faculty of Medicine Universitas Airlangga Surabaya Indonesia

Abstract

Background: The integration of the tendon graft within the bone tunnel is one of the decisive success factors of the Anterior Cruciate Ligament (ACL) reconstruction. In ACL reconstruction that uses tendons as graft, the healing process that occurs in the bone tunnel is healing with fibrotic tissue.

Aim: This study aims to determine the role of bone marrow mesenchymal stem cells and vascular endothelial growth factor intraarticularly in improving the biomechanical strength.

Methods: This study uses experimental research design by using animal as a testing tool. The animals used in this study are male New Zealand white rabbits (Oryctolagus cuniculus), with the weight ranging of 2000 grams up to 3000 grams.

Results: From the experiment, all samples from both treatment and control groups were all evaluated and no post-operative complication was found. At the evaluation time of 3 weeks, the difference between the mean of maximum strain rate between the treatment group and the control group was not statistically significant (p >0.05). At the evaluation time of 6 weeks, it was found that the difference in mean value of the maximum strain load force between the treatment groups versus the group was statistically significant.

Conclusions: From this study, it can be concluded that intraarticular BM-MSC and VEGF administration can increase the ultimate tension strength of postoperative graft tendon rosary ACL reconstruction.

Keywords: Healing of bone tendon-tunnel, ACL reconstruction, Vascular Endothelial Growth Factor (VEGF), Bone Marrow Derived Mesenchymal Stem Cell (BM-MSC).

Introduction

The process of widening the tunnel is an important concern in ACL reconstruction. This process occurs due to two things, namely the existence of micro-motion and extravasation of synovial fluid into the bone tunnel¹. The ACL post-operative rehabilitation program requires limited mobilization to provide sufficient opportunities for integrated graft within the bone tunnel². One of the critical to the success of ACL reconstruction through the process of integration between tendon graft and bone tunnel³.

Techniques used in ACL reconstruction to improve and improve integration between tendon graft and bone tunnel. The hope is, allowing the sufferer to start and undergo the rehabilitation process and ultimately speed up the chances of the sufferer to immediately return to the activity and return to the sporting activities⁴. Mesenchymal Stem Cell has been assessed to have the potential to improve the quality of integration between tendon graft and bone tunnel.

The ability of stem cells to differentiate and ease in the extraction process is one of the considerations in the use of mesenchymal stem cells in an attempt to enhance the integrity of the tendon graft bone tunnel. Several
studies have mentioned a soft tissue graft augmentation technique using mesenchymal stem cell histologically and biomechanically. Histologically, the tissue formed at the border contact of the tendon graft surface and the bone wall of the bone tunnel resembles the healing of the bone-tendon-bone graft on the reconstruction of the ACL. Another study mentions a histological picture of integration that resembles chondral enthesis of native ACL insertion.

In addition, it is biomechanically mentioned that the augmented graft tendon with mesenchymal stem cell has a failure limit on higher loads when compared with other augmentation methods. This is due to the widening of the tunnel. One theory has explained the influence of synovial fluid within the joints, in which the synovial fluid has the effect of inhibiting the process of forming the hematoma.

Bone marrow derived mesenchymal stem cells (BMSCs) are a new source of cells to help speed the healing and regeneration of new tissues. BMSCs are able to differentiate into osteoblasts that will form cartilages to form fibrocartilage tissue. Healing with fibrocartilage resembles healing in the bone-tendon-bone graft type. Biomechanical studies that have been done also provide results of fibrocartilage healing on bone-tendon-bone graft better than the healing fibrocollagen on soft tissue graft. Furthermore, histologically, fibrocartilage healing may provide an image resembling chondral enthesis in normal native ACL insertions.

One of the problems with the ACL reconstruction process is the occurrence of hypoxia in the automotive tendon tissue after harvesting or harvesting. A study in Japan has proven that VEGF can improve vascularization and improve the quality of fibroblast tissue integration. In other side, VEGF was evaluated based expression identified through immunohistochemical staining. Based on the description above, this study aims to determine the effect of intra articular bone marrow derived stem cells (BMSCs) and vascular endothelial growth factor (VEGF), to increase the biomechanical strength of the autograft tendon integrity in the bone tunnel in retaining the pull-out force ACL reconstructions.

Method

This study uses experimental research design by using animal as a testing tool. The animals used in this study are male New Zealand white rabbits (Oryctolagus cuniculus), with the weight ranging of 2000 grams up to 3000 grams. The study was conducted from June to August 2014 for the research procedure, while it takes one month (August 2014-September 2014) for the analysis of the results and the preparation of the research report. This study located at Tropical Disease Center (TDC) Airlangga University.

The anesthesia drugs used were a combination of xylazin with a concentration of 100mg/cc and ketamine, a minor surgical base set, consisting of a scalpel, tweezers, tissue scissors, skin retractor, scissors of yarn, and pean clamp, sewing threads consisting of ethibond 4.0 for graft fixation and monofilament absorbable syntetic measures 4.0 to cover the capsule and field operation. The research instrument used a ruler to measure elongation and translational distance (drawer), Autograph AG-10E engine (Shimadzu Corporation, Japan) to measure the forces required to create pullouts or ruptures from tendon graft.

After doing the research result of evaluation and biomechanical test collected then done analysis and statistical test. Data collected from result of evaluation from second time done recapitulation, tabulation, and statistical analysis. All data were analyzed using IBM SPSS v.21.0 for windows program (SPSS. Inc. Chicago, IL).

Results

Based on the results of data analysis obtained the results of posterior anterior translational distance measurement at various angles (Table 1).
Table 1. Measurements of posterior anterior translation at various angles and ultimate tension strength measurements and types of damage occurring in the tendon graft during evaluation periods 3 and 6 weeks.

From that result, statistical analysis in both groups was based on two observation times (3 and 6 weeks). From the two groups, a comparative test was performed using Mann-Whitney test method. Normality test results using Shapiro-Wilk test showed the results p >0.05 indicating the data is not normally distributed. Therefore, the test used was Mann-Whitney test (Table 3).

Evaluation of 3 weeks p >0.05

Evaluation of 6 weeks at 30° dan 60° p >0.05 and translation 90° p < 0.05

From table 4 there was a significant difference of AP translation distance at 90 degree knee angle between control and treatment group (significancy 0.020, p <0.05) (Table 4). The control group at 3 weeks evaluation period had a mean value of 0.0197, the control group with the evaluation period of 6 weeks had a mean value of 0.046 while the treatment group with 3 weeks evaluation had a mean value of 0.018 and in the treatment group with 6 weeks evaluation period had a mean value of 0.0698 (Table 2).

Shapiro-Wilk test results obtained significance value 0.291, 0.150, 0.058 and 0.337. Because the value of p >0.05 it can be concluded that the data distribution for each group is normal, so for comparative test that can be done is by t-test unpaired (independent student t test).

For comparison group comparison and treatment at 3 weeks evaluation, the result of significancy was 0.801. Because p >0.05 it can be concluded that there was no significant difference between pullout strength / ultimate tension strength of control group and treatment during evaluation period 3 weeks.

The biomechanical test was performed in 3 weeks postoperative control group and 6 tendon graft was ruptured on the intraarticular (midsubstance) part (100%) while the 3-week treatment group also obtained 4 graft tendon rupture on the intra-articular (midsubstance) (66.7%) and 2 graft tendons had pullout on the bone tunnel of the femur (33.3%).

Discussion

ACL reconstruction often uses a hamstring tendon as one of the tendon graft options. Many studies have studied aspects of the use of hamstring tendons as grafts, ranging from techniques, biomechanical, histologic aspects as well as the results of this procedure.

The success of the ACL reconstruction procedure using a hamstring tendon as a tendon graft depends not only on the initial fixation when the graft mounting operation is performed, but on the biological integration of the longitudinal graft in the bone tunnel that determines long-term outcomes, but the factors affecting the biological integration of the tendon graft on the bone tunnel remains unclear. However, from a variety of materials used, there has been no research that proves the superiority of a material that significantly outweighs other additions.

Biomechanical testing is one of the most commonly used methods to study the effectiveness of a material used as an augmentation to accelerate or increase the integration strength of tendon graft in a bone tunnel. There are different histologic features that occur in the mouth of the bone tunnel or the entrance and along the bone tunnel. In the study also mentioned that the position of the tendon graft insertion in the bone tunnel also has a role to play in the resulting force and work on the tendon graft. This is important given the various techniques and tunnel positions used in actual human ACL reconstruction.

One of the things that happen to the post-reconstruction tendon graft is the occurrence of reduction in tendon stiffness. This results from the effects of VEGF on the tendon graft which results in a decrease in the stiffness of the tendon graft itself. In the present study this phenomenon can be observed by the posterior anterior-posterior translation of the postoperative femur-graft-tibia complex compared between the control and treatment groups.

The results of this study differ from those shown by previous studies that mention significant differences in mean AP translation distances between control groups and treated groups in the form of VEGF. But at the beginning of postoperative graft tendon histologic features obtained in the form of new vascular formation areas, infiltration of new cells and the formation of new collagen fibers that have not been arranged regularly. The formation of new vascular tissues, irregular infiltration of cells and collagen fibers is a “weakness” of the tendon graft structure used. In addition external VEGF applications also enzyme matrix metalloproteinase (MMP) by several types of cells. The result of mean comparison of AP translation distance between control and treatment group in this study showed that there was no significant difference between the two groups except in the treatment group at 90 degree angle at 6 weeks evaluation.
This is consistent with the results of previous studies showing no significant difference between ultimate tension strength between the tendon groups receiving VEGF and the control group\(^7\). However, in this study for comparisons of 6 weeks evaluation results showed significant differences. In the control group, the tendon graft underwent ischemic and transient necrosis following harvesting, but after implantation, there was a normal healing process through fibroblast tissue\(^3\).

**Conclusion**

From this research it can be concluded if there is no significant difference from AP translation distance that reflects the stiffness of the tendon graft between reconstruction of ordinary ACL and reconstruction ACL coupled with intraarticular BM-MSC and VEGF delivery.

Influence of BRACA Usage on Self Improvement of Breast Cancer Patient by Post Mastectomy

Dewi Maryam¹, Iskandar Ali¹
¹Faculty of Medicine, Airlangga University, Dr.Soetomo General Hospital, Surabaya

Abstract

Background: Breast cancer is an abnormal tissue, rapid growth and uncontrolled cells found in breast tissue. This body image disorder is thought to be related to the occurrence of post-mastectomy depression.

Objectives: To know the influence between the use of BRACA with self-image improvement in patients with post-mastectomy breast cancer in Dr. Soetomo General Hospital, Surabaya.

Method: The subject was a patient who has undergone a mastectomy on one side of the breast. The study design was a queasy experimental type of pre-post control design by sorting the sample and dividing it into 2 groups where 1 control group (not using BRACA) and another group in intervention using BRACA. Statistical analysis using t-test.

Result: There was an increase in the self-image of respondents who intervened with BRACA’s use of pre and post use by showing a significant effect between BRACA use and self-improvement of post-mastectomy breast cancer subjects in Dr. Soetomo General Hospital, Surabaya (p = 0.000).

Conclusion: The major cases occur on the right side of the breast with the duration of surgery more than one month. BRACA can be used as an alternative to improve the patient’s self image after mastectomy as it increases the self-image of the patients.

Keywords: BRACA, Self-image, Breast Cancer

Introduction

In Indonesia, breast cancer known as the most common cancer experienced by women that can lead to death ¹,², and can be evaluated through common sign such as menstrual disorders ³. Breast cancer has a physical and psychological impact on the individual. Physically there is a change due to the disease process and treatment. Changes that occur due to disease processes include changes in shape, size, or texture of the breast due to an enlarged tumor mass. Changes that can occur in the form of partial or total loss of the breast and the scar due to surgery ⁴.

Chemotherapy, Intraoperative radiotherapy, and oncoplastic are the techniques to treat early stage breast cancer ⁵,⁶. For further stage, partial or total loss of the breast or the effects of chemotherapy may result in negative psycho-social consequences including one of the problems in the woman’s self-image ⁷,⁸. The study of 112 breast cancer patients showed 33.00% of women felt different from others after surgery, 12.00% felt others were aware they were undergoing treatment and made 25.00% of them worried and 50.00% of patients were disturbed by their body changes after surgery⁹. The distortion of self-image in the mastectomy patient is worse than that of the amputated patient ¹⁰. Research on patients with mastectomy that acts to cover up the loss of self-image by wearing a wide headscarf, wearing a long jacket or wearing a loose shirt but the respondent declared reluctant to use a bra for reasons the wound is still not dry, uncomfortable or feeling asymmetrical on one of his limbs.
The literature study of 45 research articles on breast cancer patient’s patient is proposed by various coping strategies used by women who have breast cancer to face both physical and psychological challenges. Some types of coping strategies used are effective/adaptive coping (such as active problem solving, and acceptance of disease/diagnosis) to maladaptive coping (such as self-blame and denial). Psychological distress such as poor self-image becomes a predisposing factor to chronic depression, eating disorders, use of illicit substances and other attitude. Several studies have found an association between coping with the self-image of post-mastectomy patients. Based on the above phenomenon researchers interested in researching and creating a tool that we named “BRACA” which can reduce the self-image disturbance experienced by patients with breast cancer primarily post-mastectomy patients or after removal of breast.

**Methods**

The subjects were breast cancer patients who had performed radical mastectomy action in Dr. Soetomo General Hospital, Surabaya. The inclusion criteria were post-mastectomy patients either breasts (either right or left), age between 30-60 years old, minimum primary school (SD) to Bachelor (S1) education, the patient was confirmed for control again within a minimum of 1 week.

The study design used quasy-experimental type pre post control design by sorting samples on entry into the room, dividing it into 2 groups where 1 group as control (not using “BRACA”) and other group intervened using “BRACA”. The sampling technique used purpuseful sampling. The location of this research was conducted in Dr.Soetomo General Hospital, Surabaya in March to May 2017. This research has obtained the approval of ethical clearance from the ethics commit- tee of Dr. Soetomo Teaching Hospital, Surabaya In- donesia.

Subjects will be retrieved data of anamnesis in the form of demographic data such as age, type of work, education, marital status, religion, and insurance in health financing, while the collection of clinical data can be in the side of the mastectomy breast, postoperative length, and use of braces or not. BRACA or Bodyfit Range Cancer is a tool created by researchers based on cotton that can absorb sweat. Inside the BRACA there are 2 versatile pockets that can be filled with foam pads or can also be filled with jelly that can be used as a cold compress (Figure 1). Measurement of self-image on the subject can be done with self-image questionnaire as many as 15 questions with yes or no answer. Statistical analysis used the t-test with significance value $\alpha = 0.05$ with SPSS version 11.5 for Windows (SPSS, Inc., Chicago, IL). While to know the degree of the power relationship between variables measured by the correlation coefficient ($r$).

**Result**

Demographic and Clinical Data Subject Research

The majority of subjects aged was 35-50 years (53.20%), worked as private/entrepreneurs (61.70%), junior high school (76.61%), married (83.00%), Moslem (87.00%), followed more than 1 social (63.80%) and financing by using National Health Organization (BPJS) (83.00%). The majority of subjects in the right side of the breast mastectomy (80.90%) and duration of surgery for more than one month (100.00%).

**Correlation Use of BRACA Pre and Post-Test with Self Image**

The pre-test showed no subjects with high self-image in the treatment group by using BRACA and in the control group was obtained more than a half had high self-image (64.00%). In the post-test, there were no subjects with a low self-image in the treatment group using BRACA and in the control group, all had high self-image (100.00%). So there was a strong positive relationship between BRACA usage with self-image enhancement ($p = 0.000$).

BRACA=Bodyfit Range Cancer
Discussion

The result of the statistical test shows that there is a strong positive relationship between BRACA usage with self-image improvement in post-mastectomy breast cancer patient. In the result of the post-test questionnaire also showed that there were no subjects with a low self-image in the treatment group using BRACA whereas previously in pre-test was obtained 40.00% subjects had a low self-image.

Women who suffer from breast cancer usually experience physical and psychological changes that can affect the appearance and activity of women in their daily life, because of cancer associated with physical problems of pain, misery, death and moderate cost of psychosocial problems that are anxious, body image and loss. Body image changes almost in all patients with breast cancer, especially in patients who do the mastectomy. If these changes are not integrated with a healthy self-concept then the quality of life will be decreased drastically even will threaten the patient’s safety. In general, the factors that affect women have body image disorder according to the body image distortion and body image dissatisfaction. Some factors may affect one’s self-concept including personal factors that include: age, sex, education, occupation, economic status, lifestyle, and personality.

Then, of the 22 people included in the treatment group, 3 respondents still had an elementary education. Education also affects the self-concept and emotional maturity of a person. A person with higher education will better understand and understand about the disease he suffered. The higher a person’s education is expected to have better self-concept and high self-image.

From the characteristics of marital status was obtained data by 20 people in the treatment group with BRACA is has a married status and only 2 people are widow status. Family support (especially the role of husband) is very influential on the condition of one’s self-image. Use of BRACA in patients can improve the self-image of the patient, especially in front of her husband. The use of BRACA makes the breasts will look prominent and symmetrical so that patients will feel more confident in front of her husband.

The majority of 61.70% subjects had a private job type, the occupation may affect patient satisfaction with health services, because the working patient is a productive patient, usually more sensitive to the circumstances around, with the patient’s activity more likely to interact with the surrounding environment. When associated with pre-test and post-test results that increase can be explained as follows that with the use of BRACA then the breasts will look like a normal woman so that other patients will become more confident and self-actualization will be increased.

Conclusion

The majority of subjects in the mastectomy of the right side of the breast and the duration of surgery more than one month. There is an increase in self-image after BRACA use in patients who have been in mastectomy. Support is needed in the form of post-operative guidance counseling and involvement of support groups and families in order not to experience post-mastectomy depression.

Ethical clearance

This research involves participants in the process using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic regulation. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice.

Conflict of Interest: The authors have not found any conflict of interest related to this research so far.

Correlation of Quadriceps and Hamstring Muscles Strength with Knee Osteoarthritis Stages and Pain Levels in Elderly Female Subjects

Mohammad Fathul Qorib, Hening Laswati

Abstract

Background: Osteoarthritis (OA) is one of the most common disease occur in elderly. It is commonly occurs in knee, hips and interphalangeal joints. Pain caused by knee OA may result in functional disorders that affect patient’s life quality.

Objective: To analyze correlation of quadriceps and hamstring muscles strength with knee OA stages and pain levels in elderly female subjects.

Methods: 38 elderly female subjects (average age of 67.18 ± 4.91) were assessed for pain scale using numeric rating scale (NRS). We used 1RM protocol (EN-Tree) to measure quadriceps and hamstring muscles strength. We performed anterior-posterior and lateral knee X-rays to determine OA stage. The process of data analysis was conducted using several tests, including Kolmogorov-Smirnov test, Pearson’s correlation test, Spearman’s correlation test and Mann-Whitney test to measure difference between knee OA level using 1RM quadriceps muscle and quadriceps/hamstring (Q/H) ratio.

Results: The average NRS was 3.68 ± 1.19, 1RM quadriceps and hamstring muscles strength were 2.68 ± 1.23 and 1.11 ± 0.44, respectively, quadricep/hamstring ratio (Q/H) was 2.53 ± 0.95. A total of 30 subjects had OA stage 2, while 8 subjects had OA stage 3.

Conclusion: The 1RM quadriceps and hamstring muscles was not correlated with NRS. There was no difference in 1RM quadriceps and hamstring muscles between subjects with OA stage 2 and 3. We found a positive correlation between Q/H ratio and the NRS. The Q/H ratio in subjects with OA level 2 and 3 was different.

Introduction

Osteoarthritis (OA) is the most common joint disorder and a major cause of disability in elderly people. Pain caused by knee OA may result in functional disorders that affect patient’s life quality. Prevalence increases with age. Ten percent of total population will have symptomatic osteoarthritis in their 70s. The number and percentage of elderly in Indonesia continues to increase each year with an average increase of 0.5% per year. Such increases will potentially lead to an increased OA prevalence. Osteoarthritis may cause socio-economic problems in family and social environment.

Osteoarthritis is a common progressive joint disorder. It is commonly occurs in knee, hips and interphalangeal joints. Even though OA is not commonly found in
knee joint, it is the most common cause of disability. Patients with knee osteoarthritis often experience disruption in their daily activities because of the arising pain. Female subjects have a greater risk of knee OA than male. The number of new patients with knee OA visiting Medical Rehabilitation Unit of Dr. Soetomo Teaching Hospital, Surabaya, Indonesia, from October 11- December 28, 2011 were 61 patients (51 females and 10 males). The osteoarthritis pathology is damages in joint cartilage and new subchondral bone formation (osteophyte). Osteoarthritis occurs due to disruption of the balance between cartilage catabolism and anabolism. Some factors affecting the balance are types of work, weight, trauma, abnormal growth process, collagen gene mutations, muscle weakness, changes in proprioceptive function, joint neurological disorders and metabolic abnormalities.

Muscle strength decreases with age particularly after 60 years old. Muscle strength will be reduced by 45% at age 65 due to a complex process including biological and functional causes. Quadriceps and hamstring muscles are the most common muscle types suffering from strength and size reduction. Muscles around the knee act as chondro-protective. A study conducted in 178 female and 164 male elderly found that quadriceps muscle weakness became a risk factor for knee OA occurrence in the female patients.

Other studies in elderly subjects found that quadriceps muscle weakness was not the result of knee immobilization due to pain, but rather a trigger factor of knee OA. Quadriceps muscle weakness eliminates one of knee stabilizer functions. Several studies have shown that quadriceps receptor failure when performing voluntary contractions is one of the causes of decreased muscle strength occurring in old age.

Hamstring muscles have a role as knee joint stabilizer. To date, there has been no study confirming correlation of quadriceps and hamstring muscle strength with pain level and knee OA, therefore is still no form of early prevention and a more measurable muscle strengthening program for pain management due to knee OA. Several previous studies have examined the relationship between quadriceps muscle weakness and OA. Those studied did not radiologically examine correlation of hamstring muscle strength with pain OA levels radiologically.

Muscle strength assessment can be easily conducted with simple and inexpensive methods. One method used to assess muscle strength is 1RM (repetition maximum), a maximum load that can be lifted with the movement of the full joint motion, or calculated according to the Oddvar Holten diagram. Previous studies conducted in healthy women subjects found no significant difference of quadriceps bench after being assessed with 1RM using EN-tree tools. Disability in elderly subjects due to knee OA pain complaint should be prevented by an early 1RM assessment and an immediate reinforcement program if it is proven that quadriceps and hamstring muscle strength is correlated with pain level and knee OA. Quadriceps bench can be made by yourself or modified easily and at very cheap cost. Muscle strength is easily assessed and enhanced by exercise using quadriceps bench. In this study, we used the EN-tree tool because the process of collecting 1RM data of quadriceps and hamstring muscles was more objective and more efficient. This study aims to analyze correlation of quadriceps and hamstring muscles strength with knee osteoarthritis (OA) stages and pain levels in elderly female subjects.

**Methods**

This observational analytic study using cross sectional approach was carried out from March to April 2012 at Medical Rehabilitation Unit of Dr. Soetomo Teaching Hospital, Surabaya, Indonesia. We used 38 elderly female subjects with knee OA who visited Medical Rehabilitation Unit of Dr. Soetomo Teaching Hospital, Surabaya, Indonesia. The inclusion criteria were as follows: (1) Women aged 60 years and over; (2) Willing to participate in this study by signing informed consent. On the other hand, the exclusion criteria were: (1) Obese subject with a Body Mass Index (BMI) of more than 30; (2) Having experienced lower extremity fracture; (3) Having impaired neurological function and cardiorespiratory disorders. The study protocol was approved by the ethics committees of Dr. Soetomo Teaching Hospital (Surabaya, Indonesia).

This study used EN-Tree protocol with NRS to assess pain level at Medical Rehabilitation Unit and X-ray machine at Radiology Unit of Dr. Soetomo Teaching Hospital, Surabaya, Indonesia. We assessed if subjects had not experienced any lower extremity fractures and/or neurological disorder. Pain level was assessed using NRS, while 1RM was calculated using EN-Tree protocol. Knee was evaluated using X-ray.
All data were processed using SPSS software (SPSS., Inc., Chicago., IL). The process of data analysis was conducted using several tests, including Kolmogorov-Smirnov test, Pearson’s correlation test (for normal data distribution), Spearman’s correlation test (for non-normal data distribution) and Mann-Whitney test to measure difference between knee OA level using 1RM quadriceps muscle and quadriceps/hamstring (Q/H) ratio.

Results

We took 1RM quadriceps and hamstring muscle data from 38 eligible subjects using EN-Tree protocol at Medical Rehabilitation Unit of Dr. Soetomo Teaching Hospital, Surabaya, Indonesia. Radiographic data of knee OA was taken after 1RM examination. All subjects had bilateral knee OA, but we only assessed the right side. The X-ray results showed 30 subjects had stage 2 OA, and 8 subjects had stage 3 OA. The subjects’ basic characteristics were presented in Table 1. The data for age, BMI, NRS and 1RM hamstring muscle parameters were normally distributed, while data for 1RM quadriceps muscle and Q/H ratio were non-normally distributed. Pearson’s correlation test showed no significant correlation between pain level with age, BMI and 1RM hamstring muscles.

On the other hand, Mann-Whitney test showed that the Q/H ration between two groups was significantly different, with \( p = 0.047 \). The average value of the Q/H ratio in the group with stage 3 knee OA was 1.969 (Table 5).

**Discussion**

Pain is an uncomfortable sensory and emotional experience associated with existing tissue damage or potentially causing tissue damage. Uncomfortable feelings include all emotional processes such as fear, sadness, anxiety, or even suicidal attempts. Pain assessment is influenced by various factors including sensory, motoric, emotional and even cultural factors. In this study, we found that subject’s pain was positively correlated and statistically significant with the Q/H ration. This result indicated that the greater the Q/H ratio, the greater the pain level. Increased Q/H ratio in this study correlated with the increase of 1RM quadriceps muscle value and the decrease in value of 1RM hamstring muscle. These findings were consistent the results of previous studies, where the value of Q/H ratio in OA subject was greater than healthy subject, even though it was not significantly different. On the other hand, some studies found the opposite result that the Q/H ration in OA subject was lower than healthy subject \( 13,14 \). Differences in the results of Q/H ratio in some of studies might be due to differences in strength assessment procedures, instruction given to subjects, subject’s position during examination (prone, supine, or sitting), subject’s stabilization during examination \( 15 \). 1RM quadriceps and hamstring muscles negatively correlated with pain level, even though it was statistically insignificant with a weak correlation coefficient (<0.5).

This negative correlation might be due to knee joint stability towards mechanical stress ismore determined by the balance between quadriceps and hamstring muscle strength, suggesting that the Q/H ratio in healthy subject is 3:2 \( 13,14 \). Another assessment of thigh muscle strength ratio is the ratio of concentric strength of hamstring-quadriceps muscles (Hcon/Qcon). The reported Hcon/Qcon ratio value is 0.43-0.90. Previous study suggested that knee injuries could be predicted by detecting the strength balance of both muscles by assessing the Hcon / Qcon ratio of at least 0.6 \( 16 \). The athlete’s and tennis player’s normal H/Q ratio is 60% to 80%. This indicates that the increased strength of quadriceps muscle that is not compensated with the increased strength of hamstring muscle of at least 60% makes the knee will be prone to injury. Quadriceps and hamstring muscles play an important role as structural stabilizers of patellofemoral joints. Quadriceps muscle strength that is not compensated with hamstring muscle strength will cause an excessive tibia translation to anterior and an excessive attraction of the ligaments around the knee joint, particularly ACL \( 17 \).

We found no difference in quadriceps and hamstring muscle strength between group of subjects with stage 2 and 3 knee OA (\( p = 0.352 \)). This might be due to the knee joint stability towards mechanical stress is more determined by the balance between two muscle strength. These imbalances lead to changes in knee joint stability, exaggerated anterior tibial translation and changes in path patellar movement (Patellar tracking), that subsequently result in increased mechanical stress. Excessive mechanical loads and mechanical stresses cause various changes in chondrocytes environment that subsequently result in decreased tissue pH and lead to decreased matrix synthesises and immature proteoglycan synthesis.

Such process causes joint cartilage damage \( 18 \). Previous study stated that the value of Q/H ratio did not affect the OA progress \( 19 \). Nevertheless, we found a significant difference in the Q/H ratio between both groups (\( p = 0.047 \)).

The average value of Q/H ratio in the group with stage 3 knee OA was smaller (1.969) than the group with stage 2 OA (2.68). This might be due to osteoarthritis in the early stages will cause pain, but it can reduce the patient’s mobility at a later stage \( 20 \). Decreased mobility can lead to decreased muscle strength, including quadriceps muscle. This simultaneous decline in quadriceps and hamstring muscle strength is believed to be the basis for the decrease in Q/H ratio in the group with stage 3 OA.

**Conclusion**

We found no correlation between quadriceps and hamstring muscle strength with pain level. There was no difference in quadriceps and hamstring muscle strength between groups with stage 2 and 3 OA. On the other hand, there was a positive correlation between Q/H ratio and pain level. There was a difference in Q/H ratio between groups with stage 2 and 3 OA, with average Q/H ratioin stage 3 OA was lower than stage 2 OA.

**Ethical Clearance:** The study protocol was
approved by the Ethical Commission to conduct basic science/clinical research in Dr. Soetomo Teaching Hospital Surabaya, Indonesia. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice.

Conflict of Interest: The author reports no conflict of interest of this work.

Abstract

A number of (80) birds (Ross 308) at one day old were obtained from a local hatchery in the area. The birds were allotted into four equal groups (no.=20) and were supplied with basal scientific diet. Palm date (PD) was supplied to G3 and the birds were challenged with virulent Infectious Bursal Disease Virus (IBDV). G4 was treated with palm date 3 days prior to challenge age. G2 was challenged without supplementation of PD. G1 was neither given PD nor challenged. Inclusion rate of PD was 10%. The challenged age was at 33 days old. Blood serum was assayed for evaluation of transaminases and lipid profile 10 days post infection period (PIP). The result showed that histopathological investigation is more accurate in determining the health state of the birds and the palm date have to be supplied in more than 10% to give its significant effect.

Key words: Date palm, GPT, GOT, HDL, ALP, Cholesterol, Triglycerid, HDL, IBDV, Histology, Broiler Chicks.

Introduction

Cereals are an important sources of food for human and animals alike. Because of the massive population growth, the world has been faced with a gap between providing food needs and maintaining the livestock and their needs for feedstuffs. Tropical and semi-tropical regions are popular in their cultivation of palm date, which is a major source of energy. The Middle East is considered one of the world’s leading producers of dates, accounting for nearly 70% of the world’s production (1). Poultry industry is regarded as the main tool for supplying human demands of animal protein. To fulfill this requirements, grains have to be supplied and this will have negative impact on the level of human requirements. Because of dates and dates fruits are rich sources of protein and energy, the later can be used as an alternate of cereal in order to save human demands for their consumption, in addition to lower the cost of feedstuffs supplied in poultry industry (2). Many researches have shown that inclusion of palm date kernel (PDK) or seed was considerably valuable in improving productive performance, feed cost and feed utilization when added to poultry feed (2,3). The palm date has been proved to be an efficient diet during food shortage or during crises because of high nutritive value. It is rich in calcium, zinc, potassium, selenium, sulphur, chlorine, iron and manganese (4,5).

Medically, palm date have been proved in preventing liver against toxic damage produced by various toxic metabolites because of its anti-oxidant property due to high availability of various tocols as well as to its phenolic compound (6). Liver is the largest organ in the body that may show lesions represented by swelling and infarct (7) as a result of infection with infectious bursal disease virus (IBDV ) and this may have a negative impact on liver function. PDK is nontoxic and had been used against hepatotoxic and mutagenic effects, hyperlipidemia, hyperglycemic inflammation, microbial infection, oxidation and immunosuppressive effect of IBDV (8,9,10,11).

Recently, poultry industry have adopted a new strategy in poultry rearing which aimed to reduce the
marketing age through genetic selection breeding with high feed conversion ratio (FCR) and high body weight gain, palm date is said to have this property in enhancing productive performance \(^{10,12}\). For all the above mentioned reasons our study have been planned to study the effect of palm date as a medical agent in preventing liver damage caused by IBDV as well as for commercial purposes to have high productive performance.

**Materials and Method**

A total number (80) of chicks type (Ross 308) at the age of one day old were purchased from local hatchery in the area. They were divided into four sub-groups. All birds were supplied with basal scientific ration in addition to 10% whole grinded dry palm date type Zahdi (Phoenix dactylifera L.), the later was supplied at the day of challenge with exception of G4 which had been supplied with palm date three days before challenge (Table -1).

The birds were exposed to oral infection with highly virulent Infectious Bursal Disease Virus (IBDV) at the age of 33 day old. Infection was done by collection of grossly representative infected bursae with local field strain. The collected samples were homogenized, tissue suspension was centrifuged for a period of ten minutes at a rate of 2500 revolution per minute, supernatant fluid was aspirated, penicillin and streptomycin were added at a rate of two thousands IU and two mg per 1 ml respectively. Five birds from each group were sacrificed 10 days post infection period (PIP) to monitor any differences between treated and non-treated groups to evaluate blood serum related to different groups. The parameters adopted in evaluation were alkaline phosphatase (ALP), glutamic oxaloacetic acid transaminase (GOT), glutamic pyruvic transaminase (GPT), lipid profile which include cholesterol, high density lipoprotein (HDL), triglyceride (TG ) and cholesterol. The technique followed was according to kits manufacturers.

- ALP kit from Biolabo SAS, France.
- GPT and GOT kits from Randox laboratories Inc. UK.
- TG and cholesterol kits from LINEAR CHEMICALS L.U. Barcelona, Spain.
- HDL kit from Bio System S.A. Barcelona, Spain.

Histopathological study of liver was done according to Luna 1968 \(^{13}\) in order to follow the differences between treated and non-treated groups histologically.

- : Not given palm date  
+ : Treated with 10% palm date

**Results and Discussion**

Table-2 showed that G1 (negative control) have no significant difference in GOT level when compared to G2 (171.1±34.974) which was not treated but was challenged with virulent IBDV. G2 showed high significant difference \((p<0.05)\) as compared to G3 and G4 (110.6±4.751 , 108.4±6.293) respectively. The result shown above indicated that IBDV increases the level of GOT in blood serum of IBDV infected chicks. At the same time G3 and G4 decrease significantly as compared to G1 and G2. Although G4 do not differ significantly from G3 but GOT level is lower than G3 and this may be due to reduced effect of virulent IBDV as a result of pre medication with palm date 3 days before challenge (Table -1). The study do not agree with Nadia K. J. Al-Dawah \(^{17}\) who mentioned that the level of GOT serum showed no significant differences as compared to negative control group.

**GPT** : G1 showed no significant difference from G2 and G3 (18.25 ± 0.491, 18.00 ± 1.416 ) respectively ,on the other hand the pre-medicated group (G4) (17.29±1.960) differ significantly from G1 at \(p<0.05\) level. This indicate that palm date have no effect on GPT level. The result remains questionable due to the absence of studies that support or oppose our study (Table-1).

**ALP** : The study showed that there were no significant differences between treated group and non-treated one or challenged or non-challenged (G1,G2 and G4) which may give an expression that ALP is non-indicative for the health status in poultry (Table-1). The result is in agreement with \(^{18,19}\) who mentioned that the highest level of ALP in chicken occur in the first two
weeks of life then decrease significantly with age. ALP level in G3 remains unexplained and available study to be compared.

</table>

Note: Different capital letters refer to significant differences between different means at 95% confidence interval.

**Cholesterol**: Table-2 showed no significant differences in the level of serum cholesterol in G1 and G4. While G2 do not differ from G3. The low level in G1 may be related to absence of challenge. Elevation of cholesterol level in the other groups could be due to the liver damage created by IBDV. Pre-treatment with PD in G4 resulted in lower cholesterol level in comparison with other infected groups (G2 and G3). This is in agreement with (20,21) who mentioned that the polyunsaturated fatty acids that compose the vegetable oils supplemented in the diet reduce both egg and blood cholesterol levels.

**HDL**: The study showed no significant differences between G1 and G2 (26.49 ± 0.899, 26.30 ± 1.349 ), (non-treated groups) on the other hand G3 and G4 (treated groups) ( 13.22 ± 5.709, 14.52 ± 9.980 ) do not differ from each others , this reflect the effect of addition of palm date to the diet, at the same time the result on HDL run in a parallel way to that effect on cholesterol (Table-2). G1 and G2 showed higher significant level than the treated groups (G3 and G4). The result agreed with (22) who mentioned that total cholesterol (TCH) level is positively correlated with HDL and LDL.

**TG**: The study showed no significant differences in different groups, treated or non-treated or challenged and non-challenged groups (Table-2). This is in agreement with (23) who mentioned that triglyceride and cholesterol concentrations were positively correlated with each other.

Pathological Study

The study revealed that IBDV have deteriorative effect on liver parenchyma and palm date have a great impact in reducing this effect. Transaminases are usually used to test for cellular necrosis and their increase in serum concentration may indicate liver malfunction. Liver is regarded as the site of amino acids metabolism, any elevation in blood serum may give indication that there is damage to the liver as a consequence to harmful agent that causes leakage of these amino acids to the bloodstream. This in agreement with.

G2 showed mild inflammatory cells infiltrations with congestion of sinusoid (Figure 2) as compared to control group (Figure 1). G3 showed milder pathological lesion as compared to G2 and more sever pathological lesion as compared to G4, this might be due to previous medication with palm date (Figures 3 and 4).

The study revealed that there is no correlation between serological tests and histological findings. G1 and G2 showed lower significant level of GPT in spite of sever pathological lesions in G3 and G4 as compared to the control group. The result remains unexplained because of no available comparative study. Most high triglycerides are associated with an increase in LDL cholesterol and decrease in HDL cholesterol also there are many factors that estimate the level of lipid profile as the sex, age, abdominal fat. This support our study that histological investigation is more indicative to determine the health status of the bird.

The study showed that IBDV have no effect in the level of TG and ALP, this is because of the positive relationship between triglyceride and cholesterol concentrations which are positively correlated with each other.

The study concluded that palm date may reduce the harmful effect of infectious agent as IBDV due to its high component of active anti-oxidants that playing an important role in neutralization of free radicals and decomposition of peroxides.

Conclusion: that the addition of 10% palm date may give no indicative serological parameters for the health status of the bird; Hisopathological investigation still remains the only way for evaluation the health status of birds.

Identifying the Correlation between the Incidence of Breast Cancer and Hepatitis B Virus of Iraqi Women

Minen Al-Kafajy

Lecturer/ Department of Pathological Laboratory Analysis, University of Sumer, Thi-qar, Iraq

Abstract

Objective: Women are half of the Iraqi community and their health should be priority to the country. Breast cancer occurs increasingly rising in Iraq due to so many problems that the country has suffered. Several previous studies have studied breast cancer; however, none of them has explored the presence of HBV and the basic molecular mechanism are generally obscure and research studies are not enough and disintegrated.

Method: Therefore, this study are focusing on discovering a novel technique to detect breast cancer as early as possible to kept women lives. Advancement in routine breast cancer risk assessment will prevent chemotherapy uptake in women. Consequently, the women with or without breast tumor have expose to plasma assay to reveal HBV, Estrogen, Progesterone, complete blood count. The women test are divided into many classes of such as age, smoke and non-smoke to test their ability to detoxify carcinogenic aromatic amines in cigarette smoke.

Result: 64% of the malignant women were smoker while 36% were none smoker. 45±12 years is the most vulnerable age to get cancer. HBsAg were demonstrated in 10% of the all malignant ladies, while anti-HBs Ag have detected in only 5% of the total number. Complete blood counts and hormonal levels were dysregulated in the breast cancer patients.

Conclusion: The hormones are negatively correlated with the presence of cancer, HBV have detected in several samples but the no significant correlation. Smoking is the most factor significantly associated with breast tumor. For all these reasons. Iraqi government strongly argue to make smoking cigarettes prohibited in public areas.

Keywords: breast cancer, progesterone, estrogen, HBV, smoking

Introduction

International Agency for research cancer (IARC) has reported that female breast cancer is responsible about 11.6% of total cancer incidence, and documented to be a common diagnosed cancer and ranked as number one leading death for women worldwide (1). Fortunately, breast cancer is highly curable if diagnosed at earlier stage, but it might be deadlier if discover at later stages (2). Breast cancer (BC) is a heterogeneous illness ranked as the highest happening of all females cancer types and number leading death worldwide (3). In 2015, 143 cases were registered as positive breast cancer in Thi-Qar represented by 11.7% off all cancer cases registered in the city. In Asia, and particularly in the Middle East there is a rising incidence of breast cancer even though they migrate to western countries years ago (4). Contrary to the latest drop in the breast cancer occurrence in Western nations in comparison the occurrence in Iraq has been increasingly rising. The estimated number of Iraq’s population in 2015 is 36,933,714 included 18,659,573 males and 18,274,141 females (Ministry of planning / Central Statistic Organization). The number of breast cancer in Iraq which is 3763 cases in 2011 as it recorded in the cancer registry data published by the Iraqi cancer board, has reached a scary number in 2015 so breast cancer raised to be second female mortal cancer in Iraq. These documents ring the bell for imminent step towards understanding the epidemiology and the reason that underline the breast cancer predisposition. The expanded rate of the this kind of sickness could be due to other trends such as lower parity, postponed childbirth, declined breast feeding, war, terrorist that reduce the
health care services and sedentary lifestyle. The survival average of breast tumor are determined by the stage of diagnosis, therefore, there is increasing occurrence of breast cancer doom for women living in the rural in comparison to women living in the urban area.

There were no obvious examples of expanded hazard related with smoking by N-Acetyltransferase 2 (NAT2) state among premenopausal ladies. In postmenopausal ladies, who are slow acetylators, NAT2 strongly changed the relationship of smoking with breast cancer risk. These data strongly support this hypothesis that discovering and detoxifying carcinogens accumulated in the body from environment might reduce the breast cancer mortality rate.

On the other hand, genetics variations are an earlier signs of breast cancer such as P53, ZHX1, 2 and 3 genes. NAT1 and NAT2 the major decrease in breast malignant growth has managed by a full term pregnancy recommends the extraordinary capability of preventive hormonal procedures. As opposed to the dangers related with delayed exposures, exogenous estrogen and progesterone for brief terms can copy the defensive impacts of pregnancy in cancer-causing agent actuated mammary tumor models. About 300 million individuals worldwide affirmed positive for Hepatitis B infection (HBV) as well as it is a basic cause of hepatic disease and hepatocellular carcinoma. HBV is an individual from the Hepadnaviridae family that incorporates A, C, D, E. HBV is a little DNA infection with uncommon characters practically identical to retroviruses and delegated Orthohepadnavirus family has a size 3.2 DsDNA genome that is secured by HBsAg. The clinical significance of the infection originates from its capacity to cause unending illness and being oncogenic. HBV reiterate by means of RNA moderate and can incorporate into the host genome. The special portrayals of the HBV replication cycle present a particular capacity of the infection to endure in infected cells. serological parameters and sub-atomic examines have been improved for the identification of various sorts of HBV connected malady and for relieving of endless hepatitis B contamination. HBV contamination is a noteworthy motivation to a wide range of liver sickness. The hepatic injuries a

Are ranging from intense such as counting fulminant hepatic disappointment to constant hepatitis, cirrhosis, and hepatocellular carcinoma. Intense HBV was contaminated human could be superbly fine or show side effect of intense hepatitis. Most adults polluted with the infection recover, while 5%–10% are unfit to clear the inflammation and become endlessly diseased. Numerous incessantly tainted people have mild liver sickness with practically no morbidity or mortality. Other individuals with chronic HBV infection may continue to compelling illness, which can continue to cirrhosis and liver malignant growth. These patient’s supplication demanding observing and remedial mediation. Extra hepatic indications of HBV disease are uncommon yet can be hard to identify and treatment. The challenges in the field of HBV illness are the poor instruments in anticipating result and movement of HBV disease and the stubborn need to comprehend the cell, immunological, furthermore, acquired premise of different ailment displays related with HBV disease.

Material and Method

Samples:

150 women have involved in the study from the main teaching hospital in Thi-qar province, 100 specimens were clinically and histopathology examined and reported to have malignant breast cancer approved via clinical examination, mammographic screening, breast ultrasound, breast magnetic resonance imaging (MRI). our study has included women have suffered breast shaping alteration characterized by the presence of hard, fixed, breast lumps and/or swollen breast of one or both sides. one-sided nipple ejection mainly bloody discharge with or without palpable lump are the chief signs of women included in my study. As the age is being the main risk factor, the patients were divided into age groups.

On the other hand, this study have involved 50 ladies were undergone breast biopsy taken, but the oncologist has reported them to be either having benign tumor or none at all so them have used as a control group. Smoking mean the lady is a smoker or live with a partner who is a smoker, non-smoking means the lady is neither she or her household smoke.

Serological tests by ELISA:

Hepatitis B infection is the most hideous kind of hepatitis; hence, I centered my examination on the estimations of hepatitis B infection antibodies and antigens in the patient’s blood. To determine the period of illness whether it is intense or ceaseless; for
all patients; it utilized HBs Ag to identify the hepatitis Ag altogether, followed by testing HBc to determine the antibodies for the center antigen for all cases by ELISA (Bioprobes - Italy). Biochemical tests were utilized to distinguish the liver protein ALT Alanine transferase (GPT) to measure the hepatic cell damage.

**physiological parameters:** These investigation have included complete blood count has been done for all the samples as well as hormonal measurements have been done by collecting the blood from the patients in the middle of their menstrual cycle. Minvidus device has been used to measure the hormones.

**Statistical analysis:**

GraphPad crystal variant 7 programming for Windows, La Jolla California USA, www.graphpad.com, it was utilized to average and plot the information in this project with standard deviation. Although performing t-test between two groups, crystal was utilized ANOVA to break down at least three bunches pursued by numerous correlations utilizing Tukey’s test. Significant information designed by star as the following: 0.01 ≤ *p <0.05; 0.001 ≤**p <0.01; ***p <0.001.

**Results**

The 100 ladies were malignant were divided into 64% to be smoke that term include an active or second-hand smoke. If the woman is an active smoke means her is the person who smoke or live in the smoking house or work at smoking environment, while 36% were not smoking women (Figure 1). The incidence of the disease where around the age of 45±12 to be the significant age to have malignant disease (Table1).

Only 10% have shown positive HBs Ag, while 90% were negative (Figure 2). On the other hand, there were 5% of the breast cancer ladies shown positive Anti-HBc antibodies while 95% were negative.

Complete blood count was normal for control group and low for the cancer group including WBC, RBC, Platelets (data not shown). Hormone test has shown normal level Progesterone for the normal group, it was around 5-20 ng/ml, while normal estrogen was 15-350 pg/dl for the pre-menopausal women and 10 pg/dl for the post-menopausal ladies (Table 2).

Discussion

The estimated number of Iraqi populations is 2,029,345 in Thi-qar Province and 7,877,888 in Baghdad city.

My project will significantly contribute to science since it examined the alteration with the presence or absence of breast cancer and link this alteration to the environment whether it is smoking or not smoking area. I presume detecting a dose response correlation between the number of cigarettes smoked and the breast cancer risk but unfortunately, it could not measure the correlation in the present project.

The full epidemiological features of breast cancer in Iraqi women are not yet fully understood. My project is novel since it aims to discover a novel method that could detect breast cancer.

There was a significant correlation between the smoked life style and the breast cancer incidence. The results are consistent with several research across the world (5,8) who found that there is a link between the carcinogenic materials in the cigarettes. In my opinion, carcinogenic materials can dispose in the human body. Then, with recurrent exposure, DNA mutation might occur and could be followed by second hit mutation to end up forming malignant mortal cancer.

Hepatitis B disease is prevalent in Iraq. So, the result 10% and 5% only infected patients were surprising since it expected more due to the epidemic virus infection. These data could be explained with the low number of patients so 100 patients is not enough to get the epidemiological study. The present study has recommend to use 500-1000 cases across the 17 provinces of the country to do a reliable research enough to get scientifically meaningful conclusion.

This study has done a case-control project and compared WBC, RBC counts between patients with breast cancer and tendency score-matched controls. Laboratory test has been examined such as complete blood count, the complete blood count WBC were in normal range from 3,700 to 10,500 for the healthy control group and a decreased WBC count in women could have undiagnosed breast cancer or may be due to chemotherapy for individuals already have cancer. It could be low due to a viral infection, a toxic reaction, or a process in the bone marrow that restrictions the body’s ability to create normal WBCs.

Hormonal tests have shown a high level of progesterone and Estrogen for pre-menopausal in women under 50 years old are expected. On the other hand, women older than 50 years or post-menopausal have expressed lower hormonal levels and was expected as it the normal physiology of the women body (Table 2).

Few cases have shown normal hormonal levels, after investigation, it appears that their doctor has prescribed medical hormones treatment which play principal roles in coordinating suitable growth and function of breast tissue. High levels of these hormones are correlated with pregnancy and seem to be responsible for the weakened risk for breast cancer among women following a full-term pregnancy. The patients samples are classified as stage I or stage II when the tumor size is £ 4cm according to (11).

This current study may be assess of the samples by smoke/non-smoke, ER/PR status, menopausal status, and body mass index (M. Al-Kafajy unpublished data) and weighed the association between WBC, RBC count, genetic expression and breast cancer encumbrance using multinomial logistic regression.

The work was aimed to set standards of breast cancer risk prognostication by analysis the alteration of gene expression and particularly spotted the specific genomics aberration in Iraqi women such as BRCA1, BRCA2, HER2/ neoucogene, progesterone and estrogen receptors, P53, ZHX1, 2 and 3 genes. Genetic alteration in P53 is not expected except in the ladies who have cancer since it is the guardian of the cell. Alteration in P53 will be anticipated in the samples that already have cancer. ZHX1, ZHX2 and ZHX3 could be altered in the expression or protein concentration or localization (12). Potential application for the project will be forcing a healthy habit for the individual and set laws that protect second hands smokers from the carelessness of most of the smokers.

Future Direction

Our study like to expand present project to examine the smoking duration and its ongoing change in the physiological and genetic level as it already have been done in the western countries and found a modest relationship in the pre and post-menopausal women (8). Our team would like to expand my project to include women from areas know to be contaminated such as factory region in Baghdad which is known to
be environmentally bad area to live in. On the other hand, the area that were under terrorist occupation has contaminated with war products and probably the women they don’t have access to suitable health care. Moreover, the refugee camps in the Kurdistan area would be another spot that could be included in the study since the poverty rate and hard circumstance in this area make it really difficult to have a good health care system.

Cyclic Fatigue Resistance of Wave One Gold, F6 SkyTaper, One Curve, and AF Blue R3 NiTi Rotary Instrumentation Systems

Zainab M. Abdul- Ameer1, Samar Abdul Hamed2, Rasha H. Jehad3, Jacob Al-Hashemi4
1Associate Prof., 2Lecturer, 3Associate Prof. Department of Conservative Dentistry, College of Dentistry, University of Baghdad, Baghdad, Iraq, 4Associate Lecturer, Department of Conservative Dentistry, College of Dentistry, Al-Mustansiriya University, Baghdad, Iraq

Abstract

Objective: This in vitro study is aimed to compare and evaluate the cyclic fatigue of four varying NiTi rotary instrumentation systems.

Method: In this study, four types of rotary files were used in four groups (10 files for each group), namely, Group A: Wave One Gold; Group B: AF Blue R3; Group C: One Curve; Group D: F6 SkyTaper. These groups were evaluated by a cyclic fatigue apparatus to measure cyclic fatigue resistance within the artificial metallic simulating canal that has a 60° angle of curvature, the curvature radius was 5 mm, whereas the inner diameter of the canal was 1.5 mm. All the files were rotated in artificial canals until they fracture. The resistance to cyclic fatigue was determined by counting the number of cycles to fracture, and the time to failure was recorded in seconds then transformed to minutes. In addition to that the fractured fragment length was evaluated.

Results: One-way analysis of variance test showed a significant difference (P<0.001) in the average values of cycle number and time needed for file fracture and average fractured portion length among all groups. The t-test results indicate a significant difference (P<0.001) among all groups.

Conclusions: The study concluded that with an apical curvature of an artificial canal with an angle curvature of 60°, AF Blue R3 and F6 SkyTaper instruments exhibit a higher resistance to cyclic fatigue than One Curve and Wave One Gold files most possibly due to surface and alloy feature variation.

Keywords: Endodontics instrumentation, cyclic fatigue resistant

Introduction

Rotary instruments for root canal systems made from nickel-titanium (NiTi) alloy exhibit more elasticity than stainless steel instruments, which are rigid and unsuitable for large apical enlargement in thin-curved canals [1]. Specifically, the elastic flexibility of NiTi instruments is approximately 2–3 times greater than that of stainless-steel instruments [2&3].

NiTi instruments feature a risk for fracture owing to cyclic fatigue and torsional shear; this condition is an unexpectedly important disadvantage of rotary files when rotate freely in a curved root canal [4-6]. In order to increase the easiness, simplicity, and speed of root canal preparation procedure for practitioners, a single file Ni Ti rotary systems with either complete rotation or reciprocation motion were introduced [7]. Wave One Gold files manufactured by Dentsply Maillefer in Switzerland are a new version of Wave One files. In this version, the geometry, dimensions, and cross section are modified while maintaining reciprocation motion. The files are made by gold, which is heated at first and then slowly cooled for file production; these files also exhibit two cutting edges with a parallelogram cross section, which may increase file flexibility as claimed by the manufacturer [8].
The F6 SkyTaper manufactured by Komet, Brasseler GmbH & Co. in Germany is a new generation of single-file, one-use NiTi system comprising one available instrument with five diverse sizes (20, 25, 30, 35, and 40) and showing a constant taper of 0.06, which is critical for shaping of the root canal. These files are distinguished by their cross-sectional design, which is a unique double-S cross section. The F6 SkyTaper instrument is produced for use in a continuous clockwise rotation motion [9].

One Curve file manufactured by MICRO MEGA in France is a heat-treated C-wire with a regulated memory of NiTi and a potential to prebending to facilitate access to the root canal. One Curve is also a single-use, single instrument rotary file employed in continuous rotation. The variable cross-section ensures excellent cutting efficiency and debris removal up to the medium and coronal parts of the canal with a perfectly centered trajectory [10&11].

AF Blue R3 manufactured by Fanta Dental Materials Co., Ltd. in Shanghai is a special heat-treated wire used for producing endodontic rotary files. However, NiTi files display a high possibility of unnoticed fracture inside root canals, different from the stainless-steel files, which are most likely to show plastic deformation signs. AFTM-Wire is a developed NiTi alloy and features excellent mechanical strength properties. The flexibility of AFTM-Wire sufficiently avoids canal transportation. Meanwhile, its hardness is large enough to allow for good cutting efficacy. Fanta AFTM-Wire offers three levels of flexibility depending on the crystallographic phases present in the alloy and rectangular cross-section of AF BLUE R3 [12].

The null hypothesis indicates that the tested rotary NiTi instruments show no differences in their cyclic fatigue resistances.

This in vitro study is aimed for comparison and evaluation the cyclic fatigues of Wave One Gold, F6 SkyTaper, One Curve, and AF Blue R3 NiTi rotary instrumentation systems.
In this article, four different rotary instruments were used, and 10 instruments for each type were investigated in the four groups.

**Group A:** Wave One Gold (primary, #25.07), 25 mm length, and NiTi rotary instruments (350 rpm/5 N cm).

**Group B:** AF Blue R3 file (#25.06), 25 mm length, and NiTi rotary instruments (300 rpm/2.6 N cm).

**Group C:** One Curve (#25.06), 25 mm length, and NiTi rotary instruments (300 rpm/2.5 N cm).

**Group D:** F6 SkyTaper (#25.06), 25 mm length, and NiTi rotary instruments (300 rpm/2.2 N cm).

The instruments were tested within an artificial simulating canal (angle curvature: 60°; Figure 1). The curvature radius was 5 mm, whereas canal width was 1.5 mm. The simulated canal constructed within stainless-steel blocks covered by a swiveling glass allowed for observation of files rotating in the canal and discard of broken instruments after each test [13].

To eliminate binding in the simulating canal, the files were created to be slightly wider than those used in the test (0.3 mm wider than the instruments used), granting a modest lateral movement inside the canal [14&15].

The cyclic fatigue testing apparatus utilized in this study, as shown in Figure 2, was previously illustrated. The apparatus consists of a wood main frame attached with an electric hand piece and a simulating canal carved in a stainless-steel block. The electric hand piece is supported to a movable apparatus, allowing accurate and repeated placement of each instrument inside the simulating canal [16].

The testing canal was filled with a lubrication medium (3-In-One Multi-Purpose Oil manufactured by WD-40, USA) to minimize the friction produced by the tested file with the canal walls [17]. A glass cover was fixed by the clipper to facilitate file insertion inside the canal and to prevent the instrument from slipping out, thus also providing a clear view of the instruments.

A button on the electric motor was pressed to initiate rotation. Meanwhile, a digital stop watch was also operated. Instrument rotation was monitored by the operator until the file fractured, and the corresponding time was recorded. The electric motor button was pressed again once to stop rotation during fracture of the instrument. The slide was opened, and the fractured file was replaced by a new one.

The time needed for instrument fracture from the beginning of the rotation was recorded in seconds then transformed into minutes by dividing over 60. Afterward, time (T) in minutes was multiplied by revolutions per minute (RPM) to conclude the number of cycles or rounds needed for each instrument to fracture (NCF) as shown in the following equation:

![Fractured fragment (mm)](figure4.jpg)
The length of fractured fragments for individual instruments was attained by measuring the instrument length after fracturing using a digital Vernier caliper (measured from the end of the handle to the fractured tip). The values were then subtracted from the file length before fracturing (25 mm), as shown in the following equation:

\[ \text{Fractured fragment} = \text{File length Before fracture (25 mm)} - \text{File length after fracture}. \]

Statistics, including maximum, mean, minimum, and standard deviation (S.D.), calculated for the cycle numbers needed to fracture each file. The data were obtained and noted using SPSS (program version 18) and used in statistical analysis.

One-way analysis of variance (ANOVA) was utilized to determine any statistical difference between the mean cycles needed for fracture occurrence for the different rotary instruments. A separate t-test was performed to assess the significance of variance between a pair of instruments.

In the present test, P values of more than 0.05 were considered statistically non-significant, whereas P values equal or less than 0.05 were regarded as significant. On the other hand, P values less than 0.01 were regarded as highly significant.

Table 1 summarizes the descriptive statistics for each system. The average cycle-to-fracture values of the AF Blue R3 group were the highest among all groups, whereas the lowest was observed in the Wave One Gold group.

The data inspected by one-way ANOVA demonstrated considerable variation (P<0.001) in the NCF mean values among all groups, as shown in (Table 2).

Using t-test, further comparisons among groups were conducted to determine where the significant difference occurred, as shown in (Table 3). The t-test results reveal a considerable variation among all groups (P<0.01), except for Group A (Wave One Gold) and Group C (One Curve) (P< 0.05), where is not a statistically significant differences in variation were reached (P=0.05).

Table 4 lists the mean, minimum, maximum, and S.D. of the fractured fragment length for each rotary instrument tested. The highest mean value of fractured fragment is noted in group D.

From the ANOVA test, as shown in (Table 5), a statistically significant difference was observed in the length of fractured fragments among the instruments.

T-test was utilized to explain the statistically significant difference in the fractured segment length of among the rotary instruments. A considerable difference was found among Wave One Gold, AF Blue R3, and F6 SkyTaper instruments, whereas a nonsignificant difference was observed in the One Curve group. Meanwhile, the AF Blue R3 group showed a significant difference in fracture length when compared with the One Curve and F6 Sky Taper groups. The One Curve group displayed a significant difference compared with the F6 SkyTaper group (Table 6).

The F6 Sky Taper group revealed the longest fractured segment length, followed by AF Blue R3, Wave One Gold, and One Curve groups.

**Discussion**

The fracture of rotating NiTi instrument is one of the most critical complications that develop during root canal preparation [18]. Diverse classes of rotary NiTi instruments show variation in resistance to fatigue failure owing to differences in numerous factors, such as their manufacture [18&20].

In this study, the resistance of rotary files to cyclic fatigue was tested under simulating conditions to reduce the effect of other failure mechanisms, e.g., canal diameter and length. Similar to other studies, the test was evaluated using stimulating canals made of stainless steel with a radius of 5 mm and 60° curvature [21&22]. Considering that this study aimed to examine the physical properties of NiTi rotary files, the extracted teeth were unsuitable models as no two root canals are exactly identical [23]. One operator has examined the files, whereas the other operator has operated the stopwatch [24]. The Wave One Gold, AF Blue R3, One Curve, and F6 SkyTaper NiTi rotary instrumentations were selected given their differing cross sections, processing metallurgic alteration, and rotation axes. Comparisons were conducted with files of similar curvature and diameter to minimize the confounding variables. This study recorded the fractured fragment mean length of the files to ensure exact positioning of the tested files inside
the simulated canals and to determine whether stresses were induced at the canal curvature. The Blue R3 files were the most resistant to cyclic fatigue, followed by F6 SkyTaper, One Curve, and Wave One Gold files. The t-test results showed a significant difference among all groups (P<0.01). However, the difference between Wave One Gold and One Curve (P<0.05) groups showed no statistical significance. In the AF Blue R3 files, the cyclic resistance may be related to a more metal mass and a larger cross-sectional area due to its rectangular cross section in addition to the AF-R Wire Technique, which depend on the crystallographic phases present in the alloy. The files are manufactured with NiTi, which undergoes an innovative heat treatment, altering its molecular structure, to achieve an increase in cyclic fatigue resistance; surface treatment of the file involves chemical polishing, and additional flexibility and a distinct blue color are also added [12]. However, no data were published until the date of evaluation of the cyclic fatigue resistance of the roots by using AF Blue R3 files. Therefore, comparison of our results with other studies is impossible. The F6 SkyTaper instruments showed more cyclic fatigue resistance compared with the One Curve and Wave One Gold instruments. This observation may be related to the decreased cross-sectional area associated with the unique double S-shaped cross-section design of F6 SkyTaper. Plotino et al. noted an inverse relation between cyclic fatigue resistance and cross-section metal mass of NiTi files [25]. This result agrees with that of a study concluding that Wave One Gold shows low resistance to cyclic fatigue [26&27]. This difference in the cross section between files might also contribute to their cyclic fatigue resistance.

Wave One Gold instruments were less resistant to cyclic fatigue and were fractured within a short period possibly due to their cross-section design (parallelogram-shaped cross section), which should be regarded for conclusions of this study. The thermal processing increased the temperature of austenitic transformation of nickel titanium alloy and improved its crystal structure arrangement [28&29]. These factors may improve instrument performance. One Curve files are manufactured with a C-wire by applying controlled heat treatment with the property of regulated memory, thus improving file resistance to cyclic fatigue. Parashos et al. noted that small core diameter enhances instrument resistance to cyclic fatigue [30]. One Curve features a low core diameter (approximately 48.327 μm²). All these findings explain the enhanced fatigue resistance of One Curve files. The instrument morphologies and geometries, such as the cross section design and core diameter, may be considered significant determinants of the position of fractured fragments of files on the curvature of root canal.

Conclusion

Considering the outcomes in this article, we can conclude that AF Blue R3 file exhibits the highest resistance to cyclic fatigue in comparison with F6, One Curve, and Wave One Gold files. Further research is advised to assess the resistance to cyclic fatigue of these files by using different canal lengths and curvatures. The clinical performance of these new files should also be evaluated.

Abstract

Background: Cardiorespiratory fitness measurement using 6MWT (Six Minute Walking Test) and walking speed measurement using 10MWT (Ten Minute Walking Test) in post-stroke patients are measurement to assess post-ischemic stroke patients in subacute or chronic phase. This study is to assess cardiorespiratory fitness and to measure walking speed of post-stroke patients in subacute and chronic. We also aim to observe the relation between cardiorespiratory fitness and walking speed in post-stroke patients.

Method: This study involved 38 subjects as samples. 6MWT assessment was conducted by measuring the mileage in six minutes. Walking speed was conducted afterwards with self-speed and fast-speed which were respectively assessed through three repetitions.

Results: We found string correlation in 6MWT assessment results with mileage in meter and VO2 max (r = 0.680 and p = 0.000). The result of 6MWT measured with VO2 max (ml/kg/minute) indicated strong correlation with 10MWT both with self-speed (r = 0.715, p = 0.000) and fast-speed (r = 0.687 p = 0.000).

Conclusions: We concluded that there was a relation between cardiorespiratory fitness and walking speed in post-subacute and chronic ischemic stroke patients.

Keyword: cardiorespiratory fitness, stroke, walk test.

Introduction

In post-stroke, continuous aerobic capacity usually occur in acute phase which reduce cardiorespiratory fitness reserve 1. In addition, the high amount of energy required for walking as well as comorbidities lead to functional limitations for this population 2. Cardiorespiratory fitness in post-stroke decreases from 50% to 70% depends on certain ages and genders. In elderly, the decrease occurs more rapidly. Cardiorespiratory fitness also decreases faster in female than in male. The sharpest decline is up to seven weeks post-stroke. The energy level required by stroke patients for routine ambulation is 1.5-2 times higher than in healthy individuals which indicates 76% of their physiological capacity 3.

This is due to post-stroke muscle fatigue and low level of cardiorespiratory fitness related to declining functional activity performance. Many studies suggested that it is associated with low peak oxygen consumption (VO2peak) 3. The average peak oxygen (VO2peak) consumption in post-stroke patients is around 11.4-17.3 mL/minute. This is 50-60% of VO2peak in healthy individuals in accordance with age and gender 4. Maximal oxygen uptake (VO2pMax) decreases to 10-17 mL/kg/minute during 0-30 days post-stroke 5.
Patterson et al. found that short-distance walking in chronic stroke patients is related to balance, cardiorespiratory fitness and weak side limb strength. The difference of ability in long-distance walking is caused by severe sensory fatigue and deficit which lead to poor gait. Balance also becomes an important factor for those who walk slower, while cardiorespiratory fitness plays bigger role in those who walk faster.\(^6\)

Janice et al. also conducted a study in chronic stroke patients and reported that stroke specific impairment was the main obstacle for chronic stroke patients to take longer distance. In the study, they found that the subjects’ heart rate in the study reached steady state after six minutes of walking. This indicates that six-minute walk test (6MWT) may depict cardiorespiratory fitness. Six-minute walk test (6MWT) also strongly correlates with self-paced walking speed.\(^7\)

There is a study on subacute stroke patients conducted by Kelly et al. suggesting that 6MWT is strongly related to peak cardiorespiratory fitness and also strongly correlated with self-paced walking speed.\(^8\)

Walking speed assessment can also be conducted using 10 meter walk test (10MWT), a time measurement required to do 10-meter walking with patients’ maximum walking speed. The test began with three minutes of warming up. Walking speed is the parameter of disability in walking fast and easily which is recommended as a measuring instrument in stroke rehabilitation.\(^9\)

It is still debatable whether or not there is a correlation between walking speed, walking distance taken by the subjects, functional walking test (including 6MWT) and aerobic capacity in post-stroke patients. For instance is a conclusion from a study conducted by Tang et al. stating that even though 6MWT might be able to spur cardiorespiratory system, the results seem to be more affected by walking ability limitations than by cardiorespiratory capacity.\(^2\)

In this research, the authors aim to find out if there is a relation between cardiorespiratory fitness level using 6MWT measuring instrument and walking speed in post-ischemic stroke patients and if walking speed in all ischemic stroke phase is related to cardiorespiratory fitness level. Such study has never been conducted before in Dr. Soetomo General Hospital Surabaya.

### Methods
This was an observational analytic study with cross-sectional design. It was conducted from July to October 2014 in Medical Rehabilitation Installation of Dr. Soetomo General Hospital Surabaya. The samples of this study were post-ischemic stroke that met the inclusion criteria (post-hemiparesis ischemic stroke patients, more than 2 weeks until 1 year post-ischemic stroke, adult age of 30 to 65 years old), able to independently walk the distance of 60 meters for six minutes with or without aids, no complains of pain, asphyxiate, heart-pounding and cold sweat, able to conform with simple commands such as “start”, “stop” and “you may rest if you are tired”) and exclusion criteria (uncontrolled hypertension, cardiorespiratory impairment, cognition impairment with MMSE score less than 24, apraxia, severe hemi spatial neglect, musculoskeletal abnormalities, neurology impairment aside of stroke, visual impairment, hearing impairment, ataxia, severe sensory impairment, and involuntary movements) and had signed informed consent. The samples were chosen using consecutive sampling technique.

We found 38 subjects stroke patients that met the inclusion criteria and did not belong to exclusion criteria. We measured cardiorespiratory fitness using 6MWT and walking speed in Dr. Soetomo General Hospital Surabaya. Data analysis then was conducted using SPSS software. The study protocol was approved by the Ethics Committee of Dr. Soetomo General Hospital.

*Annotation r = 0.6 medium correlation, r= >0.7 Strong correlation. Significant if (p= 0.05)

There were 32 subjects (84.21%) with unilateral hemiparesis and six subjects (15.79%) with bilateral hemiparesis. The number of subjects using walking aids was 20, while the other 18 subjects did not use walking aids.

Walking speed assessment in 38 subjects in this study using 10MWT indicated the results of mean time required to take 10 meters with self-speed was 0.534±0.0310 m/s. The shortest time to take 10 meters was 0.085 m/s and the longest time was 1.127 m/s. Walking speed with fast speed was 0.629±0.385 m/s with the shortest time of 0.083 m/s and the longest time of 0.083 m/s (Table 7). The mean of walking speed measurement results using 10MWT in 22 male subjects with self-speed was 0.641±0.356 m/s with minimum speed of 0.085 m/s and maximum speed of 1.127 m/s. As for fast speed, the mean was 0.769±0.442 m/s with
minimum speed of 0.083 m/s and maximum speed of 1.3 m/s. The mean of walking speed measurement results using 10MWT in 16 female subjects with self-speed was 0.389±0.141 m/s with minimum speed of 0.094 m/s and maximum speed of 0.599 m/s. As for fast speed, the mean was 0.438±0.160 m/s with minimum speed of 0.1 m/s and maximum speed of 0.710 m/s. The mean of walking speed measurement results using 10MWT in 22 subacute stroke patients with self-speed was 0.541±0.334 m/s with fastest speed of 0.085 m/s and the slowest speed of 1.127 m/s. As for fast speed, the mean was 0.635±0.431 m/s with the fastest speed of 0.083 m/s and the slowest speed of 1.493 m/s. The mean of walking speed measurement results using 10MWT in 22 chronic stroke patients with self-speed was 0.526±0.282 m/s with the fastest speed of 0.094 m/s and the slowest speed of 1.105 m/s. As for fast speed, the mean was 0.623±0.327 m/s with the fastest speed of 0.1 m/s and the slowest speed of 1.3 m/s.

The mean of walking speed measurement results using 10MWT in 32 hemiparesis unilateral stroke patients with self-speed was 0.577±0.315 m/s with the fastest speed of 0.85 m/s and the slowest speed of 1.170 m/s. As for fast speed, the mean was 0.690±0.389 m/s with fastest speed of 0.083 m/s and the slowest speed of 1.205 m/s. The mean of walking speed measurement results using 10MWT in six hemiparesis bilateral stroke patients with self-speed was 0.308±0.140 m/s with the fastest speed of 0.094 m/s and the slowest speed of 1.105 m/s. As for fast speed, the mean was 0.310±0.138 m/s with fastest speed of 0.1 m/s and the slowest speed of 1.493 m/s.

The relation between 6MWT (VO2max and mileage) and 10MWT (self-speed and fast speed)

The result of 6MWT measurement with mileage in meter indicated a strong correlation with 10MWT both self-speed ($r = 0.756 \ p = 0.000$) and fast speed ($r = 0.770 \ p = 0.000$). 6MWT measured with VOX2max (ml/kg/ minute) indicated strong correlation with 10MWT both with self-speed ($r = 0.715 \ p = 0.000$) and fast speed ($r = 0.687 \ p = 0.000$) (Table 9).

**Discussion**

The age of this study’s subjects vary between 30-65 years old with various Body Mass Index (BMI). Subjects were allowed to use walking aids during walking test.

Six-minute walk test was a simple, practical test that was easy to conduct, well-tolerated, and reflecting daily activity better than other walking tests. This test was conducted in a 10 feet (33m) hall. This test was designed to be an objective measurement for functional status and to represent cardiorespiratory fitness measurement in several individuals by converting the results of 6MWT walking test in VO2max. This test could also be used for measuring distances in meter taken by patients in six minutes. This test was able to make global and integrated evaluation from all involved system during practice including pulmonary and cardiovascular system, circulation system, peripheral circulation, blood, neuromuscular units and muscle metabolism.

Our study showed the same result in which we found VO2max decline in all samples, both subacute and chronic. This was in accordance with the result from Kelly et al. (2005 who reported cardiorespiratory fitness decline stroke onset of 4-7 weeks. Cardiorespiratory decline was significant physical impairment in post-stroke patients, regardless their genders, within approximately 30 days after stroke onset. Their findings also indicated that gait performance might be affected by cardiorespiratory fitness decline.

Our findings implied a relation between VO2max and mileage (Table 5.8). This corresponded with the statement from Kelly et al. (2005) that cardiorespiratory fitness measure was well-associated with gait performance where VO2max showed positive correlation with mileage in measurement using 6MWT in subacute stroke patients. Walking test was designed as an objective measurement for functional status and reflected cardiorespiratory measurement in several individuals. Correlation between 6MWT mileage (meter) and VO2max was within the range of 0.51-0.9.

Walking speed was a parameter of disability in walking fast and easily which was recommended as a output measuring instrument in stroke rehabilitation. Currently, there are several methods of walking speed measurement.

This study measured 10MWT walking speed in stroke patients with subacute and chronic onset where 20 subjects used walking aids and 18 others did not. The average of walking speed observation result in 22 male subjects with fast-speed was slower than with self-speed (see Table 8). This might occur when patients who had walking spasticity with fast speed would have stronger spasticity which inhibited patients in walking.
Calf muscle spasticity showed deviation of muscle tendon length pattern. The deviation pattern was more obvious in walking speed increase. In swing phase, spastic calf muscle was extracted one-third times faster than in normal state. The more deviation in muscle tendon length pattern led to the more rapid dependent velocity in spasticity. This inhibited patients’ walking process, especially in those with fast speed and therefore led to walking speed limitation in patients 11.

Observation result for correlation between 6MWT (by measuring mileage in meter) with 10MWT showed no significance (p=0.000) with correlation coefficient r=0.756. This is also in line with a study conducted by Scivoletto (2011) implying that both tests had inter and intra rater reliabilities and showed positive correlation with lower limb muscle strength 16.

The findings of this study suggesting a relation between upper and lower limb spasticity and 6MWT can be seen in Table 5.5 as stated by Ivey (2005). Mileage and walking speed were strongly related to spasticity. Skeletal muscle consisted of fibers expressing myosin heavy chain (MHC) isoform. MHC protein had higher oxidative function, resistant to fatigue and more sensitive for insulin-mediated glucose absorbance in paretic side thigh muscles. Fast and slow MHC fiber shift in thigh muscles occurred in post-stroke and it caused muscle fibers easier to get tired and there would be more insulin resistance. Low fast MHC fiber immunity led to dependency toward anaerobic or glycolytic energy production. In paretic side extremity, fast MHC fiber proportion showed strong negative relation with self-speed walking speed. This indicated that walking pattern neurological deficit walking pattern severity was correlated with 61% variants in fast MHC isoform 8. Aerobic capacity in individuals was correlated with cardiorespiratory fitness which was strongly associated with age, walking endurance and walking speed, and also associated with knee extensor muscle weakness during walking 17.

Cardiorespiratory fitness decline in post-subacute and chronic stroke patients caused difficulty in daily activities, particularly in walking. Walking was an indicator of independence in an individual. The findings in this study were expected to be able to increase awareness of the importance of cardiorespiratory fitness in daily activities and therefore it was important to conduct walking speed test and mileage in stroke patients that could independently walk or use walking aids.

The use of 6MWT and 10MWT was expected to be conducted with the proper standard and not only limited in patients in outpatient units, but also patients discharged from inpatient unit in order for us to be able to monitor patients’ fitness development objectively.

**Conclusion**

We found a relation between cardiorespiratory fitness and walking speed in post-subacute and chronic ischemic stroke.

Comparison Study of Urinary Retention Incidence in Assisted Vaginal Delivery Case with and without 24-Hour Catheterization

Eighty Mardiyan Kurniawati1, Hari Parathon2, Suskhan Djusad1, Fernandy Moegni1, Junizaf1, Budi Iman Santoso1

1Division of Urogynaecology and Reconstruction, Department of Obstetrics and Gynaecology, Faculty of Medicine, Universitas Airlangga - Dr. Soetomo General Hospital, Surabaya 60131, Indonesia,
2Head of Division of Urogynaecology and Reconstruction, Department of Obstetrics and Gynaecology, Faculty of Medicine, Universitas Indonesia - Dr. Cipto Mangunkusumo General Hospital, Jakarta 10430, Indonesia

Abstract

Background: Urinary retention is a condition commonly seen after vaginal delivery, especially in the high-risk cases, such as assisted vaginal delivery, grade 3-4th perineal rupture, or another high risk. Urinary retention caused by unsynchronized between the contraction of the bladder detrusor. Urinary catheterization is one of the preventions of urinary retention. It gives a time for perineal trauma to relieve and no longer edema, so that urethra can be fully relaxed. Therefore, 24-hour catheterization expected to prevent bladder overdistention. It also prevents the bladder from becoming atonia.

Objective: This research aims to study the incidence of urinary retention in assisted vaginal delivery with and without 24-hour catheterization.

Method: This study used randomized control trials that compared two groups with 24-hour catheterization and without 24-hour catheterization. This study was conducted on 40 women in each group who experienced assisted vaginal birth at Dr Soetomo Hospital, Indonesia.

Result: Six women (15%) experienced urinary retention with 24-hour catheterization and six women (15%) had urinary retention without catheterization. There was no significant difference in the incidence of urinary retention with 24-hour catheterization and without 24-hour catheterization (p-value = 1.00). Also, there was no significant interference of urinary retention in the normal and prolonged second stage of labor (p-value = 0.736), and there was no significant risk factor contributing to urinary retention.

Conclusion: No significant difference in urinary retention occurred in assisted vaginal delivery with and without 24-hour catheterization.

Keywords: urinary retention, assisted vaginal delivery, catheterization.

Introduction

Urinary retention is a condition commonly seen in post vaginal delivery1-3. This condition may become bladder overdistention and atrophy of bladder detrusor. If not treated immediately, this condition may become worse and increase into hospital stay 4,5. If not treated properly, urinary retention will turn into acute urinary retention 6,7. The variation incidence may occur due
to the broad definition of urinary retention. Urinary retention may be classified as overt and covert. Overt type is symptomatic, characterized by the inability to spontaneous micturition wheater covert is a type of asymptomatic while the patient cannot empty the bladder adequately so there is a little residual volume in the bladder. This classification often difficult to classified due to the difference in residual urine volume between 50-250 ml. Urinary retention incidence also varied in some country. In Canada, according to Musselwhite, urinary retention incidence occurs in 4.7%. In Denmark, previous research report it only 0.7% in 2003. Lim KJ report 6% case from 860 vaginal delivery in Korea. Glavind K and Bjork J report that 33% of women with assisted vaginal delivery experience urinary retention. Also, 17% of episiotomy may complicate urinary retention and 33% of anal sphincter rupture contribute and 33% use of epidural anesthesia may contribute as well to urinary retention. A significant risk contributed to assisted vaginal delivery and sphincter rupture. In 2010, previous study reported 10.6% urinary retention case in India. An assisted vaginal delivery and longer stage of labor significantly contribute to urinary retention. Primiparity, epidural anesthesia, assisted vaginal delivery, episiotomy, prolonged stage 1, and stage 2 labor significantly increase the risk of urinary retention. In 35 women who underwent assisted vaginal delivery, 16 of them experience urinary retention. Carley stated that assisted vaginal surgery and epidural anesthesia are independent risk factors. Yip stated urinary retention after labor may worry about the impact, even after 2-5 days of recovery.

Unidentified urinary retention may over distended bladder and need prolonged catheter use. The use of a 24-hour catheter in post vaginal delivery women with the risk factors of urinary retention is expected to prevent overdistention of the bladder. Catheters are also often used for Ventriculo Peritoneal (VP) bypass surgery, and the resulting complications are very rare. At Dr Soetomo Hospital, Surabaya, there is no certain protocol to prevent urinary retention, including 24-hour catheterization in post vaginal delivery. Since assisted vaginal delivery significantly risks to cause urinary retention, this study aims to compare the incidence of urinary retention in assisted vaginal delivery with and without 24-hour catheterization.

Method

This randomized control trial study was conducted at Dr. Soetomo General Hospital Surabaya for nine months. All subjects were gathered by consecutive sampling. The study population divided into two groups with a random lottery. One group consisted of women who underwent assisted vaginal surgery, then were treated with 24-hour catheterization, the other group was without 24-hour catheterization. Each group used a female catheter no.12 to gather residual urine and to ensure there was no residual urine bladder. Analgesia with sodium diclofenac was administered to women with post assisted vaginal delivery.

In the group with 24-hour catheterization after 24 hours, the catheter use was discontinued then observed for 6 hours. The residual urine samples were collected and classified in urinary retention if the residual urine volume were 200 ml or more. The group without 24-hour catheterization was observed for 6 hours after labor. If a subject could not spontaneously urinate in 6 hours, She was then treated the same as the 24-hour catheterization group. The residual urine volume was calculated by ultrasonography using the Koelbl formula described in Figure 1. The statistical Analysis employed T unpaired test, Chi-square test, and the Mann-Whitney test. All analyses were conducted using SPSS.

Results

As 80 subjects met the inclusion criterion, all subjects had homogenous characteristics in age, newborn birth weight, parity, instrumentation during labor, episiotomy, and perineal rupture. In stage 2 labor. As many as 75% of the women in the control group and 50% of the women in the experimental group had a prolonged second stage. These women had experienced assisted vaginal surgery before. A chi-square test was used to compare both groups with significant test results (p-value = 0.021).

The urinary retention was classified if the residual urine volume was more than 200 ml. Statistical analysis using chi-square revealed that there were no significant differences between the two groups (p-value = 1.00), as displayed in Table 2. To identify whether there was the interference of the second stage of labor in urinary retention, a statistical analysis using the Fischer test was performed. The analysis revealed no significant difference between the two groups as shown in Table 3. These subject risk factors were present and could affect
the incidence of urinary retention. To identify whether there was an interference of risk factors, multivariate analysis was conducted as displayed in Table 4. The analysis revealed no significant risk factor contributing to urinary retention (p-value >0.05).

Figure 1. Koelbl formula, \( V = 0.7 \times H \times W \times DL \). \( H = \text{height} \), highest superoinferior diameter, \( DL = \text{depth} \), highest anteroposterior diameter, the height and depth are measured from sagital aspect. \( W = \text{width} \), is the highest anterolateral diameter measured from the transversal aspect. \( KK = \text{bladder} \).

Discussion

These complex factors explained why there is no significant difference in urinary retention incidence between both groups. Therefore, 24-hour catheterization is expected to prevent bladder overdistention. It also prevents the bladder from becoming atonia. Traumatic factors such as the vulva or urethral injury cannot be eliminated. Nevertheless, the micturition requires coordination between detrusor muscle contraction and urethral relaxation. Subject characteristics in this study become known risk factors of urinary retention. Many studies report consistent risk factors for urinary retention. A previous study of a case-control study reported 52 cases of overt urinary retention in 860 postpartum women. Risk factors, such as perineal trauma and prolonged second stage, are significant in urinary retention.
In this study at Dr. Soetomo General Hospital, mediolateral episiotomy also contributed to risk factors compared to the subjects who do not undergo episiotomy (OR 3.2). Some study reported that assisted vaginal surgery is a significant risk factor for urinary retention. In this study, the researchers utilized 24-hour catheterization to prevent the weakening of detrusor muscle due to overdistention. In the group without 24-hour catheterization, a researcher found six subjects with urinary retention due to the inability to urinate in the first six hours or residual urine more than 200 ml, and 34 subjects could spontaneously urinate in six hours.

In the group with 24-hour catheterization, six subjects had urinary retention. One subject had symptom relief after first try intermittent catheterization, and five subjects were relieved after two times intermittent catheterization. Statistical analysis, t unpaired test revealed no significant difference between both groups. In this study, the second stage of labor was found as a confounding factor. In the group without 24-hour catheterization, the subjects with the prolonged second stage were greater than in the group with 24-hour catheterization. This factor was significant. To eliminate this factor, statistical analysis was conducted using the Fischer test. The result was there no significant interference of urinary retention in the group with 24-hour catheterization, where the subjects experienced a prolonged second stage or normal second stage of labor.

According to the previous study, urinary retention had occurred due to the neurological dysfunction, immobilization, trauma of the vulva, abnormality in bladder contraction, spasm of the external urethra due to perineal rupture. In this study, all subjects were administered with mefenamic acid as analgesia. Risk factors such as the duration of the second stage of labor (OR 8.179), parity (2.387), and episiotomy procedure (3.200) contributed to urinary retention incidence, respectively.

Conclusion

There is no significant difference in urinary retention incidence in assisted vaginal delivery with and without 24-hour catheterization. However, this study requires more research with a bigger number of samples to determine the effect of 24-hour catheterization as prevention of urinary retention in assisted vaginal surgery.

Effectiveness of Additional Intranasal Phototherapy through Decrease Score of Nose Symptom and Eosinophil Mucosa on Persistent Allergic Rhinitis

Hamna Fitriah¹, Roestiniadi Djoko Soemantri¹
1Departement of Otolaryngology, Faculty of Medicine, Universitas Airlangga-Dr. Soetomo Teaching Hospital, Surabaya 60285, Indonesia

Abstract

Background: Allergic rhinitis (AR) is a common atopic disease but the available treatment has limited use and success rate. It has been suggested that intranasal phototherapy represents an alternative choice in the treatment of AR.

Objective: This study aimed to analyze the effect of additional intranasal phototherapy to loratadine therapy compared with single loratadine therapy in order to decrease total nasal symptoms score (TNSS) and nasal mucosa eosinophil count in persistent AR patients.

Method: Fifty-four persistent AR patients were divided into two treatment groups: group A and B treated with 10 mg loratadine once a day with additional intranasal phototherapy at 660 nm. 4.4 minutes 3 times a day for group B. Evaluation was based on TNSS and nasal mucosa eosinophil count pre and post 14 days of treatment.

Result: The study conducted from July to August 2014 demonstrated significant average of TNSS decrease on group B compared to group A (p = 0.002). Also significant average of eosinophil mucosa nasal count decrease on group B compared to group A (p = 0.049). Both group A and B showed the smallest score of TNSS pre-therapy was 4 vs 6, however the highest score was 6 vs 12. Group A and B showed the smallest score of TNSS post-therapy was 0 vs 0, however the highest score was 8 vs 7.

Conclusion: Additional intranasal phototherapy to loratadine therapy showed more effective compared with single loratadine therapy in order to decrease TNSS and nasal mucosa eosinophil count in persistent AR patients.

Keywords: Allergic rhinitis, Eosinophil, Phototherapy intranasal, Loratadine.

Introduction

Allergic rhinitis (AR) is the most common atopic disease that becoming global health problem. In persistent AR, the symptoms happen more than 4 weeks and characterized by the accumulation of inflammatory cells, especially eosinophils. Clinical evaluation and therapy of persistent AR can be performed subjectively by calculating the total nasal symptom score (TNSS) and objectively on nasal mucosal eosinophil1. Histamine interacts with H1 and H2 receptors increased permeability of blood vessels causes nasal congestion2,3. Histamine induces the expression of intracellular adhesion molecule-1 (ICAM-1) to help eosinophils migration to the nasal mucosa4. Eosinophils actively secrete chemical mediators and Reactive oxygen species (ROS) that worsen AR symptoms5.

First-line therapy recommended Allergic rhinitis is loratadine, which can be administered singly or in combination with other anti-allergic drugs6,7. Loratadine inhibits eosinophils adhesion in the blood

DOI Number: 10.37506/ijfmt.v14i2.3366
vessels and eosinophils accumulation in nasal mucosa. Significant decrease of eosinophils infiltration, the levels of eosinophil cationic protein (ECP), histamine and expression of ICAM-1 on RA patient’s nasal rinse. Therefore some experts develop new therapeutic modalities of intranasal phototherapy to optimalize AR therapy.

Intranasal phototherapy with visible red light inhibits inflammatory mediators release by eosinophils and stimulate nitric oxide (NO). Nitric oxide inhibits mast cell degranulation and cytokine expression. Increased vascular permeability as well as adhesion and leukocyte migration ultimately suppress the symptoms of AR. An intranasal phototherapy study with visible red light 660±5 nm wavelength showed improvement in AR clinical symptoms of 70%. Intranasal phototherapy with a combination of UVA, UVB and visible light (mUV/vis) significantly decreased TNSS as well as the number inflammatory cells and mediators and were conducted with the aim of comparing the effectiveness of mUV/vis intranasal phototherapy with AH fexofenadine hydrochloride.

Separate research on the effectiveness of loratadine and intranasal phototherapy has been widely practiced abroad. Up to now, there has been no research on the effectiveness of intranasal phototherapy addition to loratadine therapy. Based on the above description the researchers aimed to determine the effect of intranasal phototherapy addition to loratadine therapy compared to single loratadine therapy in persistent AR patients which was assessed by TNSS and the number of nasal mucosal eosinophils.

**Method**

This study used a single-blind randomized controlled trial design with pre and post-test design which was held in January to November 2014 at the Outpatient Unit of Allergy Immunology Division and Clinical Pathology Installation of Dr. Soetomo Teaching Hospital, Surabaya. The samples were divided into 2 groups by block randomization with the number of 4 blocks to obtained 6 permutations. The control group (group B) received loratadine therapy and the study group (group A) received loratadine therapy combined with intranasal phototherapy. The study sample was mild to moderate-severe AR patients according to ARIA criterion 2008. All samples underwent TNSS and nasal mucosa eosinophil pre- and post-therapy.

This study used consecutive sampling with inclusive and exclusive criteria. The inclusion criteria were having a pre-therapy GHT score ≥4, aged between 21 and 60 years, free anti-allergic drugs such as: AH (1 week), systemic corticosteroids (4 weeks), topical corticosteroids (2 weeks), topical decongestants (1 week), anticholinergic and chromoline (for 2 weeks), willing to take part in the research and signing the approval sheet to follow the research. The exclusion criteria were the presence of acute respiratory infections, acute and chronic paranasal sinusitis, medical rhinitis, nose abnormalities such as tumors, nasal polyp, severe deviation septum in conditions of pregnancy or lactation and having a history of loratadine allergy.

This research required 10 mg loratadine tablets and 8 units of intranasal phototherapy devices. Intranasal phototherapy equipment used was Bionase unit of Syrolight. Bionase unit consisted of control box size 23 x 16 x 6 cm, 246 grams and 2 LED probes (Israel). The nasal mucosal eosinophil was applied to the glass object and then dried. Those preparations were stained with Wright staining and then examined their eosinophils using Olympus microscope with 1000 magnification. The sample was not allowed to receive other treatments that could interfere with the results of the study for 14 days. Then TNSS and nasal mucosal eosinophil were assessed.

The data were tabulated and analysed statistically using SPSS (SPSS. Inc. Chicago, IL) with significance level (p) of 0.05 or 5%. Analysis of age distribution, TNSS, and number of nasal mucosal eosinophils were obtained with Mann-Whitney U test. Sex distribution was analysed using Chi square test and side effects was with Fisher’s exact test. The Wilcoxon signed rank test was used to determine the ratio of TNSS and the number of nasal mucosal post eosinophils between the two groups.

**Results**

**TNSS score and Therapy**

Group A had the smallest TNSS pre-therapy of 4 and the highest score of 11 (1 patient each, 3.7%). Group B had the smallest TNSS pre-therapy of 6 (3 patients, 11.1%) and the highest score of 12 (2 patients, 2.4%). Group A had the lowest TNSS post-therapy of 0 (3 patients, 11.1%) and group B had the lowest TNSS post-
therapy of 0 (1 patient, 3.7%). Group A had the highest TNSS post-therapy of 8 (1 patient, 3.7%) while group B was 6 patients (3.7%). The average TNSS pre-therapy in group A was 7.67 (1.73) and group B was 9.41 (1.80). The average TNSS post-therapy in group A was 3.63 (2.08) and group B was 78 (1.40, Table 1).

The average percentage of TNSS decrease post-therapy in group A was 55.2% while group B was 70.9%. The Independent sample t-test showed that the percentage between group A and B was significantly different (p = 0.002, Table 2).

**Nasal Mucosa Eosinophil and Therapy**

Groups A and B had the most eosinophils pre-therapy in the range of ≥10% to <25%, respectively. Group A had the least eosinophils pre-therapy in the range of ≥25% to <50% while group B was <10%. The average eosinophil pre-therapy in group A was 21.44 (19.14) and B was 32.93 (26.46).

Group A had the most eosinophils post-therapy of <10% and ≥10% to <25%. Group B had the most eosinophils post therapy of <10%. Group A had the least eosinophils post therapy of ≥50% while group B was ≥25% - <50% and ≥50%. The average eosinophils post-therapy in group A was 12.48 (14.93) and group B was 8.78 (12.75, Table 3.)

The average percentage of nasal mucosa eosinophil decrease in group A was 22.6% and group B was 64.5%. The independent sample t-test showed that the percentage decrease of nasal mucosal eosinophils between group A and group B was significantly different (p = 0.049, Table 4.)

**Side Effect**

The most common side effects reported by patients in groups A and B were drowsy. Dry mouth or throat in both groups happened in 1 patient (3.7%). The Fisher’s exact test suggested that the distribution of side effect between the two groups was not significantly different (p = 1.000, Table 5).

Discussion

The results showed significant improvement of nasal congestion and rhinorrhea 80% and 81% (study group) and 31% and 14% (control group) respectively. A study investigated the effects of mUV/vis intranasal phototherapy versus topical azelastine therapy in moderate persistent AR. The average variation of TNSS pre and post-therapy might be due to the different sample criteria selected. This leads to differences in average TNSS pre-therapy as well as the possibility of decreasing TNSS as being summarized as average TNSS post-therapy. Another study using Bionase phototherapy tool compared 660 nm visible red light effect (study group) and sham illumination (control group). A similar study reported a decrease of all AR symptoms post 660 nm visible red light phototherapy. Other studies showed a decrease in TNSS after intranasal phototherapy of visible red light for 14 days.

Other studies used different light showing a significant improvement in TNSS post-mUV/vis phototherapy of 50% in 11 patients (61.1%). The Hex fexofenadine group showed no significant improvement with 50% TNSS improvement in 2 patients (15.4%). This study used the Bionase intranasal phototherapy apparatus with LLLT technique did not cause any harmful side effects or interactions with. Bionase efficiency as AR therapy occurred because of its role in producing NO. In this study the number of nasal mucosal eosinophil that could be analyzed was 24 of 27 patients in group A and 25 of 27 patients in group B. Three preparations of group A and two preparations of group B were not included in the statistical analysis.

Missing 5 samples happened because it had a pre value of 0 therefore in statistical analysis the result was not defined. Other descriptive research data on average percentage of nasal mucosal eosinophil pre- and post-loratadine with and without visible red light phototherapy were not found. The average percentage of nasal mucosal eosinophil decrease between the two groups was significantly different (p = 0.049). The average of nasal mucosal eosinophil decrease in group A was 22.63% smaller than the decrease in group B that was 64.46% although sample size for percentage analysis was below the minimum but with significant analysis results, the lack of eosinophil samples did not become obstacles and the results of the analysis were still acceptable.

A study showed similar results in decreasing the inflammatory cells (eosinophils, macrophages, neutrophils, lymphocytes) post-visible red light. Previous studies showed a significant decrease of eosinophils, ECP and IL-5 post- mUV/vis intranasal phototherapy and visible red light. Other studies showed a significant decrease in eosinophils, inflammatory cells, ECP, histamine and ICAM-1 expression after loratadine therapy. Eosinophils reached nasal secretions in nasal cavity within 1 - 3 hours and stayed up to 3 days. In this study Bionase phototherapy worked by producing NO which would inhibit eosinophil cell adhesion. NO also played a direct role in modulation of immune response by influencing expression of adhesion molecule VCAM-1, ICAM-1 and endothelial E-selectin that were important for eosinophil adhesion. Visible red light phototherapy with LLLT technique significantly interfered major transcription factors activity that governed IL-4 expression, IL-5 and eotaxin thus it could inhibited IgE production and eosinophil recruitment. Research conducted on mice’s BALF showed decreased infiltration of inflammatory cells (eosinophils, macrophages, neutrophils, lymphocytes), IL-4, IgE secretion and increased IFN-γ after phototherapy. The effects of phototherapy were reported having no side effects. Side effects between two groups were not significantly different. Another study obtained dry nose, mouth and throat complaints post-loratadine in 23% of patients.

Conclusion

The addition of intranasal phototherapy to loratadine therapy compared to loratadine therapy singly was more effective in reducing TNSS and the number of nasal mucosal eosinophils of AR patients.

Hydration Status and Degree of Clinical Severity Patients with Thrombotic Infarction Stroke

Agung Nugroho¹, Hendro Susilo¹
¹Department of Neurology, Faculty of Medicine, Dr. Soetomo Teaching Hospital, Universitas Airlangga, Surabaya 60285, Indonesia

Abstract

Background: Dehydration is common in acute ischemic stroke patients and associated with a poor increase in clinical outcomes. It is caused of the increase of hematocrit related to the infarct volume which is wider to the cerebra infarct patients. It is also related to the repeatedly emboli stroke and thromboembolic vena after the occurrence of the acute stroke.

Objectives: To analyze the correlation between hydration status and clinical severity in patients with acute thrombotic stroke.

Methods: This study was conducted by using control design consecutive admission sampling technique. Serum BUN and creatinine measurements were performed when patients were administered to the hospital. Dehydration was defined if the ratio of BUN/serum creatinine was >15. Patients were divided into dehydration and non-dehydrated groups. The degree of clinical severity was measured by using the National Institute of Health Stroke Scale (NIHSS) at 7 days of onset of stroke. Data were analyzed using chi square, fisher, t dependent test, and mann whitney (p <0.05).

Result: There were 19.23% stroke patients with dehydration were in the case group and the control group were 9.62%. There was no significant correlation between hydration status and clinical severity in acute thrombotic stroke patients (p = 0.126; OR = 2.625).

Conclusion: There was no correlation between hydration status and clinical severity in acute thrombotic stroke.

Keywords: Stroke, dehydration status, BUN/SK, NIHSS

Introduction

Stroke is the first leading cause of disability worldwide, the second most common cause of dementia, and the third leading cause of death. Stroke resulted in major clinical, social, and economic impacts with a total death rate of 6.2 million (+11% of the total). Around 9 million people suffered a stroke in 2008, 30 million people have had previous strokes and still alive. Stroke is the main cause of disability and this recent decline has fallen from the third leading cause of death to the fourth place in the United States ¹. The incidence of stroke has increased exponentially over the last 30 years and its causes vary by age. Ninety-five percent of strokes occur in people over the age of 45 and two-thirds of strokes occur in people over age 65. The risk of death in a person with stroke also increases with age. Stroke can occur at any age including the age of the children ².

Stroke is also a major cause of disability. It is approximately 55% of patients who survive up to 3 years will experience a decrease in quality of life. There is only 20% of patients with stroke can return to work as before ³,4. The association between renal function and stroke has been determined by a study assessing the association between hypertension and mortality with black patients suffering from acute stroke as the determinants. Stroke survivors have lower levels of...
urea than those who died. Friedman’s findings of stroke survivors in New Zealand mentioned that serum creatinine concentrations independently as predictors of mortality even after adjustment for confounding variables.

Euvolemia is important for adequate blood flow and maximizing oxygen intake into optimal tissue and organ function. Research showed blood flow to organs such as muscles and kidneys decreases significantly during dehydration. Cardiac output also decreases during dehydration. The brain has the ability to control blood flow through autoregulation that regulated constant cerebral perfusion pressure even when blood pressure changes. Dehydration has been shown to decrease the autoregulation response to orthostatic position changes, but in general does not decrease cerebral perfusion.

The role of dehydration in cerebral infarcts is thought to be multifactorial. Dehydration increases the viscosity of blood by decreasing blood flow to the brain through the decrease of intravascular volume. The increase hematocrit has been shown to be associated by a larger volume of infarction in patients with cerebral infarction. Dehydration has also been shown to be associated by recurrent embolic strokes and thrombotic events including venous thromboembolism following the onset of acute stroke. Dehydration can disrupt the distribution of oxygen to the brain, increase the risk of venous thromboembolism, and be associated with poor outcome in stroke. Dehydration can be detected by biomarkers of reduced fluid in the blood. Biomarkers that are often used to assess the presence of dehydration are the ratio of BUN/creatinine and plasma osmolality.

There is no hydration marker has been considered a golden standard, especially for mild dehydration. A total of 102 elderly patients were admitted to one of the educational hospitals who were diagnosed dehydrated. After a serum analysis, there is only 17% had an increase in serum osmolarity, 11% had elevated serum sodium, and 68% had an increase in blood urea nitrogen (BUN)/serum creatinine (SCr). BUN and SC are valuable laboratory parameters for evaluating renal function. The ratio of BUN to serum creatinine (BUN/SCr) is one of the useful laboratory indicators to determine the decrease in hydration status. Based on the description above, it is necessary to conduct an analysis of dehydration status and degree of clinical severity in patients with thrombolytic infarction.

**Methods**

The participants in this study were all acute thrombotic stroke patients who met the inclusion and exclusion criteria. The inclusion criteria included patients diagnosed clinical acute thrombotic stroke and uncompromised CT scan, first stroke occurring within 24 hours, and having National Institute of Health Stroke Scale (NIHSS) score score of <4. NIHSS is a tool used to assess stroke damage with score range of 0 to 42. Exclusion criteria include patients having chronic renal failure, congestive heart failure, hemorrhagic stroke, embolism stroke, systemic inflammatory response syndrome, and use diuretic drugs. Participants who were willing to be involved in this study were required to fill the informed consent form in advance.

The participants were selected by identifying the number of patients with acute thrombolytic stroke in the previous year at Dr. Soetomo Teaching Hospital Surabaya, Indonesia. Afterwards, we found 101 participants with acute thrombolytic stroke who met the inclusion and exclusion criteria. During the course of the study, some patients with acute thrombolytic stroke were excluded from the study because the participant went home forcibly or died in ≤24 hours before blood sampling was taken for BUN and SCr examination. After those processes, we found 52 participants that were able to be enrolled in this study.

The procedure of this study involved patients diagnosed with acute thrombolytic stroke. Patients were examined by NIHSS on the seventh day. Participants were identified and divided into 2 groups, i.e. case group (moderate NIHSS with score 4-15) and control group (NIHSS with score <4). We conducted blood pressure measurement for the participants. Blood sample of 3 ml was stored in EDTA vials and identified for the BUN, SCr, Hb, Albumin, Potassium, Sodium, and Glucose. Assessment of dehydration status (BUN/SCr) was based on two studies. The criteria of hypertension refers to Joint National Committee 8 (JNC-8).

The measurement data were analyzed according to the type of measurement results data using SPSS 22.0 (SPSS, Inc., Chicago, IL). Analysis on the participants’ gender data and blood pressure were conducted using chi square test (A p value of <0.05 was considered as
statistically significant). Analysis on age, albumin, sodium, potassium, hemoglobin, and glucose data of the participants were conducted using t-dependent test (A p value of <0.05 was considered as statistically significant) with Kolmogorov Smirnov beforehand. The correlation between dehydration status and degree of clinical severity in stroke infarction patients was analyzed using chi square test (A p value of <0.05 was considered as statistically significant).

Result

Sample Characteristic

The demographic data in this study consisted of two types of data, i.e. gender and age. In case group, most participants were female (32.69%), while in control group most participants were male (32.69%). The comparison of age between the two groups showed p = 0.027 (Table 2). In case group, the mean of the participants’ age was 55.43±9.05 years old, while in control group was 53.12±11.96 years old. The comparison of age between the two groups showed p = 0.233 (Table 1).

The Albumin, Glucose, Potassium and Sodium Level

The clinical data of albumin examination showed the value 4.00±0.36 mg/dl in case group and 4.18±0.42 mg/dl in control group. The comparison between the two groups showed p = 0.276. The sodium level was 134.12±3.38 mg/dL in case group and 135.12±2.52 mg/dL in control group. The comparison of sodium level between the two groups showed p = 0.653. The potassium level in case group was 3.76±0.53 mg/dL, while in control group was 4.05±0.46 mg/dL. The comparison of potassium level between the two groups showed p = 0.479. The level of hemoglobin was 14.00±2.81 mg/dL in case group and 14.10±4.95 mg/dL in control group. The comparison of hemoglobin level between the two groups showed p = 0.905. The glucose level in this study was 137.43±40.51 mg/dl in case group whereas in control group was 123.58±20.31 mg/dl. The comparison of blood glucose between the groups showed p = 0.694 (Table 1). Most participants had hypertension with 82.69%. The comparison of hypertension in the two groups showed p = 0.233.

Hydration Status and the Stroke Severity

According to all participants in this study, 19.23% in case group experienced dehydration. However, control group was 9.62%. We did not find any significant difference, both statistically and clinically, between clinical severity degree of acute thrombotic stroke patients and dehydration condition and those with no dehydration. The p value was 0.126 and the odd ratio value was 2.625 (IK 95%; 0.748 – 9, 210; Table 2).

**Discussion**

The results which do not correspond with the proposed research hypothesis might be due to several things. First, the study did not include subjects suffering from ischemic stroke due to thrombotic in large vessels and therefore we did not get sufficient number of subjects into moderate to severe NIHSS groups with dehydration as well. In the studies conducted by Lin et al. and Schrock et al., the inclusion criteria included ischemic stroke patients due to large vessel disease 6,16. Second, this study did not limit the age of the subjects, causing that the proportion of subjects in the dehydrated group and the severity of clinical/NIHSS were not as expected. It is known that the elderly subjects are susceptible to dehydration which is a major cause of fluid and electrolyte disturbances 12. Third, this study did not consider other factors that might determine stroke prognosis, such as the location and width of the infarct. Stroke prognosis is affected by various factors including age, stroke severity degree, stroke mechanism, infarct location, comorbidity conditions, clinical finding, and related complications 20.

Cerebrovascular disease is one of the causes of morbidity, disability, and mortality worldwide. Generally the different genders are associated with stroke events. The relationship between age and stroke is more influential to men except at an advanced age. Increased age affects the morbidity of stroke, mortality, and the old outcome in both minor and major stroke. The age of over 65 years has a higher mortality risk in 2 months after stroke 21.

Hypoalbuminemia is a poor predictor of prognosis in patients with ischemic stroke, but the mechanism is still unknown. The currently known mechanism is not only limited to energy depletion, but also related to the damage of one’s immune and hormonal responses, as well as extracellular fluid expansion. In another study, the effect of infusion of albumin on ischemic brain of experimental animals was suggested. This is presumably because albumin has a neuroprotective effect mediated by various actions including antioxidative ability, affecting endothelial function, and venular perfusion 22.

Hyponatremia is a risk factor for stroke and cardiovascular disease. Mild hyponatremia is associated with increased mortality within 30 days of myocardial infarction and post-stroke mortality in 3 years. Hyponatremia is associated with acute mortality and worse outcome trends resulting in higher mortality within 12 months after stroke 23. The mechanisms of potassium effect on stroke are still unclear. Patients with lower potassium serum levels during stroke and after dismissed from hospital have a poor prognosis, especially in elderly patients 24.

Hypertension is a major risk factor for stroke. The increase of systemic blood pressure associated with the increased intra-cranial pressure (ICP), mainly due to suppression of the brain stem. It is strongly associated with intracerebral and subarachnoid hemorrhage, but this increase in blood pressure does not appear to be associated with cerebral ischemia 25.

The dehydration condition characterized by an increase in BUN/SCr ratio is a factor that can be used
to estimate poor outcomes in patients with chronic heart failure. The increase of BUN/SCr ratio is also reported to be associated with a neurological deterioration in ischemic stroke patients. A dehydration condition that increases the BUN/SCr ratio by more than 15 is at 2.2 times risk of clinical impairment in 30 days of post-onset of ischemic stroke. Infarction stroke patients with elevated BUN/SCr ratio had a higher prevalence for cardiembolic stroke compared to those without increased BUN/SCr ratio.

**Conclusion**

There was no correlation between hydration status assessed using BUN/Serum Creatinin ratio and the clinical severity degree assessed using NIHSS in acute thrombotic stroke. However, a further confirmation is still required.

**Ethical Clearance:** The study protocol was approved by the Ethical Commission to conduct basic science/clinical research in Dr. Soetomo General Hospital Surabaya, Indonesia. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice.

Prevalence of Benign Vocal Cord Disorder at Dr. Soetomo General Hospital Surabaya Indonesia in June 2015-June 2016

Lucia Miranti Hardianingwati1, Diar Mia Ardani1

1Department of Otolaryngology Head and Neck Surgery, Faculty of Medicine, Airlangga University, Dr. Soetomo General Hospital Surabaya, 60285 Indonesia

Abstract

Benign vocal cord disorder is a common case but its prevalence is difficult to determine. Reporting on the number of benign vocal cord disorder events is important for data management to arrange the effective management. Objective this research to determine the prevalence of benign vocal cord disorders, i.e. nodules, cysts, and vocal cord polyps. Method is a retrospective descriptive study conducted using medical record data of outpatient unit of Otolaryngology-HN division of larynx-pharynx Dr. Soetomo General Hospital Surabaya in the period of June 2015 to July 2016. Result benign vocal cord disorders consisted of 65.00% of subjects with nodules, 15.00% of subjects with polyps, and 20.00% of subjects with cysts. The ratio of male and female was 1:1. The most age was 20-59 years old with 60.00%. The largest occupational group is professional voice user with 60.00%. The location of benign vocal cord disorders was in 1/3 of the bilateral anterior as much as 85.00%. The most frequently used therapy is non-operative with 65.00%. The conclusion benign vocal cords disorder with the types of vodal, polyps, and vocal cord cyst occurred in 4.21% of all patients with dysphonic complaints. Vocal cord nodules had the highest incidence among other types of cord vocal diseases with 2.73% while the highest prevalence was shown by vocal cord nodules with 4.42%.

Keyword: Benign vocal cord, nodule, cyst, polyp

Introduction

Benign vocal cord are abnormal masses of excessive and uncoordinated laryngeal tissue 1. Benign vocal cord disorders decrease the efficiency of sound production. The voice becomes husky and breathy, causing patients to make more effort to talk. This leads to the patient complaining of tiredness and discomfort in the neck and throat. Patients with benign vocal cord disorder do not feel pain. The uneven surface of the vocal cords causes the mucus to get caught in the throat and cause them to react by coughing or clearing throat 2.

Benign vocal cord disorder can be divided into two: neoplastic and non-neoplastic. Non-neoplastic benign vocal cord disorders include vocal cord nodules, vocal cord polyps and vocal cord cyst 3. The talkative extrovert people and those whose works require the high use of voice are at risk of benign vocal cord disorders. Other risk factors include smoking, acid reflux, allergies and infections 4. Benign vocal cord disorder is a common case but its prevalence is difficult to determine.

In the United States from January 2004 to December 2008, the total population was fifty-five million patients. Of the total population, the prevalence of patients diagnosed with a dysphonia is 1%, and approximately 11% of dysphonia cases in the patients are caused by a benign vocal cord disorder. Benign vocal cord disorders consist of vocal cord polyps, vocal cord nodules, vocal cord abscess, vocal cord cellulitis vocal cord granuloma, and vocal cord leukoplakia 4, 5. There was never a certain rate of prevalence of benign vocal cord disorder in Dr. Soetomo general hospital. This study aims to
determine the prevalence of benign vocal cord disorder in Dr. Soetomo General Hospital Surabaya in the period of June 2015-June 2016.

**Method**

The subjects of the study were dysphonic patients treated at Dr. Soetomo General Hospital Surabaya, Indonesia that met the criteria of inclusion and exclusion. The inclusion criteria included patients with symptoms of dysphonia, patients diagnosed with benign vocal cord disorders, i.e. nodules, cysts, or vocal cord polyps, and patients with complete data. The exclusion criteria excluded patients with a history of malignancy.

This is a retrospective descriptive study conducted in outpatient unit of Otolaryngology-HN, Division of Larynx-Pharynx, Dr. Soetomo General Hospital Surabaya. The study materials were medical record data of outpatient unit of Otolaryngology-HN, Division of Larynx-Pharynx, Dr. Soetomo General Hospital Surabaya from June 2015 to June 2016. Prior to conducting the study, we have undergone ethical test at Dr. Soetomo General Hospital Surabaya, Indonesia. The initial number of samples before the identification based on the criteria was 475 subjects. After passing through the process, the number of subjects that fit the criteria was 20 subjects.

The data was collected by retrieving the data of new patients who came for a rigid and flexible laryngoscope action procedure from June 1, 2015 to June 30, 2016. The patients’ data were taken from the register book of larynopharyngeal division of 2015-2016 and the rigid and flexible laryngoscope report books of 2015-2016.

Patients’ data included patients’ identity, anamnesis, examination results, and diagnosis after rigid or flexible direct laryngoscope procedures. The collected data were arranged in tables according to age, sex, occupation, type of benign vocal cord disorder, location of benign vocal cord disorder, and the therapy given. The occupation types of the patients in this study were divided into 4 levels. Level I refers to elite vocal performer, i.e. singers and the radio announcers. Level II is professional voice user, i.e. lecturers. Level III is non-vocal professional, i.e. teachers, merchants, and students. Level IV is non-vocal non-professional, i.e. housewives and farmers. Data measurement results in this study are presented in the form of tables and descriptions.

**Result**

The number of female and male patients in this study was comparable with 50.00% for each group. Most patients were in the age group of 20-59 years old with 60.00%, followed by the age group of 1-9 years old with 20.00%. Most of the subjects work as teachers, traders, or students (level III occupations) with 60.00%, followed by housewives or farmers (level IV occupation) with 20.00%. Most subjects had benign vocal cord disorder in the form of nodule with 65.00% (Table 1).

Benign vocal cord disorders were grouped according to the location of the lesions, i.e. anterior 1/3 of the vocal cord, medial 1/3 of vocal cord, unilateral, and bilateral. The location of the vocal cord polyps was mostly in the anterior 1/3 of vocal cord, unilateral, with 10.00%, whereas the least was found in medial 1/3 of vocal cord, unilateral, with 5.00%. In the vocal cord cysts, most vocal cords were located at anterior 1/3 of vocal cords, unilateral, with 15.00%, and the least was found in medial 1/3 of vocal cord, unilateral, with 5.00%. The location of the vocal cord nodules was mostly located at anterior 1/3 of vocal cord, bilateral, with 55.00% and the least was found at anterior 1/3 of vocal cord, unilateral, with 5.00% (Table 2). Patients with benign vocal cords were grouped according to the type of therapy given. The most prevalent treatment group was the patients treated with non-operative at 65.00% and the least one was the group of patients who did not come for further therapy with 10.00% (Table 3).

Discussion

Benign vocal cord disorders are less common than the malignant ones. Benign vocal cord disorder can be divided into two: neoplastic and non-neoplastic. Non-neoplastic benign vocal cord disorders are due to infection, trauma, and degeneration. Some examples of non-neoplastic benign vocal cord disorders are vocal cord nodules, vocal cord polyps, and vocal cord cysts. Vocal cord nodules are always bilateral and almost symmetrical. Stroboscope examination will show a decrease in mucosal movement (mucosal wave). Voice therapy will decrease or relieve vocal cord nodules. Vocal cord polyps may occur unilaterally or bilaterally with exophytic lesions that are transparent or reddish in hemorrhagic polyps. Voice therapy does not change the size of the vocal cords polyps. Vocal cords cyst may be unilateral or bilateral. The location of vocal cord cysts is near the ligaments or within the subepithelial cavity. The subepithelial cavity is an area just below the vocal cord epithelium.

In this study we found the ratio of male and female patients with same benign vocal cord disorders. The same comparison of men and women in this study suggests that the risk of vocal cord disorders is the same in both women and men. Bastian et al. explained that benign vocal cord disorders are common in women because women use excessive sound more often. In the pre-menstrual period women experience premenstrual vocal syndrome (PMVS), described as the change of vocal cord stability due to hormonal fluctuation. PMVS is characterized by the inability to achieve high notes and the loss of power to make a voice. In this pre-menstrual period there is also a dryness of the larynx due to unbalanced estrogen and progesterone levels. A dry larynx encourages the patient to cleared his throat and this may lead to the occurrence of vocal cord nodules.
The age group of patients with benign vocal cord disorders in this study was mostly 20-59 years. Another study also mentioned the same thing. This explains why benign vocal cord disorders occur in patients in the working age group. The working age group consisted of individuals who actively work. This explains that patients in working age who often use voice will have a greater risk of suffering from benign vocal cord disorders.

VHI (Voice Handicap Index) score is a questionnaire containing 30 questions about the quality of life of dysphonic patients with good validity and reliability. VHI provides information about the patient’s perception on the level of sound disability in everyday life. A retrospective study by Behrman et al. proves that the level of voice needs related to lifestyle and occupation affects VHI scores. In patients with voice disorders, the higher level of the voice need leads to a higher VHI score. The high number of patients with working age in this study explains that patients in working age are in a high need of using the voice well. This also affects the VHI score. A high VHI score encourages the patients in working age to come for treatments.

The type of work has is closely related to the occurrence of benign vocal cord disorder. Those with the types of work requiring loud sounds with high frequencies are at risk factor for benign vocal cord disorders. The types of occupations that fall into level three tend to have the misuse of sound (vocal abuse) because in working, they use their voices as their primary resources without being professionally trained. The types of work included in level three require moderate sound quality but high voice load. The voice load include working hours, noisy environment, and inadequate work facilities. The excessive number of pupils in each classroom also affects the voice load of those working as teachers.

The most common type of benign vocal cord disorders in this case is the vocal cord nodules. The similar result was obtained in another study as well. Most patients with vocal cord nodules have a job in which voice becomes the primary requirement. This is why patients with a vocal cord nodules tend to come quicker for treatment compared those with other benign vocal cord disorders. Anterior 1/3 of the vocal cord is a membranous part. When the vocal cords vibrate, the membranous portion is the scene of friction and clash between the greatest vocal cords. Strong vibration that occurs for long periods of time causes vascular congestion accompanied by swelling in the membranous part of the vocal cord. This leads benign vocal cord disorders to be more commonly encountered at anterior 1/3 of vocal cords.

In this study, one patient experienced unilateral vocal cord nodules which was due to several possibilities. In this patient the vocal cord nodules were detected very early. Thus, the possibility of reactive lesions on the contralateral side of vocal cords has not been formed yet. The facilities for vocal cord examination used in this study were rigid and flexible laryngoscopes. Rigid and flexible direct laryngoscopes have limitations in detecting benign cord vocal disorders in detail. Unilateral lesions of the vocal cord may be detected by telelaryngoscope (stroboscope) as much as 79.8% whereas rigid direct laryngoscope with general anesthesia can only diagnose as much as 60.7%.

Non-operative therapy an effort to optimize the state of the larynx. The state of the larynx can be optimized using voice therapy by eliminating the habits that can injure the vocal cords, such as screaming or whispering, using voice with no exaggeration and optimal hydration. Other health problems associated with vocal cord irritation were also treated, such as acid reflux and control of allergies. If benign lesions of the vocal cord provide excellent response to non-operative therapy, then non-operative therapy is the best option to take.

Operative therapy is more intended for benign vocal cord disorders with the types of polyps and vocal cords cyst. Exophytic benign vocal cords disorders including vocal cord polyps and lesions that cause severe mucosal stiffness such as ligament cysts show poor results in non-operative therapy. Operative therapy becomes the primary choice if the patient has dysphagia associated with aspiration, has a risk of airway obstruction, and if there is suspicion of malignancy. For patients who have undergone non-operative therapy but do not get the expected results, then operative therapy can be taken into consideration. Operative therapy is also chosen if the need for voice for everyday life is very important for the patient. Non-operative treatment of the study included antibiotics, anti-inflammatory, steam inhalation, and voice rest. The operative therapy includes excision with rigid direct laryngoscope, excision with endoscope, and external excision. The percentage of patients treated non-operatively in the study was quite high and they...
showed good results 3.

**Conclusion**

This study was conducted at outpatient unit of Otolaryngology-NH, Division of Larynx and Pharynx, Dr. Soetomo General Hospital Surabaya from June 2015 to June 2016. There were 20 new patients with nodules, polyps, and vocal cord cysts for one year and the number was 4.21% of all patients with dysphonia complaints. Vocal cord nodules had the highest incidence among other types of cord vocal diseases with 2.73% while the highest prevalence was shown by vocal cord nodules with 4.42%.

Utilization of Deconcentration Health Funds in Planning, Budgeting, and Implementation in Indonesia

Gurendro Putro1, Ristrini1, Tumaji1

1Center for Humanities Research, Development and Health Management, Ministry of Health, Indonesia

Abstract

Background: Deconcentration funds are funds that given to regions in achieving the target echelon 1 indicator of the main units in the ministry of health with program performance indicators, then translated into echelon 2 targets with the achievement of activity performance indicators. This deconcentration fund is one for health financing in achieving the National Medium-Term Development Plan (RPJMN) in the health sector.

Aim: to examine the allocation of deconcentrated funds in planning, implement, monitoring and evaluating.

Method: the secondary data document was analyzed for the allocation of deconcentrated funds, from the center in each division of the program. This research was conducted for 4 months from September to December 2018.

Result: the highest deconcentration funds from 2016 to 2017 were highest in the North Sulawesi provincial health department of 75.68% and 98.64%, while the lowest in the North Kalimantan provincial department was 39.25% and 68.03%. Whereas for 2018 the highest realization was in the Southeast Sulawesi provincial health department at 97.36% and the lowest in the Aceh provincial health department was 72.86%.

Conclusion: the deconcentration fund planning it is done top down and a menu of programs or activities has been determined. The amount of fund allocation has also been determined by the center, the regions only make and implement what has been made by the center. Activities in the area need to be monitored and evaluated both in substance and financial programs.

Keywords: deconcentrated funds, planning, monitoring and evaluation.

Introduction

Health is a basic human need to be able to live properly and productively, therefore it is necessary to conduct cost-controlled and quality-controlled health services1. Indonesia Sehat Program is implemented with 3 main pillars, namely the healthy paradigm, strengthening health services and national health insurance: 1) the pillar of the healthy paradigm is carried out with health mainstreaming strategies in development, strengthening preventive promotive and community empowerment; 2) strengthening health services is carried out with strategies to improve access to health services, optimize the referral system and improve the quality of health services, using a continuum of care approach and health risk-based interventions; 3) meanwhile the national health insurance is carried out with a strategy of expanding targets and benefits as well as quality control and cost control2,3.

The health budget allocation managed by the Ministry of Health in 2014 amounted to 50.35 trillion rupiahs with the realization of 47.58 trillion rupiahs. Large allocation and the realization of the budget has increased compared to 2014, namely the allocation of 38.64 trillion rupiah with the realization of 35.42 trillion rupiah. In terms of budget size, the increase also occurred
in the percentage of realization in 2014 compared to 2013, which was 91.66% in 2013 to 94.49% in 2014. The highest allocation of deconcentration funds in 2017 in West Java Province was Rp. 84,894,996,000 (6.2%) followed by East Java Province in the amount of Rp.83,610,717,000. (6.1%). While the fewest in the Province of DIY is Rp. 24,346,179,000. (1.8%).

In this study the emphasis is placed on an analysis of the use of deconcentration funds provided by the central government (Ministry of Health of the Republic of Indonesia) to Provincial Governments. Also seen in the process of planning, budgeting and implementation or use of deconcentration funds. The purpose of this study is to know the process of planning, budgeting, implementing and utilizing deconcentrated funds in health development. Besides knowing the allocation and realization and monitoring and evaluation of deconcentrated funds.

**Method**

In this study, a secondary data document was analyzed for the allocation of deconcentrated funds, from the center in each division of the program and information echelon 1 of the republic of indonesia’s ministry of health main unit, except for the health research and development agency and the inspectorate general, because the institution did not have deconcentration funds. besides conducting interviews with 78 planning officers of the Provincial Health Office in Indonesia. The implementation period is 4 months from December to December 2018. The ethical approval was taken from Health Research and Development Agency (Balitbangkes) of Ministry of Health Indonesia (No: LB.02.01/2/KE.231/2018).

**Results**

**Deconcentration Fund Allocation**

In general, the allocation has increased each year in each province from 2016 to Rp. 2,113,059,057,000, decreased in 2017 by Rp. 1,066,701,376.00, then in 2018 it increased to Rp. 1,102,942,700.000. -.

**Deconcentration Fund Planning**

The results of the study on the regional planning team from various provincial health department regarding the deconcentration fund planning process are as follows. According to respondents who were asked questions about the planning process stated that at most 61.0% was a combination of top down and bottom up, then followed by a top down of 28.6% and those with the least amount of bottom up was 10.4%.

**Synchronizing Planning**

From the results of interviews with the provincial department planning team, regarding synchronization of planning it was found that the majority were synchronous or matching with the Regional Budget (89.6%) and some were out of sync with the Regional Budget by 10.4%.
Figure 2: Synchronizing Planning with the Regional Budget

Budget Changes After Desk

In the deconcentration fund planning, after a desk with Echelon 1 Main Unit, according to the Provincial Health Service planning team as follows:

Figure 3: Budget Changes After Desk

Realization of the Use of Deconcentration Funds

The realization of deconcentration funds from 2016 to 2018 per Province in Indonesia can be seen from the following figure.
Deconcentration Fund Monitoring and Evaluation

Those who answered 26.8% were not monitored and evaluated, while 71.2% responded to it. From those who answered, monitoring and evaluation were carried out in one year as many as 67.7% with frequencies 1-2 times and 3.7% with frequencies 3-4 times.

Discussion

In planning the deconcentration fund from the center to the regions, it is always done using the top down method, meaning that the center has determined the menu of programs and activities, the region only follows and fills in the volume and amount that has been provided in the program menu. In the deconcentration fund planning there was no inclusion of APBD funds, but in the form of activities from other sections, for example the Health Promotion section by riding on health promotion socialization activities. The Provincial Health Office did not determine the program menu, but only had to carry out decisions from the center, although it could not be carried out at all. In the planning of deconcentrated funds, programs are not synchronized based on other funding sources, for example with the Regional Budget (APBD).
Deconcentration fund planning, correspondence and requests for documents needed to the center, then documents sent from the center. An internal meeting is held at the Farmalkes section, then by the center of each fund amount in each work unit, and this is permanent and cannot be changed\textsuperscript{10}. So that the menu does not match the needs of programs in the region, because there are too many programs from the central government but many cannot be implemented because the budget is insufficient, it seems to only pursue realization but does not guarantee program needs. The program holders are accustomed to referring to standard activities issued by the central government, so they forget the specific needs of the region. Even though the specific needs of the regions are different from those of the central government. This approach must be contextualized to the needs of the region even to the puskesmas through a system approach\textsuperscript{11}.

In the implementation of training activities sourced from deconcentrated funds, can not be on time, often late because the program implementers from the provincial health office must adjust to the schedule of resource persons from the Center, while in the Province there are other activities that are more priority. Determination of the management of deconcentrated funds by the Governor (Decree of Deconcentration Fund Managers) is often late, so the implementation of deconcentrated funds also experiences delays in achieving performance indicators both IKP and IKK. Even in the implementation of deconcentration funds, some are not in accordance with the needs of activities in the region, so what can not be financed by deconcentration funds will be allocated in planning by the provincial health office\textsuperscript{9,12}.

In the implementation of activities that use deconcentrated funds, for health human resource training activities, they have used standards created by the Center both the competency of the speaker / trainer, curriculum, participants, requirements, and certificates\textsuperscript{12}. The Provincial Health Office only implements programs or activities. In the implementation of deconcentration fund activities, absorption can be up to 70.0\%, because there are other activities carried out by the Governor’s Office that must be carried out first, but the Central Government stipulates that if the funds can be absorbed 85.0\% it can be said to be good\textsuperscript{13}.

Now facing the problem of accreditation of Puskesmas and Hospitals, all are required to be accredited, but deconcentration fund support is not in accordance with the accreditation target. BPJS will even break the cooperative relationship with hospitals that have not been accredited. Puskesmas accreditation is also being pursued, but with the highest accreditation status (Paripurna) it has not yet increased capitation from BPJS to puskesmas. This in-depth study was carried out, including the readiness of puskesmas and hospitals in achieving Universal Coverage (UC)\textsuperscript{14}. During this time there are training activities, in which the Center trains to the puskesmas which should not occur, meaning the Center conducts training at the Provincial level (master trainer), then the training is continued by Provincial master trainers at the Regency / City level, to the District and village. The central government conducts Norms, Standards, Guidelines and Decisions (NSPK) and conducts monitoring and evaluation after training both in substance and training mechanism\textsuperscript{15}. The implementation of the Kotamobagu City Government policy in the South Kotamobagu sub-district in free health services cannot be carried out optimally, this is due to the limited resources available, both medical personnel, and infrastructure facilities at the center Kotamobagu Selatan sub-district health services\textsuperscript{16,17}.

In monitoring and evaluating the use of deconcentration funds from the Central to the Province there are instruments used, and this is done once a year (annually), also seen from the realization of finance and output. There is a note, can also be seen the achievements for each health center that can be visited, the activities carried out with deconcentration funds\textsuperscript{18}. Also noted is the compatibility between program planning and implementation, for example the Farmalkes program menu in the Riau Islands, that from the Center monitoring and evaluation is conducted in 7 districts / cities (10 puskesmas and 10 pharmacies), but can only be done in 1 district with 3 puskesmas and 2 pharmacies, because the funds are insufficient. Report why and sent to the Center.

There is a monitoring and evaluation document for deconcentration funds at the central and provincial levels, there is a follow-up from monitoring and evaluation of the center to the regions, that is, the results will be processed whether the following year the activities listed in the menu are still feasible or not\textsuperscript{19}. Deconcentration funds can support the achievement of Minimum Service Standards (SPM), for example the use of high rational drugs, the use of antibiotics will go down, this can be budget efficiency (in accordance with programs and activities) but also to support the
activities of the Healthy Indonesia Program with the Family Approach (PIS-PK). For example: in the Riau Islands Province there is a cermat careful germa “which is” the movement of intelligent people using drugs”; this has been carried out in districts/cities, accompanied by cross-sector and cross-programs, the aim is to promote preventive and healthy community. In monitoring and evaluation it is necessary to prepare instruments and implementers in exploring problems until they find the root of the problem, then look for a solution to improve future programs. The monitoring and evaluation implementation is supported by quantitative data, which can provide strength and depth of analysis.20

**Conclusion**

The Study on the use of deconcentration funds in the planning, budgeting and implementation of the health sector is very important to determine the amount of ceiling, the planning menu and regional potential in carrying out activities that originate from deconcentration funds.

The Influence of Slow Stroke Back Massage, Cold-compress and Warm-compress to the Level of Prostaglandin F2α (PGF2α) in Primary Dysmenorrhea

Mukhoirotin¹, Kurniawati¹, Diah Ayu Fatmawati¹
¹Lecturer, Nursing Science Program, Faculty of Health Science, Unipdu Jombang

Abstract

The cause of primary dysmenorrhea is excessive release of the hormone prostaglandin F2-alpha (PGF2α). The aim of this study was to assess the influence of SSBM, cold-compresses and warm-compresses toward the level of PGF2α in primary dysmenorrhea, using Post Test Only with Control Group Design and Pretest-Postest Control Group Design. The subjects were 76 female-student, selected by purposive sampling. NRS used to measure the pain level and ELISA used to measure PGF2α levels. The data were analyzed by using Paired Sample T-Test, One-Way Anova and Kruskal-Wallis test. SSBM, cold-compresses and warm-compresses are effective to decreasing of pain level and PGF2α levels in primary dysmenorrhea.

Keywords: Slow Stroke Back Massage, Cold-compresses, Warm-compresses, PGF2α, menstrual pain

Introduction

This incidence of dysmenorrhea is 20% to 90% among reproductive women and 15% occurred among young female followed with pain level around 2%-29%(2). Primary dysmenorrhea commonly occurred among adolescents without any pathological problems at the pelvis(3-4). The prevalence of primary dysmenorrhea among adolescent was 55.5-90.1%(1, 5). In Mexico, dysmenorrhea affects 65% of students’ daily activities(6).

The cause of primary dysmenorrhea is an increase in prostaglandin F2-alpha (PGF2α) production(7). The treatment of dysmenorrhea commonly used nonsteroidal anti-inflammatory drugs (NSAIDs). As we know medication consumption for long time will give some impact such as medication addictive(8-9), diarrhea, abdominal pain, nausea(10), kidney-complications, liver-complications, sleep-disorders(11), digestion-problems(12). The pharmacological treatment for dysmenorrhea was successful, but about 20-25% of the failure process(13). The one of the traditional treatment for dysmenorrhea is Slow Stroke Back Massage (SSBM), cold-compresses and warm-compresses. SSBM reduces pain and effectively increases endorphin levels(14). Cold-compresses reduce prostaglandins, so it will make strengthens the sensitivity of pain and other subcutaneous at the injury site by inhibiting the inflammatory process and giving analgesic(15). The skin stimulation causes endorphin loose so it will block blocking the transmission of pain stimulus. Skin stimulation activates the transmission of sensory A-Beta nerve fibers and decreases pain transmission C and delta-A fibers so the synaptic gate closes the transmission of pain impulse(16). Cold-compresses and warm-compresses are stimulates to loosing the endorphin β levels and regulate uterine hypercontractility during menstrual pain(17).

The results of previous studies indicated that Moxibustion consumption can reduce the levels of PGF2α, OT, vWF and increase the levels of β-EP (β Endorphin)(18). However, the influence of SSBM, Cold-compresses and Warm-compresses toward the intensity of pain and PGF2α levels in Primary Dysmenorrhea have not been clearly known. The aim of this study was to analysis the effect of SSBM, Cold-compresses and Warm-compresses toward Pain Intensity and Prostaglandin F2α (PGF2α) levels in Primary Dysmenorrhea.

Method

The design in this study was Post Test Only with Control Group Design and Pretest-Postest Control Group Design. The sample was 76 female students in faculty of health science of Unipdu Jombang who
experienced dysmenorrhoea, selected by purposive sampling. The samples were divided into six groups: SSBM (n=13), cold-compress (n=12), warm-compress (n=13), SSBM+cold-compresses (n=13), SSBM+warm-compresses (n=13), control (n=12). The data were collected by two instruments: NRS (Numeric Rating Scale) to measured the pain level, ELISA to measured PGF2α. Data were analyzed by Paired Sample T-Test, One-Way Anova and Kruskal-Wallis test.

**Discussion**

The menstrual pain level before give the interventions were moderate to severe and after give treatments the average menstrual pain level in all treatment groups was mild and in control group was moderate level. The intensity of menstrual pain in this study was addressed with some previous studies which showed that the menstrual pain level among he respondents was moderate to severe level(19-20). Some risk factors of dysmenorrhea are include the early of age menarche, the longer of menstrual periods, the higher of menstrual volume, family history of dysmenorrhea, smokers, obesity, alcohol consumption(2,21-22), high
caffeine diet(23), and high levels of stress(24).

The results of this study showed that the average of menstrual pain level in all intervention groups are significantly decrease between pre-test and post-test. This showed that SSBM, cold-compresses and warm-compresses, SSBM+cold-compresses, SSBM+warm-compresses are effective to reduce the menstrual pain level. These interventions are cutaneous stimulation techniques, where the mechanism of these interventions in reducing pain level was explained according to the gate control theory. Gate control theory explained that skin stimulation can activate the transmission of the fibers of A-Beta nerve sensory(25). This process can reduce pain transmission through small diameter of C and delta-A fibers so the synaptic gate will closes the transmission of pain impulse. Generally, the cutaneous stimulation on the body is on the back and shoulders. Cutaneous stimulation are influenced peripheral fibers to send the impulses by using dorsal horn in the spinal cord, when the impulses carried by A-Beta fibers are dominate so the gate mechanism will close so the pain impulses are not delivered to the brain(26).

The average decreasion of menstrual pain level in SSBM-group. Touch and massage are the technique of sensory integration that affect the activity of nervous system. Individuals who perceived touch as a stimulation to relax, a relaxation response will appear. The use of appropriate cutaneous stimulation can reduce pain perception and muscle tension. Conversely muscle tension can increase pain perception(16). Massage of connective tissue makes relaxes on body, reduces muscle spasms, connective tissue tenderness, increases the circulation and β-endorphin plasma(27). This intervention can stimulate the autonomic nervous system to balance the sympathetic and parasympathetic nerves(28). The SSBM was effectived to reducing menstrual pain level(14). The connective tissue manipulation (CTM) can be used as an intervention to primary dysmenorrhoea and menstrual-related symptoms because this method didn’t give the potential effects such as analgesic, noninvasive and easy to do(29).

The average of menstrual pain level in cold-compress group was ranged 6.75-2.83. The intervention of cold-compress in the abdomen for 20 minutes by using a bag filled ice. The intervention of cold-compress to respondents was helpful to reduce the pain level, this because of the blood flow was decreased in area which is compressed, and gave analgesic effect by slowing the speed of nerve delivery so the pain impulses will be decrease or less to the brain. Cold-compresses was gave the physiological effects to reduce the inflammatory response, reduce blood flow, reduce edema, and reduce local pain(30). Cold therapy (ice compresses) intervention will be blocked and the impulses of pain will be reduce or loose for few times(26). Previous research results showed that cold-compresses was effective reduced menstrual pain(31).

After given of warm-compresses the average of menstrual pain significantly decreased. Warm-compresses is an intervention that can help to reduce pain by using dilated method of blood vessels so this will increasing the blood supply to the body(32). Some previous research said that warm-compresses was effected to reduce menstrual pain level(33-34).

In the control group after given management information about menstrual pain, a small proportion experienced a decreasing of menstrual pain level but was not significant. The information was included pharmacological and non-pharmacological menstrual pain treatment. Non-pharmacological treatment are regular exercise, adequate rest, warm-compresses on abdomen, yoga, warm water shower, massage, deep breath, acupunctur, acupressure, TENS, salt and sugar diet, cold-compresses and deuretics consumption (asparagus and watermelon). Pharmacological treatments are hormonal-drugs and NSAID(35).

The results of this study showed that there were no significant differences in PGF2α levels in all intervention groups, there were significant differences in PGF2α levels between intervention and control. Primary dysmenorrhoea caused by the increasing of prostaglandin production and the release of endometrial prostaglandins during menstruation so it will induce uterine hypercontractility, reduce uterine blood flow, and hypersensitive of pain(36). Menstrual cramps more worse because PGF2α was increased and PGE2 decreases, so primary dysmenorrhoea increased the ratio of PGF2α to PGE2(37-38).

Massage is a therapy to reduce the production of NF-κB, inflammatory cytokines and TNF-α(39). Inflammatory cytokines (ex: IL1-β, TNF-α) is stimulates prostaglandin production in the first day of menstrual phase(40-41). The results of previous studies indicated
that the Swedish Massage Therapy reduced the level of Mitogen-Stimulation of IL-1β, IL-2, IL-4, IL-5, IL-6, IL-10, IL-13, and IFN-γ(42). The decreasing of inflammatory cytokines impacted decreasing of prostaglandin stimulation production. Therefore, the SSBM intervention can reduce prostaglandin levels in primary dysmenorrhea.

Cold-compresses are the intervention which give vasoconstriction effects, prevented the edema, reduce inflammation, local anesthetics effect, reduce cell metabolism and increase blood viscosity. Warm-compresses are the interventions which give a vasodilation effects to blood circulation to becomes smooth and muscles relax(32). Hot stimulation can increase blood flow in blood vessels at uterus and consequently the prostaglandin vascular will be liquid, bradykinin, and histamine(25). Heat interventions in local area is as effective as NSAIDs(43). The NSAIDs mechanism to relieve primary dysmenorrhea depends on the inhibition of cyclooxygenase (COX), an enzyme which responsible for the prostaglandins production (and other prostanoids). The unbalanced amount of prostaglandins from the endometrium during menstruation are major cause of dysrhythmias contraction at the uterus, the reducing of local blood flow and the increasing of peripheral nerve sensitivity during Primary Dysmenorhea(44). Therefore, cold-compresses and warm-compresses are same effectively to reducing prostaglandins.

Conclusion

SSBM, cold-compresses and warm-compresses are effectively reduced pain level and PGF2α levels to dysmenorrhea.

The Effect of Dexterity and Perturbation Exercise on Knee Osteoarthritis through Functional Balance and Power Improvement of Quadriceps and Hamstring

Rini Lestari Ansanay, Damayanti Tinduh

Departement of Physical Medicine and Rehabilitation, Faculty of Medicine, Universitas Airlangga, Surabaya (60131), Indonesia

Abstract

Backgrounds and Objective: Osteoarthritis (OA) is a set of joint disorders caused by different factors but has the same pathological changes. OA of the knee joint occurs mainly due to the tibiofemoral and patellofemoral joints as a continuous body weight support throughout human life both static and dynamic, thus gradually causing changes in the structure of the knee joint tissue. This study aimed to know the function and strengthening of muscle strength of quadriceps and hamstring in patient with knee osteoarthritis.

Method: Twenty-two patients with knee OA (average age of 51.7 years; range 40 to 65 years) were randomly grouped into intervention group (agility and perturbation exercises plus strengthening exercise of quadriceps and hamstring muscles) and the control group (strengthening exercise of quadriceps and hamstring muscles). Both group participated in a four-week exercise. Balance function, quadriceps and hamstring muscles strength (BBS, TUG, EN-Tree 1 RM) were assessed before and after intervention.

Result: The intervention and control group improved 1 RM quadriceps muscle (p = 0.0001) and 1 RM hamstring muscle (p = 0.0001) but there was no statistically significant difference between groups, score of BBS in intervention group improved significantly (p = 0.0001) and statistically increased significant between groups (p = 0.0001), score of TUG in intervention group improved significantly (p = 0.002) but there was no statistically significant difference between groups (p = 0.324).

Conclusion: Supplementation of agility and perturbation exercises on strengthening exercise of quadriceps and hamstring to balance function provided additional benefit with respect to the BBS score after four-week intervention of patients with knee osteoarthritis.

Keyword: knee osteoarthritis, perturbation, muscle strength, Berg Balance Scale, Time up and go test.

Background

Osteoarthritis is a joint disorder caused by different factors but has the same pathological changes. Osteoarthritis (OA) of the knee joint occurs mainly due to the tibiofemoral and patellofemoral joints as a continuous body weight support throughout human life both static and dynamic, thus gradually causing changes in the structure of the knee joint tissue. If the changes do not handle properly and appropriately it will develop into a chronic pathological process that causes damage to the entire structure of knee tissue.

Rehabilitation outpatient unit of Dr. Soetomo General Hospital Surabaya reported that the number of knee OA cases between October 2011 until April 2012 was 127 new cases and 3211 old cases. The high number of old cases was due to care phase and recurrence due to undiscipline in doing knee joint conservation program on damaged knee joints of their anatomical structure and function. Based on this report it was noted that knee OA...
is the second highest case after low back pain.

Some aspects of the human body such as vestibular system, vision, proprioceptive, muscle strength and cognition, have a relationship to the control of human balance thus it is an essential ability for everyday life. In knee OA there is a pathological change in the tissue structure within the joint space, ligaments, tendons, and periarticular tissues including muscles. This condition is followed by malfunction of the knee joint receptor mechanisms resulting a decreased proprioceptive function. On histological examination it was reported that the number of sensory receptors in the knee joint ligaments with OA decreased. Eldery with physiologically impaired proprioceptive function suffers from knee OA will further aggravate its proprioceptive function, thus it is estimated that this condition may cause an increase in the incidence of falling while walking or standing.

A study in 2002 found that the addition of dexterity and perturbation exercise in women aged 73 years with instability complaints on both knees due to OA during 12 sessions indicated that instability incidence did not continue and the patient could return to recreational activities such as walking, playing tennis and golf. The difference outcomes of both studies led researchers to examine the effects of adding dexterity and perturbation exercises on quadriceps and hamstring strengthening exercises to the improvement of proprioceptive function that controlled the balance thus it could improve the performance of the stability dynamics component of knee OA patients.

Method

This research was pre- and post-test control group design. This research was conducted in January 2013 until finished in Medical Rehabilitation Installation Unit of Dr. Soetomo Surabaya. The samples were new knee OA patients based on clinical symptoms and radiological examinations that met inclusion criteria and did not meet exclusion criteria. The sampling technique of this research was consecutive sampling method and then done a simple random sampling through lottery. Ethical appeals were submitted to the Ethics Commission for basic science/clinical research at Dr. Soetomo Surabaya.

The inclusion criteria were women aged 40 - 65 years; new knee OA sufferers who met the American College of Rheumatology clinical criteria of knee pain, less than 30 minutes of morning stiffness, crepitation when the knee was moved, tenderness on joint palate, swelling of the knee joint but not warm at palpation, new knee OA sufferers who met clinical criteria according to Kellgren-Lawrence radiology degree II and III, Berg Balance Scale (BBS) examination 41-56 = low risk fall, and 21-40 = moderate risk fall, examination of Time up and go test (TUG test) ≤20 = walking without aids, willing to participate in the research by signing the approval sheet after getting an explanation.

The exclusion criteria were patients with aids for ambulation, having fall history resulting in musculoskeletal disorders, patients with severe visual impairment, the patient had undergone total knee arthroplasty, patients with uncontrolled hypertension, patients with cardiovascular disease history, patients with nerve disorders resulting body weakness, and decreased sensibility and knee pain with VAS >3 with or without knee inflammation marks. Drop out criteria was arising knee pain during exercise with VAS >3.

The samples were randomly divided into two groups. Group 1 received strengthen training of quadriceps and hamstring muscles with EN-Tree tools plus dexterity and perturbation exercise twice/week every Tuesday and Thursday for 4 weeks, while group 2 received quadriceps and hamstring strengthening exercises with EN-Tree tools twice/week every Monday and Wednesday for 4 weeks. Pre- and post-exercise evaluation of balance function was done using BBS tool, TUG test and quadriceps muscle strength and hamstring 1 RM with EN-Tree. Data were analysed and compared their improvement of balance function and increased quadriceps and hamstring muscle strength before and after treatment.

The data were arranged in sheet and tabulated, then processed statistically using SPSS 21.0 (SPSS. Inc. Chicago IL). Normality test using one sample Kolmogorov-Smirnov test was done before comparing data between groups, homogeneity test was done using Levene test. Since the data were normally distributed and homogeneous, t 2 free samples were used to compare the data between groups, whereas paired t test was used to compare the data before and after the treatment.

It could be seen from demographic characteristics in table above that treatment group that the youngest was 40 years and oldest was 65 years old with average of 51.73 ± 7.7 years, while in control group the youngest was 45 years and the oldest was 59 years with average of 51.73 ± 4.8 years. In the treatment group, the average weight was 64.82 ± 13.4 kilograms, while in control group was 67.18 ± 15.2 kilograms. In the treatment group, average height was 157.27 ± 7.2 cm while in control group was 159.82 ± 5.9 cm. In the treatment group, the average body mass index (BMI) was 26.1379 ± 4.7 while in control group was 26.22 ± 5.4. From the test result in table 1, it could be concluded that the research subject data according to age, body weight, body height, body mass index (IMT) was normally distributed.

Table above shows homogeneity test with p <0.05 was done on age, body weight, height, BMI, gender and grade of knee OA to know diversity of demographic characteristics and to determine their effect on the research results. In both groups there were no significant differences in age, weight, height, BMI, gender and grade of knee OA.

The statistical test of the average increase of RM 1 quadriceps muscle before and after exercise in the treatment group showed a significant increase with p = 0.0001. In the control group also showed a significant increase with p = 0.000. Comparison of average RM 1 quadriceps muscle between treatment group and control group showed improvement, but did not show significant difference with p = 0.867. The statistical analysis of the average increase RM 1 hamstring muscles before and after exercise in the treatment group showed a significant increase with p = 0.0001. Comparison of average RM 1 hamstring muscle between treatment group and control group showed no increase and did not show significant difference with p = 0.901.

The BBS before and after intervention in the treatment group showed a significance with p = 0.0001. while in control group showed an increase but not significant with p = 0.341. The average BBS values between treatment group and control group showed a significant increase with p = 0.0001 The average of decreased TUG before and after intervention in the treatment group showed a significant decrease with p = 0.002. While in the control group showed a decrease but not significant with p = 0.324. The average TUG between treatment group and control group showed not significant decreased with p = 0.095

**Discussion**

The results shows that the increase in quadriceps and hamstring muscle strength in both groups was due to the training intervention using EN-tree pulley, and it had not shown the feedback mechanisms of proprioceptive organ sensitivity improvement. The results of this study were consistent with previous study in 2011, which examined 231 subjects with knee OA dividing into treatment groups receiving dexterity and perturbation exercise on strengthening exercises and control groups receiving only strengthening exercises. It was estimated that elderly with knee OA tended to avoid extreme movements that required balance and agility, thus the addition of perturbation and dexterity exercises did not give optimal results 12.

Based on subject’s occupation in treatment group, 5 subjects had sedentary lifestyles such as retirees, grandchildren sitter, housewives with maids, tailors, and workers with long sitting time in the office. Researchers argued that sedentary lifestyle classified in low-level activities that led to static body movements 13. This static condition made the mechanical function of knee joint neglected therefore the optimization of mechanoreseptor organ stimulation especially dynamic mechanoreceptors such as pacinian’s corpuscles through strain, pressure and burden of knee joint became minimum or lost 14.

It was argued that the short intervention period was relatively rapid for a rehabilitation process, therefore the impact of proprioceptive exercise and balance was not fully visible at the time of assessment. Another study supported the findings in this study that dexterity and perturbation exercise included in proprioceptive exercises had not shown an increase in quadriceps and hamstring muscle strength leading to increased functional activity 15.

A subsequent study of 63 knee OA patients performed joint proprioception assessment with joint motion detection threshold (JMDT), measurement of quadriceps and hamstring muscle strength with isokinetic dynamometer and functional assessment with 100 meters walking test and GUG 16. The effect of muscle weakness was stronger on the limitations of functional ability than in accurate proprioception. A study had not shown any feedback mechanism between proprioceptive function and muscle strength, although this had been proven by other study 17.

The BBS value improvement was in accordance with a study demonstrated the effect of perturbation exercise on parental balance function with a history of instability or fall. The subjects were divided into 2 groups consisting of those receiving the perturbation and control group who receiving flexibility and relaxation exercises. That study showed proprioceptive function improvement through perturbation exercises. It had also been proven in this study that the BBS score increased significantly indicating an improvement in proprioceptive function of subjects 18.
Conclusion

It was found that the addition of dexterity and perturbation exercise in muscle strengthening exercises twice a week for 4 weeks was more effective in improving the functional balance (BBS) than strengthening exercises alone of knee OA patients, the addition of dexterity and perturbation exercise in muscle strengthening exercises twice a week during 4 weeks was no more effective in improving the functional balance (TUG) compared to strengthening exercises alone in knee OA, the addition of dexterity and perturbation exercise in muscle strengthening exercises twice a week for 4 weeks was no more effective in improving quadriceps muscle strength and hamstring muscle compared to strengthening exercises alone in patients with knee OA.

Biocompatibility Test of Decellularized Cartilage Bovine Scaffold in Vitro and In Vivo

Achmad Fachrizal¹, Dwikora Novembri Utomo¹

¹Department of Orthopedics and Traumatology, Faculty of Medicine, Universitas Airlangga, Surabaya (60131), Indonesia

Abstract

Background: Incidence of cartilage defects was reported at 65.00% of the routine arthroscopy procedures. Dr. Soetomo Teaching Hospital Network Bank developed a cartilage scaffold from bovine that has been deselularized decellularized cartilage bovine scaffold (DCBS). It takes a study of biocompatibility test to prove that DCBS is not cytotoxic to cells and not generate a host response.

Objective: To analyze the biocompatibility of decellularized cartilage bovine scaffold (DCBS) in vivo and in vitro.

Methods and Materials: The subjects were experimental rats and experimental with in vitro and in vivo trials. The subjects were treated by toxicity test with MTT assay, irritation test using Draize Scale, acute/pyogenic systemic toxicity test by observing changes in body weight and temperature, and implantation test by observing fibrous capsule formation and Immunoglobulin G. Data was analyzed by using Kolmogorov-smirnov, Independent T-test, Mutivariate Analysis of Variance (MANOVA), and Mann Whitney.

Result: The percentage of viable DCBS (81.78%) and CBS (92.45%) was ≥70% of the control; thus, it is non-toxic to the cell. Draize scale in each group was in grade 0. Changes in body weight (p = 0.981) and temperature (p >0.05) had no significant association between groups. There was a significant difference mean of the fibrous capsule (p = 0.000) thickness and no significant difference in the mean number of Immunoglobulin G which was formed at week 1 (p = 0.87) and week 4 (p = 0.63) after implantation between CCBS and DCBS.

Conclusion: The biocompatibility test shows that DCBS is compatible as a biomaterial.

Keywords: DCBS, biocompatibility, In vivo, In vitro.

Introduction

Articular cartilage is a structure that coats the diarthrodial joint and serves to protect the subchondral bone from the axial force loading ¹. Damage to the articular cartilage, either due to trauma, degenerative, or due to congenital abnormalities causes joint pain and decreased quality of life ². Incidence of cartilage defects was reported at 65.00% of routine arthroscopy procedures. If lesions in the cartilage are not treated, it will cause joint pain, joint dysfunction and osteoarthritis (OA). Currently, there is no single effective therapy for osteoarthritis treatment ³.

Current treatment options are bone marrow stimulation (microfracture), osteochondral autograft transfer system (OATS) or mosaicplasty, and autologous chondrocyte transplantation (ACT) ¹. All of the above therapies do not produce enough hyaline cartilage tissue; thus, it continues on tissue engineering to develop strategies for cartilage repair and regeneration with biomechanical characteristics, biological compositions,
and the same organization as the original articular cartilage. Trias engineering network consists of 3 components, namely cell, signal, and scaffold.

Scaffold serves as a medium for closing defects and cell regeneration media. The cells used are mesenchymal stem cells. In vitro research proved that mesenchymal stem cell can regenerate and decellularized biomaterial scaffold limited the use of growth factor resulting in better cost and resource efficiency. Dr. Soetomo Teaching Hospital Network Bank developed a cartilage scaffold from bovine that has been deselularized (decellularized cartilage bovine scaffold (DCBS). Based on the deselulerization process, it is expected that cellular components that can induce an immune response can be eliminated and provided scaffold construction that may allow penetration of cultured cells. Therefore, we need to conduct a study of biocompatibility test to prove that the DCBS is not cytotoxic to the cell and not cause response from the host.

Methods

This study used an experimental study that was conducted in 3 months (November 2016-January 2017). Before being tested, replication was conducted by generating a large sample of 9 experimental rats in 1 group. In the in vitro test, samples of mesenchimal stem cells were divided into three groups, namely, a group of DCBS Sodium Dodecyl Sulfate (RSDS) products, a group cultured with Cartilage Bovine Scaffold (CBS), and a group cultured with media (control group). All three groups were tested by its viability using MTT Assay. In vivo trials, the experimental rats were divided into three groups: the implanted group of DCBS RSDS products, CBS implanted group, and placebo implanted group. Biocompatibility test results included irritation test, acute/pyrogenicity toxicity test, and implantation test.

The treatment stage was toxicity test with MTT assay (in vitro), irritation test (in vivo), acute/pyrogenicity toxicity test (in vivo), and implantation test (in vivo). In the cultured bone marrow mesenchimal stem cells (BM-MSCs), cytotoxicity test was added DCBS+MTT reagent on culture plate. Then, it was incubated within 48 hours at 37° C in an incubator containing 5% of CO2. After that, cell viability was quantitatively calculated based on the color change of the formazan. The tested material was not assessed by cytotoxic if the percentage of living cells was ≥70% compared to the control group.

The irritation test (in vivo) was performed by intracutaneous injection of a 0.2 ml scaffold extract on the back skin of experimental animals that had been shaved at 5 sites. Evaluation was conducted within 24 hours, 48 hours, 72 hours using Draize Scale on a scale of 0 (no erythema/edema) to 4 (severe erythema/edema).

Acute/pyrogenic toxicity test (in vivo) was performed by a 1x1x10 mm scaffold sample. This process subjects (experimental animals) were performed by intramuscular implantation. Thirty minutes before implantation was conducted rectal animal temperature measurement try. If there was a difference of 1° C from basal temperature or temperature over 39.8° C, the experimental animal was excluded from 61 toxicity tests. The evaluation was performed after implantation of 72 hours through weight and rectal temperature.

At the time of sample implantation (1x1x10 mm scaffold) inserted by injection with needle no. 16, the subjects were observed periodically at week 1 and week 4. The subjects were observed at the macroscopic implantation site (observation on fibrous capsule formation around the implant) and microscopic. Reactive materials can form capsules of 2-4 mm while non-reactive materials can form invisible capsules. For tissue sampling, the rats were tried to be terminated in every interval of examination. Then, tissue samples along with the implants were taken and inserted in a 10% formalin solution.

The data recorded were grouped, analyzed, and conducted normality test by using Kolmogorov-smirnov test, homogeneous data with Mutivariate Analysis of Variance (MANOVA) test, Independent T-test and Mann Whitney with SPSS program (SPSS, Inc., Chicago, IL).

Result

In acute systemic and pirogenisity toxicity test, subjects were performed weight measurements before and 72 hours after implantation. Average weight change was 9.67 gr, 9.33 gr, and 8.78 gr for DCBS, CBS, and control group respectively. There was no significant weight difference in all groups (p = 0.981) (Table 1).
The subjects were also performed rat temperature measurements before implantation, 30 minutes, 60 minutes, 90 minutes, 120 minutes, 150 minutes, and 180 minutes’ post implantation. The statistical test results showed no significant difference from the mean of temperature change in all groups (p > 0.05) (Table 2).

In the implantation test, the average fiber fibrous caps were obtained at 1 week post implantation of 16.52 μ and 8.92 μ in Cellularized Cartilage Bovine Scaffold (CCBS) and DCBS. At week 4 post implantation, the average thickness of the fibrous capsule was 10.47 μ (CCBS) and 2.93 μ (DCBS). There was a significant difference mean of fibrous capsule thickness at 1 and 4 weeks post implantation between CCBS and DCBS (p = 0.000) (Table 3).

Immunoglobulin G was performed on Immunoglobulin G test. The mean of Immunoglobulin G was formed at 1 week post implantation of 0.05 (CCBS) and 0.03 (DCBS). At week 4 after implantation, the average number of Immunoglobulin G in CCBS group was equal to DCBS of 0.04. There was no significant difference in mean Immunoglobulin G number at week 1 (p = 0.87) and week-4 (p = 0.63) after implantation between CCBS and DCBS (Table 4).

**Discussion**

The cytotoxicity test shows a viable percentage of 70% of the control. The irritation test with Draize scale in each group is in grade 0. The acute toxicity/pyrogenicity test states that changes in body weight and temperature have no significant relationship between groups. The biocompatibility test that has been studied in previous studies on CBS showed that scaffolds have low toxicity levels in vitro and in vivo. It shows in vitro DCBS and CBS non-toxic to cells, according to the standard MTT assay that non-toxic in cytotoxicity test in vitro when the percentage of cells viable ≥70% of untreated controls.

The percentage of cell viability obtained in the DCBS group was fewer than the CBS group. This is probably because the SDS concentration used in this study is 5%, in contrast to previous studies where SDS used was 2%.

In another study, it was using 5% SDS, it also obtained a good microscopic deselularization result but because SDS is cytotoxic, it is necessary to conduct additional leaching which takes longer time with Phospat Buffered Salinese (PBS) for 4 days. However, this washing extension has an adverse effect on Extra Cellular Matrix (ECM) cartilage, which causes ECM to appear broken between the second and third days.

Irritation test in DCBS, CBS, and control group showed no irritation reaction in the form of edema and erythema in all three groups (draize score in all three groups were in grade 0). This shows that DCBS is a non-irritant material according to grading at ISO. Acute systemic toxicity and pyrogenicity test showed that DCBS, CBD. The control did not result in acute systemic toxicity and pyrogenicity reactions. This can be seen from the results of clinical observations of changes in body weight and rectal temperature of rats tested for 72 hours. There was no significant change in body weight and temperature between the 2 groups and the controls.

In this study, the evaluated implantation test was the fibrous and immunoglobulin tissue that was formed. In the evaluation of fibrous tissue of week 1 and week 4 showed that in the DCBS group, there was a better implantation test compared to CCBS which was characterized by smaller fibrous tissue formed in DCBS group although macroscopically both groups did not show any tissue reaction the formation of fibrous tissue in both groups both first week and second week does not exceed 2-4 mm. Previous studies comparing autologous ECM, allogenic ECM, xenogenic bovine collagen sponge (BCS), and synthetic scaffold (PLGA) implanted in rats showed that in the first week there was no fibrous tissue surrounding the autologous and allogenic ECM whereas in the BCS and PLGA groups formed the fibrous tissue that surrounds it.

The evaluation of the first week and the fourth week showed that the formation of Immunoglobulin G in CBS and DCBS groups. Despite the formation of Immunoglobulin G, statistically there is no significant difference. This suggests that CBS and DCBS do not generate a significant immune response but in the first week the number of Immunoglobulin G formed in the DCBS group was less than that of the CBS group.

The decellularization process is crucial in the elimination of cellular and antigenic components of tissue with the aim of preventing the transmission of the disease, reducing the immune response and inflammation, particularly in the xenogenic or allogenic donor tissue. Unlike cellular materials, ECM components are commonly found in all species. Therefore, this is tolerable enough when it is used as an allograft or xenograft. It can be seen that the DCBS used as xenograft did not result in a difference in the number of Immunoglobulin G depicting the absence of a meaningful immune response.

The previous studies of the biocompatibility of freeze-dried bovine cartilage in vivo in rabbits, it showed...
that the biomaterials were compatible and no significant immune response was obtained. Previous studies that examined the immunogenicity of chondrocytes and meniscus bovine and leporine also showed no immune response formed when chondrocytes and meniscus bovine and leporine were implanted in leporine. It is also seen that CBS and DCBS used as xenograft are also compatible and not stimulate the immune response. This study was comparing autologous ECM, allogenic ECM, xenogenic bovine collagen sponge (BCS), and synthetic scaffold (PLGA) implanted in mice, it showed that in the first week no macrophages were formed in all four groups.

However, the lowest was found in the autologous ECM group with the number of PLGA macrophages was equal to the number in the BCS group, but significantly larger than the allogenic ECM group. Besides that, this study also investigated the cytokines formed represented by interleukin-10 (IL-10), interleukin-2 (IL-2), interleukin-4 (IL-4), and TNF-α in the first week after implantation. From this study, it was found that IL-10 expression was lower in autologous ECM group than allogenic ECM, BCS, and PLGA. There was no significant difference in TNF-α transcription between the four groups although the number of TNF-α formed was lower in autologous ECM than in the other three groups. No IL-2 and IL-4 expressions were formed. It was concluded that autologous ECM stimulated the minimal cytokine against host response modulation.

**Conclusion**

The cytotoxicity test shows a viable percentage of 70% of the control. The irritation test with Draize scale in each group is in grade 0. The acute toxicity/pyrocillicity test states that changes in body weight and temperature have no significant relationship between groups. On the other hand, implantation test states that there is significant difference mean of fibrous capsule thickness and no significant difference mean of the amount of Immunoglobulin G which is formed at week 1 and week 4 post implantation between groups.

Predictors of Hospital Utilization Among Papuans in Indonesia

Agung Dwi Laksono¹, Ratna Dwi Wulandari²

Abstract

Hospitals were advanced referral health facilities or referrals for basic health services, it was very important for policymakers to know the factors that it was able to predict hospital use. The research objective was to determine the predictors of hospital use among Papuans in Indonesia. Data source from raw data of the 2013 Indonesia Basic Health Survey. Indonesia Basic Health Survey was a cross-sectional survey. The multi-stage cluster random sampling method was used to get 30,620 Papuan respondents. Multinomial Logistic Regression Test is used to determine the predictors of hospital utilization. There were 8 predictors of hospital utilization in outpatients used consisting of age, urban-rural area, gender, education level, socioeconomic status, insurance ownership, travel time and transportation costs, there were 5 predictor variables in hospital utilization in patients hospitalization consisting of gender, type of work, socio-economic status, travel time and transportation costs, and there were 2 predictors in hospital utilization in outpatient and inpatient care at the same time consisting of the cost of time travel and transportation to the hospital. Overall there were 9 predictor variables of hospital utilization in all categories (outpatient and inpatient).

Keywords: hospital utilization, healthcare, Indonesian basic health survey.

Background

Papua, which consists of two provinces, Papua and West Papua, is a province located at the easternmost tip of Indonesia. These two provinces fall into the backward category compared to other provinces located in the West. The provinces of Papua and West Papua often rank lower than many development performance indicators in Indonesia, including health development¹. Data-based health policy is needed to accelerate health development in these two provinces, including data on the utilization of health.

Hospital is a health service institution that organizes individual health services in a comprehensive manner that provides inpatient, outpatient, and emergency services. Hospitals are advanced referral health facilities or referrals for basic health services. The importance of hospitals as plenary services is the basis of the argument that it is very important for policymakers to know the factors that are able to predict hospital utilization². Evaluating the performance of the health care system, including hospitals, is important to support the performance of a better health system. It is the government’s obligation to ensure good access to hospitals for all communities without exception.

Based on the background, the purpose of this study was to determine predictors of hospital utilization among Papuans in Indonesia. It is hoped that the results of this study can become the basis for health policymakers to develop better policies in improving the access of Papuans to hospitals.

Materials and Method

The data used in this analysis was the raw data of the 2013 Indonesia Basic Health Survey. The Indonesia Basic Health Survey was a national scale survey with a multi-stage cluster random sampling method carried out by the Ministry of Health of Indonesia. The Indonesia Basic Health Survey was a five-year survey that was taken using a structured questionnaire.
The population was an Indonesian citizen who lives on Papua Island. The analysis unit in this study were respondents aged 15 years and over. It is assumed that at this age the respondent can make his own decision, to utilize the hospital or not. The sample size analyzed in this paper was 30,620 respondents.

The hospitals’ utilization was people’s access to hospitals, whether outpatient or inpatient. The time limit for outpatient was hospital use in the past month, while inpatient was the use of hospitals in the past year. It was assumed that the respondent can still remember the incidence of outpatient and inpatient properly.

Variable selection was done using the Chi-Square test to test the dichotomy variable, while the T-test was for continuous variables. This statistical test was used to assess whether there was a statistically significant relationship between the variables of hospital utilization as the dependent variable and the independent variable. There were 10 (ten) independent variables that will be tested as predictors of hospital utilization, namely age, the urban-rural area, gender, marital status, education, type of work, socioeconomic, insurance, travel time, and transportation cost to the hospital. The multinomial logistic regression test was used at the final stage to determine the variables that were predictors of hospital utilization among Papuans in Indonesia.

Findings

Bivariate analysis results show that there are significant differences between Papuans who utilize hospitals based on the category of urban-rural areas. On average Papuans who use hospitals are slightly older than those who do not use them. The results also show that Papuans who utilize hospitals are more women than men. This condition applies to all types of hospital utilization. Married people appear to dominate all types of hospital utilization. This difference is statistically significant.

Bivariate analysis results show that those who have educational status below the under primary school dominate hospital utilization. This result is in line with differences in utilization based on socio-economic status and type of work. The result illustrates that Papuans who utilize hospitals are dominated by very poor (quintile 1), and those who do not work. This condition is statistically significant. Three other variables, insurance ownership, travel time and transportation costs to the hospital, also had statistically significant differences in hospital utilization.

The results of the bivariate analysis showed that all variables tested were significant and could be continued with multinomial logistic regression. Table 1 shows the results of multinomial logistic regression tests to determine predictors of hospital utilization among Papuans in Indonesia. In this multinomial logistic regression test, “no utilization” was used as a reference.

Table 1 shows that the predictor of hospital utilization in the outpatient category which proved significant there were 8 variables. The predictors are age, urban-rural area, gender, education level, socioeconomic status, insurance ownership, travel time and transportation cost. Table 1 shows that Papuan who lives in urban areas was 0.667 times using a hospital compared to Papuan who lived in rural areas (OR 0.667; 95% CI 0.532–0.837). It was also seen that Papuan males were 0.782 times compared to Papuan females in utilizing the hospital (OR 0.782; 95% CI 0.660-0.925). Papuan with an education level of under primary school 0.661 times using a hospital compared to college graduates (OR 0.661; 95% CI 0.470-0.930). Table 1 also shows significant socioeconomic status as a predictor of hospital utilization in the outpatient category. This significance applies to all socioeconomic statuses, at least the poorest Papuans used the hospital 2.637 times compared to the richest Papuans (OR 2.637; 95% CI 1.836-3.789). Papuan, who does not have insurance, uses 0.303 times compared to Papuan who has insurance that is managed by private. Papuan with travel time ≤30 minutes utilizing hospital outpatient 2.940 times compared to Papuan who had longer travel time (OR 2.940; 95% CI 2.349-3.680). Papuan with transportation costs of 15,000 IDR utilizing a hospital 1.465 times greater than Papuan which has more expensive transportation costs (OR 1.465; 95% CI 1.166-1.841). The exchange rate of 15,000 IDR equivalent to around 1 $ US.
The hospitals’ utilization in the inpatient category, there are 5 variables that proved significant as predictors. The predictors are gender, type of work, socioeconomic status, travel time and transportation cost. In the inpatient category, Papuan males were 0.711 times compared to Papuan females (OR 0.711; 95% CI 0.565-0.895). Papuan had a single status of 0.561 times compared to Papuan who was divorced (OR 0.561; 95% CI 0.314-1.004). Papuan who did not work 0.622 times used an inpatient compared to Papuan who had other categories of work (OR 0.622; 95% CI 0.401-0.965). The rich Papuans (Quintile 4) had utilized 1.561 times compared to the richest Papuans (Quintile 5)(OR 1.61; 95% CI 1.056-2.306). Papuans who have travel time to hospital ≤30 minutes utilize inpatient 1.458 times compared to those who have longer travel time (OR 1.458; 95% CI 1.503-2.018). Papuan with transportation costs of 15,000 IDR utilizing inpatient 1.560 times compared to Papuan which has more expensive transportation costs (OR 1.560; 95% CI 1.134-2.145).

Whereas in hospital utilization in the outpatient category and inpatient there are only 2 types of variables that are proven significantly as predictors. The two variables are time travel and transportation costs to the hospital. Papuans who have travel time ≤30 minutes 1.907 times use the hospital more than Papuan who has travel time >30 minutes (OR 1.875; 95% CI 1.056-3.329). While Papuan has a transportation cost of ≤15000 IDR 1.875 times more utilizing a hospital than Papuan who has transportation costs > 15000 IDR (OR 1.875; 95% CI 1.056-3.329).

The results showed that several demographic factors were found to be predictors of hospital utilization, namely age, gender, marital status, education level and type of work. Gender is a predictor in outpatient and inpatient categories. Papuans female utilizes hospitals more than Papuans male. Marital status partially predictors in the inpatient category. Education level partially predictor in outpatients, while types of work also found partially to be predictors in inpatient categories, but not in other categories. The study results that significantly showed demographic factors as predictors of hospital use were in line with research in Ghana4, German5, and Turkey6.

Socioeconomic status became a very convincing predictor in the outpatient category. This condition is in line with some of the results of other studies that examined the same thing7. Often socioeconomic is used as an indicator to evaluate the performance of the health service system to predict disparities8,9, inequity10, and inequality11.

Insurance ownership was also found to be a significant predictor in hospital utilization in the outpatient category. Those who do not have insurance have low utilization. The results of this study are in line with the objectives of the universal coverage policy launched by the Indonesian government to provide universal access to health services12. Health finance policies to improve public access are also carried out in several other countries by gradually implementing universal coverage. Evaluation of the implementation of financing policies in some of these countries shows positive results13, although there are still some obstacles to the implementation of financing policies in other conditions14.

Other predictors found were physical access variables indicated by travel time and transportation costs to hospitals. It is evident that better physical access makes better hospital utilization in outpatient and inpatient categories. These results are in line with the results of other studies in Indonesia15,16, and recent research in several other countries, including Iran17, China18, and Italia19. Pre-hospital factors are recommended in health economics studies because they significantly affect hospital accessibility, both in travel time and transportation costs20.

The results of this study cannot be separated from limitations, because this study is more superficial. Predict the phenomenon of surface hospital use. Need more in-depth research qualitatively to be able to better understand the reasons behind each phenomenon revealed in this study.

**Conclusion**

Based on the results of the study it can be concluded there were 9 predictor variables hospitals utilization (outpatient and inpatient) consisting of age, urban-rural area, gender, education level, work type, socioeconomic status, insurance ownership, travel time and transportation cost.

Hydration Status and Degree of Clinical Severity Patients with THRoMBotic Infarction Stroke

Agung Nugroho¹, Hendro Susilo¹
¹Department of Neurology, Faculty of Medicine, Dr. Soetomo Teaching Hospital, Universitas Airlangga, Surabaya 60285, Indonesia

Abstract

Background: Dehydration is common in acute ischemic stroke patients and associated with a poor increase in clinical outcomes. It is caused of the increase of hematocrit related to the infarct volume which is wider to the cerebra infarct patients. It is also related to the repeatedly emboli stroke and thromboembolic vena after the occurrence of the acute stroke.

Objectives: To analyze the correlation between hydration status and clinical severity in patients with acute thrombotic stroke.

Methods: This study was conducted by using control design consecutive admission sampling technique. Serum BUN and creatinine measurements were performed when patients were administered to the hospital. Dehydration was defined if the ratio of BUN/serum creatinine was >15. Patients were divided into dehydration and non-dehydrated groups. The degree of clinical severity was measured by using the National Institute of Health Stroke Scale (NIHSS) at 7 days of onset of stroke. Data were analyzed using chi square, fisher, t dependent test, and mann whitney (p <0.05).

Result: There were 19.23% stroke patients with dehydration were in the case group and the control group were 9.62%. There was no significant correlation between hydration status and clinical severity in acute thrombotic stroke patients (p = 0.126; OR = 2.625).

Conclusion: There was no correlation between hydration status and clinical severity in acute thrombotic stroke.

Keywords: Stroke, dehydration status, BUN/SK, NIHSS

Introduction

Stroke is the first leading cause of disability worldwide, the second most common cause of dementia, and the third leading cause of death. Stroke resulted in major clinical, social, and economic impacts with a total death rate of 6.2 million (±11% of the total). Around 9 million people suffered a stroke in 2008, 30 million people have had previous strokes and still alive. Stroke is the main cause of disability and this recent decline has fallen from the third leading cause of death to the fourth place in the United States ¹. The incidence of stroke has increased exponentially over the last 30 years and its causes vary by age. Ninety-five percent of strokes occur in people over the age of 45 and two-thirds of strokes occur in people over age 65. The risk of death in a person with stroke also increases with age. Stroke can occur at any age including the age of the children ².

Stroke is also a major cause of disability. It is approximately 55% of patients who survive up to 3 years will experience a decrease in quality of life. There is only 20% of patients with stroke can return to work as before ³,4. The association between renal function and stroke has been determined by a study assessing

Hendro Susilo
E-mail: hendrosusilo588@gmail.com
the association between hypertension and mortality with black patients suffering from acute stroke as the determinants. Stroke survivors have lower levels of urea than those who died. Friedman’s findings of stroke survivors in New Zealand mentioned that serum creatinin concentrations independently as predictors of mortality even after adjustment for confounding variables.

Euvolemia is important for adequate blood flow and maximizing oxygen intake into optimal tissue and organ function. Research showed blood flow to organs such as muscles and kidneys decreases significantly during dehydration. Cardiac output also decreases during dehydration. The brain has the ability to control blood flow through autoregulation that regulated constant cerebral perfusion pressure even when blood pressure changes. Dehydration has been shown to decrease the autoregulation response to orthostatic position changes, but in general does not decrease cerebral perfusion.

The role of dehydration in cerebral infarcts is thought to be multifactorial. Dehydration increases the viscosity of blood by decreasing blood flow to the brain through the decrease of intravascular volume. The increase hematocrit has been shown to be associated by a larger volume of infarction in patients with cerebral infarction. Dehydration has also been shown to be associated by recurrent embolic strokes and thrombotic events including venous thromboembolism following the onset of acute stroke. Dehydration can disrupt the distribution of oxygen to the brain, increase the risk of venous thromboembolism, and be associated with poor outcome in stroke. Dehydration can be detected by biomarkers of reduced fluid in the blood. Biomarkers that are often used to assess the presence of dehydration are the ratio of BUN/creatinine and plasma osmolality.

There is no hydration marker has been considered a golden standard, especially for mild dehydration. A total of 102 elderly patients were admitted to one of the educational hospitals who were diagnosed dehydrated. After a serum analysis, there is only 17% had an increase in serum osmolarity, 11% had elevated serum sodium, and 68% had an increase in blood urea nitrogen (BUN)/serum creatinine (SCr). BUN and SC are valuable laboratory parameters for evaluating renal function. The ratio of BUN to serum creatinine (BUN/SCr) is one of the useful laboratory indicators to determine the decrease in hydration status. Based on the description above, it is necessary to conduct an analysis of dehydration status and degree of clinical severity in patients with thrombolytic infarction. This study aimed to analyse hydration status of clinical severity and degree of clinical severity in patients with thrombolytic infarction.

**Method**

The participants in this study were all acute thrombotic stroke patients who met the inclusion and exclusion criteria. The inclusion criteria included patients diagnosed clinical acute thrombotic stroke and uncompromised CT scan, first stroke occurring within 24 hours, and having National Institute of Health Stroke Scale (NIHSS) score score of <4. NIHSS is a tool used to assess stroke damage with score range of 0 to 42. Exclusion criteria include patients having chronic renal failure, congestive heart failure, hemorrhagic stroke, embolism stroke, systemic inflammatory response syndrome, and use diuretic drugs. Participants who were willing to be involved in this study were required to fill the informed consent form in advance.

The participants were selected by identifying the number of patients with acute thrombolytic stroke in the previous year at Dr. Soetomo Teaching Hospital Surabaya, Indonesia. Afterwards, we found 101 participants with acute thrombolytic stroke who met the inclusion and exclusion criteria. During the course of the study, some patients with acute thrombolytic stroke were excluded from the study because the participant went home forcibly or died in ≤24 hours before blood sampling was taken for BUN and SCr examination. After those processes, we found 52 participants that were able to be enrolled in this study.

The procedure of this study involved patients diagnosed with acute thrombolytic stroke. Patients were examined by NIHSS on the seventh day. Participants were identified and divided into 2 groups, i.e. case group (moderate NIHSS with score 4-15) and control group (NIHSS with score <4). We conducted blood pressure measurement for the participants. Blood sample of 3 ml was stored in EDTA vials and identified for the BUN, SCr, Hb, Albumin, Potassium, Sodium, and Glucose. Assessment of dehydration status (BUN/SCr) was based on two studies. The criteria of hypertension refers to Joint National Committee 8.
The measurement data were analyzed according to the type of measurement results data using SPSS 22.0 (SPSS, Inc., Chicago, IL). Analysis on the participants’ gender data and blood pressure were conducted using chi square test (A p value of <0.05 was considered as statistically significant). Analysis on age, albumin, sodium, potassium, hemoglobin, and glucose data of the participants were conducted using t-dependent test (A p value of <0.05 was considered as statistically significant) with Kolmogorov Smirnov beforehand. The correlation between dehydration status and degree of clinical severity in stroke infarction patients was analyzed using chi square test (A p value of <0.05 was considered as statistically significant).

**Result**

**Sample Characteristic**

The demographic data in this study consisted of two types of data, i.e. gender and age. In case group, most participants were female (32.69%), while in control group most participants were male (32.69%). The comparison of age between the two groups showed p = 0.027 (Table 2). In case group, the mean of the participants’ age was 55.43±9.05 years old, while in control group was 53.12±11.96 years old. The comparison of age between the two groups showed p = 0.233 (Table 1).

The clinical data of albumin examination showed the value 4.00±0.36 mg/dl in case group and 4.18±0.42 mg/dl in control group. The comparison between the two groups showed p = 0.276. The sodium level was 134.12±3.38 mg/dL in case group and 135.12±2.52 mg/dL in control group. The comparison of sodium level between the two groups showed p = 0.653. The potassium level in case group was 3.76±0.53 mg/dL, while in control group was 4.05±0.46 mg/dL. The comparison of potassium level between the two groups showed p = 0.479. The level of hemoglobin was 14.00±2.81 mg/dL in case group and 14.10±4.95 mg/dL in control group. The comparison of hemoglobin level between the two groups showed p = 0.905. The glucose level in this study was 137.43±40.51 mg/dl in case group whereas in control group was 123.58±20.31 mg/dl. The comparison of blood glucose between the groups showed p = 0.694 (Table 1). Most participants had hypertension with 82.69%. The comparison of hypertension in the two groups showed p = 0.233.

**Hydration Status and the Stroke Severity**

According to all participants in this study, 19.23% in case group experienced dehydration. However, control group was 9.62%. We did not find any significant difference, both statistically and clinically, between clinical severity degree of acute thrombotic stroke patients and dehydration condition and those with no dehydration. The p value was 0.126 and the odd ratio value was 2.625 (IK 95%; 0.748 – 9, 210; Table 2).

### Discussion

The results which do not correspond with the proposed research hypothesis might be due to several things. First, the study did not include subjects suffering from ischemic stroke due to thrombotic in large vessels and therefore we did not get sufficient number of subjects into moderate to severe NIHSS groups with dehydration as well. In the studies conducted by Lin et al. and Schrock et al., the inclusion criteria included ischemic stroke patients due to large vessel disease. Second, this study did not limit the age of the subjects, causing that the proportion of subjects in the dehydrated group and the severity of clinical/NIHSS were not as expected. It is known that the elderly subjects are susceptible to dehydration which is a major cause of fluid and electrolyte disturbances. Third, this study did not consider other factors that might determine stroke prognosis, such as the location and width of the infarct. Stroke prognosis is affected by various factors including age, stroke severity degree, stroke mechanism, infarct location, comorbidity conditions, clinical finding, and related complications.

Cerebrovascular disease is one of the causes of morbidity, disability, and mortality worldwide. Generally the different genders are associated with stroke events. The relationship between age and stroke is more influential to men except at an advanced age. Increased age affects the morbidity of stroke, mortality, and the old outcome in both minor and major stroke. The age of over 65 years has a higher mortality risk in 2 months after stroke.

Hypoalbuminemia is a poor predictor of prognosis in patients with ischemic stroke, but the mechanism is still unknown. The currently known mechanism is not only limited to energy depletion, but also related to the damage of one’s immune and hormonal responses, as well as extracellular fluid expansion. In another study, the effect of infusion of albumin on ischemic brain of experimental animals was suggested. This is presumably because albumin has a neuroprotective effect mediated by various actions including antioxidative ability, affecting endothelial function, and venular perfusion.

Hyponatremia is a risk factor for stroke and cardiovascular disease. Mild hyponatremia is associated with increased mortality within 30 days of myocardial infarction and post-stroke mortality in 3 years. Hyponatremia is associated with acute mortality and worse outcome trends resulting in higher mortality within 12 months after stroke. The mechanisms of potassium effect on stroke are still unclear. Patients with lower potassium serum levels during stroke and after dismissed from hospital have a poor prognosis, especially in elderly patients.

Hypertension is a major risk factor for stroke. The increase of systemic blood pressure associated with the increased intra-cranial pressure (ICP), mainly due to suppression of the brain stem. It is strongly associated with intracerebral and subarachnoid hemorrhage, but this increase in blood pressure does not appear to be associated with cerebral ischemia.

The dehydration condition characterized by an
increase in BUN/SCr ratio is a factor that can be used to estimate poor outcomes in patients with chronic heart failure. The increased of BUN/SCr ratio is also reported to be associated with a neurological deterioration in ischemic stroke patients. A dehydration condition that increases the BUN/SCr ratio by more than 15 is at 2.2 times risk of clinical impairment in 30 days of post-onset of ischemic stroke. Infarction stroke patients with elevated BUN/SCr ratio had a higher prevalence for cardiembolic stroke compared to those without increased BUN/SCr ratio.

**Conclusion**

There was no correlation between hydration status assessed using BUN/Serum Creatinin ratio and the clinical severity degree assessed using NIHSS in acute thrombotic stroke. However, a further confirmation is still required.

**Ethical Clearance:** The study protocol was approved by the Ethical Commission to conduct basic science/clinical research in Dr. Soetomo General Hospital Surabaya, Indonesia. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice.

The Effect of Allogenic Bone Marrow Mesenchymal Stem Cell - Platelet Rich Plasma (Bmecs - Prp) Intra-Articular Injection Effect on the Regeneration of Full-Thickness Joint Cartilage Defect on Rabbit

Ahmad Taufik.S1, Dwikora Novembri Utomo2, Hari Basuki Notobroto3

1Faculty of Medicine, Universitas Airlangga (60131), Surabaya, Indonesia, 2Departement of Orthopaedy and Traumatology, Faculty of Medicine, Universitas Airlangga (60131), Surabaya, Indonesia, 3Faculty of Medicine, Universitas Airlangga (60131), Surabaya, Indonesia

Abstract

Introduction: Full thickness cartilage defects are still a problem until present since the handling has not give any satisfactory results. Current handling is performed through cartilage engineering using mesenchymal stem cells alone and or in combination with growth factor. The purpose of this study was to investigate the effect of injection of intra-articular injection of Allogenic bone marrow mesenchymal stem cell - Platelet rich plasma (BMSCs-PRP) on regeneration of full thickness cartilage defect in rabbits.

Method: The design of this study is a post-test only control group design using 36 New Zealand white rabbits divided into three groups treated with PRP, BMSCs and BMSCs-PRP. Results are evaluated after 10 weeks.

Results: In the evaluation, macroscopic images showed the best healing in the BMSCs-PRP group. Histopathologic examination showed that in the MSCs-PRP group there was a significant increase in the amount of chondrocytes (p = 0.000), cartilage area (p = 0.000), as well as the number of Agecoprogenitor expec- tion cells (p = 0.000) and type 2 collagen (p = 0.000).

Conclusions: Intra-articular injections Allogenic bone marrow mesenchymal stem cell (BMSCs-PRP) is able to regenerate and cure full-thickness joint cartilage defects through differentiation of MSCs into condroblasts.

Keywords: Allogenic, Bone marrow Mesenchymal stem cell, Cartilage, Platelet rich plasma, Full-thickness

Introduction

Cartilage of joints is an important part of the joint component. Damage to joints often occurs in sports activities, where some studies get nearly 49% of joint damage occurring due to sports injuries. Its high ability to hold and absorb weight is helpful in resisting the mechanical forces acting on joints during sports activities 1. In the destruction of joint cartilage, the healing of the formed tissue is very fragile because it consists of fibrocartilage so that even small defects will cause degeneration over time, eventually leading to osteoarthritis 2.

The affected cartilage of the affected joints shows limited healing ability. Damage to joint cartilage that affects the subcondral bone shows signs of healing due to the release of bone marrow mesenchymal stem cells (BMSCs). This is the principle of microfracture. Current treatments such as arthroscopic management, autologous
osteochondral transfer, autologous chondrocyte implantation (ACI) all showed better results although a systematic review comparing the three methods found no consistent therapy method showed better results than other techniques ³.

Im et al. (2001) examined the ability of bone marrow mesenchymal stem cells (BMSCs) to treat defects in cartilage. BMSCs suspension is given on Ham F-12 medium before being injected into full thickness cartilage defect in the rabbit patella basin area. Evaluation after 14 weeks showed the BMSCs group resulted in full cure in the subcondral bone tissue layer. Meanwhile in the control group the healing tissue is thinner, irregular and undifferentiated with a little bit of collagen type 2 matrix. The use of BMSCs with this method improves cartilage repair although the cure is not the same as the natural content ⁴.

The previous researcher examined the ability of bone marrow mesenchymal stem cells (BMSCs) to treat defects in cartilage. BMSCs suspension was given on Ham F-12 medium before being injected into full thickness cartilage defect in the rabbit patella basin area. Evaluation after 14 weeks showed the BMSCs group resulted in full cure in the subcondral bone tissue layer ⁵. In general, mesenchymal stem cells to be implanted in joint cartilage defects are included in the three-dimensional scaffold. Some issues relating to the use of scaffolds are material selection, the ability to support cell viability and differentiation, retention problems and research have found that PRP administration has a regenerative effect because it proves to improve the healing of osteochondral defects in rabbits ⁶.

The administration of PRP to MSCs cultures can increase in vitro proliferation and there is a tendency to increase MSCs differentiation into condroblasts and osteoblasts. Allogenic MSCs can increase cartilage regeneration and do not cause autoimmune rejection reactions. MSCs have immunosuppressive syphles that allow them to be used allogenically.

Method

This is a true-experimental study with post-test only control group design. This study protocol has been approved by the Ethics Committee of Faculty of Veterinary Medicine Universitas Airlangga Surabaya. The inclusion criteria of this study were male rabbits, adulthood 6-8 months, body weight 2.5 - 3.5 kg. Exclusion criteria were infection, knee injuries and rabbits died before 8 weeks. The initial stage in this research is to prepare the manufacture of mesenchymal stem cells-platelet rich plasma (BMSCs - PRP) as follows; bone marrow aspirations for making Bone marrow mesenchymal stem cells (BMSCs); culture and expansion of bone marrow-mesenchymal stem cells (BMSCs) from the bone marrow; characterization of Bone marrow-mesenchymal stem cells (BMSCs); making platelet rich plasma (PRP); making cartilage defects in the knee joint; intraarticular injection of cartilage defect in the knee joint; Sacrifize rabbits at 12 weeks; evaluation of histological and immunohistochemical examinations and evaluation of data ⁷.

All the collected data were tabulated and statistically processed using SPSS (SPSS. Inc. Chicago IL). This research were conducted through data descriptive analysis. Normality data test was conducted to know the normally distributed data in all data of the study result. Homogeneity test of variance was done for the normally distributed data ⁸. The quantitative data comparative test result of eosin hematoxylin (HE) examination of the amount of chondrocytes and cartilage area was performed using one way analysis of variance (ANOVA) test on the data with homogeneous variance to know the difference of the examination result data in the three treatment groups ⁹. The quantitative data comparative test result of immunohistochemical examination (IHC) number of agrecan expression condenser and collagen type 2 using one way analysis of variance (ANOVA) test on data with homogeneous variant to know difference of examination result data in all three treatment groups. In the abnormally distributed data, statistic test was performed with Kruskal Wallis test ¹⁰.

Results

To obtain sufficient amount of BMSCs for $2 \times 10^7$ injections, culture was carried out for 2 weeks. This amount was achieved at passage 3. The optimal number of BMSCs for mobilization to the defect at the rabbit knee was $1 \times 10^7$ per mL (Figures 1a and 1b). Platelet rich plasma (PRP) was made with two rounds of 3000 rpm for 13 min at 1st and 3000 rpm for 15 minutes at stage 2. The final result of 20 ml of peripheral blood taken and processed was 2 ml PRP. In PRP an increase in platelet count was 5x more than the platelet count in peripheral blood (Figure 1c and d).
In groups that received BMSCs-PRP the defect was almost invisible. The defect area has been filled with the same whitish color cartilage tissue as the surrounding cartilage color. The boundary of the healing area with its surroundings is not clear with the same surface height as the surroundings. This shows the best healing occurs in the BMSCs-PRP group (Figure.2). The area of cartilage in each treatment group. The results of analysis with Brown-Forsythe Statistic obtained p value = 0.000 indicating a difference of cartilage area in PRP, BMSCs and BMSCs-PRP groups. The width of cartilage in each treatment group. The result of analysis with Brown-Forsythe Statistic obtained p value = 0.000 indicating a difference of cartilage area in PRP, BMSCs and BMSCs-PRP group (Figure.3).

The difference in numbers was seen in the agrecan expression of different cells between tissue matrices in each treatment group using x100 magnification. Based on the number of Agreecan expression cells it is found more in the BMSCs-PRP group (Figure 3E) than in the PRP and BMSCs groups. As for the difference of Agreecan expressor cells with core and were not shown with positive or negative explanation at x400 magnification. BMSCs-PRP group (Figure 3F) had the most positive cells compared to PRP group (Figure 3B).

Immuno histochemical examination of collagen type 2 in the figure above shows the difference in the number of collagen type 2 expression cells in each group. The amount difference can be seen in the network matrix in each treatment group using x100 magnification. The number of collagen type 2 expression cells was found more in the BMSCs-PRP group (Figure 3E) than in the PRP group (Figure 3A) and BMSCs (Figure 3C). At x400 magnification, each treatment group expressed a condroprogenitor cell. (Figure 3B, D and F).
Discussion

The procedure of this study was carried out according to the previous research results where the process of centrifugation done 2 times with speed 3000 rpm for 13 minutes at 1st and 3000 rpm for 15 minutes in the second round. In another study another commercial system was used where leukocytes-PRP were classified according to Dohan Ehrenfest. In this system PRP was produced with platelet concentration of about 220,000 platelets/μl. Preparation of PRP consists of a stage where the poor platelet plasma (PPP) was not disposed.

The advantage of this process is to avoid excessive manipulation that can lead to platelet stress in the second centrifuge and avoid removing growth factors that depend on PPP. Another advantage is the closed circuit system in its purification process which causes the procedure to be safer. In this process usually after centrifugation of 8 ml of peripheral blood, platelet recovery> 95% and recovery of leukocyte> 58% (mononuclear cell recovery 93%) in 4 ml PRP 11.

The platelet count levels in this study may provide optimal benefits. The concentration of platelets in PRP in this study did not differ greatly with the Anitura study which obtained platelet concentration results of about 2.5 times normal. Other studies have shown that an excessively high platelet count can decrease the expected effect (paradoxsal effect). The dose-response relationship between platelet concentration and the stimulated biological process remains unclear. Once the growth factor reaches the targeted receptor surface, the additional growth factor concentration has no effect. Growth factor will decrease the effect if the required upper (high) concentration limit is reached12.

In an intra-articular injection study of BMSCs on osteoarthritis raised by bone debris and cartilage from osteochondral fragments, there was a significant decrease in postaglandin levels in the synovium fluid.13 This effect is not found when an injection of MSCs is sourced from fat. In this study there was an increase of tumor necrosis factor (TNF) levels in the synovium fluid. The effects of BMSCs on cartilage improvement are derived from inhibition of catabolic effects and stimulation of anabolic effects through cytokine mediators 14.

A recent study on horse experimental animals for 2 to 5 years found that BMSCs produce protein core and
chondroitin sulfate with longer chain and few shorter protein molecules than chondrocytes. This shows that BMSCs produce aggrecan with younger phenotype characteristics than chondrocytes produced. These results are in accordance with the results of this study where there is an increase in aggrecan content in defects given BMSCs 15.

Allogenic BMSCs are a new hope for healing cell-based cartilage. Allogenic BMSCs allow patients to be injected only once, no longer needing 2 actions for harvesting cells and implantation. This allogenic technique makes the treatment of defects in cartilage to be reliable, easy to apply and not invasive 16.

Conclusion

Intra-articular injection of allogeneic bone marrow mesenchymal stem cell - rich plasma platelet (BMSCs-PRP) was able to increase the differentiation of BMSCs into condroblasts. It creates formation of more aggressive and collagen type 2 expression cells than those injected only with BMSCs or PRP alone in fullthickness joint cartilage defects. PRP is able to form an environment suitable for MSCs so that MSCs proliferate and differentiate into more condroblasts.

Ethical Clearance

This research involves participants in the process using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic regulation. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice.

Health Wisdom in the Traditional Healing of the Panaragan Java Subethnicity: The Case Study of Warok Ponorogo

Alip Sugianto1, Wakit Abdullah2, Sumarlam3, Sahid Teguh Widodo4

1Doctoral Student, 2Professor, Universitas Sebelas Maret, Surakarta, Indonesia

Abstract

The Panaragan Java Subethnicity has a customary leader called warok. This leader is known for his ability to possess supranatural powers which may heal diseases. This traditional skill is obtained from the ancestors. It uses natural materials complete with the mantras. The aim of this research is to know the local wisdom in the field of health, especially in the art of Reyog from Ponorogo. This research uses a descriptive-qualitative design. The data is obtained through the technique of observation and interview. The results show that there are three types of health wisdom in the Panaragan subethnicity which are the wisdoms of health profession, medicine, and healing.

Keywords: Health Wisdom, Warok, and Ponorogo

Introduction

The province of East Java, Indonesia, has ten cultural subareas which are Mataraman Java, Panaragan Java, Arek, Samin (Sedula Sikep), Tengger, Oising (Using), Pandalungan, Madura Pulau, Madura Kangean, and Madura Bawean.(1) These ten cultural subareas have various cultural characters which are different from one and another. These variations exist in the language, the arts, and the culture. One of the interesting cultural subareas is the Panaragan subarea.

According to a Western observer,(2) the Panaragan Java subethnicity is included in the Mataraman subarea which includes Madiun, Magetan, Trenggalek, Pacitan, and Ngawi. This is different from the opinion of an Indonesian researcher(3) who suggests that the Panaragan subarea is separate from the Mataraman subarea. The justification is that the Panaragan ethnicity subarea has a different language, traditional costumes, and traditional arts. It is also an autonomous area which was formerly known as the Wengker area before there was an acculturation from the Mataraman culture.

Wengker came from the words wewengkon angker (a mysterious place). As reflected from the etymology of the word “Wengker”, this place is known as sacred. There are many ancestral traditions which include mystical-magical rituals, which are still practiced by some of the Panaragan subethnicity until now. These traditions include larungan sesaji, bedhol pusaka, and kirab pusaka Ponorogo, which are practiced on the night of the first of every Sura (the first month in the Javanese calendar).

These traditions are continually practiced generation to generation by the Ponorogo people. The discussion on Ponorogo people cannot be separated from the customary leader, who is called the warok. Warok has a high social status in society. This social status makes a warok become respected. Thus, it is not strange how the warok has the role as the patron and protector of the society. If viewed from the meaning of the warok term, no clear terminology has been found up to now. According to Poerwawijaya warok came from the word war’I or wirangi (in Javanese language), which means wis pana, wis mangerti banget marang agal alus lahir batin, tumindake mung kangge tetulung marang liyan.

The warok is a central character in the art of reyog. His closeness with the spiritual word makes the warok identical with the mystical and magical world. It is believed that a warok must master reh kamusankan
sejati, which is the ‘path to true humanity’. It is obtained through the attitude of concern, fasting, penance, and even meditation. Because the warok has magical power, it is not seldom that people ask them for help regarding traditional healing. At least, there are two types of healings carried out by the warok, which are the non-physical healing and the traditional physical healing.

Examples of the non-physical healing are the action of healing diseases caused by ghosts such as witchcraft, trance, exorcism, etc. The warok also heals physical diseases such as sores, stomach ache, colds, etc. The two types of disease are healed through different treatments. The non-physical diseases are healed through rituals and mantras. Then, the physical diseases are healed by using traditional herbs or other media, depending on the type of disease.

Based on the two types of healing – which are the healing of the physical and the non-physical diseases – there is a similar view of the Panaragan people, both for the traditional and the modern healing. For example, in the modern view, stomach aches are believed to be caused by unhygienic foods, flus, the minimal condition of the immune system, or the unfriendly weather. It may also be caused by the violation of prohibitions determined by the ancestors, such as the consumption of certain foods and drinks which are prohibited as they endanger the body.

The description above, it becomes interesting to analyze the local wisdom of the Panaragan Java subethnicity in the field of health, with the case study of the Panaragan warok, in the case of their method of healing, their mix traditional medicine, supernatural prayers, or the combination of these things which are applied in the society.

**Method**

This research uses the method of qualitative research approach, as it is naturalistic. The reality is plural, heterogenous, and holistic, thus it cannot be measured or separated fragmentally. The researcher and the research objects are interrelated. They are inseparable, as the interact with each other to reveal the analyzed worldview. In the context of traditional healing, the effort to understand the local wisdom within traditional healings are not limited to what is visible. Yet, it tries to reveal what is hidden, so that we may see the ideology, the understanding, and the world view of the warok from Ponorogo.

This is a descriptive research, as it describes and explains the traditional healing by the Panaragan subethnicity. It tries to reveal the phenomenon of local wisdom. The descriptive method uses the ethnographic method, which has the characteristics of holistic, integrative, and which has thick description. The qualitative analysis is aimed to obtain the native’s point of view. There are two types of data in the qualitative method, which are the primary and the secondary data.

This research uses two main methods to obtain and to present the data. The first is observation. Second, the researcher carries out an interview. The type of interview used is the in-depth interview. Third, the researcher carries out a document analysis by collecting supporting documents such as journals and books. The analysis is created by study and development. This research uses a criterion-based sampling technique to obtain purposive samples to accommodate all possible data in the research field. Thus, there are no deviant cases or those which are forced to be part of a certain category. The data analysis technique is carried out through these steps: Domain analysis, Taxonomy analysis, Componential analysis and Cultural theme analysis.

**Results**

The health wisdom is the method carried out by the society in solving cases related to health problems, both which are physical and non-physical wisely. In the Panaragan Java subethnicity, especially in the art of reyog Ponorogo, there is the classification of three important domains related to health. These domains are the medical profession wisdom, medicine wisdom, and treatment wisdom. These three domains are inseparable as they are integral. This health wisdom is contained in several kinds of wisdoms, which are classified by the writer as follows:

**a. Medical profession wisdom**

This wisdom of medical profession is related to the skills of the Panaragan Java subethninc people in solving problems of various diseases. This profession is based on the warok’s type of expertise in handling some problems related to health. This expertise is ordained to the people because of their capabilities in handling various health problems. For example, there is the type of warok who is an expert in the field of health. Generally, they are
called *dukun* (shaman). This *dukun* usually heals general diseases, both which are physical and non-physical.

There are also *dukun* who have a specialization in healing diseases of muscles, such as sprain, twisted muscles, and broken bones. People call them the massage *dukun*. For example, Mr. M and Mr. IR. Mr. M is known as a *dukun* who can heal the disease of madness, but his specialization has shifted into massaging, even though he still heals people with the disease of madness. Meanwhile, a *warok* who has specialization for children are called the baby *dukun*. They usually handle diseases suffered by babies, as done by Mr. S and Mr. M. They handle diseases including *sawanen* (a condition where children are thought to be disturbed by ghosts), and they massage babies, and they also help anything to do with babies.

b. Medicine wisdom

The medicine wisdom is the method in handling types of diseases by making use of traditional herbal medicine. The traditional medicine used are from plants, including ginger, galangal, turmeric, *laos*. The usage of the herbal medicine is according to the type of disease, as each herbal medicine has its own use and function. Apart from herbal medicine, they also use other traditional medicine such as water and salt, which are believed to be able to neutralize negative aura in the human body. The wisdom of these medicine is according to the type of disease; thus, the type of medicine is based on the disease. For example, the type of medicine used by *warok* in the Reyog art of Ponorogo are as follows:

1) Achy rheumatic potion

Red onions, ginger, clove oil, and water are mixed together. They are mashed up by grinding. Then, this potion is smeared on the painful parts of the body. The red onions and the ginger are believed to be able to warm up the body, and that it may increase the blood flow. The achy rheumatic is usually suffered by the Reyog players, and they are usually healed by using that traditional method.

2) Head ache potion

Bitter coffee or eucalyptus leaves. Bitter coffee is believed to be able to ease the tensed-up nervous system. Then, the sufferer is advised to sniff ground cajuput leaves are believed to be able to ease the tensed-up nervous system and to ease the mind. Usually, in the Reyog art group, there are people who cannot take the aroma of the offerings, so they become dizzy. These simple methods may ease their dizziness.

3) Fever potion

(The documentary photo of Mr. P, with Coffee, Turmeric, and Water placed on a tray in front of Reyog)

The turmeric is one of the elements in the Reyog offering, with water and coffee. The philosophy of turmeric is *nirajim*, the water is clarity of thought, and coffee gives off pleasant aroma.

4) Potion to treat *sawanen*

*Dlingo* leaves are a type of soft-stemmed plant which has an aroma similar to garlic. Part of the society believes the myth that these leaves may shoo away genies, as the smell is not liked by Satan.

5) Potion for possessed people

Water and salt are believed to heal those who are possessed by evil spirits. This non-physical disease comes from the disturbance of genies, and it can be healed by using salt and water. Water is believed to be able to neutralize Satan’s disturbance. Satan is made of fire, and fire can be extinguished by water. Salt comes from sea water which has the philosophy that the sea is never dirty, as all rubbish that comes to the sea will be pushed to the shores.

c. Treatment wisdom

The treatment wisdom is the manner practiced to heal diseases suffered by a person so he/she may be healthy as before. The players of the Reyog art, which is a form of dance which uses physical moves, usually experience pains in the joints, muscles, and achy rheumatic. These types of conditions are caused by lack of warming up. It may also be caused of lack of practice of unpredictable
accident.

The type of health condition is then treated by urut (which literally means to order). The lexical meaning is to massage certain parts of the body which is in pain, such as strain, twisted muscles, pains, pinched nerves, and bruises. Before massaging the painful parts of the body, the warok will chant a mantra as follows:

Assalamualaikum Kakang kawah, adi ari ari, kiki kipu nini kipu, bahu tengen bahu kiwa, awalane srina sewengini sedulure putuku nek ngembani panjang umur rejekine anteng, eyang eyang singgungkuli bapa biyong, sing ngayomi anak putuku paringi sehat, lara encok loro ayu lara dengen, oleho sak njobone sumsum aja sak njerone belung sri tolah nek ngembani panjang umur rejekine anteng, eyang eyang singngungkuli bapa biyong, sing ngayomi anak putuku paringi sehat, lara encok loro ayu lara dengen, oleho sak njobone sumsum aja sak njerone belung sri tolah nek ngembani panjang umur rejekine anteng, eyang eyang singngungkuli bapa biyong, sing ngayomi anak putuku paringi sehat, lara encok loro ayu lara dengen, oleho sak njobone sumsum aja sak njerone belung sri tolah wasalamualaikum (Mr. M).

After praying, the warok will massage the painful parts of the body. He will smear red onions and oil on the body parts while massaging it, so that the body will feel warm. Another condition which appears to those around the reyog art show is sawanen. It is usually suffered by little kids after having watched the show. If there is a little kid who experienced sawanen, thus the warok will chant the following prayer.

Kakang kawah adi ari ari sedulure batur aja mincok ning manungsa panggonamu ning....ning ara ara asal balik neng ara ara, asale ning dwuwr balik neng dwuwr, asale ngisor balika ngisor aja mincok ning drema manungsa (Mr. M)

The warok will pray by suwuk while kissing the little child’s forehead. Usually, people can tell if a kid experienced sawanen by seeing the indicators. Usually the kid with sawanen will often cry and throw tantrums.

The reyog art show, there are usually spectators who experienced disturbance from the mystical realm. They may be possessed by evil spirits. The symptoms of this non-physical disease are the sufferer having a blank mind, daydreaming, or screaming unconsciously. The disease may be healed by reading the following mantra.

“Dhedhemit podo morat marit, Jin setan mawut ra karu-karuan, Kaya watu bledug dadi awu, kun faya kun kersaning Allah, Laillahaillaallah Muhamadar Rosullullah” (Mr. P).

After reading that mantra, the warok will smear salted water to the possessed person’s face or forehead. The water or toyo petak which has been given the mantra may absorb the positive energy of that mantra. Thus, it may help neutralize the negative effects in the person’s body.

Discussion

The traditions which exist in the society is the traditional healing. The society’s capability in mixing potions and also medicine and potions which may heal diseases are traditions from the previous generations. Based on the results of the research, there are local wisdoms in the aspect of health among the Panaragan Java subethnicity. This wisdom includes the wisdom of the medical profession, wisdom of medicine, and wisdom of healing.

The skills in the field of traditional health are obtained from the previous generation. Indonesians have long known and used plants with medical properties as one of the efforts to solve health problems. The use of natural products has been used by the ancestors since centuries ago. The evidence is that people still believe in the effects of herbal medicine to solve health problems.

The ability to mixing medical plants are usually followed with the ability to manage the mind, as done by the warok of Ponorogo. They believe that sometimes, diseases are not caused by visible things. They may also be caused by invisible things which come discreetly. Thus, the medicine is also from non-physical things. As carried out by warok P, who used the supernatural therapy to heal the diseases of someone being possessed by evil spirits or sawanen, by giving water with mantra.

This is in accordance with the opinions of Foster and Anderson. They stated that some parts of the society still believed that the source of some diseases are from the disturbance of invisible creatures. Further, they stated that this phenomenon is called ethnomedicine. Ethnomedicine is a practice regarding diseases which is a result of an original culture. It is explicit and does not come from modern medical science.

Conclusion

The conclusion of the health wisdom in traditional healing by the Panaragan Java subethnicity with the case study of warok Ponorogo are as follows. First, there is a wisdom of the healing profession, where someone has
the profession as a traditional healer. This profession is adapted with different specific abilities, such as child dukun, baby dukun, and general dukun. Second, the medicine wisdom, which is medicine which comes from natural plants, such as dlingo leaves, turmeric, coffee, and cengkeng. The third is the healing wisdom, which are all methods taken to heal a sick person, such as massage, blows, and smearing potions to the hurt body parts.

Correlation between Coenzyme Q10 Level Long-Term Steroid Inhalation in Patients with Bronchial Asthma

Deny Perdana Putra¹, Arief Bakhtiar², Muhammad Amin²

¹Department of Pulmonology, Faculty of Medicine, Universitas Airlangga, Surabaya 60285, Indonesia,
²Department of Pulmonology, Faculty of Medicine Universitas Airlangga, Dr. Soetomo Teaching Hospital, Surabaya 60285, Indonesia

Abstract

Background: The main therapy of asthma is inhaled steroids and is often used for long periods of time. Coenzyme Q10 is a potent antioxidant produced largely by mitochondria. Treatment of long-term oral steroids can cause mitochondrial damage which lowers the level of coenzyme Q10.

Objective: To analyze the relationship between coenzyme Q10 levels and long-term steroid inhalation in asthma patients.

Method: The study was conducted at Asthma Unit/COPD of Dr. Soetomo General Hospital Surabaya Indonesia, Pulmonology Unit of Dr. M. Soewandhie General Hospital Surabaya Indonesia, and Pulmonology Unit of Universitas Airlangga Hospital Surabaya Indonesia. We measured coenzyme Q10 levels and the duration of inhaled steroid use in the subjects. The data were processed using computer statistics program. The correlation between coenzyme Q10 level and long-term steroid inhalation was analyzed using Pearson correlation test (p < 0.05).

Result: Coenzyme Q10 levels in all samples were normal and increasing. There was no low coenzyme Q10 level found in all samples. The result of Pearson’s correlation test between coenzyme Q10 level with long-term steroid inhalation showed r = -0.037; p = 0.848 (p> 0.05).

Conclusion: There was no correlation between coenzyme Q10 level and long-term steroid inhalation found in this study.

Keywords: Coenzyme Q10, Asthma, long-term steroid inhalation

Introduction

Asthma is a heterogeneous disease characterized by chronic airway inflammation ¹. To this day, asthma is still a problem in both developing and developed countries. Symptoms of asthma vary from the lightest, which do not disrupt activities, to the more permanent one that disrupt activities, including daily activities ²³. Approximately 300 million people around the world suffer from asthma. The average prevalence of asthma incidence in the world ranges from 1% to 18%. In Indonesia, according to basic health research data in 2007, the asthma prevalence was 4%. Basic health research data in 2013 showed that the prevalence of asthma at all ages was 4.5%. The highest prevalence was in Central Sulawesi (6.9%), followed by East Nusa Tenggara (7.3%) and Yogyakarta (6.9%). Asthma is included in the top ten causes of morbidity and mortality in Indonesia. The household health survey (SKRT) in 1986 showed that asthma is ranked fifth out of 10 causes of morbidity along with chronic bronchitis and emphysema ⁴.
Chronic inflammation in asthma leads to an imbalance of the pulmonary antioxidant system. This increases free radicals that will impact the hyperspecific and obstruction of the airway resulting in complaints triggering the formation of oxidant enzymes Nicotinamide adenine dinucleotide phosphate (NADPH) oxidase, mieloperoksidase, eosinophil peroxidase and NO synthase. ROS is released into the airway by the inflammatory cells that occur in the lungs.

Blood antioxidant levels, especially coenzyme Q10 are low in asthma patients compared to healthy people. This is due to the occurrence of oxygen-free radical processes derived from the lipid membranes in cells that accumulate in the bronchial mucosa. Coenzyme Q10 is a potential antioxidant that protects the body from free radicals and helps the supply of vitamin E (antioxidant and major cell membranes). Coenzyme Q10 plus tocopherol and vitamin C can reduce the need for steroid dose of bronchial asthma patients. This suggests a decrease in the inflammatory process of antioxidant supplementation. International guidelines recommend assessment of an APE or spirometry series to confirm the diagnosis of asthma, but spirometry can not provide clear information about the state or degree of airway inflammation at that time.

Low blood coenzyme levels in bronchial asthma and in individuals receiving long-term oral steroid therapy. Oral administration of prednisolone steroid for a long periods can cause mitochondrial cell damage. Mitochondrial damage can cause an oxidant-antioxidant imbalance. Coenzyme Q10 is a powerful antioxidant in mitochondria. Mitochondrial damage will cause deficiency of coenzyme Q10 causing free radicals and aggravate inflammation. Long-term administration of prednisolone oral steroids can affect mitochondrial damage.

The main therapy of bronchial asthma is anti-inflammatory inhaled steroid. Many people with asthma require inhaled steroid therapy in a long time to be able to control their asthma. Inhaled steroids can affect the systemic if used continuously and in a long time, causing it to affect blood coenzyme Q10 levels. To date, there has been no study examining the correlation between coenzyme Q10 levels and long-term inhaled steroids in patients with bronchial asthma. Therefore, we are interested in conducting this study to examine the correlation between coenzyme Q10 and long-term inhaled steroids in people with bronchial asthma.

**Method**

The subject of this study consisted of patients with bronchial asthma that met the inclusion and exclusion criteria. The inclusion criteria included patients with stable asthma treated in pulmonology and asthma unit/COPD on a regular basis, aged of above 21 and treated with inhaled steroid in a long period of time. The exclusion criteria excluded patients with asthma exacerbations attack, patients with other respiratory disorders (pneumonia, COPD, or other chronic respiratory diseases), patients with systemic disorders (heart disorders, parkinsonism, malignancy, diabetes, hypertension, HIV, dyslipidemia and renal failure), patients consuming certain medication (class of statin, beta blocker, diuretic, glucophage, haloperidol), and patients consuming ubiquinone preparations on a regular basis. Subjects that were willing to be enrolled in this study were asked to fill the informed consent.

This is a cross-sectional observational analytic study conducted at Asthma Unit/COPD of Dr. Soetomo Teaching Hospital Surabaya Indonesia, pulmonology unit of Dr. M. Soewandhie General Hospital Surabaya Indonesia and Universitas Airlangga Hospital Surabaya Indonesia. The amount of subjects was determined by identifying them based on the criteria and identifying their use of inhaled steroid for 30 months or more according to anamnesis, medical records, and the records of medication taken. We obtained 29 subjects.

We conducted this study by collecting the data of the subjects’ characteristics including age, body weight, height, BMI, FEV1 pred, FEV1/FVC pred, ACT score, long-term use of steroids, coenzyme Q10, sex, occupation, controller, reliever, asthma degree, type of asthma. Measurement of serum coenzyme Q10 level using Agilent tool with HPHPLC method.

The data were collected based on data obtained during the study that met the subject criteria. The data obtained were processed manually and were presented in the form of tables and graphs. The data were processed using computer statistics program SPSS version 23.0 (SPSS, Inc., Chicago, IL). Prior to statistical test, shapiro wilk test were performed. If the test result of shapiro wilk was p<0.05 then statistical test of coenzyme Q10 and long-term steroid inhalation was analyzed using spearman rank test (p <0.05). If otherwise, the statistical
The test used was Pearson correlation test.

**Result**

The next subject characteristics were based on the frequency distribution of subject demographic data. The majority of subjects were female (93.10%). Most subjects also used controllers with Symbicort type (62.10%) and reliever with Berotec type (82.80%). The majority of subjects had asthma in the moderate category (93.10%) and most subjects had uncontrolled asthma (41.40%; table 2). Subjects used steroid medications for $44.38 \pm 11.55$ months. The shortest span was 31 months and the longest was 72 months. The mean of coenzyme Q10 profile in the sample was $1.38 \pm 0.54$ mg/L with the lowest value being 0.51 mg/L and the highest 2.53 mg/L (Table 1).

**Correlation between Coenzyme Q10 Long Steroid Inhalation Use Period**

According to the result of Pearson correlation test between coenzyme Q10 with long-term steroid inhalation usage showed $r = -0.037$ and $p = 0.848$, indicating no significant relationship between coenzyme Q10 and long-term steroid inhalation. Pearson correlation test result showed that coenzyme Q10 with long seretide® inhalation usage was $r = 0.380$ and $p = 0.912$ which means that there was no significant relationship between coenzyme Q10 and long seretide® inhalation. Pearson correlation test results showed that coenzyme Q10 with long-term symbicort inhalation usage was $r = -0.194$ and $p = 0.441$, suggesting no significant relationship between coenzyme Q10 and long-term symbicort inhalation.

Figure 1 shows that the data spreads irregularly which means there is no significant relationship between the two variables. However, the results of the Pearson correlation coefficient with minus value and the tendency of the scatter plot image indicate that the longer the use of inhaled steroids increase the tendency of lower coenzyme Q10.

**Discussion**

To this day there is no literature or research that assess coenzyme Q10 on the use of long-term inhaled steroids. Coenzyme Q10 levels are low on the use of long-term oral steroids. The cause of low levels of coenzyme Q10 is mitochondrial damage. The damaged mitochondria can be established definitively through tissue biopsy but are too invasive. The non-invasive way used to assess mitochondrial damage is by measuring the levels of coenzyme Q10 which is a natural antioxidant synthesized in mitochondria $^{11,12}$.

In this study there is no low coenzyme Q10 level and therefore we expected the function and structure of the mitochondria in this study sample are within normal limits. Mitochondrial damage can be caused by various diseases including heart problems, Parkinson’s, malignancy, diabetes, hypertension, HIV, dyslipidemia and kidney failure and patients with those problem have been excluded from this study. We have also excluded drugs that can cause low levels of coenzyme Q10 including beta blockers, diuretics, statins, glipizide and haloperidol and asthma sufferers who consume ubiquinone supplementation have also been excluded. By conducting this study we hope to understand whether or not the use of steroids in the long term can cause low levels of coenzyme Q10 and then to use the knowledge to improve the management of bronchial asthma.

The systemic side-effects that are expected for long-term use of steroid inhalation are not proven. This may be due to the duration of inhaled steroid use that was not long enough. In this study we used a 30-month baseline, following oral prednisolone steroidal studies given for 16, 24, and 30 months $^9$. With the assumption that the longest period was 30 months, the benchmark duration of steroid inhalation in this study is then more than 30 months. Systemic side effects of steroid inhalation use in asthma were related to adrenal gland disorders, osteoporosis and skin thickening. A study discusses high doses of inhaled steroids that may have adverse systemic effects. In this study we use steroid dose in accordance with the recommended GINA based on step-up and step-down therapy theory, causing the systemic side effects to be suppressed $^{12}$. Systemic effects that can cause mitochondrial damage do not occur and therefore the coenzyme Q10 levels are not low.

The use of long-term symbicort® steroids showed the trend of lower coenzyme Q10 when compared to long-term seretide® use. Budesonid turbuhaler deposited in the lungs was 2.2 times larger than the MDI fluticasone and 3.4 times larger than the fluticasone discus. The systemic availability of budesonid turbuhaler was also higher than that of fluticasone discus and MDI $^{13}$. Budesonid turbuhaler that was 4 times larger was deposited in the lung and spread to systemic when compared with fluticasone discus $^{14}$. Coenzyme Q10 is affected by its endogenous production, its use by the body’s cells and the intake of food. Endogenous production is strongly influenced by cell mitochondria. Its use is strongly influenced by oxidative stress levels.
Some food and beverage products containing coenzyme Q10 such as meat (deer, pig’s heart, beef heart, beef liver, pork liver, beef, pork, chicken and egg), dietary fat (repeseed oil, tuna, and grilled frozen fish), cereals (wholemeal bread and wholemeal bread), vegetables (whole grains, cauliflower, nuts, and carrots), fruit (blackcurrant, lingonberry, strawberries, oranges, apples), and some dairy products (yogurt, emental cheese, edam cheese, and milk with 1.5% fat)\textsuperscript{15}.

Bronchial asthma has varying levels of oxidative stress, causing the need for coenzyme Q10 to increase. This can be accomplished from endogenous formation derived from mitochondria and adequate nutritional intake. Endogenous synthesis is more influential on the adequacy of coenzyme Q10 levels compared with exogenous nutrient intake. The normal requirement of coenzyme Q10 is 30-150 mg per day and can increase as the needs increase. When the mitochondria as a coenzyme producer of Q10 is damaged, the coenzyme content of Q10 will be low\textsuperscript{15}. Some levels of coenzyme Q10 are found to be higher than the normal range. Coenzyme Q10 levels may increase with increasing BMI\textsuperscript{48}. This is due to the fat-soluble nature of coenzyme Q10\textsuperscript{11,12}.

**Conclusion**

There was no correlation between coenzyme Q10 and long-term steroid inhalation.

**Ethical Clearance:** This research involves participants in the process using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic regulation. Association between Fear of Falling, Balance and Functional Mobility in the Elderly

Fatmawaty Abasmay1, Nuniek Nugraheni S1, Reni Hendrarati Masduchi1

1Department of Physical and Rehabilitation Medicine, Faculty of Medicine, Universitas Airlangga, Surabaya (60131), Indonesia

Abstract

Background: Falling is the main problem that causes fear of falling in the elderly. Impaired balance is an important factor that causes falling. Falls Efficacy Scale-International (FES-I) is a tool to measure fear of falling, while balance condition can be measured using Biodex Balance System-SD (BBS-SD). Moreover, Timed up and Go Test (TUG) is a tool to measure functional mobility. The research aimed to determine correlation between fear of falling, balance and functional mobility in the elderly.

Methods: The research was conducted in 39 elderly subjects at Outpatient Medical Rehabilitation Clinic of Dr. Soetomo General Hospital, Surabaya, Indonesia, who were measured using FES-I, BBS-SD and TUG.

Results: The FES-I and BBS-SD probability values showed no correlation between fear of falling and balance, with p=0.064 (p>0.05). Moreover, the FES-I and TUG probability values also showed no correlation between fear of falling and functional mobility, with p=0.251 (p>0.05).

Conclusion: There was no correlation between fear of falling, balance and functional mobility in the elderly at Outpatient Medical Rehabilitation Clinic of Dr. Soetomo General Hospital, Surabaya, Indonesia.

Keywords: balance, elderly, fear of falling, functional mobility

Introduction

The aging process is not a disease or a disability condition, even though most elderly suffer from functional decline that is often caused by various chronic diseases that generally accompany the aging process. The aging process is the sum of all changes that occur by the time. These changes become the cause or are strongly related with increased body vulnerability to stimuli from within and outside the body. The real example of this aging process is a gradually limited body function capacity and reduced speed capacity. There are some peculiarities of elderly patients. Those peculiarities include more diseases, unspecified disease symptoms, reduced physiological reserves, drug sensitivity and complex biopsychosocial problems.

Falling is the most common incidence experienced by elderly, and it may result in morbidity and mortality. Falling occurs when a person suddenly loses balance that eventually makes a contact with floor or other surfaces. There are many factors can cause falling in the elderly, one of which is fear of falling. Fear of falling commonly occurs in the elderly, and it correlates with decreased balance, anxiety, depression and falling history. A community-based epidemiology study reported 32-83% incidence rates in the elderly, and 33-46% of the elderly who did not fall were afraid of falling. In the elderly who experienced fear of falling, almost 70% of them avoided activities because of fear of falling. In some cases, elderly people confine themselves at home because of the fear. The activity limitation is actually a risk factor of falling because it can lead to muscle atrophy, decreased condition and balance.

addition, this limitation cause social isolation, decreased functional activity and life quality. This research was conducted to analyze correlation between fear of falling, balance and functional mobility in the elderly. Fear of falling can be measured using Falls Efficacy Scale-International (FES-I) questionnaire. Balance and functional mobility can be measured using Biodex Balance System-SD (BBS-SD) and Timed up and Go Test (TUG) respectively.

**Method**

This research is an observational analytic study using cross sectional study design. The study was conducted in Medical Rehabilitation Unit of Dr. Soetomo General Hospital and Universitas Airlangga Hospital, Surabaya, Indonesia, from January-March 2014. The samples met inclusion criteria (males and females aged 60-89, can walk at least 6 meters without aids and can obey simple commands) and had willingness to participate in the research by signing informed consent. The study protocol was approved by the ethics committees of Dr. Soetomo Teaching Hospital (Surabaya, Indonesia).

There were 39 elderly subjects met inclusion criteria and not included in exclusion criteria. Functional mobility was measured using Timed Up and Go test, followed by a balance test using Biodex Balance System-SD. The data analysis was conducted using SPSS 17.0 software (SPSS, Inc., Chicago, IL). Afterward, the data were analyzed using Spearman’s correlation test since the data were ordinal.

**Result**

Demographic and clinical characteristics were presented in Table 1, with 39 subjects. The average subjects’ age was 67.03±6.32, with the youngest and oldest age were 60 and 80 respectively. There were 18 subjects aged 60-64 (46.15%), 7 subjects aged 65-69 (17.95%), 8 subjects aged 70-74 (20.51%), 4 subjects aged 75-79 (10.26%) and 2 subjects aged 80-84 (5.13%). Moreover, there were 8 male subjects (20.5%) and 31 female subjects (79.5%).

The results of fear of falling assessment using FES-I were less varied. The average FES-I value was 17.62±3.25, with the lowest value of 16 and the highest value of 35. The value ranged from 16 to 64, in which 16 indicated mild fear of falling and 64 showed severe fear of falling when performing 16 activities. The higher the FES-I value, the greater the fear of falling. The FES-I assessment results were shown in Figure 5.1. The study found 34 subjects with FES-I value of 16-19 (87.2%), 4 subjects with FES-I value of 20-27 (10.3%) and 1 subject with FES-I value of 28-64 (2.6%).

The results of balance assessment using Biodex Balance System-SD were varied. The average stability index was 2.36±1.36, with the lowest value of 0.60 and the highest value of 4.90. The higher the stability index, the balance gets worse thus the risk of falling is greater.

The results of functional mobility using TUG test were greatly varied. The average TUG time test was 11.33±2.73, with the lowest value of 7.90 seconds and the highest value of 20.80 seconds. The larger the TUG time, the functional mobility capacity gets worse. The assessment data were presented in Table 2.

The results of statistical test using Spearman’s correlation test showed no correlation between fear of falling, balance and functional mobility, with r=0.300 and p=0.064 (Table 3). Fear of falling did not correlate significantly with TUG, with r=0.188 and p=0.251 (significant correlation if p<0.05; Table 3)

Discussion

The subjects’ average age showed fewer subjects in the age group of elder patients. This finding correlated with average life expectancy in Indonesia (70.7 years), thus the number of elderly in Indonesia decreased with age. The subject distribution showed varied numbers of elderly subjects by age. The ratio of male to female subjects was quite far (1:3), with 8 male subjects (20.5%) and 31 female subjects (79.5%).

Fear of falling was measured using FES-I as it has good psychometric elements and it was utilized to measure fear of falling in some studies. FES-I has been tested for validity after being translated into Greek. The average results of fear of falling assessment using FES-I was 17.62±3.25, with the lowest value of 16 and the highest value of 35. The value ranged from 16 to 64, in which 16 indicated mild fear of falling and 64 showed severe fear of falling when performing 16 activities. The higher the FES-I value, the greater the fear of falling. 34 subjects (87.2%) had mild fear of falling, thus they felt very unlikely to fall when performing 16 activities. There were 4 subjects (10.3%) with moderate fear of falling and 1 subject (2.6%) with severe fear of falling.

The research found a significant correlation between fear of falling and age (p=0.036). This finding was consistent with the previous study which reported that fear of falling commonly occurred in females compared to males, and it usually increased with age.

The results of balance assessment using Biodex Balance System-SD were varied. The average stability index was 2.36±1.36, with the lowest value of 0.60 and the highest value of 4.90. The higher the stability index, the balance gets worse thus the risk of falling is greater. There were 10 subjects (25.64%) having a stability index above normal, thus they had less balance which resulted in a greater risk of falling. Risk of falling in the study was found in 1 out of every 4 subjects, with ratio 1:3. If the subjects represented elderly in general, then the risk of falling in the elderly was quite large.

Functional mobility is a term used to describe balance condition and walking activity in daily life (such as sit, stand, walk, turn around). TUG test is a commonly used balance test to examine functional mobility in the elderly. The results of functional mobility assessment using TUG test were greatly varied. The average TUG time was 11.33±2.73, with the lowest value of 7.90 seconds and the highest value of 20.80 seconds. The larger the TUG time, the functional mobility capacity gets worse. There were 9 subjects (23.08%) having TUG time above normal, thus they had less functional mobility capacity (Figure 5.3). This was resulted from walking pattern changes which was adjusted with balance, including short and slow steps. Various cross sectional studies reported that increasing age affects walking pattern changes, including slow swing and wide base patterns, longer double leg support phase, decreased stride length and torso rotation.

Frank and Patla measured correlation between capability, walking speed and fear of falling in 40 elderly subjects. They found that elderly with fear of falling showed limited capability and confidence in balance. Kalsait et al reported a correlation between fear of falling and physical performance, one of which is balance. The present study found no significant correlation between fear of falling and balance (p=0.064). This finding might be resulted from a relatively small subject distribution with fear of falling (10.3% with moderate fear of falling and 2.6% with severe fear of falling).

The results showed no correlation between fear of falling and balance, as fear of falling is a psychological factor that is associated with falling in the elderly, whereas balance is a complex interaction between sensory/
afferent system (vestibular, visual and proprioceptive) and motor/efferent system (muscles, joints and soft tissues) processed in the brain in response to changes in internal (host) and external (environment) conditions. As a result, response to fear of falling is not necessarily manifested as falling since intrinsic and extrinsic factors will respond to the body to maintain balance in order to avoid falling. Thus, self-efficacy based on psychology for fear of falling is merely one factor affecting balance. In clinical practice, this condition could be used as a precaution when serving elderly. It does not mean that elderly who has no fear of falling has a good balance, thus the risk of falling may remain.

The research found no significant correlation between fear of falling and functional mobility, with p=0.251. Falling risk identification could be performed by examining elderly balance condition when moving from one place/position to another. The study used TUG test to examine functional mobility. Someone needs a good balance to move from place/position to another. As we mentioned earlier, fear of falling is a factor affecting balance, thus there are other factors affecting elderly mobility. It can be concluded that elderly with good self-efficacy does not necessarily have good mobility since age. Meanwhile, conversely, elderly with fear of falling does not necessarily have bad functional mobility as fear of falling could be overcome with good physical condition. In clinical practice, this could become a consideration when serving elderly with fear of falling. From these findings, we could provide educational/psychological support to the elderly that falling could be prevented if one has high confidence and fitness level to avoid falling and fear of falling. It was expected that physical and psychological problems affecting balance that may result in functional mobility could be addressed by performing an exercise activity.

**Conclusion**

This research shows that fear of falling measured with FES-I questionnaire did not correlate with balance measured with Biodex Balance System-SD test. Moreover, fear of falling measured with FES-I questionnaire did not correlate with functional mobility measured with Time Up and Go test.

Relation between the Increase of Alpha Fetoprotein Serum Level and the Size of Hepatocellular Carcinoma in Multi Slice Computed Tomography Examination

Ika Putri Maharani¹, Nifa Koesmarsono¹, Budi Laraswati¹
¹Department of Radiology, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo General Hospital Surabaya 60285, Indonesia

Abstract

Background: Hepatocellular carcinoma can be diagnosed based on the result of Multi Slice Computed Tomography (MSCT) imaging only without histology result confirmation.

Objective: The aim of the study is to find out the relation between the increase of alpha fetoprotein serum level and the size of hepatocellular carcinoma in MSCT examination in Dr. Soetomo Teaching Hospital.

Methodology: This is a retrospective, observational analytic study which uses secondary data. There were 50 samples with hepatocellular carcinoma. The data were collected from the medical records of MSCT subjects and AFP (Alpha-fetoprotein) serum level result. All recorded and analyzed statistically. Results: Of all the 50 samples, 41 are male (82%) and 9 are female (18%). The ages of the samples ranged from 19 to 76 years old with the majority of 51-60 years old in 15 patients (30%). Most distribution of AFP serum level was >400 ng/ml with 29 patients (58%) and tumor size of >5 cm with 49 patients (98%). The analysis using Spearman correlation test shows the correlation value p = 0.418 (p >0.05).

Conclusion: There was no relation is found between the increase of alfa fetoprotein serum level and the size of hepatocellular carcinoma in MSCT examination.

Keywords: Hepatocellular carcinoma, Alfa fetoprotein, Multi Slice-CT, Tumor size.

Introduction

Hepatocellular carcinoma (HCC) is the most common primary malignancy of the heart ¹,². It is ranked fifth in the world following lung cancer, prostate cancer, colorectal cancer, and stomach cancer. It is also ranked as the world’s second biggest cause of death after lung cancer with the death rate of 745,000 per year ³,⁴. HCC is different from the other types of carcinoma since it is able to be diagnosed based on multi slice computed tomography (MSCT) imaging result only without histology result confirmation ⁵–⁷. Abdominal MSCT examination is a radiology examination using X-ray and computer ⁴. In hepatocellular carcinoma patients, abdominal MSCT is conducted in 4 phases: pre-contrast, arterial phase, venous phase, and delayed phase ²,⁹. Non-ionic contrast media is injected intravenously to see the hyper-vascular lesions of hepatocellular carcinoma in arterial phase and rapid wash out in venous phase ²,⁹. Therefore the researchers aimed to find out the relation between the increase of alfa fetoprotein serum level and the size of hepatocellular carcinoma in Dr. Soetomo Hospital Surabaya.

Material and Method

Subject

The subject of this study is all abdominal MSCT patients of radiology installation in diagnostic center building Dr. Soetomo General Hospital Surabaya during January to December 2014 whose hepatocellular carcinoma results has never been treated and already has AFP (Alpha-fetoprotein) serum level.

Method

This research is observational analytical with retrospective study (secondary data from Medical records). This study involved 50 abdominal MSCT patients whose hepatocellular carcinoma results have never been treated and have AFP serum level. The criteria for this study is that all abdominal MSCT patients with hepatocellular carcinoma results who come for the first time and have never undergone therapy and have AFP serum level examination results.

Two variables were used in this study as research variables: alfa fetoprotein serum level and tumor size in MSCT. The data were collected from the medical records of MSCT patients with hepatocellular carcinoma in Radiology Installation, Diagnostic Center Building, Dr. Soetomo General Hospital Surabaya. The data were categorized based on the research criteria and AFP serum level result. All documentation results were gathered for data tabulation and statistical analysis later. Analysis test in this study was conducted using Spearman test. Statistical measurement was done using SPSS software. The authors have obtained ethical clearance permission from Medical Research Ethics Committee of Dr. Soetomo General Hospital.

Result

Research Subjects’ Characteristics

The result of this study showed that there were 50 abdominal MSCT patients (n = 50) with hepatocellular carcinoma results who came from the first time, had never undergone therapy, and had AFP serum level examination results in Radiology Installation of Dr. Soetomo General Hospital Surabaya in the period of January 2014 to December 2014. Of all the 50 patients, 41 were male (82%) and 9 were female (18%), all of them met the criteria, as shown in Table 1.

In this study, the distribution of hepatocellular carcinoma based on AFP level are AFP level of <20 ng/ml with 11 patients (22%), 20-400 ng/ml with 10 patients (20%) and >400 ng/ml with 29 patients (58%). The most distribution is found in tumor size of >5 cm with 49 patients (98%), while tumor size of 3-5 cm has 1 patient (2%). No patient is found with tumor size of <3 cm. From the data, it can be inferred that there is a significant difference between tumor size of <3 cm and >5 cm. The age group of hepatocellular carcinoma patients in this study was ranged between 19-76 years old. The most frequency is found in the age range of 51-60 with 15 patients (30%), followed by the age range of 41-50 with 14 patients (28%) (Table 2).
Hepatocellular carcinoma characteristics based on AFP level was shown in Table 3. AFP level and divided into 3 categories. In this study, the most distributed was found in AFP level category III (>400 ng/ml) with 29 patients (58%), while category II (20-400 ng/ml) had 10 patients (20%) and category I (<20 ng/ml) had 11 patients (22%).

The result of hepatocellular carcinoma distribution data analysis based on tumor size was shown in Table 4. In this study, the most distribution was found in tumor size of >5 cm with 49 patients (98%), followed by tumor size of 3-5 cm with 1 patient (2%). No patient was found with tumor size of <3 cm.

Statistical data analysis using Spearman’s correlation statistic test Spearman Correlation Test shows the correlation value $p = 0.418$ ($p >0.05$) which indicated no relation between the increase of alfa fetoprotein level and the size of hepatocellular carcinoma in MSCT examination.

**Discussion**

In this study, there were 50 hepatocellular carcinoma patients in January to December 2014 who meet the research criteria, with sex-based distribution of 41 males (82%) and 9 females (18%) and the ratio between male and female is 4:1. This is in line with several previous studies mentioning the ratio between male and female of 4:1. In this study, the most age is 51-60, with the age range of 19-76 and the mean age of 49. This finding is in accordance with the previous study.

The number of hepatocellular carcinoma patients in this study with tumor size of <3 cm is much less (none) compared to those of with tumor size of >5 cm. This is probably because the majority of patients who come to Radiology Installation Dr. Soetomo Teaching Hospital Surabaya in the period of January to December 2014 are already in intermediate or advance stage (where the

</table>
tumor size is 3-5 cm or >5 cm) when are diagnosed. Therefore, no patient is found in early stage with small tumor size or <3 cm and there are variations of time range between AFP and MSCT examination result.

In this study, tumor with high AFP might appear small in size, but there is also tumor with low AFP yet has big size. This might due to the variations of hepatocellular carcinoma tumor that do not generate AFP or generate antigen that does not react with antibody used in immunoassay. 

Conclusion

No relation between alfa fetoprotein serum level and the size of hepatocellular carcinoma in MSCT examination, p = 0.418 (p >0.05). From the result of this study which has been statistically analyzed using Spearman’s correlation statistic test (Spearman Correlation Test), the correlation value is p=0.418 (p >0,05) which indicates no relation between the increase of alfa fetoprotein serum level and the size of hepatocellular carcinoma in MSCT test.

Abstract

Gastrointestinal symptoms are relatively common in clinical practice in patients with type II diabetes mellitus. type II DM has been described as possible risk factor for the development of gastroesophageal reflux disease, in this study we aim to detect the prevalence of GRED in symptomatic patients with type II DM , also to see the accuracy of reflex disease questionnaire ( RDQ) in the diagnosis of GERD in patients with type II DM in relation to the esophagogastroduodenoscopy finding and to study the relation of autonomic neuropathy to the prevalence and stages of GERD in diabetic patients .

Methods: A ninety patients with upper gastrointestinal symptoms was divided in to tow groups according to whether had type II DM or not and then each group involved in a two stage process (a ) – a RDQ , ( b ) – OGD. And patients in the DM group underwent another step to detect diabetic neuropathy by a bed side clinical test .

Results: The prevalence of esophagitis in this study was higher in the DM group. RDQ had a statistical significance in detecting esophagitis in the DM group. There is no relation of autonomic neuropathy to the prevalence of GERD in diabetic patients .

Conclusion : The prevalence of GERD was high in patients with type II DM , RDQ is a sensitive tool for the diagnosis of GERD in diabetic patients , Autonomic neuropathy did not increase prevalence of esophagitis in diabetic patients .

Key words: diabetes mellitus ,gastro esophageal reflex disease , RDQ, Esophagogastroduodenoscopy, Esophagitis.

Introduction

The current concept of GERD is “symptoms or complications associated with regurgitation from the stomach and or the duodenum to the esophagus”, It is estimated that 15%-30% of the general population are affected by GERD(1,2)

GERD develops when the esophageal mucosa exposed to gastroduodenal contents for prolonged periods of time, resulting in symptoms and, in a proportion of case , esophagitis(2).

Note that some degree of gastroesophageal reflux is normal, physiologically connected with the mechanism of belching (transient LES relaxation), but esophagitis results from excessive reflux, often accompanied by impaired clearance of the refluxed gastric juice. Restricting reflux to that which is physiologically intended depends on the anatomic and physiologic integrity of the oesphagogastric junction, a complex
sphincter comprised of both the LES and the surrounding crural diaphragm. Three dominant mechanisms of esophagogastric junction incompetence are recognized: (a) transient LES relaxations (a vagovagal reflex in which LES relaxation is elicited by gastric distention), (b) LES pressure decrease, or (c) anatomic distortion of the esophagogastric junction inclusive of hiatus hernia(1,2).

Transient LES relaxations account for at least 90% of reflux in normal subjects or GERD patients without hiatus hernia, in many studies the first two mechanisms and other factors such as abdominal obesity, delayed gastric emptying, disruption of esophageal peristalsis, autonomic neuropathy, metabolic syndrome were thought to be a possible risk factors for the high prevalence of the typical GERD symptoms in patient with DM, but up to present, the pathogenesis of GERD in type II DM patients has not been fully clarified(3,4,5).

Peripheral and autonomic neuropathy especially has become a research hotspot in recent years, however, the impact of the above factors on the presence of GERD symptoms in type II DM patients is still under debate(3,6).

Patients with GERD may present with heartburn and regurgitation which are the major symptoms of GERD, somewhat less common are dysphagia and chest pain and a variety of other features has been described, and depending on this a clinical system of symptom-based diagnosis of GERD was made the so called reflex disease questionnaire RDQ(7).

RDQ comprises 6 questions assessing the frequency of heartburn, substernal chest pain, acid regurgitation, nausea, need for the medication, and trouble getting a good night sleep because of heartburn or regurgitation, per week, as shown in table 1.

### Table 1: GerdQ Questionnaire

<table>

</tbody>
</table>

**NOTE:** Add the point values for each corresponding answer. Total score of 0 to 2 points = 0 percent likelihood of GERD; 3 to 7 points = 50 percent likelihood; 8 to 10 points = 79 percent likelihood; 11 to 18 points = 89 percent likelihood.

Several investigation used to evaluate patients with suspected having GERD of which endoscopy is the initial investigation of choice, it used for the diagnosis and grading of GERD and to exclude other upper gastroduodenal disease that can mimic GERD and to identify complications.

**Aim of the study**

To study the prevalence of GERD in symptomatic patients with type II DM in relation to non DM, also to
see the accuracy of RDQ in the diagnosis of GERD in patients with type II DM in relation to the OGD finding and to study the relation of autonomic neuropathy to the prevalence of GERD in diabetic patients present with upper gastrointestinal symptoms.

**Patients and Method**

This study was conducted in Alsader medical city, in Alnajaf center for gastrointestinal and hepatic diseases in which 122 adult patients referred for upper endoscopy because of upper gastrointestinal symptoms suggestive of GERD between march 2014 and march 2015 participate in this study.

Exclusion criteria were type I DM, esophageal motility disorder other than ineffective esophageal motility, patient with hiatus hernia and patient with a RDQ less than 8.

After performing the exclusion criteria a 90 patients were considered eligible for this study 31 of them were females and 59 were males.

The recruitment patients were divided into two groups according to whether had a type II DM or not, the diagnosis of type II DM based on WHO definition (Defined as fasting blood glucose >= 7 mmol/l or on glucose medication for raised blood glucose or with a history of diagnosis of diabetes.) (8)

the then every group involved in a two stage process 
(a)- Reflux disease questionnaire (RDQ) and patients with at least a minimal score of 8 had been chosen as the (RDQ) likelihood of GERD were as fellow(7):

1- A total score 0 to 2 = 0 percent likelihood
2- A total score 3 to 7 = 50 percent
3- A total score 8 to 11 = 79 percent
4- A total score 12 to 18 =89 percent.

(b)- OGD by the use of Olympus or pentax ED-3490 TK 4.2 HOYA corporation endoscopy system, which used in the diagnosis and staging of esophagitis according to Savery-Miller classification in these patients (9)

(c)- the patients with DM group underwent another step during interview by being underwent a simple clinical test to detect the diabetic autonomic neuropathy( a bedside test for the absence respiration-associated sinus arrhythmia by monitoring the pulse rate by a pulse oximeter while the patient instructed to breathe slowly and deeply at a rate of 6 breaths per minute, heart rate normally increase with inspiration and decrease with expiration, and at a respiratory rate of 6 per minute the difference between fastest and slowest heart rate is usually more than 15 per minute , a difference of 10 beats per minute or less are observed in autonomic dysfunction(10).

**Statistical Analysis**

Statistical analysis were performed using spss 16 program correlation analysis was also performed.

A P value <0.05 was considered significant.

**Results**

Ninety patients were included in this study and divided in to two groups a thirty patients in DM group and sixty patients in the non DM group.

In the non DM group 22 of them were females(36.66%) and 38 were males(63.33%) with a mean age of (46.7years±8.2).

In the DM group 9 were females (30%) and 21 were males (70%) with a mean age of (51.2 years±9.3). As shown in table 2.

<p>| Table-2 the demographic characters of both groups (DM and non DM) |</p>

</tbody>
</table>

The prevalence of esophagitis in this study were higher in the DM group as upper OGD results showed
esophagitis in 32 patients of the non DM group (53.3%) and in 23 patients of the DM group (76.66%) with a statistical significant results (p value=0.03236) as shown in table 3.

Table 3 (the prevalence of esophagitis by OGD in both study groups)

<td>23 of 30</td>
<td>0.00244*</td>
<td></td>
</tr>
</tbody>
</table>

In the DM group the clinical bedside test for autonomic neuropathy revile an autonomic dysfunction in 16 patients of 30 (53.33%) and 14 patients show not (46.6%).

13 (81.2%) of the 16 patients with DM and autonomic dysfunction were diagnosed with esophagitis by OGD and 3 patients show no sign of esophagitis by OGD(18.7%), while in patients with DM and without autonomic dysfunction there were 10 patients of 14 (71.4%) diagnosed with osephagitis by OGD and 4 patients (28.5%) are not, so there were no statistical significance P value=0.5287 as shown in table 5.

Discussion

Diabetes is a major health problem, as it is an important contributor to various other disease and its incidence still continues to rise. Gastrointestinal symptoms are relatively common in clinical practice in patients with type II DM. Type II DM has been described as possible risk factor for the development of GERD. Several studies reported that the prevalence of GERD symptoms in the type II DM was approximately 25%-40% in different populations (11,12,13), in these studies several methods used in the diagnosis of GERD includes; RDQ which had a sensitivity of 79% in the diagnosis of GERD at 8-11 score level in non DM patients, Endoscopic examination which had high
specificity but low sensitivity for the diagnosis of GERD with a sensitivity about 55% for detecting esophagitis and other complications\textsuperscript{(14,15)} and ambulatory PH monitoring which is indicated if diagnosis is unclear or surgical intervention is under considering. Although the test yields accurate and reliable information it is inconvenient for the patient and many clinicians do not have access to the appropriate instrumentation and are unable to perform this test\textsuperscript{(16)}.

In this study a combination of RDQ and OGD is used to study the prevalence of GERD in patients with type II DM as a previous study by Lemeneh Tefera, B.A., Martin Fein. \textsuperscript{(16)} shows that this combination had a high proof value 98% and high specificity 97% for the diagnosis of GERD in non DM patients, in this study we found that the prevalence of GERD in adult symptomatic patient with type II DM as diagnosed by OGD were high 76.7% comparing to non DM patients 53.3% with a P value =0.03236.

We also found that the RDQ at level score >8 had a good prediction rate for esophagitis which about 80% in symptomatic patient with type II DM as the OGD result showed esophagitis in 76.66% in patients with type II DM comparing to non DM patients in regard to the sensitivity of RDQ with a P value=0.00244. and this was constant with a study by Yu Bai, Yiqi Du, Duowu Zou, Zhendong Jin and others, that suggest that the RDQ may be used for the diagnosis of GERD\textsuperscript{(17)}.

In previous studies neuropathy were thought of as possible risk factor for the prevalence of the typical GERD symptoms in DM patients (13,20), for example, in 2008, Wang et al. \textsuperscript{(13)} reported that the prevalence of GERD symptoms was higher in patients with neuropathy than in patients without neuropathy, in this study there were no significant difference in the prevalence of esophagitis in DM patients with or without neuropathy with a P value=0.05287, this results are similar to the studies of Clouse and Lustman \textsuperscript{(21)} and Lee et al. \textsuperscript{(19)}.

In 1989, Clouse and Lustman, through analyzing 114 diabetic subjects with gastrointestinal motor dysfunction symptoms, reported that gastrointestinal symptoms occurring in diabetic patients were poorly related to neuropathic complications. In 2011, Lee et al. \textsuperscript{(19)} studied 119 patients with type II DM and found that there was no significant difference in the proportions of patients experiencing typical GERD symptoms between the two groups of type II DM with and without neuropathy.

**Conclusion**

The prevalence of GERD were high in patients with type II DM, RDQ is a sensitive tool for the diagnosis of GERD in those patients, Autonomic neuropathy did not increase prevalence of esophagitis in diabetic patients.

**Conflicts of Interest**: None of the authors have any conflicts of interest relevant to this research subject.

Association between Dose and Duration of Cisplatin Exposure with Sitotoksity Effect on Nasopharyngeal Carcinoma Stem Cell

Widodo Ario Kentjono¹, Lakshmi Kusuma Wardhani¹, Achmad C Romdhoni¹

¹Department of Otorhinolaryngology, Faculty of Medicine, Universitas Airlangga, (60131), Indonesia

Abstract

Background: Nasopharyngeal carcinoma (NPC) is ranked 6th of malignant tumors in Indonesia, while cisplatin is an effective chemotherapy therapy but the side effects and resistance problems are two major constraints limiting its application.

Objective: To analyze the correlation of dose and duration of cisplatin exposure with cytotoxic effects on nasopharyngeal carcinoma stem cells

Methods: A true experimental laboratory in vitro with the factorial design was used in this study. The biopsy NPC tissue was cultured and processed to obtain NPC stem cells to be treated with cisplatin exposure at different doses (0.05, 0.1, 0.2, 0.4, 0.8, 1 and 2 μg) and different durations (24 and 48 hours). The number of dead cells after exposure will be calculated using a hemocytometer after 24, 48, and 72 hours of NPC stem cells free of cisplatin.

Results: Death stem cell density of NPC was mostly obtained at the exposure of 2 μg/ml cisplatin dose after 24 hours observation was 81.37%, while the smallest death cell density a dose of 0.05 μg/ml after a 72-hour observation was 21.3%. Statistical analysis with multiple regression correlation tests between the density of death cell and cisplatin dose was obtained the coefficient correlation 0.827 and value p = 0.000. The analysis of the correlation between cisplatin exposure duration and death cell was also significant with the correlation coefficient -0.357 and the value p = 0.001. The cutoff point that correlated the dose and death stem cell of NPC by 50% in both 24 and 48 hours of exposure was 1 μg (EC₅₀).

Conclusion: There was a correlation between the increased dose of cisplatin with the cytotoxicity effects on NPC stem cell.

Keywords: Nasopharyngeal carcinoma (NPC), Dose, Duration Of Exposure, Cisplatin, Cytotoxicity

Introduction

The incidence of Nasopharyngeal Carcinoma (NPC) in Indonesia is 6.2/100,000 inhabitants every year. NPC is ranked 6th of malignant tumors in humans after malignant tumors of the cervix, liver, breast, lung, and skin. According to research both national and international, it is reported that most of NPC patients (80%) come in advanced stages III and IV. During the last five decades, NPC handling is mainly in various forms of chemotherapy and radiation therapy. The damage effect caused by chemotherapy is called cytotoxicity, that most chemotherapy drugs work by interfering cell mitosis and primarily targeting cells with high cleavage rates ¹.

Cisplatin is an effective chemotherapy, but side effects and resistance problems are two major constraints limiting its application. The biochemical mechanism of cisplatin cytotoxicity includes the correlation between...
DNA and non-DNA targets which will induce death cell through apoptosis, necrosis or both. The cytotoxicity indicator used is EC50 (effective concentration 50) which is the dose/concentration of certain compounds that needed to produce a cytotoxic effect of 50% death cell in cell culture in vitro. This indicator is often used as a benchmark of eukaryotic cell cytotoxicity in culture 2.

Research that correlated the role of resistant cancer stem cells to cisplatin and the progression of many malignancies were included in ca mammae studies was reported that the presence of tumor cells were expressing the normal tumorigenic stem cell characteristics by 5.9% of the tumor cell population 3. The population of these cells significantly increased to an average of 8.8% in primary transplants that only responded partially to cisplatin, while in secondary tumor transplants, the population increased to 22.8% 4.

In vitro research on the effect of cisplatin on DNA suggests that cisplatin toxicity is affected by dose and time/dose also time-dependent. The previous research mentioned the concentration of certain cisplatin was needed to kill 90% of cancer cells. While the other studies reported that 24-hour cisplatin exposure was significantly much more cytotoxic than the first hour duration of exposure 5. Based on these descriptions, this study was conducted to reveal the cytotoxic effects of cisplatin chemotherapy drugs on NPC stem cells and the dose also duration that affect them. This approach useful for understanding how NPC stem cells process cisplatin exposure and determining the effect of the dose also the duration of cisplatin exposure resulting in cytotoxic effects on NPC stem cells 6.

**Method**

This study is experimental laboratory in vitro with the factorial design. Biopsy specimens from a patient suspected of NPC were taken in sufficient quantities, and some were sent to the Anatomical Pathology Installation Dr. Soetomo Genera hospital in formalin solution. Nasopharyngeal carcinoma stem cell culture divided into two plates 7.

After the culture procedure, stem cells nasopharynx carcinoma confirmed with CD44 + staining that divided into two plates of each containing 24 well. Each well is filled with 100,000 stem cells of nasopharyngeal carcinoma. One plate was incubated for 24 hours and another plate for 48 hours, after 24 hours exposure, NPC stem cells in one plate were cleared of cisplatin and observed at 24, 48, and 72 hours before calculation. The same procedure for 48 hours of cisplatin exposure was performed in a similar method 8. The density of the dying cell from the original mixture will be calculated according to the percentage of total number of dead NPC stem cells divided by total number of NPC stem cells (dead and alive cells) 5.

**Results**

The data shows the number of cells experiencing mortality at 24 hours cisplatin exposure and observation periods at 24, 48 and 72 hours. The number of cells that died after cisplatin administration increased along with increasing the doses (compared with controls). The pattern increase occurs with a little fluctuation were the decrease in the dose of 0.4 μg at 24 and 48 hours of observation then increase again. At 72 hours observation the decrease occurred at a dose of 0.8 μg and then the number of dead cells increased (Table 1).

Death stem cell density of NPC mostly in the 24 hours cisplatin exposure was obtained at 2 μg/ml with the post-observation time after exposure was 81.37%, while the smallest death cell density at 0.05 μg/ml dose calculated after 72 hours observation was 21.3%. The proportion of dead cells was relatively high after post-24 hour observation, while post-observation 48 and 72 hours of the relatively close coincident pattern but not as high as post-24 hour observation.

Table 2 shows a similar pattern to 24-hour cisplatin exposure that is an increase in dose-dependent death cell, there was a slight decrease in the dose of 0.1 μg, then increased again. On a 48-hour observation, death cell was high at a dose of 0.05 μg, dropping at 0.1 μg, then just increasing again at 0.4 μg. On a 72-hour observation, death cell dropped at a dose of 0.1 μg, then increased at a dose of 0.2 μg. Density stem cells of NPC mostly at 48 hours cisplatin exposure was obtained at 2 μg/ml cisplatin dose exposure with a post-observation time at 72 hours after exposure was 51.32%.

Table 2 shows that death cell density after 48 hours of cisplatin exposure tends to increase according to the observation period. The density of death cell at 48 hours of observation was relatively higher than 24 hours, while after 72 hours observation showed the highest density. From statistical analysis with multiple regression correlation tests between the density of death cell
(proportion of dead cells) and cisplatin dose was obtained the correlation coefficient 0.827 and \( p = 0.000 \). Table 1 and 2 show tendency pattern of increased death cell with higher cisplatin doses. Both of these showed that there was a significant correlation between the increased dose of cisplatin and cytotoxicity in NPC stem cells (\( p < 0.05 \)).

Data correlation of cisplatin exposure duration with death cell was obtained coefficient correlation -0.357 and \( p = 0.001 \) indicating that there was the correlation between duration of cisplatin exposure with cytotoxicity profile on NPC stem cells which also significant (\( p <0.05 \)).

Discussion

In a population of tissues or cells, apoptosis and necrosis are two extremes of death cell. Low cisplatin concentrations that correlated with apoptotic death cell and high doses cause the death cell due to necrosis. Apoptosis is a response to cellular stress at the intensity of exposure below the necrotic threshold. High doses of cisplatin resulted in the damage of a number molecules that involved in the supply of cell energy adenosine triphosphate (ATP) 9.

The proteins directly involved or indirectly in the apoptotic process leading to the death of necrotic cells, as evidenced by the appearance of necrotic cell features at exposure to high doses of cisplatin resistant keratinocyte tissue. Exposure to high doses of cisplatin causes the reduction of ATP cell levels resulting in severe ATP depletion. Then, it will cause a rapid metabolic collapse resulting in necrotic death cell. The fewer ATP depletions correlated with lower doses of cisplatin cause apoptosis by the release of mitochondrial cytochrome 10.

Some studies suggest two lag phase in cisplatin cell growth inhibition in accordance with the results of this study that within the first 6 hours, no cisplatin inhibition effect was detected. It was estimated that in that period cisplatin accumulates and reaches the DNA genome to then express its pharmacological activity. After that period there was a rapid decrease in cell viability up to 20 post-exposure hours 11. The second lag phase of static cell/plateau growth occurs at 20-24 hours, which estimated to occur due to inactivation of cisplatin by thiol compound, only by then, there will be a significant decrease in cell viability. At the length of exposure duration up to 48 hours, there was an extensive membrane blockade of platelet function, the proportion of dead cells did not parallel with the drug content of assumption that saturation at the receptor has been achieved 12.

In the 48-hour duration of cisplatin exposure, cell proliferation has lasted for 2-4 generations of cells (assuming doubling the time of NPC cell line time in varies from 10.5 to 28.5 hours). The highest level of cisplatin uptake (passive diffusion) at the early time, that the more death cell at the beginning of the duration exposure with the proliferation of cells have lasted 2 to 4 cells generations within 48 hours, the number of dead cells becomes less than the new living cells resulting from the proliferation that occurs after the cell undergoes recovery 13.

The EC₅₀ indicator was the concentration or dose that required by a drug to achieve the desired effect of 50% in vitro. EC₅₀ for cytotoxicity means at concentrations of 50% cells showing the effect of death cell 14. Measurement of drug concentrations or doses usually follows a rapidly increasing pattern of sigmoid curves in relatively small dose changes. The effective dose point mathematically determined by drawing the corresponding line that was more easily determined by a graph than a complex statistical equation 15.

A number of studies used both EC₅₀ and IC₅₀ indicators with similar results. Another study reported that the cisplatin dose of 0.5 μg in the cell line of NPC CNE1 cellular was damage but the cells still respond actively that characterized by the inhibition of cell growth in the early period of observation but then recovered 16. Kadashiet conducted a study of cisplatin cytotoxicity on several cell culture types using IC₅₀ indicators obtained different values. Different doses that effect cytotoxic effects dissimilar between cell types because the mechanisms of apoptosis induced by cisplatin were unlike, and highly specific in each cell. This difference might also be due to the doubling time difference between cell types, especially in the growth-regulated neoplastic cells 17.

Conclusion

There was the correlation between the dose increased of cisplatin and cytotoxicity in NPC stem cells. Moreover, there was a correlation between the duration of cisplatin exposure and cytotoxicity in NPC stem cells. The effective dose of cisplatin resulting in a cytotoxic effect on NPC stem cells was by 1 μg at 24-hours exposure duration.

Ethical Clearance: This research involves participants in the process using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic regulation. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice.

Conflict of Interest: The authors have not found any conflict of interest related to this research so far.

Abstract

Protein purification has always been one of the most critical and challenging stages of drug-protein production. Streptokinase as the most common, and currently, the most cost-effective fibrinolytic drug is no exception. In this study, the mutated streptokinase producing clone (SK263cyc) to which the histidine tag was added was grown in TY2x medium, and SDS-PAGE assessed protein expression after induction of protein expression. Three different methods did protein purification; in the first one, metal, ion affinity chromatography (IMAC) technique was used. In the second solution, first, by filtration with ammonium sulfate, the purification was carried out, and then by affinity purification, chromatography continued. In the third solution, hydrophobic chromatography was used to purify the streptokinase protein. The purity of ophthalmic purity was 93.2%, and the purity of hydrophobic purity was about 90.4%, whereas the combination of pre-treatment with ammonium sulfate and the purity of the ophthalmic method did not achieve more than 88%. In general, the results of this study show that the IMAC method is more suitable as a final method in the process of streptokinase purification than the other two approaches.

Keywords: Streptokinase, Recombinant protein, Affinity chromatography, Hydrophobic gel purification, Ammonium sulphate

Introduction

When a blood clot forms in the circulatory system, it can cause blood clots, which can cause dangerous complications and, ultimately, death. A healthy balance system prevents clots from forming in a natural circulation system. The mechanism of blood clot formation is one of the most important and complex physiological systems in the body, and streptokinase is the most common and currently the most cost-effective fibrinolytic drug for this purpose. The most important part of designing a suitable “downstream process” for purification of a protein for analysis and treatment purposes is the separation of the desired protein from other available impurities and contaminants using various purification methods. The highest increase in concentration is due to the separation stage of the product, but the quality of the products dramatically increases during the initial purification stage. SK263cys is a mutant protein that contains cysteine amino acid at position 263 instead of glutamic acid and is designed to perform specific pegylation on cysteine amino acid. High purity protein is required for this process. Generally, in industrial processes and most research, the HIC method is used to purify streptokinase. Because this process is costly and low yield. In this study, purification of streptokinase protein was performed by applying and optimizing the IMAC method and combining it with one step pre-purification by ammonium sulfate deposition method. We also tried to purify this protein with the highest purity and higher efficiency.

Materials and Method

Protein Expression

The most commonly used host for the expression of Escherichia coli, the strain of Escherichia coli BL21 Rosetta (DE3), was used to express the mutant streptokinase protein. First, in a 5cc TY2x medium containing kanamycin antibiotic 50 ml / μg, a unique culture was prepared overnight. After 24 hours, after transferring the vertex tube, 100 μl of this medium was
transferred to 50 ml of fresh and warm TY2x medium containing kanamycin antibiotic and stirred at 150 rpm at 37 °C until ambient light absorption at 600 nm (600 OD) (0.4 to 0.6).

To produce protein and induce protein expression in large quantities, 50 µl of stock (M1 IPTG) was added to the culture medium to increase its concentration in 1 mM medium. The medium environment-friendly was returned to the incubator again and incubated for 3–4 h at 150 rpm at 37 °C. After incubation, the OD600 medium was re-recorded.

**Protein Purification**

Cell failure was performed by cell lysis (8 mM urea + 10 mM tris + 100 mM sodium dihydrogen phosphate). To prepare cell extracts from 50 ml TY2x culture medium, the culture medium was pre-divided into two falcons and centrifuged at 5000 rpm for 10 min.

The supernatant was discarded, and the precipitate was kept. To the precipitate was added 5 ml of lubricating buffer. After one to two hours, the crystalline contents of the Falcon were centrifuged at 5000 rpm for 10 minutes, and the supernatant was kept in the freezer after separation. The cell extract obtained was used in three strategies.

1: Hydrophobic Interaction Chromatography

2: Immobilized Metal Affinity Chromatography

The first strategy is the use of affinity chromatography without pre-purification, and the second strategy is the use of ammonium sulfate precipitation as the pre-purification and the affinity chromatography as the final purification. Both of these solutions were compared with the primary approach used in the industry.

Purification by Hydrophobic Interaction Method (HIC)

Gel filtration chromatography was performed using Sephadex-25G gel. By passing column equilibration buffer (20 mM tris, 0.2 mM sodium chloride and 8.5 = pH), the sample was prepared for injection, and then 5 mL of sample was slowly loaded into the column by the sampler.

Purification by Affinity Chromatography

One of the important features of this Purification system is its high capacity for binding to His-tag proteins (5-10 ml / mg) and insensitivity of the system to the precise 3D structure of the protein. For small-scale denaturing purification, after breaking the cell wall and extracting the cell contents, we centrifuge the liquid and load the supernatant after centrifugation on the chromatography column. After complete removal of buffer (pH 8), urea 8 mM + 10 mM tris + 100 mM sodium dihydrogen phosphate (5 ml sample was injected into the column by the sampler). When the sample was completely removed from the column, the washing buffer passed through the column. In the process of this study, pH of the buffer of the washing step was optimized in the range of 6.3 to 5.3 and a suitable pH of 5.7 was obtained. Figure 2b shows the effect of pH regulation on the efficiency of the IMAC method. At this point, proteins that are weakly bonded with nickel or have no bond at all with histidine are removed from the column. If the pH of the buffer used in the washout phase is not adequate, the target protein may also be removed from the column, resulting in a negative effect on the final purification. In the wash step, the buffer is introduced into the column at pH 4.5 to remove the target protein. The column outlet was collected in sterilized microtubes in a volume of 1 ml [4, 10].

2.2.3 Pre-Purification by Ammonium Sulfate Deposition and Purification by Affinity Chromatography: After preparation of the cell extract, the product was prepared with a pre-purification step by ammonium sulfate precipitation to enter the IMAC column. The amount of protein in the samples from each step of the process was determined by electrophoresis. Figure 5 illustrates these results. Table 3 also relates to the results of the gel analysis by software.

**Protein measurement**

**Method: SDS-PAGE**

To confirm the presence of the protein and to evaluate its value, the samples obtained from each step of the studied strategies were used by PAGE-SDS electrophoresis [7].

**Optical Method for Calculating Total Protein:**

OD of each sample was measured using a spectrophotometer at 280 nm. The mean ODs were obtained and multiplied by the dilution and extinction coefficient of 0.925 for streptokinase, and the total protein content of the sample was obtained [9].
Calculate the process efficiency for the target protein and its purity

The gel electrophoresis image of each process was analyzed by Lab Image software, and the percentage of protein purity was determined at each step; the purification efficiency is then calculated using the degree of purity.

degree of purity = Total Streptokinase / Total Protein Concentration * 100

Yield = Purified Protein Concentration * Degree of purity / total protein concentration

Results

The results of electrophoresis showed that the protein was produced properly (Fig. 2). In the HIC purification strategy, the urea in the protein solution was first removed (Fig. 1A), and then the isolated proteins were isolated from streptokinase by HIC using S-650 butyl gel (Fig. 1B).

In vitro analysis of purified samples showed that all three purification strategies performed well. After optimizing the pH of the wash buffer, the amount of protein produced by IMAC at a concentration of 1.71 mg / ml was higher than the other two methods (Fig. 2B). After careful examination using Lab Image software and determination of purity, it was found that the highest purity was related to IMAC 93% method. The results of electrophoresis showed that the protein was produced at the appropriate level at the beginning of the work.
Measurement of protein concentration by the HIC method showed that the highest amount of protein and the highest yield was obtained by the IMAC method, while the lowest yield was obtained by combined IMAC method and deposition with ammonium sulfate (Fig. 3A and B).

![Graph showing protein concentration and yield](image)

**Conclusion**

The results of this study showed that the IMAC method had better efficiency than HIC in purification of streptokinase with histidine tag. Also during the IMAC process based on the results, it was found that the pH of the wash buffer for the purification of streptokinase protein was 5.7.

Effect of Dietary Energy Density on Increasing Blood Glucose Pattern and Hunger-Satiety Sensation

Ni Luh Putu Ayu Putri Sariningrat\textsuperscript{1}, Purwo Sri Rejeki\textsuperscript{1}, Irfiansyah Irwadi\textsuperscript{1}
\textsuperscript{1}Department of Medical Physiology, Faculty of Medicine, Universitas Airlangga (60131), Surabaya, Indonesia

Abstract

\textbf{Background:} There was no data how these food density could effect on glucose and visual analog levels based on hunger-filled scales in Indonesian population.

\textbf{Objective} To determine the effect of food energy density on glucose levels and hunger-satiety sensation.

Material and Methods: Seventeen women 18-22 years of age with BMI> 25, were given low energy density breakfast (n = 9) and high energy density (n = 7). The subjects were fasted for 10 hours, fasting blood glucose levels was measured as well as hunger-satiety sensation with a visual analog scale (VAS), prior to treatment. Breakfast was started at 08.00 a.m chew up to 32 times for 15 minutes. Blood glucose levels and VAS measurement were taken back in 2 hours and 4 hours afterward.

\textbf{Result:} There was a significant differences in glucose levels between 4 hours postpandrial and 2 hours postpandrial (p = 0.031) and also between 4 hours postpandrial and fasting state (p = 0.042) in both groups. Analysis of hunger level VAS (p = 0.02) and satiety level VAS (0.04) at 4 hours postpandrial also differ significantly. Correlation analysis between hunger level VAS and blood glucose was different significantly (p = 0.01) with r = -0.59.

\textbf{Conclusions:} The low energy density foods produce a pattern of increasing blood glucose levels were more stable, thus, more able to suppress the sensation of hunger than high energy density.

\textbf{Keywords:} Energy Density, Blood Glucose Level, VAS, Hunger-Filled Sensation

\section*{Background}

Obesity and overweight increased very sharply, almost 35\% of the world’s adult population has been in this condition. Women are more susceptibility into the condition than in men. The obese population is beginning to stabilize in the United States, and its prevalence continues to increase in some countries in Europe and Asia. Obesity is a core component of the metabolic syndrome and includes the top ten health risk factors by WHO that are associated with chronic disease \textsuperscript{1}.

The causes of obesity are multifactorial, including genetic, environmental, physiological, cultural, political and socioeconomic factors. Pathophysiological, obesity occurs when the balance of energy shifts in a positive direction and closely related to high calorie intake. The phenomenon of food that has high energy density also triggers a large calorice intake. Therapy used in limiting caloric intake during this time using sympathomimetic drugs that increase satiety or inhibition of fat absorption so that the calorice intake will decrease. But on the drug has side effects and can not be used in all conditions of the patient \textsuperscript{2}.

Indonesia has a high of food diversity. For example, the composition of Madura rice, an ethnic food in East Indonesia, has high fiber and low energy density. However, there was no data how these food density could effect on glucose and visual analog levels based on
hunger-filled scales. The aim of this study was analyzing the effect of energy density of food on blood glucose levels and Visual Analog Scale (VAS). Therefore, it can be used for prevention and therapy in handling obesity through the influence intake of calories into the body.

**Material and Method**

The study was conducted with a time series true experimental design under the approval of the Research Ethics Commission of Health Faculty of Universitas Airlangga (No. 284-KEPK). Subjects of the study were 17 people who participated and signed informed consent, BMI >25, women aged 18 to 22 years were given a low energy density breakfast (n = 9) and a high energy density diet (n = 7). Ten hours before breakfast, subjects were not allowed to eat, and measurements of fasting blood glucose and visual analog scale (VAS) were performed before breakfast. Breakfast was done at 08.00 then chewed up to 32 times for 15 minutes. Blood glucose and VAS levels were measured after 2 hours and 4 hours postpandrial.

**Food Energy Density**

Low food energy density is a low-calorie breakfast with a density of <1.6 calories/gram given food in the form of Madura corn rice that consisting of corn rice, pepes fish, fried fish, orem tempe, eggplant sauce, kothok salted fish, vegetable urap and water 200 ml. Madura maize rice used has a mature weight of 320 grams, with food density of 1.4 cal/g, protein 22.18 g (19.47%), fat 16.42 g (32.54%), carbohydrate 56.38g (49.51%), fiber 6.4 g with total energy 455.47 kal.

High energy density food is a low-calorie breakfast with a density >2.1 calories/gram given fast food meals consisting of fries, fried chicken flour, tomato sauce and 200 ml water. This food has a density of 2.2 cal/g, with mature weight of 200 g, protein 13.73 g (12.15%), fat 30.29 g (27.64%), carbohydrate 31.22g (27.64%), fiber 1.8 g with a total energy of 451.81 cal. Data were analyzed for distribution normality by Kolmogorov Smirnov test, mean difference test using independent t-test for normal distribution, and Mann Whitney test for abnormal distributed. Data analysis using SPSS version 16.

**Results**

Seventeen women were enrolled in this study with 18 to 22 year age range, with the distribution that are shown in table 1. Based on IMT, 55.55% of the low energy density group were categorized in BMI 25.0-29.9 whereas 62.5% of high energy density group were categorized in BMI of 30.0-34.9 (table 2).

From figure 2 and 3, it showed that fasting blood glucose levels in low energy density groups are higher than in high energy density groups. The low energy density group obtained a mean of fasting blood glucose by 65.67 ± 13.33 g/dL, 2 hours postpandrial by 81.89 ± 11.11 g/dL, and 4 hours postpandrial by 106.00 ± 56.00 g/dL. Meanwhile, density high energy has mean of fasting blood glucose of 72.00 ± 13.00 g/dL, 2 hours postpandrial of 83.38 ± 10.16 g/dL, and 4 hours postpandrial 96.75 ± 14.38 g/dL.

Figure 1 and 2 showed that low energy density group has higher glucose levels than high energy density group. Even in D2 and DT, there were significant differences between low and high energy density p <0.05, i.e., differences blood glucose levels of postpandrial between 4 hours and 2 hours D2 p = 0.031 and DT p = 0.042.

Visual Analog Scale is used to assess how hungry, satiety or appetite certain foods in a person. In table 3 we can see how the VAS of each question on fasting conditions, 2 hours postpandrial and 4 hours postpandrial. On examination of normality of data distribution got p >0.005 for all data except at third question at 4 hours postpandrial got p = 0.037. To see the average difference was done independent t test got significant difference on VAS number one at 4 hours postpandrial with value p = 0.02. A significant difference was also found in the mean VAS number three 4 hours postpandrial using the Mann Whitney test, value p = 0.037.

On the answer to question VAS number one is to assess how hungry the research subjects and the third question how much satisfied is obtained significant difference is done the correlation test on glucose levels in 4 hours postpandrial. The results can be seen in table 4. Additionally, from table 4 are shown that those who have hungry conditions (VAS1) correlated with blood glucose levels with p = 0.01. The lower the glucose level will be greater (R = -0.59).
Discussion

This study shown that breakfast with low energy density increases low blood glucose levels than high energy density levels at 2 hours postprandial, therefore this glucose levels tends to be maintained even slightly increased at 4 hours postprandial. There were a significant differences in D2 and DT where the mean of the differences in the low energy density group have higher glucose levels than high energy density group. This suggests that there was a stable increase in glucose levels of the low energy density group rather than high energy density. This result was similar to previous research that high-glycemic index diet will decline rapidly in glucose.

Decreased glucose levels in the high energy density group due to increased levels of hyperinsulinemia response by a rapid increase of glucose levels, thus, the decreased in glucose levels was faster than the low energy density group. This activity is known as glucostatic. The differences of corn fiber with fenugreek fiber were able...
to make a significant difference of glucose levels. The research by David stated that these fibers did not affect glucose levels postprandial compared to the control group 10.

The results of this study implied that low-energy food density have more stable and favourable pattern of glucose levels in short and medium-term of energy homeostasis regulation. The energy density of the VAS affects the sensation of hunger and satiety at 4 hours postprandial 11. The energy density does not affect the desire for certain types of food, such as sweet, salty or savory. If this condition was connected to the blood glucose levels, then food density will affect hunger sensation. Low energy density can maintain glucose levels in the blood better to suppress hunger sensation 12.

This result was similar with some previous studies, Sholehah (2019) suggested that high index glycemic carbohydrates make satiety sensation in a short period (within one hour), however low glycemic index levels will keep it moderate at about two or three hours after eating. Meanwhile, it was different from a study by Mathern that stating the provision of fenugreek fiber on the diet will lower calorie intake, increase satiety, and reduce hunger. Even though in both these satiety and hungry sensations have no correlation with postprandial glucose 5.

Hunger and satiety were affected by the glucose levels that circulating in the peripheral and cerebral and the volume strain by the fibers in gastrointestinal tract, although glucose levels have a greater role than fiber strain. It said that the method of giving glucose either orally or intravenously did not affect the sensation of hunger satiety measured by VAS. It seems that satiety is not by the way inlet of glucose into the body, but by blood glucose levels 13.

When an individu has mild hypoglycemia, the limbic-striatal region of the brain will be activated and will create a strong appetite for high-calorie foods. Meanwhile euglikemia was more activate in medial prefrontal cortex that could lead to reduce food stimuli, in the other hands, high levels of glucose will bring out more powerful stimulation 14. Thus, circulating glucose modulates stimulation regulation or barriers to food motivation. Increased of circulating glucose levels in the brain also increase functional connectivity between the hypothalamus, thalamus and striatum as well as decrease the cerebral blood flow thus full sensation will be achieved 15. The result of this was the low energy density food produces a more stable blood glucose levels that lead to decreased hunger sensation than in high energy density food 16.

Low energy density food have a higher fiber composition than high energy density food. Higher fiber in diet could increase the satiety within 1.5 to 2 hours after eating. Increased of satiety sensation is caused by the stimulation of satiety hormone production; peptide YY and glucoagon-like peptide-1. According to Oide et al. (2019), provision of high fermented fiber has a tendency to decrease the appetite. The provision of this fiber did not affect glucose levels, PYY, GLP-1 and ghrelin 17.

Based on the previous studies, the provision of a high glycemic index will increase hunger and reduce satiety in short-term interventions. However, this effect is varied when intervention performed in a long period. Increased blood glucose levels will trigger hyperinsulinemia and suppress ghrelin secretion. This study showed how the role of low and high energy density as an exposure to glucose levels, and hunger-satiety sensations. It has been found that low energy density food could maintain blood glucose levels and used as a way of decreasing caloric intake into the body. Further studies and explanations are needed if the low density food are exposed in the repeated frequency in a long term, thus its role in homeostasis energy will clearer.

**Conclusions**

The low energy density foods produce a pattern of increasing blood glucose levels were more stable, thus, more able to suppress the sensation of hunger than high energy density.

Effect of Phenytoin Usage Duration Against Hs-Crp Levels in Epilepsy Patients

Ratna Wajiayanti1, Kurnia Kusumastuti1
1Departement of Neurology, Faculty of Medicine, Dr Soetomo Teaching Hospital, Universitas Airlangga, Surabaya, 60285 Indonesia

Abstract

Background: Patients with epilepsy have a higher risk of death than the normal population. Epilepsy patients have increased mortality due to cardiovascular disease with standardized mortality ratios ranged between 1.2 and 2.5. The incidence of non-fatal coronary heart disease also increased significantly between 34% and 63%. Atherosclerosis as an inflammatory state has an important biomarker namely hs-CRP. Long-term use of phenytoin will have an effect on hs-CRP. hs-CRP is an atherosclerotic biomarker with a better cardiovascular predictor than blood lipid and homocysteine levels

Methods: This study was conducted in epilepsy patients who fulfill ESR the criteria of inclusion and exclusion in Outpatient Unit of Dr. Soetomo General Hospital from October 2014 to April 2015. Patients were divided into a control group and case group. The control group was patients with hs-CRP levels <1.7 meanwhile, control group was >1.7. Tracking of phenytoin usage duration was performed in both groups.

Results: Thirty-four subjects were enrolled in this study which consisted of 21 males (61.76%) and 13 females (38.23%). The mean age of subjects in the case group was 31.6 ± 12.6 years and control group was 26.5 ± 11.3. Data of phenytoin usage duration and hs-CRP levels were analyzed.

Conclusion: There was no significant difference between hs-CRP levels on phenytoin usage duration of >2 years and <2 years with p = 0.290

Keywords: Phenytoin Usage, Hs-Crp Levels, Epilepsy Patients

Introduction

Patients with epilepsy have a higher risk of death than the normal population. It was found a positive correlation between epilepsy and vascular comorbidity with mortality of 5.3 and morbidity up to 71. This was a reason why this group has a higher risk of death. Epilepsy patients have increased mortality due to cardiovascular disease with standardized mortality ratios (SMRs) between 1.2 and 2.5. The incidence of non-fatal coronary heart disease also increased significantly between 34% and 63%. An increased mortality caused by cardiovascular disease in epilepsy patients They found an increased mortality in patients with epilepsy who used the old type of anti-epilepsy drugs. Studies conducted on epilepsy group treated with phenytoin found intima media thickening of the carotid artery. This was a risk factor for the incidence of cerebrovascular and cardiovascular diseases. This supports the study that atherosclerotic factors were involved in vascular death and morbidity in epilepsy patients.

It was needed to measure the thickening of the media tunica and intima tunica in the carotid artery in order to determine the presence of atherosclerosis. This measurement in epilepsy patients treated with phenytoin showed a strong association with the risk of stroke and myocardial infarction at all ages. There was a significant increase in the thickness of the media tunica and intima tunica in epilepsy patients with phenytoin therapy. Long-term use of phenytoin has altered metabolic...
function thus it increases atherosclerosis in epilepsy patients. He further mentioned that long-term use of phenytoin has been found to increase the thickness of the intima tunica and the media tunica of the carotid artery. Atherosclerosis as an inflammatory state has an important biomarker namely hs-CRP. hs-CRP increased in patients with epilepsy phenytoin. There was a conducted study about changes in the use of anti-epilepsy drugs (AEDs). They substituted carbamazepine or phenytoin with non-enzyme-inducing AEDs then they found that hs-CRP levels dropped to > 30%. This results suggested a substantial role of phenytoin to the atherosclerosis process. This process underlies the occurrence of cardiovascular and cerebrovascular disorders thus it is necessary to examine the biomarkers of atherosclerosis in epilepsy patients with phenytoin usage. Atherosclerotic biomarker was better as cardiovascular predictors than blood lipid levels and homocysteine. Professionals from the National Academy of Clinical Biochemistry mentioned that hs-CRP was the most acceptable biomarker and also served as a marker. There has been atherosclerosis that may progress to cardiovascular and cerebrovascular disease. The correlation between phenytoin usage duration and the levels of hs-CRP in the blood remains unclear. Phenytoin has an influence on the immune system by stimulating macrophages to secrete IL-1 and IL-6. IL-1 and IL-6 will stimulate hepatocyte cells to secrete hs-CRP. Therefore, the presence of hs-CRP is a result of phenytoin and the process of atherosclerosis.

Method

This study was an observational analytic using a case-control study design that was performed from June 2014 to April 2015 in the Neurology Outpatient Unit of Dr. Soetomo General Hospital Surabaya. The subjects were all epilepsy patients who received Phenytoin therapy and fulfill ESR the inclusion and exclusion criteria. The sampling technique used was consecutive sampling.

Preliminary data were obtained by performing anamnesis, physical and neurological examination, and confirmation of medical records. All recorded data were collected for data tabulation and statistical analysis. Collected categorical data were analyzed using chi-square test with α = 0.05. Meanwhile, the normality test was performed for numerical with Saphiro Wilk test. Numerical data with normal data distribution (age, BMI, leukocytes, GD2) was analyzed using an unpaired t-test, whereas, numerical data with abnormal data distribution was analyzed using Mann Whitney U test in order to determine differences in both groups.

Results

Subjects Characteristics by Sex

There are two characteristics of subjects, such as male and female. Thirty-four subjects were enroll ESR in this study that consisted of 21 males (61.76%) and 13 females (38.23%). The case group has male subjects by 10 people (58.8%), it was less than in the control group by 11 people (64.7%), meanwhile female subjects in case group was 7 people (47.6%), more than control group that has 6 people (35.3%) (p = 0.724). Different percentage of sex in each group was not statistically significant (p = 0.724)

The number of leukocytes in the case group was 6.781 ± 1.970 years, it was higher than the control group by 7.229 ± 1.53 years. It was found that the data distribution of leukocytes was normal (p = 0.428) in both case and control groups. 2-independent sample T-test was conducted to identify the difference of leukocyte in case and control group and it was found that there was no significant difference with p = 0.460.
Subjects Characteristics Based on Postprandial Blood Sugar (GD 2)

Blood sugar levels 2 hours post-prandial in case group was $96.529 \pm 16.144$, it was slightly higher than control group by $84.564 \pm 12.631$. It was found that the data distribution for blood sugar 2 hours post-prandial was normal with $p = 0.149$ for case group and $p = 0.253$ for the control group. Therefore, 2-independent sample T-test was conducted to identify the difference of blood glucose in case and control group, thus it was found that there was no significant difference between two groups with $p = 0.279$ (Table 2).

Subjects Characteristics Based on Erythrocyte Sedimentation Rate (ESR)

The ESR in the case group was $8.41 \pm 4.89$; it was higher than the control group by $3.76 \pm 2.704$. It was found that the data distribution for ESR was not normal ($p = 0.150$ for case group and $p = 0.02$ for the control group). Mann Whitney U test was performed to identify the difference between LED in case and control groups. There was a significant difference with $p = 0.003$ (Table 4).

Subjects Characteristics Based on Phenytoin Usage Duration

Based on the duration of phenytoin usage, 12 (70.6%) subjects with phenytoin therapy >2 years were found in the case group; it was more than the control group by 9 subjects (52.9%). Subjects with phenytoin therapy <2 years from the case group was 5 subjects (29.4%); it was less than the control group by 8 subjects (47.1%). The differences in case and control groups were not statistically significant with $p = 0.364$ (Table 5).

Effect of Phenytoin Duration >2 years and <2 years against hs-CRP Levels

There were 12 people (70.6%) who used phenytoin for >2 years in the case group, it was higher than in the control group by 9 people (52.9%). Meanwhile, there were 5 people (29.4%) in the case group who used phenytoin for <2 years, it was less than the control group by 8 people (47.1%). This difference was not statistically significant with p = 0.364 (Table 6).

</tbody>
</table>

This suggested that the use of phenytoin for >2 years has no significant relationship to elevated levels of hs-CRP (95% CI, OR = 0.516-8.761). It indicated that the use of phenytoin for >2 years was 2.133 times more frequent to increase hs-CRP compared to the use of phenytoin for <2 years (Table 9).

**Discussion**

We found no significant differences in basic characteristics of subjects. Clinical exclusion data of subjects in the form of ESR, leukocyte, GDI/GD2 were analyzed to eliminate bias against hs-CRP. The subjects were 34 patients that consisted of 21 males (61.76%) and 13 females (38.23%). This result was in accordance with epidemiological data in Indonesia which stated epilepsy occurred more frequently in male than female. The mean age in the case group was 31.06 ± 11.3 years and the control group was 26.53 ± 11.3 years, there was no significant difference in both groups with p = 0.278. This demographic data were compared to a study by Teng-Yeow Tan, Cheng-Hsien Lu et al, which stated the mean age was 36.0 ± 11.3 in the case group and the control group was 36.2 ± 11.2 with p = 0.838. Age range was almost similar because older subjects often had accompanied metabolic disease which became one of the exclusion criteria.

Chi-square test on BMI, the number of leucocytes, GD1, GD2 did not obtain any significant difference between case and control groups. This indicated that
there was no effect of BMI, the number of leukocytes, GD1 and GD2 on hs-CRP levels in this study. In contrast, Teng-Yeow Tan et al. study did not control the BMI variable although Simionescu stated that fasting blood glucose, BMI, systolic blood pressure affected hs-CRP12. Subjects with increased ESR levels above the normal level have been excluded, however, higher ESR levels was obtained in case group that by 8.41 + 4.89 than the control group by 3.76 + 3.12. There was a significant difference (p = 0.003) of ESR levels in case and control group. It was mentioned that increased production of hs-CRP will increase the blood viscosity, thus it was associated with increased levels of ESR.

There were 12 subjects (70.6%) who used phenytoin >2 years in the case group, it was more than in the control group by 9 people (52.9%). Meanwhile, there was 5 subjects (29.4%) in the case group who used phenytoin <2 years, it was less than the control group by 8 subjects (47.1%). The difference was not statistically significant p = 0.290 thus it indicated that the use of phenytoin for >2 years had no significant correlation to the increase in hs-CRP levels.

The function of drugs in the body is influenced by the activity of CYP 450 in the liver. The different levels of CYP 450 affect the activity of drugs in the body. Phenytoin is an inactive metabolite. CYP 1A2A will hydrolyze phenytoin to active hydroxyphenitoin14. CYP 450 has various variants. The emergence of some types of the allele is due to the occurrence of several mutations that occur in the reproductive cells of each individual. The difference of alleles in the individual is caused by the changes in the structure of DNA bases such as the change of one of the DNA bases, the deletion or the rearrangement of DNA in one of its locus of chromosome15.

One variant of the CYP 450 is CYP 1A2A. CYP 1A2A is manufactured in the heart and is induced by some drugs such as oral contraceptives, coffee and cigarettes. That activity requires higher doses of phenytoin in smokers and female who use oral contraceptives. It was found that there were different types of phenotypes in each race. There was low CYP 1A2A activity <5% in Asian and African compared to CYP 1A2A activity in Caucasian. A Higher dose is required for phenytoin in Caucasian than in Asian16.

Cholesterol synthesis is influenced by CYP 51 A1 gene. A Higher dose of phenytoin leads to greater induction of the CYP 51 A1 gene, thus cholesterol production is also increased. This mechanism contributes to the onset of atherosclerosis.

**Conclusion**

There was no difference between hs-CRP levels in epilepsy patients who used phenytoin for >2 years and phenytoin for less than 2 years in Dr. Soetomo General Hospital Surabaya.

Abstract

Background: Stroke is a cause of disability and dependency in both humanity and economic. Studies on the association of Matrix metallopeptidase 9 (MMP-9) levels with improved clinical severity are currently limited.

Objectives: To determine the improvement of clinical severity in acute thrombotic stroke patients with high and low MMP-9 levels.

Methods: Patients acute thrombotic stroke were grouped into low and high MMP-9 levels. MMP-9 levels were considered low when <840 ng/mL and high when ≥840 ng/mL. Clinical severity improvement was assessed using the ΔNIHSS scale.

Results: Eighty subjects were enrolled that consists of clinical severity improved patients with lower MMP-9 (37.9%) that higher than high MMP-9 (21.6%). This difference was not statistically significant (p = 0.115).

Conclusion: There was no difference in clinical severity improvement in patients with acute thrombotic stroke with low MMP-9 levels in blood serum compared to high MMP-9 levels.

Keywords: Acute thrombotic stroke, MMP-9, NIHSS Level

Introduction

Stroke is the main cause of death and disabilities in Indonesia and the world. Stroke has enormous clinical, social, and economic implications and demands a significant effort. The average mortality in 30 days for stroke is about 7.6%. There are currently four million people in the United States living with physical limitations due to stroke and about 15-30% of them suffer from the permanent disability. In 1990 the death rate caused by the stroke was 4.5 million worldwide.

Elderly with hypertension have a greater risk for ischemic stroke. The number of stroke patients will increase every year, it is estimated that the number of stroke patients will increase to 7.7 million by 2020. Todays, strokes not only affect the elderly population but also young adults and productive. Stroke could cause disability and dependency in both human and economic, impaired cognition and death function. Stroke survivors who could survive up to 30 days after the attack were about 20% and it requires further treatment. The cost of stroke treatment during acute phase treatment to long-term care in the United States is approximately US $ 51.2 billion every year. Several studies have demonstrated an inflammatory process that involved in the pathogenesis of stroke. Brain blood flow that stops could cause death in nerve cells that trigger an immune response that causes inflammation, cell activation, and infiltration.

Once activated, inflammatory cells release various cytotoxic agents including the Metalloproteinase Matrix (MMP) which, if in the active state it could cause further cell damage and disturbances in the blood-brain barrier. Among some MMP, MMP-9 has a more dominant role in stroke.

MMP levels in circulating plasma could be used as a marker of stroke in predicting bleeding in embolic stroke, predicting clinical outcomes and the magnitude of infarct volume. The elevated MMP-9 levels after the occurrence of brain ischemia in the plasma were positively correlated with the severity of stroke as measured by the National Institutes of Health Stroke Scale (NIHSS) scores. However, until now there has been no study in Indonesia that observed the correlation between the magnitude of clinical severity improvement with low and high MMP-9 levels in patients with acute thrombotic stroke. Then, if this study proves the existence of such linkage, then the MMP-9 examination could be used as an alternative examination that helps explain the prognosis of healing stroke thrombotic acute in patients.

**Method**

An observational analytic study using case-control design was used, which was implemented in January to August 2015 in Seruni room, in Emergency Unit, Seruni A, Seruni B of Dr. Soetomo General Hospital Surabaya. The samples used in this study were those with acute thrombotic stroke as well as meeting the inclusion and exclusion criteria. Sampling technique used was consecutive sampling.

The inclusion criteria were: Patients with acute thrombotic stroke with onset of attack between 24 to 72 hours, age over 18 years, willing to participated the research (signed informed consent). Patients with acute thrombotic stroke who have sepsis, liver disorder or renal failure were exclude from study. The independent variables were MMP-9 in serum and the dependent variables were Clinical severity measured by NIHSS, while confounding variables were Smoking, hyperglycemia and hypertension.

This study used venous blood research material from patients with acute thrombotic stroke that needed to determine the MMP-9 level in serum. The research started by taking data of all subjects included in the inclusion and exclusion criteria and the responsible family of the patient (spouse, child, parent, close relative or another family part) briefed on the purpose, usefulness, and risk of the study, then the subject was requested to follow the research without coercion.

Preliminary data were obtained by taking anamnesis, physical examination and neurology, examination of MMP-9 level in *prodia* laboratory Surabaya, examination of clinical severity degree were assessed twice, at the same time with blood taking for MMP-9 (onset 24 to 72 hours) examination and at day 5 onset by using the NIHSS method. All recording results are collected for further data tabulation and statistical analysis then, the collected categorical data were analyzed by using odd ratio test. This research have been proposed of ethical clearance in the Research Ethics Committee of Dr. Soetomo General Hospital.

**Results**

**Basic data**

The means age in the group with the improvement of clinical severity was 51.23 ± 10.708 years and with no improvement was 57.02 ± 10.838 years. The mean age difference in both groups was not statistically significant with p = 0.35 (Table 1).

In the group with clinical severity correlation, the male subject was 10 (24.4%), it smaller than the female gender subject by 12 (30.8%). This difference was not statistically significant with p = 0.523 (Table 1).

Improvement of the severity in subjects group with normotension was 9 (64.3%), it bigger in a group of subjects with hypertension by 13 (19.7%). This was statistically differented with p = 0.001 (Table 1).

Improvement of clinical severity in group of subjects with normoglycemia was obtained by 14 (32.6%) subject, it higher than in the subjects group with hyperglycemia by 8 (21.6%). This difference was not statistically significant with p = 0.275 (Table 1).

The improvement of clinical severity in the non-smoking subjects group was 17 (29.8%), it higher than in the subjects who smoked as 5 (21.7%) was found. The differences in both groups were not statistically significant with p = 0.464 (Table 2).

The improvement of clinical severity in the subjects group with low MMP-9 levels was 11 (37.9%) subject,
it higher than in the subjects group with high MMP-9 levels by 11 (21.6%). The differences in both groups were not statistically significant with \( p = 0.115 \). It also obtained the odds ratio by 2.222 (CI 95% 0.814-6.064) with the \( \beta \) error was 38% (Table 3).

Discussion

The mean age in the group with the improvement of clinical severity was 51.23 ± 10.708 years and in the group of no improvement was 57.02 ± 10.838 years. In accordance with literature that the highest incidence of ischemic stroke was at the age of 20-54 years and tended to decrease in the older age group. The incidence of stroke every 10,000 population increased from 22% (age group 45-55 years) to 32% (age group 55-64 years) and 83% (age group 65-74 years). The difference between each group was not significant (p = 0.35).

The sex ratio of the men subjects was 41, it higher than women by 39. It was in accordance with epidemiological studies that men have a higher risk of stroke than women, especially in the age group less than 65 years. Murphy et al also revealed that the incidence of stroke in men was 1.25 times higher than for women. Several studies have also reported that men were more likely to suffer a stroke caused by a disruption of large or small blood vessels. In this study, there was no difference in sex proportion between the two groups (p = 0.523).

Hypertension is a major risk factor for stroke and an increase in blood pressure often occurs in acute stroke. 50% of thrombotic stroke patients have hypertensive risk factors. The response of acute hypertension is an increase in blood pressure above normal and usually occurs within the first 24 hours in stroke patients. Increased blood pressure reaches 75-80% in acute stroke patients and will decrease spontaneously within a few days. Increased blood pressure in the acute phase of thrombotic stroke will provide severe output. Studies conducted on experimental animals with acute thrombotic stroke showed that autoregulation of cerebral blood flow in the penumbral area was impaired. Increased blood pressure is a natural response to increased perfusion and collateral blood flow in the penumbra to prevent ischemic damage.

Based on the analysis of clinical data obtained a significant result (p = 0.001). This was in accordance with research conducted by Kvistad CE et al. that there was a correlation between increased blood pressure and stroke severity when the patient was admitted to the hospital. A study conducted by Ishitsuka K et al., against 1874 patients with acute thrombotic stroke performed blood pressure measurement in 24 hours onset of stroke, it has resulted in a correlation between hypertension with poor outcome and hypertension with the minor improvement of clinical severity.

IST (International Stroke Trial) conducted by Leonardi et al. performed randomly in 17,398 patients with thrombotic stroke that showed a correlation between systolic blood pressure at the onset of acute stroke with death and disability in U-shaped (U-shape relationship) American Diabetes Association and Clinical Endocrinological Consensus The American correlation define hyperglycemia in patients undergoing hospitalization as hyperglycemia stress in which blood glucose levels> 140 mg/dL without the prior history of diabetes. Patients with hyperglycemia stress were often found in acute thrombotic stroke because in the acute phase there was the release of cortisol and norepinephrine which will manifest the decrease in insulin. Stress hyperglycemia might improve if the acute phase of a stroke was passed and 60% of hyperglycemia sufferers might become diabetic within a year.

When comparing between normoglycemia and the improvement of clinical severity in this study, the results were not significant (p = 0.275). Not much research data suggests that lowering blood sugar levels could improve the outcome. The largest study was a decrease in blood glucose levels with potassium-glucose-infusion infusion compared to standard saline infusion that showed no improvement in output and decreased mortality in patients.

Based on cohort studies conducted by Ueshima H et al, there were several things that could increase the risk of stroke and the occurrence of intracranial also extracranial atherosclerosis, including the number of cigarettes smoked in one-day, how long a person smokes (in years) and current smoking conditions. In this study, when comparing the non-smoking history and clinical severity improvement (ΔNIHSS), the results were not significant (0.464). This was in accordance with research conducted by Altafi D et al. that compared clinical outcomes (NIHSS) of thrombotic stroke smokers and non-smoking thrombotic stroke patients who resulted in a lack of correlation between thrombotic and non-smoking thrombotic stroke patients with clinical outcomes.
MMP-9 is a zinc-dependent proteolytic enzyme that significantly increases its cadmium in patients with thrombotic stroke (Castellanos M, et al., 2003). Based on a study conducted by Lisovaya OA it was found that elevated MMP-9 levels were not only correlated with an increase in cardiovascular incidence but were also associated with long-term vascular remodeling phenomena (Lisovaya OA, 2014).

The final result showed that the improvement of clinical severity in subjects with low MMP-9 level was 37.9% higher than in the subjects group with the high MMP-9 level by 21.6%. The differences in both groups were not statistically significant with \( p = 0.115 \) and the odds ratio value was 2.222 (CI 95% 0.814-6.064). This was not in accordance with the proposed research hypothesis. Inappropriateness with the proposed research hypothesis could be due to several things.

First, this study did not consider the infarct volume into the subject. Montaner J et al., Conducted a study of 39 thrombotic stroke patients evaluated at onset of stroke, 12, 24, and 48 hours of onset, and found that MMP-9 values had a positive correlation with NIHSS and infarct volume also revealed that MMP-9 was a strong predictor in predicting infarct volume \(^9\). Ning et al., Through a study conducted on 52 thrombotic stroke patients, explained that MMP-9 has a correlation with infarct volume and clinical severity \(^{21}\).

Second, in this study did not distinguish the location of the infarction that could affect the output of stroke in the study subjects. Montaner et al., Explains that there was a correlation between MMP-9 and the location of the infarct \(^9\), it was similar to a study conducted by Lucivero et al., In 29 thrombotic stroke patients, explained that high MMP-9 levels had a correlation with partial anterior cerebral infarct compared to cerebral infarct lacunar \(^{22}\).

Third, MMP-9 might be affected by the stiffness of arterial blood vessels. Arterial vascular stiffness could have an effect on hemodynamic disorders that trigger blood vessel remodeling and increase cardiovascular risk. Yasmin et al., Conducted a study of 116 patients with hypertension by measuring pulse wave velocity (PWV) in the aorta and brachial also measured MMP-9 levels and serum elastase activity (SEA) levels. From a study by Yasmin et al., Stated that arterial vascular stiffness was significantly correlated with MMP-9 levels (Yasmin et al., 2005).

**Conclusion**

There was no difference in clinical severity correlation in patients with acute thrombotic stroke with low MMP-9 levels in blood serum compared to the patients with acute thrombotic stroke with high MMP-9 levels in blood serum.

The Effect of Model Intervention Towards the Intention of Early Detection of Cervical Cancer with Via Test

Sondang Sidabutar¹, Santi Martini², Rachmat Hargono³

¹Faculty of Health, Efarina University, Simalungun, Indonesia, ²Department of Epidemiology, Faculty of Public Health, Airlangga University, Surabaya, Indonesia, ³Faculty of Public Health, Airlangga University, Surabaya, Indonesia

Abstract

The purpose of this study was to evaluate the woman of childbearing age decision’s model towards the intention of early detection of cervical cancer with the VIA (visual inspection with acetic acid) test. The design was quasi-experimental. The population of women of childbearing age and sample size was 70. Technique: Paired samples statistics. Statistical analysis using the Wilcoxon test with a probability of 0.05. The difference in the value of the pre and post test were seen from the difference in the mean value between the pre and post test. In the treatment group, the difference test results were significant between the pre and post test, the value of p = 0.000. In Control group, the results of the difference test were not significant between the pre and post test, the value of p > 0.05. The Decision Model was a new finding of research where have the highest level of situation awareness on the situation, events and dynamics of its health condition. The decision model showed that with a high level of awareness, the women decided to make early detection of cervical cancer supported by high self efficacy and intention.

Keywords: Model, Intervention, Early Detection of Cervical Cancer

Introduction

Deaths from cervical cancer are projected to increase by almost 25% over the next 10 years. Based on the Globocan estimate, the 2012 International Agency for Research on Cancer (IARC), the incidence of cancer in Indonesia 134 per 100,000 people with the highest incidence in women was breast cancer by 40 per 100,000 followed by cervical cancer 17 per 100,000 and colorectal cancer 10 per 100,000 women(1).

WHO mentioned four important components that became pillars in the treatment of cervical cancer, namely: prevention of HPV infection, early detection through increased alertness and organized early detection programs, diagnosis and treatment, and palliative care for advanced cases. Early detection of cervical cancer includes an organized screening program targeting women of childbearing age groups, the establishment of an effective referral system at each level of health services, and education for health workers and women of productive age. Pre-cancerous lesion screening and treatment requires a lower cost compared to treatment and management of cervical cancer.

The target of early detection of cervical cancer was 50% of women until 2019, early detection programs in Indonesia were prioritized for women aged 30-50 years. The fact was that the coverage of the results of activities from 2007 to 2014, namely the achievement of early detection of cervical cancer screening was 2.45%(1).

In 2030 there will be a surge in cancer patients in Indonesia up to seven times(2). The number of cancer patients who died also became increasingly alarming. The number of cervical cancer cases in Indonesia is getting worse because more than 80% of cases that come to the hospital are at an advanced stage.

By the complex problem, the idea arose to screen cervical cancer with a simple method, namely VIA.

In dr. Pirngadi Medan Hospital, In 2007 there were 345 cases, in 2008 there were 25 cases, in 2009 were 48 cases and in 2010 were 40 cases. The high rate of cervical cancer patients in Indonesia was caused by this disease did not cause symptoms and low awareness of women to check their health(1). If more women were accustomed to doing early detection, and the disease has
spread to someone, it can be dealt with more quickly(3).

Behavior factors which include predisposing factors, supporting factors and driving factors. Other factors that affect the efforts of early detection of cervical cancer are individual factors that influence the woman to detect early cervical cancer, namely SA (situation awareness). SA was a continuous process that involves assessing events in the environment so as to give meaning to information to help decision. Comprehension of cervical cancer hazards and the purpose of screening, assisted in making decision about screening, was an important factor in whether respondents made choices regarding information about screening(5). Determinants influence intention on the behavior of early detection of cervical cancer was significant, one of which was perception of the national cancer screening program as well as perceptions about the risk of cervix cancer(6).

There was an effect of attitude on intention to do early detection of cervical cancer(7). The implementation of the VIA program mentioned based on the recapitulation of VIA examinations in Pematangsiantar, which showed the percentage of woman participating in the 2015 - 2016 VIA test and was not seen achieving the VIA test target for each puskesmas. By the national percentage that has attended the VIA test was still far below the effective screening coverage of 50%, even far below the target coverage of Pematangsiantar Health Department’s screening coverage of 20% per year.

Self-efficacy was an individual’s belief about his ability to organize and complete a task, mastering the situation needed to achieve certain results. Some dimensions of self-efficacy), namely magnitude, generality, and strength(8). The addition of self-efficacy increases the predictability of the TPB. Self-efficacy was the strongest predictor of intention(9).

This study, wanted to expand the research by integrating the framework of TPB. Ajzen (1991) with Theory Situation Awareness (Endsley, 1988), and Social Cognitive Theory explains that the TPB model was very open to add another predictor variable to predict intention and behavior about the object under study(10-11). This study will examine the decision model of women to perform early detection of cervical cancer with the VIA test.

Material and Method

The study design was quasi-experimental. The population of women of childbearing age and sample size was 70. Research variables were: perceptions, comprehension, attitude, subjective norms, projection, self-efficacy, intention and decision making intention to perform VIA within such specific period.

The data of the study consists of primary and secondary data. The primary data had obtained from interviews with spreading questionnaires. The obtained data through interview consists the data of projection, self-efficacy, intention, toward decision to perform VIA. Before, the instruments were used to measure each variable, then the necessary act would include performing an instrument test, which had performed validity test and questionnaire reliability.

Statistical analysis using the Wilcoxon test with a probability of 0.05. To analyze the difference in mean and standard deviation before and after treatment in each intervention and control group, a statistical analysis was performed using the Wilcoxon test with a probability of 0.05

Result

The intervention activities in the following research were compiled based on the model formed by providing Health Education through training to women of childbearing age to improve the women ‘decision to do early detection of cervical cancer with the VIA test. The number of samples obtained 35 utsamples in the treatment group and 35 samples in the control group, so that 70 respondents were obtained.

To analyze the difference in mean and standard deviation before and after treatment in each intervention and control group, a statistical analysis was performed using the Wilcoxon test with a probability of 0.05. The results of the analysis could be seen in the following table.

In table 3, it showed that the Mann Whitney test results in the post control group and post treatment group, there were differences in mean rank values in the post control and post treatment. The difference in the value of the post control and treatment was seen from the difference in mean rank values, there was an increase in the mean value of the treatment post rank. The difference in problem recognition indicators in the control group with the treatment group obtained \( p = 0.016 \) (\( p < 0.05 \)), the difference in information search indicators in the control group with the treatment group obtained a value of \( p = 0.000 \) (\( p < 0.05 \)), different alternative evaluation indicators in the control group with the treatment group obtained \( p = 0.000 \) (\( p < 0.05 \)), the difference in indicators of early detection in the control group with the treatment group obtained \( p = 0.000 \) (\( p < 0.05 \)), differences in behavioral indicators after deciding in the control group with the treatment group obtained \( p = 0.000 \) (\( p < 0.05 \)).

Based on the results of the analysis in the table above, it can be concluded that the intervention model found can improve the decision of women to do early detection of cervical cancer with the VIA test.

The results of this study also found that from 35 women in the intervention group, after observing that in the second week after intervention, there were 20 women who decided to have early detection of cervical cancer with a VIA test and at the third week there were 10 people who decided to do early detection cervical cancer with VIA test. In the control group, after observation there were 5 women who decided to detect cervical cancer early with the VIA test.

Discussion

Based on the analysis of differences in decision of the women to do early detection of cervical cancer with VIA test between groups given intervention and groups not in the decision model intervention using non-
parametric test, and for Post test using the Wilcoxon test and for the Control vs test. The Mann Whitney Test treatment with the SPSS 22 program showed that the mean increase in the group given the intervention was greater than the control group. In the hypothesis test there were differences in the decisions of women between the groups given the intervention and the control group obtained significant values. Thus there was a change in the decision of women to do early detection of cervical cancer with an VIA test between the intervention group and the control group in Pematangsiantar.

The population in this study was less aware of cervical cancer. The increasing incidence of cancer and death, which was very alarming, caused by a lack of awareness of early detection of cervical cancer(12). The increase in cancer cases was more prevalent in developing countries than in developed countries(13) because cancer was detected most in the late stages in most developing countries, this poses several challenges in care, recovery and survival(14). Screening for early detection of cervical cancer in pematangsiantar was not optimal. This evidence-based information was an advocacy tool for policy making and the development of appropriate interventions. Health workers, especially in Puskesmas, need to improve their outreach services and provide health education to the community and increase timely information dissemination to the public regarding routine early detection of cervical cancer.

The study also showed a significant increase in the intervention group for cervical cancer. Woman of school understood more about each risk for cervical cancer. All participants agreed that women with complaints of public area should immediately check without delay. The preventive approach coupled with timely treatment was the only solution to overcome the burdensome cancer challenges. There was an urgent need to accelerate efforts to communicate accurate information, among different layers of society, about preventable cancers, especially cervical cancer, which was a leading cause of death in women(15).

To stimulate regular early detection among women, there must be aggressive health promotion interventions, designed to raise awareness and to improve the impression of cervical cancer in the community(16). Effective education and mass examinations are needed for successful cervical cancer screening programs in India because the creation of awareness and increased access to screening services was very important to reduce the burden of preventable cancer(17). This was consistent with research which found that women had poor knowledge about cervical cancer screening and lack of awareness of symptoms, risk factors and cervical cancer prevention screening. Importantly, the results of early detection would guide the management of conditions throughout life, including the decision-making process, where the individual would become an important part(15). Interventions to promote culturally sensitive public health programs designed to provide information and services across various age groups, levels of education, culture and social strata must be developed and implemented(18-20).

In conclusion, intervention with the decision model of women of childbearing age was able to change the decision to conduct an examination of early detection of cervical cancer to health services.

The Role of Wide Pore Drain in Successes of Spontaneous Closure of the Cysto-Biliary Fistula after Hydatid Disease of the Liver

Jalil Ibrahim Awaid Alrubaye1; Hussein Ali Abed Ahmad2; Salah Mahdi Tager3

1The Specialty Doctor, MBCHB, FICMS Department of surgery/Al-Zahra Hosp Al-Kut; 2Assist prof. Wassit Medical Collage M. B. Ch. B- F.I.C.M.S ; 3Consultant General Surgeon(MBCHB.CABS)

Abstract

This study to determine the role of wide pore use up in successes of spontaneous closure of cystic-biliary fistula after surgery of liver hydatid disease and decrease the postoperative morbidity. The study was conducted in AL-Zahra teaching hospital from May 2006 until May 2014. On 134 patients undergo surgery operation used for the liver hydatid cyst, complain of drain amount produced reliable with a biliary form and a bilirubin level elevated compared with serum bilirubin level after fifth postoperative day, patients were divided based on the presence of wide pore drain(64 patient) group A or classical drain(70 patient) group B. Sex, age, length of hospital stays, drain output, postoperative intervention relationship between cyst diameter and time for fistula to close spontaneously recurrence, and mortality were compared among both group. In group A, meantime for spontaneous fistula closure was 12.3 days, no recurrence or death reported, while in group B, meantime for spontaneous fistula closure was 17 days. There were three patients(4.3%) recurrence after one year follows up. There was one old female patient (1.4%) died.

Key words: Cysto billiary fistula CBF, Hydatid Cyst HC, Echinococcus Granulosis EG, Echinococcus Multilocularis EM, Wide Pore Drain WPD.

Introduction

Hydatid cyst is one of the oldest known diseases in humans. It was first illustrated in the Talmud as a result of a bladder filled with water and Hippocrates (379 BC) illustrated it as a liver filled with water. Hydatid disease is an epidemic disease in Iraq, and many Mediterranean countries and lead to disasters in health, economic and social. Iraq now is one of the most epidemic areas of this disease. Hydatid cyst is a worldwide infection caused by the larva’s state of parasite.

It belongs to the category of tapeworms named Echinococcus⁴. The areas where sheep and cattle breeding are the most epidemic in the world with parasitic worms especially South Australia, New Zealand, the northern part of Africa and some South American countries, as well human infections occur regularly in the European continent, Siberia, Mongolia, northern China, southern Japan, Vietnam, Philippines, Syria, Lebanon, Iraq, and Saudi Arabia⁵. Hydatid disease is a health, social and economic problem in the countries of the Eastern Sea Region.

The prevalence of infection is common in these areas because dogs are widely used in the care of cattle and sheep and have direct contact with humans, which leads to the continuation of the chain of infection which includes dogs and sheep as well as cattle, camels, goats and other animals (carnivores)⁷. In Iraq, the disease is epidemic and is a serious health problem, especially in the central regions between the Euphrates and the Tigris, these areas are inhabited by many producing farmers for grains and breeders for sheep as well as the presence of catalysts for the spread of hydatid disease such as lack of cleanliness and the presence of the middle host ⁸.

Female was higher than male patients ⁹, the main surgical occurrence was present in the 41–50 years age ¹⁰. ¹² The liver in males and females was more frequent site concerned than further organs and lung is next ²⁷. Since a best management, surgery was considered to be not dangerous, on the other hand minor and major problems speeds were wrote 32.2% and 25.0%, correspondingly, with a transience rate of 0.71%⁴, cystobiliary statement is the majority frequent
and difficult problem\textsuperscript{13} although these communication that under high pressure, may result in biliary obstruction, fistula, infection cholangitis, elevated bilirubin, elevated ALP levels and secondary biliary cirrhosis\textsuperscript{18} \textsuperscript{16} \textsuperscript{17} but the majority communication are occult in environment, and patients could stay clinically silent in the majority cases, with no any specific conclusion being noticed in the pre-operative develop and just being exposed through or next surgery\textsuperscript{18}.

**Material and Method**

Between May 2006 and May 2014, five hundred and one persons undergo surgery for liver hydatid cyst in Al-Zahra teaching hospital and Alkarama hospital in Al-Kut-Iraq. All persons undergo a complete blood cell (CBC) count and tests of liver function (LFT), fasting blood sugar (FBS), an abdominal ultrasonographic exam, chest radiography, were performed for all persons. Patients with gall stone, common bile duct stone and jaundice were excluded from the study.

The type of surgical procedure performed was laparotomy, packing the operative field with sponges soaked in 10% povidone iodine as scolicidal and injection of 10% povidone iodine to the cyst cavity, partial cystectomy with sclerotics and endocyst removal leaving pericyst and washing with 10% povidone iodine swab then tube drain inserted in the cyst and closed, there are two type of drain wide pore drain 32f-36f and classical drain 22f-26f, we use one drain for each patient randomly. Anyone from those five hundred and one patients complain of drain production reliable with a biliary form and bilirubin level upper than plasma bilirubin level after fifth postoperative day were included in this study and they are 134 patients. Persons were divided based on the presence of wide pore drain 32f-36f (64 patient) group A or classical drain 22f-26f (70 patient) group B.

Postoperative follow up of both group were done and a comparative study regarding, Sex, Age, length of hospital stays, drain output, postoperative intervention, relation ship between Cyst diameter and time for fistula to close spontaneously recurrence, and mortality were compared among both group. non compliance patient and patient with bad follow up were excluded from study.

**Finding**

The 64 patients (group A) 10 (15.6%) were male, and 54 (84.4%) were female. The median age was 42 years (range 16-74 years). The mean hospitalization time was 7 days, the mean daily drain output was 250 ml. Intervention need in, two female (3.1%) patient as catheter placement under USG regulation to control the biliary collection due to slipping of drain. The cyst diameter ranged from 5 cm to 20 cm (median, 9.0 cm). Mean time for spontaneous fistula closure was 12.3 days, no recurrence or death reported in this group. Of the 70 patients (group B), 15 (21.4%) were male, and 55 (78.6%) were female. The median age was 46 years (range 19-76 years). The mean hospitalization time was 9 days, the mean daily drain output was 450 ml. Intervention need in 5 patients (7.1%) four female and one male required catheter placement under USG guidance to control the biliary collections that were not adequately drained and obstructed. The median cyst diameter was 9.5 cm, mean time for spontaneous fistula closure was 17 days. There were three patients (4.3%) 2 female and one male recurrence after one year follow up. There was one old female patient (1.4%) deaths in this group due to biliary collections with subsequent sepsis. A comparative study regarding sex, age, length of hospital stays, postoperative intervention, relationship between cyst diameter and mortality were compared among both group and shown in the figures and tables below.
The relation between cyst diameter and median time for closure of fistula study found that larger cyst in group A closed earlier than middle and even small cyst while in group B study found that the time was proportional to the cyst size.

Discussion

Postoperative hydatid biliary communication could effect in many morbidity and mortality\textsuperscript{19}, hydatid fistulae were described to be high resistant and not often stopped spontaneously. In spite of pre-operative and operative attempt to avoid this problem, most communication are occult in nature and appear after surgery.

In our series, postoperative cystic-biliary fistula occurred in 134 (26.7%) patients compared to 31% reported by Langer et al\textsuperscript{1-4}, women was affected more than men, 109 patients (81.3%) and 25 (18.7%) respectively, this confirming that most of hydatid cysts states between the housewives that present by many other researchers\textsuperscript{8-20}, on the other hand, elevated occurrence of the disease between housewives could be because of their close contact with infected dogs and most of them were from rural and agriculture area. The highest median age prevalence was 42 years in group (A) and 46 years in group (B), it is usually conventional that the majority of hydatid cysts are obtained in childhood, but could get several years to obvious themselves as harmful lesions\textsuperscript{25} hospital continue was more in group (B) compared with group A (9 vs 7 days) due to fever and wound infection in group (B), whilst the lowest was with group (A) indicating that wide pore drain is safer than classical drain and smooth postoperative days. Kemal et al reported anaphylactic shock and high fever and cholangitis and morbidity up to 10% in persons with liver hydatid disease\textsuperscript{21}.

The mean daily drain output was higher in group (B) compared with group (A) (450 ml vs 250 ml) Zeybek N et al show a postoperative biliary drainage volume less than 100 ml selected the only important forecaster of impulsive conclusion\textsuperscript{22}. The intervention need in group (B) was 7.1% (5) patients (%4 female and one male requisite catheter site under USG control to manage the biliary collection that were not sufficiently drained and obstructed while 3.2% in (A) as two female patient need catheter site under USG control to manage the biliary collections due to slipping of drain, drain slipping occur due to large drain diameter and can be solved by frequent suturing of drain.

Drain slipping and unavailability of wide pore drain are the most two deteriorating factor that we in faces in our study Some study intervention with ERCP sphincterotomy and the puncture, aspiration, injection and re aspiration (PAIR) procedure\textsuperscript{23} In This study about 35.9% of fistula closed within 10-15 days in group (A) while only 26.9% in group (B), and 4.7% only need more than one month to close in group (A) while 17.1% in B. The relation between cyst diameter and median time for closure of fistula we found that larger cyst in group (A) closed earlier than middle and even small cyst while in group (B) we found that the time was proportional to the cyst size, this can be attributed to Bernoulli’s principle and Poiseuille’s law on our drain and use 36 French instead of 22 French there will be more flow of drainage and decrease in intracystic pressure and decrease in surface tension this will lead to early fistula closure,
and decrease the postoperative morbidity, also can be attributed to that high intraabdominal pressure on rapid empty cyst cavity lead to collapsing the cyst early and blockage of fistula.

The reappearance speed was 4.3% in group (B), but zero in group (A) more than the similar time of ordinary postoperative follow up, this might be considered as evidence that wide pore drain is much more effective than classical drain these attributed to that communicate through the biliary structure, resultant in an increasing disease of the cyst contents and bacterial super infection could destroy the parasite and wide pore drain allow good drainage of missed small scoliosis the recurrence rate in most literature did not exceed 10%.²⁴ In this study, Postoperative mortality was 1.4% in group (B) and zero in group (A). Which near the literature that stated as 1-3%,²⁴ so redaction in postoperative mortality also can be achieved.

**Conclusion**

According to Bernoulli’s principle and Poiseuille’s law on our drain and use 36 French instead of 22 French there will be more flow of drainage and decrease in intracystic pressure and decrease in surface tension this will lead to early fistula closure, and decrease the postoperative morbidity and mortality.

Security permits: clearance was taken from a government hospital in Wasit province with the knowledge of the government administration and patients.

Ethical statement of the subject of research came with the approval of the doctors supervising the condition of their patients in addition to the reviewers to follow up their healthy condition throughout the research period.

Research funding was done by the researcher himself and without any government funding.

Causes of Emergency Hysterectomy in AL-Fallujah Maternity & Children Teaching Hospital

Huda Hamid Al-Janabi1; Omar Mahmood Shakir2; Bashar Talib Huweidy3

1College of Medicine, AL- Fallujah University, Obstetrician in AL-Fallujah Maternity &Children teaching hospital, Iraq, 2College of Medicine, AL-Fallujah University, urosurgeon in AL-Fallujah teaching hospital, Iraq, 3College of Medicine, AL- Fallujah University, Pediatrician in AL-Fallujah Maternity &Children teaching hospital, Iraq

Abstract

Objective is to detect hysterectomy and maternal morbidity and mortality that occurs in emergency hysterectomy in secondary hospital. This retrospective study of 9 patients done for obstetrics indications from January 2018 to January 2019, in department of Gynecology and obstetrics Al-Fallujah teaching hospital. patients and methods 9 cases at this study period underwent emergency hysterectomy, data collected from hospital record their personal data, chief compliant, past obstetric, cause of hysterectomy and complication was recorded. Result There were 9 cases emergency hysterectomies done for obstetric condition. The indications and surgical complications was studied.

Conclusion: The emergency hysterectomy is mandatory to save life of patients. The outcome is depending on the decision time and the expert of the judgment because any delay may cause increase mortality and morbidity

Keywords: Emergency; hysterectomy; AL-Fallujah Teaching Hospital.

Introduction

Emergency obstetric hysterectomy mean uterine removal at any time of cesarean section, after caesarian section, after normal delivery or in perpartum period in order to save the patients. (1)

Horatio Storer did ported the first operation at 1898, but it was un successful. After seven years Eduardo Porro did the first successful operation with subtotal hysterectomy it is called “PORRO OPERATION” (2)

In developed countries, hysterectomy is done mainly for sterilization and uterus tumors. In developing world it is done mainly when there is frailer of controlling of hemorrhage after delivery. (3) The rate ranges from 0.4 to 2.5 per 1000 births and has risen significantly during the past few decades. Most of this increase is attributed to the increasing rates of cesarean delivery and its associated complications in subsequent pregnancy (4).

Hysterectomies, approximately to One half to two thirds are total, whereas the remaining cases are supra cervical (5).

Hysterectomy mainly done due to uterine atony that occur in 1:1000 delivery (5) Post partum cause
of hysterectomy occurs if the patients have previous caesarian section and the placenta implant over the previous scar(6) These as well as other less frequent indications are found in table (1) For example, large leiomyoma may preclude satisfactory hysterotomy closure and necessitate Hysterectomy . Or, postpartum infectious morbidity from an infected , necrotic uterus will prompt uterine removal for recovery (7).

Uterine atony is failure of contraction of the muscles after separation of the placenta that cause sever bleeding .The majority of PPH cases (75-80%) are due to uterine atony .

The factors predisposing to postpartum uterine atony are listed in table (2).

Most of the blood loss due to uterine atony occurs from the myometrial spiral arterioles and decidual veins that previously supplied and drained the intervillous spaces of the placenta. As the contractions of the partially empty uterus , hemorrhage happens and continue and stopped if the uterine muscle contrac and press the blood vasculature and cause ligation physiologically(8). The hemorrhage occurs also when there is rupture of uterus especially when there is a rupture scar ,from manipulation ,trauma ,congenital anomaly of the uterus or may be occur spontaneously.

Rupture also occur in abnormal delivery, operated labor and placenta accrete Placenta accrete is abnormal attachment between placenta and lining of the uterus with loss of decidua basalis. the incidence of placenta accrete occur in about 3:1000 . Other important risk factor are previous cesarean section of the uterus .(9)

Placenta percreta causes invasion of urinary bladder that presented with hematuria . Placenta accrete mostly diagnosed antenatally by radiological facilities (ultrasound is the preferred ). Placenta previa mean presence of the tissue of placenta on or closely to the internal cervical os .(10)

There are two types of placenta previa in recent classification .The true placenta previa in which placenta covers the internal os completely .The second type is low lying placenta in which the placental tissue presented within two cm away from cervical os and doesn’t cover it . The incidence of placenta previa is about 1 : 200 births. The placenta previa occur upto 6% in second trimester and cause painless vaginal bleeding . The bleeding occur at least once in about 70% to 80% of the patients .(11). Risk factor are Increasing parity, age, race , Cigarette smoking and cocaine use , Prior placenta previa , Prior uterine surgery and prior cesarean delivery (10).

Logically , the risk factors for peripartum hysterectomy mirror the risks of these indicated complications Major complications of peripartum hysterectomy include increased blood loss and greater risk of urinary tract damage Blood loss is usually appreciable because hysterectomy is being performed for hemorrhage that frequently is torrential , and the procedure itself is associated with substantial blood loss (7).

The maternal death mainly caused by shock ,DIC ,complication of operation and post operation complication.
The hysterectomy had been reduced due to advanced method of management of the labor, use of antibiotics, oxytocin and prostaglandins. It is also decreased by use of internal iliac artery ligation (11).

After anticipated or planned cesarean hysterectomy, there are lower rates of blood loss, less need for blood transfusions and fewer urinary tract complications compared with emergent procedures (12).

This study attempts to highlight the extent of availability and utilization of antenatal services, identify avoidable factors and stress the need to organize health care services so as to improve maternal and fetal outcome.

The decision about Hysterectomy should be made by an experienced consultant clinician (preferably after discussion with a second experienced consultant clinician) and the procedure should be carried out by a surgeon who is experienced in carrying out hysterectomy. Do not delay hysterectomy until the woman is in extremis or while less definitive procedures with which the surgeon has little experience are attempted. Resort to hysterectomy sooner rather than later (especially in cases of placenta accrete or uterine rupture). Subtotal hysterectomy is the operation of choice in many instances of PPH requiring hysterectomy unless there is trauma to the cervix or lower segment (13).

Aim of this Study is to determine the indications of obstetric hysterectomy, maternal morbidity and maternal mortality associated with emergency obstetric hysterectomy at a secondary hospital, Department of Gynecology and Obstetrics.

Patients and methods

We retrospectively analyzed by case series a total of 9 women who underwent emergency peripartum hysterectomy between January 2018 and January 2019 at Al-Fallujah teaching hospital, Department of Obstetrics. The data was collected from the hospital records. All women included in this study underwent hysterectomy within first hour of delivery.

The medical record sheets of all identified women were reviewed regarding age, occupation, geographic area, blood group, parity, miscarriage, multiple or single pregnancy, chief complaint at admission, past obstetric history which include: (previous e/s, myomectomy, hysterotomy, placenta previa or and accrete, any previous pelvic surgery), causes of hysterectomy which include: (placenta previa or and accrete, rupture uterus, H.mole, and uterine atony) and complication in operative room which include: (bladder injury, bowel injury, and ureteric injury).

Results

Case Finding:

Case 1: A 30 years old female, housewife from rural area o- blood group P5M0 presented to ER with abdominal pain and slight vaginal bleeding for 30 min before admission. The pain started after few minutes from receiving IM injection of oxytocin at midwife house. After examination she diagnosed as uterine rupture and she underwent emergency C/S in operative room. Surgeon decided to do emergency hysterectomy; The surgery was associated with ureteric injury.

Case 2: A 39 years old female, housewife from Urban area o- blood group P6M0 single pregnancy admitted as elective C/S and she was known case of placental abruption. She had previous 3 C/S and other past obstetric history was negative. The patient prepared for surgery and at operative room surgeon discovered multiple adhesion and bleeding started so surgeon decided to do emergency hysterectomy; The surgery was associated with bladder injury.

Case 3: A 35 years old female, housewife from rural area A+ blood group P5M0 single pregnancy presented to ER with loss of consciousness. Patient lost her consciousness during labour at midwife; she received IM injection of oxytocin at midwife house. She had previous 3 C/S and other past obstetrical history was negative. Examination done and she diagnosed as uterine rupture so she underwent emergency C/S and in operative room surgeon decided to do emergency hysterectomy; The surgery was associated with bladder injury.

Case 4: A 38 years old female, housewife from Urban area A+ blood group P6M0 single pregnancy presented to ER with vaginal bleeding. She had previous 6 C/S other past obstetrical history was negative and she underwent emergency C/S, and in operative room there was placenta accrete with multiple adhesion and severe bleeding so patient underwent emergency hysterectomy; The surgery was associated with bladder injury.
Case 5: A 29 years old female, housewife from Urban area B- blood group P6M1 single pregnancy admitted for elective C/S. She had 3 previous C/S and other past obstetric history was negative. The patient prepared for surgery during operation the surgeon discovered there is placenta accrete and multiple adhesion, so decided to do emergency hysterectomy; The surgery was associated with bladder injury.

Case 6: A 36 years old female, housewife from rural area B+ blood group P8M0 single pregnancy presented to ER with abdominal pain. She had 3 previous c/s and other past obstetrical history was negative. The patient prepared for surgery, during operation the surgeon discovered there was placenta accrete and multiple adhesion. Emergency hysterectomy was done; the surgery was associated with bladder injury.

Case 7: A 30 years old female, housewife from Aruban area O- blood group P5M0 single pregnancy presented to ER with vaginal bleeding. She had 4 previous c/s and other past obstetrical history was negative. The patient prepared for surgery during operation surgeon discovered there was placenta accrete with multiple adhesion there was severe bleeding so decided to do emergency hysterectomy; The surgery was passed without complication.

Case 8: A 30 years old female, housewife from Urban area O+ blood group P5M0 single pregnancy presented to ER with vaginal bleeding. She had 1 previous c/s and other past obstetrical history was negative after examination she diagnosed as uterine rupture and she underwent emergency C/S during surgery there was severe bleeding started bleeding and decided to do emergency hysterectomy; The surgery was passed without complication.

Case 9: A 21 years old female, housewife from Urban area O+ blood group P1M0 single pregnancy presented to ER with abdominal pain for 30 min before admission pain colic in nature radiated to the back associated with gash of watery vaginal discharge. Past obstetric history was negative. Examination done and she referred to vaginal delivery room after 4 hours she delivered Baby and after less than 30 min delivered the placenta and bleeding started and not stopped by conservative measures so referred to operative room also all available measure done without benefit, so the surgeon decided to do Emergency hysterectomy, The surgery was passed without complications.

Discussion

Peripartum hysterectomy is a major surgical intervention usually done as an urgent procedure that associated with significant maternal and fetal complications. (14)

Nine cases of emergency hysterectomy in the study period from January 2018 to January 2019 at Al-Fallujah teaching hospital, Department of Gynecology. Eight cases out of 9 that underwent obstetric hysterectomies were multigravida.

Most common indication of hysterectomy in this study was placenta accrete. 5 from 9 cases underwent emergency hysterectomy due to placenta accrete. All patients had previous c/s.

The second most common was ruptured uterus 3 from 9 cases underwent emergency hysterectomy due to ruptured uterus. And one case due to uterine atony. The age of females ranging from 21 to 39 year and all of them were housewife, most of them from Aruban area.

From case series three patients were diagnosed with ruptured uterus they went to midwife and received IM injection of oxytocin and two of them had previous c/s. and two of them from rural area. Intraoperative records revealed 5 of these cases had bladder injury, 1 ureteric injury and 3 of them surgeries ended without complications.

Conclusion

1. Peripartum hysterectomy is the “near miss event in both developed and developing countries. It has been described as one of the riskiest and most dramatic operations in modern obstetrics. It is therefore associated with significant maternal mortality and morbidity. Its prevention is the foremost goal in obstetrics.

2. Identification of high risk cases, early referral, timely performance of caesarean section careful monitoring and resort to conservative procedures can reduce the near miss event.

3. Most difficult situation is doing hysterectomy in primigravida or in patients with no living children. So it should be performed judiciously weighing the need to sacrifice the obstetric future of the patient in favor of patient’s life.
4. Special provision of blood transfusion, dialysis facilities and good ventilatory support is necessary round the clock.

5. Availability of multidisciplinary team involving an experienced Obstetrician, anesthetist, urologist, interventional radiologist and a physician round the clock is necessary.

6. Availability of communications and transport facilities for these emergency patients are required. Provision of emergency ambulance facility services provided by the government has played a huge role in quicker access for health care facilities.

7. Further such measures will help in reducing maternal and perinatal morbidity in emergency peripartum.

**Conflict of Interest:** non

The Immunological Study of Salmonella Infantis in white Mice Immunized with Killed Antigen

Basimraihan Sahar¹, Khalied Yassenzakairalzamily¹, Alaa SalimHamzah²

¹Department of Medical Laboratory Techniques, Kut Technical Institute, Middle Technical University, Baghdad, Iraq, ²Department of Nursing, Institute of Medical Technology, Middle Technical University, Baghdad, Iraq

Abstract

The present study was carried out to investigate the effect of formalin-killed antigen for Sallmonellainfantis in vivo with the study of cellular immune response through the study of cytokines.Sallmonellainfantis were isolated and diagnosed from local milk products (milk and cheese). 74 milk samples and 53 cheese samples were taken. The media were used general and special culture media as well as biochemical tests were used to diagnose the isolates and the diagnosis was confirmed by using API 20.

Sallmonellainfantis antigens were used systemically. 50 Swiss white mice of both sexes were randomly divided into three groups. The first group prevented (20 mice) with the bacterial antigen killed by formalin in a dose (0.3) I.P for each animal. The group was injected with a booster dose and the same first immunization dose two weeks after the first dose. The second group (20 mice) and the third group (10 mice) were counted as positive and negative control groups respectively.

The first group and the second group received a dose of 0.3 ml of stuck S.infantis containing (1×10⁸ live cells / ml) I.P, while the third group injected 0.3 ml of neutral phosphate buffer solution under the skin. The results showed that 4 animals from the first group were killed and all the remaining animals from the first group were killed 20 days after the challenge dose and serum was taken to measure cellular immunity. The results of serological tests showed that the level of (IL-4 and IL-6) were (38.48 ± 2.1 and 31.81, 3.01) respectively, as well as the results of measurement of concentration (INF gamma and TNF-α) were (401 ± 2.12 and 173.421 ± 3.11) respectively. We conclude from the study that there was a high percentage of S.infantis isolated from milk products as well as we conclude that the formalinS.infantiskilledantigen partially protected against the infection.

Key Words: Sallmonellainfantis, killed Antigen , IL-4, IL-6, INF gamma, TNF-α.

Introduction

Non-typhoidal Salmonella enterica (NTS) are considered to be one of the main common causes food borne infection worldwide that effect on humans (1). Salmonella Infantis is the most recurrence strain in numerous countries, involving Asian countries. detection and isolate of S. Infantis from animals, humans and vegetables (2,3). when salmonellosis causes infect of animals, due to increase in death -rate in infected animal leads to economic loss for countries, these Infected animals act as a source of infection that during to direct or indirect contact injury to humans (4). The humans and animals infected with salmonella contaminate the environment and nutrition at most by feces (5) also Salmonella colonizes at most in the intestinal tract (6). The dairy products and Milk, especially poorly pasteurized, are among the possible causes of the transmission of many pathogens to humans through food (7). The feces of infected cattle, infected udder, milking equipment, contaminated skin, feed and from milkers considered as main sources of contaminate raw milk, causes salmonellosis and other pathogen (8, 9, 10).

The present study was carried out to investigate the prevalence of Salmonella infant in milk and cheese, and revealout the serotypes of the Salmonella isolates.
Materials and Method

Sample collection:

Dairy products (milk and cheese) samples were collected from local supermarkets in Kut city. The samples were collected during the period from January to April 2019. Samples were rapidly put in selenite broth containing sterile tubes and transmitted by ice box during 2 hour to the laboratory of bacteriology in pathological analysis department in Kut Technical Institute.

Bacterial Isolation:

All samples collected were cultured onto MacConky agar and incubated at 37°C for 24-48 hour. The growing colonies were examined by naked eye concerning their color, shape and size, sub-cultured onto selective media such as Eosin Metheline blue, SS and XLD agar and incubated at 37°C for 24 hour. Method of culturing was done according to (11).

Bacterial Identification:

The colonies were examined by eye according to their color, shape, size, the Gram stain was done in addition to biochemical tests including: Catalase test, Oxidase test, Lactose fermentation, Urase test, Indole test, Citrate utilization test these test were done according to (12), then confirm diagnosis of the isolates by API 20E according to (13).

Challenge dose

The Salmonella Infantis was cultured, growth and purification on the media of this study, the live bacterial cell counted according to (14).

Antigens (killed Salmonella Infantis antigen):

The killed S. Infantis antigens were prepared according to (15).

Cytokine assessment:

Interleukin-4, Interleukin-6, INF gamma and TNFα Assay Procedure, The procedure is performed at room temperature according to manufacturer’s instructions (Boster’s – Korea).

Experimental design:

Fifty white mice were used (male and female), the ages (8-10 weeks) and their weight ranged between (25-30 gram), obtained from institute of sera and vaccines ministry of health, and reared in cages furnished clean sawdust, and fed concentrate feed during the duration of the experiment. The white mice were divided into three groups were first group includes 20 mice immunized inoculated with 0.3 ml of formalin killed antigen, two dose, 2 weeks intervals at day 30 post immunization, and it was inoculated I/P with 1X10^8 cfu/ML. The second group includes 20 mice was considered as positive control, it was inoculated I/P with as 1st group. Third group includes 10 mice was inoculated I/P with 0.3 ml of sterile normal saline and served as control negative group. At day 30 post infection, all animals were sacrificed and blood samples were collected for determine cell mediated immune response by measurement of cytokines including IL-4, IL-6, INF gamma and TNF-α.

Results

Bacterial isolation:

The results were revealed the percentage of bacterial isolation from dairy product (milk and cheese) as in table 1:

Discussion

The present study recorded highly percentage of bacterial isolated in milk and cheese (62,16 and 58,49)% respectively. This result could indicated that the food product (milk and cheese) were thought of a supply a microorganism infection of human once dangerous handling, particularly in Asian country, the individuals consumed great amount of diary product, these results agreement with The farm product and Milk, particularly poorly change integrity, are among the attainable causes of the transmission of the many pathogens to humans through food. The current study showed the immunized group with virulence salmonella infantis when infected with lethal dose the death only 4 mice from this group (20 mice) during post 48 hr lethal dose infection, these may be, the killed antigen give partially protection, these results agreement with (16,17) who showed this might be indicate that antigens stimulate response with partial protection potential that destroys some microorganism at website of immunisation however sizable amount of those organism reach to internal organs and proliferation but the body tried to localize of this organism by neoplasm reaction. While positive Control (non immunized group) when infected these animals with lethal dose, the death of all animals during 24 hr post lethal dose infection may indicated that, the S. infantis is highly virulence bacterium that overcome traditional defense mechanisms of the host and spread to internal organs cause bacteraemia and sepsicaemia that cause high mortality, this results are agreement with (18) UN agency showed that, non infectious disease enterobacteria is major causes of morbidity and mortality post dissemination infections.

These results of present study were revealed that serum levels of IL4 and IL6 in immunized group were (38.4±2.1 and 31.81±3.01) respectively. The cytokine profile in immunized mice were showed the killed bacteria as a good immunogenic antigen which stimulate immune response with an intrinsic immunologic adjuvant which can lead to enhancement off immune response and at the same time can immunosuppressed. The cells which affecting their function might be through regulation T-cell (19). At sites of microbial invasion, leukocyte and other cells send out distress signals by releasing cytokines or chemokines. These proinflammatory signals activate local cardio vascular endothelium (IL1, TNFα) to express selection molecules, increase expression of chemotactic molecules (IL1 and IL8) and activate leukocyte (IL1, IL6, IL8, IL12 and TNFα), these results agreement with (20,21).
The result of current study may be due to bacterial component which stimulate TLRs that mediated pro-inflammatory cytokines production such as TNFα, IL8 and IL6 which considered attraction of neutrophil, these results are agreement with (22). who showed that salmonella infection in animal models characterized by abundant neutrophils infiltration.

The our results of immunized mice were showed that serum levels of IFN gamma and TNFα were (401±2.12 and 173.421±3.11) respectively. These results showed decreasing bacterial load in the present study with stimulated cell mediated immune response may indicated that both innate and acquired immune response may indicated play important role in eradication of S. infantis infection, these results are agreement with (23) who recorded that innate immune system which included phagocytic cells and cytokines can controlled the low virulence of these pathogen required both innate and acquired immune response including TNFα, IFN gamma, IL12, NK cells, humeral and cellular immune response particularly in the previous immunized or exposure to sub lethal infection showed that both B and T cell play important role in the protection against salmonella infection (24).

These was few bacterial isolated from examined organs of immunized infection mice which all of them were death during first 24hr post infection with sever bacterial load in all examined organs, these results agreement with (25) who recorded that vaccinated mice provided Th1-cytokines (TNFα, IFN gamma and IL12) as well as salmonella specific antibodies that controlled challenge with virulence salmonella infection.

The Inhibition Effects of *Withania somnifera* leaves Extracts for Multi Drugs Resistance Bacterial Isolates

Kareem Ibrahim Mubarak

*Biology Department. College of Science, Diyala University*

**Abstract**

The continuous resistance of pathogenic bacteria to antibiotics and failure of treatment of human diseases cause by these micrograms in addition to important of *withania somniera* plant in herbs medicine the present study carried out to assessment the antibacterial effect of three types of leaf extract: acetone, methanol and water in different concentrations to four multidrug resistance pathogenic isolates were selected two Gram positive and two Gram negative, the result showed that all types of isolated were inhibited by leaf extracts whereas the acetone record the highest effect were the inhibition zone (millimeter) of growth of four bacteria isolates *pseudomonas aeruginosa*, *Klebsiella pneumonia*, *Staphylococcus aureus* and *Streptococcus pneumonia* reach 15, 14, 13 15 mm respectively at 100 mg/ml concentration of acetone, the current finding indicated that leaf extracts useful as a good natural alternative drug from antibiotics in treatment of numerous infectious diseases these result from both Gram positive and Gram negative bacteria.

**Key words:** *Withania somnifera*, leaf extracts, antibacterial effect.

**Introduction**

Pathogenic bacteria responsible for the serious diseases to human and important causes of morbidity and mortality worldwide, The continuous increase and development of pathogenic bacterial resistance to antibiotic according to different mechanisms of resistance, and due to random usage of antibiotic in human treatment and veterinary medicine (1), multidrug resistance (MDR) of bacteria cause reduction in the effectiveness and failure of the synthetic drugs to treatment the microbial infections either Gram negative or positive species (2) (3), in addition to high cost of antimicrobial manufacture so that the scientist carried several studies and researches’ to dissolve and to minimize the treatment problems to found alternative drugs from the natural source.

Worldwide reported the presence important compounds as constituents of medicinal plants and posses high activity against bacteria and considered natural, low cost, available sources use as drugs in treatment of microbial diseases. (4)

*Withania somnifera* from Solanceae family known Ashwagandha Indian ginseng winter cherry use in Ayurvedic folk medicine has potent effect to treatment several diseases as Arthritis stress, Sedative, cough, others (5). Leaves constitutes of *Withania somnifera* riches with withanolides, alkaloids, Steroidal lactones, tannin, flavonoids, other compounds (6). Several studies carried to detect the action of *Withania somnifera* extracts against the growth of pathogenic bacteria isolated from different clinical samples, Rizwana et al 2012 showed in their study of antibacterial affect of acetone, Methanol, Chloroform extracts of *Withania somnifera* the high inhibition effect of the extracts on the growth of seven species of human pathogenic bacteria (7).

*Withania somnifera* plant useful as drug in treatment of wounds, skin diseases, anti cancer, digestive system disorders, respiratory tracts infection (8,9). Antibacterial activity of leaf extracts at concentration 6.25 - 12.25 mg/ml give high growth inhibition of *Escherichia coli*, *Salmonella typhi*, *klebsiella pneumonia* *citrobacter freundii*, *pseudomonas aeruginosa* (10).

The objective of our current study was performed to focus the light on the potential of antibacterial effect of *Withania somnifera* leaf extracts against growth of four Multi Drugs resistance bacterial isolates.
Materials and Method

Bacterial Isolation & Identification:

The present was carried during January 2019 to April 2019 in Baquba city for isolation and identification of bacteria from pathogenic samples (urine, wounds swabs, nasal swab, Sputum). Each sample was inoculated on to the 50% sheep blood agar, MacConkey agar (without crystal violet), each plate were incubated overnight under aerobic condition at 37°C the identification of bacteria performed on the base of colony characteristics, morphology of bacteria (staining, shape and arrangement), and biochemical tests include (IMPIVC, Oxidase test, urease test, Coagulase and DNase test for *Staphylococcus aureus*, Catalase, Hemolysin test, Triple – sugar iron agar test, & confirmation of isolate identification performed by Vitek 2 Compact System (11).

Multi Drug Resistance (MDR) Isolates:

To detect the percentage of resistance of pathogenic bacterial isolates fourteen antibiotics were used include Gentamicin (10), Ampicillin (10), Tetracycline (30), Amikacin (10), levofloxacin (10), Ciprofloxacin (5), Trimethoprim – Sulfamethoxazole (25), Cefepime (30), Meropenem (10), Erythromycin (15), Pencillin G (10), Amoxicillin calvulanic acid (10), Vancomycin (30), Norfloxacin (10), using Kirby – Baure (Disc Diffusion method), suspension of bacteria with 1.5 x10 cell/ml were prepared in three replicates, leave the plate for 30 minutes in room temperature to allow the diffusion of the inhibition zone of each extract were recorded by 0.22 mm Millipore filter paper (12).

Four concentrations (25, 50, 75, 100 mg/ml) of acetone, methanol, water extracts were prepared by dissolved 1 gm of leaf powdered of each types of extract in 10 ml of acetone, methanol, distill water, then dilute to obtained the demand concentrations and sterilize by 0.22 mm Millipore filter paper (13).

*Withania somnifera* leaf Extract Activity

Agar well diffusion method were used to investigate the activity of leaf of *Withania somnifera* leaf extracts at concentrations 25, 50, 75, 100 mg/ml in three solvents (Acetone, Methanol, Water) against the growth of MDR isolates belongs to four pathogenic bacteria species. Colonies of isolates activate by subculture in brain heart infusion broth and incubate for 24 hours at 27°C at bacterial suspension with 5x10 cell/ml were used by compare with McFarland standard 0.5 solution, 100µl then spread by sterile cotton swabs on the surface of Muller- Hinton agar and on blood agar for *Streptococcus pneumoniae*, wells with 6mm diameter were makes by sterile cork bores and transport 50uL from 25, 50, 75,100mg/ml of plant extract to the wells each treatment performed in three replicates, leave the plate for 30 minute in room temperature to allow the diffusion of extract, the plates incubated for 24 hours at 37°C reach the inhibition zone of each extract were recorded by millimeter and calculated the mean of the zones from three replicates (14).

Results and Discussion

The result sensitivity of isolates belongs to four species of pathogenic bacteria against fourteen antibiotics identified from clinical samples showed the presence of several isolate has multidrug resistance( multi drug resistance isolate include two species of Gram negative *Pseudomonas aeruginosa* and...
Klebsiella pneumonia, and two species of gram positive Staphylococcus aureus and Streptococcus pneumoniae were selected to investigate the antibacterial activity of three types of Withania somnifera leaf extract. Our the finding revealed that multi drug resistance of each isolates, pseudo monas aeruginosa resistant to five antibiotics include Gentamicin, Amikacin, levofloxacin, Tetracycline, Ciprofloxacin, Klebsiella pneumonia resistant to four antibiotics: Amikacin, Trimethoprim – Sulfamethoxazole, Cefepime. The results of sensitivity of Gram positive isolates showed multidrug resistance to other groups of antibiotics Staphylococcus aureus resistant Gentamicin, Ampicillin, Tetracycline, Amikacin and Streptococcus pneumonia resistant to Meropenem, Erythromycin, Pencillin, Ampicillin, Tetracycline, Amoxicillin antibiotics.

The presence of different clusters gens in specific sites on plasmids or chromosomes responsible for the antibiotic resistance of bacteria and the association between those genes and other gens increase the chance of bacteria survival and adaptation may be result to the presence of multiple resistance genes in the bacteria strains, in addition of genetic processes mainly conjugation which considered one of the major mechanisms conjugative plasmids for transmission of resistance elements between bacteria strains as class 1 integron which considered as a part of antibiotic resistance Island which & into different conjugation plasmids.

Anti bacterial effect of leaf extracts:

The result in tables (2 & 3) revealed that antibacterial activity of leaf extracts in three solvents that the acetone leaf extract of Withania somnifera were the highest inhibition effect on the four species of pathogenic bacteria in the all concentration, the maximum inhibition zone recorded in 100 gm/ml were Pseudomonas aeruginosa 15 mm; klebsiella pneumonia 13 mm; the antibacterial activity on Gram positive bacteria were 13 mm for Staphylococcus aureus and 15 mm for Streptococcus pneumonia.

Methanol extract of leaf has strong inhibition activity against all multidrug resistance of pathogenic isolates, the range of their effect for different concentration about (8 -13 mm), the highest effect in 100 mg/ml concentration on (Pseudomonas aeruginosa, Klebsiella pneumonia, Staphylococcus aureus, and Streptococcus pneumonia) were the inhibition zone 12, 13, 11, 12 mm respectively.

The third types leaf extract were used in current study water extract showed the weak antibacterial activity on bacteria the lower inhibition zone observed in all concentration and species of bacteria isolate these
use in our study the diameter of growth inhibition zone on four pathogenic isolates by well diffusion method reach at highest concentration 100 gm / ml were 4 - 5 mm.

The result of the study agreement with the finding of previous finding that showed acetone extract of leaf has high a potent effect against pathogenic bacteria (20)(21). The high potential antibacterial of acetone and methanol leaf extract of *Withania somnifera* due to leaves components well extracted in polar solvent more than non polar solvent (22). The result of water extract became agreement with the some studies which showed that water extracts inhibited the growth Gram negative isolate due to withanolides compounds can by well extracted in water (23)(24) obtain similar result they showed the strong ability of crude extract of *Withania somnifera* to inhibition the growth five species of clinical bacterial isolates at 100 mg / ml concentration.

The strong inhibition effects on the growth of bacteria isolates of *Withania somnifera* extracts due to the active biochemical components as withanolides (major constituents of leaves), Amino acids, glycowithanolide, Alkaloids, flavonids and other compounds with the high effect to different diseases of extraction and purification(25).

**Conclusion**

Current investigation of antibacterial leaf extract of *Withania somnifera* showed that acetone and methanol extract exhibit strong activity against the four species of multidrug resistance pathogenic isolates, since we recommended to future studies to identify the chemical compounds to increase the drug activity and reduce the toxicity, to use the plant as antibacterial drugs for treating the disease specially for multidrug resistance isolates.

Abstract

Background: Primary Sjogren’s syndrome (pSS) is a chronic disorder described by its immune devastation to the salivary and lacrimal glands. The detection of pSS is complicated especially at the early stage. Thus, the emergence of novel markers preceding the conventional diagnostics for early detection of pSS before its aggravation is required. Objective: This study purposed to reveal the possible use of anti-SP1 as a beneficial indicator for early revelation of pSS in some Iraqi patients. Methods: Eighty-seven Iraqi patients (42 and 45 patients with newly diagnosed pSS and idiopathic sicca symptoms, respectively) enrolled in this study between February 2018 to July 2019. The diagnosis of pSS reliant on AECG and ACR criteria. All patients were assessed for RF, ANA, anti-Ro/SSA, and anti-SP1 by ELISA. Results: A greater prevalence of anti-SP1 was shown in pSS patients than control patients. Anti-SP1-positive pSS patients revealed significant shorter sicca duration with lowered Schirmer’s test and USFR, and predominant ANA and anti-Ro. Anti-SP1 evinced positive correlations with disease duration, ANA, and anti-Ro, and negative correlations with Schirmer’s test and USFR. Higher sensitivity (92.9%) and specificity (95.6%) of anti-SP1 in pSS patients than other diagnostic parameters. Conclusion: Despite small sample size, anti-SP1 still be a dependable marker for diagnosis of pSS at the early stage and discrimination of pSS patients than those with idiopathic sicca symptoms.

Keywords: primary Sjogren’s syndrome, anti-salivary gland protein-1 (anti-SP1), sicca symptoms

Introduction

Primary Sjögren’s syndrome (pSS) is a chronic autoimmune disorder that distinguish oneself by lymphocytic recruitment and devastation of the lacrimal and salivary glands with autoantibodies production, leading to sicca symptoms (eyes and mouth dryness) [1]. However, when the disease occurs alongside other autoimmune disorders like systemic lupus erythematosus (SLE), rheumatoid arthritis (RA) and systemic sclerosis, it is called secondary SS (sSS) [2].

The identification of pSS is complicated due to the lack of biomarkers with high efficiency and precision to prophesied the disease at the preliminary phase [3]. In addition, another diagnostic obstacle is that the sicca symptoms with limb pain and fatigue are very common in the people and may be accompanied with other pain syndromes [4].

Alternatively, the American-European Consensus Group (AECG) and American College of Rheumatology (ACR) created criteria to recognize pSS dependent on the utilization of clinical manifestations, measurements of sicca symptoms, histopathology of salivary/lacrimal glands, and autoantibodies production [5]. Several autoantibodies presently offer assistance to the identification of pSS include antinuclear autoantibody (ANA), rheumatoid factor (RF), anti-Ro/SSA, and anti-La/SSB whom may emerge with the disease’s exacerbation [6].

Consequently, alternate, non-invasive and dependable markers with high sensitivity and specificity are required to improve and simplify the early diagnostic process of pSS. Hence, novel biomarkers like anti-salivary gland protein-1 (SP1) were studied in mice and in patients with SS, which established to be manifested earlier in the disease phase [7].
The apparition of SP1 was originally in mice and Shen et al., five years later, evidenced identical proteins appeared in human salivary glands and the more significantly antibodies to SP1 were existent in pSS patients [8]. Besides, these autoantibodies were observed to be infrequently detected in healthy persons or patients with other autoimmune diseases [3].

The occurrence of anti-SP1, in several studies, has been detected in the early phase of pSS preceding anti-Ro/-La [9]. Notwithstanding, Theander and her colleagues study proclaimed anti-Ro/La might manifest a long time preceding the exhibition of pSS clinical features in particular patients [10]. Whilst the timing of anti-SP1 autoantibodies emergence in pSS patients is controversial, this study aims to disclose the bearable utilization of anti-SP1 as susceptible indicator for early identification of pSS.

**Materials and Method**

Patients: A cross-sectional study of 87 Iraqi patients (42 and 45 patients with newly diagnosed pSS and persistent idiopathic sicca symptoms (iSS), respectively) attended the Department of Rheumatology/Baghdad Teaching Hospital during the period from February 2018 to July 2019. The detection of pSS was dependent on the AECG and ACR classification criteria [5]. Patients that unachieved these criteria were classified as iSS. Patients with sSS or other rheumatic diseases, hepatitis viruses, acquired immuno-deficiency syndrome, IgG4-related disease, head/neck radiation, graft versus host disease, amyloidosis, and medications that may affect salivary/lacrimal gland function were excluded from the study.

**Result**

Significant differences amidst pSS patients and those with iSS regarding sicca duration, Schirmer’s test, USFR, ESR, and CRP were illustrated in Table (1). In contrary, non-significant differences were noted between the study groups for age and gender. However, RF, ANA, anti-Ro/SSA, and anti-SP1 were significantly prevalent in pSS patients.

Discussion

The most debatable things is the time of autoantibodies appearance that may precede the clinical onset in pSS patients. The current study revealed significant elevation in patients with newly diagnosed pSS and those with persistent iSS for diagnostic parameters (Schirmer’s test, USFR, RF, ANA, anti-Ro, and anti-SP1). These results were consistent with findings by Lee et al., which showed a raised predominance of these diagnostic parameters in pSS patients comparing those iSS ones [13], suggesting the superior inflammatory pathways in patients with pSS than with sustained iSS. Nevertheless, the marker(s) that undoubtedly confirm suspected patients with pSS was needed, so significant higher prevalence of positive anti-SP1 was demonstrated in pSS than iSS patients comparing other diagnostic markers. Besides, positive anti-SP1 patients with pSS having elevated CRP and prevalent RF, ANA, and anti-Ro conflicting those with negative anti-SP1. Moreover, sicca duration, Schirmer’s test, and USRF were noticed markedly minimized in pSS patients with positive anti-SP1, suggesting the appearance of anti-SP1 in pSS patients with shorter duration and acute-phase. A study by Everett et al. was in harmony with our findings, they found that anti-SP1 was disclosed in pSS patients with ≤2 years duration and abnormal Schirmer’s test, and anti-Ro/La antibodies might not be detected before two-years of disease onset [14].

Referring to the possible replacement of anti-Ro/La with anti-SP1 in the early detection of pSS, Vishwanath et al. study reported iSS patients with negative Ro/La antibodies exhibited positive anti-SP1, hence, tissue-specific autoantibodies (e.g. anti-SP1) are reliable markers for early identification of pSS [15]. In contrary, the findings by Suresh et al. were discrepancy with our results as they found (based on their study design) that anti-Ro/La, in contrast to anti-SP1, might be linked with the disease’s acuteness and exhibited higher sensitivity in the discrimination between normal and diseased individuals [16].

Several explanations may clarify the earlier emergence of anti-SP1, contrasting anti-Ro/La, during the early stage of pSS. Among them the early immunogenic inflammatory processes that may occur initially in the salivary and lacrimal glands destroying the epithelial cells with activation of B cells via the recruitment of follicular T-helper cells [17]. Besides, patients with pSS may develop hyperglobulinemia that leads to the formation and potentially deposition of immune-complexes in the secretory glands causing irreversible damage with the expression of epithelial cells contents and stimulation of chronic immune responses [18].

Another explanation, both Ro and La are parts of extractable nuclear antigens that existed in many cell types, therefore anti-Ro/La can be found in several autoimmune disorders resulting in decreased their specificity to pSS particularly at the early phase [19]. In return, the tissue specificity of SP1 (salivary gland secretory protein) making anti-SP1 potentially tissue-specific antibodies that may correlate with the early diagnosis of pSS due to the initial inflammatory devastation of the salivary and lacrimal glands [20].

The study findings displayed that anti-SP1 antibodies were correlated positively with the sicca duration, the inflammatory markers, ANA, and anti-Ro, as well as, correlated negatively with the clinical signs’ measurements in pSS patients. Therefore, this relationship of anti-SP1 with the shorter disease duration, and the inflammatory as well as immunological markers indicating the involvement of immunoinflammatory reactions in the salivary glands with early emergence of these autoantibodies during the disease onset. Phung et al. [21] referred that anti-SP1 was more specific than anti-Ro/La for early identification of SS since SP1 was located particularly in the salivary glands contrasting Ro/La that existed in any nucleated cells. Likewise, the anti-SP1 was rarely detected in healthy persons (<5%), and the patients suffering early SS have >60% of novel autoantibodies (e.g. anti-SP1) and 20-30% of anti-Ro/La, whereas in patients with late SS these proportions were inverted. Karakus et al. declared that anti-SP1 discovered in >20% of SS patients contrasting 13% of iSS patients, also anti-SP1 was the only autoantibody correlated significantly in those with ≤5 mm of Schirmer’s test [22].

The diagnostic performance of the studied parameters elucidated excellent performance of anti-SP1 with higher sensitivity (92.9%) and specificity (95.6%) in the pSS detection comparing other parameters, suggesting the possible utilization of anti-SP1 antibody for early detection of pSS due to its higher specificity to the salivary glands, and eventually more sensitive to the pSS especially at the early stage. Jin et al. stated that anti-SP1 elevated obviously in patients suffering early pSS with shorter disease duration and negative anti-Ro/La antibodies; indicating the effective use of these
autoantibodies as a diagnostic marker particularly during the early stage at which anti-Ro/La antibodies were negative[23]. In conclusion, notwithstanding small sample size, the current findings are still worthy to proclaim the beneficial use of anti-SP1 as a marker for pSS detection especially at the early phase and discrimination patients suffering pSS from those with iSS. Molecular studies with a larger cohort are required to estimate the time of SP1 expression in human salivary gland for possible use of anti-SP1 as a predictor of pSS.

Effect of Sunlight and Vitamin D3 on some Men Fertility Parameters

Riyadh Hussein Wally
Lecturer, Medical laboratories techniques /Kut-Technical Institute/Middle Technical University

Abstract

The current study aims to clarify the effect of the exposure to sunlight on the vitamin D level and the effect of this on characteristics of seminal fluid and some hormones in infertile men. The study included 45 men (aged between 18-44 years) who suffer from infertility. These men attend the Infertility Treatment Centre at Kut Hospital, Wasit, Iraq. Infertile men were exposed to the sunlight without using sunscreen for ten minutes at daily intervals over 3 months. Seminal fluid parameters, as well as the level of Vitamin D3, Follicle-stimulating hormone (FSH), Luteinizing hormone (LH) and Testosterone, were measured before and after exposure to sunlight. The study showed that there was a significant increase in count, activity and normal morphology of seminal fluid as well as elevation in LH, FSH, testosterone and vitamin D3 level in blood after the exposure to sunlight.

Keywords: Sunlight, Seminal Fluid, Vitamin D3, LH, FSH, Testosterone.

Introduction

Sunshine contains ultraviolet (UV) rays, which are three types: type A (320 nm - 400 nm), known as UVA, which causes skin damage and the appearance of signs of aging, type B (290 nm - 320 nm) and symbolized by the (UVB) and type C (100 nm - 290 nm) known as UVC which is absorbed mostly by the ozone layer at the upper atmosphere and does not reach to the earth ¹. UVB gives the skin the energy needed to make vitamin D3 when 7-dihydroxy cholesterol reacts with ultraviolet (type B) at wavelengths between 270 and 300 nm, and peak formation is between 295 and 297 nm. ². These wavelengths are in sunlight when the UV index is greater than three ³. Vitamin D manufacture in the human skin following sun exposure is depend on the location of the sun in the sky and the zenith angle ⁴. Zenith angle depends on the latitude, season, weather conditions, and time of the day ⁵. even though the sun is closer to the earth in winter, it enters a more slanted angle (azimuth angle) and more UV radiation is absorbed by the ozone layer and passing in more distance which leading to fewer UV rays reaching to earth ⁶. The latitude above 37 ° affects the angle of the sun’s peak from November to February, where there is a marked decrease in the amount of UV radiation reaching to the earth surface. Therefore, very little vitamin D3 is produced in the skin during the winter, while the latitude less than 37 degrees and closer to the equator, the production of vitamin D3 in skin is higher throughout the year ⁷. In the case of the first morning or late in the day, the azimuth angle is highly tilted and the production of vitamin D3 is very low in the skin even in the summer and exposure to the sun is need between 1000 and 1500 hours, as a result, the optimal times for vitamin D manufacture in human skin is in the summer among the hours of 10 AM and 3 PM ⁸. A 15-minute exposure to sunlight on the face, arms, and legs without sunscreen is enough to produce 1500-3000 vitamin D units. This is enough for one to three days ⁹.

Generally, exposure to sunlight for 15-20 minutes three times a week is safe, does not cause skin damage, and enough to provide healthy amounts of vitamin D to the body ¹⁰. Dark-skinned people have increased melamine, which absorbs UV rays more effectively, and therefore need longer exposure to the sun to get the similar amount of vitamin D3 when compared with people with white skin ¹¹. It should be noted that the production of vitamin D3 by sunlight has a comparative advantage, such as fish oil, where the production of vitamin D through the sun does not reach the excess rates or harmful. As there is a process of balance performed by the skin automatically, and the excess of vitamin is eliminated ¹². Vitamin D that produces by skin or comes from the diet is physically inactive and need to add hydroxyl group in the liver.
by aidthe 25-hydroxylase enzyme to 25(OH)D. Also, vitamin 25(OH)D needto additional hydroxyl group in the kidney byenzyme 25(OH)D-1-OH-ase to produce 1,25(OH)2D the physically active of this vitamin. Vitamin D is one of the most powerful vitamins necessary for bone health because it helps absorb important calcium for bone and dental health and plays a vital role in building muscle mass, strengthening the immune system and nerve signals. According to some research, vitamin D affects the health of internal cells. The lack of vitamin D in men leads to what is known as erectile dysfunction problems due to weak blood flow in the male genitalia, so men are not able to have an erection, which results in erectile dysfunction. Another study showed that sexual desire is linked to the level testosterone is associated with vitamin D. The elevated the level of vitamin D, the elevated the testosterone. When the vitamin decreases, the sexual ability of men is diminished. This is mostly in the winter because of the lack of the sun to supply vitamin D, which raises the level of testosterone.

Several factors contribute to the process of production and activation of sperm and sexual activity for men, including vitamin D, which shows that the presence of the receptor on the head and the med body of sperm. Vitamin D is essential in the absorption and metabolism of calcium where it is vital for spermatogenesis and sperm activity.

**Materials and Method**

The study was conducted on 45 infertile males between the ages of 18-45 years and who attended the Infertility Treatment Center at Kut Hospital, Wasit, Iraq. The information required for the study was collected from the subjects including age and duration of the marriage. Also, we looked at the previous surgery, stimulant therapies for the reproductive system during the past 6 months, and chronic diseases with excluded smoking persons.

Semen samples were collected in a clean screw plastic tube by masturbation method from subjects after a period of abstinence for 3-5 days and placed in the incubator at 37 °C to allow them to have normal liquefaction. After the liquefaction occurred, the semen was examined for sperm count, movement, availability and sperm morphology. The blood samples were collected in sterile plastic tubes and the serum separated by centrifugation at 3000 rpm for estimating of hormones and vitamin D3 before exposure to sunlight and sent to the laboratory immediately for analysis. Participants then exposed to direct sunlight for continuous 10 minutes daily during 10.0 am and 3.0 pm o’clock without using any sunscreen for three months from 1-3 to 1-6-2019, samples of semen and blood collected after the end of the sunlight exposure and sent to laboratory for analysis. Seminal fluid concentration and motility estimated by using a Microcells counting chamber methodand sperm morphology estimated by use Diff-Quick kit according to World Health Organization criteria. 25-hydroxyvitamin D (vitamin D3), total testosterone, luteinizing hormone (LH), and follicle-stimulating hormone (FSH), were estimated by using Electrochemiluminescence-Immunoassay (ECLIA) kits.

**Statistical Analysis**

Statistical analysis was completed with use the student T-test. The results were expressed as a mean and standard-deviation (SD). The P values of ≤ 0.01 were expressed as significant values.

**Finding**

Study showed there were significant increase in serum vitamin D3 (42±2.62) in men after exposed to sunshine as compare with before exposure (28±1.59) (table 1, figure 1), significant increase in serum LH (7.13 ± 1.37) in men after exposed to sunshine as compare with before exposure (5.06 ± 2.77), significant increase in serum FSH (6.24 ± 2.58) in men after exposed to sunshine as compare with before exposed (4.87 ± 1.75) and significant increase in serum testosterone (12.84 ± 2.77) in men after exposed to sunshine as compare with before exposed (9.23 ± 3.82) (table 1, figure 2). In addition, the study showed a significant increase in sperm count (42.23 ± 29.8) in men after exposed to sunshine as compare with before exposed (28.72 ± 23.48), significant increase in sperm active motility (29.07 ± 20.2) in men after exposed compared with before exposed (12.93 ± 11.92) significant increase in normal sperm viability (45.26 ± 27.4) in men after exposed to sunshine as compare with before exposed (28.33 ± 18.6) and showed a significant increase in normal sperm morphology (58± 11.54) in men after exposed to sunshine as compare with before exposed (39.5 ± 16.49) (Table-2, Figure-3).

Figure 3: Show count, motility, viability and morphology of sperm before and after exposure to sunlight

### Discussion

The present study showed that there is a significant increase in the level of vitamin D3 that formed after the skin is exposed to direct UVB sunshine 10 min daily for 3 months and this elevation has a direct effect on reproductive testosterone hormone and increases the level of testosterone and vitamin D, which in turn, causes increased release of LH and FSH hormone. Eventually, this leads to increase count, motility, viability, and morphology of sperm. Also, it increases the level of vitamin D3 when the skin exposed to direct sunlight.

This is conformity with many earlier studies shown the association between sunlight and vitamin D3 where skin exposure to the direct UVB sunlight 7-dehydrocholesterol in the skin changed to pre-vitamin D3 which is changed in the liver to vitamin D3. The study also showed that there is a noticeable increase in the level of reproductive hormones LH, FSH, testosterone after exposure to direct sunlight and this is due to the effect of the increase in the level of vitamin D3 and this is consistent with previous research.

Some studies have confirmed the relation between the presence of vitamin D receptors (VDR) on the body of sperm and sperm activity and any deficiency in the level of vitamin negatively affects the activity of sperm and also through the future, vitamin D regulates the level of calcium necessary for the reproductive system and sperm activity.
Conclusion

Sunlight causes increase vitamin D3 level by action of UVB ray this lead to increase in the level of the reproductive hormones testosterone, LH and FSH, increase this parameter improve fertility by increase seminal fluid total count, actively motile, viability and normal morphology.

Recommendation

Expose to sunlight at least 10 min daily from 10.0 am to 3.0 pm o’clock to improve the fertility of infertile men before taking any drug for this purpose.

Abstract

The objective of this in vitro study was to evaluate the vertical marginal gap pre and post-cementation of IPS e.Max CAD crowns constructed using different die materials.

Materials and method: The thirty standard aluminum dies were fabricated to receive a full contour IPS e.Max CAD crowns. An impression with two-stage putty-wash impression with spacer technique was taken. The thirty impressions were distributed into three groups as follows; Group (A) Ten impressions were poured with type IV die stone, Group (B) Ten impressions were poured with type V die stone and Group (C) Ten impressions were poured with Exacto-form model resin die material. Each die was scanned and IPS e.Max CAD full contour crown was fabricated using Sirona CEREC in-Lab CAD/CAM System. Sixteen gap measurements were taken for each sample (Buccal, Mesial, Lingual and Distal), Pre and post-cementation process were measured using a digital microscope. The results of this study showed that there were statistically highly significant differences (P<0.01) between three different die materials groups of pre and post-cementation procedure. From the results of this study, it could be concluded that the Exacto-form provided the least vertical gap, when used IPS e.Max CAD full contour restorations. Die stone type V could be the next choice, which is preferred over to die stone type IV. Cementation step increased the marginal gap significantly.

Keywords: Die Materials, IPS e.max CAD, CAD/CAM , Pre and Post- Cementation Procedure, Marginal Fit.

Introduction

To obtain accurate and precise models with no distortion, it is important to acquire accurate impressions and to use stable and precise die materials. Die material is one of the factors affecting the accuracy of the replica[1] Type IV, type V gypsum (die stone) and polyurethane resin (Exatofrom) were widely used to pour the impressions. The properties of gypsum include high strength, low expansion easy to use, and allowing easy separation of the working cast from the impression. Polyurethane resin (Exatofrom) has been also used as die material for its accurate reproduction and maximum edge stability, extremely high fluidity of this resin allow pouring of impression with high precision and without the formation of bubbles[2].

Material and Method

A dentoform maxillary right first molar tooth (Dentoform, Nissin, Kyoto, Japan) was used in this study as an in vitro model and was duplicated to aluminum dies. The dentoform tooth then received a preparation with the following features: planar occlusal reduction of 1.5 mm, axial reduction of 1-1.5 mm, 0.8 mm circumferential chamfer finishing line and a 6° total convergence angle a modified dental surveyor. The prepared dentoform tooth was to fabricate 30 aluminum dies for each aluminum dieconventional impression using two-step putty/wash impression technique with spacer was taken using a specially designed special tray for this study. The impressions were randomly all located into three groups of 10 each according to the type of die material; Group A: die stone type IV (SHER AHRAD-ROCK ISO 6873, LOT78083LemfÖrde, Germany); Group B: die stone type V (schouten group dental N chang: 17.2595 Netherland); and Group C: Exatofrom resin die materials (Bredent,Senden, Germany LOT No.52000173). The die materials were mixed and the impression were poured with the die materials following the manufacturers instructions. After setting, the dies
were separated from their impressions and checked for any defect as air bubbles or imperfection.

In EosX Scanner (Sirona dental system, bensheim. Germany) was used to make ascans for each die model and MCX5 milling unite was used to millIPS e.max CAD crowns with 120µm spacer parameter. The marginal gap of the each sample was determined by seating the e-max CAD crown on its own aluminum die with the aid of a specimen holding device to provide a standard load of 5 Kg. Adigital microscope (Dino-Lite, Taiwan), was used at magnification of 230X connected to the computer to capture the images which were processed with Image J software to measure the marginal gap. Sixteen points were selected for measurements, 4 for each surface and the average was calculated for each specimen(3); the crowns were then cemented using Rely X U200 (3M ESPE, USA) self-adhesive resin cement with the aid of a surveyor under 5 Kg load(4). After cementation, the same points of measurements were re-examined again using the same procedure described previously to calculate the vertical marginal gap.

**Findings**

Table (1) shows the descriptive statistics which includes (mean and standard deviation values) of vertical marginal gaps pre-cementation. The results is evident that the lowest mean of vertical marginal gap values was scored by group C (55.073±6.299) (while the highest mean of vertical marginal gap values was belonged to group A (76.517±9.152). One-way ANOVA and LSD tests between the studied groups was a highly significant difference (P< 0.01).

The means and standard deviations of the marginal gap which were calculated for each group post-cementation are shown in (Table 2) and it showed that lowest mean value was recorded by group (C) which was 73.442±6.007 while the highest mean value recorded by group (A) which was equal to 94.0706±6.694. One-way ANOVA and LSD tests between the studied groups was a highly significant difference (P< 0.01).

Paired samples t-test was used to compare between the e.Max CAD crowns per-cementation and post-cementation , Table (3) and Figure(3) It is evident that the cement on increased the vertical marginal gap was statistically highly significant degree for all groups.

Discussion

High marginal accuracy is considered to be major determining factor for successful clinical performance of a restoration[6].

The results of this study showed that mean value of vertical gap of the three different groups revealed that at group(C) (Exacto-form) produced statistically the least vertical marginal gap both pre- and post-cementation. The findings was in agreement with [6] who that the mean marginal gap was consistently larger for type IV stone dies than polyurethane resin dies. The superiority of Exacto-form regarding vertical marginal gap in this study could be attributed to:

Figure (1): mean values of the marginal gaps for three groups pre- and post-cementation (in micrometer).

Figure(2)Microscopical image of the marginal gap for group A, Band C at a magnification of 230X pre-cementation procedure, (A: Crown, B: Marginal gap, C: Aluminum die).

Figure(3)Microscopical image of the marginal gap for group A, Band C at magnification of 230X post-cementation procedure, (A: Crown, B: Marginal gap, C: Aluminum die).
A. **Dimensional accuracy:** Gypsum die materials have been reported to exhibit setting expansion of 0.01 to 0.1%. This minimal expansion has been said to compensate for the dimensional changes inherent in the fabrication process of an indirect restoration. The process of gypsum crystallization is an expansive growth of crystals from a core of crystallization. Based on the interlacing of dihydrate crystals, the growth of the core crystals can combine and block the growth of adjacent crystals. If this process is repeated by thousands of crystals during their growth, an external tension will be developed that leads to “expansion of the mass, and the product of the gypsum reaction is larger than its external volume but smaller in crystalline volume due to dimensional change of die after final set”\(^1\). On the other hand, polyurethane resin (Exacto-form) was showed lower mean values in the vertical gaps, during polymerization the materials presents low shrinkage (0.060%) this change however was compensated and controlled by increasing the silica filler particles of the mix to 60% resulted in lower polymerization shrinkage of 0.025% to improve the dimensional accuracy of polyurethane die lead to more accuracy fit of indirect full veneer crown comparison gypsum die materials\(^7\).

B. **Detail reproduction:** Polyurethane resin has ability to reproduce details of up 1-2µm contrary to gypsum material which cannot reproduce details smaller than 20µm due to its crystal structure. With gypsum dies air bubbles are often formed at the interface of the impression and gypsum cast because freshly mixed gypsum does not wet some elastomeric impression materials led to it do not reproduce surface detail resin die materials because the surface of the set gypsum is porous on a microscopic level thus; polyurethane resin “Exacto-form” showed the best performance to the fine details present in this gypsum die\(^8\).

The results of this study revealed that at group (A) produced statistically the highest vertical marginal gap than group (B) both pre- and post-cementation in this study could be attributed to.

A. **Dimensional accuracy:** Type 4 gypsum differs from type 5 in that type 4, die stone V contain small amounts of extra salts (Sodium chloride) for shortens the setting reaction due to increased more number of nuclei of crystallization per unit volume increases, the setting expansion of the gypsum mass increases of 0.3% of type V stones than the 0.1% setting expansion of type IV stones, the desirable in this technique because it compensates for the contraction of the framework metals especially base metals\(^9,10,11\). On the other hand, setting expansion of the gypsum mass decreases it causes deformation of the prepared tooth was removed from impression might be another possible source for such inaccuracy\(^12\).

B. **Detail reproduction:** Die stone type V has ability to reproduce details than the die stone type IV because it had on Sodium citrate is a dependable retarder. Borax, Na2B4O7, is both a retarder and accelerator. A mixture of calcium oxide (0.1%) and gum arabic (1%) resulting in improved properties, compressive strength, hardness, abrasion resistant and reproduction details than the die stone type V, all properties with effected direct impact on fitted of final restoration\(^7,13,14\).

2. **Effect of cementation process**

The results showed that after cementation, the vertical marginal gap increased significantly. The cement layer may increase the marginal gap uncontrollably and unequally depending on the cement viscosity. One study revealed that the marginal gap increased by 18 to 22 µm when the crown was luted with cement. The high viscosity in self-adhesive cement resin create the problem of escape of excess cement and hydraulic pressure that is going to push the cement upward, this will result in great amount of luting cement to be accumulated on the occlusal surface of the prepared tooth, probably caused interfere with proper seating of crown restoration and prevents the crown from complete seating post-cementation process\(^15,16\). Vertical marginal gap values were increased significantly post-cementation; this is in total agreement with other previous studies: \(^5,17,18,19,20,21\).

**Conclusions**

Exacto-form resin showed better vertical and horizontal fitness than both die stone type IV and die stone type V. Cementation process significantly increased the vertical marginal gap values for all groups regardless the type of die materials but still within the clinically acceptable (< 120 µm).

Evaluation Inhibin B, FSH, and LH in Male with Thalassemia

Fatimah Kadhim Ibrahim AL- Mahdawi¹, Zaid Nabeel Elia², Hayder Abdulhafedh Kurji³
¹Medical Laboratory Technology Department, Bilad Al-Rafidain University College.²Medical Laboratory Technology Department, Erbil Polytechnic University.³Faculty of Pharmacy, Bilad Al-Rafidain University College.

Abstract

Background : - Hypogonadism is the most frequently reported endocrine problem, affecting 70–80% of patients with thalassemia. Aim of study: - The current study is aimed to found correlation among inhibin-B, FSH, LH and testosterone in male with thalassemia. Material and Subject: The study carried out 40 healthy volunteer male, age range between (18-30) years, and enrolled 40 patients with thalassemia major age range between 18-30 years. The concentrations serum inhibin-B was estimated by two-side enzyme-linked immunosorbent assays (ELISA), While FSH, and LH estimated by using Cobas e analyzers. Results: LH reduce significantly in thalassemia patients when compared with healthy individuals, while FSH and testosterone decrease significantly in thalassemia patients when compared with healthy. Inhibin B was reduced significantly in thalassemia patients when compared with healthy individuals. Conclusion: Infertility common in thalassemia patients, that correlation with decrease inhibin B. Key Words: - Inhibin B, FSH, LH and thalassemia

Introduction

Beta-thalassemia is a genetic blood disorder characterized by absent or β globin chain synthesis, resulting in decrease hemoglobin in red blood cells, reduced RBCs production and anemia[1].

The direct effect is an imbalance of the α and β globin chain synthesis that results in anemia from ineffective erythropoiesis and hemolysis[2].

The severity and prevalence of hypogonadism in thalassemia major differs among studies, dependent on the genotype of thalassemia and age group studied[3][4][5][6][7]. Dysfunction of the sexual and infertility due to hypogonadism are well-recognized disorders of the hypothalamic pituitary gonadal axis[8].

Hypogonadism is the most frequently reported endocrine problem, affecting 70–80% of patients with thalassemia. Luteinizing hormone (LH) and Follicle-stimulating hormone (FSH) are involved in the regulation and activation of the reproductive axis. Hormones produced via the gonad control LH and FSH synthesis and excretion in a feedback loop[9]. Inhibin-B exhibit a physiological role in the feedback regulate of FSH secretion, and reflects FSH-stimulated Sertoli cell to be the function[10]. Testicular functions can be evaluated via the basal hormonal FSH and LH[3].

Inhibin’s are presently predictable as paracrine testicular controllers and have many paracrine effects representing a promising marker for infertility in male[11].

Aim of study: - The current study is aimed to found correlation among inhibin-B, FSH, LH and testosterone in male with thalassemia.

Patients and Method

The study carried out 40 healthy volunteer male, age range between 18-30 years, and enrolled 40 patients with thalassemia major age range between 18-30 years. All patients received blood transfusion every 4-5 weeks.

The concentrations inhibin-B was estimated via two-side enzyme-linked immunosorbent assays (ELISA), While FSH, and LH estimated by using Cobas e analyzers.

All data are stated as mean ± stander error. The comparisons among groups were completed via t test.

The relationship between inhibin B, testosterone, FSH, and LH were determined using a pearson-correlation coefficient. P less 0.05 was measured significant. The SPSS software for windows, version 20 were achieved to all analyses.
Findings

Table 1 illustrated fertility parameters and inhibin B in male with thalassemia, the result showed LH within normal range (1.7-8.6mlU/ml) in thalassemia patients (3.37±0.62 mlU/ml) but reduce significantly when compared with healthy individuals (8.60±0.26 mlU/ml) p<0.000, while FSH and testosterone decrease than the normal range (0.5-4.3 ml/mL, and 3-10 ng/mL) respectively in thalassemia patients (3.07±0.31mlU/mL, and 2.20±0.28ng/mL) respectively, as well as decrease significantly when compared with healthy individuals (6.52±0.34mlU/ml, and 7.08±0.29ng/mL) respectively p<0.000. Inhibin B was within the normal range (25-325pg/mL) in thalassemia patients (45.61±4.69pg/mL), and also reduce significantly when compared with healthy individuals (102.14±3.10/mL) respectively p<0.000.

Discussion

Physiological inhibin-B production via the adult testis needs a normal population of Sertoli cells, Spermatogenesis and FSH stimulation, to be existing and it displays an significant role in feedback hormone regulation between the gonads and the pituitary gland\[12\][11]. Current results show a significant positive correlation among inhibin-B, FSH and LH in male with thalassemia. Bergada et al. 2002 report a significant positive correlation of men inhibin-B with men LH\[13\]. These results then funding the inhibin-B has a role in the physiological regulation of LH and FSH excretion in male and inhibin-B is the testicular feedback signal for FSH\[14\]. Testosterone and inhibin-B
and originate from different forms of cells in the testis [15]. In our results we found positive correlation among inhibin-B and testosterone concentrations. Inhibin excretion from Sertoli cells is controlled via interaction with germ cells and expression of α- and βB-subunit mRNA is maximal at stages of spermatogenesis which are greatly sensitive to FSH [16][17][18]. The mean values of inhibin B, LH, FSH and testosterone, in this study, there was highly significant decrease in thalassemia patients when compared with healthy individuals. An earlier study displayed that histological investigation of the testicular tissue in patients with thalassemia proved variable degrees of fibrosis in testicular interstitial with small deeply pigmented undifferentiated seminiferous tubules, hyalinized, and an absence of Leydig cells[19]. Because of developments in the current medical care systems, males with β-thalassemia major who receive life-long blood transfusions now live longer. Therefore, the fertility and reproductive endocrinology requirements for such men are becoming more significant. The results of this study showed a significant decrease in the level of pituitary and testicular hormones, and this may afford additional strong evidence to suggest that iron overload at high risk of being related with reduced function of gonad[20].

Serum Inhibin concentration have been stated useful to evaluate testicular function in many conditions [21]. In this study, they were lower than the healthy controls. This suggested that Sertoli cell function is abnormal in thalassemia patients and regular blood transfusions[22].

Serum testosterone levels, FSH and LH in patients with major were different significantly when compared with healthy controls suggested that the hypothalamic–pituitary–gonadal axis is defect. In addition, serum testosterone levels in thalassemia patients were lesser than in controls. This suggested that testicular function is weakened[23]. Other causes of these abnormalities may be related to the catabolic iron catalyzes the production of free radicals, resulting in oxidative stress in lipid membranes, lysosomes, mitochondria, DNA, proteins. This is maybe induced oxidative stress and direct effect in many organs, like, pituitary gland, hypothalamus, and female reproductive organs, other organs indirectly effected such as, pancreas and liver, and this will be contributing to the impaired the processes of metabolism of serum antioxidants and hormones [24]. Oxidative stress modulates the age-related decline in infertility in patients suffer from β-thalassemia [25].

Conclusion

Infertility common in thalassemia patients, that correlation with decrease inhibin B.

Anti-phosphoryl Choline and hs - CRP in Serum of Atherosclerosis Cardiovascular Patient with Chronic Periodontitis

Reham Adnan Radhi1 Alaa Omran ALmosawi1
1College of Dentistry, University of Baghdad/Iraq

Abstract

Background: Periodontitis and Atherosclerosis Cardiovascular disease are chronic inflammatory diseases which are highly prevalent. Over the last two decades, the amount of evidence corroborating an association between dental plaque bacteria and coronary diseases that develop as a result of atherosclerosis has increased.

The aim of study: was to evaluate the periodontal health status in study groups (Atherosclerotic cardiovascular disease patients with chronic periodontitis (ATH+CP) and patients having chronic periodontitis (CP)), to investigate the serum level of antiphosphorylcholine antibody-IgG(Anti-PC IgG), and the systemic level of inflammatory marker of cardiovascular diseases like high sensitivity C-reactive protein (hs-CRP) in chronic periodontitis with and without atherosclerosis cardiovascular disease as well as to examine the relationships between these mediators and clinical periodontal parameters.

Material and Methods: Blood samples were collected from sixty patients (30 CP patients and 30 CP+ATH patients) and from 25 apparently healthy volunteers were enrolled in this study. Periodontal parameters used in this study were plaque index (PI), gingival index (GI), bleeding on probing (BOP), probing pocket depth (PPD) and clinical attachment level (CAL) and Serum levels of Anti-PC IgG was estimate by enzymelinkedimmunosorbent assays (ELISA) and hs-CRP was estimate by immunoturbidimetric.

Results: The current data revealed a significant elevation (p<0.01) in median level of hs-CRP in CP group and CP+ATH group in comparison to that in healthy control, moreover, the comparison between two groups of patients showed significant differences between two groups (p<0.05). Whereas the serum level of antiphosphorylcholine-IgG was not observed significant differences between study groups (p>0.05) except for CP group when compared to control group (p≤0.05). Moreover, in regards to the correlation between serum antiphosphorylcholine –IgG and hs-CRP, and clinical periodontal parameters, did not show any correlation with clinical parameters of periodontitis (p>0.05).

Conclusion: inflammatory mediator (hs-CRP) may increase inflammatory activity in atherosclerotic lesions and potentially increasing the risk for cardiovascular events in CP+ATH, furthermore, about the effect of Anti-PC IgG in ATH +CP group, further studies are needed to obtain more understanding result.

Key words: Atherosclerosis cardiovascular disease, chronic periodontitis, Antiphosphorylcholine, hs C-reactive protein.

Introduction

Periodontitis is described as a multifactorial, irreversible and cumulative condition initiated and propagated by both bacteria and host factors and is also associated with various systemic conditions.

Atherosclerosis and its cardiovascular ischemic complications are the most common causes of death and disability worldwide. It’s a chronic lipid-driven inflammatory disease of the arterial wall characterized by the involvement of the innate and adaptive immune systems. Inflammation plays a critical role in the atherosclerotic process, starting from endothelial dysfunction through all stages of plaque build-up until its detrimental clinical ischemic complications.
Associations between periodontitis and atherosclerosis would be predicted based on inflammatory mechanisms initiated by bacteria associated with periodontal lesions, locally or systemically, that then influence the initiation or propagation of the atherosclerotic lesion. Such lesions may be initiated by inflammatory stimuli including systemic and locally produced inflammatory cytokines and chemotactic agents that cause changes in the endothelium such as up-regulation of adhesion molecules. These changes promote interactions with leucocytes, such as monocytes, that promote leucocyte migration into the intimal layer of the artery (5).

C-reactive protein is an acute-phase reactant that is mainly produced in the liver in response to a variety of inflammatory cytokines such as IL-6. It therefore serves as a marker for systemic inflammation in a variety of conditions (6). Abd et al. reported that elevated cell- and cytokine mediated markers of inflammation, including C-reactive protein, fibrinogen, and various cytokines, are associated with periodontal disease. The same elevated proinflammatory factors in PD have also been linked with atherothrombogenesis (7).

Phosphorylcholine (PC) is an immunogenic epitope in the capsular polysaccharide of Streptococcus pneumoniae and it has been suggested that the presence of serum anti-PC is partly a result of exposure to this organism (8). However, periodontitis patients exhibit elevated levels of anti-PC and this antibody reacts with 30–40% of bacteria in dental plaque samples, including periodontitis-associated bacteria and is demonstrated by higher serum levels of antibodies directed toward phosphorylcholine (anti-phosphorylcholine IgG) in patients with attachment loss, in comparison with those with healthy gingiva (9).

Shaw et al., in 2003 suggests that antibodies produced against certain periodontal bacteria would also react to phosphorylcholine bearing oxLDL (10) and, therefore, magnify the uptake of this lipid by foam cells, promoting further progress of atherosclerosis.

**Results**

The demographic results of patients groups and controls group included in this study are presented in Table 1, there was male’s predominance among study groups when compared to females. Furthermore, the differences in clinical periodontal parameters in patients and healthy controls are summarized in Table 2.

The current results revealed a significant elevation in median serum level of hs-CRP in CP group (0.210 mg/dl) and in CP+ ATH patients (0.575 mg/dl) as compared to healthy control (0.180 mg/dl), (p<0.01). Moreover, the comparison between two groups of patients showed that the median level of hs-CRP was increase in CP group but statistically not significant (p>0.05). Whereas the serum level of antiphosphorylcholine-IgG was not observed significant differences between study groups (p>0.05) except for CP group when compared to control group (p≤0.05) as revealed in table 3. Furthermore, in regard to the correlation between serum hs-CRP and Anti-PC IgG, and clinical periodontal parameters did not show any correlation with clinical parameters of periodontitis (p>0.05) as shown in table 4.

**Discussion**

The possible association between periodontitis (PD) and atherosclerotic cardiovascular disease (ASCVD) has received much attention over the past two decades. A comprehensive review was performed by an American Heart Association (AHA) working group (11), which concluded that “periodontal disease is associated with atherosclerotic vascular disease independent of known confounders”.

In the present study a predominance of CP group among males than a female as male less attitude toward good oral hygiene (12) as well as in ATH+CP as the Estrogen is protect female as it has multiple effects including effects on lipids, nitric oxide, vascular tone and antioxidant properties (13).
The current result was found that the mean value of (P.I, G.I, and CAL) were higher in ATH+CP group as compared to CP group which is in accordance with the observations of the Kumar et al.\(^{(14)}\), as they found that there was significant increase in mean of periodontal parameter (P.I, G.I) in ATH with CP patient compared to healthy control, Similarly Mohamad et al.\(^{(15)}\) found that the mean value of each P.I, G.I were significantly higher in periodontitis patients when compared to healthy controls, while Thakare et al.\(^{(16)}\) Deepa et al.\(^{(17)}\) found that CAL was more in ATH with CP as compared to CP group. The possible explanation the presence of dental plaque is the main clinical finding for CP and it is coincide with the severity of the disease and the time being with the disease and it is expected to be accumulating more in CP, another possible explanation of such results as the hospitalized ASCVD patients neglect the oral hygiene measures and didn’t brush their teeth regularly. In addition, CAL indicates the amount of the root surface denuded of periodontal attachment, thus it was used as an indicator of disease severity. The percentage of score 1 of BOP sites and CAL demonstrated by CP group were higher when compared with ATH+CP group, and these result was consistent with Androsz-Kowalsa et al.\(^{(18)}\) and Raheem et al.\(^{(19)}\) they found mean bleeding index in chronic periodontitis was significantly higher than in CAD with chronic periodontitis and control. The possible explanation for that percentage of BOP sites demonstrated by CP group was higher when compared with ATH+CP group, may be due to the presence of more inactive sites during clinical periodontal examination of ATH+CP group, also in CP the examining sites more than in ATH+CP group so ASCVD might be lead to tooth loss.

The present work is found increase in serum levels of hs-CRP in CP+ATH patients when compared to CP and control groups which is in accordance with the observations of the previous researchers\(^{(16,20)}\). The possible explanation for positive association existed between the presence of chronic periodontitis and high serum CRP levels because it is biologically plausible that inflammatory mediators, especially IL-1 and -6 and TNF-a are released under conditions of periodontitis and present the capacity to stimulate hepatocytes to produce CRP\(^{(21)}\). In addition direct actions of CRP which contribute to the induction of a prothrombotic state may be the enhancement of the procoagulant activity\(^{(22)}\) on the other hand, regarding IgG antiphosphylcholine revealed significant difference between CP group when compared to control group and these result in agreement with\(^{(9,23)}\) who found that patients with periodontal attachment loss have higher concentrations of anti-PC IgG than do individuals who demonstrate no attachment loss. The possible explanation for the higher level of serum IgG anti-phosphoryl-choline antibodies among CP patients in our study that inflamed periodontal tissues permit ingress of antigens from oral bacteria which leads to increased systemic production of anti-PC\(^{(23)}\).

Regarding the correlation between serum (hs-CRP and anti-PC IgG) and clinical periodontal parameters, hs-CRP did not show significant correlation. And these was agreed with Ide and co-workers reported that there were no correlation between serum hs CRP and clinical periodontal parameters and they concluded that improvement in periodontal health status by non-surgical periodontal treatment did not influence the serum levels of hs CRP\(^{(24)}\), in contract were inconsistent to that reported by others investigators \(^{(16,25)}\) they found that there was significant positive correlation between serum CRP levels and clinical periodontal parameters in ATH with CP and CP group. Finally, antiphosphoylcholine IgG did not show significant correlation with clinical periodontal parameters and our result disagreed with Schenkein et al.\(^{(11)}\) as they reported higher serum levels of antibodies (antiphosphorylcholine IgG) directed toward phosphorylcholine in patients with attachment loss, in comparison with those with healthy gingiva. The discrepancies observed between various studies could be caused, in part, to the differences in the sample size of each study, differences in types of samples used for each study and differences in sampling methods.

In conclusion current results suggest that elevation in inflammatory mediators (hs-CRP) may increase inflammatory activity in atherosclerotic lesions and potentially increasing the risk for cardiovascular events in CP patients. While for Anti-PC IgG the data show that many commonly occurring bacterial species found in dental plaque contain PC antigen and as a consequence of inflammation and periodontal attachment loss may influence systemic anti-PC antibody concentration, and on his role in atherosclerosis cardiovascular disease, further studies are needed to obtain more understanding result.

The Diagnostic Test in Lumbosacral Vertebrae Image towards Magnetic Resonance Imaging in Radicular Low Back Pain

Dhimas Hantoko¹, Isti Suharjanti¹, Sri Andreani Utomo²

¹Department of Neurology, ²Department of Radiology, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo Teaching Hospital, Surabaya 60285, Indonesia

Abstract

Background: Lower back pain is one of the most common consulted cases in neurology and neurosurgery. The approximately 80% of these cases are musculoskeletal disorders. Magnetic resonance imaging (MRI) is still a rare examination in the suburban area and requires a relatively high cost. Moreover, there are contraindications in patients who have cardiac pacemakers and metal objects in the body. The examination of lumbosacral image is easy to conduct. The price is relatively inexpensive and there are no contraindications to perform the test. Objectivity: This study aimed to assess the sensitivity and specificity of the lumbosacral image towards MRI in patients with radicular lower back pain. Method: The study was a clinical, cross-sectional study, analytical, and a diagnostic test design. It was performed on all patients with radicular lower back pain in Dr. Soetomo Teaching Hospital Surabaya from April to July 2012. There were 34 subjects who fulfilled the inclusion criteria. Results: The sensitivity of plain images to MRI in detecting radicular lower back pain was 87.5%. This figure indicated that the plain image had a high sensitivity. However, the specificity was only 50.0% which meant that plain image had a low specificity. Conclusion: The lumbosacral image had high sensitivity. However, the specificity was low for the examination of radicular lower back pain.

Keywords: diagnostic test, radicular lower back pain, sensitivity, specificity.

Introduction

Lower back pain (LBP) is one of the most heavily consulted cases in neurology and neurosurgery unit and approximately 80% is musculoskeletal disorders. Most patients who complaint of acute LBP will experience relapse after healing. LBP complaints can disturb daily activity and work productivity as well as most often attack the productive age which is less than 45 years ¹-³. The prevalence of LBP is about 67.6% of the entire adult population per year in Australia, 42.6% of whom have mild LBP and mild disability; Another 10.9% had severe back pain and mild disability, while the remaining 10.5% had severe disability ⁴. The mean prevalence of lower back pain in African teenagers was 12%, and adult age was 32% ⁵. The estimated prevalence of lower back pain in the United States is about 5-20% and around 25-45% of the population in Europe ⁶. Although epidemiologic data on LBP is not observed yet in Indonesia, it is estimated that 40% of Central Java residents aged between 65 years old have suffered from back pain and its prevalence in males was 18.2% and 13.6% in females. LBP is one of the ten causes of patients visiting a doctor. The cause of the pain is often not found even with neuroimaging test; thus, the patient returns with an idiopathic LBP diagnosis ².

One of the LBP diagnostic support tools is radiological examination. The best radiological modality to evaluate herniated disc is MRI with sensitivity and specificity of 96% and 97%. MRI has sensitivity of 89% - 100% whereas the specificity was 43% - 57%. MRI is the golden standard of herniated disc. Besides that, MRI can detect soft tissue abnormalities (muscles, tendons, and ligaments) as well as edema that occurs around herniation nucleus pulposus (HNP) and detect other serious disorders such as tumors or infections ⁷. MRI is still a rare examination in the suburban area.
and requires a relatively high cost. Moreover, there are contraindications in patients who have cardiac pacemakers and metal objects in the body. The examination of lumbosacral image is an easy task to be conducted because almost all local hospitals have conventional x-ray aircraft and they are relatively inexpensive. Furthermore, there is no contraindication to conduct such examination.

Based on several previous studies of lumbosacral bone radiographic assessment of 200 patients with non-specific back pain and no neurological signs, it suggests that radiographic examination of the lumbosacral vertebra is adequately represented by a projection that is only antero-posterior or lateral to reduce the risk of radiation. The National Institute of Clinical Studies Emergency Care Community of Practice issued a recommendation that routine radiological examination is not recommended for non-specific acute lower back pain (level III-2 evidence) in May 2007. Similarly, a study published by the British Journal of General Practice in May 2002 examined the psychological effects of lower back pain patients who performed radiological examination (X-ray photograph of the lumbar vertebra) at the beginning of LBP diagnosis established.

This study attempted to re-examine the diagnostic test of lumbosacral image towards MRI in radicular lower back pain patients to assess the sensitivity and specificity of the lumbosacral plain image towards the lumbosacral MRI. In addition, a neurological clinical examination has been performed to determine the diagnosis of radicular lower back pain.

**Method**

The study was a clinical, cross-sectional study, analytical, and a diagnostic test design. The sample collection was conducted in Neurology Unit dr. Soetomo Teaching Hospital Surabaya for 3 months. The research subjects are 46 patients with radicular low back pain who visited the neurological clinic Dr. Soetomo Teaching Hospital Surabaya, Indonesia and willing to fill and sign the informed consent. Then, a neurologic clinical examination was performed: anamnesis, provocation test, physiological and pathological reflex tests, motor, and sensory tests. Afterwards, it was examined a plain radiograph (Rontgen) in lumbosacral vertebrae of antero-posterior, lateral, and oblique projection after receiving description of the advantages and disadvantages of the photograph. Afterwards, a lumbosacral MRI was examined. The results of the examination were observed whether the abnormality was obtained or not.

The data was collected on the data collection sheet and the measurement result was expressed on the dichotome scale which was the nominal scale of positive and negative. The clinical examination results of lower back pain with radiological examination was analyzed using SPSS program (SPSS, Inc., Chicago, IL). The differences in the number of positive clinical and radiological findings were compared with the negative findings; then, it was also compared to MRI.

**Results**

Overall, there were 17 subjects of female patients and 17 male subjects. The subjects had the same complaints of radicular lower back pain or lower back pain that spreads to the back of the leg. There were 17 samples of males (50%) and 17 female samples (50%) with a ratio of 1:1 in this study. Table 1 described the characteristics of research subjects based on gender.

Note: MRI = Magnetic Resonance Imaging

Table 6 showed the sensitivity of plain images to MRI in detecting radicular lower back pain by 87.5%. This figure indicated that the plain image had a high sensitivity. However, the specificity was only 50% which meant that plain image had low specificity.

**Discussion**

This study obtained a description of the lumbosacral plain photographs, including osteophytes, end plate sclerosis, narrowing of the intervertebral gap, and spondylolisthesis, that is corresponding to MRI examination results: bulging intervertebral disc, protrusion, extrusion, causing radicular lower back pain or radiating from the root to the length of the sciatic nerve. This condition is diagnosed as herniation nucleus pulposus (HNP). Another finding in this study by examining the lumbosacral plain photograph is the description of the destruction of the corpus, vertebral pedicles and scalloping features. This corresponds to the results of MRI examination in the form of tumor masses, both metastases and primary tumors in the lumbosacral area.

The characteristics of the subjects by gender in this study obtained the same number of male and female that was 17. This is not in accordance with the epidemiology of lower back pain that stated that 40% of Central Java residents aged 65 years old have suffered from lower back pain and the prevalence in males was 18.2% and in women was 13.6% 14. The cause of this discrepancy can be some of the epidemiological shifts of most males with lower back pain. However, females mostly cause of the vast majority with LBP. They consisted of factory and office workers. Another reason was that the most frequent LBP patients who visited Neurology Unit in Dr. Soetomo Teaching Hospital was males than females. The subjects who experienced a drop out in this study was 12 male subjects. In addition, the most frequent age was 41-50 years old. This is consistent with the epidemiological theory that the majority of LBP patients are of productive age because their load is also greater. LBP complaint disturbs daily activity and work productivity as well as most often attacks the productive age which is less than 45 years old 14.

The most frequent onset was more than 24 weeks and categorized as chronic. It should be distinguished between specific lower back pain and nonspecific. Because this study only focused on the specific LBP subjects, most of them are in chronic condition that conventional or medical treatment was usually not solve the problem and recurrence often occurs. Unlike the nonspecific LBP types that are mostly due to musculoskeletal or mechanical factors, the complaint can be relieved usually by 2 to 6 weeks of therapy according to the severity of pain 1,15.

Table 3 showed the sensitivity of the lumbosacral plain image compared to the lumbosacral MRI (as the golden standard) as the figure was 87%. The specificity of the lumbosacral plain photograph was 50%. This corresponds to the literature: a radiographic examination of a plain photograph to detect lumbosacral vertebral abnormality has a sensitivity of about 85% and a specificity of approximately 60% 16. Thus, the hypothesis of this study aims to know the examination of plain images of the lumbosacral vertebra has a high sensitivity and specificity towards the lumbosacral MRI in patients with radicular lower back pain has been proven for the sensitivity of the lumbosacral plain photographs, but not for the low specificity.

The sensitivity here illustrates the sensitivity of the lumbosacral plain photograph as a diagnostic tool in detecting a radicular lower back pain, whether the subjects are really sick or not, and how likely it is that
the outcomes are positive or there are abnormalities. This sensitivity rate is derived from the proportion of the patients with positive diagnostic test results (true positive) over all patients (true positive + false negative). On the other hand, the specificity is the ability of the lumbosacral plain photograph to determine that the subject is not sick or normal and indicates how much probability the test result will be negative. In the results of this study, the positive predictive value of 96.6% is categorized as high. This means that if the subjects were examined with a plain lumbosacral image with a positive result, then 96.6% of the subjects suffered from a disease that causes radicular lower back pain. The negative predictive value is the probability that the subject does not suffer from the disease if the test result is negative. In this study, the results of negative predictive value of 20% indicates that there is a possibility of 20% of subjects who have been examined with plain lumbosakral image which results are negative and not suffer from disease that causes radicular lower back pain.

The interpretation of the diagnostic test result is influenced by several things, particularly the prevalence of disease and the severity of disease at the time of diagnostic testing. Other things to consider in assessing the accuracy of lumbosacral plain photographs include lateral and oblique positions are often confused by the iliac crest and gas image in the intestine and influenced by the accuracy of the radiographic technique as well as the radiologist’s skill. The weakness of plain photographs cannot detect abnormalities in the ligaments, muscles, nerves, and other soft tissues around the bone. A plain photo sensitivity of 85% and a specificity of 60% only applies to detect solid organs such as bone. Generally, neuroimaging has advantages as well as deficiencies that should be complementary, such as plain photographs (conventional radiography) and CT-scans have advantages in detecting abnormalities of solid organs such as bone and calcification.

On the other hand, MRI has more ability in detecting abnormalities in the soft tissues. Besides that, MRI can be drawn by multiple slices which can be rotated electronically on several orientations without changing the patient’s position. MRI is also non-ionic and non-invasive; thus, it does not have radiation effects on body tissues and make patients feel uncomfortable during the examination. However, MRI has several disadvantages, including hearing loss can occur temporarily due to the noise of this tool during the examination. A research showed a loss of hearing <15dB when the subjects did not wear earplugs in 43% patients, whereas only 10% when the subjects used earplugs with an average length exposed to the sound for 42.1 minutes. Furthermore, there may be an effect of increased temperature of the network by radio frequency absorbed of <1 W/kg. Ventricular fibrillation also can occur due to the influence of the magnetic field. This situation is influenced by the length of the pulse radiofrequency (RF) signal and repetition. It is stated that frequency >60Hz decreases the threshold value of ventricular fibrillation. MRI has a low sensitivity in detecting sub-arachnoid classification and bleeding and not provide comfort in patients with claustrophobia.

**Conclusion**

The lumbosacral image had high sensitivity (87.5%). However, the specificity was low for the examination of radicular lower back pain (50.0%).

Study of Gastroesophageal Reflex Disease in adult Type II Diabetes Mellitus Patients with Upper Gastrointestinal Symptoms

Maysam Riyadh Mohammed Hussein Alaasam¹, Sadiq Jabar Almohana², Hayder Nadhum Muhsen³, Jalal Jasim ALbdairi⁴

¹Internal Medicine, Lectural/Medical College Kufa University /Iraq, ²Internal Medecine Professor/Medical College Kufa University/Iraq, ³Internal Medicine / Alsader Teaching Hospital /Iraq, ⁴Internal Medicine. /Alsader Teaching Hospital / Najaf/ Iraq

Abstract
Gastrointestinal symptoms are relatively common in clinical practice in patients with type II diabetes mellitus. type II DM has been described as possible risk factor for the development of gastroesophageal reflux disease, in this study we aim to detect the prevalence of GRED in symptomatic patients with type II DM , also to see the accuracy of reflex disease questionnaire ( RDQ) in the diagnosis of GERD in patients with type II DM in relation to the esophagogastroduodenoscopy finding and to study the relation of autonomic neuropathy to the prevalence and stages of GERD in diabetic patients .

Methods: A ninety patients with upper gastrointestinal symptoms was divided in to tow groups according to whether had type II DM or not and then each group involved in a two stage process ( a ) – a RDQ , ( b ) – OGD.

And patients in the DM group underwent another step to detect diabetic neuropathy by a bed side clinical test.

Results: The prevalence of esophagitis in this study was higher in the DM group. RDQ had a statistical significance in detecting esophagitis in the DM group. There is no relation of autonomic neuropathy to the prevalence of GERD in diabetic patients .

Conclusion : The prevalence of GERD was high in patients with type II DM, RDQ is a sensitive tool for the diagnosis of GERD in diabetic patients, Autonomic neuropathy did not increase prevalence of esophagitis in diabetic patients .

Keywords: diabetes mellitus ,gastro esophageal reflex disease , RDQ, Esophagogastroduodenoscopy, Esophagitis.

Introduction
The current concept of GERD is “symptoms or complications associated with regurgitation from the stomach and or the duodenum to the esophagus” It is estimated that 15%-30% of the general population are affected by GERD(1,2)

GERD develops when the esophageal mucosa exposed to gastroduodenal contents for prolonged periods of time, resulting in symptoms and, in a proportion of case , esophagitis(2).

Note that some degree of gastroesophageal reflux is normal, physiologically connected with the mechanism of belching (transient LES relaxation), but esophagitis results from excessive reflux, often accompanied

DOI Number: 10.37506/ijfmt.v14i2.3405
by impaired clearance of the refluxed gastric juice. Restricting reflux to that which is physiologically intended depends on the anatomic and physiologic integrity of the oesphagogastric junction, a complex sphincter comprised of both the LES and the surrounding crural diaphragm. Three dominant mechanisms of esophagogastric junction incompetence are recognized: (a) transient LES relaxations (a vagovagal reflex in which LES relaxation is elicited by gastric distention), (b) LES pressure decrease, or (c) anatomic distortion of the esophagogastric junction inclusive of hiatus hernia (1,2).

Transient LES relaxations account for at least 90% of reflux in normal subjects or GERD patients without hiatus hernia, in many studies the first two mechanisms and other factors such as abdominal obesity, delayed gastric emptying, disruption of esophageal peristalsis, autonomic neuropathy, metabolic syndrome were thought to be a possible risk factors for the high prevalence of the typical GERD symptoms in patient with DM, but up to present, the pathogenesis of GERD in type II DM patients has not been fully clarified (3,4,5).

Peripheral and autonomic neuropathy especially has become a research hotspot in recent years, however, the impact of the above factors on the presence of GERD symptoms in type II DM patients is still under debate (3,6).

Patients with GERD may present with heartburn and regurgitation which are the major symptoms of GERD, somewhat less common are dysphagia and chest pain and a variety of other features has been described, and depending on this a clinical system of symptom-based diagnosis of GERD was made the so called reflex disease questionnaire RDQ (7).

RDQ comprises 6 questions assessing the frequency of heartburn, substernal chest pain, acid regurgitation, nausea, need for the medication, and trouble getting a good night sleep because of heartburn or regurgitation,per week, as shown in table 1.

**NOTE:** Add the point values for each corresponding answer. Total score of 0 to 2 points = 0 percent likelihood of GERD; 3 to 7 points = 50 percent likelihood; 8 to 10 points = 79 percent likelihood; 11 to 18 points = 89 percent likelihood.
Several investigation used to evaluate patients with suspected having GERD of which endoscopy is the initial investigation of choice, it used for the diagnosis and grading of GERD and to exclude other upper gastriointestinal disease that can mimic GERD and to identify complications.

**Aim of the Study**

To study the prevalence of GERD in symptomatic patients with type II DM in relation to non DM, also to see the accuracy of RDQ in the diagnosis of GERD in patients with type II DM in relation to the OGD finding and to study the relation of autonomic neuropathy to the prevalence of GERD in diabetic patients present with upper gastro intestinal symptoms.

**Patients and Method**

This study was conducted in Alsader medical city, in Alnajaf center for gastrointestinal and hepatic diseases in which 122 adult patients referred for upper endoscopy because of upper gastrointestinal symptoms suggestive of GERD between March 2014 and March 2015 participate in this study.

Exclusion criteria were type I DM, esophageal motility disorder other than ineffective esophageal motility, patient with hiatus hernia and patient with a RDQ less than 8.

After performing the exclusion criteria a 90 patients were considered eligible for this study 31 of them were females and 59 were males.

The recruitment patients were divided into two groups according to whether had a type II DM or not, the diagnosis of type II DM based on WHO definition (Defined as fasting blood glucose $\geq$ 7 mmol/l or on glucose medication for raised blood glucose or with a history of diagnosis of diabetes.)

The then every group involved in a two stage process (a) Reflux disease questionnaire (RDQ) and patients with at least a minimal score of 8 had been chosen as the (RDQ) likelihood of GERD were as fellow:

1. A total score 0 to 2 = 0 percent likelihood
2. A total score 3 to 7 = 50 percent
3. A total score 8 to 11 = 79 percent
4. A total score 12 to 18 = 89 percent.

(b) OGD by the use of Olympus or pentax ED-3490 TK 4.2 HOYA corporation endoscopy system, which used in the diagnosis and staging of esophagitis according to Savery-Miller classification in these patients.

(c) the patients with DM group underwent another step during interview by being underwent a simple clinical test to detect the diabetic autonomic neuropathy (a bedside test for the absence respiration-associated sinus arrhythmia by monitoring the pulse rate by a pulse oximeter while the patient instructed to breathe slowly and deeply at a rate of 6 breaths per minute, heart rate normally increase with inspiration and decrease with expiration, and at a respiratory rate of 6 per minute the difference between fastest and slowest heart rate is usually more than 15 per minute, a difference of 10 beats per minute or less are observed in autonomic dysfunction.

**Statistical Analysis**

Statistical analysis were performed using spss 16 program correlation analysis was also performed.

A P value $<0.05$ was considered significant.

**Results**

Ninety patients were included in this study and divided in to two groups a thirty patients in DM group and sixty patients in the non DM group.

In the non DM group 22 of them were females(36.66%) and 38 were males(63.33%) with a mean age of (46.7 years±8.2).

In the DM group 9 were females (30%) and 21 were males (70%) with a mean age of (51.2 years±9.3). As shown in table 2.

The prevalence of esophagitis in this study were higher in the DM group as upper OGD results showed esophagitis in 32 patients of the non DM group (53.3%) and in 23 patients of the DM group(76.66%) with a statistical significant results (p value=0.03236) as shown in table 3.

</tr>
</tbody>
</table>

In the DM group the clinical bedside test for autonomic neuropathy revile an autonomic dysfunction in 16 patients of 30 (53.33%) and 14 patients show not (46.6%).

13 (81.2%) of the 16 patients with DM and autonomic dysfunction were diagnosed with esophagitis by OGD and 3 patients show no sign of esophagitis by OGD(18.7%), while in patients with DM and without autonomic dysfunction there were 10 patients of 14 (71.4%) diagnosed with osephagitis by OGD and 4 patients(28.5%) are not, so there were no statistical significance P value=0.5287 as shown in table 5.

Discussion

Diabetes is a major health problem, as it is an important contributor to various other diseases, and its incidence still continues to rise. Gastrointestinal symptoms are relatively common in clinical practice in patients with type II DM. Type II DM has been described as possible risk factor for the development of GERD. Several studies reported that the prevalence of GERD symptoms in the type II DM was approximately 25%-40% in different populations\(^\text{11,12,13}\), in these studies several methods used in the diagnosis of GERD includes; RDQ which had a sensitivity of 79% in the diagnosis of GERD at 8-11 score level in non DM patients; Endoscopic examination which had high specificity but low sensitivity for the diagnosis of GERD with a sensitivity about 55% for detecting esophagitis and other complications\(^\text{14,15}\) and ambulatory PH monitoring which is indicated if diagnosis is unclear or surgical intervention is under consideration, although the test yields accurate and reliable information it is inconvenient for the patient and many clinicians do not have access to the appropriate instrumentation and are unable to perform this test\(^\text{16}\).

In this study a combination of RDQ and OGD is used to study the prevalence of GERD in patients with type II DM as a previous study by Lemeneh Tefera, B.A., Martin Fein.\(^\text{16}\) shows that this combination had a high proof value 98% and high specificity 97% for the diagnosis of GERD in non DM patients, in this study we found that the prevalence of GERD in adult symptomatic patient with type II DM as diagnosed by OGD were high 76.7% comparing to non DM patients 53.3% with a P value =0.03236.

We also found that the RDQ at level score >8 had a good prediction rate for esophagitis which about 80% in symptomatic patient with type II DM as the OGD result showed esophagitis in 76.66% in patients with type II DM comparing to non DM patients in regard to the sensitivity of RDQ with a P value=0.00244. and this was constant with a study by Yu Bai, Yiqi Du, Duowu Zou, Zhendong Jin and others, that suggest that the RDQ may be used for the diagnosis of GERD\(^\text{17}\).

In previous studies neuropathy were thought of as possible risk factor for the prevalence of the typical GERD symptoms in DM patients (13,20), for example, in 2008, Wang et al.\(^\text{13}\) reported that the prevalence of GERD symptoms was higher in patients with neuropathy than in patients without neuropathy, in this study there were no significant difference in the prevalence of esophagitis in DM patients with or without neuropathy with a P value=0.05287, this results are similar to the studies of Clouse and Lustman \(^\text{21}\) and Lee et al. \(^\text{19}\), In 1989, Clouse and Lustman, through analyzing 114 diabetic subjects with gastrointestinal motor dysfunction symptoms, reported that gastrointestinal symptoms occurring in diabetic patients were poorly related to neuropathic complications. In 2011, Lee et al.\(^\text{19}\) studied 119 patients with type II DM and found that there was no significant difference in the proportions of patients experiencing typical GERD symptoms between the two groups of type II DM with and without neuropathy.

Conclusion

The Prevalence of GERD were high in patients with type II DM, RDQ is a sensitive tool for the diagnosis of GERD in those patients, Autonomic neuropathy did not increase prevalence of esophagitis in diabetic patients.

Conflicts of Interest: None of the authors have any conflicts of interest relevant to this research subject.

Ethical Clearance: the study was conducted in accordance with ethical principles that have their origin in the Declaration of Helsinki. The study protocol, care of patients and subject information were reviewed and approved by a local Ethic committee.

The Effect of Health Information Technology on Time and Cost Saving in Remote areas of Iran

Mahdie Shojaei Baghini¹, Massume Mir Nejad², Sedisghe Shojaei Baghini³
¹Medical Informatics Research Center, Institute for Futures Studies in Health, Kerman University of Medical Sciences, Kerman, Iran, ²Zabol University of Medical Sciences, Zabol, Iran, ³District Education 2, Education Department of Kerman Province, Kerman, Iran

Abstract

The present study aims at investigating the effect of health information technology on time and cost saving in the perspective of users of teaching hospitals in in remote areas of Iran.

This is an applied study with a descriptive-analytical and cross-sectional method conducted on users of hospitals in remote areas of Iran using stratified random sampling. Data collection instrument was a self-made questionnaire, the face validity and reliability of which were confirmed by Cronbach’s alpha 0.94. Data were collected in person and analyzed by SPSS software V. 21 and descriptive and analytical statistics.

Based on the Chi-square test results, there was a significant relationship between the effects of health information technology on time saving as well as cost saving. The results of Kruskal-Wallis test showed no significant relationship between education level, age and work experience and time and cost saving as well.

User satisfaction is one of the most important aspects of the success of information systems, therefore, it is recommended that senior managers pay attention to the individual aspects of the employees working in the organization, provide them with necessary training before implementing the information systems, and involve them in the decisions in using such technologies.

Keywords: Health information technology, time saving, cost saving, remote areas

Introduction

The application of information technology¹ in organizational activities is one of the most important reasons that distinguishes the organizations. As such, organizations that use IT widely and optimally have a sustained competitive advantage and are more distinguished in the perspective of stakeholders.¹ Obviously, IT plays a significant role in organizations. It can enhance the capabilities of organizations and reduce costs.²

Based on the literature, it is expected that in health care organizations, using health information technology² can improve the quality of health services, prevent medical errors, optimally manage health care costs, increase management efficiency, improve productivity, and reduce paperwork.³ However, in practice, according to the results of various studies, using HIT can have different and sometimes contradictory effects. For example, the results of some studies indicate the positive effect of technology on enhancing the quality of documentation, frequency, accuracy and completeness of nursing diagnosis, quality of health services, preventing medical errors, managing costs and increasing efficiency⁴, 5, 6, 7 & 8. In addition, people who experienced numerous failures in using the clinical information system were less inclined to the new information system. They believe that the benefits of HIT depends on the type of technology used and on how the technology is applied⁹, 10, 11, 12, 13, 14, 15, and 16. Nowadays, the tendency to use health information systems has grown dramatically as the role of information

in the field of health care delivery becomes more important, but clearly, there is no clear answer to the question that how much investment and spending costs on this issue improves the quality and reduces cost of health care services and more profitability for health care providers and physicians. Responding to this ambiguity will convert the IT concept as a costly plan into a means of achieving value added, and prevents ambiguities that delay or even prevent some centers from investing in IT, and considering the importance of accurate and timely provision of health services and patient information and the role that health information technology can play in this regard, the present study is mainly concerned to investigate the effect of health information technology on time and cost saving.

Method

This is an applied study with a descriptive-analytical and cross-sectional method conducted on users of hospitals in remote areas of Iran in 2017, in which stratified random sampling method was used. Based on the Morgan formula, 256 subjects out of 720 Health Information System users were selected through stratified random sampling with proportional allocation. Data collection tool was a 24-question self-made questionnaire with 5-point Likert scale, designed using theoretical foundations. The first part of the questionnaire was measured the demographic information of the respondents. Out of 24 questions in the second part, 10 questions pertained to measuring the effect of health information technology on time saving and 14 questions pertained to measuring the effect of health information technology on cost saving. Considering that the Likert scale (very high, high, moderate, low, very low) was used for scoring, the range of scores varies from 1 to 5 in each phrase, therefore, all of the questions had a positive score, with the score 1 for very low and 5 for very high. Validity of the questionnaire was confirmed by health information management experts. In order to calculate the reliability, the questionnaire was distributed among 40 subjects and confirmed by Cronbach’s alpha coefficient 0.94. Data collection was conducted through in person referring to the workplace of the research population. If necessary, the research population was provided with explanations to the questionnaire items. Questionnaires were completed through self-administration at the same time and / or as a follow-up in the future. Data were analyzed by SPSS software version 21 and descriptive statistics (Frequency, standard deviation, mean,) and inferential statistics (Kruskal-Wallis, chi square tests) and the P-value was considered 0.01. Finally, the mean scores were classified, with the mean score of 1-3 in the low effect range, 4-4 medium effect and 4-5 high effect.

Findings

The majority of respondents aged 26 - 35, with a work experience of less than 5 years, with a Bachelor’s degree. According to the research findings, the effect of information technology on time and cost saving was positive in the perspective of the research population, with a mean score of 4.23. Subjects evaluated the effect of information technology on time saving with a mean score of 4.09 and on cost saving with a mean score of 4.37. Chi-square test results indicated a significant relationship between the effects of health information technology on time saving as well as cost saving (Table 1).

The Kruskal-Wallis test was used to analyze the hypotheses of the relationship between the effect of health information technology on time and cost saving in terms of education level, age and work experience. Test results indicated no significant relationship between education level, age and work experience and people’s perspective on the effect of health information technology on time and cost saving (Tables 2 - 4).

**Discussion**

The findings in the present study indicated that the amount of time saving of information technology is high in the perspective of users. This finding is consistent with the results of Dehghan and Ghorbani, Bertsche et al., Rollman et al., Lyerla et al., Walsh et al., Akbari-Nassaji et al., McMullin et al., and Nies et al.

To justify this issue, it can be stated that HIT plays a significant role in personal health management, health care delivery and public health. In these domains, widespread use of IT can improve the quality of health services, prevent medical errors, increase management efficiency, reduce paperwork and increase productivity of health services.

Concerning the effect of health information technology on cost saving, the findings also indicated that information technology has significantly led to cost saving. This finding is consistent with the results of Dehghan and Ghorbani, Bertsche et al., Rollman et al., Lyerla et al., Walsh et al., Akbari-Nassaji et al., McMullin et al., and Nies et al.

Investing in HIT has many benefits that may sometimes have measurable financial effects such as improving physician-patient relationships and increasing incentives for physicians and nurses, however, some of these benefits are simply measurable, including those that have the most benefits in the field of inpatient and outpatient care. These items include reducing the need for repeating tests and radiographs, reducing the cost and amount of medication, reducing patients’ length of stay, reducing the cost of documentation and reducing overtime and reducing nurses’ wasted time, increasing patient access to care, and reducing costs, decreasing the process time, increasing the variety of services provided, reducing the complaints from treatment personnel, and increasing the staff retention in their posts. In order to justify this point, it can be stated that according to the indicators of the US Health Care Management Information Center, there are fourteen areas of use in hospitals for information technology, so that using such applications are important in terms of affecting the quality of care, reducing costs and budgeting priorities.

Based on the results, there is no significant difference between the effects of HIT on time and cost saving and demographic information of users of hospitals in remote areas of Iran’s including education, age and work experience. Younger users reported that HIT had a greater effect on time and cost saving. Also, users who had less experience reported that HIT had a greater effect on time and cost saving. No similar research was found in this regard.

In general, the results of this study were consistent with the findings of Dehghan and Ghorbani, Bertsche et al., Rollman et al., Lyerla et al., Walsh et al., Akbari-Nassaji et al., McMullin et al., and Nies et al. The application of HIT not only enhances the status of clinical decision-making through the speed of...
and ease of information retrieval, but also affects other managerial and executive processes and other applied aspects of information in education and research which also leads to the effectiveness of the health system, which leads to the realization of the main goal of the health system, that is the promotion of community health. HIT plays a role in personal health management, health care delivery and public health. Of course, evidently achieving these benefits depends on the acceptance of technology by users, i.e. the positive attitude of users towards technology. The results of the study by Ayanlade et al., Kindratt et al. and Sebetci indicated that the strong understanding of staff and patients about the implementation and acceptance of HIT leads to achieving its benefits.

**Conclusion**

User satisfaction is one of the most important aspects of the information systems success. In addition, when using a new technology is supported by health professionals with respect to existing values and professional needs, they will not only have greater confidence in the use of IT, but also a higher degree of understanding and benefits of the system and will likely make better use of this technology, therefore it is recommended that senior managers and healthcare professionals pay more attention to the individual aspects of the organization, provide the training required prior to the implementation of information system, familiarize them with the benefits and capabilities of new technologies and also involve them in the decisions made to use such technologies. In the present study, it can be concluded that the positive view of the staffs in teaching hospitals of remote areas of Iran on the effect of HIT on time and cost saving indicates the availability of proper cultural groundwork for development of the information technology in university hospitals. Considering the growing global demand for health care information systems and competitive efforts in health care centers, the awareness of system managers and users on the effectivity of this technology on the qualitative and quantitative improvement of the health care services and developing a strategic HIT programs will guarantee the effectiveness of investing in this area with greater confidence.

**Acknowledgment:** Thereby the authors appreciate the cooperation and contribution of officials and personnel of the teaching hospitals of remote areas of Iran.

Iron Overload Complication in Thalassemia Patients

Khdsayer T. Rotha
Lecturer, Kut Technical Institute/Middle Technical University, Iraq

Abstract

Thalassemia is an inherited disorder. All the types of thalassemia that require continuous blood transfusion, lead to increase of absorption of iron, which will lead to iron overload eventually. The precipitation of iron will affect many organs in the human body, and can be measured by S- ferritin.

In this study, patients with all kinds of thalassemia that require multiple blood transfusion, have been evaluated for the level of ferritin and iron overload as well as other complications such as liver diseases, heart diseases, bone disorders, and hormone disorders. One-hundred patients have been selected randomly with different ages to evaluate the serum ferritin, calcium level, liver enzymes, and Hb by use enzyme linked assay. This study confirms the use of chelation therapy to remove the iron overload.

Keywords: iron overload, thalassemia, GPT GOT, hormone disorder

Introduction

Hemoglobin, which is a red pigment that gives the RBCs their color, is presented around the RBCs. This pigment has the ability to transport loaded oxygen from the lung to other cells of body tissues and carries carbon dioxide from tissues toward lung. The globulin, which is the proteinaceous subunit of the hemoglobin, contains two kinds of chains; alpha and beta. These two chains are in association with the hem group that contains the iron atoms in form of Fe^2+. Despite the fact that the two chains are required for normal oxygen transportation, the alpha chain is expressed before birth, however, the beta chain does not and its expression is delayed for few months after birth. The synthesis of hemoglobin is controlled by specific genes in DNA. There are four genes control alpha chain expression whereas there are two genes control the beta chain expression.

The normal value of serum ferritin (a protein that stores iron in the body) is 160-180 mg/dl and the daily requirement is deferent from man and woman. In the adult man (19 years and older) the value is about 8mg/dl, whereas this value in the pregnant female may reach up to 27mg/dl. However, this value is only about 18mg/dl in non-pregnant women.

Many food sources are rich in iron especially animal products such as meat, liver, fish, and chicken. The non-hem sources such as plant iron.

We need to examine hemoglobin (HB test) in many cases such as the state of anemia (hemoglobin deficiency) and the iron overload which leads to hemochromatosis. Generally, the determination of the level of iron is carried out at the morning because during this period, the level of iron is in the maximum. Usually, the measurement of the level of iron, which represents the iron binding with transferrin, the total iron binding capacity, the ability of iron of binding with transferrin (TIBC) and the amount of iron. The mean the amount of iron that binds with transferrin is (400-250) mg/dl and transferrin saturation is (10%-50%) in men and (15%-50%) women ferritin. This gives the most indicators to the level of iron normally.

Heamatochromatosis means the accumulation of iron more than the normal value, which is genetic disorder, and may be resulted from the repetitive blood transfusion such as in thalassemia.

The symptoms and signs of Hematochromatosis are the change in the skin color into dark color, jaundice due to elevated bilirubin which gives yellowish of color of the skin, and painful joints that occurs due to iron precipitation in different organs of the body such that occurs in thalassemia.

Finally the iron overload (Haemotochromatosis), which occurs as a result of repeated transfusion of blood to the patient of thalassemia represents one huge...
problem to these patients because the human body does not have the ability to eliminate the excess iron, therefore, patients with thalassemia suffers from many disorders and disease and discoloration of patient such as liver disease, diabetes, heart abnormalities, disease Ferro protein disease, and decrease the secretion of hormones \(^{(4)}\)

Continuous blood transfusion to the patient with thalassemia the main reason of iron overload which precipitate in the deferent organ and tissue and cause many deferent problems, to prevent happen iron overload use long term of chelation treatment to prevent (indochrinopathies and cardiomyopathy) \(^{(5)}\)

**Material and Method**

About100 patients of thalassemia, who are all suffering from iron overload, have been selected randomly regardless of gender, age, and social background at the Center of Thalassemia in Kut province. by drawing venous blood from the patients, preserving their blood by cooling using the refrigerator not long to make the tests like s-calcium, s-ferritin and the other tests in table (2), and the instruments use in the tests, the electrophoresis and spectrophotometer, all the tests carried out in labs of kut center ofthalassemia treatment

**Statistical Analyses**

The data statistically analyzed by using spss-18 and sample t-test statistical program and the result of analyzing find the parameter report and the control and p-value for every parameter report p-value 0.05 or less consider significant.

**Findings**

The results showed that most of the patients were at the ages of youth and childhoods. Most of the sampled patients were from relative parents who were with different education levels; however, most of the parents were non-educated (Table 1). Most of the families were having one patient with the average value to the serum ferritin was about 4316 ng/ml. Deferoxamine, which is used as chelating factor to prevent overload of iron, is only used in patients who are less than 18 year of age. To diagnose thalassemic patients, electrophoresis method is used routinely in order to differentiate between the normal hemoglobin and defected hemoglobin. This test could differentiate the patients with thalassemia according to the particle size of the hemoglobin and electrical charge of these particles. All other parameters measure with colorimetric method which the concentration proportion with depth of color includes the serum Ca\(^{2+}\), serum ferritin, serum GOT, serum GPT, serum Urea, and serum Creatinin.

In this study 100 patients with thalassemia have been selected randomly during 2018. Their ages were from one month to 30 years. However, only few were at 51 years of age and most of them were less than 30 years. The number of male and female was nearly equal. The table also shows the presence or absence of more than one patient in the same family and the frequency of the complicating disease (Table 1). Most of patients were taking chelating factor Deferasirox.

Table 2 shows the differences in value of some parameters between the patients' serum and the apparently healthy individuals. The value of the serum ferritin was highly elevated in patient than in control (4316± 311.22 ng/dl, whereas the normal 150± 80 ng/dl). No bilirubin was detected more than normal (no jaundice). In addition, enzymes of liver were also with high reading level than to the normal GOT and GPT as reported. The HB less than to the normal especial before transfusion HB=8.92±8 when the control equal13±0.6
so can see the deference and the anemia that the patient suffering as a result of decrease of HB.

**Discussion**

From the data parameters changing than to the normal as a result of elevated ferritin in blood, and this could be attributed to the precipitation of iron on deferent glands and organs. The free iron found in the blood is highly toxic to cells in the body. On the other hand, iron in serum bind with transferring, however, some of iron may present as non-binding iron especially when the concentration of iron exceeds the iron binding capacity of blood. There are a number of mechanisms to protect against the toxicity of free iron, which binds iron to various parts of the tissues. Ferritin appear in the blood although its role is unknown thalassemic patients need blood transfusion continually causing excess load of iron in human body. These patients not have any physiological method to remove excess load of iron. Non transferrin iron binds easily to translated with calcium canal to the liver (hepatocyte), heart (cardiac myocytes), and the other endocrine glands. The accumulation of iron in these organs leads to multiple complications. The most important complication of iron over load is the siderosis of heart, which may lead to heart failure, and considered as main reason of death. In addition, liver dysfunction could be observed for the same reason. Reports indicated that 25% of cardiac siderosis affect the patient of thalassemia in South East Asia and affecting 15 -20 % in Middle East (6).

From the data in (Table 1), we found that the level of calcium was less than normal in the patients because of the precipitation of iron on and in the parathyroid gland, which will reduce the secretion of parathyroid hormone. This hormone is the main factor that controls the level of calcium and phosphorus ion iron over load (7). This occurs in large number of patient of thalassemia as a result of increase absorption of iron in gastrointestinal tract and multiple transfusion of blood and inappropriate iron chelation therapy and this will lead to accumulation of iron in liver, endocrine glands, and heart eventually (8-9).

In our study, we found that the level of ferritin was 4316 gm/dl and this value is about eight fold higher than normal (Table 2), which lead to precipitate iron in liver and injury and fibrosis. Therefore, the levels of the transaminase enzymes s-GOT and GPT were highly elevated in comparison to the normal (s-GOT 39 IU/L and S-GPT 46 IU/L, respectively) (10,11,12).

Liver is the main organ to metabolism and for storage iron, hence, highly affected by the toxicity of iron. When iron accumulates in liver, it may cause lipid peroxidation may and may lead to hepatocyte necrosis and apoptosis. The end results for this pathway is hepatic fibrogenesis, which affects the collagen production and lead to fibrosis (13,14). As mentioned above, the complication of iron overload include heart disease (heart failure due to cardiac siderosis), chronic anemia, liver disease liver injury, liver fibroses, and as result viral hepatitis, hypogonadism, and bone disease. Our results indicated the absence of any effect of the iron overload on kidney and the parameters limited the health of renal function s-urea, and s-creatinin found in normal value as indicate in table (2).

Relationship between Diet Quality and Obesity in Tikrit Secondary Schools Students

Athraa Essa Ahmed; Shaimaa Essa Ahmed

1 Family and Community Medicine Department, College of Medicine, Tikrit University; 2 Basic Science, College of Dentistry, Tikrit University, Iraq

Abstract

This study to estimation the relation between diet quality and adiposity measures among secondary school students in Tikrit City. Patients and methods: cross-sectional descriptive epidemiological study was carried out to estimate the relation between diet quality and it’s association with anthropometric changes among 153 students (80 girls and 73 boys) in secondary school students in Tikrit city and also its association with demographic differences selected by means of a simple random sample. Results: In this study, a total of 153 secondary school students were surveyed. The majority were females (52.29%) and most of them (41.25%) were between 16-18 years old. Most of them (55.56%) had a BMI range from 18.5-25 and their waist-to-height ratio (< 0.5) were (67.32%). (32.03%) of students had a family history of obesity while (67.97%) had a negative family history. Conclusions: Most of the students have a normal BMI (55.56%) , so the frequency of overweight was more common in female gender (60%), while in male (50.68%). And (32.03%) of students had a positive family history of obesity while (67.97%) had negative family history, From students who have a positive family history, (32.66%) had an overweight BMI (25-30) and (44.9%) waist-to-height ratio which considered as indication of central obesity.

Keywords: diet quality ; adiposity measures ; secondary school students ; Tikrit city

Introduction

In adolescence and childhood , it was suggested that food should have a lasting impact on the child’s development in various aspects of life also on Chronic disease as the obesity (1) . Good nutrition with healthy diet during childhood and adolescence is essential for growth, development, health and well-being (2). Unhealthy diet is considered as a behavioral risk factor for hypertension and other cardiovascular disease (3). Obesity increased in the societies due to poor eating habits like increase consumption of sweetened beverages, energy-dense foods and change in the eating behaviour to Consumption of refined grains; fats added; sugars added; snacks; Drinks; eat away from home (4). Obesity is often defined as a state of abnormal or excessive fat accumulation in adipose tissue, to the extent that health may be impaired (5) and obesity is measured in various ways such as body mass index (BMI); percentage of body fat measurements; Waist-to-hip ratio; waist circumference; and skinfold (5).

High rate of overweight and obesity in many countries has been described as a global pandemic (6-8). In the previous, the obesity is a problem in only high income countries , but now obesity and overweight become increased in both low- and middle-income countries, especially in urban region (9).

In 2016, more than 1.9 billion adults, 18 years and more than , were overweight from 650 million were obese (10), also in in 2016 more than 41 million children with age less than 5 years suffering from overweight or obese (11). Also in 2016, more than 340 million children and adolescents with aged range from 5-19 were suffering from overweight or obese (11). So prevalence of overweight and obesity among children and adolescents in age range 5-19 years were increased from 4% in 1975 to 18% in 2016, overweight in boy (19%) more than girls (18%) (11). Nearly 1 in 5 children and adolescents are overweight or obese (11).

Diet quality also associated with mental health problems such as depression (12). Eat perfect food is associated with an increase in life expectancy, a
significant reduction in the risk of chronic disease throughout life, and improved gene expression\(^{(13)}\).

In one study found good diet quality associated with 12-28\% reduced risk of all causes, cardiovascular disease and cancer mortality in men and women\(^{(14)}\).

Good diet quality should associate with good water as Good hydration is vital for good health and well-being\(^{(14)}\), and physical activity as it reduces the risk of chronic disease and obesity\(^{(14)}\).

Physical inactivity was associated with higher risk of diabetic (type-2), regardless of BMI ; Gender ; age and ethnicity \(^{(15)}\). Individuals with mild, moderate or active physical activity were at lower risk of CVD deaths, regardless of their metabolic risk factors \(^{(16)}\), therefore the aim of current study to estimate how diet quality of meals can affect anthropometric measures ; identify amount of water intake and its association with anthropometric measures ; identify students with a family history of obesity and its association with anthropometric measures; determine daily activities of students, including the frequency and duration; and measure frequency of obesity among secondary school students in Tikrit city.

Patients and Methods

Cross-sectional study was used to assess the diet quality of secondary school students in Tikrit city and its association with anthropometric measures (BMI and waist-to-height ratio). The duration of the whole study was almost four months, the data was collected from the 1\(^{st}\) of November to the 1\(^{st}\) of January. The data was analyzed and the report was written from 1\(^{st}\) of January to the 25\(^{th}\) of March. The data was collected by simple random sample and the number of samples are 153 cases of both genders from secondary school students.

The data was collected by the members of our study group from the following secondary schools (Ibn-almotam ,Al-Khansaa and Al-Mustansrya). A suitable questionnaire was designed in Arabic language and contained (name, age ,class ,gender ,types of foods eaten regularly by students ,water intake ,activity ,family history of obesity) to achieve the objectives. The questionnaire directed by interviewer.

The weight is measures for each student participant in the study. It is measures without shoes. The height of students is measures without shoes by using measuring tape of height 2 meters. The individual should stand on a flat surface, the head upward and the head, back and heel are against the wall.

The BMI is calculated as weight (kilograms) / height (meters)squared. The height was taken (to the nearest 0.1centimeter) and weight (to the nearest 0.1kilogram). Waist: height ratio will calculated as waist circumference / height and the measures was taken to the nearest 0.1centimeter. We explained the purpose and aim of the study and only those who agreed to participate in the study and we also focus on the privacy of the information that taken from the students.

Finding

A total of 153 secondary school students were surveyed. The majority were females (52.29\%) and most of them (41.25\%) were between 16-18 years old. Most of them (55.56\%) had a BMI range from (18.5-25) and their waist-to-height ratioas(\(< 0.5\)) were (67.32\%) so (32.03\%) of secondary school students had a family history of obesity while (67.97\%) had a negative family history.

Figure (1): - percent of secondary school students who eat these important sources of carbohydrate in a regular manner weekly.

The figure shows bread as the most common source of carbohydrate in diet among male students 59/73 (80.82%), and also female 63/80 (78.75%).

Also The figure shows that second most common source of carbohydrate in diet among male students 57/73 (78.08%) was rice, and also female 58/80 (76.25%).

Figure (2): - percent of secondary school students who eat these important sources of protein in regular manner weekly.
The figure shows poultry as the most common source of protein in diet among female students 71/80 (88.75%), and also male 63/73 (86.3%).

Also, the figure shows that the second most common source of protein in diet among male students 48/73 (65.75%) was egg, and also female 41/80 (51.25%).

![Figure (3): percent of secondary school students who eat these important sources of saturated fat in regular manner weekly.](image)

The figure shows milk and dairy product as the most common source of saturated fat in diet among male students 42/73 (57.53%), and also female 38 (47.5%).

Also, the figure shows that red meat comes behind milk and dairy product as a second source of saturated fat in diet among male students 32/73 (43.84%), and also female 30/80 (37.5%).

![Figure (4): percent of secondary school students who eat these important sources of unsaturated fat in regular manner weekly.](image)

The figure shows olive as the most common source of unsaturated fat in diet among female students 42/80 (52.5%), and also male 35/73 (47.95%).
Also The figure shows that the nut comes behind olive as a second source of unsaturated fat in diet among male students 26/73 (35.62%), and also female 24/80 (30%).

This table shows that Most of the secondary school students 85/153(55.56%) had a BMI range from 18.5-25, were 48/80(60%) from female and 37/73(50.68%) from male within this BMI range.

### Discussion

The majority of secondary school students with normal BMI (55.56%) and their waist-to-height ratio (<0.5) were (67.32%) and this is matching a result from a research which was done 6 years ago in United states of America that found two thirds of samples had a normal BMI and waist-to-height ratio was 0.49. (17)

According to this study, the most common age group was between 16-18 years which was (41.18%), and this agree with research was conducted in United States of America in 2012 which show that the most affected age group were between 12 18 years old (42.3%). (17) According to this study, the most common source of protein was poultry (88.75%) among females and in males (86.3%) and this is agree with another study done in United kingdom in 2012. (16) According to this study, the most common source of carbohydrate was bread (80.82%) among male and among females (78.75%) while in another study done in Norfolk, United Kingdom at 2012 found that fruit and vegetables were more common but this study not mention the percentage (16)

In this study the percentage of family history of obesity in students was (32.03%) and this is disagree with another study in Kirkuk city which reveal that (59.2%) of them has a family history of obesity (16). Also this matches with another study occurred in Kirkuk city before 5 years (61.5%) was the percent of secondary school students with normal BMI, this study indicated that female students (60%) more obese than male students (50.68%) and this disagree with a study in Erbil that reveal male students (18).

### Conclusion

- Most of the students have a normal BMI (55.56%).
- The frequency of overweight was more common in female gender (60%), while in male (50.68%).
- The frequency of obesity was more common in female gender (10%), while in male (9.59%).
- Most common age group involved in the study were between 16-18 and account for (41.18%).
- (32.03%) of students had a positive family history of obesity while (67.97%) had negative family history.
- From students who have a positive family history, (32.66%) had an overweight BMI (25-30) and (44.9%)waist-to-height ratio which considered as indication of central obesity.
• Regarding carbohydrates, the most common source taken by students is bread (79.74%).

• Regarding protein, the most common source taken by students is poultry (87.58%).

Conflict of Interest: None.

Relation of Epstein Barr virus with interleukin-10
Level among men with Prostate Cancer in Ramadi City

Arkan Abdullah Abbas1, Israa Hashim Saadoon1
1Department of Microbiology, College of Medicine, Tikrit University, Tikrit, Iraq.

Abstract
The study aimed at evaluating the relation of Epstein Barr virus (EBV) with level of interleukin-10 (IL-10) in men with prostate cancer (PC). The study was carried out in Ramadi city from 12th of January to 12th of September 2018, and included a total of 95 women with breast cancer who admitted to oncology clinic of Ramadi Teaching Hospital whose ages were between 40-80 years. Patients were investigated for detection of EBV by using Real Time PCR and interleukin-10 (IL-10) by ELISA technique. The rate of prostate cancer men with EBV was (16.84%). The highest rate of prostate cancer men was within the age group 50-59 years with no significant relation between prostate cancer and age. The study showed that the highest means of IL-10 level (19.43 pg/ml) were found in prostate cancer men without EBV. There was significant difference (P value < 0.05) between EBV infection with IL-10. The highest rate of men with prostate cancer was from urban areas.

Keywords: Prostate cancer, EBV, IL-10, Ramadi.

Introduction
Prostate Cancer (PC) is the second most common cancer among men in western populations, and despite its high mortality, its etiology remains unknown. Inflammatory processes are related to the etiology of various types of tumors, and prostate inflammation, in particular, has been associated with prostate cancer carcinogenesis and progression (1).

Epstein- Barr Virus (EBV) has been linked to the development of variety of human malignancies including prostate tissues that range from benign prostatic hyperplasia (BPH) to prostatic adenocarcinoma (PAC). Somatic point mutations in Rb gene have been detected in prostate cancer and are involved in progression steps of prostate carcinogenesis (2).

Interleukin-10 (IL-10) is a key regulator of immune responses described as cytokine synthesis inhibitor, immune suppressive and anti-angiogenic factor produced by Thelper2 (Th2) cells and inhibits Thelper1 (Th1) cells by inhibiting pro-inflammatory cytokines. In addition, IL-10 can inhibit monocyte/macrophage functions including monokine synthesis, nitric oxide production, and major histocompatibility complex (MHC) class II and CD80/CD86 co-stimulatory expression. In vitro and in vivo studies revealed pleotropic activities of IL-10 on B and T cells and, taken together, that a critical function of IL-10 is to suppress multiple immune responses through individual actions on T and B cells, antigen presenting cells and other cell types, and skew the immune response from Th1 to Th2. In malignancy, IL-10 might promote tumor development, by acting to suppress anti- tumor immune responses(3).

Material and Method
Across a sectional study was carried out in Ramadi city from 12th of January to 12th of September 2018, and included 95 men with prostate cancer whose ages were between 40-80 years old. These patients admitted to oncology clinic of Ramadi Teaching Hospital.

Blood samples were taken from prostate cancer men. Samples were examined by immunological methods, enzyme linked immuno sorbent assay (ELISA) for detection interleukin-10(IL-10) and molecular technique (real time PCR) which included DNA amplification of Epstein Barr virus based on the specific primers.

Seven and half ml of blood was collected by vein puncture using vacutainer tubes from each patient
enrolled in this study. Blood samples were divided into two sterile test tubes, in one of them 2.5 ml of blood was put in test tube containing anticoagulant ethylene diamine tetra acetic acid(EDTA) and used for DNA extraction ofEBV. The second part of sample (5ml) was placed in plain tubes left for 30 minutes at 37 °C then was centrifuged at 3000 round per minute(rpm) for 15 minutes then the clot was removed and the remain re-centrifuged at 3000 rpm for 10 min and the obtained sera were then aspirated using automatic micropipette and transferred into two clean test tubes, for serological tests. Label was fixed on each test tube which then stored in deep freeze at -20°C for late serological testing for determination the level of IL-10 by using ELISA technique.

For DNA extraction, kit was purchased from Gene Aid(USA) company for molecular detection of EBV by Real Time PCR using Anatolia Gene Works(Turkey). Detection of IL-10 was done by using ELISA kit Elabscience(China), which depends on the Sandwich-ELISA principle.

**Statistical Analysis**

Computerized statistically analysis was performed using T-Test probability. The $P$ value $>0.05$ was considered statistically significant, and for result which its $P$ value was less than 0.01 was considered highly significant, while for those which its $P$ value greater than 0.05, was considered statistically non-significant.

**Findings**

A total of 95 prostate cancer men, their age ranged between 20-89 years old, were investigated for detection of EBV by using real time PCR and estimation the level of IL-10. The present study revealed that EBV was detected in 16.84% of men with prostate cancer, as shown in Table 1.

Relation of EBV infection with IL-10 among prostate cancer men.

Table 5 shows that the means of IL-10 level was higher in prostate cancer men without EBV infection (19.43), highly significant P value <0.05 between EBV and IL-10.

The present study revealed that there was a positive correlation between EBV infection with IL-10 among men with prostate cancer but the difference between them was statistically non-significant (R value: 0.198).

Prostate cancer is the second most frequently diagnosed neoplasm in men and the fifth cause of cancer death worldwide (4). Viruses are etiologic factors in the development of several types of human tumors. At least 15–20% of all human tumors worldwide have a viral cause (5). The present study revealed that 16.84% of men with prostate cancer had EBV infection. Several studies confirmed the presence of EBV in prostate tissues. In Sweden, EBV was present in 8.8% of benign and malignant prostate tissues (6), and in the United States, EBV was present in 8% of all normal, benign, and malignant prostate tissues (7). In another study, approximately 37% of prostate cancer patients had EBV infection (8).

The current study showed that the highest rate of EBV infections (7.36%) was found in those within the age group 50–59 years. The reason for EBV to exert its oncogenic influences in a particular patients is unknown but is probably associated with co-factors. The findings in the research by have supported hypothesis that the prostate is a habitat for multiple viral and other infectious agents, some of which have oncogenic potential (9).

The current study showed that no significant difference was found between EBV infection and residence in men with prostate cancer P value > 0.05. The study of urban–rural differences in prostate cancer in Australia showed that the higher rates of prostate specific antigen (PSA) testing particularly aggressive prostate cancer in regional and rural Australia. Other studies have found urban–rural differences in the management of other cancers (10).

The highest mean of IL-10 level was in men with prostate cancer without EBV infection (19.43%). There was significant difference P value < 0.05 between EBV with IL-10, and there was a positive correlation between EBV infection and IL-10. Several studies have indicated that IL-10 has both pro- and anti-tumoral effects. IL-10 inhibits NF-κB signaling; therefore, it can down regulate pro-inflammatory cytokine expression (11). Interleukin-10 is immunosuppressive and anti-inflammatory. Interleukin-10 inhibits NF-κB activation through ill-defined mechanisms, and consequently inhibits the production of pro-inflammatory cytokines,
including TNF-α, IL-6, and IL-12 \(^{(12,13,14,15)}\).

**Conclusions**

The present study revealed that 16.84% of men with prostate cancer had infection with EBV. The relation between EBV infection and age was statistically non-significant. The highest rate of men with prostate cancer who were infected with EBV was from urban areas. The highest mean of IL-10 level was detected in men without EBV infection.

A Histological Study of the Renal Corpuscle Nephron Distribution in Iraqi Camels (Camelus dromedaries)

Ali Fayadh Bargooth1, Ahmed Saad Al-A’araji 2, Masarat Swadi Medakel2
1Department of Biology, College of education for pure Sciences, University of Wasit, Wasit, Iraq,
2Department of Anatomy and Histology / College of Veterinary medicine- University of Baghdad, Iraq

Abstract

Aims: The present histological study was carried out to map the renal corpuscle nephron distribution and their histological properties in Iraqi camels(Camelus dromedaries). Materials and methods: Both kidneys from each of 10 (5 males and 5 females) adult camels were collected as soon as possible after the camels were sacrificed for human consumption purposes in a slaughterhouse. Following the preparation of tissues(cortex and medulla), the sections were slide-stained using alum hematoxylin and eosin (H&E) stain and Periodic Acid Schiff (PAS) stain. The renal corpuscle diameters (numbers and percentages) in the subcapsular area, the cortical area, and the juxtamedullary area were measured using an ocular micrometer. Results: The findings demonstrated that the renal capsule in camels is thick. The numbers of the renal corpuscles were low in numbers in the subcapsular region which keep increasing towards the midcortical and the Juxtamedullary regions. Moreover, the camel kidney has high numbers of long-loops of Henle nephrons and low numbers of short-loop nephrons. No significant (p<0.05) differences in the renal corpuscle diameters were noticed between midcorticaland juxtamedullaryareas. However, a significant (p<0.05) decrease in diameters of the renal corpuscles was seen in the subcapsular region. In addition, two layers consist the renal corpuscles with a tuft of capillaries. The proximal convoluted tubules (PCTs) showed wide lumens with the presence of cuboidal epithelial cells (CuECs) and spherical nuclei. The distal convoluted tubules (DCTs) displayed the presence of CuECs (smaller and lighter than those in the PCTs with apical spherical nuclei (ASN). Large lumens and simple columnar epithelial cells (CoECs). Furthermore, PAS staining showed high positive results in the basement membrane of the renal corpuscles. Conclusion: The current histological study provides insight about the renal corpuscle nephron distribution and their histological properties in Iraqi camels(Camelus dromedaries).

Keywords: Camels (Camelus dromedaries), nephron, renal corpuscles.

Introduction

In Iraq, camels are considered as one of the main economic resources that provide the country with various forms of human needs such as meat and milk consumption and, in some areas, as a transportation method. The major cleaning-out organs in the camel body are the bean-like shaped kidneys. The kidneys provide the body with very important roles such as getting rid of the end-products of the body metabolic processes. The kidneys also enhance body balance of fluids, electrolytes, and acid versus base ratios by changing the solute concentration and water volume in urine(1).

Moreover, kidneys in camels have specific anatomical characteristics that allow for hypertonic-based urine production via the camel-specialized loop of Henle-collecting tubule distance that promotes for maximum reabsorption of water from urine(2;3;4;5). Interestingly in camels, the cortical layer can reach up to the half of the kidney size with a ratio of 4:1 of medulla to cortex of thickness(6).

Renal insufficiency, as shown by various researchers, could be due to pre-renal, renal, and post-renal causes, however, nephritis and glomerulonephritis are among rare disease conditions that affect camels with low incidence rates which had only been discovered in slaughtered camels(7;8).

The present histological study was carried out to map the renal corpuscle nephron distribution
and their histological properties in Iraqi camels (*Camelus dromedaries*). Understanding those anatomical properties in camels may enhance better knowledge for developing new medicines and techniques to treat various kidney diseases in camels.

**Materials and Method**

**Animals and samples**

Both kidneys from each of 10 (5 males and 5 females) adult camels were collected as soon as possible (within 20 mins) after the camels were sacrificed for human consumption purposes in slaughterhouses distributed in various regions of middle of Iraq. The kidneys were rapidly rinsed and placed in 10% buffered neutralized formalin solution for 48 hrs.

**Tissue and tissue section preparation**

Following the preparation of tissues (cortex and medulla) that were dehydrated, cleared, and embedded in paraffin wax and cut-sectioned for pieces measured 5 to 7 µm by employing a rotary microtome, the sections were slide-stained using alum hematoxylin and eosin (H&E) stain and Periodic Acid Schiff (PAS) stain. The renal corpuscle diameters (numbers and percentages) in the subcapsular area, the cortical area, and the juxtamedullary area were measured using an ocular micrometer.

**Statistical Analysis**

The renal corpuscle diameters (numbers and percentages) in the subcapsular area, the cortical area, and the juxtamedullary area were measured using an ocular micrometer. Those data were analyzed using an F-test. The null hypothetical problem was refused if $p$ was less or equal to 5%. The finding values were processed using SPSS software.

**Findings**

The findings demonstrated that the renal capsule in camels is thick. The numbers of the renal corpuscles were low in the subscapular region which keep increasing towards the midcortical and the juxtamedullary regions. Moreover, the camel kidney has high numbers of long-loops of Henle nephrons and low numbers of short-loop nephrons. No significant ($p > 0.05$) differences in the renal corpuscle diameters were noticed between midcortical and juxtamedullary areas. However, a significant ($p < 0.05$) decrease in diameters of the renal corpuscles was seen in the subcapsular region, table 1.

**Table 1: Distribution and diameters of renal corpuscle regions in camel kidneys.**

</tbody>
</table>

Different letters refer to significant ($p \leq 0.05$) differences.

In addition, two layers consist the renal corpuscles with a tuft of capillaries. The proximal convoluted tubules (PCTs) showed wide lumens with the presence of cuboidal epithelial cells (CuECs) and spherical nuclei. The distal convoluted tubules (DCTs) displayed the presence of CuECs (smaller and lighter than those in the PCTs with apical spherical nuclei (ASN)). Large lumens and simple columnar epithelial cells (CoECs). Furthermore, PAS staining showed high positive results in the basement membrane of the renal corpuscles, figure 1A, B, C, and D.
Discussion

The numbers of correctly functioning renal nephrons decide the proper action of a kidney; however, kidneys may face ineffectiveness in their work if there is insufficient renal blood supply, deficient in the glomerular filtration, and defectiveness in the reabsorption of tubules. The first factor can be pre-renal initiated due to some circulatory emergency conditions such as dehydration, hemorrhage, and shock in responses to vasomotor control. While the other two factors can be induced as results to improper functions of the kidney itself (11).

The current work was focused on finding the actual histological distribution of the renal corpuscles in the camel kidney which might help better understanding the functions of the kidney nephrons.

The findings demonstrated that the renal capsule in camels is thick. Interestingly in camels, the cortex can reach up to 50% of the kidney size, and this shows the huge length of the loops of Henle and vasa recta, also discovered in the current study, which adds more evidence that camel kidneys are able to concentrate their urine as part of their fulfillment of water preservation (12).

A significant decrease in diameters of the renal corpuscles was seen in the subcapsular region. In addition, two layers consist the renal corpuscles with a tuft of capillaries. The PCTs showed wide lumens with the presence of CuECs and spherical nuclei. This piece of result agrees with the previously identified facts that renal corpuscles and glomeruli in camel kidneys are larger than those recognized in kidneys of other animals, and this is supported by the approved ideas that camels suffering dehydration have 73% reduction of the reabsorption of sodium from tubular lumens resulting in concentrating the camel urine and better preserving water (13;14). Furthermore, PAS staining showed high positive results in the basement membrane of the renal corpuscles. This indicates highly normal glomeruli of the camel kidneys with presence of glycoprotein, glycolipid, and mucin structural components (15).

Conclusion

The current histological study provides insight about the renal corpuscle nephron distribution and their histological properties in Iraqi camels (Camelus dromedaries).

Correlated between Sera Levels of Interleukins (IL-6, IL-17 and IL-23) with Virulence Genes Detected in Carbapenem-Resistant E. coli

Mhesen A. Mohammed Al-Warmeziary¹, Suzan Saadi Hussain¹, Nihad Khalawe Tektook²

¹Biology department, College of Science, Al-Mustansiriya University, ²Medical laboratory techniques Department, College of Health & Medical techniques, Middle Technical University

Abstract

Current study demonstrated that 14.58% of isolated E. coli which positive for each of Omp-A, IMP-A, NDM-A and Fim-H genes were resistant to carbapenem and the study showed that 30.51% of E. coli isolates with KPC were resistant to carbapenem while other E. coli isolates with negative all genes were resistant to carbapenem, so the percentage as 72.92% of isolated E. coli were positive for each of Omp – A, IMP – A, NDM – A and Fim – H genes were occurred in females compared with 27.02% occurred in males and 40% of isolated E. coli with positive for KPC gene were in females with UTI. as well as 10, 50% of isolated E. coli were positive for each of Omp - A, IMP - A, NDM - A and Fim - H genes were occurred in the age group 15-24 year and no isolate were form patients above 54 year.

the highest mean levels IL-6 and IL-17 was recorded in UTI patients infected with E. coli positive for each of Omp-A, IMP-A, NDM-A and Fim-H comparing with patients infected with E. coli negative to these genes. Conclusion Carbapenem-resistant E. coli correlated with founded each of genes ( Omp-A, IMP-A, NDM-A, and Fim-H ) , whilst highest correlated between Carbapenem-resistant E. coli with KPC.so sera levels of both interleukins (IL-6 and IL-17) were recorded in UTI patients infected with E. coli positive for each genes ( Omp-A, IMP-A, NDM-A and Fim-H ) comparing with patients infected with E. coli negative to these genes.

Keywords: sera levels of interleukins (IL-6, IL-17 and IL-23); virulence genes; carbapenem-resistant E. coli

Introduction

E. coli belongs to the Enterobacteriaceae family and is present in the natural microbiota of humans and other homoeothermic animals. The E. coli associated with UTIs are denoted uropathogenic E. coli(UPEC) (¹), With the widespread use of antibiotics, the carbapenem-resistant strains have become a serious public health issue in the worldwide and are usually resistant to almost antibiotics (²). Carbapenem-resistant Enterobacteriaceae (CRE), specially included three species of the Enterobacteriaceae family, the Klebsiella, Enterobacter and Escherichia coli have developed resistance to a group of antibiotics called “Carbapenems”, which are often used as the last line of treatment when other antibiotics are not effective in treating infections caused by them (³). Carbapenem-resistant E. coli strains is a main risk for global public health, but little is known of carbapenemase producing E. coli in Iraq.

E. coli strains have some gene regions responsible for virulence factors which may encode adhesins, toxins, siderophores and haemolysin. Outer membrane protein A (OmpA) is a major protein in the Escherichia coli outer membrane, it is the abundant outer membrane proteins (OMPs), with typically 100,000 copies per cell (⁴).

Type I fimbriae, coded by plasmid-mediated fimA gene and commonly found in these strains from lower urinary system infections, enable E. coli to adhere to human ureteral mucosa epithelial cells (⁵). Afimbrial adhesin encoded by plasmid- or chromosomemediated afa and S fimbriae encoded by plasmid sfa gene regions are commonly found in urinary system infection originated in isolates as well as sepsis and meningitis (⁶).
The most important virulence factors for urinary tract infections are fimbriae. It was reported that no important difference in presence frequency of type I fimbria between low and high virulence isolates in the urinary tract (7) (Plos et al., 1991).*FimA*, associated with ancillary proteins *FimF, FimG*, and the adhesin protein *FimH*, encoded by the *fim* gene cluster (8). This type of fimbria is common among Enterobacteriaceae, also several variants have been strongly associated with UPEC (9). Their role in infection is unclear, although it has been suggested that they may be involved in the initial stages of colonizing in the upper respiratory tract (9;10).

Interleukin (IL)-6 is a pro-inflammatory cytokine, the concentration of which increases in the early stage of bacterial infection. Interleukin-6 has regenerative activities, which, when absent, aggravated the development of the inflammatory process.

So IL-23 is believed to be important in the expansion and survival of these IL-17-producing cells (naïve T cells) (11). In addition, an intact IL-23-IL-17 axis seems to be essential for host protection against infections, as well as in the pathogenesis of certain autoimmune diseases (12). Aim of current study was evaluate the possible correlations between carbapenem-resistant *Escherichia coli* and frequency of virulence gene in UTIs infections, and correlated between carbapenem-resistant *E. coli* and level of IL-6; IL-17 & IL-23.

Specimens collection

All specimens were collected during the beginning of September 2018 to the end of April 2019, One hundred and eighty midstream urine specimens were collected from patients attending hospitals (Baghdad Teaching Hospital/ Medical city; Abn Al Baladi hospital; Imam Ali hospital and Al-Numman hospital, Iskan) hospitals.
The Specimens were collected according to\(^{(13)}\). Urine cultured immediately after collection (from hospital laboratory) by streaking 0.01 ml of urine on Blood agar, MacConkey agar, and Eosin Methylene Blue agarin order to isolate Escherichia coli only.

Estimation of IL-6 ; IL-17 and IL-23 in Serum: according to commercially available kit, using the quantitative sandwich enzyme.

**Extraction of DNA from E.coli and Each bacterium was isolated in this study was subjected to molecular screening study using PCR amplification.**

To determine the phylogenetic groups of all isolates in the current study, five primers were used which are IMP ; NDM-1; KPS ; Omp A and Fim h gens by PCR

**Statistical Analysis:** Data analysis was done by descriptive statistics and using SPSS version 20. values of \( p \leq 0.05 \) were regarded as statistically significant relationships.

**Findings**

The study demonstrated that 14.58% of isolated E. coli which positive for each of Omp -A, IMP- A, NDM-A and Fim- H genes were resistant to carbapenem and the study showed that 30.51% of E. coli isolates with KPC were resistant to carbapenem while other E. coli isolates with negative all genes were resistant to carbapenem (Table 1).

Discussion

Carbapenem-resistant Enterobacteriaceae (CRE) is an urgent public health problem worldwide. These multidrug-resistant organisms exhibit resistance to most, if not all, available antibiotics today and are associated with considerable mortality.(14) In one study, approximately 32% of patients with bloodstream infections caused by carbapenemase-producing CRE died within 14 days.(15) SO (16) Explain the rapid spread of CRE is due to the clonal and plasmid-mediated dissemination of clinical carbapenem-resistant strains,(17), Whilst (18) found that 32.2% of UTI patients with carbapenem-resistant E. coli were females.

Cytokines IL-6 and IL-8 are mediators of inflammation in response to bacterial infection, and when measured in plasma or serum these may be used as early biomarkers of infection.(19) IL-6 and IL-8 levels are also known to be elevated in the urine of patients with UTI, whereas reportedly none are measurable in the urine of healthy controls. The high levels of interleukin 6 in women with acute UTI contribute to increase body temperature and stimulate the production of the C-reactive protein and indicating systemic response of the body toward infection.(18).Moreover, (20) reported higher levels of IL-6 and IL-8 in urine in patients with UTI caused by fimbriated E. coli compared to patients with UTI caused by non-fimbriated E. coli. On the other hand, elevated level of IL-17 in addition to IL-6 in patients with UTI as early innate reaction. Additionally, in murine model that both IL-17 and IL-23 enhance the body to eradicate uropathogenic E. coli.(21). The early innate responses include bacterial expulsion, urothelial exfoliation, and bladder inflammation that is characterized by the production of the pro-inflammatory cytokine interleukin 6 (IL-6), granulocyte chemotactic cytokines such as IL-8, the hormone granulocyte colony stimulating factor (G-CSF), and the T cell-associated, pro-inflammatory cytokine IL-17A (22).

Carbapenem resistance may also be due to AmpC type enzymes or ESBLs along with imperme ability of the membrane (23).Membrane imperme ability can be linked to modifications or absence of OmpC and/or OmpF porin channels or presence of drug efflux pumps (24).

Conclusion

1- levels of interleukin( IL-23 ) were increased significantly (P<0.05) in UTI patients who positive with CRP test compared with CRP negative , also IL-17 elevated moderately in patients with CRP positive while no difference in level of IL-6 between the two groups.

2- Carbapenem-resistant E. coli correlated with founded each of genes ( Omp -A, IMP- A, NDM-A and Fim- H ) , whilst highest correlated between Carbapenem-resistant E. coli with KPC.

Evaluation of KV Reduction on image quality in OPG X-Ray

Mohammed Abdul Sattar1, Sajid Hamza Aluaan2, Wael Abdul Alrazzaq1

1Department of Prosthetic Dentistry, College of Health & Medical Technology, Middle Technical University, Baghdad, Iraq; 2Department of Radiological techniques, College of Health & Medical Technology, Middle Technical University, Baghdad, Iraq

Abstract

Panoramic radiographs are widely used to obtain an overall survey of the maxillofacial complex. One of the advantages is the reduction in radiation dosage compared with complete intraoral radiography. Digital imaging was first introduced in dentistry for intra-oral radiography, but is now widely available for panoramic radiography. Many studies have demonstrated that it is possible to achieve a degree of dose reduction in digital panoramic radiography.

Keywords: K V, Reduction; image quality; OPG X-Ray

Introduction

In all aspect of radiography digital images have become the new way of view radiographic data to the monitor[1]. In the daily practice of dentistry panoramic radiography takes the second place in vital to intraoral radiography, however, panoramic imaging may be more useful to patients because it offers both excellent anatomical assessment and excellent evaluation of mandible fractures, tooth development and maxillary sinus disorders[2].

The ionizing radiation is an investigative method and the biological effects of radiation have established so much accuracy in the past that the radiation exposure has come to be a public attention fear. According to the ALARA principle (As Low As Reasonably Achievable) which holds that the amount of information must be acquired with the smallest possible amount of radiation[3]. The exposure reach of various digital systems has been described but we still lack information regarding benefit exposure which can produce diagnostically appropriate images[4]. The decrease of radiation dose is considered as one of the most important benefits of digital radiography. It is however, debatable whether digital radiography really offers benefit to intraoral and extra-oral imaging. The conventional extra-oral radiography is depended on screen-film cassette, intensifying screen provides a major dose decrease in comparison to non-screen film-based imaging. Gaining the image digitally, hence, does not enhance much to the dose lessening in extraoral imaging [5]. It is well-known that early detection and intervention of misdirected development can prevent substantial and difficult corrective treatments at later stages and that early detection and intervention most often depend upon radiographic examination. More generally for any group of dental patients, good oral health is not possible without the use of x-ray; so then how to balance between these good diagnostic goals and the hazards of achieving them[6]. The patient dose has also been reported as the effective dose E, this method of reporting resulted from the inability to make direct comparisons between radiographic techniques themselves and background radiation exposure in terms of dose because of the limited area of the body exposed during diagnostic radiology. It is only through the E that possible adverse effects from irradiation to a limited portion of the body can be compared with possible adverse effects from irradiation of the whole body[7]. The special effects of low dose radiation are demonstrable only as a statistical increase in the frequency of normally occurring disease states among the general population[8]. The grade of danger that may be related to exposure to ionizing radiation and may be expressed in two ways; equivalent natural exposure and probability of stochastic effects[9]. From dental radiography, the main hazard is radiation-induced cancer because of low doses exposure[10]. The dentist must use professional judgment when prescribing diagnostic radiograph for dental patients. Diagnostic radiography must be only utilized after clinical examination taking into consideration

DOI Number: 10.37506/ijfmt.v14i2.3481
patients' history, dental and general health needs[11]. Every patient must be assessed for dental radiographs on an individual basis[12]. The clinician is advised to use the fastest film type available to minimize patients exposure. Two distances commonly used for intraoral radiography; these are 8 inches and 16 inches[13]. The tissue area which are exposed to the primary beam must not exceed the minimum coverage and should be consistent with clinical feasibility[14]. The collimation is utilized to confine the shape and size of the x-ray beam and to decrease the patient exposure. Patient exposure and dose are reduced when an x-ray beam is properly filtered. Filtration improves the quality of the beam by removing long-wavelength, low energy x-ray so that the mean energy of the beam is increased such that x-rays constituting the beam are nearly all in the use full diagnostic energy range [15]. Leaded thyroid collars are strongly suggested, though scatter radiation to the patient’s abdomen is very low, leaded aprons must be utilized to diminish patient’s exposure to radiation. The lead apron reduces exposure of the reproductive organs and the haematopoietic tissues and organs. The advent of digital imaging has developed radiology due to the improvement of computing systems for image retrieval and transmission and technologic innovation in image acquisition processes[9]. Panoramic radiography is a radiographic technique that creates a single image of the structures in the face, including both maxillary and mandibular arches and their supporting structure[16]. The panoramic radiograph is an excellent means of dental identification when utilized with the Polaroid photograph of the dentition[17]. The Paatero in 1954, introduced the orthopantomograph, the apparatus of panoramic tomography of the maxilla and mandible. It has become widely used in otorhinolaryngology, for radiographic examination of the maxillofacial region[18]. The panoramic radiograph permits professionals to observe a large area of the maxilla and mandible on a single image. The aim of the study was to evaluate the effect of reduction of kilo voltage on interruption of certain anatomical landmark in O.P.G x-ray.

**Patients and Materials**

The Planmeca Proline digital panoramic x-ray machine was used in this study with Dimax3 software, the machine is manufactured by planmeca and has the following specifications [19]: X-ray tubes / focal spot size : D-052SB/0.5* 0.5 mm ; Target angle: 5° ; Total filtration: 2.5 mm Al ; Anode voltage: 60-80 kv ±2.5kv ; Anode current: 4-12 mA ±1.0 mA ; Exposure time: 2.5-18 s as indicated ±10% ; SID : 480 mm ; Magnification: constant 1.2 ; Sensor height: 136 mm ; Line voltage:100,117, 220-230, 240v ; Regulation: automatic ±10% ; Line current: max. 8A at 230v, 15 A at 100v ; Weight: 108 kg ; Cooling period: automatically controlled

**Methods**

After consultation with the engineer responsible about the standardization and maintenance of the x-ray machine, all the subjects were examined radiographically by using digital panoramic radiography machine. Two digital panoramic images were obtained for each subject at 5 minut es interval, the first image was with standard exposure setting, which is recommended by the manufacturer. The second image was taken to the subject with reduced tube current by 50% and so each subject had two digital images. The kVp was kept constant throughout the study; all images were obtained by one radiographer. These tandardization of subject position after first image taking in order to take the second image was achieved by lines drawn on the face to coincide with the horizontal and vertical light beams on the machine. In addition a line was drawn on the floor for the feet position[19].

**Panoramic procedure**

1-The procedure about to be performed was explained for the patient.

2-All objects like eyeglasses, ear rings, necklaces hearing aids, and hair pins, complete or partial dentures should be removed.

3-The patient was advised to stand or sit with the back straight and erect.

4-The patient was instructed to use the plastic bite-block to be bitten on so that the lower and upper anterior teeth were located in an end to end position in the groove (notch), which is on the bite block. This groove is utilized to align the teeth in the focal trough, light was positioned between the canine and lateral incisor of the patient.

5-The middle sagittal plane was positioned vertical to the floor so that the patients head not be tipped or tilted to avoid image distortion.

6-The Frankfort plan was positioned parallel with the floor, so that the occlusal plane is locate dat the correct angle [19].
Finding

Two images for each subject were assessed by the two examiners for evaluation of the fourteen anatomical landmarks. Each examiner gives the score of comparison of each landmark independently and separately.

1. The Sample

This study was based on the analysis of 20 subjects, 10 male and 10 female. The age distribution was between 20-30 years old. For each subject we have two digital panoramic images. There were unacceptable images for viewing for seven of the subjects.

So those seven subjects with their images were excluded from the sample. The seven excluded subjects consisting 14% of the total sample. So the sample that has been examined is 20 samples.

2. Rating scores for male sample by the first examiner

The results show that scores were distributed between equal and worse score with the higher number and percentage for the equal score. For the equal score, 13 landmarks were above 90%. For the worse score, 3 landmarks recorded with zero worse score with higher number and percentage of worse score in one landmark. There was no reading for other scores, Table (1).

Discussion

Past studies have demonstrated that it is possible to achieve a degree of dose reduction in digital panoramic radiography without impairment of image quality. The aims of the present clinical study were to evaluate the effect of 15% dose reduction with the digital panoramic radiography unit on subjective image quality and interpretation performance hoping to achieve the desirable amount of information with the smallest amount of radiation.

Conclusions

This study has shown that in digital panoramic radiography, a dose reduction of 15% can be achieved while maintaining satisfactory image quality and interpretation performance.

Recommendations:

1- Design to assess the perfection of interpretation of certain anatomical landmarks at reduced dose digital panoramic radiography.

2- The capability of minimizing hazardous effects of radiation through studying the effect of dose reduction on human living tissue in digital panoramic radiography.

Conflict of Interest: non

Source of Findings: self

Ethical Clearance: This research was carried out with the patients.

Population Prevalence of Asthma in Aljiza District

Khalil Altaif1, Nahla Aqel1, Ghazi Al Jabal1, Mohamed J Saadh1
1Department of Pharmacy, Faculty of Pharmacy, Middle East University, Amman, Jordan

Abstract

Background: Asthma is a condition in which your airways narrow and swell and produce extra mucus. Objective: In this study we determine the prevalence of asthma among the population of Aljiza District, Jordan. In order to determine the prevalence of asthma in Aljiza District (Amman, Jordan), Method: a questionnaire was distributed to 4200 respondents of different age and gender. Results and Conclusions: The responses were reviewed and the incidences were determined. From the 4200 questionnaires by respondents 131 person (3.1%) suffered from physician-diagnosed asthma. No attempt was made to confirm the diagnosis and the results relied upon responses to questionnaire. The prevalence of asthma in adult females was higher than that of males in all groups. Adult females and males showed a significant priority on other age groups, and children, 5-10 years group have higher prevalence than children, 10-15 years group, in both males and females. In order of frequency, the triggering factors were common cold, dust, allergens, smoke, exercise, and chest infection. A relationship between asthma and paternal smoking, family history and to a lesser extent recurrent chest infections was suggested. The prevalence of asthma in Aljiza District is less than that reported in the southern and northern parts of Jordan and some Middle East countries. Although our results show a low prevalence of asthma, it still is a health problem among children and the adults in Aljiza District.

Keywords: Asthma, population prevalence, Aljiza District, Jordan

Introduction

Asthma is one of the most common chronic respiratory diseases and is a major health problem worldwide, affecting people of all ages, genders and religions (1). The prevalence of asthma may be as high as 334 million according to a report from the Global Asthma Network published in 2014 (2).

The disease represents a significant burden at life not only in term of morbidity and quality of life, but also in terms of health cost, especially in developing countries (3, 4).

Though most of the available information regarding the prevalence of asthma indicates that West European countries have some of the highest prevalence rates of asthma in the world, nevertheless Latin American, Asian, Middle Eastern and some Arab countries also showed a relatively high prevalence of this disease (4, 5). Moreover, results on the prevalence of asthma in Arab countries suggest that the highest rate was reported among people who lived in desert (6) and lowest is among people living in urban areas (7).

In Jordan and though the disease is increasing recently there is a limited information on the prevalence of asthma in many parts of the country (8). The aim of the present study is to investigate the prevalence and severity of asthma and asthma related symptoms in Aljiza District.

Material and Method

Aljiza District is located about 50 km. south of Amman with a population of about 60000 inhabitants and also the study protocol conformed to the ethical guidelines of the 1975 Helsinki Declaration and the approval was obtained from ethical committee of Middle East University-Amman-Jordan.
The design of this study was cross-sectional. It was carried out among people living in this area to include a random sample of school children, university students and families. For the school children a self-administered questionnaire was distributed to parents via their children, who returned the questionnaire after it had been completed by one of their parents. The questionnaires asked for the following details: age and sex, chest diseases, allergic rhinitis, family history of asthma, parental smoking.

The data were analyzed using statistical package for social science (SPSS) version 23. Descriptive statistics. Chi – square test (X2) was used in this study on a level of significance less than (P <0.05).

Results

A survey was conducted on a sample of 4200 individuals. For this purpose a questionnaire was prepared and distributed. The completed questionnaires include 2500 males and 1700 females. The questionnaires revealed that 131 subjects (3.1%) have physician diagnosed asthma including 71 males (2.8 %) and 60 females (3.5%). The results are presented in Table 1.

Table II shows that in all age groups the prevalence in females is higher than that in males, and that it is significantly higher in adult female than in the other two female age groups (5-10 yrs.) and (10-15 yrs.). The same trend is observed within male prevalence asthmatic groups where prevalence is significantly higher in the adult group than in the 5-10 yrs. and 10-15 yrs. groups. The results also show that children (5-10 yrs.) have higher prevalence than that of (10-15 yrs.) and this trend is consistent in both female and male groups.

Most of asthma episodes appeared to be triggered by common cold (64.1%), dust (31.3%) and allergens (30.5%) and to less extent smoke (14.5%), exercise (12.2%) and chest infections (3.8%) (Table III).

Table IV shows the relationship between asthma and the risk factors studied. The results revealed that paternal smoking (42.7%), family history (24.4%) and recurrent chest infections (19%) are the most significant factors associated with this disease. (Table IV).

Discussion

The primary objective of this study was to estimate the prevalence of asthma in a semi-desert area (Aljiza). The result of this study revealed an overall prevalence of asthma of 3.1% which is lower than that reported from Jordan and many other Middle East countries (1, 9-13). However, a study carried out in Anatolia, Turkey showed that a prevalence of asthma as low as 1% in age group of (15-29 yrs.) and 2.6% in the (13-49) age groups. This is a low a low prevalence and is aligned with our findings (14).

Result on asthma from different countries and localities have consistently shown a high prevalence of this disease in women during adulthood (1, 10, 15, 16). Consistent with this, our result revealed a similar finding in that a significant higher prevalence in women compared to men (p>0.05). Though there are many explanations for this phenomenon no single explanation can fully explain the gender difference. Among these hypotheses female hormones might play a role in inducing this higher prevalence (1).
Concerning age groups, the present study showed that children of age group 5-10 yrs. was slightly higher than age group of 10 to 15 yrs. group. This is in agreement with results reported by other authors (9,17). Furthermore, our findings concerning gender difference showed that the rate of physician diagnosed asthma was higher in female age group 5-10 yrs. and 10-15 yrs. respectively. This is not in agreement with previous studies in Jordan and elsewhere (9, 12, 18).

Several triggering factors were examined in this study. Two among them, namely common cold and allergens show highly significant association with the disease; others like smoking and dust also have a role in triggering asthmatic attack. This confirmed earlier findings from different localities in Jordan and elsewhere (9, 14).

Finally, with regard to risk factors paternal smoking and family history appears to be the most important risk factors in this survey, (42.7 %) and (24%) respectively. This is an agreement with Weitzman et al. (1990) findings (18).

Though the present results indicated a low prevalence of asthma to confirm these results a further study is needed in the area.

**Conclusion**

The observed prevalence of asthma in Aljiza is 3.1 % which is comparatively lower than the reported prevalence in many parts of Jordan and Middle East countries. Though the present results indicated a low prevalence of the disease still there is a belief that asthma and wheezing have a negative impact on health and the quality of life and therefore further studies are needed to obtain a reliable data in the prevalence of asthma in both children and adults by using a Standard European community Respiratory Health Survey (ECRHS) questionnaire and tools.

Abstract

Introduction: Myasthenia gravis (MG) is an uncommon autoimmune disease that is caused by acetylcholine receptor antibodies (AChRA) at the neuromuscular junction. Its pathogenesis involves complement fixing antibodies directed against acetylcholine receptors, muscle-specific tyrosine kinase or low density lipoprotein receptor–related protein.

Method: A descriptive case series study investigating rituximab in refractory MG was conducted in Baghdad teaching hospital. Patients who were included in the study had received a regimen of rituximab that was deemed appropriate by their treating physician.

Results: A total of 24 patients with mean disease duration of 6.3 years ±3.6 standard deviation were included in this study. The results showed that the average age of patients was 33.3 years ±10.1 SD and 62.5% was females. All twenty four patients showed an obvious improvement in clinical status after finishing the follow-up period. The results demonstrated from all patients that enrolled in our study, only one patient that was on 14 sessions of plasmapheresis was in need for plasmapheresis after induction of rituximab and this difference was statistically significant.

Conclusion: There were a great clinical improvement as shown with MMT score in addition to discontinuation of plasma exchange treatments following treatment with rituximab.

Keywords: Rituximab, Myasthenia gravis, Refractory, plasmapheresis

Introduction

Myasthenia gravis (MG) is an uncommon autoimmune disease that is caused by acetylcholine receptor antibodies (AChRA) at the neuromuscular junction\textsuperscript{[1]}. Its pathogenesis involves complement fixing antibodies directed against acetylcholine receptors, muscle-specific tyrosine kinase or low density lipoprotein receptor–related protein\textsuperscript{[2]}. Muscle weakness, with abnormal fatiguability, and improvement after rest, characterize myasthenia gravis. Symptoms tend to be worse at the end of the day, and after repetitive use of muscles for a particular task\textsuperscript{[3]}. Commonly, MG affects the ocular muscles first and this results in ptosis and diplopia\textsuperscript{[4]}. Many studies was done to clarify the meaning of refractory myasthenia gravis and use specific standards like failed response to standard duration and doses of traditional treatment with immunosuppressive drugs, undesirable adverse reactions to conventional therapy, the need for frequent use of short period therapies such as IV Immunoglobulin and plasmapheresis, and/or suffering patients from repeated myasthenic crises\textsuperscript{[5]}. It can occur at any age but most commonly affects women under the age of 40 and men over the age of 60\textsuperscript{[6]}. There are only a few studies on the epidemiology of myasthenia gravis based on complete populations\textsuperscript{[7]} prevalence rates have increased to about 20 per 100,000 in the US population\textsuperscript{[8]}. There are a deficit in epidemiological data on MG in Arab countries. The incidence rate reported from Libya is similar to the worldwide incidence rate of 5.3 per million person-years estimated in a systematic review of population-based studies, and showed a higher
The neuromuscular abnormalities in MG are thought to be an autoimmune response related to specific anti-AChR antibodies, but how the autoimmune response is started and preserved in MG is not fully understood \(^{[10]}\). AChR antibodies mostly belong to the IgG1 and IgG3 subclasses, which stimulate the complement cascade to destruct the postsynaptic membrane, which may lead to up regulation of inflammatory cytokines \(^{[11]}\). The ultimate goal of treatment is to achieve complete stable remission, defined as no myasthenic symptoms or signs without any ongoing treatment for at least 1 year \(^{[12]}\). Therapies in MG should therefore eliminate patients’ symptoms within the boundaries of adverse events associated with treatment itself \(^{[13]}\).

### Patients and Method

A descriptive case series study examining rituximab in refractory MG was performed in Baghdad teaching hospital. Patients who were included in the study had received a regimen of rituximab that was deemed appropriate by their treating physician. Total of twenty-four patients identified with refractory generalized MG were enrolled in the study. Physical tests were estimated before and after treatment with rituximab. MMT score is used to show clinical improvement. MMT is a procedure for the evaluation of strength of individual muscle or muscles group based upon the effective performance of movement relation to the forces of gravity or manual resistance.

There were no specific criteria used to stage clinical response against no clinical response. The main outcome of the study was the improvement in MMT score and symptoms of patients, with the other outcomes being the change in the frequency of plasma exchange which were done at the estimation of the clinician. Patients that are included in the study are 13 to 90 years old that must have refractory MG, that not respond to glucorticoid and other immunosuppressive therapy. Subjects must be on a stable standard immunosuppressive regimen with no history of thymoma, tumor, infection, or interstitial lung disease on chest CT, MRI, or chest x-ray. Patients that are excluded from the study are patients with history of chronic degenerative, psychiatric, or neurologic disorder other than MG that can produce weakness or fatigue. Female subjects who are premenopausal who are pregnant, breast feeding or not use effective method for contraception. Protocol for Rituximab was administered in a standard dose of 1g. Every cycle is estimated as one infusion for two weeks. The space between cycles was adjusted as 6 months. To see the safety and adverse events, we collected notes from the infusion center and also, a complete blood count and liver function test profiles present in patient’s medical records. SPSS version 22 was used for data entry and analysis. Mean and standard deviation was used to represent the numerical data while the frequency and percentage for categorical data. Independent student T test and the test chi-square (Fischer exact test if not applicable) were used to confirm significance \(p < 0.05\) was considered significant.

### Results

A total of 24 patients with mean disease duration of 6.3 years ±3.6 SD were included in this study. The results showed that the mean age of patients was 33.3 years ±10.1 SD and 62.5% was females. All twenty-four patients showed a marked improvement in clinical status by the end of the follow-up period. Five of the patients underwent a single cycle of rituximab, two received two cycles of rituximab while the remaining received either three or more cycles of rituximab. The results indicated there was no significant difference \((p=0.5)\) in plasmapheresis session that as needed after induction of rituximab when compared according to number of cycle of rituximab in term of < 4 or ≥ 4 cycles, where the results showed that only one patient was in need for plasmapheresis session of those who received less than 4 cycles of rituximab while no one in need for plasmapheresis session of those who received more than 4 cycles of rituximab as seen in table 1.

The finding revealed that from 4 patients who was with score one before treatment with rituximab, 3 patients was improved to score 4 and 1 to score 5. From 12 patients who were in score 2 before using of rituximab, 4 patients were improved to score 3, 3 patients improved to score 4 and 5 patients to score 5. From 8 patients who were in score 3 before treatment with rituximab, 2 patients were improved to score 4 and 6 patients to score 5. So the results revealed that the frequency of patient who had pretreatment high score of MMT, who were reach the highest score after treatment with rituximab was higher than those who were already had low score before using the rituximab but this difference was non-significant as seen in table 5.

Discussion

In this study of 24 patients that present with refractory generalized myasthenia gravis, we see that rituximab result in a sustained clinical improvement as demonstrated by improved MMT score in addition to reduce frequency or lack of need for plasma exchange treatments as shown with Anderson et al study[14]. At time of this study, all patients were followed for 1 year following infusion with rituximab. The results of this analysis favor the theory that rituximab can be effective for treatment of refractory MG which is compatible with small reports that were done previously as in Zebardast et al and other studies[15,16]. Most patients may need two or more cycles of rituximab for obvious decrease and discontinuation of other immunosupressant, in addition to the attainment of disease remission. As there is no fixed protocol for rituximab use in myasthenia gravis, retreatment is decided based on disease activity and clinical improvement, with a minimum interval between infusions of 6 months which is similar to Peres et al[17]. A perfect protocol has not yet been confirmed, however, some studies used peripheral B-cell count as a guide for retreatment with rituximab and to decrease toxicity and side effects[18,19]. An additional studies are required to recognize the best objective clinical indicators and to fix pharmacokinetics in this kind of patients. Immunoglobulin levels, B-cell counts, titers for antibody would seem the most helpful objectives at this time but in our study we depend on symptoms improvement and MMT score. All patients in this study can tolerate rituximab with no severe hematologic derangements[20,21]. The patients in this study were monitored clinically for rituximab adverse effects while in the infusion center as well as with CBC and LFT at baseline and after each infusion. All patients in this study can tolerate rituximab with no severe hematologic derangements. Infusion reaction is the most common side effect reported in general[22]. There is a need for a larger prospective controlled trial to gain more definitive conclusions about the efficacy of rituximab in the treatment of refractory MG. The strong effect of rituximab in patients with refractory MG in our center as well as in similar studies is promising and suggests that further investigation of this agent in MG is warranted[23,24].

Conclusion

There were a great clinical improvement based on MMT score, in addition to decrease or cutting the use of plasma exchange following treatment with rituximab. Rituximab is an attractive treatment because of its mechanism of action that result in targeting CD20-positive B cells which are engaged in the production of antibodies. Most patients in this study can tolerate rituximab with no sever hematologic derangements and mild infusion reactions were the most common side effects associated with our study.

Evaluating the Antifungal Efficacy of Incorporating Kappa-Carrageenan Powder Into “Heat-Cured, Acrylic-Based Soft Denture Lining Material

Hiba A. Salih¹, Faiza M. Abdul-Ameer¹
¹Department of Prosthodontics, College of Dentistry, University of Baghdad/Iraq

Abstract
Denture stomatitis is one of the serious problems that are related to the continuous use of soft lining material due to the accumulation of microorganisms. It is caused mainly by fungal growth, especially of Candida albicans. It, therefore, becomes necessary to examine the effectiveness of incorporating an antifungal drug into the soft lining material.

This study was conducted to investigate the efficacy of adding the kappa-carrageenan powder to heat-cured, acrylic-based soft lining material against Candida albicans adherence.

A pilot study was performed to decide the best concentration of kappa-carrageenan to be used with the heat-cured, acrylic-based soft liner. Five percentages by weight of kappa-carrageenan powder (0.5, 1, 1.5, 2, and 2.5 wt.%) were evaluated and compared with the control group (0 wt.%). The Candida albicans adherence test was performed to assess the efficacy of kappa-carrageenan powder in preventing the adherence of Candida albicans. Results showed the 1.5 wt.% and 2 wt.% groups as having the best effect.

The main study included preparing thirty samples and dividing them into three groups based on the percentage of powder of kappa-carrageenan added to the heat-cured acrylic-based soft lining material (control: 0 wt.%; experimental: 1.5 wt.% and 2 wt.%). The purpose of performing Candida albicans adherence test was to evaluate the antifungal efficacy of kappa-carrageenan powder addition, and all the resulted data were analysed using “one-way analysis of variance (ANOVA) and Dunnet T3 post-hoc test at a significance level of $p<0.05$”.

The results of Candida albicans adherence test revealed a highly significant decrease in the values of the adhered Candida albicans cells after incorporation of 1.5 wt.% and 2 wt.% of kappa-carrageenan powder when compared to the control group ($p<0.01$).

The result of this study suggests that the addition of kappa-carrageenan powder is an effective drug against Candida albicans adherence on the surface of the heat-cured acrylic-based soft lining material, and the addition of 2 wt.% is more effective than 1.5 wt.%

Keywords: soft liner, kappa-carrageenan, Candida albicans, denture stomatitis.

Introduction
Denture resilient lining materials that are applied over the intaglio surface of the denture to work as a cushion to absorb the stress generated by occlusal forces and to decrease continuous trauma on the denture-bearing area, making wearing the denture more tolerable to the patients¹.

The ideal soft lining material exhibits a number of properties to ensure maximum benefits for denture wearers; which may include dimensional stability, colour stability, good resiliency, biocompatibility, sufficient bond strength with the denture base material, low water solubility, and resistance to microbial growth².
The colonization of microbes in the soft lining material is one of the serious problems that affect its long-term efficacy. The most common clinical condition associated with this problem is “denture-induced stomatitis”; this condition is mainly caused by *Candida albicans*, which is the most popular fungi responsible for oral infections(3).

Topical antifungal medicaments can be considered as the most common line of treatment for “denture-induced stomatitis”. However, certain difficulties are associated with this type of management, such as the inability of the elderly to deliver the optimum dosage of the drug due to a lack of motor dexterity. To overcome this issue, a suggestion has been made to develop a drug delivery system by incorporating the drug into the denture materials. Furthermore, the development of fungal resistance against the drug due to its continual use for a prolonged time makes it necessary to search for a new effective medicament to be used as an alternative to synthetic drugs(3,4).

Herbal medicines have proved to be an excellent alternative treatment line for the management of oral infections, and this makes it necessary to investigate these products to ensure their biological safety and antifungal properties(5).

Carrageenan is a water-soluble sulphated galactan and major cell-wall component in red algae. It has been identified as possessing high anti-coagulant, anti-oxidant, anti-tumour, and anti-microbial activity(6). In addition, carrageenan has been used for many years as a food additive and in pharmaceutical applications due to its stabilizing, thickening, and emulsifying properties, and it is accepted by the U.S. Food and Drug Administration(FDA) and the World Health Organization(WHO). The recommended usage of carrageenan as an additive is advised to be in the range of 0.005–3%(7). Its suggested that these sulphated polysaccharide are negatively charged molecule which have inhibitory effect through its ability to produce alteration in the cell wall by interacting with the positive charge on the cell surface(8). Thus, this study was conducted to evaluate the effect of kappa-carrageenan against *Candida albicans* adherence to the heat-cured, acrylic-based soft lining material.

### Materials and Method

#### Pilot study

Heat-cured, acrylic-based soft liner(Vertex,Netherlands) was used. Kappa-carrageenan powder(Sigma-Aldrich,Denmark) was added to the powder of the soft liner in six percentages by weight of the powder (0, 0.5, 1, 1.5, 2, and 2.5wt.%). These groups were used to decide the two groups that produced the best effect against *Candida albicans* adherence. Mixing was done according to manufacturer instructions for the control group without the additive (0wt.%), while for the experimental group, the weight of kappa-carrageenan powder was subtracted from the weight of the soft liner powder to maintain an optimum powder/liquid ratio(9). The *Candida albicans* adherence test was conducted; four samples were used for each group. The results of the pilot study demonstrated that 1.5wt.% and 2wt.% produced the best effect against *Candida albicans* adherence to the denture soft lining material, so it was selected for the main study.

The pilot study also assessed the efficacy of using kappa-carrageenan powder in disinfectant form by adding it to the distilled water to be used as an immersion solution for denture disinfection. However, as the powder was added to the distilled water in the room temperature, it formed a gelatin that was thick in consistency; thus, the procedure was excluded from the main study due to a lack of feasibility.

#### The main study

A total of thirty samples were prepared and divided into three groups, with ten samples for each group: control group(C): heat-cured, acrylic-based soft liner without the additive; experimental group(E1): heat-cured, acrylic-based soft liner with 1.5wt.% kappa-carrageenan powder additive; and experimental group(E2): heat-cured, acrylic-based soft liner with 2wt.% kappa-carrageenan powder additive.

#### *Candida albicans* adherence test

**Sample preparation**

A plastic disc measuring 10×2 mm in diameter and thickness, respectively, was fabricated to make the final shape of the soft liner samples used for the *Candida albicans* adherence test(10). These plastic molds were invested in addition-type silicone material (Zermack,Italy); molds with the silicone replica were
then invested in the lower portion of the dental flask with freshly mixed dental stone (Zermack, Italy). Samples of the control group were prepared according to manufacturer instructions for the heat-cured, acrylic-based soft liner (powder/liquid ratio: 1.2 g powder/1 ml monomer), and mixed together using a clean glass container. For experimental samples, the weight of the kappa-carrageenan powder was subtracted from the weight of the soft liner powder to obtain an accurate powder/liquid ratio. An amalgamator device (Perfection Plus, United Kingdom) is used to mix the two powders for 40 seconds to obtain a homogeneous mixture. All samples were cured according to manufacturer instructions using a thermostatically controlled water bath (Lab.tech, Korea) heated to 70°C for 90 minutes; temperature was then raised to 100°C for 30 minutes. After processing, samples were finished with sharp scissors and polished with a fine-grit, silicone polishing bur under continuous water cooling. All samples were stored in distilled water for 24 hours at 37°C before being tested to eliminate any residual monomer.

Isolation and identification of Candida albicans

A patient with signs and symptoms of “denture-induced stomatitis” attending the College of Dentistry/University of Baghdad was selected. The Candida was isolated from the patient’s mouth using a sterile cotton swab and gentle rubbing of the intra-oral lesion, which was cultured on the surface of a “Sabouraud dextrose agar” (SDA; Oxoid, England) plates and incubated at (37°C) for 48 hours.

Candida albicans identification was made using macroscopic examination. The Candida albicans had a pearl-shaped appearance, with a creamy and pasty texture on SDA. A microscopic examination was conducted using a light microscope (Olympus, Japan) and gram stain procedure (Fig. 1) biochemical identification was made using the API-20C-AUX system and API-Candida system.

Candida albicans adherence test

The Candida albicans adherence test was accomplished by preparing a Candida albicans suspension using normal saline, which is equivalent to 0.5 McFarland standards. Then, 0.1% of Candida albicans suspension was added to a test tube containing 0.9% sabouraud dextrose broth (Oxoid, England) using micropipette; samples were immersed in this tube and incubated at (37°C) for 1 hour. After incubation, samples were taken out of the suspension and washed with phosphate-buffered saline for 1 minute, and dried using absorbent paper. Fixation of the adherent cells is done using methanol 80% for 30 seconds, followed by staining with crystal violet stain for 1 minute.

An inverted light microscope (Karl Kolb, Germany) was used to examine the samples using 40× magnification power, with the microscope being connected to a computer. Four standardised fields were examined in each sample.

Statistical analysis

Results of the presented research were analysed using SPSS “version 24 computer software”. The descriptive statistics that have been “made, includes means, standard deviation, and graphical presentation by bar chart”. “Inferential statistics” were also made, including one-way analysis of variance (ANOVA), for comparison means among all groups, and Dunnet T3 multiple comparison tests, which shows the significance between each of the two different groups, with P<0.05 considered significant.

Results:

Evaluating Candida albicans adherence

Results of the Candida albicans adherence test were evaluated by counting the number of adhered Candida on the surface of the control and experimental samples through the use of an inverted light microscope, in which it appeared as round or oval violet cells (Fig. 2). The results for both experimental groups showed lower mean values compared with the control group, with the experimental group (E2) revealing the lowest mean value of Candida albicans (4,910 cells) compared with the control group (C), which had the highest values of adherent cells (36,600 cells) (Fig. 3; Table 1).

**Discussion**

Herbal medicine is considered to be very reliable alternative to antimicrobial drugs, with little or no side effects; for this reason, there is worldwide interest in medicinal plant extracts. Therefore, much research has been conducted regarding their biological safety (4).

Kappa-carrageenan is a sulphated polysaccharide and major cell-wall component in red algae. Carrageenan has been studied recently for its several medicinal benefits, and it has been suggested that it can alter the cell wall by interacting with the positive charges on the cell surface (8).

The *Candida albicans* adherence test was performed because the adherence of *Candida albicans* on the fitting surface of dentures has been proven to be of critical importance in the development and maintenance of denture stomatitis in continuous denture wearing (18).

In this study, the incorporation of kappa-carrageenan into the heat-cured, acrylic-based soft lining material resulted in a decrease in the number of *Candida* cells adhered to the surface of the experimental samples when compared to the control groups.

The effect of kappa-carrageenan on *Candida albicans* is explained by Souza et al. (2018) who stated that these macromolecules possess antifungal activity and induce resistance to fungal organisms. This is in agreement with Soares et al. (2016) who suggested that carrageenan extracts promote morphological alterations in the cell wall of *Candida* species. After the exposure of *Candida* cells to kappa-carrageenan, the chitin cell wall content is decreased significantly. This alteration is associated with a decrease in beta-glucan content, which may influence cell death.

Another factor that affects the adherence of *Candida albicans* cells is that the surface of the soft lining material is considered to be a hydrophobic surface that enhances the adherence of the *Candida* species. The use of kappa-carrageenan, which is considered to be a hydrophilic material, may improve the hydrophilicity of the surface of the soft lining material, which eventually minimises the adherence of *Candida albicans* on the surface of
the heat-cured, acrylic-based soft lining material, as suggested by Yoshijima in 2010 (21).

The highly significant difference that occurred between the two experimental groups (E1 and E2) is due to the increased concentration of kappa-carrageenan powder, which resulted in an increase in its effect (22).

**Conclusion**

From the presented research, it can be concluded that kappa-carrageenan powder can be considered as powerful antifungal material and the incorporation of kappa-carrageenan powder into “heat-cure acrylic-base soft lining material” can successfully be accomplished to produce a soft lining material with antifungal properties against Candida albicans microorganisms. Also, experimental group(E2) showed a better antifungal activity when compared to the control and experimental group(E1).

Age Related Changes of Mandible and Maxilla In Human (Morphometric Study)

Noor Ghazi Saab¹; Abdul-Jabbar Jameel ²
¹Department of Anatomy & Histology, College of Medicine, Tikrit University/Iraq

Abstract

The properties of bones change during life and with age, it may improving in function, but in some times function deteriorates. Throughout development and aging, bone shape alters in response to load. This study provide information on the development and normal growth of dental arches in both sex.

Forty adult person of both sex were used. They divided in to 4 groups (A, B, C, and D). We will use different size of trays and take alginate impression material to get anatomical impression for the upper and lower jaw from the male and female and obtained a dental cast which is identical to the dental arch and make a table for all measurement that acquired.

The results showed that the age have a reliable degradation effect in both sex specially after 40 years old and except in the transverse measurement of female in mandible which started to decline after 30 years excluding the inter canine width which decrease after 40 years.

Keywords: human; Morphometric study ; Age Related Changes

Introduction

The skeletal system in the body consist of ligaments, cartilages, bones and other tissues that carry out critical roles for the human body. Osseous or bone tissue, is a dense, hard connective tissue that form the internal support structure of the body and shapes the majority of the adult skeleton. Osseous tissue are not a static tissue require to be regularly maintained and remodeled. The bone mechanism are sustained in a balance to resist crack whereas optimizing the skeleton weight. As we age, the bones density initiates to reduce in both sex. This loss in density goes faster in women after menopause. Accordingly, in old age bones become more likely to break and delicate. About age 30, most people get to their peak bone mass. For a while following reaching peak bone mass, your body substitutes about as much as it loses. However less bone is replaced around age 40 and this causes the bones to be converted into weaker and thinner, increasing the risk for osteoporosis.

In response to load throughout development and aging, the shape alters. As the shape changes (narrowing walls, shifting the center of gravity and lengthening), the functional capability may also be modified, the size of cortical bone, volume of trabecular bone and bone strength turn down with age. There is some discuss in humans as to whether the patterns of formation and resorption are comparable in both gender. It must be distinguished, however, in men the age-related loss is chiefly due to thinning of the individual struts, while the loss in women is due to a diminish in connectivity.

Material and Method

40 normal healthy person with normal occlusions from both sex (male & female), with age ranging from 20-60 years were taken from normal patient in dentistry clinic in Salahddin during period extending from October 2018 to April 2019. Patients were chosen with normal Class I occlusion and they don’t have any discrepancy or disharmony in the arrangement of their teeth.

Those patient were divided in to 4 groups according to age and each group was composed of ten adults (5 male and 5 female) as follows: G1(20-29), G2(30-39), G3(40-49) and G4(50-59) year.

In response to load throughout development and aging, the shape alters. As the shape changes (narrowing walls, shifting the center of gravity and lengthening), the functional capability may also be modified, the size of cortical bone, volume of trabecular bone and bone strength turn down with age. There is some discuss in humans as to whether the patterns of formation and resorption are comparable in both gender. It must be distinguished, however, in men the age-related loss is chiefly due to thinning of the individual struts, while the loss in women is due to a diminish in connectivity.

The stock tray is chosen for impressions. Alginate possess the qualities of excellent surface detail and faster response at higher temperatures. A dental impression is an imprint of the teeth and mouth from
which shaped items can be created (11), and after pouring the impression by stone a dental cast were made. The following measurement were made for the upper and lower dental cast to illustrate the changes that occurred in dental arch:

A. Transversal measurement:
Which include
- Inter central incisor width (I1-I1)
- Inter lateral incisor width (I2-I2)
- Inter canine width (C-C)
- Inter first premolar width \{DM1(PM1)-DM1(PM1)\}
- Inter second premolar width \{DM2(PM2)-DM2(PM2)\}
- Inter first molar width (M1-M1)

B. Anterior-posterior measurement:
Which obtained by
- Incisor-canine distance (I1-C): the line between the most mesial end on the central incisor and the most distal end on the canine.
- Canine-first molar distance (C-M1): the distances between the most mesial spot on the canine and the most distal spot on the 1st molar.
- Incisor-first molar distance (I1-M1): the distances between the mesial dot on the central incisor and the distal dot on the 1st molar.
- Total arch length (TAL): the total of the spaces between the most mesial spot on the canine and the most distal spot on the 1st molar on both sides.
- Dental arch length (DAL): the area between the line of inter molar distance and the labial surface of the most prominent central incisor.

C. Vertical measurement:
Which mean palatal deepness of maxilla (PD)

We made the transversal and anterior-posterior measurements as definite by Foster et al (12). Transversal measurements were obtained by calculating the means of the biggest and smallest distances between right and left identical teeth of the jaws. Anterior-posterior measurement were made only on left side. Palatal depth and dental arch length and their length above were taken by electronic digital caliper 100 (4").

Figure (1): Transversal measurements were measured amid analogous teeth on each side of the dental arch. The width was calculated for each pair of teeth, as the mean of the maximum and minimum distances between them (A+B/2).

Figure (2): Dimensions of total arch length, Dental arch length, Incisor-canine, Canine-first molar, Incisor-first molar.

Result

The analysis including the standard deviation values and their means shown in table 1. There is no significant differences in the result of $t$ test which shown that (p>0.05) between males and females, except the inter canine width in the G1 (20-29 years) which have a significant difference (p<0.01), inter first premolar width in G2 (30-39) which have (P<0.05) and in G4 (50-59) there is difference in significant which was (P<0.05). The inter second premolar width also revealed a significantly difference of (P<0.05). The statistical analysis of male in four age groups revealed that the transversal measurement of dental arch enlarge starting from Group 1 to Group 2 but in G3 there is general decrease in all measurement of dental arch. While in female the statistical analysis shown that in G3 the all measurement began to decreased except in the inter first premolar and inter second premolar which start to decreased in the G2 (30-39) and this revealed in table (1).

As can be seen in table 2 the all anterior-posterior and vertical measurement of male in maxilla they exhibited significant increase from G1 to G2 but the G3 revealed a significant decrease in all above dimensions, while in female also there is significant increase in G1 to G2 and decrease in G3 except the incisor-first molar distance and total arch length there is a significant increase with aging from G1 to G4. Furthermore the palatal depth (PD)
show significant decrease in G4 in female while in male began in G3. Also from table 2 we can see there is a significant difference in the G2 and G3 between both sex of (P<0.05) . A significant difference of (P<0.05) also seen in G2(30-39) in incisor-first molar and total arch length.

Measurement of table 3 exposed that in female revealed a universal decrease of all measurement in G2 except the inter-canine distance that start to decrease in G3 as in male . Also a comparison between male and female in the table three, which shown no difference of significantly between them excluding the inter first premolar in Group 2 and Group 4 which is (p<0.05), and inter second premolar in Group 2, Group 3, Group 4 of (p<0.05) in addition the inter first molar in Group 2.

The statistical analysis of table 4, show that the male in G3 have a significant decrease in incisor-canine and canine first molar distance and the all anterio-posterior measurement show the decrease from G2, other than in female there is an increase from G1 to G2 and the decrease started in G3.

There is no significantly difference between male and female in anterio-posterior measurement of dental arch except the canine first molar distance and the dental arch length illustrate a significantly difference (p<0.05*) in G1.

**Discussion**

Morphometric result in the dental arch including transverse, anterio-posterior and vertical depth measurement agreed in a large degree with many others authors. Current research investigate the arch length, arch circumference, inter-molar, inter-premolar, inter-canine distances, width of all teeth and arch form on dental cast from several orthodontic centers across Jeddah city in the western region of Saudi Arabia between April 2015 and May 2016 illustrate the arch width measurements were significantly greater in male subjects than in female subjects. This result supports the findings of several previous studies, Bishara et al\(^{(13)}\) which agreed with our finding except the inter canine width of mandible that greater in female in the G1 and G3 than the male and dental arch length in G3\(^{(14)}\).

A significant bone resorption with loss of projection of the maxilla in young and old patients demonstrated when Pessa\(^{(15)}\) measured the maxillary angle (superior-to-inferior maxilla at the articulation of the inferior maxillary wing and alveolar arch) . A significant reduction of the maxillary angle with aging noted by Shaw and Kahn\(^{(16)}\) and this approve our study about the age changing of maxilla which increase in G1 and G2 but the resorption start in G3 and in female some measurement degenerate in G2.

The crowded of front teeth among the elderly caused by human jaw shrinks with age in a new study has found. Plaster molds prepared for the jaws of dental students in 1949 when the individuals were in their 20s, and record jaw molds of the same people made in 1959 and 1989 which done by swedish researchers “We found that over these 40 years there was less and less room for teeth in the jaw,” said in a university news release by Lars Bondemark, a professor of orthodontics at Malmo University. A few millimeters of shrinkage in both the length and width of the jaws, primarily the lower jaw occurred and this due to reduction in the amount of space for front teeth. Hereditary and anatomical factors affect the amount of jaw shrinkage which varies between individuals\(^{(17)}\), this agreed with our study in which all the measurement increase from age 20 and 30 and started to decrease in 40 years except transverse measurement in female which started to decrease in 30 years.

Abstract

Introduction: The inferior alveolar nerve (IAN) is one of the most important vital structures found in the mandible, knowing the precise location of the mandibula canal is helpful to decrease the incidence and avoid the injury to the (MC).

Material & Method: 30 males & 30 females were selected from the data of the (CBCT) stored in the computer joined to the device and the measurements were taken as follow “ The first section in transaxial view after mental foramen, where the loop of mandibular canal is formed, was selected as point A and interludes of 10 mm were selected for subsequent measurements (respectively, points B,C,D). On these sections, the shortest linear distances (in mm) from the most lingual aspect of the canal to the outer lingual cortical plate of the mandible(L) and from the mandibular canal to the inferior border of mandibular body(I) were measured. Furthermore, the minimum distance between the buccal cortices and the mandibular canal(B) were evaluated” as in (Fig. 1). Using SPSS software Version 15 the data that had been obtained was analyzed.

Results: The results had been showed that there is no significant difference in measurements were taken between males and females groups in the measurement of the distance of the inferior dental canal to the buccal cortical and in the measurement of the distance of the inferior dental canal to lingual cortical bone of the mandible, only in the measurement of the (IDC) to inferior border of the mandible there was a significant difference in only one point

Conclusion: It can be concluded from this study that the information can be obtained by the (CBCT) about the location of the (MC) can helpful for the surgeons to avoid damage to (MC) throughout surgical procedures in the mandible, and those information can give good overview and conception for course of the (MC) through the mandible.

Key words: inferior alveolar canal, cone beam computed tomography

Introduction

The inferior alveolar nerve (IAN) is one of the most important vital structures found in the lower jaw, it is the largest branch of the mandibular nerve which is the 3rd division of the trigeminal nerve, the (IAN) has a great attention in the surgical treatment of the area of the mandible, the inferior dental canal (IDC) changes the buccolinguinal direction and the vertical direction in its course inside the mandible, it is very important to locate the precise location of the mandibular canal (MC) to make the treatment plan for the surgery would be involving the mandible and avoid the injury of the (MC) throughout the surgery. The difference in the anatomical location of the (MC) must be constantly taken into consideration to avoid (MC) injury throughout surgical procedure involving the mandible such as dental implant, extraction of impacted 3d molar, osteotomy, repair of fractured mandible, placemen of screw, and orthognathic surgery. During dental implant procedures and orthognathic surgeries it was noticed that the average of neurosensory disturbance of (IDC) was up to 77.8 and 65.1% respectively, throughout the surgical extraction of the impacted mandibular third
molar the rate of (IDC) injury was recorded to be 0.4-13.4%\(^5\), studies showed that during the bilateral sagittal split osteotomy of the mandible as the (MC) closer to the buccal aspect of the mandible the rate of (MC) injury would be increased\(^6-10\).

using cone beam computed tomography in the evaluation of the course and anatomic location of the mandibular canal was carried out in previous studies\(^{11-13}\). The aims of this study were to evaluate if the difference in the gender would be effective in the prediction of the relative location of the canal and to assess the relation of the location of the (MC) to the cortices of the mandible utilizing CBCT.

**Material and Method**

The study was approved by the Ethical Committee of Collage of Dentistry, University of Tikrit, the study was done in the department of radiology in the specialized dental center, ministry of the health in Tikrit city, from the pool of data of the cone beam computed tomography (care stream) made in Germany, 30 males and 30 females were selected without any pathological condition or fracture can affect the normal position of the Inferior Dental Canal, after making reconstructed panorama to reveal the course (IDC) from the mental foramen to the mandibular foramen in slice thickness 0.5 mm , according to the study was done by Hooman Khorshidi et al in 2017\(^{13}\) the measurement were taken as follow “ The first section in trans-axial view after mental foramen, where the loop of mandibular canal is formed, was selected as point A and interludes of 10 mm were selected for subsequent measurements (respectively, points B,C,D). On these sections, the shortest linear distances (in mm) from the most lingual aspect of the canal to the outer lingual cortical plate of the mandible(L) and from the mandibular canal to the inferior border of mandibular body(I) were measured. Furthermore, the minimum distance between the buccal cortices and the mandibular canal(B) were evaluated” as in (Fig. 1). Using SPSS software Version 15 the data that had been obtained was analyzed.

**Results**

The results had been showed that there is no significant difference in measurements were taken between males and females groups in the measurement of the distance of the inferior dental canal to the buccal cortical and in the measurement of the distance of the inferior dental canal to lingual cortical bone of the mandible , only in the measurement of the (IDC) to inferior border of the mandible there was a significant difference in only one point as the table (1) and the abbreviation were used in the table as follow:

A: the 1\(^{st}\) point
BA: the distance of the (IND) to the buccal cortical pate in the point A
LA: the distance of the (IND) to the lingual cortical pate in the point A
IA: the distance of the (IND) to inferior border of the mandible in the point A

B: the 2\(^{nd}\) point
BB: the distance of the (IND) to the buccal cortical pate in the point B
LB: the distance of the (IND) to the lingual cortical pate in the point B
IB: the distance of the (IND) to inferior border of
the mandible in the point B

C: the 3rd point

BC: the distance of the (IND) to the buccal cortical plate in the point C

LC: the distance of the (IND) to the lingual cortical plate in the point C

IC: the distance of the (IND) to inferior border of the mandible in the point C

D: the 4th point

BD: the distance of the (IND) to the buccal cortical plate in the point D

LD: the distance of the (IND) to the lingual cortical plate in the point D

ID: the distance of the (IND) to inferior border of the mandible in the point D

Table -1- the measurements of the distances of the inferior dental canal to buccal and lingual cortical plates and to the inferior border.

Discussion

Several studies have been concluded that the knowledge of the relative position of the (IDC) to the buccal and lingual cortical bone of the mandible and to the inferior border of the mandible is important to predict and avoid the loss of sensory in the mandibular nerve\(^{(7,9)}\), the textbooks of anatomy do not describe in detail the course of the mandibular canal, there are several studies to give comprehensive understanding of the course of the mandibular canal such as clinical observation throughout surgical procedures\(^{(14)}\), measurement on dry skull\(^{(2,15-17)}\), traditional radiograph\(^{(6,18-20)}\), and computed tomography scan\(^{(7,8,21-24)}\), each one of the methods mentioned above has limitation such as change in dimension in dry skull, 2D and change in the size in the traditional radiograph, and high dose of radiation in CT scan, Kamburoğ˘lu et al. and Eizenbud et al. showed that the method of the using of CBCT to predict the course of the mandibular canal is the most non invasive and precise method used till now \(^{(25,26)}\), the results of this study have been showed there is no significant difference in the buccolingual relative position of the mandibular canal between males & females groups and those come in accordance with the studies of Simonton JD, et al\(^{(27)}\), Kane AA, et al., Angel et al\(^{(28)}\). The studies of de Oliveira Ju´nior et al\(^{(29)}\) al. and Hooman Khorshidi et al\(^{(13)}\) showed that the all measurements were smaller in female group than males group in our study that com in agreement only in measurement of mandibular canal to inferior border of the mandible and only in one point of the measurements and in the other 3 points there were no significant difference and may be difference in the races was the reason, the whole results were fairly constant in both males and females groups, our results have been suggested that as the mandibular canal runs from the entrance of the mandible in the mandibular foramen to the mental foramen the (MC) would be toward the buccal side as the (MC) runs anteriorly and the values of the means of the lingual measurements decreased as (MC) runs anteriorly and that is come in agreement with the studies of Ylikontiola L\(^{(6)}\), and Hooman Khorshidi et al\(^{(13)}\), de Oliveira Ju´nior MR. et al\(^{(29)}\).

It can be concluded from this study that the information can be obtained by the (CBCT) about the location of the (MC) can helpful for the surgeons to avoid damage to (MC) throughout surgical procedures in the mandible, and those information can give good overview and conception for course of the (MC) through the mandible.

Correlation of Urine Leukocytes and Urine Bacteria Using Current Sitometry Using Urine in Patients of Children Channel Infection

Adriyani Amin¹, IGAA Putri Sri Rejeki¹, Ninik Soemyarso Asmaningsih¹

¹Department of Clinical Pathology, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo Teaching Hospital, Surabaya, Indonesia, 60285

Abstract

Background: Urinary tract infection (UTI) in children is a common illness. The gold standard for UTI diagnosis is urine culture, but it takes a long time and often gives negative results. Currently developed a method of flow cytometry for checking urine sediments. This tool is able to detect leukocytes urine and urine bacteria in quick time. The purpose of this study is to analyze the relationship of urine leukocyte count and the number of urine bacteria using flow cytometry with urine culture in patients with UTI.

Method: Eighty-four patients were enrolled in this study that consisting of 43 patients with suspected UTI and 43 patients with non-ISK treated at Inpatient Installation, Emergency Installation Department of Health Sciences at Dr. Soetomo General Hospital, Surabaya for 4 months. The examination of urine leukocytes and urine bacteria was using current cytometry method (UF-500i, Sysmex, Japan). While, examination of urine culture using blood agar plate and Mac. Conkey.

Results: There was a significant relationship between the number of leukocytes and the number of colonies. The relationship between leukocytes and the number of colonies was weak, this was indicated by Spearman correlation coefficient (rho) value of 0.376. There was a significant relationship between bacteria and the number of colonies. p <0.05. The relationship between the number of urine bacteria and the number of colonies was quite strong indicated by rho = 0.729.

Conclusion: There was a relationship between urine leukocyte count and the number of urine bacteria using flow cytometry with urine culture.

Keywords: Urine leukocytes, Urine bacteria, Urine culture, Urinary tract infections.

Introduction

Urinary tract infection (UTI) in children is a common illness that found in addition to upper respiratory tract infections and diarrhea and the second most common cause of fever after upper respiratory tract infection ¹. Urine culture examination takes a long time and can give false negative results. It may delay the diagnosis of UTI, which in the end the management of UTI is also delayed, which may lead to poor UTI prognosis. The incidence of UTI in children at Indonesia ranges from 0.1% to 1.9% of all cases that children treated within 5 years (1984-1989) ².

The high incidence of UTI causes many requests for urine culture examination³,⁴. Positive urine culture when bacterial growth of more than 100,000 colony forming units (CFU)/mL from one pathogen⁵. 60-80% urine culture examination did not contain any infectious bacteria or just contaminants that can be solved by filter test ⁴,⁶,⁷. Examination of bacteria with Gram staining (sensitivity 96%, specificity 93%), examination
using 10 cell/μL hemositometer (83% sensitivity and specificity) ⁸. Microscopic examination can give results faster than culture, more simple and inexpensive. But the results of the examination require skilled, trained, and interpretation among interrogators can be different ⁶. In addition to microscopically, examination of urine and urine leukocyte bacteria can use the method of flow cytometry. Current cytometry methods can distinguish particles in urine and quantitatively calculate them, including leukocytes, erythrocytes, epithelium, bacteria, fungi, cylinders, and crystals. Sysmex UF-500i is one example of urine sediment examination tool using current cytometry method. This tool is able to check large quantities of samples with fast time ⁶,⁹,¹⁰

The sensitivity and specificity of the examination using flow cytometry to confirm the diagnosis of UTI is non-existent. Previous studies have suggested that the 65-bit bacteria/mL and 100 leukocyte/mL cutoff points gave 98% sensitivity, specificity 62.1%, negative predictive value 98.7%, positive predictive value 53.7% ¹¹. Other studies also stated that at the point of cutting of 230 bacteria/μL, urine culture <10⁵ CFU/mL obtained 95% sensitivity and 80% specificity and able to reduce the number of urine culture examination by 52% ⁹. Research using flow cytometry in Indonesia is still rare. In this research will be examined using flow cytometry to assess the relationship of urine and urine leukocytes with urine culture results.

**Method**

This research was an observational analytic research with the cross-sectional design. The research started from the literature search, research proposal preparation, sample collection and workmanship, data management, and research report preparation conducted from March until June 2013. The research was conducted at Inpatient Installation, Outpatient Installation and Emergency Installation of Department Child Health Science Dr.Soetomo General Hospital/Faculty of Medicine Universitas Airlangga Surabaya, as the place of sampling. Sample examination was performed at the Clinical Pathology Installation of Dr.Soetomo/Faculty of Medicine Universitas Airlangga, Surabaya. The sample of the study was the pediatric patient and divided into two groups: groups of patients with UTI and Non-UTI that meet the inclusion criteria.

The inclusion criteria for samples meeting the criteria in this study included patients with suspected UTI aged 2 to 18 years, patients receiving antibiotics, doing urinalysis examination and obtaining positive esterase leukocyte, positive nitrite, uric microstatic leukocyte>5/μLpb or found urine bacteria microscopic, and willing to sign informed consent. Urinalysis results obtained negative nitrite, leukocyte esterase negative, leukocyte urine microscopic <5Lpb or not found microscopic urine bacteria.

This study was started by selecting the sample according to the inclusion criteria, then the urine sampling was performed by catheterization in children less than 6 years old and the way of urine transmit clean in children more than 6 years old. After the urine sample is directly sent to the Installation of Clinical Pathology Dr.Soetomo General Hospital for urine examination using flow cytometry (UF 500i) (Sysmex Corporation, Japan) and urine culture was done within ≤ 1 hour.

All collected data collected in the data collection sheet was presented in tabular form, the diagram was processed statistically in the form of descriptive analysis. To calculate sensitivity, specificity, positive predictive value, negative and ROC curve, and to know the relation of urine leukocyte count and urine bacteria, statistic analysis test using Pearson correlation test if the data was normally distributed if the data not normally distributed using Spearman correlation test.

The results of the examination of the number of urine bacteria obtained the lowest value of 0.0/μL and the highest 58017.8/μL. Median examination results of urinary bacterial counts in the UTI group of 671,85/μL with a range of 19.4/μL to 58017.8/μL. Median examination results of urinary bacterial counts in the non-UTI group were 7.2/μL with a range of 0.0/μL to 832/μL. There was a significant difference in the number of urine bacteria between group UTI groups rather than UTI, p <0.05 (Figure.4B). Current cytometric examination can also display a scattergram image that can be viewed on scattergram B1 (Figure.3BA). Urine bacteria is represented by a purple (purple) color. There are two typical features of the slope of the bacterial scattergram namely the inclination 1 (Figure.3BB) and the slope 2 (Figure.3BC). 26 samples were tested to match the results of identification of urine cultures with current isometric illustrations. There were 18 samples that can be tested suitability and 18 samples cannot be analyzed because it does not give a typical picture. The 18 samples had bacterial counts <105 CFU/mL. The slope of 1 was 66.7% according to the culture of urine, whereas on the slope 2 there was 93.3% according to the culture of the urine (Table 1). The results of the examination of leukocyte counts with 40/μL cutoff points were 28 (32.56%) of the samples, and 58 (67.44%) of the samples were not-UTI (Table 2). The sensitivity of leukocyte examination with cutting point 40/μL to the culture of urine was 65.4%, with specificity 81.7%. The positive predictive value and negative predictive value was 60.7% and 84.5% respectively. The diagnostic value of urine leukocyte examination using flow cytometry (Table 3).
The ROC curve formed for examination of urine leukocyte counts using flow cytometry at the cutting point ≥40/μL against urine culture results ≥ 5x10^4 CFU/mL (Figure 5A). The under the curve (AUC) area was 0.793 (medium), p < 0.05. (95% CI 0.69 - 0.89). When using the cutoff point 30/μL then obtained the sensitivity of 69.2% and specificity 71.7%. The results of the examination of the number of bacteria with 125/μL intake point were 21 samples (24.4%) and 65 samples (75.6%) samples instead of UTI (Table 2). The sensitivity of examination of urine bacteria with the 125/μL cutting point for urine culture was 69.2%, with specificity 95.0%. Positive predictive values and negative predictive values were 85.7% and 87.7% (Table 3) respectively. The ROC curve formed for examination of the number of urine bacteria using flow cytometry at the point of ≥ 125/μL against the urine culture result ≥ 5x10^4 CFU/mL (Figure 5B). The under the curve (AUC) area was 0.946 (very good), p < 0.05. (95% CI 0.902 - 0.989). AUC obtained on bacterial examination is wider than in urine leukocyte examination.

**Discussion**

Based on the results obtained, there was the growth of 3 kinds of colonies of germs or more without dominant species that considered as contaminants. If there were 3 or more different organisms in urine culture then a strong allegation of shelter errors and handling of urine samples. But it can also be found in patients who use permanent urinary catheters.

There is a growth of fungi in urine culture results, these results are consistent with earlier studies, in which UTI may also be caused by pathogens (fungi, parasites, and viruses) colonizing the urinary tract. Mushroom (Candida spp) is one of the causes of UTI. The presence of fungi in urine culture is an indicator of pyelonephritis that derived from hematogenous spread (descending path). Haematogenous spread is usually as a result of bacteremia or in patients with immune system disorders.

The result of urine culture obtained significant growth. These results were different from previous studies, the difference may be due to the screening of patients suspected of strict UTI. When more rigorous screening was performed then the possibility of a positive urine culture percentage will be even more. However, it is also known that the main problem of urine culture examination lies in the collection of samples, the length of urine in the bladder, the density of the urine, if the low urine weight may be due to increased urinary frequency, the number of colonies obtained is also low. Sampling and transportation of samples, culture techniques and interpretation of results also greatly influence urine culture test results.

The incidence of UTI depends on age and sex. In this study, girls with UTI were more likely to be in the age group 0-1 years and over 5 years, while the 1-5-year-olds were more likely to suffer from boys. Girls are more at risk of developing UTI by the first year of life than boys because of different anatomical features. Moisture of the periurethral and vaginal areas stimulates the growth of uropathogenic. A shorter urethral size increases the chances of ascending infection to the urinary tract. Besides, women are more likely to receive UTI because the uropathogenic, which is part of the normal flora of the stool, can colonize in the perianal which can then rise to the vaginal introitus. The spread of uropathogenic into the periurethral, urethra and bladder can be inhibited by the normal vaginal flora (Lactobacillus sp) causing the acidic vaginal pH. If the vaginal flora is also impaired it can cause uropathogenic to stick to the urinary tract and multiply and the incidence rate of UTI will increase in estrogen deficiency.

The most common pathogenic bacteria causing UTI were Escherichia coli (E. coli). E. coli was associated with childhood UTI in developing countries. Bacteria can survive and replicate because they have virulence factors such as expression of fimbriae, synthesis of aerobactin and enterobactin (iron-binding protein), which is very high affinity to iron, useful for bacterial replication, producing hemolysin, glycocalyx-mediated adherence, somatic Ag expression, producing urease, may move and be resistant to serum bactericidal activity. There was a significant number of urine bacteria between group UTIs rather than UTIs. p < 0.05, so the number of bacteria with current cytometric examination can be used for screening examination of suspected UTI patients, thus reducing the number of urine culture requests. However, it is known that direct bacterial examination cannot distinguish between uropathogenic or contaminants.

There were two images of the slope of the scattergram bacteria (scattergram B1), which a slope of 1 that formed from densely dispersed points and extends along a diagonal line. This describes was suspected of the bacteria in the form of coccus. Tilt 2 was the slope...
formed from the points collected/concentrated in the narrow zone. This picture of the possibility of urine bacteria in the form of stems 16. The compatibility between the slope 2 and the shape of the stem bacteria was 93.3%, while for slope 1 only 66.7%. The same result was obtained in the previous research which got 2 slope suitability of 100% while the slope of 1% was 75% from 47 samples under study 16. The formation of a typical slope image is caused by the working principle of bacterial examination using a red (semiconductor) laser that concerns the bacterial distribution of B_FSC (describes particle size) and B_FLH (describes the intensity of the nucleic acid color of the particles) 14.

The result of the analysis shows that there was a significant correlation between urinary leukocyte count and the number of colonies, but the relationship was weak, it indicated by the correlation coefficient (Spearman) only 0.376. The flow of urine can usually clear the urinary tract of pathogens. Urine itself also has specific antimicrobial properties, including low urine pH, high urea content, high organic acid content, polymorphonuclear cells, and Tamm-Horsfall glycoprotein, which can inhibit bacterial adherence in the bladder mucosal wall 6,15. The relationship between urine bacteria and the number of colonies was quite strong, this indicated by the value of the correlation coefficient (Spearman) that quite large by 0.729. Urine bacteria found in current cytometric examination was associated with positive urine culture results but direct bacterial examination cannot distinguish between uropathogenic or contaminants 15.

**Conclusion**

Based on the results of research and discussion can be concluded that there was a weak relationship between urinary leukocytes and the number of bacterial colonies, but a strong relationship between urine bacteria with the number of bacterial colonies.

Abstract

This research aims to describe the forensic examination in the handling of the sexual crime which happened to an Indonesian migrant worker in Taiwan. It is well known that the level of human rights protection in Taiwan is quite good compared that of the other destination countries for migrant workers. Yet, is the good level of human rights protection balanced also with medical treatment or medical forensic examination of the Indonesian migrant worker sexual crime victim who worked in that country. This research uses a non-doctrinal method. This is because the law is not only a normative theory. Yet, it also views the sociological aspects which happen in the society. The research results show that Taiwan is a country with a worrying rate of sexual crime. Yet, it has underwent good procedures in forensic examination, including in visum et repertum and other examinations for sexual assaults which happened to migrant worker victims. The visum et repertum preliminary examination which applies in Taiwan is done through a special unit which is provided for sexual assault victims. The results are acknowledged as evidences of sexual crime. It will be directly coordinated with the Taiwan special unit of justice for sexual crime.

Keywords: Forensic, Sexual Crime, Migrant Worker

Introduction

Sexual crime is a serious crime which causes prolonged physical or psychological trauma if it is not handled properly, not only for the victims but the effect can also befall upon the victims’ family.¹

The number of sexual crimes in Taiwan is considered high and the rate tends to increase every year. In 2017, the number of sexual crimes reported to the Taiwan women’s protection bureau was 14,217 cases, and it increased 50 cases to 14,267 cases in 2018. Although in 2018, a special movement for the protection of sexual crimes victims has been formed with the “me too” movement, which is the slogan of a global movement in the protection of sexual crimes victims, in which the Taiwanese government has actively participated in this global campaign, but it seems unable to reduce the reported number of sexual crimes cases in Taiwan.²

Sexual violence which occurs to Indonesian migrant workers in Taiwan each year is no less than 100 cases, which is usually carried out by the employers, the employer’s close relatives and their own employment brokers. During the last 6 years since 2012 – 2018, there are 633 cases of sexual violence which have befallen to Indonesian migrant workers.³

Sexual violence or crime is indeed the crime that has been the highly reported, but the number of cases that are successfully handled and processed until tried and sentenced is tiny, especially if the case happened to Indonesian women migrant workers in Taiwan.⁴

and dirty hence they are afraid and very embarrassed to report it (5).

Forensic visum et repertum examination has an effective time span of 72 hours so that if the crime is not handled as soon as possible, namely in the golden time where the time span is 72 hours after the rape, it will be arduous to find the evidences needed (6). Since these female migrant workers usually report the assault weeks or years after it happened, hence the perpetrators rarely get caught in the law, except for one phenomenal case that has been recorded to successfully enter the court and the perpetrator was severely sentenced to 7 years and 10 months of imprisonment (7).

The perpetrator is a member of the city council in Hualien, Taiwan. He committed a violence against an Indonesian migrant worker who was employed as a nurse at his house. Even though the case was appealed to the Taiwanese Supreme Court by the perpetrator, the court of appeal and the Taiwanese Supreme Court still rejected it. (8)

Most of the sexual crime’s perpetrators escaped the law due to the lack of knowledge from the victims and the response from law enforcement officials themselves. Most perpetrators will try to eliminate the evidences by threatening the victims not to report or order them to bathe in order to remove the traces of sexual intercourse on the victim’s body, thus making it difficult for the law enforcers to carry out visum et repertum as a forensic effort, furthermore the victims who do not want to report immediately, will make the evidences disappear after 72 hours. (9)

Forensic medical science is a solution for the verification difficulty in ensnaring the sexual crimes perpetrators (10). With forensic medical science, the law that was still in the dark in finding or ensnaring the perpetrators can find a bright spot in allowing the perpetrators to be ensnared by the law. (1)

Rape is an act of violence which the sexual intercourse is not on the basis of mutual consent but it is forced. Rape is difficult to prove legally even though there may have been the evidences collection and examination, unless forensic test is carried out (11). In the Taiwanese Constitution which is the criminalization basis for rape, it is stated that “anyone who with violence or threat forces a woman without marriage relations to have sexual intercourse with him and because of his offense of rape, is sentenced with an imprisonment up to 12 years”. (12)

From here, the verification that the intercourse happened must be proven first thus to be called a rape. While to verify it, one of ways is by identifying the presence of the perpetrator’s sperm in the victim’s body through a forensic test conducted in a more specific area in her vagina. However, it needs to be understood that the sperm can only live in the vaginal cavity for a maximum of 3 days or 3x24 hours. While in a dead state, the sperm can still be found or remain in the vagina for a maximum of 7 days or 7x24 hours. (13)

It will be difficult to prove the rape if after a crime has been committed by the perpetrator, the victim then does not report it within a specific timeframe so that it becomes difficult in proving through visum et repertum (14). Not to mention if after the rape, the perpetrator forces the victim to clean the body and all the traces of rape that had occurred (15).

So in such rather complex occurrences, forensic science may help revealing the occurrence of sexual crimes and the perpetrator of said case. (16) Forensic Medicine has techniques which are commonly used in serious crimes such as murder and rape, based on automatic fingerprint recognition or search technology and automatic DNA database search or visum et repertum examination or forensic post and ante mortem which result major changes altogether on forensic medical techniques in the resolution of criminal cases. (16)

The role of Forensic Sciences in obtaining clarity for the sake of proving that a rape crime has indeed occurred is to examine the victim thoroughly in order to obtain the evidence through the examination of special forensic expert doctors for rape victims who have died and obstetricians for examination of victims. The results of the examination were written in the form of visum et repertum which would later be used as evidence in the category of letter evidence to be used in court plus the statements of the expert or doctor concerned (who conducted the forensic/visum et repertum test) to be present if necessary for questioning as an expert before a court hearing. (16)

The accuracy of a forensic doctor or forensic laboratory in analyzing victims to obtain evidence will determine the fairness which will be obtained by the victims and also the perpetrators (17). Because if there has been found any errors or misdiagnosis in the forensic laboratory analysis conducted by certain doctors or
specialists, it may result in fatal consequences such as the perpetrators may be in released or they may be arresting the wrong person who did not commit the said crime.

Method

This study is a legal normative study using literature study. It discusses the visum et repertum and forensic examination of a rape case as a sexual crime towards an Indonesian migrant worker in Taiwan.

Finding and Discussion

The steps required to find evidences of sexual crimes such as rape in Taiwan against Indonesian migrant workers is similar to the general procedures applied for the other citizens, thus there is no specific exception and discrimination in law enforcement treatment in Taiwan in this case. As rape and sexual crime cases in Taiwan has indeed become major issue which is of a serious concern of the Taiwan government itself. (9)

The stages to find evidence through a forensic examination in supporting further forensic analysis of victims of sexual crimes such as rape which befall upon migrant workers are as follows:

1. Investigating the crime scene by officer (police) stage
   - Check the victim’s condition whether it requires first aid, identify the victim’s age, and analysis of alleged sexual accident scheme
   - Identify the victim’s body condition to check whether there are signs of violence
   - The process of securing evidence and the crime scene from unauthorized persons
   - The process of collecting evidence properly such as victim’s pants and shirts, blood stains, mucus, scattered strands of hair, spots on fabric, et cetera.
   - Examine the victim’s expression
   - Examine the condition of the victim’s clothing (torn, broken, and such)
   - Sending the victim by providing the visum et repertum form to the nearest hospital and have them refrained in washing themselves, escorted by police thereby the results would be more precise.

   - If required, the victim may be isolated for the purpose of forensic examination.

2. The stage of collecting the evidences at the crime scene by the police
   - Materials which involves chemicals, drugs, and alcohol
   - Physical materials which includes clothing and cloth used to bind or lock the victim
   - Biological materials such as sperm, blood, hair and mucus/saliva

3. The early stage prior conducting visum et repertum upon the victim by a doctor
   - Mandatory written request from Taiwan prosecutors or a particular police who has been mandated
   - The victim came with special police assistance
   - There is a victim’s consent, if the victim is unconscious, the consent may be obtained from the victim’s family
   - To be examined as early as possible to avoid the destruction of evidence

4. The examination of the victim

This victim examination is divided into two parts which are general and special examination. The general examination is as follows:

   - The face, hair, and emotions of the victim
   - Signs of the victim was intoxicated, unconscious, and/or was exposed to narcotics
   - Signs of violence by examining all parts of the victim’s body thoroughly
   - Evidences which might be attached to the body of the victim who is allegedly belongs to the perpetrator
   - Identification of the perpetrator’s age
   - Identification of height and weight
   - Further identification if required
   - Special examination includes (19):
     - Genital skin, to check whether there’s rupture or other signs of violence
- Eritema vestibulum examination
- Vaginal bleeding
- Vaginal abnormalities which might result in infection
- Hymen examination
- For female victims who have had intercourse prior the incidence of rape/sexual crime, would then be sought whether there has been another rupture for the women who have never given birth
- Examination of the presence of sperm cells left in the vagina
- Anal examination under the allegation of anal rape possibility, rupture/scar might be visible
- Laboratory tests such as blood tests, sperm fluid, pregnancy tests, examination of other diseases such as the potential of contracting HIV, Gonorrhea, and hepatitis. Also an examination of body fluids or hair which might belong to the perpetrator.

5. History/interview to the victims
6. Victim’s physical examination
7. Assessment

There are two traumas which become the result of the assessment after the alleged presence of sexual crime, which are as follows:
- Non-genital trauma
- Genital Trauma

The aspect of sexual crime victim’s physical examination, based on the procedures practiced by medical forensic in Taiwan are as follows: (20)

Margareth Stark states that the doctor’s description of sexual crime may become the main reference of law enforcers in examining the victim. The doctors them selves will become the reference when they are present in court as expert witnesses. (22)

What was practiced in medical forensics in the handling of sexual crime towards migrant worker are actually almost the same as that which happens in Indonesia (23). It’s just that the support of technology in medical forensics and in the examination process in Taiwan is more advanced as they are equipped with more updated technologies.

**Conclusion**

Sexual crime in Taiwan is a serious crime which attracts special attention from the government. This is because the rate of cases is high. It worries the society. Moreover, there is a tendency for the increasing rates of sexual crime, which makes it become a serious crime in that country.

Rape is a form of sexual crime, which is also a crime against the human rights. This is because it causes severe and serious effects for the victim and the family. The evidencing process is also complicated and difficult to handle. Yet, it can be done through detailed forensic
examination, supported by technological advancement in Taiwan. This eases the process of catching the perpetrators. The evidences obtained in the Taiwanese medical forensics are valid evidences in court in front of the judges from the district to the Supreme Court level. They are to decide whether the defendant is guilty or not. Forensics may show the identity of the perpetrator/defendant in a sexual crime, as well as the pattern and type, the time, the location, the modus operandi and the motives of that crime.

Forensic and Toxicological Tests for Protecting the Patients of Esthetic Beauty Clinic as the Constitutional Right in Indonesia

I Gusti Ayu Ketut Rachmi Handayani1, Pujiyono2, Siska Diana Sari3

1Professor, Faculty of Law, Universitas Sebelas Maret Surakarta, Indonesia, 2Professor, Faculty of Law, Universitas Sebelas Maret Surakarta, Indonesia, 3Lecturer, Faculty of Law, Universitas PGRI Madiun, Indonesia, Corresponding Author:

Abstract

Esthetic beauty clinic is many people’s need, but the critical point of protection for its patients is still weak. Many problems often affect the patients of esthetic beauty clinic. Patients deserve protection of medical service standard constituting something important to maintain and to improve. Forensic and toxicological medical sciences are needed to give adequate protection to the patients of esthetic beauty clinic. Through its scientific method, the state could prove, prevent, and take action all at once against the esthetic beauty clinics operated haphazardly. The clinic selling, concocting, using, and promoting hazardous and toxic drug and cosmetic can be detected and acted on, while forensic test was intended to prove the consequence or output of esthetic beauty clinic’s service. This scientific method supported the protection and the right of patients of esthetic beauty clinic, corresponding to the constitution.

Keyword: clinic; protection; forensic; toxicology; aesthetic

Introduction

A new trend of medical aesthetica, is an individual’s aiming to get healthcare treatment including both general checkup and rehabilitation; it is usually performed by the patients in developing countries looking for medical service in the developed countries in order to get high-technology service quality, as shown by the finding of research below.

In recent years, a variety of beauty clinics appear more prevalently in Indonesia, for example, Dr. Affandi’s esthetic beauty clinic, Natasha Skin Centre, London Beauty Centre, Erha, and Larissa providing beauty treatment product that can make the patients excited. Beauty Clinic is an ambulatory healthcare service provider providing medical care service (consultation, examination, treatment, and medical action) to deal with many beauty-related conditions/diseases (appearance esthetics) among individuals, conducted by medical workers (physician, dentist, specialist, and dental specialist) corresponding to their skill and authority.1

The result of researches on trend beauty in Asia today shows that:

This beauty business growth builds on women and metrosexual men’s want to appear perfectly in Indonesia, so that to achieve their want they voluntarily spend their money to buy the expensive facial and body treatment products. The wish to appear beautifully or charmingly and well-groomed is a human’s physical need, particularly to women. Even along with the times, men as if do not want to be left behind the women in the term of tidy and charming appearance; such the men are called metrosexual men. It is this reality that encourages many companies operating in Beauty and Personal Care to keep innovating to create high-quality product the patients look for in order to win the market.

Beauty and esthetic clinic is inseparable from the contribution of physician serving as consultant and the one giving treatment or taking action in the beauty clinic’s service, and the business of beauty clinic itself. It is important to study because physician is bond to
Indonesian Medical Ethical Code as the legal source in undertaking his/her profession and Indonesian Honor Chamber for Medical Discipline as the supervision of physician’s professionalism in Indonesia; therefore when a physician is suspected to break the law, he/she should be processed immediately, because knowledge and science he/she has should be used duly rather than for profit-oriented purpose only and breaking medical ethical and professional code.

The protection of patients from the service provided by esthetic beauty clinic is a distinctive problem, so the basic problem in this study is how the law protection model is for the patients of esthetic beauty clinic in the citizen’s constitutional right perspective. The form of protection provided to the patients of esthetic beauty clinic is, among others, forensic test on esthetic clinic.

Responsible of the state for fulfilling the citizens’ constitutional right to the service of Esthetic Beauty Clinic in Indonesia are public and private. The government’s responsibility has been mentioned in Article 28D, clause (1) of 1945 Constitution concerning the right to guaranty, law protection and certainty and Article 28H clause (1) related to the right to health and to get healthcare service. The rights fulfillment is accomplished using the legal instrument and the institution of state authorized in licensing, organization, building, supervision, monitoring, and evaluation in the organization of esthetic beauty clinic. The esthetic beauty clinic’s responsibility includes: fault, risk, product, and professional.

Forensics is always related to crime (unlawful deed). In books of forensic science, forensic science is generally defined as the application and the utilization of certain science for law enforcement and justice purpose. In investigating a criminal case, observation on physical evidence and interpretation on the result of analyzing (examining) evidence is the main instrument of investigation. Forensic test, in this case, examines the evidence existing, coming from, used, and sold in esthetic beauty clinic, to find out whether or not it has been appropriate or there is malpractice, default, or other finding. In addition to forensic test, there is toxicological test on cosmetics and services provided by esthetic beauty clinic to find whether or not the cosmetics contains mercury or other hazardous materials.

State or state apparatus is authorized to conduct forensic and toxicological tests on esthetic beauty clinic and to test the drugs used to find out whether or not they have been corresponding to the standard specified. The authorized one is also entitled to conduct toxicological test on the drugs sold by esthetic beauty clinic for the sake of protecting patients. Drugs or cosmetics used by esthetic beauty clinic and having obtained license from BPOM and halal certificate from MUI could undertake forensic and toxicological tests suddenly to find out whether its ingredients or contents have been corresponding to what proposed when the halal certification or BPOM license was filed or are different.

**Method**

This study was a sociological research. The analysis used in this sociological research was socio-legal approach, the law interacting with people (law in action). In addition, social (non-doctrinal) research method was also used with interactional (micro) approach using qualitative analysis or qualitative method.

**Findings and Discussion**

The factual condition occurring should be the legal relationship between physicians handling the patients in esthetic beauty clinic and the patients; it is called therapeutic relation. Juridically, therapeutic relation can be defined as a legal relation between physician and patients in esthetic beauty medical service professionally based on the competency corresponding to certain expertise and skill in medical field. Therapeutic relation builds on mutual trust, as formulated in the Preamble of Indonesian Medical Ethical Code contained in Republic of Indonesia Minister of Health’s Decree Number 434/Men.Kes/SK/X/1983 about the enactment of Indonesian Medical Ethical Code to physicians in Indonesia.

“Since the beginning of written history regarding mankind, a trust relationship has been known between two individuals: the curer and the sufferer. In modern age, the relation is called therapeutic one between physicians and patient, conducted in confidential circumstance and enclosed with any emotion, expectation, and worry of human creature”.

The problem arising later is the implementation of norms and rules of law included in many regulations, because the facts existing are sometimes different from the ideal norms, moreover if anything to be governed has distinctive characteristic and specification. Similarly, healthcare (service) has its typical characteristics, as explained below:
1) Uncertainty principle. It means that an individual does not know certainly when he/she will need healthcare service. Basically, no one wants to be sick and hospitalized; everyone to keep healthy.

2) Information asymmetry. When an individual is sick, the decision to purchase healthcare service as needed is on the physician’s hand or healthcare center (clinic or hospital). If they are told to follow a surgery procedure, patient can be said as not knowing whether or not they need the operation. Although informed consent\(^8\), has been known recently to involve patients in making decision over medical action to be done by physician in esthetic clinic, the patients remain to be not on the position knowing their health status at that time like the physician treating them.\(^1\)

Another factor also resulting in the expensive healthcare service is labor-intensive one. To provide healthcare service, multidisciplinary approach and automation production process are required.

The legal implications sometimes arise along with the relationship between healthcare service provider and service patients, the ones instead are understood very poorly by the public. For example, see Prita case or other malpractice cases. The point the people (or perhaps service provider) understand poorly is the presence of such therapeutic relation. The understanding on the emergence of legal relation in service in esthetic beauty clinic is called medical service, legal foundation of medical care service relation, legal position of parties in medical service, and risk of medical service.

A new protection model is required to protect the patients of esthetic beauty clinic. The old law protection model has been replaced with the new one. It is this reconstruction of law protection model that will be the guideline or guidance in organizing esthetic beauty clinic in Indonesia in the form of forensic test that will be prevailed periodically and randomly.

It was reported for the first time that Josep Bonaventura Orfila in a trial with toxicity trial in animals in France in the 19th century and with his toxicological book can convince the judge to remove an assumption that the toxicity-induced death is cause by mysticism.

Recently in an investigation of a criminal action, it is an imperative to apply authentication and examination of physical evidence scientifically so that the material truth can be achieved. In the presence of scientific authentication, police, district attorney, and judge should not rely on the suspect or live witness’ admittance admission for investigating and settling a case. Because live witness may lie or may be told to lie, based on the information of witness intended, the achievement of truth enforcement objective in the criminal case process intended.

In authenticating and examining scientifically, we know the terms forensics and toxicology.

Generally, forensics can be defined as the application or the utilization of certain science for law enforcement and justice purpose. Forensic medical science is one of specialist branches of medical science utilizing medical science to help law enforcement and problem solving in legal domain. Indeed originally the forensic medical science is intended only to justice purpose, but in its development it is also utilized in non-justice areas, including protection or prevention.

The scope of forensic medicine develops over times, from originally the death of crime’s victim, unexpected death, unknown corpse, to still alive victim of crime, or even biological skeleton, tissue, and material putatively coming from human being, and to concoction and its consequence to human beings.

The type of case also expands from murdering, mistreatment, sexual crime, domestic violence, child abuse and neglect, dispute in divorce, paternity testing, to human right infringement. While Forensic medical science used to deal with the dead victim is called forensic pathology, the one dealing with the live victim or the suspect is called clinical forensic medicine or called police surgeon in some states. Forensic test on esthetic beauty clinic is called clinical forensic medicine.

Toxicology itself has been known since the human civilization development in looking for food, of course having tried a variety of materials including botany, plant, and mineral. Through its experience, it identifies food safely and dangerously. Meanwhile, the word toxic is a term used to explain and to represent a variety of “chemicals” clearly hazardous to body. The word “toxic” come from Greek stem ‘tox’, meaning bow and arrow.

In which bow and arrow is used at that time as the weapon in war, the arrow of which is always toxic (poisonous). “Papyrus Ebers (1552 B.C.)” of ancient Greek contains complete information on medication and drug. Papyrus also contains toxic concoction such
Indian Journal of Forensic Medicine & Toxicology, April-June 2020, Vol. 14, No. 2

as antimony (Sb), cooper, lead, hiosiamus, opium, turpentine, and verdigris (green crust in copper surface). Meanwhile, in India (500 - 600 B.C.)

Susrata Samhita wrote about many poisons coming from food, plant, animal, and snake bite antidote. Hippocrates (460-370 B.C.) was known as toxicologist in his time. He wrote about snake poison and in his book also represents that ancient Greek has had knowledge on antidote. In his book, he groups poison from plant, animal, and mineral. It proves that toxic effect resulting from toxin has bee known by human beings since the early development of human civilization. Therefore, this toxic effect is utilized widely for murdering or suicide purpose. To prevent poisoning, people always attempt to find and to develop the attempt of preventing or offering poison (toxin).

This attempt is in line with the development of toxicology itself. The objective of toxicological test is to find out whether or not the drugs and the chemicals used in the beauty treating process contain toxin or prohibited material, its use has been consistent with the dosage expected, patients know the risk and ingredient of drugs and cosmetics in the services in esthetic beauty clinic.

Orfila designed a variety of methods to detect toxin and to show the importance of chemical analysis as the legal evidence. Orfila worked as a medicolegal expert in Sorbonne, Paris. Orfila played an important part in LaFarge (murdering case using arsenic) in Paris, using arsenic analysis method; he proved death due to arsenic poisoning. M.J.B. Orfila was known as father of modern toxicology because of his interest in the effect of toxin. In addition, he also introduced quantitative methodology into a study on toxic action on animal; this approach yields a modern toxicological area, forensic toxicology.

Simply and briefly, toxicology can be defined as a study on the essence and the mechanism of hazardous effect (toxic effect) of many chemicals on living organism and other biological systems. It can also discuss the quantitative assessment on the severity of and frequency of such effect in relation to the creature’s exposure. While chemicals are said to be toxic, most of them are defined as substance potentially exerting hazardous effect on certain biological mechanism in an organism.

Toxicity is a term usually used in comparing a chemical with others. It is common to state that a chemical is more toxic than other chemicals. Comparison is less informative, unless the statement involves information on biological mechanism discussed and in what condition the chemical is hazardous. Therefore, toxicological approach should study on the effect of many chemicals emphasizing on the mechanism of the hazardous effect of such chemical and various condition in which the hazardous effect occurs. Generally, hazardous/pharmacological effect results from the interaction between chemicals (toxin or biological active substance) and receptor.

Scholarship in forensic and toxicological medicine is the fundamental basis the authorized apparatus can use in conducting forensic test and toxicological test on esthetic beauty clinic in Indonesia. Patients’ rights can be fulfilled if the clinics evidently endangering the patient by using, storing, and selling hazardous toxic drugs and cosmetics or hazardous substance can be acted on by Health Act, and sentenced with imprisonment.

**Conclusion**

Forensic and toxicological tests are scientific methods very effective in protecting the patients of esthetic beauty clinic. The relationship between physician and patient in esthetic beauty clinic is therapeutic one based on honesty and first-rate service. The protection for the patients of beauty clinic from malpractice and physician and medical worker’s default in clinic is a constitutional right.

The esthetic beauty clinic evidently hazardous, using hazardous drug, committing malpractice or default should be acted on legally. Forensic and toxicological tests should be conducted suddenly, randomly and routinely, thereby can give security and protection for the patients of esthetic beauty clinic.

Principal Fairness and Equity within Healthcare Services based on BPJS Kesehatan

Sulardi¹, Yusufa Ibnu Sina Setiawan²

¹Associate Professor, Universitas Muhammadiyah Malang, ²Master of Law Student, Universitas Muhammadiyah Malang

Abstract

Health services are the right of all Indonesian citizens. The health service system in Indonesia refers to the class system because based on the Law on BPJS itself it explains that the Indonesian public health service is in accordance with the premiums paid. The class system often triggers differences in services that are not the same equity and risk discrimination against health services. BPJS is a Universal Health Coverage (UHC) system in Indonesia. UHC system abroad, the health service is not based on classes, premium payment is the same. Comparison to other countries is not a wise view but it can be a benchmark of the progress or value of the service system in our country. Gradually, non-class based health services must be implemented to equalize and prevent discrimination in health services so that a conducive, fair and patient-based service environment can be created.

Keywords: BPJS, fairness, universal health coverage, healthcare

Introduction

Declaration of Human Rights Article 25 explicitly stipulates that every citizen has the right to get protection if he/she reaches old age, is sick, disabled, unemployed and dies.¹ Health financing in Indonesia, only around 2.2% of the Gross Domestic Product (GDP), is very risky in administering state health with a high morbidity rate. The funding is very far compared to the WHO’s recommendation (5% of GDP/year). Moreover, it is found out that around 70% of Indonesian people pay for health services independently which can affect family/individual finances.²

WHO shows that nearly 89 countries have formed a legal unit that regulates the implementation of UHC and on average it has imposed UHC financing on the tax sectors. Such sectors include the cigarette tax and liquor tax which were indeed enhanced for one of them subsidizing national health financing in several countries.³

Who itself conducts research on UHC in general. That is because related research is caused by the uneven prevalence of advice given by UHC to recipients of health services. For example, there are many patients who have HIV-AIDS throughout the world who have not been covered for antiretroviral therapy. Aspects to be investigated by WHO include among others concerning maternal and child health, infectious diseases, services and available health systems.⁴

In the framework of organizing national health insurance that can reach all levels of society, in Indonesia Law No.24-2011 concerning the Social Security Organizing Agency (BPJS) which on January 1, 2014, began to organize social health insurance for all Indonesian. In Article 3 of Law No.24-2011 concerning BPJS, the National Social Security System aims to provide guarantees for meeting the basic needs of a decent life for each participant and/or family member.⁵

The implementation of the Social Security System (SJS) in Indonesia refers to the operationalization of Workers’ Social Security (Jamsostek) under Law No.3-1992 because it is a permanent program that is mandatory and is open to all workers. Therefore, Jamsostek was reformed into the National Social Security System (SJSN) based on Law No.40/2004. The operationalization of...
Jamsostek for >20 years is still exclusive in the sense that it has not yet reached the entire membership of workers including informal sector workers. Problems arise related to the Social Security program membership target at the end of 2013 which only reached 25% of the workforce. If the Jamsostek program is continued, there will be human rights violations that can be addressed to the Government, because of its attachment to the UN Universal Declaration of Human Right dated December 10, 1948, so that Indonesia as a UN Member needs to comply with the UN-Declaration.\(^{(6)}\)

In its implementation, the National Social Security System implements a law to guarantee the rights of all citizens in Indonesia to obtain equal health services. It is expected that with the existence of SJSN, all citizens will later register as JKN-KIS participants which incidentally aims to ease health financing for the Indonesian people in general.\(^{(6)}\)

BPJS which is categorized as social insurance applies the equity principle, which is the similarity in obtaining services in accordance with its medical needs that are not bound by the number of contributions paid. BPJS also has the authority to collect payment of participant contributions and provide administrative sanctions for participants who do not fulfill their obligations.\(^{(7)}\)

There are fundamental problems, namely the premiums that must be paid by participants are not in accordance with the counts of experts or do not match the actual counts commonly used in programs like this. This condition creates an underfunded program situation that structurally will affect the sustainability of the health insurance program. The challenges facing the implementation of the JKN-KIS program today are faced with the issue of the financial soundness of the Social Security Fund (DJS), which is experiencing a deficit due to inadequate contribution rates compared to the extent of the benefits stipulated.\(^{(8)}\)

Basically, social security is carried out in line with the principles of the welfare state (Welfare state) that is developing widely in Western European countries, the United States, Australia and New Zealand. This system is implemented as an alternative to overcome poverty and multidimensional inequality. This paper intends to compare the differences in the health care system in Indonesia with other countries and then look at the justice side of the health services received by each citizen. Later this comparison will provide input that is expected to be a reference to improve the UHC system in the future for Indonesia.

**Findings and Discussion**

In the framework of organizing national health insurance that can reach all levels of society, in Indonesia has been passed Law No.24-2011 concerning the Social Security Organizing Agency (BPJS) of Health which on January 1, 2014, began to organize social health insurance for all Indonesians, able communities or unable. In accordance with Article 3 of Law Number 24 of 2011 concerning BPJS, the National Social Security System aims to provide guarantees for meeting the basic needs of a decent life for each participant and / or family member.\(^{(9)}\)

BPJS according to the BPJS Law No.24-2011 About BPJS is a public legal entity formed to carry out social security programs that are accountable to the president. BPJS funding sources are from the government (Recipient Contribution Assistance (PBI) and participants who pay contributions. BPJS membership according to Article 16 paragraph (1) explains that all citizens (other than Employers, Workers and PBI) are required to register themselves and their family members as Participants to BPJS. So the organizer of the JKN BPJS is the government and social security program participants, including foreigners who work for a minimum of 6 (six) months in Indonesia.\(^{(9)}\)

Problems often arise in the implementation of the Health BPJS. These problems include the low premiums paid, under-standard premium calculations, differences in claims of INA-CBGs with real costs, indications of fraud by health service providers, differences in perception of coding in hospitals, BPJS claims arrears to hospitals, and BPJS socialization to the community is still quite low.\(^{(10)}\)

These various forms of problems have the risk of causing discriminatory services to the community. Coupled with the provisions of the class system, which distinguishes the amount of premium to be paid for BPJS membership every month. If we look at developed countries, one of which is Finland, the health care system is different. The Local Government Health Service System in Finland regulates almost the majority of all health services in the country.\(^{(11)}\)

This system applies to all Finnish residents who are registered as permanent residents. Every citizen has the
right to receive all types of health services desired, according to the level of specialization needed. The services provided include holistic services from promotive, preventive, curative and rehabilitative.

Figure 1. Finland’s Health Financing System

Figure 2. Health Financing System of Australia
Then the health financing system in other countries can also be used as an example, namely Australia. In Australia, the health financing system is called Medicare, which is funded by Medibank, funded by the government through state agreements. States have an obligation to maintain the health of the population included in their area. The medicare financing itself comes from the income tax of Australian residents and there is income from people who can contribute to health through(12)

Comparison of the two types of health services in developed countries implies the absence of a class system in the payment of health contributions. The absence of such a class system can also reduce discrimination in health services. The principles of equality in services that promote justice based on effective and efficient services have been listed in some regulations.

Some of these regulations are reflected in one of them the 1945 Constitution which explains explicitly that each health service must not be treated differently from one another, in accordance with article 28 I paragraph (2).(13)

In addition, Act 36 of 2009 concerning Health, articles 4-7 states that every citizen has the right to health services that are equitable, safe, affordable and the community has the right to independently determine the best health services for themselves. Article 9-13 explicitly describes the government’s obligation to fulfill equitable access to health services for the community.(14)

In-Law No.24-2011 concerning BPJS itself, it explains in article 2 that the principle of administering BPJS is to provide health care guarantees based on social justice for all Indonesian people.(15) Each country agrees and recognize the right of everyone to get health services with good standards which include: efforts to improve children’s health by reducing infant mortality; improvement of aspects of industrial health services; and comprehensive holistic management for any endemic, pandemic or other diseases that require treatment.(16)

In the Doctor’s Oath Pledge, which is listed in Government Regulation No.26-1960 Article-1, explicitly explains that a doctor must carry out the medical profession without observing differences in ethnicity, religion, race, culture and social position.(17)

Most of the regulations that describe health services mandate health service providers not to discriminate or discriminate against health services. The BPJS class classification itself, whose nominal fee is different, in the technical field has a significant impact, especially when compared to the service of no BPJS participants who use public facilities (without insurance costs from BPJS).

However, justice in health services from the perspective of the theory also clearly states that the theory of justice proclaimed by Aristoteles divides justice from two different sides. Justice for Aristotle is a form of ownership of goods. The goods must be owned by every living thing, equally, without exception. (18) The corrective action is aimed at giving birth to new regulations that can later meet the demands of the community for something to be “more” just than before. (19)

The government’s obligation to protect the rights of the public to obtain health services has been fulfilled, but the fulfilment of government obligations to health services that are equitable, fair and without discrimination is not yet fully visible. Frictions that arise in handling BPJS patients due to BPJS compensation in the payment of monthly claims are not in accordance with the INA CBGs Package and there is a delay in disbursement of funds, which can delay (even unpaid) medical and non-medical services for months. These conditions can trigger a decrease in the quality of health services due to rights that have not been fulfilled.(20)

Judging from sociological jurisprudence, according to the theory put forward by Roscoe Pound, the orientation of the view is on the “legal reality” rather than the position and function of law in society. Sociological Jurisprudence reflects a careful blend of written law as the needs of the legal community for the creation of legal certainty (positivism law) and living law.(21)

So that the legislation can run as it should, the legislation that was formed in accordance with what is at the core of the Jurisprudence sociological school that is good law should be in accordance with the law that lives in society.(22) Yet what we have to realize is, the law was made and fully enforced for the benefit of the public interest in society, especially health services. The regulations made did not reflect equality in service.

The Health System in Indonesia, which is now run by BPJS, payment of contributions are divided by class. When referring to the explanation of the article contained in the BPJS Law, it clearly states that the principles of health administration are equal, but in reality, according
to Permenkes-59-2014, it is attached that financing all types of diseases, has a package (maximum) of financing. The bigger the class, the greater the nominal money package allocated by BPJS.

The difference in tariff will inevitably trigger an efficiency on the part of the health provider. Moreover, BPJS has delayed the payment of claims due to (again) underfunded BPJS Health financing. In the community, BPJS patient services for each class are not entirely good. A striking difference is seen in BPJS Class I participants, who can advance to special classes (VIPs) while for Class II and III the maximum will only rise to one level above each.(22)

Compared to developed countries in Finland, Australia and Singapore, most of them attract health funding from taxes. Then there is no known class payment system (I, II, and III). All premiums are the same, depending on the income tax. All citizens are entitled to health services and do not need to worry about the class system. In these countries, all types of services are guaranteed, from promotive to rehabilitative. Even though it is in a state far from the city centre, the community still gets maximum health services, if for example there can also be a supporting examination.(22)

All types of service based on class violate the principle of justice, which prioritizes the principle of equal treatment with one another. In addition, the government also guarantees that it will be responsible for the implementation of health services that are equitable, affordable and safe (prioritizing patient safety). The difference in services can lead to discrimination and the most dangerous is when the act can physically harm the patient.

Conclusion

The class system in the health insurance system in Indonesia can trigger discrimination related to health services enjoyed by the community. The system limits the number of claim payments which causes demands to reduce the quality of health services. These things certainly violate regulations/policies regulated in the laws and regulations of the minister of health, including violating human rights. Reference to the health financing system in other countries can be used as an example to improve the health financing system in Indonesia.

Forensic Examination and Restorative Justice for Drug Abusers: An Alternative in Handling Drug Cases in Indonesia

Warsino Warsino¹, Supanto Supanto², Widodo Tresno Novianto³

Abstract

The approach of restorative justice is a new paradigm in responding the crime of drug abuse. So far, the efforts in acting upon drug abuse uses the prohibitionist principle. This approach has the perspective that the drug abuse is illegal and a violation of law, and therefore must be prohibited. The focus of this policy is the efforts of controlling policies in minimizing drug black markets through punitive ways and imprisonment. Restorative justice is the most logical and humane choice for drug abusers who are not involved in the distribution network. They are victims who must be healed and restored, as opposed to being imprisoned. There are many positive effects of drug abuse rehabilitation. The drug abuser will be saved from their problem of addiction of illegal drugs. It is hoped that when they are healed, they can return to the society and socialize with the people as before.

Keywords: drugs; restorative justice; penal; forensic test.

Introduction

Restorative justice is an approach model in the effort to solve criminal cases as a response towards the criminal justice system, which are often thought to not be able to contain the aspirations of the victim and perpetrator.¹ This restorative justice is different from the criminal justice system as it emphasizes the concept of mediation and reconciliation as the mechanism of conflict or dispute resolution in the case of criminal actions. It is something which is nonexistent in the criminal justice system.²

The restorative justice approach is a new paradigm in responding the criminal act of drug abuse. In the perspective of the restorative justice approach, the criminal action is understood as a dispute or conflict which may disturb the relations between an individual and the society. It is not merely understood as a violation of law, where as a consequence, the perpetrator is faced with the state. Thus, justice may only be achieved when the related parties are given a space to participate actively in the process of the drug abuse case to find the best solution which emphasizes healing, reconciliation, and teamwork.

The focus of this policy is the efforts of control policies on minimizing drug black markets through punitive methods or through imprisonment, which are believed to minimize the negative impacts of the drugs. Ironically, this policy will actually cause various violations of the human rights for the drug abuse perpetrator; the violation of the health rights by limiting the access of general medicine and the limitation of health services for prevention, the treatment and handling of HIV, etc.

There are some facts which cannot be ignored when we talk about the violation of the human rights and the arbitrary actions for the addicted people or the drug abusers. This case of policies which emphasize criminalization and which ignore the holistic public health will cause cases which are not easy to be resolved in the future. On 2019, there are 140.423 inmates, 37 295 of them were criminalized for drug abuse. Among them, 285 people died in prison and 89 of them died due to HIV/AIDS.⁴

From the case above, it can be concluded that the research problem is, how is the restorative justice as an alternative method in handling the drug abuse cases in Indonesia, and how is the role of forensic examination for drug abusers in the implementation of restorative justice?

**Research Method**

The method of this research was the juridical-normative legal analysis. A legal research was based on the legal concept used. According to Wignyosoebroto, there are five legal concepts, which are:

1. The law is an absolute principle of truth and justice which applies universally;
2. The law is positive norm in the system of national legal constitution;
3. The law is what is decided upon by the *inconcreto* judge, and it is systemized as a judge-made law;
4. The law is patterns of social behavior which is institutionalized and it exists as an empirical social variable;
5. The law is a manifestation of symbolic meanings of social actors and is visible in the interaction between them.

In the second concept of law, there is the normative concept, where in this concept, the law is a norm, and which is identified as a justice which must be manifested (*ius constituendum*)

The norms which is manifested as an explicit order and is positively and clearly formulated (*ius constitum*) to guarantee its certainty. This research combines two approaches, which are the doctrinal/normative method and the non-doctrinal/empirical method, or what is known as the mixed method.
Result and Discussions

The application of the criminal law in Indonesia is as a method to prevent or to handle crime. It does not inherently become a problem if it is able to achieve the main goal which is to create happiness of citizens; a wholesome and cultural living; social welfare; and equality. The use of punitive efforts (sanctions/criminalization) in managing the people through the constitutions are basically part of the stage of policy.9

Meanwhile in the constitutional concept which applies the double-track system, the stelsel sanction simultaneously regulates two things, which are penal sanctions and non-penal sanctions.10 The law regarding drug abuse also has non-penal sanctions, which is an element of the restorative justice for drug abusers, which is rehabilitation until the addiction is healed.

In its development, the world nowadays tends to not see drug abusers as criminal perpetrators anymore. Yet, they are regarded as victims or patients which must be given empathy. The approach of punishment may make the people who need help ironically hide themselves.11 The data shows that on 2019, there are no drug abusers who are classified as users who must be rehabilitated.

If analyzed carefully, especially in the medical perspective, there are many parties who think that they are actually victims of a syndicate, or part of the distribution chain of drug trade who have trouble getting over addiction. This may happen even though they actually want to get over drug addiction which binds them. Yet, because their nerves are bound by addictive substances, it is difficult to be done. Users or addicts need a different treatment from other patients in general. There is an urgency for the change of policies in imprisoning drug users and other drug prosecutors. It should be based on the principles of justice, and based on the values of humanity.12

The stipulations on rehabilitation for drug abusers are regulated on Articles 54, 55, 56, 57, 58, and 127 of the Constitution No.35 of 2009 regarding Drugs. One of the principles in criminal law which is parallel with this view is known as the term of restorative justice. It is one of the efforts of legal approach which is used to prevent criminal case resolution. It emphasizes on healing the victim maximally and to return them to the original state.13 This is because in some cases, the sanction of imprisonment is aimed to punish the inmates physically and to give them a deterrent effect. Yet, it does not give a positive benefit in changing the perpetrator and make them deter in repeating their behavior. It cannot guarantee the achievement of healing for the victims.

Restorative Justice is the most logical and humane choice for drug abusers who are not involved in the distribution network. They are victims who must be healed and restored. They should not be imprisoned. The policy in applying the criminalization sanction for drug abusers has so far created new problems which are quite complex, for example, it will affect the condition of the prison.14

In the sociological perspective, the drug users are regarded as acting out from the social norms. Drug abuse may cause death, addictions, diseases, the increase of violence and criminality. It may cause the destruction of the society and may cause a lost generation. In the juridical point of view, drug users who are addicted have on one side violated the law regarding drug usage. This is because there are the legal stipulations on the Constitution on Drugs and Psychotropics which regulates the sanction of imprisonment for perpetrators of drug abusers. If the drug abusers are addicted, they must undergo medical and social rehabilitation. The period of medical treatment and rehabilitation are regarded as the period of undergoing criminal sanction.

The Constitution No. 35 of 2009 regarding Drugs states that the judge which examines the case of drug addicts may undergo two things. First, the judge may give the verdict of ordering the person to undergo medical treatment or healing, if the drug addict is proven to be guilty of drug abuse crime. Second, the judge may give the verdict of ordering the person to undergo medical treatment or healing, if the drug addict is not proven to be guilty of drug abuse crime.

The issuing of SEMA No. 4 of 2010 has given a guide for judges to give a verdict based on restorative justice, which places drug addicts in medical and social rehabilitation institutions. The main consideration for the soul and spirit of the Constitution No. 35/2009 regarding Drugs is the acknowledgement of drug addicts as prisoners. It also protects drug addicts and drug abuse victims by placing them in medical and social institutions.

Above is the data of prison inmates on 2019. On that year, it is shown that most of the prison inmates from drug cases are users. It shows the alignment of the restorative justice paradigm to place victims of drug abuse in a rehabilitation institution. It has long been voiced and is regulated in the Constitution No. 35 on 2009 regarding Drugs, even though not much has been implemented. Thus, until now, drug abuse victims still have to go through court processes. Drug abuse victims do not need to be captured nor punished. Yet, they need to be given medical treatment and rehabilitation.

The judges’ verdict for the drug abuse victims is right when they are placed in rehabilitation institutions. On the contrary, if they are imprisoned, the drug abuse victims will not obtain rehabilitative treatments. Since there is no treatment, the drug abuse victims will try
to obtain drugs illegally, both through the family or through the drug distribution network in the correctional institutions. This restorative justice is only given to the users. Yet, the drug distributors or drug dealers will still be given penal punishments.

Criminal policies certainly do not only use penal law, yet it also uses non-penal laws. Basically, these two have different ways of working. The effort in preventing crime through the penal method emphasizes “repression” (oppression/elimination/eradication). This form of punishment is given to drug distributors, smuggler, and drug producers. Meanwhile, the non-penal method has the preventive orientation (prevention/deterrence/control) and focuses on curation (healing) which is suitable for users.

According to Pakpahan, the resolution method of restorative justice is more effective than giving sanctions in the form of imprisonment punishments. One of the reasons why restorative justice is more effective in handling the case of drug users is based on the worry regarding the condition of prisons. There are many criminal cases which are given the verdict of imprisonment by the judges, which makes prisons crowded, without the addition of rooms or the betterment of facilities. The rehabilitation of drug users has more positive impacts. For example, the drug users will have a solution for their problem of addiction and it is hoped that when they are healed, they may go back to the society and socialize again as before.

How to differentiate between drug users, distributors, smugglers, and producers? There needs to be a forensic examination to the perpetrators, so as to obtain facts, whether they are drug users, distributors, smugglers, and producers. This is so that the correct action of law may be taken. To detect drug users, forensic examinations may be carried out, including urine tests, hair tests, or blood tests.

The time needed to undergo the urine test form of forensic examination is around one hour. Meanwhile only the lab of BNN and the forensic lab of POLRI can carry out the hair and blood tests. Thus, there is no certain information on the price needed. Another form of forensic examination is by using the Learning Vector Quantization (LVQ). In the research of Sulaiman the forensic examination algorithm uses this method, and it has a high accuracy of 99%. Then in the research of Leleury and Aulele (2016), the Learning Vector Quantization (LVQ) has an accuracy rate of 95,92%. Through this system, it is hoped that the primary identification of drug abusers may be eased, so that it may be treated quickly. It is also hoped to be able to detect and differentiated users, distributors, and producers.

**Conclusion**

Dropping the verdict of imprisonment sanction for drug abusers cannot actually change their behavior and stop them from using drugs. Meanwhile, the deterrent effect which becomes the main aim of penal punishments is not equivalent with the negative effects which are created. Restorative justice becomes the right choice in treating drug abuse in Indonesia, especially for users who need rehabilitation and healing.

The restorative justice approach is a more effective resolution method compared to giving the sanction of imprisonment. One of the reasons why the restorative justice approach is more effective for handling drug users is the worry regarding the supply of prison rooms. There are many criminal cases which are given the verdict of imprisonment by judges which makes the prisons filled. It happens without the addition of rooms nor the betterment of facilities.

The restorative justice method of approach is preferred as it is hoped for by the victims. They want to undergo rehabilitative treatment and return to their previous state. Even though it might not run optimally nor maximally, at least the victims’ rights are guaranteed. The rehabilitation of drug users gives more positive impacts. For example, the drug users may heal from their problem of addiction to dangerous substances. It is also hoped that they may return to the society and socialize again as before after they are healed.

The Hegemony of The Exxonmobil and Freeport Contract in Investing in Indonesia and Also The Abandonment of The Local People’s Health Rights

Yuli Tri Cahyono1, Khudzaifah Dimyati2, Harun Harun2, Bambang Setiaji3

1Lecturer, Universitas Muhammadiyah Surakarta, Indonesia, 2Professor, Universitas Muhammadiyah Surakarta, Indonesia, 3Professor, Universitas Muhammadiyah Kalimantan Timur, Indonesia (email:bs260@ums.ac.id)

Abstract

The type of contract carried out nowadays, which is the Product Sharing Contract (PSC) and contract of work in the natural resource sector results to product sharing, which is on one hand thought to not yet fulfill the principle of justice for the state. On the other hand, the government still needs funds from foreign investors to carry out economic development. The balancing position between the foreign investment and the domestic investment in the capital market investment in the oil, gas, and the gold-copper mining sector of Freeport in Papua and Exxonmobil in Indonesia shows a foreign domination. It means that there is a natural resource sector investment hegemony by foreign investors. The implication of this condition is the lightening burden of the state budget, the increase of workforce absorbment and the transfer of technology. It also causes opportunity cost. There is the environmental destruction, including the aspect of healthcare for the local people in the mining location as a compensation. For that, the government needs to review the contract regulation for these two natural resources and revise what is necessary.

Keywords: hegemony, investment, contract of work, production, product sharing contract, health.

Introduction

Sources of oil and gas are potential reserves of energy wealth since Indonesia was still invaded by the Dutches until the government in the Reformation era. There have been explorations and exploitations by foreign contractors which are divided into blocks of oil and gas management, as stated by Arifin1. According Mubyarto2 Until now, this cooperation contract is still maintained, even though it often causes problems. Now, the government still makes sure that the management of natural resources which require high capital, high technology, high skill, and of high risk, which are almost impossible to be done independently by domestic contractors, may still be done through a cooperation with foreign contractors, as stated by Suherman.3

According to Dimyati4, the sociological impact which appears in the period of contract renegotiation is that the politicians, groups of society, and the people who live around the mine areas were preoccupied by the pro-cons of the parties who supported the extension and those who did not with their own argumentations. This is very reasonable, remembering that on the side of the contractor, with the contract extention, the capital gain of their investment will continue to be received, as said by Adolf5. Meanwhile, on the side of the local people, especially those who receive direct impacts from the mining project, will feel that the compensation received is not equal with the social, environmental, and health sacrifices they had to make, as opined by Asshiddiqie6. Thus, the welfare of the local people is relatively stagnant. There is no improvement. Worse, there are environmental deterioritations which are difficult to fix.

In the economic point of view, the natural resource management cooperation contract with the foreign companies is the hope of the government. The government wishes this investment to be continued and to even be increased, considering that the foreign investment may
lighten the burden of the state budget for infrastructure development, said Ahmad 7. It may also increase the work opportunity for the local workforce. ExxonMobil and Freeport are the largest foreign contractors in the natural resource management sector compared to other companies which invest in Indonesia. The two contribute quite a large portion of capital compared to that contributed by the domestic companies in the same sector.

The data from the Capital Investment Coordinating Board (Badan Koordinasi Penanaman Modal/BKPM) shows that on 2017, the total investment was Rp 692,8 trilyon. This number is divided into that from foreign investment, which was Rp 430,5 trilyon, and domestic investment which was Rp 262,3 trilyon. Thus, the ratio between foreign investment and domestic investment was 62,1:37,9. The sectors of water, oil, and gas (including that managed by ExxonMobil), and electricity contribute 11,8%, meanwhile mining (including that managed by Freeport) contribute 11,4% out of the total investment, as stated by Mubyarto 8. From the 24 existing investment sectors, oil and gas, electricity, and water stands in the first rank of investment income, whereas mining stands in the second rank. This condition indicates the foreign domination in the investment in Indonesia.

**Method**

This research is a juridical-normative study. It uses a literature review approach. As said by Rusli 9, this research uses a qualitative analysis in analyzing the present problems.

**A. The Extention of Natural Resource Contract**

The Constitution No. 25 of 2007 regarding Investment is one of the government’s regulation in the investment sector, which aims to accelerate the development of the national economy. If it succeeds, it will create success for the state of Indonesia, which will then bring its people towards a higher and more widespread level of welfare. As good business actors, both foreign and domestic investors are encouraged by the government to realize that aim.

In the natural resource sector, the phenomena which happened was the fight for the power to manage it. This means that there was a competition between foreign and domestic business actors in investing in Indonesia. The sector of oil and gas and the sector of mining were two of the many natural resources which were fought for by the investors. Even so, considering that to run the business of these two sectors need much capital, sophisticated technology, special skills, and contains high hazard, foreign companies still dominate this sector, as stated by Wahab 10. ExxonMobil and Freeport are the two foreign contractors in the oil and gas and mining (gold-copper) sector, which have dominated those natural resources from a long time ago up to now, even though their presence in Indonesia still causes much problems in the implementation and in the substance of the contract. According to Redi 11, to minimize the unwanted things and so that investment still goes on safely and so that it reaches the aim, the government regulates it through adequate regulations, which are the Constitution No. 22 of 2001 on Oil and Gas and the Constitution No. 4 of 2009 regarding Mineral and Coal Mining.

Even though all oil and gas management contracts are based on the Oil and Gas Law, and that the mining of gold and copper is already based on the Mining Law, there are still problems here and there which needs extra attention from the government. Problems appear when the contractors (both foreign and local) face an expiring contract, where they will undergo a renegotiation for contract extention. In this case, even though the renegotiation has been agreed upon by the contractors and the government, the substance and the implementation of the contract are not always in line with the hopes of the government regarding investment policies, which is the balance between foreign and domestic investors, as said by Hodd in Newcomb 12.

**B. Legal Protection of the Indonesian Natural Resource Management**

The management of natural resources in Indonesia is based on the legal protection in which its source is the 1945 Constitution. On Article 33 paragraph (2), it is stated that the important branches of production for the state and that which has the power over many people’s interests are under the power of the government. Meanwhile, paragraph (3) states that the earth, water, and natural resources in it are under the power of the state, and must be used maximally for the welfare of the people. Meanwhile, the management of every kind of natural resource, including oil, gas, and gold-copper mining is regulated on some of its own Constitutions, which are derived from the 1945 Constitution.

The Indonesian oil and gas management was first based on the Constitution No. 44 of 1960 article 2 which
states that the oil and gas mining materials which are in Indonesia’s legal mining territory are part of the national wealth which is under the power of the state. Then, in its development, it is now regulated on the Constitution No. 22 of 2001 regarding Oil and Gas. Meanwhile, for the gold-copper mining, it is regulated on the Constitution No. 4 of 2007 regarding Mineral and Gas, as stated by Redi11.

C. ExxonMobil and Freeport in the capital market

In the beginning, the oil and gas contract in Indonesia was a contract of work. Then, since 1971, it implements the product sharing contract, as stated by Partowidagdo.13 Then, after going through some changes in the contract model, the Constitution No. 22 of 2001 regarding Oil and Gas was issued as the legislation which regulates the oil and gas management. Since the issuing of that constitution, the management of oil and gas by foreign contractors are carried out through a contract of work with the product sharing contract (PSC) model.

ExxonMobil which has operated since 1899 is one of the tens of oil and gas contractors which invested their capital in Indonesia through the PSC system, said Mubyarto2. The latest data (2019) showed that there was the domination of foreign contractors in the management of oil and gas, with foreign contractors managing 70% of the sources of those sectors in Indonesia. With ExxonMobil’s contract extention, its contributions towards the conductivity of capital investment in Indonesia is highly significant, even though there are still problems in its implementation and product-sharing, as stated by Partowidagdo13.

ExxonMobil’s contract extention gives a huge contribution towards the foreign investment in Indonesia, even though it indicates that Indonesia’s sovereignty in managing oil and gas is not possible yet. Apart from that, it is highly ironic that the oil and gas, which are natural sources which support the lives of many people are not treated as the state’s strategic commodity anymore, as its management is regulated according to the wishes of the foreign contractors. The impacts of this condition are felt by people of Cepu, Bojanegara, who live around the oil and gas blocks managed by ExxonMobil. They feel that they are not yet living a prosper life. Their area experiences environmental destruction and the people’s health rights are disturbed. These things should be covered by the ExxonMobil company for the people surrounding the mines.

Freeport, a gold-copper mine foreign contractor, has carried out a contract extention the third time after fifty years of managing the oil and copper mines in Timika, Papua. Freeport was the first company to enter Indonesia some time after the G30S PKI phenomenon which forced President Soekarno to step down from presidency. The legal basis of the first-generation work contract at that time was the Constitution No 1 of 1967 regarding the Foreign Capital Investment with the period of 30 years since it first operated on 1973 until 1999, said Partowidagdo13. On 1991, the second-generation contract of work was issued for the period of thirty years (1991-2021). Then, after the contract period ran out, the contract status was changed into the Special Mining Business Permit (IUPK) based on the Governmental Decree No. 1/2017 with the period of ten years, and may be extended for another ten. Freeport contributes 5% of the total investment in Indonesia.

The positive implication of the contract agreement, which has now changed into the Special Mining Business Permit, was the reemployment of around three thousand people, the majority of them from Biak, Jayapura, Sorong, Serui, which was formerly fired. Meanwhile, the negative implications include environmental deterioration, as stated by Mubyarto8. The Amungme tribe has also felt being out of place in their own land, as their positions were pushed by the presence of foreign mines. The health factor of the Amungme people has not improved either, as there is still a high rate of infant and maternal mortality. They are prone to diseases, and there is still a low rate of the Amungme people’s survival said Syeirazi14.

The issuing of the constitution on Capital Market has brushed aside the beliefs that the foreign companies’ presence in investing in Indonesia imply that: (1) there is the decrease of the savings rate or domestic investment by creating an unhealthy competition from exclusive contracts between the multinational companies and the Indonesian government; (2) reinvestment is not reached from the income obtained.

D. Irony of the Natural Resource Contracts in Indonesia

The constitutional regulations in Indonesia are created in the form of constitutions which reflect on the 1945 Constitution. The main part of the constitutional regulations, which are the substance of this research are
the constitution on mineral and oil natural resources, the constitution on minerals and coal, and the constitution on investment, according Syirazi. In the economic perspective, the writer is pessimistic that with the regulations on natural resource management contact extension which still do not support the interests of the people, the results of the oil and gas in the blocks and in the gold-copper mines in Papua will succeed in increasing the welfare of the local people. Based on the existing data, the extent of the natural resource contact extension is identical with shifting 70% of its outcome to the foreigners, which means that only 30% of it may be enjoyed by the surrounding people, said Aviliiani. Worse, there is still the environmental factor, and the abandonment of the local people’s health rights which are disturbed by the mining activities, and which do not receive any attention from Exxonmobil and Freeport, said Newcomb.

The data from the Capital Investment Coordinating Board shows that during the period of 2017, the amount invested by foreign investors were Rp 430.5 trilyon, and that from domestic investors were Rp 262.3 trilyon. Thus, there is a ratio of 62.1: 37.9. This shows the domination of foreign investors in investing in Indonesia, said Partowidagdo. The water, oil and gas, and electricity sectors contribute 11.8% of the total investment, whereas the mining sector contributes 11.4%. From the total of 24 investment sectors, the sectors of oil and gas, electricity, and water stands in the first rank, with mining following on the second rank of investment income. This means that ExxonMobil and Freeport, which are the largest American companies in these sectors dominate in the largest investment sectors in Indonesia, according to Sycirazi. This condition is suspected to be an impact of the consequent implementation of the Constitution on Capital Market, in which one of its articles states that it does not differentiate foreign investors based on their country of origin. As an impact, if there is no control from the government, there will be a continual hegemony of foreign investors towards the domestic ones, which means that there will be an unhealthy imbalance between the two types of capital investment.

Stage III-B Cervical-cancer of Young Age in Medical, Bioethics and Clinical Ethics Perspectives

Nasrudin Andi Mappaware¹,4, Septian Sima², Erlin Syahril³, Shulhana Mokhtar⁴, Ida Royani⁴, Muhammad Mursyid⁴

¹Obstetrics and Gynecology Department, Medicine Faculty, Universitas Muslim Indonesia, ²Obstetrics and Gynecology Department, Medicine Faculty, Universitas Hasanuddin, ³Radiology Department, Medicine Faculty, Universitas Muslim Indonesia, ⁴Bioethics and Professionalism Department, Medicine Faculty, Universitas Muslim Indonesia

Abstract

Background: The incidence of cervical-cancer in Indonesia is mostly obtained at the age of 40-50 years. But now many are found at the age of 25-40 years. Method: Case-report. Findings: Female, 25 years old with a diagnosis of cervical-cancer stage 3B planned for chemotherapy. Patients complain of vaginal bleeding. Married 2 times, at the age of 16 years and 19 years with infertility. The central dilemma: a young woman with advanced stage cervical-cancer was planned for chemotherapy as a gold standard, in terms of patient-autonomy and family refusal. Informed consent was required in the delivery of bad-news and human approaches based on Kubler-Ross’s theory (denial, anger, bargaining, depression, acceptance) with the concept of SPIKES (Settings, Listening-Skills, Patient’s Perception, Invitation to share Information, Knowledge transmission “bad-news”, Explore Emotions and Empathize, Summarize and Strategize). Both medical indication and quality of life were appropriated but in terms of patient preference and contextual feature were refused by patient and families. Resolving this case was not enough with medical-aspects, it also required a bioethical and clinical ethics approach. Conclusion: Medical, bioethical and clinical ethics approaches are methods of resolving a case with an ethical dilemma.

Keywords: cervical-cancer, perspective of medical, bioethics and clinical-ethics

Introduction

According to WHO (2012), around 8.2 million deaths were caused by cancer. Ministry of Health reported the number of cancer sufferers in Indonesia reaches 6%. Based on data from the Ministry of Health, the Indonesian Cancer Foundation, and the Indonesian Association of Pathologists, 64.4% of cancer suffered by women.1,2

The high mortality rate because most of cervical-cancer sufferers were aware of the disease after being in an advanced stage, because in the early stages the patient did not feel any complaints or symptoms. If it was at an advanced stage, cervical-cancer would cause more physical complications and death. Cervical-cancer is a type of cancer that is caused 99.7% by oncogenic human-papilloma-virus, which attacks the cervix (Indonesian Journal of Cancer, 2009). In Indonesia, only 5% patients did the screening for cervical-cancer, while 76.6% of patients had entered an advanced stage (III-B and above) when detected because cervical-cancer is usually asymptomatic at its initial stage.2,3

Method

The method of this study was case-report.

Findings

A 25-year-old woman escorted to Wahidin Sudirohusodo Hospital by her sister for chemotherapy. Patients diagnosed with stage III-B cervical-cancer with complaints of vaginal bleeding for 3 months that had not
stopped, she also had a history of post-coital bleeding 6 months ago. Two times marriage history at the age of 16 years with a 3-year old marriage, divorced and has no children, the second husband last 1.5 years, has no children as well. No history of contraception. She worked as a cafe/waitress assistant, her husband is still alive and works as a driver.

The physical examination: vital-signs=normal, good general condition, compos mentis, BP=100/60 mmHg, pulse=82x/minute, RR=18x/minute, T=36.5°C, height=149 cm, weight=51 kg, BMI=22.97 kg/m². Gynecological examination: high palpable uterine fundus, tumor mass and pain were absent, blood flux was present. Speculum examination found no vulva abnormalities, the vagina looked bumpy at 1/3 proximal, the portion was lumpy, fragile, easily bleed, blood flux was present. The results of examination in the vagina, obtained 1/3 proximal palpable mass with fragile bumps, easily bleed mass on the entire surface of the portio and parametrium.

Ultrasound examination: mass in the lower segment of the uterus measuring 4x5 cm, uterine size slightly enlarged 7x6x5 cm in size, both adnexal normal, no free fluid appeared in the Douglasii cavity, the kidney appeared hydronephrosis bilaterally. The diagnosis of this patient was Stage III-B Cervical-cancer Pro ChemoTherapy.

**Discussion**

**Medical-Analysis**

The quality of palliative-care focuses on client-choice, collaboration, interdisciplinary and holistic approach and orientation to the client and family. During the recovery-period, support for the client and family is a focus in curative and non-curative services, this is known as supportive care. Supportive care services for the physical and psychosocial can be provided in the form of education, research and promotion of clinical services and improving the quality of life of clients with cancer.4,5

Based on 30 analyzed literature, concluded that changes occur in an end-stage cancer causes changes in quality of life because quality of life consists of four dimensions namely physical, psychological, social relationships and environmental dimensions that are not only dealt with curatively but need a more personal approach so that it can be concluded that palliative-care plays a role in achieving maximum quality of life in stage IV cancer thereby reducing pain or preparing for death. Good palliative-care can change the life quality of cancer-sufferers for the better. However, palliative-care are still rarely performed in hospitals in Indonesia, because focuses are still on curative, while physical, social and spiritual changes cannot be intervened entirely with curative. In order to make the life quality of cancer patients remain high, there are several things that need to be done, among them is by implementing a comprehensive and integrated palliative-care from the palliative team.6

Kubler-Ross state that there are five stages of emotional reaction that are associated with chronic-diseases: denial, anger, bargaining, depression, and acceptance.7

a) Denial

Denial is a defense system that makes a person try to avoid the effects of illness.

b) Anger

The patient tries to question “Why do I have to suffer from a chronic illness?” Analysis: the patient is in this stage because the patient feels that she still has a lot of hope that she wants to do in the future, for instance having children, enthusiasm in finding fortune, but this disease makes her hopes disappear.

c) Bargaining

The cancer-sufferer divert anger better with different strategies.

d) Depression

Depression as a lack of control is a realization of the worsening of symptom as a condition of a disease that does not improve.

The cancer-sufferer will feel fed up, tightness, fatigue, difficulty eating, difficulty controlling herself, difficult to focus attention, avoid pain and feeling uncomfortable.

e) Self-acceptance

The cancer sufferer is no longer angry and has familiarized herself with the idea of death which makes her depressed and also faces unpleasant thoughts.
This patient was in the anger stage, it was evident in every time we provide education related to the disease, the patient had difficulty concentrating and unstable emotions, there was an acceptance stage to start chemotherapy due to coercive factors from parents.

KODEKI (Indonesian Medical Code of Ethics) states that “Any doctor’s actions or advice that might weaken psychic or physical endurance, must obtain the patient’s/ family’s approval and are only given for the benefit and good of the patient”. To reduce drastic emotional changes of patients, the delivery of information about their illnesses is carried out with the “SPIKES”:

1. Setting, Listening-Skills

Before delivering bad-news to patients, it is necessary to prepare ensuring the smooth delivery of information to patients before delivering bad-news, you should prepare the ability to ‘hear’, include: silence, repetition, availability.

2. Patient’s Perception

Before delivering bad-news, the doctor should know the patient’s perceptions of: her own medical condition and her expectations of the results of the medication she was taking, ask the patient’s estimate of the results of the medication

3. Invitation to share Information

Ask whether the patient wants to know the developments regarding her situation or not. If the patient claims not to be ready, consider delivering at a more appropriate time and ask the patient to prepare in advance. If the patient states that she wants to know the progress of the situation, ask the extent to which she wants to know.

4. Knowledge transmission “Delivering bad-news”

Before delivering bad-news, do a ‘warning shot’ as an opening to tell the patient that there is ‘bad-news’ to be delivered to the patient so that the patient is not surprised.

5. Explore Emotions and Empathize

Always observe the patient’s expression and emotion as well as what underlies changes in her emotion, examine the patient’s emotional state.

6. Summarize and Strategize

At the end of the talk, review the entire conversation again: conclude the ‘bad-news’ that was delivered in stages (piecemeal). Conclude the response given by the patient during the bad-news delivered, show that the doctor listens and understands what the patient is delivering, gives the patient the opportunity to ask questions, gives feedback, and discusses plans to follow up on the bad-news that has been conveyed to the patient.

Bioethics Analysis

As stated in the Geneva Declaration the doctor stated: “Patient health will always be my first consideration” and the International Medical Ethics-code states: “Doctors must give their patients full loyalty and all the knowledge they have”. The doctor must tell the patient the consequences of the decision taken. Patient must understand clearly what the goals of a test or treatment are, what results will be obtained, and what the impact would happen if they delay the decision.

The rules of bioethics are an absolute law for doctors. The Indonesian Medical Council, by adopting the principles of western medical ethics, stipulates that the practice of Indonesian medicine refers to 4 basic moral principles which are often also called the basic principles of medical ethics or bioethics, namely:

1. Beneficence

It’s a principle that a doctor is doing good, respecting human dignity, the doctor has to make every effort so that the patient remains in good health. The principle of beneficence emphasizes the role of the doctor to provide convenience and pleasure for patients in taking positive steps to maximize the good results rather than the bad things. The principles contained in this rule are: prioritizing altruism, guaranteeing the basic values of human dignity, looking at a patient or family is not an action that only benefits the doctor, trying to have more good or benefit compared to a bad one, paternalism is responsible/compassion, ensuring the good and minimal life of humans, maximizing the rights of patients as a whole, implementing the Golden Rule Principle, giving an efficacy but inexpensive prescription, developing the profession continuously, and minimizing bad consequences.

Analysis: the doctor has done the best for the
patient in the treatment effort by doing chemotherapy in accordance with the procedures of medical-treatment in hospital which all costs are borne by the Government (BPJS).

2. Non-Malfeasance

Non-maleficence is a principle in which a doctor does not perform actions that aggravate the patient and choose the treatment with the most minimal risk for the patient who is treated by him. The ancient statement, first, do no harm, still applies and must be followed. Non-maleficence has the following characteristics: helping emergency patients, treating injured patients, not killing patients, not looking at patients as objects, not insulting/abusing/utilizing patients, protecting patients from attacks, patient benefits outweigh the doctor’s losses, no endangering patients because of negligence, avoiding misrepresentation, giving life spirit, not committing white collar crime.

The principle applied to this patient is that when chemotherapy is performed, the patient is given premedication drugs so that in the process of chemotherapy the side effects are minimized.

3. Autonomy

Every individual must be treated as a human who has the right to self-determination. The Autonomy rule has the following principles: respect the right to self-determination, honestly respect privacy, maintain patient secrets, respect patient rationality, carry out informed consent, allow adult and competent patients to make their own decisions, not intervene or impede patient-autonomy, prevent others from interfering with patients in making decisions-including the patient’s own family, patiently waiting for decisions to be taken by patients in non-emergency cases, not lying to patients even for the patient’s benefit, and maintaining relationships or contracts.

Analysis: After receiving counseling, information and education about the disease related to complications and prognosis, the patient chose to undergo chemotherapy. Autonomy requires that patients must first receive and understand accurate information about their condition, the type of proposed medical-treatment, the risks, and also the benefits of the medical action.

4. Justice

Justice has the following characteristics: applying everything universally, taking the last portion of the process of sharing that he has done, providing equal opportunity to individuals in the same position, respecting the health rights of patients, respecting the legal rights of patients, respecting the rights of others, maintaining the rights of others vulnerable groups, do not differentiate services to patients on the basis of SARA, social status, etc., do not abuse, make contributions that are relatively equal to the needs of patients, request patient participation in accordance with their abilities, return rights to their owners at the right time and competent, not giving a heavy burden unevenly without valid or appropriate reasons, respecting the rights of the population with the same vulnerable to disease or health problems, and wise in macroallocation.

Analysis: doctors provide the same treatment of chemotherapy services to all patients who need these services for the benefit of patients without looking at the economic, social-status, elements of SARA and so forth.

Clinical-Ethics Analysis

Jonsen, Siegler and Winslade (2002) develop ethical-theories that use 4 essential topics in clinical services, namely:\textsuperscript{13,14}

Figure 1. The essential topics in clinical-services
1. Medical-Indication

All relevant diagnostic and therapeutic procedures are included to evaluate the patient’s condition and treat it. Ethical questions on this topic are similar to all information that should be conveyed to patients in the doctrine of informed-consent.

After answering all the above medical indication questions using the principle of beneficence and non-malificence, it is determined the choice of advanced chemotherapy to prevent further complications of metastasis to the surrounding organs.

2. Patient-Preferences

The ethical questions include questions about the patient’s competence, volunteer nature, attitudes and decisions, understanding of information, who makes the decision if the patient is incompetent, the values and beliefs held by the patient, and others.

In this case it is more the autonomy principle where the patient is mentally capable and legally competent in realizing and understanding her current clinical condition so that she agrees to do further chemotherapy. Previously the patient had understood the advantages and disadvantages of this chemotherapy procedure through informed-consent.

3. Quality of Life

This is the actualization of one of the goals of medicine, which is to improve, maintain or increase the quality of human life. What, who and how to assess quality of life are ethical questions around prognosis.

According to WHOQOL (1996), that there are some things that need to be considered when assessing life quality, where life-quality is closely related to the domain being assessed, namely: 1) physical-health, 2) psychological, 3) degree of independence, 4) social-relations, 5) environment, 6) spirituality/religion/ individual beliefs. To find out how one’s quality of life can be measured by considering the physical, psychological, social and disease conditions.15

According to Ferrell et al. in Zeng (2010), there are 4 domains in measuring life quality of cancer patients: 1) physical-control or relief of symptoms and maintenance of function and independence, 2) psychological (efforts to maintain life control over threatening diseases marked with emotional disturbances, changes in life priorities, fear and positive life changes), 3) social (efforts to deal with the impact of cancer on individuals, their roles and relationships), 4) spiritual (ability to maintain the hopes and meaning of a cancer experience which marked by uncertainty).16

4. Contextual-Features

The principle in Contextual Features is Loyalty and Fairness. Here ethics questions are discussed around non-medical-aspects that influence decisions, such as family, economic, religious, cultural, confidentiality, resource allocation and legal factors.

The patient’s own motivation to run chemotherapy is still lacking. There are no obstacles in making good decisions from the family, all support her in undergoing treatment. There are no religious, cultural or belief factors that conflict with decision-making.

Conclusion

Medical-treatment has been carried out in accordance with medical-aspects, bioethics and clinical-ethics.

Malaria Prevention and Eradication Program Towards Malaria-Elimination in West-Seram

Sahrir Sillehu,1 Wiwi Rumaolat1, Sunik Cahyawati1, Tri Niswati Utami,2 Dewi Kartika3, Wa Rina4, Suparji5

1Researcher, STIKes Maluku Husada, 2Researcher, Universitas Islam Negeri Sumatera Utara, 3Researcher, Universitas Gorontalo, 4Researcher, Poltekkes Kemenkes Maluku, 5Researcher, Poltekkes Kemenkes Surabaya

Abstract

Malaria is a health problem in the world spread in 95 countries. The research objective describes the evaluation of malaria-prevention and eradication programs including inputs, processes, and outputs using qualitative approach. Data were collected by in-depth interview. Research informants were 1 key-informants and 4 supporting-informants. Malaria-elimination program in West-seram District based on the guidelines of the Ministry of Health of the Republic of Indonesia and operationally outlined in the form of a technical guide. Case surveillance has not been carried out. Malaria vector control was done by eradicating mosquito nests and using mosquito nets containing insecticides. Cross-program and cross-program cooperation had been going well, but cross-sectoral collaboration, still needs to be improved. The funding was largely supported by donor agencies namely the Global Fund for AIDs, TBC, and Malaria (GF-ATM) while Government of West-Seram allocates microscopic slide examination costs. It is necessary to increase health personnel, facilities and infrastructure, discovery, prevention, and case management.

Keywords: malaria, elimination, evaluation, prevention, eradication

Introduction

Global Malaria Program (GMP) states that malaria is a disease that must be continuously monitored, monitored and evaluated and the appropriate formulation of policies and strategies is needed. The Global Malaria Program aims to reduce the burden of global disease by 40% by 2020, and by 90% by 2030.(1)

The Indonesia Government establishes efforts to eliminate malaria in Indonesia through Health Minister Decree No.293/MENKES/SKI/IV/2009 regarding malaria-elimination, so malaria is a complex problem so malaria-elimination must be carried out in an integrated manner by all related components and become part of national development. So that the realization of healthy people who are free from malaria gradually until 2030.(2)

Malaria cases in Maluku Province in 2015 was 1,332 positive cases, with a morbidity-rate/ Annual Parasite Incidence (API) of 3.2 per 1000 population. MDGs target for API 2015 is <1%. 2014 as many as 1086 positive cases with API of 4.5 per 1000 population. This means that for 2015 there was a decrease in the number of malaria-cases, although it did not show a sharp decline. Health Profile of West-seram Regency in 2018, positive malaria-cases in West-seram in 2015 were around 1087 cases. This number decreased when compared with positive malaria-cases in 2014, which were 1915 cases. The West-seram administratively has 11 Subdistricts, of which 7 of the 11 districts are malaria-
endemic areas, the sub-district with the highest malaria-endemic is Huamual. Positive malaria-cases were based on a microscopic examination of 1087 cases. The sub-districts with the highest endemicity were found in the village of Uweng Beach in 2015 (546 cases). In 2016, the highest malaria-cases occurred in Talaga Kambelu, which was 120 cases. In 2017, Tanah Goyang sub-village was in the first place of malaria-cases with 256 cases and in January to July 2018 the highest number of malaria-cases occurred in Talaga Kambelu (15 cases). (6)

Based on API of West-Seram, the highest malaria-incidence in the last five years occurred in 2015 (55.60 per million). Whereas for the Annual Malaria Incidence (AMI) indicator in West-seram, the highest malaria-incidence rate based on clinical-symptoms occurred in 2015-2018 occurred in Talaga Kambelu with the highest occurrence in 2015 (85.88 per million)(6)

The malaria-elimination program in the regency is carried out thoroughly and integrated by government together with partners and the community. Malaria-elimination program was carried out in 18 health centers in sub-districts. The Government through the primary health care has done various things, starting from finding malaria sufferers, establishing malaria diagnoses through microscopic examination, treatment using Artemisinin Combination Therapy (ACT), treating malaria in pregnancy, provision of facilities (microscopy, Rapid Diagnosis test/RDT) for laboratory materials and medicines, distribution of mosquito nets, improvement of human-resources quality and eradication of mosquito breeding-sites.(6)

This study aims to describe malaria-prevention and eradication programs based on input, process and output.

**Method**

This type of research was qualitative study, involved 1 key-informant (the program manager at the West-Seram Health Office) and supporting-informants namely: the head of the West-Seram Health Office, 1 surveillance officer, and 2 community members living in West-Seram. The study was conducted in September to October 2018. Data validity was done by triangulating data sources. Stages of data analysis: 1) writing interview transcripts, 2) reading and reducing data, 3) providing data codes based on the meaning of data 4) drawing conclusions.

**Findings**

Respondents were 2 people consisting of supporting informants and key-informants. It was found that all informants had the same answer to the main questions about the malaria-elimination program. Another thing was revealed from interviews:

“The malaria-elimination program in West-Seram began in 2006 in collaboration with the central government through GF and began in 2007-2008. The background to the malaria-elimination program is that malaria-cases are very high in West-seram”(BT,PA).

Next question;

“For an organization in the malaria-elimination program in West-seram in the head directly by the Head of the Health Office then under the head of the malaria-elimination program office is headed by the head of the malaria-elimination program field. In addition, the elimination process also involves various health workers such as the program manager in the DHO, MCH and immunization program manager. For facilities and infrastructure for malaria-elimination in West-Seram, it is financed by two sources, GF and the Government of West-Seram” (BT,PA)

**Facilities and infrastructure**

“Every primary health care in West-seram is required to have a laboratory and laboratory personnel. However, most primary health care in the district do not have laboratories and laboratory personnel, so most malaria examinations in primary health care using RDT. Of the 17 health centers in West-seram that have trained/trained laboratories: Kairatu, West Kairatu, Waimital, Piru, Waisala, Taniwel” (BT)

“Other health centers do not have laboratory personnel and malaria testing still uses RDT system”.

“There are no specific policies issued by the Head of the Local Health Office, in the form of malaria-prevention programs in West-seram District, both in the form of standard operating procedures (SOP) and implementation guidelines (operational guidelines). “However, in the planning and implementation of malaria-prevention programs, the health department compiles technical guidelines (Technical Guidelines) which contain, among others, the objectives of the program, program indicators, types of activities and activities funded for a period of one year. Technical
guidelines compiled by the health office become a reference for the implementation of malaria-prevention programs at the level of health centers and health offices. The reference used to compile the Technical Guidelines is the malaria-prevention program guidelines from the center, in this case, the Ministry of Health of the Republic of Indonesia” (BT).

Process: Discovery and management of patients

“The mechanism of finding malaria is seen from the health center data. There are two activities carried out by the government in the malaria-elimination program, namely active activities and passive activities in terms of activities inside and outside the building. Passive activities in the form of health services only accept or wait for malaria sufferers to come for a check-up while active activities or outdoor activities are Mass Blood Survey (MBS) activities with a record that all people in West-Seram Regency must be examined and MFS activities that are only in the form of searching for the sick. The sick person in question is only people with malaria-symptoms who are examined not everyone. How to find people with malaria-symptoms is done by asking the community about people who have malaria-symptoms”.

In the next question;

“In the malaria-elimination process, the most influential obstacle is funding. Because of this lack of funding there are still many planned programs that have not yet been implemented. In addition, the geographical location of the health center is also very influential, for example, the distance and the road taken is not good. In addition, there are also some primary health care that are located if they have to use a motorized boat to cross the road so that the access of health workers to the primary health care is a bit difficult and the mobility of sufferers from their homes is still relatively difficult to reach a more adequate health service center”.

“In addition, obstacles from the patient’s side are not compliant or routine taking medication and do not follow re-examination. Every patient who has been taking malaria medicine for three days must return to health services to do a re-examination. The lack of awareness among the people that causes malaria in West-Seram Regency is still fairly high” (BT).

Malaria-elimination program in West-Seram are: 1) Discovery and management of patients (discovery, treatment), 2) Prevention and control of risk factors (distribution of insecticide-treated bed nets, health promotion), 3) Surveillance epidemiology and epidemic prevention (SKD-KLB reporting, prevention of outbreaks, malaria information-systems), 4) Improvement of Communication, Education and information (cross-sectoral coordination and cooperation in malaria-elimination), 5) Increasing human-resources (training for health workers and microscopic personnel).

Prevention and control of risk factors

“The prevention and control of risk factors are carried out by spraying the walls of houses or IRS, but IRS activities are also still ineffective due to funding constraints. In addition, there are activities in the distribution of mosquito nets in each health center and other activities, namely the distribution of abate powder and IRS”. (BT)

“West-Seram District last experienced an outbreak of malaria in 2010. During the last 8 years (2011-2018), although malaria-cases were fairly high, it did not reach the KLB. The information system in Seram Barat Barat has four health centers that have been trained, namely, Tomalehu, Kairatu, Kairatu Barat and Piru. The most perceived obstacle in the information system is that it is difficult to signal, especially for primary health care which is located in remote areas”. (BT,PA)

Information Education Communication Improvement

“To increase IEC, it is carried out under the supervision of GF. Supervision is carried out in the form of direct supervision of officers from the health center level starting from reporting on laboratory supervision and work processes carried out at the health center” (BT,PA).

Increase in human-resources

“Human-resources have been trained, especially for microscopic personnel. In minimizing the obstacles to the malaria-elimination program, the malaria-elimination program section of the West-Seram Health Office is working with the planning department to coordinate every activity proposed by the program manager. Malaria-cases in West-seram have decreased from 2016 8.00 / mil and in 2017 to 4.92 / mil”. (BT,PA)

It was found that malaria-elimination in West-seram chose 4 stages:
a. Eliminating criteria, not all primary health care have been trained with microscopic staff

b. Before eliminating the criteria, all officers have been trained and 100% have taken medicine

c. Eliminating criteria, all primary health care still have malaria but with a very small percentage.

d. Maintenance is no case (0%) (PA, 05 October 2018)

Output

“The hope of the implementation of malaria-elimination in the West-seram District Health Office is to reduce malaria positive cases and the target of malaria-elimination in West-seram in 2021 can be achieved. Suggestions and funding, as well as community participation in supporting malaria-elimination programs, are highly expected by the government because to date community awareness and community participation is still lacking” (BT,PA).

Discussion

The goal of malaria-elimination in West-seram will be achieved in 2021 so that in that year it is expected that a healthy living community is free from malaria transmission.(2) There is no specific organization for the malaria-elimination program in West-Seram, the organization still uses the structure of the West-Seram Health Service. The malaria-elimination program in West-Seram began in 2006 in collaboration with the central government through the GF. Guidelines from the Ministry of Health (Technical Guidelines) as operational guidelines that contain goals, targets, indicators, and budgets sourced from the Government of West-Seram for malaria control.

Process

The implementation of the discovery of malaria sufferers in West-Seram was carried out passively and actively. Case finding is passively carried out through services at primary health care while waiting for patients who come for treatment. Patients who come to the clinic with clinical-symptoms of malaria, blood is drawn and examined microscopically. Whereas patients with clinical-symptoms of malaria who come to the primary health care have their blood drawn and blood tested using RDT.(7)

Patient discovery is actively carried out in areas with cases that are still high by means of MBS. This is in accordance with the guidelines for malaria management, that the method of finding patients can be done through these activities(6). The patient discovery activity in West-Seram is the same as the activity carried out in the Principe Islands, Taiwan, with PCD and MBS to support malaria-elimination efforts in Taiwan. Malaria sufferer discovery activities in Purworejo, besides PCD, ACD activities are carried out not only by SBM but through active search activities in the community by the Village Malaria (JMD).(9)

Proof of malaria based on PfMSP-1 allele K, MAD20 and RO33 polymorphisms found in closed communities living in malaria-endemic areas. Early-detection and screening are very helpful in eliminating malaria.(10) Laboratory tests to determine malaria diagnosis are carried out microscopically and using RDT. Microscopic examinations are carried out if the patient comes to primary health care, whereas RDT are done if the patient with clinical-symptoms comes to the nurse. Laboratory tests carried out in West-Seram are in accordance with the standards set by the Ministry of Health, even though the gold standard is microscopic examination. The guideline in conducting standard diagnosis is that every case of suspected malaria must be examined by a blood supply using a microscope or RDT.(2)

The role of the local government in the malaria-elimination program includes mobilizing potential resources including funding support. The results showed that the West-seram Government Fund for the implementation of malaria control programs was minimal and the budget provided for microscopic slide examinations by primary health care in endemic areas. The source of funds for the discovery and treatment of sufferers and vector control by the use of insecticide-treated bed nets comes from donor agencies, the GF.(11)

Output

West-seram is an area with a target of 2021 has reached elimination status. The target can be achieved if there is a commitment of the local government, especially in financing. The number of malaria-cases in West-Seram is in line with the number of malaria-cases nationally, which tends to decrease. The number of malaria-cases nationally in 2010 was 465,764 cases with
an API of 1.96 “and decreased in 2014 to 252,027 cases with an API of 0.99”\(^{(12)}\).

The number of cases and deaths in the world (WHO), there was a decrease from 2000-2015 there was a decrease in cases by 60% and a decrease in deaths by 37\%\(^{(1)}\). The South Buru Health Office noted that 494 cases of malaria were positive in 2014 and API 6.86\%\(^{(5)}\). Sillehu et al. (2019) stated that the high and low cases of malaria in Buru Regency in closed and open community groups were related to the interaction of the host with agents due to agricultural land opening, high population mobility to endemic areas\(^{(10)}\). The malaria-elimination in West-seram will be maximal if there is support from all parties, across sectors and across programs and is supported by public awareness in participating in the success of malaria-elimination activities.

**Conclusion**

The malaria-prevention and eradication in West-Seram is carried out across sectors, inputs such as facilities and infrastructure are available as needed. The process in terms of implementation in the form of case finding. Increasing the capacity of human-resources in supporting malaria-elimination programs through active case detection education and training programs, supporting local governments in providing diagnostic and financing support facilities. Prevention program with the use of mosquito nets to avoid contact with mosquitoes. The availability of medicines is adequate for vector control.

Abstract

Stress at work can not be avoided, nurses are at risk of experiencing work stress. The purpose of this study is to find factors related to the nurse’s work stress. This type of research was observational analytic using a cross-sectional study design. The sample was 96 nurses working in the Toto Kabila hospital. Data were analyzed using chi-square tests. The marital status (p-value=0.001), length of work (p-value=0.001), working conditions (p-value=0.004), social support (p-value=0.010) had significant relationship with work stress. The results of this study are expected to be used as input and consideration for nurses at Toto Kabila Hospital to maximize how to deal with stress.

Keywords: work stress, marital status, length of work, working conditions, social support

Introduction

Nurses’ work routines that require speed and responsiveness to situations, especially nurses working in the emergency department, result in heavy work pressure resulting in work stress (distress). Work in the formal and informal sectors in government and non-government institutions has rules of working time, demands for good performance, and maximum productivity. This results in pressure on the workforce so that it can cause negative work stress.(1)

In the emergency room at all times, there are cases with varying degrees of emergencies that must be served immediately. Nurses as health workers who are always in the first contact with patients must always be fast, precise, and careful to prevent death and disability.(2)

According to WHO (2014), in many countries 8% of occupational diseases are depression. Research results in 2014 found 440,000 cases of work-related stress in the UK with an incidence of 1,380 cases per 100,000 workers experiencing work-related stress. A survey of nurses at Medan Haji Hospital found nurses’ work stress to have a negative impact (distress) 32% mild stress, 62% moderate and 6% severe.(1) The impact of work stress experienced by nurses is the low positive image of nurses.(3)

There are 35% of work-related stress is fatal and it is estimated that working days are lost by 43%. Based on a survey of West Australian health statistics it was stated that male workers lost approximately 50.8 working days and female workers lost approximately 58.5 working days.(4)

The national prevalence of mental-emotional stress prevalence is 6% and is not differentiated between workers and non-workers. The survey conducted stated that 64% of workers in Indonesia experienced an increase in stress compared to 2011. As much as 1.6% of the population of Jambi Province were estimated to experience mental-emotional disorders. Health problems related to work result in economic losses of 4-6% of GDP for most countries. Stress due to work is an important occupational health problem, which will result in a significant decrease in work productivity.
Utami (2015) states that public health does not only look at the community in general but also the working community because public health is a multidisciplinary science consisting of 7 disciplines, one of which is occupational health.\(^{(5)}\)

The survey at Toto Kabila District General Hospital showed that there were 111 nurses in 2015, 111 nurses in 2016 and 132 nurses in 2017. The survey obtained from the results of the number of patients in 2015 was 8,561 patients, in 2016 there were 9,782 patients, and in 2017 there were 9,891 patients. The division of nurses’ work with 3 work shifts, and divided by units namely ICU, IGD, Interna 1, Children, Neonatal Intensive Care Unit, puerperal midwifery, midwifery, Flamboyant / VIP, Surgery, and room Interna 2. Based on these data it is necessary to research work stress problems so that the formulation of this research problem is: what factors are related to nurse’s work stress? The purpose of this study: to find factors related to the nurse’s work stress.

### Method

The design of this research was cross-sectional. The study was conducted at the Toto Kabila Hospital, Bone Bonelango District, from February to March 2018. The population was all nurses who worked at Toto Kabila Hospital in 2018 (97 people). The sampling technique was total sampling.

The dependent variable was work stress and the independent variables were: age, marital status, length of work, working conditions and social support. Data were analyzed using Chi-square test.

### Findings

The characteristics of respondents such as age, sex, employment status, and education, the results are presented in the table 1.

<table>

**Discussion**

Age is the length of time of life or existing (since birth or held). Older employees tend to have a greater sense of attachment or commitment to the organization compared to the younger age so that it increases their loyalty to the organization.(7) Utami (2015) elaborates that in general the discussion of variables on individual characteristics is age, gender, and ethnicity. Age groups under 40 years have a high mortality rate. Several studies describe that health, illness, and treatment are age-related.(5),(8)

It was concluded that there was no significant relationship between the age of nurses and work stress. The results of this study are following research by Ibrahim et al. (2016) which states that workers under 40 years experience more stress than workers aged over 40 years. According to him, workers aged 40 years and over have good abilities in controlling work stress.(9)

The results of this study are in line with the results of research conducted by Mareta 2016 which was obtained from the results of data analysis using the Chi-square Test obtained p-value = 0.908, which means there is no significant relationship between the age of nurses with work stress in the nursing room of Dr. Soehadi Prijinegoro Hospital, Sragen. One research shows that employees who get married have fewer absences, experience lower turnover, and are more satisfied with their work than bachelor coworkers.

It was concluded that there was a significant relationship between the marital status of nurses with work stress. The results of this study are not in line with the results of research conducted by Mareta 2016 where obtained from the results of data analysis using the Chi-square Test obtained P-value = 0.444, which means there is no significant relationship between work time with work stress on nurses in the room inpatient Dr. Soegiri Hospital, Lamongan.(7)

Length of service (length of work) is an individual experience that will determine growth in employment and occupation, work period shows how long a person

...
works in each job and position.\(^{(7)}\) It was concluded that there was a significant relationship between the length of time the nurse worked with work stress. The results of this study are not by previous studies, Ibrahim et al (2016) the relationship of work tenure with work stress has a p-value = 0.70 (>0.05) which means that work tenure is not related to work stress. Workers who have long years of work experience less work stress, and fewer new workers who work stress. The assumption is that the longer a person works, the greater the responsibility he receives.\(^{(9)}\) Seniority determines the greater responsibility placed on workers. Yanto & Rezeki (2017) argue that nurses are young and have no experience, but are more energetic and energetic at work. The results of his research found that the age of the nurse together with the mentoring program had a significant effect on reducing nurses’ work stress.\(^{(10)}\)

The work period provides experience for the worker, the longer he works, the more experience he gets. Contradicts previous research. Research conducted by Mareta 2016 which was obtained from the results of data analysis using the Chi-square Test obtained p-value = 0.255, which means there is no significant relationship between work time and work stress on nurses in the inpatient Dr. Soegiri Hospital, Lamongan.\(^{(7)}\)

Social support is an act that is helpful by involving emotions, providing information, material assistance and positive assessment of individuals in dealing with their problems. It was concluded that there was a significant relationship between nurses’ social support and work stress. Working conditions can be a motivation for workers. Purwandari (2015) research results nurses who have good work motivation, are at mild work stress levels.\(^{(11)}\)

Fuada et al (2017) examined factors related to nurse stress, one of the factors that influence work stress is career development. Nurses who experience heavy work stress are dominated by nurses who develop poor careers. This means that social support in the work environment such as no career development is the cause of the emergence of work stress. The results of this study are not in line with the results of research conducted by Hany Ummu which obtained results using multiple regression analysis with the enter method with the results of the analysis obtained values R = 0.633, R² = 0.400, F = 39.050, P = 0.000, shows there is a significant relationship between stress and social support for nurses.\(^{(12)}\)

It was concluded that there was a significant relationship between the working conditions of nurses and work stress. Fajrillah (2016) high nurse work stress has an impact on low nurse performance.\(^{(13)}\) Working conditions are a series of conditions or working environment conditions of a company that is a place of work of the employees who work in the environment and what is meant here is a good working condition that is comfortable and supports workers to be able to carry out their activities well.\(^{(14)}\) Working conditions such as shift work and workload are factors that cause work stress. Previous studies found a significant relationship between work shift and work stress in nurses, due to perceived fatigue.\(^{(15)}\) Azizah & Nopti’s research (2019) shows that there is a relationship between workload and the stress level of nurses working in Tangerang District public hospitals in the emergency department.\(^{(16)}\) Elizar (2020) based on the results of his research found a relationship between workload and work stress.\(^{(17)}\)

The characteristics of the social environment become a source of stress in an organization because it can form interpersonal relationships between coworkers, superiors, and consumers that have the potential to trigger conflict.\(^{(18)}\) The results of this study are in line with the results of a study conducted by Mareouw in which the results obtained from the chi-square test obtained value = 0.001, which there is a significant relationship between working conditions with work stress on nurses in the medical emergency room at the Central Hospital Prof Dr. R.D. Kandou, Manado.

Conclusions

Factors related to nurses’ work stress at hospital Toto Kabila hospital are marital status, length of work, working conditions, social support.

microRNA as Potential Biomarker for Pediatric Tuberculosis?

Ayling Sanjaya¹, Dwi Yuni Nur Hidayati², Susanthy Djajalaksana³, HMS Chandra Kusuma⁴

¹Student, Doctoral Program of Medical Science, Faculty of Medicine, Universitas Brawijaya / Department of Pediatrics, Faculty of Medicine, Universitas Wijaya Kusuma Surabaya, ²Associate Professor, Department of Microbiology, Faculty of Medicine, Universitas Brawijaya, ³Assistant Professor, Department of Pulmonology, Faculty of Medicine, Universitas Brawijaya, ⁴Professor, Department of Pediatrics, Faculty of Medicine, Universitas Brawijaya

Abstract

The diagnosis of pediatric TB is based on history taking, clinical symptoms, physical examination and support. In recent years the role of microRNA (miRNA or miR) has become a concern for researchers as biomarkers of diagnosis and therapy in TB in adults and children. MicroRNA is a ribonucleic acid that does not encode proteins with 18-25 nucleotide transcripts that interact with gene targets and regulate mRNA expression. miRNA works with other regulatory elements such as transcription factors to control mRNA translation. More than 100 different miRNAs are expressed by immune system cells; they have the potential to broadly influence the molecular pathways that control the development and function of innate and adaptive immune response regulation. During TB infection, the innate immune response provides an initial defense mechanism against infection. It is well known that macrophages are the main stem cells for mycobacteria, survival in macrophages is determined by host-pathogen interactions. Several studies have shown that miRNA can be used as a biomarker and TB therapy agent because it is stable in plasma and other body fluids, difficult to degrade and excreted in the form of exosomes or micro vesicles. Other studies say miRNA is stable despite repeated exposure to heat, cold, acids, bases, and other extreme conditions. miRNA levels are reported to be increased in individuals with TB.

Keywords: pediatric tuberculosis; diagnosis; therapy; microRNA; biomarker

Introduction

Tuberculosis (TB) is a chronic infectious disease caused by infection with Mycobacterium tuberculosis (M.tb). This disease is the second leading cause of death in the world due to infection after HIV / AIDS¹,². It is estimated that around two billion people suffer from latent TB infection and cause new TB cases in 9.2 million people and deaths in 1.7 million people in the world. About 5-10% of people who suffer from latent TB infection will become active TB in the first five years after becoming infected with TB germs³,⁴. In 2015 there were 10.4 million new TB cases worldwide, 10% of which were Pediatric TB⁵.

The diagnosis of pediatric TB is based on history taking, clinical symptoms, physical examination and support. However, children infected with TB often show typical symptoms⁶,⁷. Tuberculin testing based on cellular immunity is considered impractical because it requires a minimum of two diagnostic visits. Tuberculin test can be affected by various conditions so that it can produce false positives or false negatives⁶–⁸. Other investigations that are believed to be used in the diagnosis of TB include Interferon Gamma Release Assay (IGRA). The use of IGRA for the diagnosis of TB in children is still limited due to the high cost of examinations and the lack of examination tools and techniques. This examination still cannot distinguish active and latent TB infections⁹,¹⁰.

The definitive diagnosis of TB is made by finding TB germs on direct smear examination and culture which is a gold standard examination. But a definitive diagnosis in children is difficult to obtain because of the small number of germs (pausibasiler), the child is difficult to expel phlegm, the location of germs in the parenchyma area far from the bronchus. Indonesia has developed a TB scoring system for children and is still being applied to help establish a diagnosis of TB in children\textsuperscript{(7,8,10,11)}.

In recent years the role of miRNA has become a concern for researchers as biomarkers of diagnosis and therapy in TB in adults and children. Identification/profiling studies of miRNA in TB with microarray profiling have been carried out in countries. There are significant differences between levels of miRNA expression in pediatric TB patients compared with healthy children and have significant diagnostic values. This suggests that miRNA can be one of the tools to diagnose TB in children that needs to be developed\textsuperscript{(9,12-20)}.

**microRNA**

microRNA is a ribonucleic acid that does not encode proteins with 18-25 nucleotide final transcripts that interact with gene targets and regulate mRNA expression. miRNA works with other regulatory elements such as transcription factors to control mRNA translation. Most miRNAs are encoded in parts of the introns that used to be considered non-coding regions. The miRNA genes are distributed in the genome and are estimated to make up 2-5% of the human genes. miRNA is often expressed as a polysistronic transcript. One miRNA can have many target mRNAs so it is estimated that more than 1/3 of human genes are regulated by miRNA\textsuperscript{(13,20,21)}.

More than 100 different miRNAs are expressed by immune system cells; they have the potential to broadly influence the molecular pathways that control the development and function of innate and adaptive immune response regulation. Apart from impaired immune function, miRNA is also known to play a role in infection. microRNA plays an important role in cell processes such as cell differentiation, cell cycle, embryonic development, apoptosis and associated with infectious diseases including TB\textsuperscript{(22,23)}. Research has shown that stable miRNA serum faces repeated freezing and thawing as well as heat, acid and base conditions and other extreme conditions. This has the potential to be a useful biomarker for disease diagnosis, the effects of therapy and prognosis\textsuperscript{(20)}.

**microRNA Biogenesis**

microRNA is a small, encoded RNA molecule that regulates several biological processes by interfering with mRNA translation. miRNA biosynthesis through a process involving several proteins and enzymes found in the nucleus and cytoplasm. miRNA biosynthesis originates from the miRNA gene in the nucleus where the main miRNA undergoes transcription as a large double-chain primary transcript called pri-miRNA by RNA polymerase II. Pri-miRNA folded into structures such as hairpins undergo polyadenylation and capped. The Drosha RNAse type III enzyme converts this precursor into a double chain miRNA precursor from 60 to 100-nt hairpin known as pre-miRNA. Pre-miRNA consists of a local stem-loop structure that encodes the miRNA sequence that is exported from the nucleus to the cytoplasm by exportin 5\textsuperscript{(9,23)}.

In the cytoplasm, pre-miRNA is further processed by Dicer RNAse III to become duplex miRNA. This unstable duplex consists of guide strand (miRNA) and passenger strand (miRNA *). The miRNA strand guide chain will become mature miRNA, where miRNA * is degraded. Mature miRNA is facilitated by Argonaut protein incorporated into RNA-induced silencing complex (RISC), which recognizes specific miRNA targets and triggers post-transcriptional silencing genes to regulate protein expression, target cleavage mRNAs, suppress / inhibit translation processes, and deadenylate mRNA\textsuperscript{(9,22)}.

**The Role of microRNA in Tuberculosis**

Studies show that different miRNAs play a major role in the process of cell differentiation involved in protection against bacterial infections, such as differentiation and function of immune cells, control of chemokine production and regulation of the immune response. miRNA regulates gene expression by targeting mRNA3'-regions that are not translated, modifying translation and / or degradation. During TB infection, the innate immune response provides an initial defense mechanism against infection. It is well known that macrophages are the main stem cells for mycobacteria, survival in macrophages is determined by host-pathogen interactions\textsuperscript{(24-31)}.

Study found disturbed gene expression profiles in macrophages and NK cells from active TB, latent TB and healthy controls that appeared to be regulated by miRNA. Some miRNAs play a role in the regulation of
T cell differentiation and function. Research shows that miRNA plays an important role in regulating the innate functions of macrophages, DC and NK cells (12,32). Hundreds of miRNA encoded in the human genome and thousands of mRNAs have been shown to be involved in cell development, differentiation, proliferation, apoptosis, DNA methylation, DNA repair and regulating anti-inflammatory or pro-inflammatory stimuli (33).

Research by Zhou found 14 miRNAs that are very important in pediatric TB. RT-qPCR validates that miRNA-1, miRNA-155, miRNA-31, miRNA-146a, miRNA-10a, miRNA-125b and miRNA-150 are downregulated while miRNA-29 experiences upregulation in children with TB compared to children with TB not infected (20).

Modulating the expression of miRNA-125b, which, in turn, will reduce the level of TNF-α and other major cytokines for controlling M. tb. The targets of miRNA-132 and miRNA-26a show a mechanism by which M. tb can limit macrophage responses to IFN-γ by interfering with the expression of host miRNA (35). A study reported that miRNA-21 inhibits the expression of proinflammatory cytokines and increases the production of anti-inflammatory cytokines, IL-10. miRNA-21 is upregulated in un-sensitized DC and macrophages via the TLR/Erk/NF-κB pathway and also regulated following macrophages together with M.Tb which secretes 6 kDa protein (ESAT-6). Inhibition of IL-12 expression by targeting 3′UTR IL-12 mRNA directly and suppressing Th1 response (2,36).

Clinical and in vitro studies note that miRNA-29 is over-expressed after M.Tb infection in several types of human cells. miRNA-29 suppresses the immune response to M.Tb by downregulating IFN-γ. Besides targeting IFN-γ mRNA 3′UTR, miRNA-29 forms an IFN-R mRNA relationship with Argonaut 2 protein (Ago2) to form RNA-induced silencing complexes and subsequently suppress IFN-γ expression post-transcriptionally. Several studies indicate that miRNA-29 also targets anti-apoptosis B-cell lymphoma 2 (Bcl-2) proteins and regulates the apoptotic pathway in immune cells (16,18,37,38). Understanding the expression patterns and regulation of miRNA in active TB and latent TB infection opens the possibility that miRNA can be used as a potential diagnostic marker candidate for TB.

**microRNA as a Biomarker in Tuberculosis**

Early diagnosis is important in efforts to control or effectively treat TB. The heterogeneous clinical presentation of M.tb infection (active TB, latent asymptomatic TB, pulmonary TB, and extra pulmonary TB) is a reason for the development of diagnostic biomarkers. It aims to improve the quality of diagnostic papal bacillary TB or TB cases that are difficult to ascertain for example in children, individuals with HIV, extra pulmonary cases.

The mechanism of LTBI and its transition to active TB is still unclear. Many studies provide evidence that this transition arises if cell-mediated immunity fails. Previous studies have shown that gene expression profile is disrupted in macrophages and NK cells from active tuberculosis and LTBI is thought to have a major role in controlling miRNA expression and describing significant markers for knowing and diagnosing active tuberculosis and LTBI (39).

Sputum, serum, plasma, or other body fluid specimens can be used for non-invasive miRNA analysis, in addition the level of miRNA expression seems stable and can be reproduced in serum, which makes them a potential marker for disease diagnosis so that miRNA can be considered a biomarker which is ideal for TB disease diagnosis (40).

Overall previous research revealed the role of miRNA in the immune and inflammatory response to TB. There is evidence that circulating miRNA exerts biological functions as part of intercellular communication and can be used as biomarkers for human disease. The attractiveness of using plasma miRNA in clinical applications is very high, because the separation and storage of plasma or serum samples is already a clinical routine in TB endemic countries (19).

Several studies have shown that miRNA can be used as a biomarker and TB therapy agent because it is stable in plasma and other body fluids, difficult to degrade and excreted in the form of exosomes or micro vesicles. Other studies say miRNA is stable despite repeated exposure to heat, cold, acids, bases, and other extreme conditions. MiRNA levels are reported to be increased in individuals with TB (14,17). Studies conducted on children show that there are significant differences between miRNA levels in children with TB compared to healthy children and have significant diagnostic values. This shows that miRNA can be one of the tools to diagnose TB in children that needs to be developed (15,18).

Abstract

Quality of life is a global concept that emphasizes dimensions of health status including finance, housing, and work. The quality of life of post-stroke sufferers can experience disturbances or obstacles due to physical disabilities, cognition, psychological and social disorders. The purpose of this study was to determine the effect of ACT interventions on changes in the quality of life of post-stroke patients at Aloe Saboe Hospital. The method used in this research is quasi-experimental research method pre-posttest with the control group. The sampling technique used was the purposive sampling technique. The number of samples studied was 60 respondents divided into the experimental group (ACT Therapy and health education) and the control group (health education). The variables used are independent variables namely ACT therapy and the dependent variable is the quality of life of patients after stroke. Based on the results of the analysis, there is an effect of ACT intervention on improving quality of life in post-stroke patients as evidenced by the results of \textit{t} count = -9.015, then the Significant value is 0.000. This shows that the value of \textit{p} < 0.05 then Ho is rejected, so the research hypothesis is proven that there is an effect of ACT therapy on the quality of life of post-stroke patients at Aloei Saboe Hospital, Gorontalo City.

\textit{Keywords}: ACT; post-stroke; quality of life; therapy; acceptance; commitment

Introduction

Stroke is a disease in the brain in the form of impaired local or global nerve function that appears suddenly, progressive, and fast. Impaired nerve function in stroke is caused by nontraumatic brain blood circulation disorders. Symptoms that cause paralysis of the face and limbs, speech is not smooth and impaired vision. Stroke can be interpreted as any damage to the brain of the central nervous system caused by abnormalities/abnormalities of blood vessels. The term stroke is always used when the symptoms occur acutely, while the term cerebrovascular disease is used more generally and is not related to the time of brain damage. The World Health Organization (WHO) states that stroke is a functional impairment of vocal and global brain affecting the quality of life of sufferers.\textsuperscript{(1)}

The incidence of stroke in Indonesia has been declining over time but the prevalence of rates has increased. This shows that the number of old stroke cases increases each year, thus meaning more people with disabilities due to stroke so that the rehabilitation function is more important. Stroke recovery rates are still low, as many as 15-30\% sufferers will experience paralysis or permanent disability, loss of voice or memory and various other consequences. About 25\% of stroke patients die within the first year after a stroke and 14-15\% experienced a second stroke in the same year after a first stroke.\textsuperscript{(2)}

According to the 2013 Basic Health Research (Riskesdas) data, the prevalence of stroke in Indonesia is 12.1 per 1,000 population. That number is up compared to Riskesdas 2007 which amounted to 8.3 percent. Judging from its characteristics, many strokes are experienced by the elderly, have low education, and live in cities. Based
on data from Aloe Saboe Hospital, Gorontalo City, it was found that there were 1560 stroke sufferers in nerve poly consisting of 739 Hemorrhagic stroke sufferers and 821 Non-Hemorrhagic Stroke sufferers.

Acceptance and commitment therapy (ACT and Commitment Therapy / ACT), is one of the most popular therapies today and is considered more flexible and more effective in handling various cases. This therapy teaches patients to accept thoughts that are distracting and considered unpleasant by placing themselves following their values so that patients will accept existing conditions.\(^{(3)}\)

Acceptance and commitment have a huge impact on the development of patients with anxiety to be better. Commitment means an agreement (attachment) to do something. ACT is very effective in creating acceptance, attention and being more open in developing the capabilities of depression, anxiety, drug abuse, chronic pain, schizophrenia patients and is very effective as a model of self-training. Therefore ACT is expected to improve the quality of life in patients with post-stroke.

The results of Bays\(^{(4)}\) in the United States showed a decrease in the quality of life of post-stroke patients including daily activities, communication patterns, social activities, work, rest and recreation. Declining quality of life can affect the lives of sufferers and caregivers. Therefore the family also plays a role in improving the quality of life of sufferers. According to Nurrohma\(^{(5)}\), quality of life as a center for health promotion, quality of life is based on three areas of human life that are important dimensions in human experience, namely: Being, Belonging and Becoming. These three things occur due to interactions between a person and his environment.

Based on the description that has been explained, the researcher is interested in researching with the title the effect of acceptance and commitment therapy on the quality of life of patients after stroke in Aloe Saboe Hospital, Gorontalo City.

**Method**

This research was conducted at the Regional General Hospital (RSUD) Aloe Saboe Gorontalo City. This type of research is a quasi-experimental research pre-post test with a control group. This research was a type of research that tests an intervention in a group of subjects with a comparison group. The intervention that was tested was the provision of ACT, which in the implementation stage was modified by researchers using a spiritual approach. The study population was patients who visited the Aloe Saboe Hospital in Gorontalo City, amounting to 60 patients who were determined by the purposive side technique. The sample used was by the inclusion criteria set by the researchers, namely a) outpatients diagnosed after stroke; b) experiencing changes in quality of life; c) the level of consciousness of compos mentis; d) cooperative and willing to be respondents given ACT therapy. Data were collected using a demographic data questionnaire, namely the WHOQOL-BREF quality of life questionnaire, which contained aspects of quality of life that included physical dimensions, psychological dimensions, social relations dimensions, and environmental dimensions. Besides, an examination of risk factors, namely blood pressure, and cholesterol to see the effect on the quality of life. Data were analyzed by paired sample t-test to prove the research hypothesis by looking at differences in quality of life in the intervention and control groups before and after the intervention. To determine the homogeneity of variables between the intervention group and the control group, the equality test was conducted. The independent sample t-test was used to determine the differences between the two groups. A multivariate analysis process was carried out to prove the relationship between the characteristics of post-stroke patients with the quality of life.

**Findings**

The results of the study are presented in the table 1. Based on the table 1, it shows that the characteristics of respondents consisted of gender, age, last education, and last occupation.

Discussion

According to Wijaya & Putri\(^6\), the incidence of stroke increases with age. Data reported by the American Heart Association in the Heart Disease and Stroke Statistics-2011 Update that young stroke sufferers between 20-45 years have increased dramatically in recent years. In 2009 the age range of ischemic stroke patients was between 20-60 years, with an average age of 58.8 years. Meanwhile, in 2010 the age range of ischemic stroke patients was between 24-90 years with an average age of 48 years. This shows that both in Indonesia and in the world, stroke has attacked many productive ages and even children.\(^7\)

Based on the results of the study, the gender frequency distribution of stroke clients in this study was more dominated by men. This is in line with the theory that men are more often found to suffer a stroke than women.\(^6\) Bowman also revealed that the incidence of stroke in men was slightly higher than in women, this difference occurred probably related to the increased incidence of hypertension and diabetes in the group.\(^9\) The study is in line with the theory that men are more at risk of stroke than women, with a percentage of 20 percent higher in men than women. But after a woman turns 55, when estrogen levels decrease due to menopause, the risk is actually higher than men.\(^4\)

The results of the analysis of the relationship between work and the incidence of stroke show that most respondents have jobs. Researcher’s assumption, there is a significant relationship between work and the incidence of stroke. Work is a risk factor for stroke. This might be caused by the relationship between work and one’s stress level. A large workload, the salary that is not as expected, and pressure from superiors can trigger stress and be a risk factor for stroke. Stressful conditions can produce the hormones cortisol and adrenaline which contribute to the process of atherosclerosis. This happens because the two hormones increase the platelet count and the production of cholesterol which can damage cells lining the arteries making it easier for fat tissue to be buried in the artery walls.\(^5\)

The analysis showed that cholesterol risk factors before and after health education and ACT intervention had a significant effect on improving the quality of life of respondents. Meanwhile, the risk of hypertension after being given health education and ACT Interventions has a significant effect on improving the quality of life of respondents. Researcher’s assumption that cholesterol
and hypertension are risk factors that affect the quality of life of respondents after a stroke due to increased body cholesterol can cause atherosclerosis and the formation of fat embolism so that blood flow slows into the brain, brain perfusion decreases.\(^{(6)}\)

Based on the results of the study, it shows that before being given ACT therapy the average quality of life score in the intervention group had a mean value of 67.0 with the bad category. And after the intervention, it becomes 81.0 with a good category. The researcher’s assumption, this shows an increase in the quality of life score that shows the increased quality of life experienced by respondents. ACT therapy with a spiritual approach to quality of life can be said to be influential because it gets the result of \(t\) count = -9.015, then significant is 0.000. an important role in determining abnormalities. Neurons or nerve cells are the basic units of structure and function in the nervous system. Neurons are communicators that send information between the body and brain.\(^{(7)}\)

Emotional problems are common, anxiety and depression reactions are left-brain damage reactions while the damage to the right brain often causes a strange feeling or different from the situation at hand. This is experienced by many stroke patients. They cannot assess precisely the damage done. As a result, depression arises as a symptom that often accompanies this disease. Thus, psychospiritual assistance is very helpful in dealing with depression in dealing with this disease.\(^{(8)}\) In implementing ACT therapy, researchers modify the therapy given at each stage with a spiritual approach.

At the ACT therapy stage which is the stage of “practicing accepting selected events and values”, the spiritual approach taken is to understand that illness, recovery, and treatment are provisions and decrees from God. Similarly, at the ACT stage “commit and prevent recurrence”, it was conveyed that prevention and treatment efforts can be done by surrendering and getting closer to God.

Some neurologists examine the existence of a god spot (God’s point) in the human brain. This spiritual center is located between the connections of nerves in the temporal lobe of the cerebrum. Based on observations using emission topographic observations and positrons, the area reacts when the research subjects discuss topics with religion. Worship, regardless of religion, will lead us to focus attention in the mind with the aim of contemplation. The activity, besides having a spiritual function, also has a health function. In the spiritual function, the prefrontal cortex will work actively. This area is associated with positive emotions and makes the cerebral cortex thicken, due to the growth of glial cells supporting neuron cells and neurons that show positive reactions by forming relationships between neurons or synapses. This synapse plays a role in the delivery of information to and from the brain.\(^{(9)}\)

Based on the results of the study, it shows that before being given a health education intervention, the average quality of life score in the control group had a mean value of 77.13 with a bad category. Then after the intervention, it becomes 78.80 with a good category. In this study, health education interventions on quality of life can be said to not affect because the results obtained \(t\) count = -1.520, then significant is 0.139. The researchers assume that ACT therapy with a spiritual approach is more effective in improving the quality of life of post-stroke respondents compared to health education in the control group because there is no significant difference between the quality of life scores before and after health education interventions are given. The control group only experienced an increase in the quality of life score of 1.67.

**Conclusion**

Based on the study it was concluded that the difference in the response to improving the quality of life in post-stroke patients in the intervention group with the control group, where after the intervention of respondents the ACT treatment group the average quality of life score increased to 81.0 while the improvement in the quality of life of the control group of respondents after being given health education became 78.8 this can be interpreted that the improvement in the quality of life of patients after stroke in the intervention group was higher than in the control group.

Determinant Factors on Active and Latent Tuberculosis among Children in Surabaya

Ayling Sanjaya¹, Dwi Yuni Nur Hidayati², Susanthy Djajalaksana³, HMS Chandra Kusuma⁴

¹Student, Doctoral Program of Medical Science, Faculty of Medicine, Universitas Brawijaya / Department of Pediatrics, Faculty of Medicine, Universitas Wijaya Kusuma Surabaya, ²Associate Professor, Department of Microbiology, Faculty of Medicine, Universitas Brawijaya, ³Assistant Professor, Department of Pulmonology, Faculty of Medicine, Universitas Brawijaya, ⁴Professor, Department of Pediatrics, Faculty of Medicine, Universitas Brawijaya

Abstract

Background: Pediatric tuberculosis (TB) is a major health problem in the world and Indonesia. The difficulty of diagnosis is a major factor in eradicating TB in children. Active and latent tuberculosis in children often shows no symptoms so it is difficult to diagnose and affect the treatment. Several determinant factors need to be assessed with the hope of optimal handling of TB in children. Objective: To analyze the determinant factors on active and latent tuberculosis among children in Surabaya. Methods: A case control study was done with 25 cases with TB divided into active TB, Latent TB. Pulmonary tuberculosis was diagnosed using the Indonesian Pediatric Tuberculosis Scoring System. Determinant factors for tuberculosis development were history of contact with a TB patient, age, BCG immunization, knowledge, socioeconomic status and overcrowding living condition. Analysis was done using Fisher’s Exact and Mann-Whitney test. Findings: The characteristics of the study subjects consisting of 16 active TB children and 9 latent TB children. In the group of active TB children the largest population is girls (11 children), whereas in the latent TB group are boys (8 children). There was a significant difference between groups of active TB children and latent TB children (p = 0.000 <0.05). The other factors are showing nothing different in the both of group TB. Conclusion: The most significant determinant factor in active TB and latent TB in children is the appearance infiltrate of chest X-ray where active TB shows filtration and normal appearance in latent TB.

Keywords: Tuberculosis; children; active; latent; determinant factors.

Introduction

Tuberculosis (TB) is a chronic infectious disease caused by infection with Mycobacterium tuberculosis (M.Tb). This disease is the second leading cause of death in the world due to infection after HIV / AIDS. In Indonesia, pulmonary TB is still one of the main causes of morbidity and mortality in children¹,². The highest TB cases were found in the provinces of West Java, East Java and Central Java with the number of cases from the three provinces reaching 38% of all new TB cases in Indonesia³.

It is estimated that around two billion people suffer from latent TB infection and cause new TB cases in 9.2 million people and deaths in 1.7 million people in the world. About 5-10% of people who suffer from latent TB infection will become active TB in the first five years after becoming infected with TB bacterias. Children with latent TB infection are more likely to develop into a serious disease than adults⁴,⁵.

The diagnosis of paediatric TB is based on history taking, clinical symptoms, physical examination and support. History of contact, especially with active adult TB sufferers accompanied by a collection of clinical symptoms of children suspected of TB including coughing > 3 weeks, weight loss or not rising for no
apparent reason despite having received adequate nutritional treatment, prolonged or recurring fever for no apparent reason > 2 weeks, anorexia and inactivity. However, children infected with TB often show typical symptoms\(^{(6,7)}\). Chest radiographs to establish a TB diagnosis in children are not typical except in miliary TB. Tuberculin test based on cellular immunity is considered impractical because it requires a minimum of two diagnostic visits. Tuberculin test can be affected by various conditions so that it can produce false positives or false negatives\(^{(3,6,7)}\).

The problem of TB in children is caused by several factors, including limited data on active TB and latent TB infection in children and difficulty in establishing a diagnosis that affects the management of TB therapy in children. The definitive diagnosis of TB is made by finding M. Tb on direct smear examination and / or culture which is a gold standard examination. But a definitive diagnosis in children is difficult to obtain because of the small number of bacteria (pausibasiler), the child is difficult to expel sputum, the location of bacteria in the parenchyma area far from the bronchi\(^{(3,7,8)}\).

Indonesia has developed a TB scoring system for children and is still being applied to help establish a diagnosis of TB in children. Constraints in the scoring system include parameters used such as tuberculin test and chest X-ray not always available at primary health facilities\(^{(3,9,10)}\). This study aims to analyze the determinant factors that influence TB disease in children infected with Mycobacterium tuberculosis so that prevention can be done so as not to become ill with TB.

**Method**

Observational research with case-control design was conducted at the polyclinic and inpatient at Perak Timur Primary Health Care and the Lung Hospital in Surabaya in the city in October until Desember 2019.

Sample of study were pediatric patients aged 0 - <18 years who suffer from active TB and latent TB who examined themselves at the Perak Timur Primary Health Care and Surabaya Lung Hospital in the period October-Desember 2019. Inclusion criterion includes children aged 0 - <18 years, newly diagnosed pulmonary TB active or latent TB, has a history of contact with adult TB with positive microbiology examination, is willing to be the subject of research, that is stated by signing the consent sheet by the child’s parents. Meanwhile, the exclusion factors are children with congenital diseases, children with other chronic illnesses such as diabetes, malignancy, kidney disease, liver disease, blood diseases, allergies, malaria, and immunocompromised diseases such as HIV, children who have received TB treatment, children who are receiving immunosuppression therapy. Calculation of sample size in research uses consecutive sampling based on the number of patients available during the planned study period.

History and physical examination, nutritional status, chest X-ray and lateral position were performed. A positive tuberculin test showed TB infection. The diagnosis of tuberculosis was made by the scoring method. The scoring system for pediatric tuberculosis diagnosis included TB contact, tuberculin testing, nutritional status, fever ≥2 weeks without apparent cause, cough ≥3 weeks, enlarged lymph nodes, swollen joints / bones, chest X-Ray. The TB scoring system based on interviews conducted by researchers includes positive smear contacts and TB symptoms as well as tracking of risk factors using a questionnaire. This study was approved by the Medical Research Ethics Committee of the Faculty of Medicine, Wijaya Kusuma Surabaya University in 2019. Data analysed with Fisher’s Exact and Mann-Whitney with SPSS 20.0 (SPSS.Inc., Chicago, IL). Significant level was reached when p <0.05.

**Findings**

Table 1 shows the characteristics of the study subjects consisting of 16 active TB children and 9 latent TB children. In the group of active TB children the largest population is girls (11 children), whereas in the latent TB group are boys (8 children). The distribution of maternal education data in the group of active TB children showed that the most mothers with a high school education level were 12 people (75%). In the group of latent TB children, there were 7 mothers with the most recent education graduating from high school (77.8%). Whereas in the most types of father’s work was private sector which were 18 people (18%) in the active TB children group and there are 9 people (100%) in the latent TB children group.

Likewise in the educational characteristics of most fathers graduating from high school there were 12 people (75%) in the group of active TB children and there were 6 people (66.7%) in the group of latent TB children. Whereas in the most types of father’s work was private sector which were 18 people (18%) in the group of active TB children and employees/labourer’s/migrant
workers were 6 people (66.7%) in the group of latent TB children.

Nutritional status in active TB children group were 13 children (81.2%) with good nutrition while in the most latent TB children group also in good nutrition (6 children (66.7%)). In the active TB children group it was found that there were 11 children (68.7%) showing weight loss symptoms and in latent TB children there were 4 children (44.4%) showing weight loss symptoms and there were 5 children (55.6%) showing no symptoms. MTX/Tuberculin test showed positive all in the group of active TB children (16 children) and in the latent TB children group (9 children). Likewise, the BCG vaccine for all children has had a BCG vaccine, both in the active TB children group (16 children) and in the latent TB children group (9 children). In the group of active TB children showed contact TB was found there were 15 children (93.8%) and in the group of latent TB children found that there were all TB contacts which were 9 children (100%).

Fisher’s Exact test showed chest X-ray had a significant difference between active TB children and latent TB children (p = 0.000 <0.05). It was shown that there were 16 children (100%) in X-foto showing TB / infiltrates in the group of active TB children and there were 9 children (100%) in Chest X-ray showing normal in the group of latent TB children. (Table 3)

However, in smear or fast molecular examination there were 10 children (62.5%) negative in the active TB children group and 9 children (100%) in the latent TB children group. This shows that there was no significant difference in microbiology or fast molecular examination of the two groups (p = 0.057> 0.05).

Note: If the p-value < 0.05 means it is significant and if the p-value > 0.05 means no significant difference.

Seen in the free sample t test results in Table 4 shows there is no difference in the age of the child (p = 0.175 > 0.05) between children in the active TB group with the mean ± standard deviation of 62.4 ± 36.4 months with the average latent TB group of children ± standard deviation ie 85.6 ± 45.1 months.

Likewise, maternal age showed no significant difference (p = 0.262 > 0.05) between mothers in the active TB children group (30.56 ± 4.29 years) and mothers in the latent TB children group (33.44 ± 8.38 years). The two mean ages of the two groups were almost the same. This means that at the age of the mother has also shown homogeneous.

</tr>
</tbody>
</table>

Legend: If the p-value < 0.05 means there is a significant difference and if the p-value > 0.05 means there is no significant difference.

* T sample test results are free

** Mann-Whitney test results

Using the Mann-Whitney test showed no significant difference (p = 0.391 > 0.05) of the father’s age between the fathers of the active TB children group (33.81 ± 6.84 years) and the fathers of the latent TB children group (37.11 ± 8.11 years). The two mean ages of the two groups did not differ greatly. This means that at the age of the father also showed homogeneity.

**Discussion**

A factor that significantly indicates the occurrence of TB in both children with active TB and latent TB is chest x-ray images showing infiltrate. Significant differences were shown in chest X-ray images in the two groups, where the active TB group showed the presence of inflammation and the latent TB did not look normal. In another study it was stated that primary tuberculosis demonstrates radiologic findings that include lymphadenopathy, consolidation, pleural effusion, and miliary nodules. Radiology reports should describe whether the radiograph shows entirely normal findings, shows infiltrate, calcified granulomas, shows fibronodular scarring (noting the duration of stability), or shows findings that raise concern for active tuberculosis(11).

In both TB groups it was noted that microbiology examination testing showed the highest number was a negative result. Other studies say that children exposed to smear (+) 60% -80% are infected with TB(12). The age distribution of children who have TB in both groups shows that in the distribution of data about the age of the child has shown a homogeneous age. As said in previous studies that children aged <5 years have a higher percentage than age > 5 years(12). Children aged <5 years have a greater risk of progressing infection into TB disease due to imperfect cellular immunity(13). While, another research said that the majority of the cases of definite TB in this study were amongst the 10–15 year olds (58.3%)(14).

For the age of parents in both groups also showed homogeneity. This shows that there is no difference between the two TB groups related to the age of the parents. External factors related to the age of the parents become a factor that does not generally affect the incidence of TB in both groups.
**Conclusion**

The most significant determinant factor in active TB and latent TB in children is the appearance of chest X-ray, whereas active TB shows filtration and normal appearance in latent TB.

Musculoskeletal Disorders Complaints by Part Body
Fishermen Village Labuang Namrole South Buru District

Masudin Sangaji1, Kuswandi Saalu2, Sahrir Sillehu2, M. Taufan Umasugi2, Johanis Hursepuny2, Tri Niswati Utami3, Suparji4

Abstract

Indonesian people living in coastal areas work as fishermen. Musculoskeletal disorders are felt by fishermen in the muscles and bones resulting in the decreased system of movement. The purpose of the study was to identify differences in musculoskeletal complaints based on body parts. The study design uses observational analytic, using a cross-sectional design. Fishermen’s research samples amounted to 35 people. The results of the majority of respondents aged 51-55 years and 61-65 years, tenure of > 10 years and unnatural work postures. Nordic Body Map (NBM) measurement, musculoskeletal complaints due to unnatural/forced work postures experienced by respondents. Low extremity musculoskeletal complaints with a mean value of 18.8 and the lowest score of 12 while the highest is a score of 20. Conclusions based on the Nordic Body Map (NBM) musculoskeletal complaints occur because of unnatural/forced work postures. The majority of complaints experienced are found in the lower extremities. It is recommended that fishermen dynamically adjust their work positions.

Keywords: musculoskeletal complaints, nordic body map, muscles, work posture

Introduction

Indonesia is an archipelago consisting of 17,504 islands and 2/3 of them are sea areas, where most of the coastal population has livelihoods as fishermen. Fishermen are people whose whole or part of their livelihood depends on fishing. The sea is a natural resource that is used for the benefit of people’s welfare.

By implementing occupational safety and health control technology, it is expected that workers will achieve physical endurance, workforce, and a high level of health. Besides that, occupational safety and health can be expected to create work comfort and high work safety. So, the elements in occupational health and safety are not focused on physical factors, but also mental, emotional and psychological factors.

The world food organization (Food and Agriculture Organization) entitled “The State of World Fisheries and Aquaculture 2014” released on March 2, 2016, reported that as many as 24,000 fishermen died at sea. The report mentioned that there were 4 factors that caused the high mortality rate of traditional fishermen and sea transportation users. The main cause of marine accidents that lead to loss of human life is purely human error (human error). Other causes are neglect by sea transportation providers and related agencies, as well as sea transportation safety equipment that is far from adequate and lack of standard work procedures. Specifically, in fishery activities, as much as 80 percent of marine accident factors are caused by human negligence.(1)

Fishermen in carrying out their activities face risks, among others in the form of safety risks at sea and the risk of uncertainty of catches that can be obtained. In carrying out their activities, sea cucumber fishermen need fishing facilities such as boats, engines, compressors, masks and frog legs. These facilities cannot be bought by mustard fishermen. Efforts to overcome this are
pursued by establishing a working relationship with the civil servants. This condition then becomes the starting point for the establishment of a working relationship between Ponggawa and mustard in the sea cucumber fishery business, where they agree to establish a working relationship because each has a goal to be achieved through the relationship.

Fishermen are those who have a livelihood by utilizing marine resources such as fish and other marine biotics (except seaweed) that contain the economic value (can be consumed and marketed) both continuously and seasonally, using facilities such as boats and equipment. Fishing gear (Lampe 1989: 1). Meanwhile, according to the Director-General of Fisheries, fishermen are a group of people whose lives depend directly on sea products, either by catching or cultivating. They generally live on the beach, a residential neighborhood close to the location of their activities. The development of science and technology has made the industrial world compete for efficiency and increase productivity by using increasingly complex means of production. The more complex work equipment used will increase the potential for workplace accidents if not handled as well as possible. Potential or risk of danger is a condition that there is a possibility that a work accident will arise due to a hazard. Therefore handling and controlling work accidents can be done through risk management. Risk management is a management process with a view to minimizing risk or even avoiding work accidents altogether.(2)

Capture fisheries activities are full of challenges and are faced with risks and uncertainties. One form of risk and uncertainty is accidents at sea. The International Maritime Organization (IMO) in 2007 explained that an accident was an undesirable event involving death, injury, loss or damage to ships, property loss or environmental damage. FAO (2009) says that the main cause of marine accidents that result in the loss of human life is purely human error (human error). FAO (2010) estimates that around 30 million fishermen work on 4 million fishing vessels operating in the world, around 98% of these fishermen work on vessels less than 24 meters long, which for this measure is not written in international regulations.(1)

The number of global deaths is estimated by the International Labor Organization (ILO, 2007) in 1999 to be 24,000 deaths worldwide each year.(3) FAO (2010) adds an explanation of this, namely the global death rate will be higher because there are some countries that do not have statistical data or information on global death rates. Previous studies published in the journal work intensity of fishing activities on the operation of Soma Pajeko (Mini Purse Seine) in Bitung according to Handayani et al. (2015) a fishing fisherman is required to have a strong physique so that he can work productively and his catch is satisfying.(4)

Method

This type of research is analytic observational research using cross-sectional. Data collection is done once for a particular object at a certain time period (point time approach). The population is fishermen in Labuang Village, Namrole District, Buru Regency. Samples were taken by accidental sampling technique, which was found at the time of research and was willing to be a research respondent. Univariate data analysis uses the frequency distribution to describe the characteristics of respondents. The bivariate analysis uses the Kruskal Wallis test to determine differences in musculoskeletal complaints based on the part of the body being analyzed.

Findings

The following are presented characteristics of research respondents such as age, education, occupation, marital status, length of work and length of service in the following table:
Table 1. Distribution of Respondent Characteristics

Based on the Nordic Body Map (NBM) musculoskeletal complaints due to unnatural/forced work postures that were experienced by many respondents occurred at lower extremities with a mean value of 18.8 and the lowest score of 12 while the highest was 20. The least complaints were experienced namely Complaints of the neck and head with a mean value of 3.6 and the lowest score of 2 while the highest score of 4.

Discussion

1. Respondent characteristics

Complaints of muscles and bones due to a permanent
posture at work, repetitive and for a long time can be fatal if this condition is left. Complaints of perceived pain can be temporary if the burden that causes pain is stopped. But if musculoskeletal complaints are felt at work and loading is not stopped it can cause persistent pain. In general, cases of musculoskeletal disorders are often found in workers in the industry, loading, and unloading of goods and workers who exert 90% of their work activities.

According to Tawaka\(^5\), increasing age will be followed by a decrease in maximal oxygen volume, sharpness of hearing and vision, speed of discerning things, making decisions and ability to remember long-term. So that the older the age of the worker, then he will tend to behave unsafely. One form of unsafe behavior or substandard practice is in the form of violations of SOPs. The first complaint of musculoskeletal pain is felt at the age of 35 years, the age of complaints increases.\(^5\) According to Pratiwi that age is in line with unsafe behavior, the older a person is, the higher the category of unsafe behavior is carried out, and conversely, the younger the person’s age, the category of unsafe behavior carried out is lower or even included in the safe category.\(^6\)

The education level of the majority of respondents had an elementary school education. One’s education influences one’s mindset in facing the work entrusted to him. In addition, education will also affect the level of absorption of training provided in the context of carrying out work and work safety\(^7\).

Length of work all respondents work> 3 hours. The length of work is the length of time a person has gone through since pursuing work. The length of work is a period of time or the length of time the workforce works in a place\(^8\). The length of work can describe a person’s experience in mastering the area of their duties. The longer a person works in an organization, the more experienced the person will be so that his work skills are better\(^9\).

Respondents based on tenure as fishermen> 10 years. According to Setyawati\(^10\), the longer a person’s working period, the more emotional their stability tends to be so that they can work safely and avoid unsafe actions when working. This is because adjustments to the environment have been going on for a long time along with the experience gained. Experience is someone who has worked for 15 to 30 years, can be considered an experienced fisherman and can be used as a handler\(^11\). The fishermen’s fishing experience also has an impact on the fishermen’s catch. Experience factor, according to Foster\(^12\), what determines whether a person is experienced or not can be seen from the length of time or work period taken by a person so that he can understand the tasks of a job and have done the job properly.

The respondent’s work position is to work with unnatural/forced work postures. Work posture is defined as the posture or position of body parts such as arms, body, head and other body parts during work, such as sitting, standing, squatting or posture of the arms and hands when using work tools. The results of Manoppo’s research obtained a relationship between physical activity with musculoskeletal complaints with the Spearman correlation test.\(^13\)

2. Musculoskeletal complaints

Musculoskeletal disorders based on the Nordic Body Map (NBM), unnatural / forced labor postures that are mostly experienced by most respondents with complaints on Lower Extremities with a score of 20, this occurs in tonda fishermen who carry out daily activities at sea with an unusual position natural or forced to cause musculoskeletal disorders, especially the lower extremities with a static sitting position, this is experienced by fishermen when getting fish with a certain weight requires power to attract fish by using a footstool in pulling a load of fish to be lifted into the boat lounges.

The research on Tonda fishermen in the Namrole Subdistrict of South Buru Regency was supported by Budiman\(^14\) suggesting that this unnatural position occurred because of interactions between workers and work tools that were not balanced or work tools used were not in line with worker anthropometry. An unnatural work position is a work attitude that causes parts of the body to move away from their natural position. The farther the position of the body from the center of gravity, the higher the skeletal muscle complaints. Job attitudes are not natural in general because of the incompatibility of work with the ability of workers. The position of kneeling, bending or squatting usually causes pain in the lower back or in the knee if done for a long time and continuously results in serious problems in muscles and joints.\(^7\)
One of the factors that influence the occurrence of skeletal muscle disorders. The recommended weight is 23-25 kg, while according to MoH-RI the burden should not exceed the rule, namely adult men at 15-20 kg and women (16-18) at 12-15 kg. In this case, the capture fishermen make repetitive movements and lift the fish with a load of 10 tons every day within 30 days at sea so the weight of the load exceeds the threshold value. Previous studies have found physical activities such as lifting, holding loads that are classified as heavy workloads on fishermen associated with musculoskeletal complaints.\(^{(13)}\)

**Conclusion**

Most of the Tonda fishermen in conducting activities at sea have unnatural work positions. There are differences in complaints of musculoskeletal disorders based on body parts in tonda fishermen in Labuang Village, Namrole District, South Buru Regency. It is recommended to fishermen to change positions at work, to reduce musculoskeletal complaints. Workers can do physical fitness to relax muscles and body tissues.

Factors Related to Hearing Disorder on Traditional Fishermen in Namrole Sub-District South Buru Regency

Masudin Sangaji1, Sahrir Sillehu2, M.Taufan Umasugi2, Ira Sandi Tuny3, Rapiah Sarfa Marasabessy3, Wa Rina4, Irhamdi Achmad4

1Researcher, Faculty of Fisheries and Marine Sciences Pattimura University, 2Researcher, Institute of Health Science Maluku Husada, 3Researcher, Universitas Darussalam Ambon, 4Researcher, Poltekkes Kemenkes Maluku

Abstract

Namrole sub-district, South Buru regency, is one of the sub-districts in Maluku province where the majority of the people have a livelihood as fishermen. The process of fishing is done by diving using a compressor at depths exceeding 10 meters. This causes various complaints such as headaches, spasms and hearing disorder. The purpose of this study was to determine the factors associated with a hearing disorder in traditional fishermen. The research method used is quantitative descriptive. Statistical test results using the chi-square test showed that the depth of diving has a significant correlation with a hearing disorder with a value of $\alpha = 0.01$, while the period of work, duration of work, and frequency of diving do not correlate with the hearing disorder in traditional fishermen in Namrole district, South Buru Regency.

Keywords: Fishermen, Divers, Period of Work, Depth, Hearing Disorder

Introduction

Maluku Province is an archipelago that is included in 7 island provinces out of 34 provinces in Indonesia. Maluku Province has 11 city districts that are surrounded by oceans and have very promising water resources, including South Buru Regency. South Buru Regency is a district with an administrative area of 6723 Km2 with a water area of 1,603 Km2. South Buru Regency has the potential of marine natural resources which has a large contribution to regional development, especially in the fisheries and marine sector.

This is what causes many people in the South Buru district, especially Namrole district, to have a livelihood as fishermen. These fishermen are generally more focused on catching tuna because besides its sale value is higher than other types of fish, this fish can also be exported to other countries. The fishing process carried out by the fishermen is still traditional by using simple fishing gear and carried out by diving using a compressor.

Diving is done in calm weather or during extreme weather. This results in the emergence of disease and cause accidents. The average dive process is more than 2 hours with the frequency of diving above 3 times. The duration of dive frequency causes the fishermen often experience complaints in the form of headaches, spasms, ear pain, and hearing disorder. Diseases that can be caused by diving are decompression, poisoning, vertigo, hypotemia and barotrauma. (1) The factors that cause frequent accidents are the process of diving by using a compressor for a long time. Previous studies have shown that the number of accidents of fishermen using compressors is higher than not using compressors. (2) Other factors that influence the occurrence of accidents in traditional divers are the depth of diving and the duration of diving. Both of these factors can cause decompression. (3) Another disease caused by traditional diving is ear barotrauma. According to research (4), there is a significant correlation between the use of the compressor as a diver and the occurrence of ear barotrauma. Another factor that can cause barotrauma is the depth and duration of diving. (5) For this reason, research is needed to determine the correlation between the period of work, duration of work, frequency of diving and depth of diving with the hearing disorder on traditional fishermen in Namrole Sub-district, South Buru Regency.

DOI Number: 10.37506/ijfmt.v14i2.3511
Methods

This research was a quantitative descriptive study that aimed to determine the factors associated with hearing disorders in traditional divers in Namrole Sub-district, South Buru Regency. This research was conducted in Namrole Sub-district, South Buru Regency for one month.

The population in this study were 50 fishermen with active diving activities in archery fish in Namrole Sub-district, South Buru Regency. The sample in this study were divers who have the qualifications and meet the inclusion criteria. The samples size studied was 35 fishermen who actively dive.

This research was carried out through several stages as follows:

1. Initial Survey

This stage aimed to find out the problems in the field.

2. Problem Statement

In this stage, the discussion was formulated based on the field and literature review conducted.

3. Distribution of Questionnaires

Questionnaires were distributed to capture information about the characteristics of respondents, duration of diving, frequency of diving and other information related to research.

4. Data Processing

In this stage, the questionnaire data processing was done.

5. Analysis

In this stage, an analysis was carried out with considering the results of research and supporting theories and also prior research which is related to this research. The analysis was performed using chi-square statistical analysis to see the correlation between the period of work, duration of work, frequency of diving and depth of diving with a hearing disorder.

Findings

Characteristics of Respondents

After calculating, a frequency distribution was obtained based on the characteristics of the respondents as shown in table 1.

<table>

</table>

From table 1 it can be seen that based on the age characteristics, the most respondents are respondents with an age interval of 26-30 years totaling 14 people (40%) and the least are respondents with an age interval of 46-50 years which amounted to 3 people (8.6%). Based on the level of education, the majority of respondents in this study had an elementary school level (SD) with a total of 17 people (48.6%) and the least were respondents with an education level of high school (SMA) with a total of 4 people (11.4%). Based on work, all respondents are 35 traditional divers (100%). Based on marital status, respondents who were married were 32 people (91.4%) and not yet married were 3 people (8.6%).

Correlation Between Period of Work, Duration of Work, Depth of Diving, and Frequency of Diving with Hearing Disorders
The correlation between the period of work, duration of work, depth of diving and frequency of diving with the hearing disorder are described in the following tables 2, 3, 4, and 5.

**Table 2. Correlation Between Period of Work with Hearing Disorders**

<table>
<thead>
<tr>
<th>Period of Work (year)</th>
<th>Hearing Disorder Complaint</th>
<th>Total</th>
<th>p-value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Yes</td>
<td>No</td>

<td>9</td>
<td>26</td>
<td>35</td>
</tr>
</tbody>
</table>
Table 5 shows that there was no correlation between the frequency of diving with complaints of hearing disorder (p > 0.05).

**Discussion**

**Characteristics of Respondents**

Based on the results of the study in table 1, most divers are 26-30 years old. According to (6), increasing age will be followed by a decrease in maximal oxygen volume, sharpness of hearing and vision, speed of distinguishing things, making decisions and the ability to remember long-term.

The education of respondents in this study was dominated by workers with primary school education. Worker education influences the knowledge or willingness of workers to carry out their work following occupational safety and health rules.

**Correlation between the period of diving with the hearing disorder**

In the research that has been done, the results show that from 35 respondents, 2 respondents are included in the category of long-time workers (have worked ≥ 6 years). Of all respondents who were old workers, none had complaints of hearing disorder. Whereas for the category of respondents as new workers there were 33 people, 9 of them had complaints of hearing disorder and 24 others did not experience the hearing disorder. The results showed a value of α = 0.39 or the absence of a significant correlation between the period of work and hearing disorder. This study is in line with research (7) and research (8) that there is no correlation between the period of work and hearing disorder.

**Correlation between duration of diving with a hearing disorder**

The duration of the dive is the length of the diver under the sea from the first down to the surface before making the next dive. Based on the results of research that has been done, it is obtained that from 35 divers who became respondents in this study, as many as 2 people included in the category of long-time workers (have worked ≥ 6 hours). Of all respondents who were old workers, none had complaints of hearing disorder. Whereas for the category of respondents as new workers there were 33 people, 9 of them had complaints of hearing disorder and 24 others did not experience the hearing disorder. The results showed a value of α = 0.39 or the absence of a significant correlation between the period of work and hearing disorder. This study is in line with research (7) and research (8) that there is no correlation between the period of work and hearing disorder.

**Correlation between the frequency of diving with a hearing disorder**

The frequency of diving is the number of times the respondent dives in a day. According to Edmonds et. al (in Ekawati, 2005), a diver who frequently dives will more often experience trauma to the repetitive pressure on the eardrum. This will cause the balance organ in the inner ear to experience tissue swelling and blockage of the Eustachian Tubes until the perforation of the tympanic can even cause the eardrum to bleed and tear. Therefore, the more often the frequency of diving is done, the more dangerous it is to the health of the divers because they will increasingly receive pressure and they must try to equate the pressure in the ear cavity with the pressure of the surrounding water. In the research that has been done, the results show that out of 35 respondents, 2 people who have a diving frequency > 3x a day, do not experience complaints of hearing disorder, while 9 people who have a diving frequency < 3x a day, experience complaints of hearing disorder. Meanwhile, 24 other people did not experience complaints of
hearing disorder. Another thing that can affect hearing is the physical condition at the time of diving. From interviews at the time of the study, information was obtained that sometimes divers forced to dive even though they felt unwell. After an analytical test using the Chi-Square statistical test, a value of $0.392 > \alpha (0.05)$ was obtained. This shows that there is no significant correlation between the frequencies of diving with the hearing disorder in traditional divers in the Namrole Sub-district, South Buru Regency. The results of this study contradict the research conducted by Fatmawati. (10) This is caused by the lack of open character of the respondents and motivation factors in carrying out the work of fishermen as a source of livelihood so that sometimes traditional fishing communities override perceived complaints. Traditional fishermen who do not use personal protective equipment such as earplugs are not good for hearing. Ear protection devices are proven effective in protecting against hearing loss. Research by Utami (2019) through his research on the use of earplugs as protectors against noise exposure, the results of research shows that workers who use ear protection equipment, due to noise exposure in the industry, do not experience hearing loss. Earplugs are useful as a barrier to entry of noise intensity. Audiometry results have a relationship between hearing loss in the right and left ear. (11)

Conclusion

Based on the results of the study it can be concluded that the variable that has a significant correlation with the hearing disorder is the diving depth variable while the period of work, duration of work, and frequency of diving do not correlate with the hearing disorder in traditional fishermen in Namrole Sub-district, South Buru Regency.

Abstract
This research aims to analyze and carry out theoretical criticism related to the open court principle, in the implementation of courtroom television in Indonesia. There are differences in the implementation of courtroom television in several cases in Indonesia. As in the case of Jessica Kumalawongso, the entire trial process, including the verification process, was broadcasted live. The research method is the social-juridical method. In such events, the presumption of innocence principle and the principle of witnesses being prohibited from communicating with each other were also damaged. The implementation of courtroom television affected the defendant’s psychological condition. Thus, this research will conduct a theoretical study related to the open court principle in the implementation of courtroom television in Indonesia and its consequences.

Keywords: Open Court, Courtroom Television, Psychological, Defendant, Principle

Introduction
Screening of court proceedings via television or what is known as courtroom television shows the influence of information technology advantages in the legal world.¹ Until now, there is no definite definition of the term courtroom television, but in his book, Paul Lambert states that courtroom television is “...one of central concerns in relation to television courtroom broadcasting is that television cameras or television operators will distract the various people who are required as part of the courtroom process. This includes witnesses, the jury, judges, lawyers, and court staff.”²

Screening of criminal case trial proceedings has also taken place in America, namely courtroom television of the O.J Simpson case in 1994.³ Courtroom television is also carried out in Indonesia, in the case of a planned murder trial with cyanide coffee. The defendant was Jesica Kumala Wongso and this event reaped a lot of pros and cons. Also, a courtroom television was held for the blasphemy case against the accused Basuki Tjahaja Purnama or Ahok (ex governor of Jakarta Special Territory).

The implementation of courtroom television is inseparable from the discussion regarding the open court principle. Also, the application of courtroom television certainly has various consequences. Another interesting thing about it is the independence of judicial power in deciding a case amid the multiple public perceptions of the trial process, which is broadcasted live on television.⁴ As is known, the truth should not influence a judge to shift their views according to the public or social trust. “Judges are accountable to God, not to social trust.” The magnitude of the judges’ responsibility to God and the important role of enforcing justice in the society require the realization of judicial power freedom from various influences, especially public opinion.⁵

That’s why what is more important is how the power of the media should be used to guard the people, and the media is also expected to have a conscience (the conscience of the press).⁶ Courts in the UK also apply the open court principle. English criminal trials are held in public. A fundamental principle of the law of many

DOI Number: 10.37506/ijfmt.v14i2.3512
modern societies is that justice should be done in public before an open court. An open court principle is one way to maintain public confidence. Another purpose of the open court principle is “to protect trial fairness by preventing abuse judicial authority.” This certainly affects the court process and it indirectly impacts the evidence. So, the manifestation of the criminal law procedure’s function to seek and to find material truth or to come close to material truth is null and void.

The trial process, as a process of law enforcement in the context of prosecution must be independent. It is part of the judicial power duty. The independence, after this referred to as the independence of judicial power, is a complex idea, not merely as a value, but also a useful instrument to pursue other higher values, namely the rule of law. Independence implies giving authority to a judiciary that is free from interference from any party and is also free from the influence of other powers.

The application of open court principle in the era of information technology development has shifted and may cause multi-interpretations. As a result, there is the trial by the press, which becomes a consequence of this open court principle. It has the potential to violate other principles, such as the principles of legality, the defendant’s presumption of innocence of, and the principle of where witnesses may not communicate with each other. Also, the implementation of the courtroom television is still different in each court in Indonesia. This is because the trial broadcasting permit policy is returned to each related court.

It is undeniable that openness by conducting broadcast in court is a demanded for transparency. It is an effort to maintain the integrity of judges as law enforcers, and also to control the proceedings of the judicial process. However, if this openness turns out to have consequences that damage other principles and other rights in a fair trial, including the condition where the defendants are disturbed as they receive the public’s judgement before receiving verdict, there needs to be an idea to regulate the implementation of the broadcasting process by the mass media in the judicial process.

Based on the explanation above, it becomes a crucial question for sure, how the meaning of the open court principle shifted in the era of information technology development and the consequences of applying courtroom television in Indonesia. This is the urgency of the research.

**Research Method**

The method used in this paper is a legal research method. This research will explain the shift in the meaning of the open court principle in the era of information technology development and the consequences of the implementation of courtroom television in Indonesia, so that it can find a solutive regulatory model related to courtroom television. This study uses a statutory approach, a conceptual approach, a comparative approach, and a case approach.

**Results and Discussion**

1. **Conceptual Meaning of the Open Court Principle**

The principles of law are the basics or directions (richtlijn) in the formation of positive law. Regarding that, Meuwissen explained, “From that principle, positive law obtains its legal meaning. It also contains criteria by which the quality of the law can be assessed ... the code can be understood against the background of a principle ... a principle that underlies”.

When we come to the discussion of the law principles, we also discuss the most important and the most essential elements of the rule of law. It is reasonable that the principle is interpreted as the heart of the legal regulations. Because the legal principle holds ethical requirements, the legal principle is a bridge between the legal regulations and social ideals and the ethical views of the people. So, it can be said that through this legal principle, the rule of law changes its nature and becomes part of the ethical level.

Fuller put forward an opinion to fathom whether we can talk about the existence of a legal system. The measure is mentioned in eight principles which he called the principles of legality. Fuller himself said that the eight principles he proposed were actually more than just requirements for the existence of a legal system, but instead, he gave qualifications to the legal system, as a legal system that contained an absolute morality.

If we examine, there is a contradiction between the application of the open court principle which is achieved through courtroom television, with the presumption of innocence and also how the defendant’s psychological condition is affected by the public’s judgement. The
absence of laws related to the courtroom television implementation subsequently violates the values of the other. The presence of courtroom television’s excessive reports on judicial cases in the process of the trial also has an indirect impact on judges, witnesses, and defendants. It is what puts pressure on the psychological burden on the defendant regarding the judge’s decision.

Besides contradicting the principle of the presumption of innocence, the implementation of courtroom television that has no clear boundaries will also conflict with other provisions. It is contrary to the regulations governing the protection of witnesses and victims to maintain their security, safety, and comfort in providing their statements in the court. The domino effect of courtroom television can cause law enforcement to be hampered. It may even be dangerous for the defendant and their psychological mind.

2. The Shift in the Open Court Principle Meaning in Criminal Law Procedures

Criminal law procedure has principles which accompany the act. One of them is the open court principle. Basically, in a criminal case, an open trial is the right of the defendant, namely the right to be tried in a trial that is open to the public. Everyone can see and monitor the proceedings of the trial. The law requires the trial to be conducted not only by the parties concerned but also by the public. The purpose is to create a fair trial, to avoid arbitrary or deviant hearings so that the trial process becomes a media of educational prevention. It may also give information to the general public.

The practice of courtroom television in the narrow sense is by broadcasting the proceedings of the trial directly, whether it is a translation by the press in interpreting the open court principle or not. As a principle, of course, the sentence has an intense philosophical foundation. The nature of technology in a mediating position changes from the quality of transparency in the relationship to the quality of opacity in the hermeneutical relationship.

The development of courtroom television in response to the demands for openness in the era of information technology development turned out to be a boomerang for the parties in the trial. Judges, defendants, witnesses, and victims were targeted by the community’s opinion and the media to be discussed during the trial process. Public enthusiasm about the trial’s direct broadcast became very high. These methods of press reporting can lead to “trial by press or trial by masses opinion” and because this contradicts the principle of presumption of the defendant’s innocence, where a person must be deemed as not guilty before a definitive ruling from an unauthorized public judge.

Although sometimes the coverage made by the mass media related to a case is not entirely true, with the continuous reporting through various media, it can ultimately lead to public opinion and make people believe that the defendant must be guilty. This phenomenon is also influenced by what is called the post-truth, which can turn a thousand lies into a truth. At this stage, justice begins to experience siltation. Justice only becomes a textual narrative and is separated from the context. Justice brings about simplification, which reduces various details of the value it contains, because it is covered by the post-truth reality. As an illustration, there is an artificial reality in the tangible court, in the emergence of various kinds of public opinion regarding negative opinions created by the mass media related to the defendant which affects the truth value of the community, that the defendant must be convicted.

3. Ideal Concept of the Courtroom Television Implementation in Indonesia

Openness is a human right and is a means to maintain the spirit and integrity of the judiciary. The government and all law enforcement devices have committed to carrying out justice based on the open court principle. With regard to the process of applying the open court principle in America, the United States also did not allow coverage in any form in the courtroom, but in 1994 in the O.J. Simpson case was broadcasted due to the demands from public to access the progress of the case. Finally, the court conducted courtroom television for the O.J. Simpson’s case. But, the trial process which was broadcasted live by the mass media was apparently able to lead the opinion of the public that O.J. Simpson was innocent. The public opinion was able to influence the decision of the jury who has the authority to determine someone guilty or innocent. On October 3, 1995, O.J Simpson was found not guilty.

Therefore, in the implementation of the principle to open to the public in Poland, the practice of courtroom television is common. The courtroom television project is referred to as the Re Court Project. The difference between the implementation of courtroom television in
Poland and other countries is that the witnesses who are asked for witness evidence by judges can directly see the recording of themselves live on the live broadcast appearance screen.[29] Based on the implementation of courtroom television in the United Kingdom, America, and Poland, it can be concluded that they apply strict rules and restrictions for the application of courtroom television for trial processes. These strict limits are aimed to maintain a noble court spirit, to minimize the misuse of recording results, and to protect the identity and security of all parties in the court.

Based on comparison with several countries, Indonesia must also make strict rules and limits related to the reporting and broadcasting mechanism of the trial process that is open to the public. So, the authors provide recommendations for setting courtroom television in Indonesia as follows: The strict regulation on the mechanism of courtroom television in Indonesia is expected to be able to prevent and minimize various interventions in the trial process. It is hoped to guarantee the fulfillment of the presumption of innocence principle, to protect the psychological mind of defendant from public judgement, and to protect the safety of the parties in the trial. These regulations are also aimed to create a fair trial.

Closing

Conclusions

The meaning of the open to the public trial principle underwent a change along with the development of the information technology era. At first, the meaning of ‘open to the public’ meant that the general public could attend and witness the proceedings in the courtroom. In its development, the public wishes to be able to witness the trial process anywhere, both inside and outside the courtroom, and also anytime. Then courtroom television came as an answer to the demands of openness in the trial process in the era of information technology development.

However, in its practice, the implementation of courtroom television in Indonesia, has various consequences. These consequences include broadcasting the trial process directly by the media and that the press can continuously create public opinion, which can then lead to trial by the press. It may also disturb the psychological condition of the defendant. In addition, the limitless courtroom television violates the defendant’s rights and may disturb the principle of presumption of innocence. In fact, broadcasting the trial directly which highlights the parties in the trial also endangers the security of these parties, both directly and indirectly.

The Criminal Liability of Doctors in the Case of Malpractice in Indonesia

Tongat
Associate Professor, Universitas Muhammadiyah Malang, Indonesia

Abstract

One of the Human Rights elements that must be achieved in accordance with the ideals of the Indonesian people is the Health aspect, the profession as a doctor devotes his/her knowledge to the public interests, has freedom and independence which is oriented to human values in accordance with the code of ethics. In implementing the code of medical ethics, it as much as possible avoids the occurrence of medical error. The error can occur in the diagnostic stage such as error or delay in diagnosis, not implementing the appropriate examination, using an examination method that is no longer used or does not act on the examination or observation result, etc. The risk that occur if it is not carried out thoroughly and carefully, is that it will result in a fatal error. The method used in this research is the normative juridism method, namely the addition method by holding on to the applied norms or legal rules. The result in this research is the liability’s manifestation of the doctor who performs medical malpractice as a form of criminal legal protection in Indonesia, it is basically based on intentional or unintentional mistakes or negligence. If it results in the victim’s death, it is equal to murder, and if the victim does not die it is called an act of persecution with the sanction of persecution.

Keywords: Criminal, Legal Protection, Malpractice, Doctor

Introduction

Health is element of Human Rights which must be realized in accordance with the ideals of the Indonesian people, the general welfare of national goals. To achieve the ability to live healthy for each people in order to realize an optimal degree of public health. The profession as a doctor devotes his/her knowledge to the public interests, it has freedom and independence which is oriented to human values in accordance with the code of ethics. This code of medical ethics aims to prioritize the interests and the safety of patient, to ensure that the medical profession must always be carried out with noble intention and use the right way.

In implementing the code of medical ethics, it avoids the occurrence of medical error as much as possible, namely a failure of a medical action that has been planned to be completed resulting in not as expected, an error of action or wrong planning to achieve a goal. The error that occurred will result in or potentially injure to patient, it can be in the form Adverse Event (KTD). This is very detrimental and dangerous; the patient can experience bad things and the action giver can also be exposed to Article of law violation.

Near Miss (NC) is an event resulting from carrying out an action or not taking the action that should be taken, which can injure the patient, but serious injury does not occur because of luck. This can be seen from the number of actions taken that are dangerous but can be prevented before they occur or are handled before they cause effects, for example, the patient receives a contra indication medicine but there is no drug reaction occurred, prevention of a medicine with an overdose will be given, but other staff know and cancel it before the medicine is given, and relief of a medicine with an overdose is given, it is known early and then given the antidote. Adverse Event (KTD) is an event resulting in an unexpected injury to the patient due to an action or not taking the action that should be taken, and not because of the patient’s condition.
The error can occur in the diagnostic stage,(6) such as error or delay in diagnosis, not implementing the appropriate examination, using an examination method that is no longer used or does not act on the examination or observation result;(7) In the treatment stage, such as error in treatment procedures, therapy treatment, drug use method, and delay in responding to the result of improper care checks; in the preventive stage, such as not providing prophylactic therapy as well as inadequate monitor and follow-up; or in other technical matter such as communication failure, device or other systems failure.(8)

The risk occurred in human is so vulnerable to an action. If it is not carried out carefully and thoroughly, it will result in a fatal error. The existence of medical risks, both those that have been detected previously and those that were not detected before or unexpected at all before, in the implementation of health services is only an adequate information.

Even so, in carrying out their professional duties, health workers are normatively obliged to remain cautious, to comply with the medical standard, to carry out the professional standard of expertise, and to respect the patient rights. This is done in order to obtain legal protection for them.

In this normative definition of a worker, it raises the definition that health worker who carries out the professional duties has a special legal position, it means that in carrying out their professional duties, they are exposed to high medical risk. Based on these explanations, it needs a criminal legal protection against doctor malpractice in Indonesia.

**Research Method**

This research used library research which is a research method that is carried out by reading and studying theories relevant to the subject matter. The data collected was then processed using data processing method which consists of: Normative juridism method, namely the addition method by holding on to the applied norms or legal rules. This discussion method is used in accordance with its need to produce an acceptable discussion both in juridical and scientific terms.

**Discussion**

A jargon that reads *errare humanum est* (error is humane), seems need to be contemplated. A theory of respectable minority rule which states that a doctor is not considered negligent if he/she chooses one of the many ways of treatment that is recognized by the medical world. Basically, a doctor will be brought before a court if there has been a loss to the patient. The loss arises as a result of a breach of obligation in which an agreement had been previously made. Even though the doctor’s obligations are not detailed in the therapeutic contract, but the doctor’s obligations are not covered by the medical services standard. While the medical services standard is made based on the rights and obligations of the doctor, both those regulated in the Code of ethics and those regulated in statutory regulation.

Legal protection for the implementation of the doctor’s duty and authority who has medical risk in the Criminal Code is formulated in Article 359 and 360, the action that causes others to be seriously injured or die which was done inadvertently. As for the elements of Article 359 and 360, there are the negligence element (culpa), the existence of certain form of action, and there are serious injuries or death of others, and the existence of a causal relation between the form of action with the result of that other person death.

Elements of medical risk and medical malpractice are as follow, in the medical risk is found the negligence element, while in the medical malpractice it is clear that there is a negligence element. In addition, specifically in health services, negligence is also associated with services that do not meet or below the medical services standard which in its practice also needs to be used to distinguish between medical risk and medical malpractice. If upon the patient, it has been performed procedures according to the medical services standard, but the patient ends up seriously injured or dead, this is a medical risk. Whereas for patient who has suffered serious injury or death as a result of doctor performing services below medical standard, this means that there is a medical malpractice.

In order to avoid misunderstanding about the emergence of risks that are detrimental to the patient, it is necessary to have clear and complete information by the doctor in a language that easily understood by the patient and by remembering where the communication is carried out. This is where the importance of a health interview is, so that in the end the patient is willing to give consent for the medical action to be taken by the doctor in the effort to cure his illness in a therapeutic transaction.
It means that the negligence element is very instrumental in determining whether a doctor is convicted or not and negligence in the medical field is very closely related to the implementation of doctor professional standards. Not only the negligence element in medical risk, it also means that both Article 359 and 360 of the Criminal Code cannot be applied to the doctor’s action that has medical risk, because one of the elements of Criminal Code Article 359 or 360 is not fulfilled in medical risk.

In the case of medical accident, there is a judge’s decision to adjudicate a case that in Indonesia it indeed requires that a doctor must act carefully on every action taken. But we cannot just regard it as a negligence act for something that is actually an accident. Regarding the mistake of clinical examination, it is actually also understandable because after all, as a human being a doctor cannot escape from the possibility of making a mistake.

In addition, the doctor’s action toward patient also has justification reason as mentioned in Criminal Code Article 50 and Article 51 paragraph 1. Meanwhile, for the conviction of an error that can be interpreted as liability in criminal law, it must meet 3 elements, namely: the ability to be responsible for the action, the inner connection between the actor and the action that can be intentional (dolus) or negligence (culpa), and there is no forgiving or erasing reason.

Thus, to make sure that a medical action is not against the law, the action must be performed in accordance with the medical profession standard or carried out legeartically, as reflected by: The existence of medical indication in accordance with the concrete treatment goal, performed according to the standardized medical procedures standard, fulfilled the patient’s rights regarding informed consent.

We need to realize that doctor’s medical actions sometimes indeed produce undesirable consequences both by the doctor and the patient, even though doctor has tried their best. Because almost all medical actions are essentially persecution justified by the Constitution, especially those related to acts of anesthesia and surgery. So that the possibility of the risk of injury or even death is very difficult to avoid. Based on the analysis, the criminal law adheres to the principle of “no criminal without error”. Furthermore, in Article 2 of the Criminal Code mentioned, “criminal provisions in Indonesian statutory regulation are applied to everyone who commits an offense in Indonesia”.

The formulation of this article determines that every individual who is in the Indonesian legal territory, can be held liable for criminal liability upon the mistakes he/she made. Based on that provision, the doctor profession is inseparable from the provision of the article. Moreover, a doctor in his daily work is always involved in the acts regulated in the Criminal Code. Even though the criminal law recognizes the abolition of criminal act in the health service, namely justification and forgiving reasons as well as those contained in the jurisprudence, it does not necessarily mean the justification and forgiving reasons abolish a criminal offense for the doctor profession.

One of the jurisprudences that contains justification reason and forgiving reason in health services is the jurisprudence. This jurisprudence contains “informed consent” as a criminal offense omission. However, this does not mean that the doctor profession is freed from all criminal liability, because the justification reason and forgiving reason for the doctor’s action is only in a certain exception.

Legal protection toward doctor’s legal liability can be distinguished between liability that is not related to the implementation of his/her profession and legal liability related to his/her profession. The implementation of the doctor profession in Indonesia can still be distinguished between responsibility for professional provisions, namely the Indonesian Code of Medical Ethics (KODEKI) contained in the Decree of the Minister of Health No. 434/Men.Kes/SK/X/1983 and responsibility for legal provisions covering the administrative law, the criminal law and the civil law. Action or behavior of doctor as legal subject in their performance in society can be distinguished between daily actions that are not related to his/her profession.

There are special factors in Medicine that are not found in general applicable law, for example medical accident or risk of treatment. Some basis for the omission of penalties or special error in medicine, namely: Risk of treatment, Medical accident, Non-negligent error of judgment, Volenti non fit iniura and Contributory negligence.

Criminal law in Indonesia in the implementation of certain medical act, there is always a risk inherent in the medical act (inherent risk of treatment). If the doctor performs the medical treatment carefully, with the
patient’s permission and based on the Medical Service Standard (SPM), but it turns out that the risk persists, for example if there is an unexpected allergic reaction, as well as complications that cannot be predicted beforehand (for example, there occurs amniotic water embolism during labor), then the doctor cannot be blamed.

Article 44 of Constitution on Medical Practice as an official explanation is determined as follows, “service standard” is a guideline that must be followed by doctor or dentist in carrying out medical practice. “Service facility level” is the level of service in which the standard of personnel and equipment are in accordance with the capabilities provided. Attitude and action that must be carried out by doctor are regulated in various standards. The profession has at least 3 kinds of standards, namely: Competency standard, Behavior standard, and Service standard.

Constitution No.36 of 2009 concerning Health has formulated the criminal threat, hence the criminal threat against the error or the negligence committed by doctor resulting in patient suffering from disabilities or injuries, no longer refers solely to the provision of Article 359, 360, and 361 of the Criminal Code. The threat is contained in Article 198 of Constitution No. 36 of 2009 concerning Health. The arrangement of doctor’s legal liability towards patient in the event of malpractice, the Indonesian health law does not officially mention the term Malpractice, but only mention error or negligence in carrying out the profession (listed in Articles 54 and 55).

Thus, the malpractice term is a legal term used in Articles 54 and 55 mentioned above. Error or negligence in carrying out the profession is listed in articles 54 and 55 of Constitution No.36 of 2009 concerning Health. Article 54 and 55 stated that the sanction on medical malpractice is the imposition of disciplinary action determined by the Medical Disciplinary Council to doctor who based on the judgment of the Council have committed negligence. Whereas the compensation that must be fulfilled by the doctor concerned is carried out in accordance with the applicable statutory regulations.

Criminal offenses are listed in Article 80, Article 81 and Article 82, while criminal violation is listed in Article 84. If in the relation between a doctor and a patient in a therapeutic transaction based on the agreement of both parties, there is an inadvertent or uncareful action by the doctor, so as to cause disability or death of the patient, then the consequences are regulated in criminal law.

Indonesian law gives full rights to its people to obtain justice and to obtain it, it is done by submitting application, complaint, and lawsuit. Both in civil, criminal or administrative cases. Therefore, as a legal protection for Indonesian people, they will be tried through a free and impartial judicial process, which referred to legal procedures that guarantee an objective examination by honest and fair judge. The sanction in criminal law is basically sanction in the form of torture or restriction of freedom against the perpetrator of criminal act. With the hope that after undergoing the criminal sanction, it will cause a deterrent effect on the perpetrator or there is a preventive element against others (the society).

Conclusion

Criminal legal protection against doctor malpractice in Indonesia in the Criminal Code can not be applied to the doctor’s action who has medical risk. This is because at the medical risk, there is one element that cannot be fulfilled, namely the negligence element. However, if the negligence element from a doctor’s action can be proven, then according to the Criminal Code, the doctor can be imposed on committing act that cause serious injury or loss of patient’s life. Besides that, based on the basis of doctor’s mistake omission, namely the justification reason (treatment risk) and forgiving reason (accident occurs in difficult operation). The liability’s manifestation of the doctor who performs medical malpractice is basically based on intentional or unintentional mistake or negligence. For intentional mistake, if it results in the victim’s death, it is equal with murder, and if the victim does not die it is called an act of persecution with the sanction of persecution.

Abstract

Background: Child nutritional status needs to be assessed accurately so that early and appropriate management can be carried out. Indonesia has launched child growth standards in 2005, known as Growth Diagrams of Indonesian Children (GDIC), while the WHO 2006 child growth standards (WHO-CGS) is currently use as standards to assess growth of Indonesian children.

Aim: This study aims to analyze differences in the interpretation of nutritional status between 2006 WHO-CGS and 2005 GDIC.

Method: This is a cross sectional study. 1162 children aged 0-60 months in five selected villages in a public health center in East Java, Indonesia were included in this study. Interpretation of growth was categorized into weight-for-age, length/height-for-age, and weight-for-length/height based on two growth assessment standards; 2006 WHO-GCS and 2005 GDIC.

Results: 2005 GDIC detected underweight, stunted, wasted, and obese children fewer than the 2006 WHO-CGS. There are significant differences in the interpretation of weight-for-age in girls aged 0-50 weeks (p<0.001) and length/height-for-age in children aged 0-60 months (p<0.001). While weight-for-length/height showed significant differences in boys aged 0-60 months (p=0.008) and aged 6-36 months (p=0.027).

Conclusion: 2005 GDIC detects fewer children with malnutrition than 2006 WHO-CGS. The significant difference on interpretation between two growth charts was particularly found in height-for-age.

Keywords: 2006 WHO child growth standards, 2005 Growth Diagrams of Indonesian Children, malnutrition, children 0-60 months

Introduction

Malnutrition is one of the important public health problems, affecting more than 900 million people worldwide. It is responsible for the highest death rates in children and has long-term physiological impacts. Malnutrition in children has been linked to poor mental development and school performance as well as behavior disorders. Children’s height for 2 years of age is the best predictor of human capital, therefore malnutrition is associated with lower human capital. Damage suffered early in life leads to permanent decline and may also affect future generations. Malnutrition prevention might bring important health, educational, and economic benefits. Chronic diseases are especially common in malnourished children who gain rapid weight gain in their growth. Cooperation of all stakeholders is needed to act to overcome malnutrition.

The prevalence of underweight children under five years old within the world in 2011 is estimated at 16% (101 million) and has shown a decrease from 1990 with 159 million. The prevalence of stunted and very stunted toddlers in the world in 2016 was 22.9% (155.8
million). But this data has shown a decrease compared to 2011 which was 26%.\(^4\) The 2018 national prevalence of underweight and stunted children is higher than the world prevalence (17.7% and 30.8%, respectively), but it shows lower prevalence than 2013 national data (19.6% and 37.2% respectively).\(^5\) Those prevalence rates were obtained from interpretations of nutritional status using the 2006 WHO child growth standards (2006 WHO-CGS).

Large number of malnutrition prevalence becomes national priority program and concern in daily clinical management. Nonetheless, several studies have concluded that the interpretation of nutritional status using the WHO child growth standards results in overestimation of malnutrition prevalence rate.\(^6\)–\(^10\) Those studies were conducted to compare interpretation between the 2006 WHO-CGS growth chart and the national growth charts of each country. This suggests that specific factors play a role to affect child growth in each country.

Indonesia has developed 2005 growth diagrams of Indonesian children (2005 GDIC), even though it has not been widely used.\(^11\) This research will analyze the different interpretations between 2006 WHO-CGS and 2005 GDIC, and also underline the importance of using national growth charts to measure nutritional status more accurately.

**Method**

This study was cross sectional study conducted on October-November 2017. Secondary data were obtained from medical record of five selected villages in the working area of Berbek community health center in East Java, Indonesia. A total of 1162 boys and girls aged 0-60 months who took part in the routine Pos Pelayanan Terpadu (posyandu)/integrated healthcare center in their respective villages on August 2017 were included in this study. Patients with congenital anomalies, chronic diseases, or patients taking long-term corticosteroids were not included in the study.

The selection of five villages from nineteen villages was chosen used simple random sampling. Children were divided into boys and girls, and each sex group were divided into three age groups; 0-5 months, 6-36 months, and 37-60 months. Anthropometric data was collected, both weight (kg) and length/height (cm). The data were plotted based on its nutritional status using two growth charts, the 2006 WHO-CGS and 2005 GDIC. The nutritional status is categorized into weight-for-age, length/height-for-age, and weight-for-length/height. The data were statistically analyzed through comparison test using the Wilcoxon Signed-rank Test. \(p<0.05\) was considered significant.

**Results**

Table 1 shows the sample characteristics of children. From a total of 1162 children under five the majority of children were male (53.4%) and their age were 6-36 months (55.5%). Measurements using the two growth charts cannot be done in all age groups because the weight-for-age diagram of 2005 GDIC is only available for children aged 0-50 weeks and weight-for-length/height diagrams of 2005 GDIC is only available for children with length/height <60 cm. Of about 1162 children, only weight-for-age of 374 children were measured using those 2 standards, and only weight-for-length/height of 1094 children were measured using those 2 standards. However, length/height-for-age can be measure in every sex and age groups. The total prevalence of underweight, stunted, wasted, and obesity among children was smaller when interpreted using 2005 GDIC growth chart.

Most of children have normal weight-for-age, both according to 2006 WHO-CGS or 2005 GDIC. 2005 GDIC detects fewer underweight children in both sexes and fewer obese boys than 2006 WHO-CGS. The difference of weight-for-age interpretation was significant only for girls (p<0.001). Most of children have normal weight-for-length/height, both according to 2006 WHO-CGS or 2005 GDIC. 2005 GDIC detects fewer both wasted and obese children than 2006 WHO-CGS. The difference of weight-for-length/height interpretation was significant only for boys aged 0-60 months (p=0.008) and boys 6-36 months (p=0.027).

Height interpretation based on age comparison on male toddlers 0-60 Months old, 0-5 Months old, 6-36 Months old, 37-60 Months old (p<0.000)

Discussion

Abnormalities of child growth either under-nutrition or over-nutrition are associated with morbidity and mortality as well as long term impacts in adulthood, such as cardiovascular and metabolic disease. Therefore, precise measurement of growth is important to monitor child health and prevent malnutrition.

This study shows that both growth charts mostly detect normal growth in our study participants. Prevalence of national under-five underweight, stunted, and wasted children were higher (17.7%, 30.8%, 10.2%, respectively), but obese children was fewer (8.0%) than prevalence found in this study. However, prevalence of stunted children in this study was higher than world prevalence in 2016.
stunted, wasted, and obese children than 2005 GDIC. However, significant differences were only found in weight-for-age of girl, height-for-age of all age and sex groups, weight-for-length/height of 0-60 months boys, and 3-36 months boys.

This indicates that Indonesian children are lighter and shorter than the standard population used to develop the 2006 WHO-CGS. Previous study also suggest that the nutritional status of Indonesian children according to weight-for-length/height tends to be the same as the population of American children because Indonesian children are lighter and shorter. Previous study also suggests that the nutritional status of Indonesian children according to weight-for-length/height tends to be the same as the population of American children because Indonesian children are lighter and shorter. 11

Weight-for-age interpretation was only significantly difference in 0-50 weeks girl, and weight-for-age interpretation was only significantly difference in 0-60 months boys and 3-36 months boys. This suggests that gender plays an important role in child growth. Genetic expressions that affect body weight appear to be significantly higher in girls starting at 9 months compared to boys. 14

Racial factor is thought to be associated with child growth difference between Indonesian and American populations. But the influence of race in child growth is still controversial. Despite differences in race, WHO Multicentre Growth Reference Study Group (2006) found similar child growth rate among their subjects. It is thought that environmental factor such as nutrition have more impact on child growth, because poor nutrition and infection can increase risk of stunted children. 15 Previous review also indicate that application of specific racial and ethnic groups growth chart is not recommended because child growth are more affected by environmental factors rather than genetic factors. Therefore, WHO recommends to use only one growth chart for all child populations in the world. 16

However, some studies show that the interpretation of height-for-age using WHO chart shows different result than interpretation using height-for-age national chart of some countries. 18 Racial difference in child growth is a fact but this phenomenon is caused by inequality in environmental factors such as economics, psychosocial, and cultural factors that affect minority groups. However, previous study has shown the biological influence on child growth. Hong Kong Chinese children is shorter than WHO growth standards as a result of epigenetic constrains on growth rather than environmental factors. 19 Lipid metabolism, fat distribution, and bone age are also related to race/ethnicity. African American children have less visceral and hepatic fat, lower rates of lipolysis, and lower adiponectin than white children. African American and white children bone age mature slower than Asian and Hispanic children.

A meta-analysis from 55 countries also showed that the standard deviation score, (SDS) of European children in general are +0.5 SD, while children from Saudi Arabia and India are -0.5 SD compared to the WHO 2006 chart reference population. Research by Batubara et al (2006) also shows that Indonesian children have lower SDS than the 2000 CDC chart reference population. This data shows that there are different characteristics of child growth in various regions.

The different interpretations of two growth chart in this study indicate that estimation of children malnutrition in Indonesia using 2006 WHO-CGS is exaggerated, and perhaps Indonesian children have grown in accordance with their genetic potential. This can lead to unnecessary examination and intervention which can interfere exclusive breastfeeding and cause excessive supplemental feeding. Formula milk and excessive supplementation of food can cause excess weight which will be accompanied by long-term complications in the future. It must be considered in the national policy of malnutrition management in Indonesia. However, because children’s growth is not only influenced by race or genetic factors, good environmental factors must also be considered. Interventions to correct problems that affect the nutritional status of the population such as lack of breast milk, low or high calorie food, lack of health facilities, sanitation, and poverty must be continued.

This study also has several limitations. Our study analyzed secondary data collected from integrated healthcare center, hence anthropometric measurements tend to vary in each center. Nutrient intake including breast milk and parent socioeconomic status were not evaluated. This might lead to some bias in evaluating differences in interpretation of nutritional status.

Application of growth chart that developed from Indonesian children as standard population should be considered in estimating children with malnutrition. Further study is needed to confirm whether the interpretation of child nutritional status using growth chart is consistent with their clinical condition and also to determine whether Indonesian children have grown...
according to their genetic potential.

**Conclusion**

2005 GDIC detects fewer children with malnutrition than 2006 WHO-CGS. The significant difference on interpretation between two growth charts was particularly found in height-for-age.

New Record of the Species Synthesiomyia Nudiseta (van der Wulp, 1883) (Diptera, Muscidae) with Forensic Study from Kerbala City, Iraq

Naeem Al-Ashbal1, Rafid Abbas Al-Essa1, Hanaa H. Al-Saffar2

1College of Education for Pure Sciences/ University of Kerbala, Kerbala, Iraq,
2Iraq Natural History Research Center and Museum, University of Baghdad, Baghdad, Iraq

Abstract

The present study aimed to investigate Synthesiomyia nudiseta (van der Wulp, 1883) in the carcasses of dogs and rats in four different localities of Kerbala governorate, during four seasons. The results indicated the appearance of S. nudiseta only in the spring and autumn seasons within the urban and agricultural areas, as well as the appearance of this species on the bodies of dogs only without rats. Taxonomy and morphological futures were described. S. nudiseta is belonging to the family Muscidae (Order: Diptera) is described as a first time recorded in Iraqi entomofuna. The specimens wear collected from carcasses of dogs and rats at agriculture and urban regions of Kerbala city. The diagnostic characters and mean morphological features were photoed.

Key words: Diptera, Forensic Entomology, Iraq, Kerbala City, Muscidae, Synthesiomyia.

Introduction

The species Synthesiomyia nudiseta (van der Wulp, 1883) is a wide distributed in the tropical and subtropical regions of the old and new world (1). This fly has contributed to criminal investigations for many countries such as Costa Rica, India, Malaysia, Thailand, and USA (2-9).

This species has been recorded in numerous studies on human bodies in Mexico and Peru (10). It is often recorded on human bodies in urban areas because it feeds on rubbish and decaying vegetables (11). Larval stages were found as well as the presence of adults on the body of a woman in a 13-storey building in Malaysia, the presence of its larvae determined the time of death was nine days (12). Larval stages of this species on human corpses have been studied in detail in Europe, specifically in the Institute of Forensic Medicine as well as the Spanish Legal Institute because of its importance in criminal investigations (13).

The larval stage is very important in future of criminal investigations because its presence on human bodies is evidence that the body was in indoor or urban environments (14).

In recent years, high temperatures have affected the distribution of these insects, so it is necessary to know the temperature of those areas from which the samples were taken and where they are distributed in the same area, and the association of this species with bodies as well as wounds plays an important role in determining the time of death post-mortem interval (PMI) (15). The aim of current study to investigate the presence of this species on the bodies of animals (dogs, rats) in different localities of Kerbala city.

Materials and Method

The study was during the period from 1/3/2018 to 28/2/2019 within the four seasons (spring, summer, autumn and winter). Two types of vertebrate animals were used in the study (dogs and rats) as shown in Table (1).

The animals used in the experiment were killed in two ways: the first using a sharp knife and the second by a toxic substance (Strychnine sulfate tablet), with dissolving 1 gm of the Strychnine in 5.0 ml of water and administered orally to rats at a dose of 3 ml using a medical syringe, while dogs were given the tablet directly, after killing the animals by the proves kill
methods of S. nudiseta was investigated after the corpse was placed on the ground after killed immediately to the point of complete decomposition (16).

Use three duplicates in each of the above-mentioned transactions. The insects were collected by air net and fly roll trap. The samples were taken to the laboratory and killed by freezing (24h) and so as they mounted by insect pins, the locality and date of collection were recorded. (17,18)

For identification of genus and species were using taxonomical keys: (13) (19-21).

The habitat and morphological features were taken photos by the aid of the digital microscope dino-light with scales of measurements.

Table (1) showed animals with their weights.

Results and Discussion

Morphological study

In the current study, the genus Synthesiomyia and species nudiseta were registered as new record to fauna of Iraq. this genus can by recognized from closely genus by: Arista bare; prosternum setulose; scutellum with numerous setae on sides (plate: 1) it has one species (19).

**Synthesiomyia nudiseta** (van der Wulp, 1883)

Scientific classification

Order: Diptera
Suborder: Brachycera
Family: Muscidae
Subfamily: Azeliinae
Trib: Reinwaardtiini
Genus: **Synthesiomyia** Brauer & Bergenstamm, 1893: 9, 110, 178
Species: S. nudiseta
Synonyms: *Cyrtoneura nudiseta* Wulp, 1883  
**Hyadesimyia grisea** Gigliotos, 1893

**Synthesiomyia brasiliana** Brauer & vonBergenstamm, 1893

**Discretion of the species**: S. nudiseta can be diagnostic easily by the antennae and palpi are orange \ yellow in color, the last terminal segment of the abdomen is yellow.

**Body**: grey to black in color; length about 7-10 mm male and female (Figure 1 A, B)

**Head**: compound eye bare without hairs, dioptic in male but in female holoptic; antenna, pedicel with clear longitudinal fissure and has hard short bristles, flagellum yellow with arista bear; maxillary palpi yellow (Figure 2 A, B)

**Thorax**: consists of four longitudinal vittae on mesothorax, sternopleron triangular with four long bristles, the interior is longer and thicker than other.

**Legs**: black in color, the hind coxa with hairs at inner posterior margin

**Wing**: hyaline, costa expanded to R_{3+4}, subcostal not striate, apical section of vein M strongly curved forward (Figure 1B)

**Abdomen**: gray with checker board and differ from sarcophagids flies by the terminal segment is yellow.
Figure 1: (A) Adult male of *S. nudiseta*; and (B) Adult female of *S. nudiseta* with wing M1, R4+5, wing veins.

Figure 2: (A) *S. nudiseta*, with orange flagellomere (fl) and tip of abdomen (abd); and (B) head of *S. nudiseta* with flagellomere (fl) and palpe orange.

Figure (3) Level of appearance that *S. nudiseta* abut, a= autumn; s= summer
Environmental Study

The results of the study indicated the effect of attracting *S. mudiseta* insect species according to the type of animal as a number of adults were collected near the bodies of dogs, while no insect was collected near the bodies of mice may be due to the difference in the size of the body (17). The size of the body has an effect on insect attraction.

As for the method of killing the animal, it has had a great influence in attracting insects. The results of the research indicated that all the insects collected were near the dead bodies with a sharp knife, while no insect was found in the dead bodies using the poison. The amount of blood accompanying the dead body is injurious and does not exist in the case of poisoning (22).

The temperature had an effect on the appearance of *S. mudiseta*. It was observed during the research that the insect is present during the spring and autumn seasons and not fund in winter and summer. The study has indicated that the appropriate thermal range for the appearance of the insect within a temperature range of 20-30 and this is consistent with (23,24).

The results in Figure (3) indicate the geographical area of the environment has had a significant impact on the presence of the insect *S. nudiseta* as it appeared in urban and agricultural areas and does not appear at all in the desert and industrial areas. The puffiness stage is fresh (12)(24).

Call for Papers / Article Submission

Indian Journal of Forensic Medicine & Toxicology has commenced publication since 2007. IJFMT will be published two times in a year.

**Purpose & Scope:** Indian Journal of Forensic Medicine & Toxicology is a peer reviewed six monthly Journal. It deals with Forensic Medicine, Forensic Science, Toxicology, DNA fingerprinting, sexual medicine and environmental medicine. It has been assigned International standard serial No. p-0973-9122 and e-0973-9130 website: www.ijfmt.com. This journal is also indexed with Index Copernicus (Poland).

The journal encourages research from theoretical perspectives, research reports of evidence based practice as well as praxis research work that focuses on the interface between theory and practice and how each can support the other. In addition, the journal strongly encourages reports of research carried out within or involving countries in the Asia-Pacific region.

**Invitation to submit papers:**
A general invitation is extended to authors to submit journal papers for publication in IJFMT.

**The following guidelines should be noted:**
1. The article must be send by E-mail in word only as attachment. Hard copy need not be send.
2. The article should be accompanied by a declaration from all authors that it is an original work and has not been sent to any other journal for publication.
3. References should be in Vancouver style.
4. As a policy matter, journal encourages articles regarding new concepts and new information.

**Please submit paper in following format as far as applicable**

1. Title
2. Names of authors
3. Your Affiliation (designations with college address), email id
4. Corresponding author- name, designations, address, email id
5. Abstract with key words
6. Introduction or background
7. Material and Methods
8. Findings
9. Discussion / Conclusion
10. Conflict of Interest
11. Source of Support
12. Ethical Clearance
13. References in Vancouver style.
14. Word limit 2500-3000 words, MSWORD Format, single file
15. Please quote references in text by superscripting

See website for all details
