Indian Journal of Forensic Medicine & Toxicology

EDITOR in Chief
Prof. R K Sharma

Formerly at All India Institute of Medical Sciences, New Delhi, E-mail: editor.ijfmt@gmail.com

EDITOR
Prof. Dr. Adarsh Kumar
Forensic Medicine & Toxicology, AIIMS, New Delhi

INTERNATIONAL EDITORIAL ADVISORY BOARD

1. Prof Mete Gulmen Cukurova University, TURKEY
2. Prof. Leandro Duarte De Carvalho, Minas Gerais, Belo Horizonte, Brazil
3. Prof. Donata Favretto (Full Professor) Forensic Toxicology at University of Padova, Italy
4. Prof. Babak Mostafazadeh Department of Forensic Medicine & Toxicology, Shahid Beheshti University of Medical Sciences, Tehran-Iran
5. Prof Halis Doggoz, Mersin University, TURKEY
6. Prof Jozef Sido, Comenius University, Bratislava, SLOVAKIA
7. Dr. Rahul Pathak (Lecturer) Forensic Science, Dept of Life Sciences Anglia Ruskin University, Cambridge, United Kingdom
8. Dr. Hareesh (Professor & Head) Forensic Medicine, Ayder Referral Hospital, College of Health Sciences, Mekelle University, Mekelle Ethiopia East Africa
9. Dr. Mokhtar Ahmed Alhrami (Specialist) Forensic Medicine & Clinical Toxicology, Director of Forensic Medicine Unit, Attorney General’s Office, Sana’a, Yemen
10. Dr. Sarathchandra Kodikara (Senior Lecturer) Forensic Medicine, Department of Forensic Medicine, Faculty of Medicine, University of Peradeniya, Sri Lanka
11. Dr Noha A. Magdie El Rafie, Forensic Toxicology, Ain Shams University, Cairo, EGYPT

SCIENTIFIC COMMITTEE

1. Prof Udai Pratap Singh, Department of Anthropology Lucknow University Lucknow
2. Dr Anil Rahul (Associate Professor) Dept of Anatomy, Govt Medical College Nagpur
3. Dr Shankar Bakkanwar (Associate Professor) Forensic Medicine, Kasturba Medical College, Manipal, Karnataka
4. Dr. K. Ravikumar Raksha Shakti University, Ahmedabad, Gujrat.
5. Dr. Pragnesh Parmar (Associate Professor) Forensic Medicine, Valsad, Gujrat
6. Dr. Vandana Mudda (Awati) (Associate Prof) Dept of FMT, M.R.Medical College, Gulburga, Karnataka,
7. Dr. Asha Srivastava (Senior Scientific Officer) Forensic Psychology, Central Forensic Science Laboratory, CBI, Delhi
8. Dr. Lav Kesharwani (Asst.Prof.) School of Forensic Science, Sam Higginbottom Institute of Agriculture Technology & Sciences, Allahabad U.P.
9. Dr. Anu Sharma (Associate Prof) Dept of Anatomy, DMCH, Ludhiana (PB)
10. Dr. Shalini Gupta (Prof.) Oral Pathology and Microbiology, Dental Sciences King George Medical University, Lucknow, UP
11. Dr. Rituja Sharma, Associate Prof, Law Banasthali Vidyapeeth Jaipur

NATIONAL EDITORIAL ADVISORY BOARD

Chairman
Prof Sudhir K Gupta - Head, Department of Forensic Medicine
All India Institute of Medical Sciences, New Delhi

Members
1. Prof. SK Dhattarwal, Forensic Medicine, PGIMS, Rohtak, Haryana
2. Prof. N K Aggrawal Forensic Medicine, UCMS, Delhi
3. Prof Ajay Ghangale Forensic Medicine Dr DY Patil Medical College, Pune, Maharashatra
4. Dr. Amar Jyoti Patwory Professor, Forensic Medicine NEIGRIMS, Shillong
5. Dr. S. Venkata Raghava Professor, Forensic Medicine, Banglore Medical College, Bengaluru
6. Prof Praveen Arora, Professor Department of Forensic Medicine & Toxicology, SAIMS, Indore
7. Dr. Pankaj Datta (Principal & Head) Department of Prosthodontics, Indraprastha Dental College & Hospital, Ghaziabad
8. Dr. Mahindra Nagar (Head) Department of Anatomy, UCMS & GTB Hospital, Delhi
9. Dr. Virender Kumar Chhoker Professor Forensic Medicine and Toxicology, Santosh Medical College, Ghaziabad, UP
10. Dr. Dayanand G Gannur (Professor) Department of Forensic Medicine & Toxicology, Shri BM Patil Medical College, Hospital & Research centre, Bijapur, Karnataka
11. Dr. Alok Kumar Professor Department of Forensic Medicine & Toxicology, UP Rural Institute of Medical Sciences and Research, Saifal, Etawah, U.P.

Published at
Institute of Medico-legal Publications
Logix Office Tower, Unit No. 1704, Logix City Centre Mall, Sector-32, Noida - 201 301 (Uttar Pradesh)
1. A One Year Epidemiological Study of Mechanical Injury Cases brought to SIMS Hospital, Western Uttar Pradesh .................................................................................................................. 1
   Abhishek Sharma, Sumit Tellewar, Barkha Gupta, Vishwajeet Singh, Gurdeep Singh

2. Estimation of Age by Modified Gustafson’s Method from Incisor and Canine Teeth.............................. 5
   Ajay V Patil, Chandrakant M Kokatanur, Vinay S Bannur

3. Study of Demographic Pattern of Poisoning in Patients Presenting to Emergency Department of a Tertiary Care Centre, SIMS, Hapur ........................................................................................................ 12
   Gurdeep Singh, Barakha Gupta, Sumit Tellewar, Vishwajeet Singh, Abhishek Sharma

4. Forensic Evaluation of Various Osteometric Parameters of Human Mandible in both Sexes .................. 16
   Priyamvada Kurveti, Gyanendra Kumar, Dheeraj Singh Verma, Jayanthi Yadav, B. P. Dubey

5. An Autopsy Study of Drowning Deaths in and around Visakhapatnam ................................................. 23
   Raja Sekhar Uppu, BVS Ananda Rao, Beemsetty Rajesh

   Kushdeep Kumar Gupta, Abraham Johnson

7. Pattern of Abdominal Viscera Injuries in Blunt Abdominal Trauma Deaths in Ahmedabad ................. 34
   Kunjan Modi, Rajesh Joshiyara

8. Pattern of Fatal Firearm Injuries Pertaining to Manner of Death: An Original Research Article ............ 38
   Kaulaskar Shashikant V., Kolpe Dayanand V., Udaykiran Bhalge, S K Pandey, Manoj Pathak

9. Epidemiological Profile of Snake Bites over 1-Year Period from Tertiary Care Centre in Maval Region of Maharashtra, India: Original Research Article .................................................. 44
   Rajesh Kharat, Rahul Kedare

10. Informed Consent in Clinical Practice and Research and Its Awareness among Under Graduate Medical Students ............................................................................................................................................. 50
    S.R. Saritha, C.S. Sreedevi

11. Sexual Dimorphism in Mandibular Canine Crown Dimensions in Early Adolescents: A Hospital based Study .................................................................................................................................................. 56
    Kanak Priya, Poonam Agrawal, Dinesh Kumar Bagga, Hiten Kalra, Disha Sirohi, Ritika Gupta

12. Rationale of Evaluation of Potency in Medicolegal Cases of Sexual Assault by Penile Color Doppler with Injection of Papaverine .............................................................................................................. 61
    Shilpa Domkundwar, Varsha V Jadhav, Sonal Khandelwal
13. Determination of Stature from Anthropometric Measurements of Thyroid Cartilage in the Population of Punjab.......................................................................................................................................................... 67
   Sunil Subramanyam, Dalbir Singh, YS bansal, SP Mandal

14. Study of Patterns of Injuries by Road Traffic Accidents.................................................................................................................. 73
   Jakaregari Srinivas

15. Socio- Demographic Study of Deaths Due to Poisoning in Autopsies Conducted at KIMS Hospital, Bangalore.......................................................................................................................................................... 77
   Senthil Kumar V, A. Dominic Infant Raj, Naveen Kumar T

16. Lifelines as a Tool to Predict Death .......................................................................................................................................................... 81
   Sneha.S, Aswath, Priyadarshee Pradhan, P. Sampath Kumar

17. Agar-Paraffin Double Embedding Over Conventional Embedding for Minute Oral Biopsies- Cohort Study84

18. Severity Grading, Management, Outcome and Epidemiological Profiling of Snakebite Victims in Tertiary Care Hospital in South India: 5 Years Retrospective Study .......................................................................................................................................................... 89
   Smriti Sinha, Sathyajith Karanth, Avinash Kumar

19. Study of Organo- Phosphorous Compound Poisonings with Blood Sugar Levels in Telangana Population . 96
   Jakaregari Srinivas

20. Correlation and Comparison of Cheiloscopy, Dactyloscopy and Palatoscopy with Blood Groups among Dental Students From Western Maharashtra.......................................................................................................................................................... 99
   Srigiri Surath, Sushma Bommanavar, Sudha B Mattigatti, Uzma Belgaumi, Vidya Kadashetti, Wasim Kamate, Nupura Vibhute

21. Unnatural Female Deaths within Seven Years of Marital Life: An Autopsy based Study ................. 105
   Jeeveswararao Bagadi, Srinivasulu Pothireddy

22. Study of Dimorphism of Humerus in Maharashtra Population .......................................................................................................................................................... 110
   Mohammad Abdul Mateen

23. Perception of Students Regarding Gender based Violence .......................................................................................................................................................... 113
   Muzaffar A, Shenoy VK, Vaswani VR, Badiadika KK

24. Legal & Intellectual Property Dimension of Health & Access to Medicines in India ..................... 118
   M.Z.M. Nomani, Alaa K.K.Alhalboosi, Mohammad Rauf

25. Assessment of the Awareness of Knowledge of Dental Records in Forensic Dentistry among Undergraduate Dental Students .......................................................................................................................................................... 123
   Shyam Sundar Behura, Shirsha Mukherjee, Roquaiya Nishat, Lipsa Bhuyan, N Aravindha Babu

26. A Study to Compare the Stress Patterns in the Edentulous Mandibular Bone around the Two Implant Retained Over Denture and the Prosthesis Restored with All-On-Four Concept Using the Three Dimensional Finite Element Analysis .......................................................................................................................................................... 130
   Puneeth Hegde, Satish Shenoy, Shobha Rodrigues, Thilak Shetty, Umesh Pai, Sharon Saldhana, Mahesh M
27. Prosthetic Rehabilitation of Patient with Mixed Connective Tissue Disease Using Glove Type Silicone Finger and Toe Prosthesis .................................................. 134
   Thilak Shetty, Abhinav Sharma, Shobha J Rodrigues, Vidya K Shenoy, Umesh Pai, Sharon Saldanha, Mahesh M

28. Perception of Students Regarding Gender based Violence ........................................ 138
   Muzaffar A, Shenoy VK, Vaswani VR, Badiadika KK

29. Evaluation for Correlation of Cheiloscopy and Dermatoglyphics in Gender Determination .......... 143
   Tim Peter Thermadam, Laxmikanth Chatra, Auswaf Ahsan

30. A Study to Compare the Stress Patterns in the Edenulous Mandibular Bone Around the Two Implant Retained Over Denture and the Prosthesis Restored with All-On-Four Concept Using the Three Dimensional Finite Element Analysis ............................................................................ 149
   Puneeth Hegde, Satish Shenoy, Shobha Rodrigues, Thilak Shetty, Umesh Pai, Sharon Saldhana, Mahesh M

31. Assessment of Needle Stick Injury in an Institutional Set up: A Retrospective Analysis ............... 154
   Shobha Rodrigues, Thilak Shetty, Umesh Pai, Sharon Saldanha, Mahesh M, Puneeth Hegde, Mandakini Mohan

32. A Study to Compare the Stress Patterns in the Edenulous ................................................ 158
   Shobha Rodrigues, Thilak Shetty, Umesh Pai, Sharon Saldanha, Mahesh M, Puneeth Hegde, Mandakini Mohan

33. Root Canal Morphology of Mandibular Second Molars Using CBCT ................................ 162
   Mohamad Qulam Zaki Bin Mohamad Rasidi, Mahesh Ramakrishnan

34. Comparative Evaluation of Effect of Auxiliary Grooves on Retention of Complete Cast Crowns in Molar Teeth – An In-Vitro Study .................................................. 168
   Thilak Shetty, C T Anand, Sharon Saldanha, Shobha J Rodrigues, Umesh Pai, Mahesh M, Puneeth Hegde

35. Risk Assessment, Risk Management, and Risk Communication of Welding Work at PT Dok and Perkapalan Surabaya (Persero) .......................................................... 172
   Aditya, I Made Muliatna, Abdul Rohim Tualeka

36. Prediction of The Needs for Benzene Detox with Foods Intake Containing CYP2E1 Enzyme, Sulfation, and Glutathione at Gas Stations Pancoranmas Depok, Indonesia ...................... 177
   Abdul Rohim Tualeka, Pudji Rahmawati, Ahsan, Syamsiar S Russeng, Sukarmin, Atjo Wahyu

37. Determination of Safe Benzene Concentration at Ciputat Gas Station ................................. 183
   Cut Suci Almadiana, Abdul Rohim Tualeka

38. Forensic Implications of Saliva: An Overview ............................................................... 189
   Debesh Nilendu, Arjun Kundu, Avaish Chand, Abraham Johnson

39. Risk Management by Implementing Hazard Identification, Risk Assessment and Determinant Control (HIRADC) Method in the Research Center of the University in Surabaya, Indonesia .............................................. 195
   Ade Titis Kurniawati, Putri Ayuni Alayunnur, Dani Nasirul Haqi, Tri Martiana, Shintia Yunita Arini, Alikin Wahyuudiono F

40. Evaluation to Identify Benzene Safe Concentration in Oil and Gas processing Facility in East Java Area Due to Process Fugitive Emission ................................................................. 201
   Ahmad Muslih Bambang Sugiharta, Aditya, Abdul Rohim Tualeka

    Nawal M Abdullah, Abdul Kareem Q Mohamed, Sameh S Akkila3

65. Evaluation of Root Canal Morphology of Permanent Maxillary Canine Using CBCT – A Cross-
    sectional Study ................................................................................................................................... 339
    Nor Masitah Mohamed Shukri, Mahesh Ramakrishnan

66. Relationship between Radiographic Evaluation with Age and Gender – A Radiographic Study .......... 346
    Nor Syakirah Binti Shahroom, Gheena.S

67. Corrosion of Orthodontic Metallic Brackets Immersed in Solutions of Salt and Spices in Artificial Saliva
    351
    Nurul Afiqah Amani Binti Zaaba, Harish Babu

68. Cheiloscopy: The Study of Lip Prints in Sex Identification between Indian and Malaysian Population..... 356
    Nurul Afiqah Amani Binti Zaaba, Gheena.S

69. Study of Certain Immunological Aspects in Diabetes Mellitus Type 2 Patients Infected by Helicobacter
    Pylori .................................................................................................................................................. 362
    Qusay Abdul-Wahab Khalaf, Rajwa Hasen Essa, Khetam Habeeb Rasool
70. Detection of ESBLs CTX-M Gene of *E. coli* Isolated from Clinical Cases in Maysan Province .......... 368
   Rabab Naeem Alag, Zahid Sa’doon Aziz

71. Impact of Electronic Games on the Behavior of Children and their Academic Achievement upon Schools in Mosul City ................................................................. 374
   Radhwan Husain Ibrahim, Abdul Kareem Ghanim, Hana A. Alkhaderjameel

72. Hazard Identification, Risk Assessment, and Determining Control (HIRADC) Method in a University Laboratory in Surabaya, Indonesia .......................................................... 380
   Rika Fauziah, Putri Ayuni Alayyunnur, Dani Nasirul Haqi, Sho’im Hidayat, Alfin Wahyudiono F

73. Investigating Relationship between Positive Organizational Behaviors and Organizational Commitment among Nurses at Imam Khomeyni Hospital in Jiroft, Iran, in 2017: A cross Sectional Study ........................................................................................................ 386
   Saadat Salari, Fereshteh Daneshi, Motahare Pilevarzadeh

74. Alcoholic Extract of Shilajit as Anti Protein Denaturation, Anti Blood Hemolysis, and Anti Microbial..... 392
   Saba Hadi, Sundus Hameed Ahmed, Noor Talib, Hassan Abdul Hussein and Isam Hussain T. Al-Karkhi

75. A Stereomicroscopic Analysis of Dentinal Micro Cracks after Root Canal Preparation Using Four Different Rotary Instruments ..................................................................................... 397
   Samar Abdul-Hamed, Rasha H Jehad, Zainab M. Abdul-Ameer, Jacob Al-Hashemi

76. Studying Effective Factors on Overweight and Obesity in High School Students in Erbil .................. 403
   Sarhang Qadir Ibrahim, Tariq S. Al-Hadithi, Kameran Hassan Ismail

77. Removing Methods of Ultracide Residues in Imported Apple Peels in Iraqi Local Markets .................. 409
   Sedik A.K. Al-Hiyaly; Saba Riad Khudhaier ; Jazzer, A, J. Al-Temmemi and Ahmed S.A. Al-Tae

78. Evaluation of Benzene Threshold Value in Benzene Exposed Work Environment: Case Study at Ciputat Gas Station ................................................................................................. 413
   Shinta Arta Mulia, Zikri Fathur Rahman, Ahmad Muslih Bambang Sugiharta, Lili Susanti, Abdul Rohim Tualeka

79. A Complete Perusal of Polluter Pays Principle “Incorporation and Application In India” .................. 419
   Shyamantak Misra, Hiranmaya Nanda

   Suherdin, Noeroel Widajati, Ratna Dian Kurniawati, Abdul Rohim Tualeka

81. Work Safety Risk Assessment at Container Load Unloading Jobs at PT. Pelabuhan Indonesia II (Persero) Palembang Branch 2017 ........................................................................ 429
   Tedi levinrarian, Zikri Fathur Rahman, Abdul Rohim Tualeka

82. Correlation of Smoking and National Institutes of Health Stroke Scale (NIHSS) in Acute Ischemic Stroke Patients ........................................................................................................ 433
   Yunike Tourisiana, Mohammad Saiful Islam, Joseph Ekowahono Rahardjo

119. Study the Toxicity and Anticancer activity of Some New Amic Acid and Their Derivatives of Mefenamic acid ........................................................................................................................................ 642
   Ali A. Sabah, Muna S. Al-Rawi, Jumbad H. Tomma

120. Investigating Effects of Salvia Officinalis (Sage) on Development of Mice Embryos Kidney and Some Hormonal Effect of Treated Mothers ........................................................................................................................................ 649
   Ban Thabit Al- Ani, Rana R Al Saadi, Raad Ghazi Reshan

121. Association among Vitamin D Deficiency with some Inflammatory Marker in Iraqi Patients with Autoimmune Thyroiditis ........................................................................................................................................ 655
   Noor Alhuda Kh. Ibrahim, Zaid Nsaif Abbas, Wasnaa J. mohammad

122. A Statistical Study on Microorganisms that Cause Tooth Decay and Prevention and Treatment Methods . 661
   Widad sameer jaaz, Ohood Salman Jawad, Hassanain Jwad Abid Al Hussein

123. In vitro Antifungal efficacy of Saccharomyces Cerevisiae Mediated Nanoparticle Against Resistant Candida Albicans Isolates ........................................................................................................................................ 666
   Hussein A. R. Abbood, Bari L.Mohammed, Hawazin A.Aboid

124. Application of Chemical Techniques in the Manufacture of Some Industrial Dental Materials .............. 672
   Hamed Ibrahim Mohammed, Aara Ali Hadi, Hassanain Jwad abid al Hussein

125. Isolation and Identification of Pantoea agglomerans from Open Heart Operations Unit of Marjan Hospital in Hilla City ........................................................................................................................................ 676
   Enas R. Al-Kidsawey, Kawther H. Mhdi, Mohammed A. Al kaif
X

126. Immunological and Molecular Study of Human Cytomegalovirus contribution to Anemia in patients with Chronic Kidney Disease ................................................................. 680
    Zahraa Abdulridha Baqer AL-Fayyadh, Musa Nima Mezher

127. Comparison between HSP70 Levels in Acute and Chronic Coronary Artery Diseases ................. 686
    Wurood A.Kadhim, Noora M.Kareem, Samar A. Al-Shami

128. A Statistical Study to Determine the Factors of Vitamin D Deficiency in Men: the City of Baghdad as a Model ........................................................................................................ 691
    Suad Turky Ali, Hind Tahir Qadir, Shaimaa Khalid Moufak, Mohammed Ali Mohammed Al-Badri, Mohammed Nsaif Abbas

129. Mutation Evaluation in P53 exon 5 in Iraqi AML Patients with 4 Growth Levels .......................... 697
    Ishtar Imad, Abdulameer N. Ghaloub, Mehmet Ozaslan, Alaa F. Alwan

130. Assessment of Antagonistic Effect of Alcoholic Extract from Cyanophyta (Spirulina Platensis) Against Several Human and Plant Derived Pathogenic Fungi ...................................................... 703
    Raghad J. Fayyad, Rasha Saad Nuaman, Noor T. Hamdan, Rasha Saatam Hameed, Sara A. J. Maliki

131. The Differentiation between Premenstrual Tension Syndrome and Dysmenorrhea in Young Age Group in Kerbella City: Cross-Sectional Study ................................................................. 710
    Manal Nasih Ahmed Hamdan Maysaloon Adnan Abdul Razzak

132. Bacteriological and Pathological Study on Kidneys of Slaughtered Sheep in Fallujah City ............ 716
    Ahmed Sami Jarad, SMA AL-Kubaisi, Roua Jamal Abdulkhaliq, Mustafa Salah Hasan

133. Prevalence of Dental Anomalies (Mesiodens and Enamel Hypoplasia) Among Primary School Children in Badra/Iraq .............................................................. 723
    Sanaa Rasheed Abd Al-Aaloosi, Maitha Sameer Kadhim, Basma Fathi Alanbari

134. Evaluation of the PCR Method for the Diagnosis of Cutaneous Leishmaniasis in AL Hawija District, Kirkuk, Iraq .................................................................................................................. 729
    Husain F. Hassan, Moath M. Salman, Burhan M. Mohammed

135. Evaluation of Some Blood Parameters in Anemic Patients in Relation to Periodontal Condition ....... 734
    Noor Sabah Irhayyim

136. Effect of Algal Extracts on the Growth of Tow Bacterial Types Isolated from Pollutants Discharge ....... 741
    Thaer Mohammed Ibrahim, Raad Abdul Hadi Nayyef, Buthaina Abdul- Aziz Hassan Al-Magdamy

137. Prevalence of Aerobic Bacterial Vaginosis and Trichomonas Vaginalis Associated with Socioeconomic Factors among Women in Misan Governorate ...................................................... 745
    Zahrah Adnan, Huda Dhaher, Mohammed F. Marjani

138. Synthesis, Characterization of New Tris Hydrazones based on Cyanuric Acid and Studies the Biological Activity as Antibacterial and Antifungal ...................................................... 753
    Thaer Saleh Ghali

139. Assessment of Hyperurcemia in Patient with End Stage Chronic Kidney Disease ...................... 759
    Sarah Salih Mahdi, Elaf Ayad Kadhem and Nada Nazar Al-faris

203. Assessment of the Correlation between the Salivary Flow Rate and Dental Caries Experience among
   Children with β-Thalassemia Major ...................................................................................................... 1122
   Mudhafar Fadhil Jaddoa, Alhan Ahmed Qasim

204. Determine Effect of Carbothera Therapy on Foot and Leg Ulceration for Diabetic Patients in Endocrine
   and Diabetic Center at Al-Nasiriya City ................................................................................................. 1128
   Dr. Sameer Razak Oleiwi, Dr. Oday Faris Washeel, Dr. Hassan Al-Yassin, Dr. Adel Gassab Mohammed

205. Outcome of Endoscopic Endonasal Repair of CSF Rhinorhea using Fascia Lata Graft ...................... 1135
   Hani Musa Al-Akbi, Ahmed Adhab Mayan, Ammar Jabbar Najem Alkelabi, Laith Ali Mahmood

206. Genotype and haplotype of HLA-class II in Type I and Type II Diabetes Mellitus in Iraqi Patients ...... 1140
   Abeer Mazin, Abdulnabi J Abid

207. Cloud Point Extraction, Preconcentration and Spectrophotometric Determination of Co (II) and Cu
   (II) using 15-Crown-5 .......................................................................................................................... 1146
   Yussra O.Mussa, Azhar A. Ghali, Ashwaq S.Husseini

208. Hormonal and Immunological Study in Serum of Pregnant albino rats Treated with Nickel Oxide
   Nanoparticles ........................................................................................................................................ 1153
   Haneen M. Alsoltane, Amel A.Altaee

209. Assessment of Mental Health of Healthcare Professionals Working in the Infectious Diseases Units:
   Comparative Study ............................................................................................................................... 1158
   Maysaa Niama Aboalshon, Hayder H. AL-Hadrawi, Ammar Abbas Shalan

210. Emotional Intelligence and Work-related Stress among Nurses Working in Psychiatric Hospitals......... 1164
    Zaman Ahmed Hrefish, Hayder H. AL-Hadrawi

211. The Relationship between Smoking and Urokinase Gene 3’-UTR T/C Expression on Occurrence of
    Bladder Cancer .................................................................................................................................... 1169
    Zainab Nizar Jawad, Kamal Abdul Rasool, Weaam Awad
XVI

212. Effect of Carcinogenic Substance (7,12 Dimethylbenz [a] Anthracene (DMBA)) on Tissue, Hematology Character and Enzyme Activity in Rat .............................................................. 1172
Abdulridha Mohammed Al-Asady, Ntisar Kadhum Ghaleb, Abeer Muhammedali Jasim Alnasrawi, Thoalffakar A. Alhamed

213. Psychological Factors Affecting on Developing Reading Skills and Evaluation of Reading Strategy Knowledge.............................................................................................................. 1177
Wathiq Al – Husseini, Asst. Prof. Dr. Diaa Oued Al Arnousi, Qassim Raheem

214. Comparison Between Photoselective Vaporization of Prostate by Diode Laser and Monopolar Transurethral Resection of Prostate in Single Center Experience ...................................................... 1183
Zaid Ali Abdul Hussein, Ali Hamdan Fahad

215. Tympanometric Findings among Adults with Chronic Nasal Obstruction Due to Sinonasal Pathology ... 1189
Salim Hussain Ibrahim

216. The impact of Mindfulness Education on Elementary School Students .............................................. 1195
Rawaa Saadoun Al-Abedi, Rassem Ahmed Al-Jerayi

217. Prevalence of Bronchiolitis among Hospitalized Children less than Two Years in Babylon Province ..... 1200
Maha. A. Kadim, Nuhad M. Al-Door

218. Nanotechnology issues included in the subjects of the Department of Biology in the Colleges of Education ........................................................................................................................................ 1204
Mazen Thamer Shenif, Mustafa Abdel Amir Raheem Al-Zamili

Shatha Abdul-Kareem, Ahmed G. Al-Maroo, Noor H. Fadhil

220. Bergamot Essential Oil Effect against Candida Albicans Activity on Heat Cure Acrylic Denture Base ... 1216
Zinah Salah Mawlood, Ghassan Abdul-Hamid Naji

221. Antimicrobial Activity And Characterization of Some Oxazole, Thiazol And Quinoline .................. 1222
Atia, Iman Rajab. Mohammed, Zaman Ahmed. Hussein

222. Nurses Staff Knowledge Regarding Standard Hand Hygiene Precautions in Rania City/Kurdistan Regional Government of Iraq .................................................................................. 1229
Blend B. Ameen

223. Risk Factors Increasing Prevalence of Type 2 Diabetes Under the Age of 40 Years attending Al-Diwanyia Teaching Hospital ...................................................................................... 1235
Hassan Raji Jallab, Zahraa Abdul Ameer Kadhim

224. Psychosocial Consequences of Children with Idiopathic Growth Hormone Deficiency in Baghdad ...... 1241
Adraa H. Shawq, Zaid W. Ajil

225. Prevalence of Hepatitis B and Hepatitis C Viruses in β-thalassemia Major Patient in AD-Diwnaya province, Iraq ........................................................................................................... 1245
Hassan Raji Jallab, Zahraa Muayad Eesa
226. Deposition of TaN Film on Commercial Pure Titanium Disk by Modified Reactive Plasma Sputtering Technique ................................................................. 1250
   Hassan Jawad Farhan, Raghdaa Kareem Jassim, L. Thair

227. Influence of Carcinogenic Substance (7, 12 Dimethylbenz [A] Anthracene (DMBA)) on Tissue, Hematology Character and Enzyme Activity in Rat ................................................................. 1255
   Abdulridha Mohammed Al-Asady, Intisar Kadhum Ghaleb, Abeer Muhammed ali Jasim Alnasrawi, Thoalffakar A. AlHamed

228. Immunohistochemical Expression of CD68, P53 and Bel2 in Thyroid Tumors .................................................. 1260
   Samar Abdul Raheem Al-Gharrawi, Ali Hussein Mohammed Ali Alkhafaji, Rana Zuhair Naji

229. Prevalence of Lung Cancer in Non Smoker Patients Attending Al-Diwaniyah Teaching Hospital .................. 1267
   Hassan Raji Jallab, Thimar Malik Khudhair

230. Effects Hydrocortisone on the Body Weight of the Pregnant Rabbits and their Embryo with Histological Effects Skin, Stomach and Small Intestine of Embryos .................................................. 1273
   Abid AL Shammary, Rasha Noori Abid AL Shammary

231. Comparison of Preoperative Ultrasound Report with Intraoperative Findings of Laparoscopic Cholecystectomy in Gallstone Disease in Al-Diwaniyah Teaching Hospital ......................... 1280
   Adel Shakir Al-Timimi, Anwar Majeed Hussein

232. Frequency of Arrhythmia after Acute Myocardial Infarction During Admission to the Coronary Care Unit in Ad_diwaniyah Teaching Hospital .......................................................... 1286
   Radhi F. Shlash, Sarah Abdul Kareem Abdul Jabbar

233. Sex Determination of in Vitro Produced Goat Embryos by Epididymal Spermatozoa Selected by Swim up Technique ........................................................................................................ 1292
   Sura Shakir Hammood

234. Associations System for Breast Cancer Microarray Data .................................................................................. 1298
   Kain R. Qasim

235. Physico-Mechanical Behavior of Room Temperature Vulcanized Maxillofacial Silicon after Addition of Glass Flakes ........................................................................................................ 1304
   Ghassan Abdul-Hamid Naji *, Mohammed Moudhaffer Ali, Firas Abdulameer Farhan

236. Investigation the Anti-Sterility Role of Ubiquinone-10 Against Procarbazine-Induced Infertility in Male Rats .................................................................................................................. 1311
   Ayyed Hameed Hassan, Wafaa Kadhim Jasim

237. Association of BRCAI Epigenetic, with Breast Cancer .................................................................................. 1317
   Rana S. Jawad, Rafal N. Abbas, Abdul. Ameer N Ghloub Al. Rekabi

238. Evaluation of Hematological Parameters And DHEA-S Hormone Association with Acne In The Province Of Thi-Qar .......................................................................................................................... 1321
   Ayat S. Saleh Ali N. Salman

239. Evaluation of Humoral Immunological Profile in Infertile Women after IVF Failure in Baghdad City ... 1329
   Heba Mohammed Abed Al-Tamimi, Farhan Abood Risan
240. The Socio-Psychological Variables in the Meaning of Self-Consciousness and Movement Satisfaction of Physical Education and Sport Sciences Students

Amer Saeed Jassim, Mustafa Jawad Mraidi, Sanna Jabbar Gatea, Saleh Chuaied Hilaiel

241. Evaluation of Efficacy and Safety of Oral Cyclosporine in the Treatment of Severe Alopecia Areata

Sahar A. Majeed, Asmaa Abdul Jaleel Swadi, Ekhlas Sabah Hassan

242. Removing Methods of Ultracide Residues in Imported Apple Peels in Iraqi Local Markets

Sedik A.K. Al-Hiyaly; Saba Riad Khudhaier; Jazzer, A. J. Al-Temmemi and Ahmed S.A. Al-Tae

243. Perception of Roles as Peer Educators in High Schools to Prevent Drug Abuse among Adolescents

Ira Nurmala, Elisa Dwi Pertiwi, Yuli Puspita Devi, Muthmainnah, Riris Diana R

244. Identification of Recurrent Laryngeal Nerve and Parathyroid Glands Intraoperatively by Methylene Blue Spraying Technique

Zeena Noor eldeen Abdulrahman, Waleed Qahtan Rajab, Zainab Jameel Ali

245. Evaluation of the Mexiletine Effects on Normal Cats’ Electrocardiogram

Alireza Narenjian, Nastaran Rahimi, Seyed Ali Shabestari Asl

246. The Role of BRAF Mutation (V600E) in Papillary Thyroid Carcinoma (PTC)

Azhar Azher M. Al-Ankoshy, Karrar A. Alqershi, Hussein W.S. Rabeea

247. Forensic and Legal Victimology Education: The Actualization of Ethical Values in Law

Djunaedi

248. Risk Factor based on the Type of Stroke at RSUD Dr. Soetomo, Surabaya, Indonesia

Abstract

Aim: To find out causes and factors responsible for the mechanical injuries. Materials & Methodology: This prospective study was conducted at Saraswathi Institute of Medical Sciences, Hapur, from 1st JULY 2017 to 30th JUNE 2018. There were total 306 patients of mechanical injury cases reported to the department of emergency during the study period. Result: Of the total 306 cases 228 (74.51%) cases were male and 78 (25.49%) cases were female. Most susceptible age group was between 21-30 years (30.1%) of age and RTA were the leading cause of death (83.66%).

Key words: Mechanical injuries, Road Traffic accident, Fall from height, Assault

Introduction

India is passing through a major socio-demographic, epidemiological, technological and media transition. The political, economic and social changes have altered the health scenario. In a developing country like India, infectious diseases were the leading cause of mortality in the past decades, but at present, non communicable diseases and traumatic injuries are on the rise. Globally about 5.8 million people die each year as a result of traumatic injuries. [1] Mechanical injuries are injuries produced by mechanical force-blunt, sharp or firearms. The severity and extent of mechanical injuries depend on amount of force delivered to the body- if the weapon deforms or breaks on impact; some energy is spent in deforming or breaking. Lesser energy is thus delivered to the body, injury is less severe. Legal definition of injury- Any harm, whatever illegally, caused to any person in body, mind, reputation or property. [2] A road traffic accident (RTA) can be defined as “an event that occurs on a way or street open to public traffic; resulting in one or more persons being injured or killed where at least one moving vehicle is involved”. [3] Worldwide, every day about 3400 people die due to road traffic accidents (RTA) and predicted to result in death of around 1.9 million people annually by 2020. [4] Among trauma road traffic accidents are one of the major cause of disability and mortality in younger population and projected to the fifth leading contribution to global burden. [5]

Materials & Method

This study was conducted at Saraswathi Institute of Medical Sciences, Hapur, from 1st JULY 2017 to 30th JUNE 2018. There were total 306 patients of mechanical injury cases reported to the department of emergency during the study period. All Mechanical injury cases including Road traffic accidents, assault and fall from height.

Result

In our study, 306 cases of injuries were reported to the Emergency of Saraswathi Institute of Medical sciences (SIMS) Hapur, out of which 74.51% cases were male and 25.49% cases were female. In age group analysis, maximum number of cases was seen in the age group of 21 – 30 years (30.1%), followed by 11 – 20 years (22.9%). Least number of cases was seen in the age group of 0 – 10 years (3.3%) (Table 1). In the present study, majority of cases (68.30%) were from rural background and remaining 31.70% were from urban background (Table 4). In maximum cases the
place of incidence was road comprising of 88.89% cases and least cases of injuries were found happening at work place comprising of 1.96% cases (Table 2). In distribution of nature of injuries, simple injuries were seen in 52.61% of cases and in grievous injuries 47.39% of cases were noted (Table 3). Most of the cases were conscious at the time of arrival (80.39%) (Table 5). Most common type of injury noted was blunt mixed injury (47.71%) (Table 6).

Discussion

During the study period a total of 306 cases of injuries were reported to the Emergency of Saraswathi Institute of Medical sciences (SIMS) Hapur, out of which 74.51 percent cases were male and 25.49 percent cases were female. In age group analysis, maximum number of cases were seen in the age group of 21 – 30 years (30.1%), followed by 11 – 20 years (22.9%). Least number of cases were seen in the age group of 0 – 10 years (3.3%). Out of 306 cases 83.67 percent cases were of Road traffic accidents, 12.41 percent were cases of Assault and 3.92 percent cases of fall from height. The present study is in agreement with the study of Malik Y et al, where maximum incidence took place on road (51%).

In distribution of nature of injuries, simple injuries were seen in 52.61 percent of cases and in grievous injuries 47.39 percent of cases were noted. In the cases of road traffic accident (n=256), simple injuries were seen in 53.12 percent and grievous injury cases were 46.88 percent. In the assault cases, 57.90 percent of cases had simple injury and grievous injury was seen in 42.10 percent of cases. In this study of fall from height, in majority of cases grievous injury (75%) was seen while Simple injuries were seen in 25.00 percent of the cases. The present study results are consistent with study of Kumar S et al, where majority of cases (62%) suffered from grievous injury. [8]

In the present study, Majority of the patients (80.39%) were Conscious at the time of presenting to emergency. Unconscious was noted in 13.40 percent cases and 6.21 percent cases were in Semi conscious condition. In the cases of Road Traffic Accidents (n=256), blunt mixed injuries were reported in maximum (54.29%) cases, followed by abrasion (26.95%) and laceration in 12.50 percent of cases. In the cases of Assault in this study (n=38), blunt mixed injury (34.21%) was reported in maximum number of cases, followed by abrasion in 26.31 percent of cases. In this study out of total 12 cases of fall from Height (n=12), blunt mixed injury (33.33%) was reported in maximum number of cases, followed by abrasion in 25.00 percent of cases. A study, Chakraborty P N et al, done in road traffic accident cases showed maximum number of injuries were of blunt mixed type (91.83%) followed by lacerations (44.38%) and least were of sharp injuries (4.08%) which is in agreement with the present study. [9] The present study is in disagreement with the study of Jaiswal K et al, done in road traffic accidents, where maximum injuries were laceration (53.46%). [10]

Conclusion

This study shows the workload of medico legal cases reporting to the emergency department of this tertiary care hospital. From this study it is clear that Road Traffic accidents are making huge number to the emergency department and hence putting burden on health care system.

Thus recommends:

• Availability of well trained medical and supporting
staff along with well equipped trauma centre round the clock for prompt treatment.

• To post more number of medical and supporting staff on weekends and during evening hours.

• To be well prepared to tackle the large number of cases reporting at the same time.

Apart from above recommendations, incidence of RTA can be decreased by combined efforts from the community, governmental and non-governmental organizations.

Conflicts of Interest: We declare that there is no conflict of interest.

Source of Funding: None

Ethical Clearance: Taken from Saraswathi institute of medical sciences.

Estimation of Age by Modified Gustafson’s Method from Incisor and Canine Teeth

Ajay V Patil¹, Chandrakant M Kokatanur², Vinay S Bannur³

¹Professor, ²Associate Professor, ³Assistant Professor, Department of Forensic Medicine, Krishna Institute of Medical Sciences Karad, Maharashtra,

Background: Estimating age from teeth is generally reliable as they are naturally preserved long after all the tissues and even bones have disintegrated. Aim of the study: The present study was an attempt to estimate the age of an individual by using modified Gustafson’s method from age related alteration in incisors and canines in Karad. Materials and methods: A cross sectional study was conducted in Karad for a period of 4 months from Nov 2018 to Feb 2019. Results: 95 teeth were observed, out of which 59 were incisors and 36 canines. The coefficient of variations among parameters ranged from 22.61 to 29.92%. Conclusion: - The estimated age error was minimized to 1.15 years. The age calculated by this method was found to be more accurate, reliable and reproducible.

Keywords: Age, tooth, incisor, canine, attrition, secondary dentin, cementum apposition.

Introduction

Identification of the person is of paramount importance in forensic practice. Age estimation is one of the important factors employed to establish identity. Estimating age from teeth is generally reliable as they are naturally preserved long after all the tissues and even bones have disintegrated¹⁻⁵. Recent natural disasters like earth quakes in different states of India, world trade center attack etc. has brought in to focus the importance of teeth in determination of age of an individual and thus helping in their identification. Age estimation from the teeth may be the only useful method especially when the skull is only available as skeletal remains⁶.

In children age estimation from the teeth is relatively simple and accurate. For adults, the methods are often based on degenerative modifications, such as attrition, periodontosis, transparency of the root, secondary dentin, cementum apposition and root resorption⁷⁻¹⁰. With the lack of quantification in the Gustafson’s system, modified method which is based on the quantitative evaluation of four parameters: the attrition, the secondary dentine, cementum apposition and the transparency of root was used to estimate age where standard error of ± 1.50 years was claimed⁶, ⁷. In this study incisors and canines were used as these are less affected by pathological conditions such as caries as compared to the molars and premolars.

Aims and objective:

To estimate the age of an individual by using modified Gustafson’s method from age related alteration in incisors and canines in Karad.

Material and Method

A cross sectional study was conducted in department of Forensic medicine and Toxicology, Krishna institute of medical sciences, Karad for a period of 4 months from Nov 2018 to Feb 2019. Criteria for selection of specimen (Incisors and canines) were the tooth should be caries free and should not have either root or crown fracture.

The incisors and canine were collected from known cadavers between the age group of 20 to 70 years dissected by medical students in the department of Anatomy, Krishna institute of medical sciences, Karad. They were cleaned under tap water and then kept in 10% formalin for 24 to 48 hours. The sample bottles were labeled with actual age of the person from whom the specimen was collected and also labeled to the type of
Prior to grinding, incisors and canines were kept in water. Then 1-2 mm sections were prepared to the central axis of each tooth symmetrically from both sides using the rough carborundum stone grinder with supplementation of continuous water flow from an IV set to reduce the heat produced during grinding. Precautions to avoid cracks and cleavages were taken during grinding of tooth.

After grinding the tooth up to 2 mm, the section of 0.1 mm thickness was prepared on the Arkansas stone. The Arkansas stone was kept in enamel tray containing water. The grinding action was only in one direction to avoid irregularities in sections.

Following dehydration, tooth sections were mounted on glass slides with DPX mountant for microscopic observations. The microscopic parameters were observed at the magnification of 0.25 using light microscope.

**Principles:**

The formulae of the various index values for each parameter are as follows.

Each index value of the various parameters undergoing regressive changes were calculated by relating the measured change to a fixed measurement on the tooth. The changes in the various tooth parameters were due to functional changes along with age.

1. **Attrition (A):**

   \[
   [A] = \frac{a}{A} \times 100
   \]

   ‘a’ is width of the tooth in mm at tip showing attrition.

   ‘A’ is the width of the tooth in mm at cervical margin.

2. **Secondary Dentin (D):**

   The index value of secondary dentin was measured as percentile value of secondary dentin deposited and the total length of pulp cavity.

   \[
   [D] = \frac{d}{D} \times 100
   \]

   ‘d’ is length in mm of secondary dentin deposition in the pulp cavity.

   ‘D’ is the length of entire pulp cavity of the tooth.

3. **Translucency of the root (T):**

   \[
   [T] = \frac{t}{T} \times 100
   \]

   ‘t’ is the length in mm of the translucent region of the root.

   ‘T’ is the length in mm of the entire tooth.
Measurement of parameters:

This is known as modified Gustafson’s formula for age determination from tooth which was used in the present study. The data was collected and analysed with SPSS 20 Statistical Software and presented as descriptive statistics. The efficacy of proposed modified Gustafson’s method in relation with actual age was assessed by computing mean, coefficient of correlation and student t test.

The average age was calculated from different index values and it was estimated as

\[
\text{Age} = \frac{(A) + (D) + (T) + (CE)}{4}
\]

Discussion

In the present study, total of 95 teeth were observed, out of which 59 were incisors and 36 canines. Attrition, secondary dentin, root translucency and cementum apposition were four parameters used in calculating the age of an individual. The coefficient of variations among parameters ranged from 22.61 to 29.92%. The variations are biologically induced variations. They are interrelated with each other. The extent of variation among the observation for actual age and estimated age was almost same.

The relationship between actual age (AA), attrition (ATT), secondary dentin (SD), root translucency (T), cementum apposition (CE) and estimated age (EA) was expressed in the form of correlation of coefficient (r). All the values of (r) obtained were positive indicating the positive correlation between various parameters. There is significant positive correlation between age and index value of all four parameters as shown in table no 3. Both the values of actual age and estimated age showed a similar trend regarding its relationship with attrition, secondary dentin, root translucency, cementum apposition.

The difference between the actual age and estimated age was insignificant from statistical t test (p > 0.05). So on the basis of values obtained from correlation of coefficient and t test it is confirmed that the age of the subject can be safely calculated by the modified Gustafson’s method.

Index value of attrition was ranging from 13.99 to 57.62, with a mean 39.28 and standard deviation ± 11.12. The value of r = 0.927 between actual age and attrition represented a significant correlation coefficient at 0.001 level. Though attrition varies according to functional variation, it can be used as a reliable index in age estimation. From the present study, it can be concluded that root translucency above the age of thirty can be a valuable criterion in age estimation. Root translucency can be used as a sole criterion only when the remains consist of root portion. But more accuracy can be obtained when root translucency is used with other three criteria.

In this study, index value for cementum apposition ranged from 10.06 to 64.13 with mean of 35.39. Value for correlation coefficient among actual age and cementum apposition is (r=0.2089) which shows positive correlation.

Though a number of modifications have been suggested by investigators, the modified Gustafson’s method still remains the most reliable method in determination of age from tooth. The findings of the present study are in accordance with this.

After complete evaluation of this method, it can be stated that the root translucency and secondary dentin can only be used in estimation of age of an individual, because these two criteria show a simultaneous increase as the age advances. Most commonly affected criterion by pathology is the attrition and cementum apposition. So it is stated that, though no one of the four criteria can be used alone, all four are useful if used in combination. The estimation of changes should be evaluated. For example: in the cases of attrition, occlusion and articulation must be taken into consideration. Their variations are in the old age individual depending upon factors, such as periodontal conditions and habits.
5. Estimated age:

</tbody>
</table>

In the present study, the estimated age error was minimized to 1.15 years. Thus the age calculated by this method was found to be more accurate, reliable and reproducible.

Conclusion

The present study showed that the correlation coefficient between actual age and various parameters was found to be significant. The estimated age error was minimized to 1.15 years. Thus the age calculated by this method was found to be more accurate, reliable and reproducible.

Study of Demographic Pattern of Poisoning in Patients Presenting to Emergency Department of a Tertiary Care Centre, SIMS, Hapur

Gurdeep Singh1, Barakha Gupta2, Sumit Tellewar3, Vishwajeet Singh4, Abhishek Sharma1
1Post-Graduate, 2Professor, 3Associate Professor, 4Assistant Professor, Department of Forensic Medicine & Toxicology, Saraswathi Institute of Medical Sciences, Hapur, UP, India

Abstract
Poisoning is a common medical emergency and one of the important cause of mortality and morbidity in developing countries like India due to easy availability of poisonous substances and its low cost. This study was carried out on poisoning cases reported to casualty of Saraswathi Institute of Medical Sciences, Hapur, UP in eighteen-months duration from 1st January 2017 to 30th June 2018. In this study, incidence was more among men (58.70%) compared to women (41.30%) and maximum cases were of age group 21 – 30 years (48.91%). More cases from rural area (89.13%) were reported and highest number of poisoning cases were admitted in the month of June 2018 (10.87%) followed by May 2017 (8.70%). Maximum cases (60.87 %) reported to casualty between 8am to 4pm. Aluminium phosphide poisoning (44.26%) constituted the highest number of cases and in maximum cases manner of poisoning was of suicidal in nature (59.78%). Majority of cases 53.26% were discharged after improvement and 3.26% cases died.

Key Words: Poisoning, Mortality, Sociodemographic profile, Agrochemical poisons.

Introduction
The word poison has been evolved from Latin word potion i.e. to drink for health. Poison is defined as any substance (solid, liquid or gaseous) which if introduced in the living body or brought into contact with any part thereof will produce ill-health or death by its constitutional or local effects or both. [1]

National Poisons Information centre (NPIC), New Delhi, received a total of 2719 poison calls over a period of 3 years (April 1999-March 2002). The age of victims ranged from <1 to 70 years, with the highest incidence in the range of 14-40 years, with males (57%) outnumbering females (43%). The most common mode of poisoning was suicidal (53%), followed by accidental (47%). [2]

According to WHO data, in 2012 an estimated 1,93,460 people died worldwide from unintentional poisoning. Of these deaths, 84% occurred in low- and middle-income countries. In the same year, unintentional poisoning caused the loss of over 10.7 million years of healthy life. [3]

Everyday around the world almost 700 people die from the poisoning and several thousands more are affected by poisoning, of this 90% of fatal poisoning occurs in developing countries like southeast Asia particularly among agriculture workers. [4]

Aims and Objective
1. To analyse pattern of poisoning cases in patients presenting to Emergency department of Tertiary health care center, Saraswathi Institute of Medical Sciences, Hapur.

2. To study demographic variables of poisoning cases.

3. To study the nature, pattern & magnitude of the morbidity and mortality due to poisoning.
Material and Method

The study was conducted at Saraswathi Institute of Medical Sciences, Hapur, from 1st January 2017 to 30th June 2018. Total 92 patients of poisoning were reported to the department of emergency during the study period. A detailed history was taken from patient, patient relatives and relevant data of the individual poisoning cases were collected from medicolegal cases register of casualty and case papers from concerned department.

Observation and Results

In our study, out of total 92 poisoning cases 58.70% were males and 41.30% were females. Male female ratio was 1.42: 1. (Table 1)

Maximum incidence was seen in the age group of 21 – 30 years (48.91%). (Table2)

The rural population (89.13%) was affected more both in males and females. (Table 3)

Maximum cases (60.87 %) reported to casualty between 8am to 4pm. (Table 4)

In this study, it was observed that 66.30% of cases gave history of known poisoning while 33.70% gave history of unknown poisoning at the time of admission to casualty. Out of total 61 cases of known poisoning it was observed that Aluminium phosphide (44.26%) constituted the maximum number of cases followed by Rat Poison (14.75%) and Mosquito Poison (14.75%). (Table 5)

More number of suicidal and accidental poisoning was seen in male than female. Homicidal poisoning was only observed in females. (Table 6)

Maximum number of poisoning cases (53.26%) was discharged after improvement. (Table 7)

Discussion

Pesticide poisoning is a major health problem in India. Aluminium Phosphide is an effective fumigant and rodenticide and used extensively in India. Acute poisoning from these poisonous substances is one of the commonest causes of emergency hospital admissions.

During the study period 92 poisoning cases were admitted in the Emergency of SIMS, out of which 58.70% were males and 41.30% were females. This finding in the study is in agreement with the study of Md Ziya Ahmad et al[5] in which more cases were of males as compared to females. The reason for more number of male cases is more exposure to harmful poisonous substance in occupation, more stress and strain due to financial burden of the family.

In present study majority of cases were seen in the age group of 21 – 30 years (48.91%) followed by 11 – 20 years (32.61%). This finding is agreement with the finding of Hareesh. S. Gouda et al[6], in which, incidence was highest in age group 21 – 30 years (38.60%) followed by 11 – 20 years (35.08%). Higher incidence of poisoning in the younger age group of 21 – 30 years is reflective of the social causes like failure in love, failure in examinations, stress of the modern life style and scolding from parents or teachers.

The current study shows that rural population (89.13%) was more affected than urban (10.87%). In female incidence of cases in rural area was more as compared to male. These results are in agreement with study of Md Ziya Ahmad et al[5], Hareesh. S. Gouda et al[6] and Barkha Gupta et al[7] who also show rural population to be more affected than urban population. It can be concluded that the rural areas, having increased farming activities, agricultural and domestic use of insecticidal compounds

In the present study, maximum number of cases 56 (60.87 %) reported to casualty between 8am to 4pm. These results are consistent with study of Vivek Gopinathan et al[8], as time of poisoning in majority of cases (39%) was observed during day.

In the present study, history of known poisoning was noted in 66.30% cases and unknown poisoning in 33.70% cases. Out of total poisoning cases Aluminium phosphide was the leading cause of poisoning. Aluminium phosphide poisoning (44.26%) constituted the highest number of cases followed by Rat poison (14.75%) and Mosquito poison (14.75%). The results of present study are consistent with study of R K Mathur et al[9] as Aluminium phosphide was the most common poison (19.71%), leading to maximum fatalities.

In the present study incidence of suicidal cases (59.78%) were highest followed by accidental (38.04%). The present figure is in agreement with Md Ziya Ahmad et al[5] where majority of patients 79.23% consumed poison with suicidal intent as compared with 20.76% of the patient exposed accidentally. Reasons are inability to face adverse situations in life like unemployment in spite of being graduates, failure in love and examinations, failure of crops, family disputes, poverty, mental instability etc.

The present study reveals that most of patient had a shorter stay in the hospital. 53.26% were discharged after improvement while 15.22% cases were referred to higher centres. In present study mortality rate was 3.26% and all these cases were of Aluminium Phosphide poisoning. This observation is in the agreement with the study of Prashant Gupta et al[10] in which 78.4% cases were discharged after improvement.
Conclusion

The present study includes 92 cases of alleged poisoning during the study period from January 2017 to June 2018, conducted at Emergency department of Saraswathi Institute of Medical Sciences.

- The present study indicates that younger age and males are at higher risk for suicidal poisoning. Poisoning is an important preventable public health problem especially in the developing countries.
- To decrease the incidence, mortality and morbidity of the poisoning cases following precautions and measures should be taken -
  - The farmers should be educated regarding the appropriate measures which needs to be taken in cases of accidental exposure.
  - The face and hands should be thoroughly washed with soap and water after handling toxic agrochemicals.
  - Strict rules and regulations over the sale of insecticides, rodenticides and pesticides should be formulated.

Conflict of Interest: We declare that there is no conflict of interest.

Forensic Evaluation of Various Osteometric Parameters of Human Mandible in both Sexes

Priyamvada Kurveti1, Gyanendra Kumar2, Dheeraj Singh Verma3, Jayanthi Yadav4, B. P. Dubey5

1Assistant Professor, 2Ex Resident, Dept. of Forensic Medicine and Toxicology, Gandhi Medical College, Bhopal, Presently Assistant Professor, Late Baliram Kashyap Govt. Medical College, Jagdalpur, Chattisgarh, 3Demonstrator, Dept. of Forensic Medicine and Toxicology, Gandhi Medical College, Bhopal, 4Ex Professor and Head, Dept. of Forensic Medicine and Toxicology, Gandhi Medical College, Bhopal, Presently Additional Professor, Dept. of Forensic Medicine and Toxicology, AIIMS, Bhopal, 5Ex Professor and Head, Dept. of Forensic Medicine and Toxicology and Ex Dean, Gandhi Medical College, Bhopal, Presently Dean, L. N. Medical College, Bhopal

Abstract

Identification of sex could be made on differences in the size and shape of the morphological markers i.e. shapes of chin, size of condyles etc. Morphological traits are more subjective and sex determination depends on experience of the investigator. So, visual methods of sexing mandible are likely to be inaccurate when performed by an inexperienced worker and sometimes produce misleading results. Hence, metric analyses are found to of superior value owing to their objectivity, accuracy, reproducibility and lower incidence of inter and intra observer errors as compared to that of descriptive traits.

The focus on present study is to use morpho-metric analytical method to evaluate the ability of selected parameters to determine sex in forensic sample.

Aims and Objectives: To study the various osteometric parameters of human mandible and evaluate their utility in sex determination

Material and Method: Some measurements of the 200 mandibles were taken using sliding calliper and mandibulometer and statistically analysed.

Findings: On statistical analysis, it is found that height of the symphysis menti, bigonial width, shows a higher index of sexual dimorphism. Hence, these can be used for determination of sex. Other parameters such as bicondylar width, mandibular angle are found to be statistically insignificant in this study.

Conclusion: When the findings of present study were compared with those of past investigators, marked variations in the various osteometric parameters of mandible was noticed, which differed all over the world as well as in different regions of India. Hence, it is suggested, not to apply the findings of study of one region over the samples of other region, to avoid fallacies.

Keywords: symphysis menti, bigonial width, bicondylar width, mandibular angle

Introduction

100 % accuracy in determining sex could be achieved if entire skeleton is available (Krogman1946). But problems arise, when either incomplete or fragmentary remains of skeleton are brought for examination. Then it depends largely on the available parts of the skeleton. A number of literatures have shown sexual dimorphism in
almost every bone of human skeleton. As evident from the past studies, skull is the most dimorphic and easily sexed portion of skeleton after pelvis, providing accuracy up to 92%. But in cases, where intact skull is not found, mandible may play a vital role in sex determination, as it is the most dimorphic bone of the skull.

Identification of sex could be made on differences in the size and shape of the morphological markers i.e. Shape of chin, size of condyles etc. Morphological traits are more subjective and sex determination depends on experience of the investigator, so visual methods of sexing mandible are likely to be inaccurate when performed by an inexperienced worker and sometimes produce misleading results. Hence, metric analyses are found to of superior value owing to their objectivity, accuracy, reproducibility and lower incidence of inter and intra observer errors as compared to that of descriptive traits.

The focus on present study is to use morpho-metric analytical method to investigate the sexual dimorphism and to evaluate the ability of selected parameters to determine sex in forensic context.

**Material & Method**

The present study was undertaken in the Department of Forensic Medicine and Toxicology, Gandhi Medical College Bhopal. 200 mandibles were measured, of which 130 were male and 70 were female. All the pathological, deformed and fractured mandibles were excluded from the study. The numbers of female samples were limited, because all sample were forensic cases and the female skeleton brought for examination are limited.

**For sex determination, following point was taken into consideration** –

1. Size – larger / thicker heavier in male, smaller, thinner lighter in female.
2. Surface – smooth relatively in female and rugged in female.
3. Shape of chin – square shaped in males and pointed or rounded (U shaped) in females.
4. Condyles – bigger and larger in male and smaller in females.

Allotment of mandibles to different sexes was carried out by experts in the department, namely, forensic medicine experts and forensic anthropologists.

**Instruments used for taking measurements** – were sliding caliper and mandibulometer.

Of the various measurements of mandible mentioned in different standard anthropological studies, 4 anthropometric parameters were selected (Table-II). To ensure familiarities of reference and forensic anthropologist alike, landmarks were selected to correspond closely to those common in both traditional and geometric morphometric studies,(Table- I) To minimize the intra observer error, all the measurements are taken with sliding caliper (0.1 mm precision) 3 times and the average value were utilized for the analysis.

</table>
Statistical methods used for analysis were as follows:

**Index of Sexual dimorphism (ISD)**

ISD = Mean value of Male / Mean value of female X 100.

It indicates the level of difference between sexes; values close to hundred indicate low level of sexual difference and on the other hand the level of sexual difference increases with the increase of the distance from hundred.

1. **Mean**

Arithmetic mean was calculated by dividing the total number of individual observations by number of cases

\[ \text{Mean} = \frac{\sum x}{n} \]

Where \( \sum x \) = summation of individual observation,

\( n \) = number of cases

2. **Standard Deviation**

It is the square root of the arithmetic average of the square of the difference between the observations and their mean. The formula is as follows:

\[ \text{S.D.} = \sqrt{\frac{\sum (x - x)^2}{n}} \]

Where \( \sum (x-x)^2 \) = Summation of each squared deviation

\( n \) = number of cases

3. **Level of Significance (‘t’ test)**

This test was used to find out any significant difference between the means of different groups. It was calculated by the formula, given below:

\[ \text{S.E.}(d) = \sqrt{\frac{(S.D.1)^2}{n1} + \frac{(S.D.2)^2}{n2}} \]

Where S.E. (d) = Standard error of difference

\( S.D.1 \) & \( S.D.2 \) = Standard deviations of observations in two samples

\( n1 \) & \( n2 \) = No. of cases in the 2 samples

**Probability( P value )**

\( P<0.001 \) = extremely significant

\( P<0.01 \) = very significant

\( P < 0.05 \) = significant

\( P>0.05 \) = not significant
Findings

The data is represented in the master chart, the observation were statistically analysed and the results obtained were compared with the findings mentioned in pre-existing literature.

1. Height of Symphysis Menti

Mean of symphysis menti height for males is found to be 30.1508 with a standard deviation of 4.0136; and that of females is 28.4672 with a standard deviation of 2.4168. P value obtained for the parameter is <0.001 that means the difference between the two variables is extremely significant. Also the ISD is above 100, which shows the significant level of sexual differences between two means. In the study conducted by Fabien and Mpembeni in the year 2002, on 25 male and 25 females; they found this parameter to be statistically significant and a reliable parameter for sex determination. Ionescu et al (2007) in his study on 50 male and 50 female mandibles have also found this parameter to be statistically significant.

Similar finding was observed by Corici et al in 2009 in his study conducted on 80 dry specimen of mandibles.

2. Bigonial Width

The mean for this parameter is 98.5049 with a standard deviation of 5.8765; and for females mean found is 93.3166 with standard deviation of 5.4786. Probability level of P < 0.001 is obtained, showing an extremely significant statistical difference. Also, ISD is above 100, meaning the level of sexual difference for this parameter is significant.

Similarly, in 2002, Fabien and Mpembeni in their study of sexual dimorphism in 25 male and 25 female mandibles of homogenous black population of Tanzania; found this parameter to be statistically insignificant.

But, the finding in the present study is in contradiction with a study carried out by Ionescu et al in the year 2007 on 50 male and 50 female mandibles; that showed the bicondylar width to be a statistically significant parameter.

3. Bicondylar Width

The mean obtained for this parameter in males is 111.4213 with a standard deviation of 7.9183; and that for female is 110.4887 with standard deviation of 6.0136. In this case, p = 0.39, which is insignificant, also ISD obtained is just few decimal points above 100. Hence, it can be concluded by these observations that, this parameter is not that significant statistically.

Also, Ionescu et al in 2007 while studying sexual dimorphism in mandible, using 25 male and 25 female samples, found this parameter to be statistically significant.

Badiu et al in his study on 80 preserved adult skull with matching mandibles in 2010 found that this parameter to be extremely significant statistically and having a higher ISD. He stated that “the bigonial width could be used for sex determination of an unidentified skull.”
4. Mandibular Angle

As observed in the present study, the mean + standard deviation for male on right side is 122.8672 + 4.2976; on left side, 122.7861 + 4.2472. For females, on right side, the mean is 124.7661 with a standard deviation of 4.0974; on left side, the mean and standard deviation are 124.6760 and 4.0471 respectively. Also, ISD is below 100, which gives an indication that the level of sexual difference is insignificant. But, on comparing means of male and female in adult and elderly age group separately, though the difference is statistically significant (p< 0.001), but the ISD calculated is below 100, indicating that the level of sexual difference for this parameter is insignificant.

Similarly, Ionescu et al\(^6\) in the year 2007 in his study on 25 male and 25 female mandibles found this parameter to be insignificant to study sexual dimorphism. This finding is also supported by the study of Oettle et al (2006)\(^10\) who stated that “In the assessment of human remains, the mandibular angle is not very usable in determining sex.” Loth and Henneberg (2000)\(^8\) in their study have shown that the gonial form has a highly heritable component that appears to be associated with overall facial architecture and determining sex using this trait has an accuracy of only 45 %

On the contrary, Acsadi and Nemeskeri (1970)\(^1\) and Novotny et al (1993)\(^9\) stated the gonial eversion to be a sex marker for adults. Same is also considered a male characteristic by Ferembach et al (1980)\(^4\)

When the findings of present study were compared with those of past investigators, marked variations in the various osteometric parameters of mandible was noticed, which differed all over the world as well as in different regions of India. Hence, it is suggested, not to apply the findings of study of one region over the samples of other region, to avoid fallacies. It is also recommended, to carry out more studies incorporating a larger sample; to make the data more precise and useful in terms of anthropological and medico-legal application.

An Autopsy Study of Drowning Deaths in and around Visakhapatnam

Raja Sekhar Uppu¹, BVS Ananda Rao², Beemsetty Rajesh³

¹Associate Professor, Department of Forensic Medicine and Toxicology, GVP IHC & MT, ²Assistant Professor, Department of Forensic Medicine and Toxicology, GIMSR, ³Professor, Department of Forensic Medicine, KMCT Medical College, Manassery, Kozhikode

Abstract

Introduction: According to World Health Organisation, drowning is among the ten leading causes of death for children and young people in every region of the world. Drowning amounts to an estimated incidence of about 5.6 per 100,000 of population worldwide. This study is aimed to know the incidence, manner and epidemiology of deaths due to drowning in and around Visakhapatnam.

Materials and Method: It is a one year prospective post-mortem study of drowning in and around Visakhapatnam. All the deaths due to drowning that were autopsied at the mortuary, KGH, Visakhapatnam were studied based on inquest, post mortem examination findings to know the profile of drowning deaths.

Results and Conclusion: Out of 1675 total autopsies done at our centre during the study period, 79 bodies that are found in water are studied. Males in the age group of 21-30 are the most common victims. Sea water drowning amounted for most cases of drowning in contrary to other studies. About 58% of cases of drowning were during the day. Most number of drowning deaths occurred in the month of October and monsoon season. Accidental drowning is the most common manner of death in males and suicidal manner in female drowning victims. About 32% of drowning victims in the study are from low socio-economic status. Most of the female victims are married while male victims are unmarried.

Keywords: Drowning, Sea water drowning, season, manner of death, Socio economic status.

Introduction

According to the World Health Organization, drowning is defined as “The process of experiencing respiratory impairment from submersion/immersion in liquid”¹. India is a vast country having abundant of water supplies from rivers, ponds, wells and an extensive seacoast. The world incidence of death by drowning is estimated at about 5.6 per 100,000 of population². About 150,000 people die from drowning each year around the world³. In 2013, all India survey made by the National crime record bureau (NCRB) showed 8% of total unnatural deaths are due to drowning⁴. 25% occur in the sea and the rest in inland waters; the majority of victims are young adults and children⁵; two-third is accidental and one-third is suicidal; homicide by drowning is rare⁶. All unattended drowning cases should be presumed homicide until proven otherwise⁷. Drowning and alcohol intoxication may represent accidents or suicides. In suicidal attempts by drowning, the suicidal attempter often leaves behind a letter or a phone call before departing to jump into the water. Homicidal drowning is uncommon and requires either physical disparity between the assailant and the victim or a victim incapacitated by disease, drink or drugs or taken by surprise⁸. Disposal in water may be attempted where the victim has already been killed by other means⁹.

Aim of the Study

To study and analyze the incidence, epidemiology,
manner and the circumstances of drowning deaths reported in and around Visakhapatnam.

**Materials and Method**

In this study, all the autopsies done on persons died due to drowning are studied based on the requisition for conduct of autopsy, the inquest report (panchanama), the post-mortem examination and the clinical record (Hospital data) in certain cases were used to relate, correlate and to substantiate after ruling out other causes of death.

First charts were made for collecting all the information regarding the drowned body entering the details regarding age, sex, marital status, medium of immersion, history from inquest etc.,

Then individual information charts were prepared such as month wise distribution, age, sex, occupation, marital status, medium of drowning, timing and manner of drowning. Out of them the possible number of bar graphs, and pie charts were drawn to show the statistical trends in drowning.

**Observations & Discussion**

In the study year, a total of 1684 autopsies were done. Among these, the drowning cases reported amounts for 79 cases i.e., a percentage of 5 cases of all post-mortem examinations. The number of drowning cases occupy the sixth place among the 10 most common or frequently encountered cases during study period as shown in the bar diagram 1. It amounted to about 35% of all asphyxial deaths.

Diagram 1: A Bar diagram showing Number of different autopsy cases based on cause of death during study period

During the study period, the number of cases of drowning that is reported show a male preponderance. As it is evident that nearly 76% of drowning deaths have occurred in males as opposed to a mere 24% in females. These figures further establish and correspond with the already existing data regarding more number of drowning deaths in male

The study of age highlights that the maximum number of cases were reported in 21-30 years group i.e., 26.5% and closely competed by 31-40 and 11-20 respectively with 23 and 20%. In both males and females, the highest number of victims is from the age group of 21-30 years with 27% and 26% of cases respectively. The study further confirms and more or less matches the already established figures of previous studies in India. The maximum number of cases occurred between 15 and 25 years of age in males there by establishing the exuberance, excitement and eagerness among the youth coupled with zeal for adventure. Whereas in females, most number of cases encountered were aged between 21-35 years. There are very minimal or negligible numbers of cases in age groups 1-10, 61-70 and 71-80.

Diagram 2: A Bar diagram showing Age wise distribution of cases of deaths due to Drowning.

A large number of drowning deaths have occurred in the month of March, August and October i.e., summer month of March and monsoon months of August and October. The summer and monsoon seasons almost matched each other nearing 37% and 43% cases respectively. The summer and monsoon seasons have almost 80% of deaths occurred due to drowning. This phenomenon is denoted by the holiday season in summer, when a large number indulge in adventurous exploits and monsoon draws one towards adventure and is as well occupation related. These findings are similar to those in Phad and Dhawane study.

In our study we have found that sea water is the main culprit which amounts to 64%, fresh water 25% and alternate media for 11% of drowning deaths. There is gross disparity between the existing data and our study data where the figures are reversed in relation to sea water over freshwater drowning. The main reason to be attributed to this statistic is the vast and expansive coast, easy accessibility to the sea, dependence on sea as a vocational resource, adventure and related professional pursuits.

The manner of death in cases of drowning is of prime importance. In the study, the maximum number of deaths that were reported as drowning are as a result of an accident, next in order is suicides and one case registered as homicide although a handsome number of cases which are listed as undetermined amount to 11 i.e., nearly 20% of sum. The manner at inquest and based on circumstances, drowning deaths show accidental (41 cases i.e., 68%) as most common manner in males and suicidal (10 cases 53%) as most common manner in females. These findings are in contrary to other studies.

Another important aspect of our study is to determine the relation of time with drowning deaths. A vast number of cases of drowning were reported during day time, a 15% of cases were reported during night and in about 25% of cases it appeared that the time of occurrence of the incident remained indeterminate upon inquest and circumstances.

The occupation and its relation to drowning deaths is studied based on inquest which showed a large number of accidental deaths due to drowning were seen in labourers or coolies is 25 cases i.e., 32%, fishermen is 6 cases i.e., 8% and officials 9 of which 3 cases were a result of accidental drowning at work i.e., 30%. The other indicators (occupations) students, officials, no occupation have been usually suicides and that too the large chunk of the unemployed being women.

The analysis of Table 5 points to almost an equal number of deaths due to drowning in married a well as unmarried males. Coming to the female sex, the number of cases of drowning among married women was reported at 9 cases while those of unmarried women amounts to 4 such cases, similarly owing to the non-establishment of identity i.e., 6 out of 60 in males and 6 out of 19 in females, their marital status could not be assessed. Of the unmarried males, the manner of such deaths was usually accidents and a few suicides, but in the females who were reportedly unmarried most of the deaths could be attributed to suicides.

**Conclusion**

From this study it is evident that drowning amounts to significant number of deaths in young males in the age group of 21-30 years. Sea water is the commonest source of drowning medium in this study. Most of the drowning deaths occurred during day time. Most of the victims died accidentally and are labourers which denotes the lack of safety measures in the fishing industry from which they belong and the necessity of improving the safety of fisherman by providing them with safety equipment. All people particularly school going children and college going youth should be made aware of the rules of safety near and while in water and the authorities has to improve the safety at beaches by commissioning the rescue teams after identifying the places with high activity and saving these young victims. Provision of mechanical boats, monitoring systems, systems of surveillance will go a long way in aiding accident struck victims.

**Ethical Clearance:** There were no ethical issues involved as the study was analytical and did not violate any ethical principles.

Morphologic and Radiographic Effects of Acids on the Teeth: An in-Vitro Forensic Study

Kushdeep Kumar Gupta¹, Abraham Johnson²

¹Postgraduate Student, ²Assistant Professor, Laboratory of Forensic Odontology, Institute of Forensic Science, Gujarat Forensic Sciences University, Gandhinagar, Gujarat, India

Abstract

Background: Teeth are generally considered as the most durable structures that resist physical, chemical and biological insults than skeletal tissue. Human identification through dental remains is of prime importance when the remains are found in chemical accidents such as acid attacks or uneventful accident in chemical industries, where soft tissues cannot provide reliable information. Proper examination and analysis of dental remains can provide vital information in forensic context.

Objective: The present study aims to evaluate the morphology and radiographic features of teeth after exposure to highly acidic environment.

Material and Method: A sample of total 80 extracted permanent teeth was used. Teeth were exposed to different acidic conditions like - 35% hydrochloric acid (30ml), 69% nitric acid (30ml), 98% sulphuric acid (30ml), 85% phosphoric acid (30ml) at intervals of 30 min, 1 hr, 2 hr, 4 hr, 8 hr, 16 hr and 24 hr. Before and after exposure to acids, radiographic and stereomicroscopic images were taken.

Results: The effect of acids on teeth depends on various factors such as the type and concentration of the acid, and also the time period. The morphological and radiological changes normally includes - changes in dimensional stability, changes in texture and colour, changes in the appearance of fissures and cracks and also appearance of the fracture and fragmentation of the samples.

Conclusion: Teeth can serve as a tool in identification of the victim when in contact with acidic condition. Hydrochloric acid, nitric acid and sulfuric acid cause changes in the teeth and it is possible to deduce the approximate duration for which a body has been immersed in acid based on the changes observed. The characteristics of teeth may be of assistance in cases of human identification where soft tissue features are unavailable.

Keywords: Acids, stereomicroscope, dental identification, teeth, forensic odontology.

Introduction

Forensic odontology has now evolved among the intriguing branches of forensic sciences over the past few years. Forensic dentistry contributes well by way of reconstruction through dental structures. The forensic odontologist mainly deals with the identification based on recognition of unique features present in an individual’s oral structures.¹

Teeth normally survives in most natural disasters and are a possible tool for personal identification of an otherwise unrecognizable body.² Teeth can survive in extreme climatic condition because enamel is the hardest substance in the body being 96% mineralized, compared to bone which is approximately 70% mineralized.³ The posterior teeth are well protected by soft tissues like the

tongue, facial musculature, and adipose tissue. Due to its hard structural integrity it survives prolonged immersion, decomposition, desiccation, extensive trauma, and direct heat in excess of 1000°F.

In chemical accidents, the hard tissues including the skeletal structures are destroyed completely and soft tissues cannot provide reliable information, hence thereby rendering a challenge for identification of the individual. Moreover, there is an apparent lack of data on radiographic alterations along with morphologic changes in teeth at various acids which necessitates study in this area.

The purpose of the study was to identify the acid that may be used by criminals for destruction of hard tissue – teeth and to find out the approximate time taken for total destruction of tooth after immersion in an acid. The objective was to observe the stereomicroscopic and radiographic changes.

**Material and Method**

Eighty extracted human natural teeth were obtained for an in-vitro experimental study.

All teeth were non-carious and had been extracted for orthodontic treatment or periodontal reason. Before exposing to various acids, teeth used for the study were rinsed thoroughly in tap water and cleaned with a toothbrush in order to remove any soft tissue and later were disinfected by using 10% formalin. Deposits of calculus were removed using a manual scaler.

Thirty-five percent hydrochloric acid (conc. HCl), 69% nitric acid (conc. HNO3), 98% sulfuric acid (conc. H2SO4) and 85% Phosphoric Acid (conc. H3PO4) are used in this study.

Twenty samples were immersed in 30 ml of each acid solution and were observed for 24 hours. Teeth were retrieved at intervals of 30 min, 1 hr, 2 hr, 4 hr, 8 hr, 16 hr and 24 hours from the acidic environment, washed in distilled water, dried, photographed, and later radiographed. Each of specimen’s morphology was observed under a stereomicroscope at 15X magnifications (Zeiss Stemi DV4 Stereo Zoom Microscope) at time intervals of 30 min, 1 hr, 2 hr, 4 hr, 8 hr, 16 hr and 24 hours. The macroscopic and radiographic changes were well noted.

**Results**

The teeth samples that were subjected in 30 ml of 35% hydrochloric acid (conc. HCl) showed following morphological and radiographic changes. (Table -1) (Figure-1)

**Discussion**

This study justified that the natural teeth are the most durable of all the living tissues as they persist by chemical agents.

Teeth can be used as a source of evidence in cases of human identification, especially those cases where the soft tissues are unavailable as a possible identification tool. 5, 6

In this study, the morphologic and radiographic changes were observed to the teeth exposed to varied acidic medium. From this experimental study, we could conclude that teeth do not react in the same way in all acids.

In case of 35%HCl and 69% HNO₃ the teeth were completely dissolved but in HNO₃ medium, the color change in the form of the yellow colored deposit was mainly because of the nitrate formed in the chemical reaction and in \( \text{H}_2\text{SO}_4 \) and \( \text{H}_3\text{PO}_4 \) there was no dissolution; instead, a white precipitate was formed because of the formation of a non-soluble salt. Thus, there are clear differences in the destructive capacities of the different acids.

Recognizable morphological and radiographical appearances of teeth persisted for 8 hr. in HCl but Raj et al (2013) ⁴, in their study reported that mild to deep cracks developed in tooth in 15 to 30 mins, and the tooth started dissolving in 1 hour, the tooth was completely dissolved in 8 hours, for Nitric acid is same as 8 hr. in HCl where as Jadhav et al (2009)⁷ observed in their study that yellow colour appears in 15 min, disintegration of apical 3rd in 4 hours, splitting of teeth in 8 hours, and completely dissolved in 15 hours. Cope and Dupras note in their study that the teeth immersed in hydrochloric acid took on a “jelly-like appearance” which describes the outer layer translucency observed in this study ⁸, and for Sulphuric and phosphoric acid morphological and radiographical appearances of teeth persisted even after 24 hr Mazza et al (2005)⁹ found in their study that no changes seen till 5 hours..

Thus by seeing the morphological and radiographical feature we can determine the type of acid used and for which duration it can also determine, slight elevation of dimension were observed in Sulphuric and phosphoric acid during 16-24 hr. Thus there are clear differences in the destructive capacities of different acids used in the study.

**Conclusion**

The durability of these teeth may be utilized as a successful identification tool in forensic science. According to this study, the morphological and radiographical changes observed in teeth after particular time interval of immersion in an acid solution can be utilized for identification of the acid used and to deduce the approximate duration of immersion in the acid. However, the final decision on which acid has been used should be based on biochemical tests. It should also be noted that the effect of acids on teeth not only depends on the type of the acid or the concentration of acid or the time period but it also depends upon the size of the teeth or the position of the teeth.

Pattern of Abdominal Viscera Injuries in Blunt Abdominal Trauma Deaths in Ahmedabad

Kunjan Modi¹, Rajesh Joshiyara¹
¹Tutor (MD), Department of Forensic Medicine, B. J. Medical College, Ahmedabad

Abstract

In this age of speed and traffic accidents, the incidence of blunt injuries to the abdomen has been at its height due to the development of the modern industrial era with the development of the automobile. This study was conducted to describe the frequency and pattern of intra-abdominal injuries in patients with blunt abdominal trauma.

The present study was undertaken on 693 victims who died due to blunt abdominal injuries which were autopsied at B. J. Medical College mortuary, Ahmedabad during the year 2016-2017. This study shows that most common organ involved in blunt abdominal injuries is liver. Most common associated injuries with this is chest injuries. Highest number of people died due to shock and hemorrhage.

Keywords: Blunt abdominal trauma; Intra-abdominal injuries.

Introduction

Trauma is one of the leading preventable causes of death in developing countries, and is a major health and social problem. Trauma affects generally the young people, and accounts for loss of more years of life, than lost due to cancer and heart diseases put together. Since prehistoric times, the abdomino-pelvic cavity has been looked upon as one of the most vulnerable regions of the body and injuries involving it have always been considered very serious. As early as 460 BC, Hippocrates was aware of the danger to life caused by injury to liver and spleen ¹.

Most of the information about abdominal trauma has been gained through military experiences, as Sir Winston Churchill stated, “War is an epidemic of trauma” ². It is only in the recent time that the automobile became more deadly than the rifle. Deaths are occurring every day, in many different settings, from injuries to the upper abdomen and lower rib cage that produce damage to the liver, spleen and pancreas. The location and severity of the blow and the position of the victim when injured determine which combination of organs is affected.

In open cases of abdominal trauma the clinical manifestations, diagnosis and management will be easier. But closed cases of trauma, offers a great challenge to the treating surgeon. Sometimes it may escape detection or lead to an error in diagnosis from medico-legal point, and the same is often true with autopsy doctor, where in closed cases of abdominal trauma, the autopsy findings may sometimes be trivial or complex and frustrating. It may be difficult to interpret the anatomic abnormalities to understand the mechanism of death, and may require a lengthy explanation. The object of the dissertation is to make a comprehensive study of pattern of blunt abdominal injuries, which are fatal and resulting in death.

Materials and Method

The present study was conducted at B. J. Medical College, Ahmedabad. Total 693 cases of deaths of all age groups and both sex from blunt abdominal trauma during the year 2016-2017 were taken up for study. Death due to head injury, chest injuries where abdominal injuries are minor and badly decomposed bodies where significant injuries were not visible also not included in
this study. Routine information like age, sex, occupation brief facts of the cases collected from the inquest report. Clinical history like time of admission, and deaths and other relevant data was collected from the hospital case sheets and death summaries. Pattern, nature of injuries and other information were obtained from a detailed follow up and study of the autopsy cases and reports. Finally all the data thus collected, complied and presented in the tables.

**Results**

The present study comprised 693 (15.1%) autopsy cases of deaths due to blunt abdominal injuries, out of total 4588 medico-legal autopsies (Table-1). Liver was commonest organ injured in 74% cases. Out of 511 cases, 333 cases were due to injury by motor vehicles, 116 cases were due to fall from height. splenic injury was found in 36.65% cases. Out of 254 cases, 170 cases were due to injury by motor vehicles, 56 case due to fall from height and 16 cases due to railway hit. Injury to intestine was found in 13.85% cases. Out of total 96 cases, 63 cases were due to injury by motor vehicles. Kidney was found injured in 11.11% cases. Out of 77 cases, 49 cases were due to injury by motor vehicles 20 case due to fall from height and 6 cases due to railway hit. Stomach was found injured in 4.76%. Out of 33 cases, 26 cases were due to injury by motor vehicles 5 case due to fall from height. Urinary bladder was found injured in 1.15% cases. All cases were injured due to injury by motor vehicles. Most common associated injuries with blunt abdominal injuries are chest injuries. It is followed by fracture and head injuries. In males out of 549 cases hemorrhage is seen in 460 cases and in females in 117 cases, where as infection cases 77 cases are of males and 25 cases are of females. Multi organ failure is seen in 2.00% of cases.

**Discussion**

The observations and results of the present study were compared and contrasted with the work of preceding researchers.

As shown in Table 2, Liver was commonest organ injured in 74% cases. It was consistent with the findings of Abdelrahman H and Morales Uribe CH. Out of 511 cases, 333 cases were due to injury by motor vehicles, 116 cases were due to fall from height, 23 cases were due to direct blow on abdomen by lathi, hockey etc., 3 cases were due to fall of roof upon the deceased. Tonge et al had reported 24.9% incidence of liver injury in fatal road accidents. Kaur study showed liver injuries in 16.55% cases of motor cyclists. 22.7% liver injuries were reported by Hussain et al and 15% by Hoyt.

As shown in Table 2, splenic injury was found in 36.65% cases. Tonge et al reported splenic injury in 21% of cases. Another observation derived in the present series shows out of 254 cases, 170 cases were due to injury by motor vehicles, 56 case due to fall from height and 16 cases due to railway hit.

As shown in Table 2, injury to intestine was found in 13.85% cases. This incidence was 6.2% in the observation of Tonge et al. Out of total 96 cases, 63 cases were due to injury by motor vehicles.

As shown in Table 2, Kidney was found injured in 11.11% cases. Out of 77 cases, 49 cases were due to injury by motor vehicles 20 case due to fall from height and 6 cases due to railway hit. It is consistent with the findings of Kaur in which she reported that kidney injury was found more commonly in fatal heavy motor vehicular and two wheeler accidents.

As shown in Table 2, stomach was found injured in 4.76%. Out of 33 cases, 26 cases were due to injury by motor vehicles 5 case due to fall from height. Tonge et al reported the incidence of 0.8% while Bruce et al (1965) reported stomach injury in 2% of cases. Urinary bladder was found injured in 1.15% cases. All cases were injured due to injury by motor vehicles. Incidence of urinary Bladder injury reported by Tonge et al was 4.9%. Kaur in her study of fatal auto vehicular two wheeler accidents reported incidence of 1.37%.

Gall Bladder was found injured in 3.17% cases and pancreas was found injured in 5.05% cases. The incidence of gall bladder & pancreatic injury reported by Tonge et al was 1.7%; the similar explanation had been given by Orr.

The present study showed that parenchymatous visceral injury is common than hollow visceral injury in both sexes (2:1). This is because consistency of parenchymatous viscera and hollow viscera has some
capacity to absorb the force of blow. In most of the cases multiple organ involvement was very common.

Involvement of uterus in female cases was a rare phenomenon as it is strongly protected by pelvic cage. In all cases bladder involvement is associated with fracture pubic symphysis. The most commonly associated part along with abdomen involved is chest due to its close proximity with abdomen. It showed rib fractures and lung injuries. Hemorrhage is more common with parenchymatous injury where death has occurred within 12 hours after sustaining trauma (57.43%).

Infection is more common with hollow visceral injury where death is delayed. The ratio of incidence between hemorrhage and infection is more or less common in both males and females. In males out of 549 cases hemorrhage is seen in 460 cases and in females in 117 cases, where as infection cases 77 cases are of males and 25 cases are of females.

**Conclusion**

The present study was undertaken to focus light upon the pattern of blunt abdominal injuries in relation to various factors in the Ahmedabad. Total No. of 693 cases were studied in the year 2016-2017. The result of the present study is summarized as follows.

1) Liver is the most commonly involved organ in blunt injuries of abdomen followed by spleen, small intestine, kidney, myosentery, stomach, gall bladder, urinary bladder and pancreas in decreasing order respectively.

2) In most of the cases, involvement of more than one viscera is reported.

3) Very high incidences of associated injuries in the form of chest injuries, followed by fractures and head injuries were noted. Chest injury is the most commonly associated injury (41.88%) due to its close proximity with abdomen.

4) Most common cause of death was shock and haemorrhage (83.26%), especially when the person dies within few hours. In those cases where death was delayed, cause of death was infection (14.72%)

Pattern of Fatal Firearm Injuries Pertaining to Manner of Death: An Original Research Article

Kaulaskar Shashikant V.,1 Kolpe Dayanand V.,2 Udaykiran Bhalge3 S K Pandey4 Manoj Pathak5
1Associate Professor, Dept of Forensic Medicine, 2Professor & Head, Dept of Forensic Medicine, 3Assistant Professor, Dept of Community Medicine, MIMSR Medical College, Latur, 4Assistant Professor, 5Professor & Head, Dept of Forensic Medicine, IMS, BHU, Varanasi

Abstract

The purpose of this study was to collect a data related to, but are not limited to, medico legal aspect, manner of death, type of firearm used, anatomical site involved, range of fire and their direction pertaining to manner of death in fatal firearm injury (FFI) cases, as limited data are available for such fatalities in this region. The direction of the internal bullet path has not been investigated in this area. This study was designed to address that deficiency.

Method- A prospective study over a period of 22 months was carried out on FFI cases brought to the mortuary.

Result –Among 54 FFI cases during study period, homicidal deaths were outnumbered the accidental and suicidal cases. Country made firearm was used in 37.03% FFI cases. More than one entry wound found only in homicidal cases. The typical entry wounds (n-59) in homicide were fired from close or near distance (61.02%), thorax were commonly involved (44.07%) with direction of fire running backward 73.08% (n-19), downward 69.23% (n-18) and towards the right 76.92% (n-20). Entry wound (n-5) in accidental FFI cases were fired from close or near range in 80%, abdomen involved in 80% (n-4) with direction of fire downward 75% (n-3), towards right 75% (n-3) and forward in 50% (n-2),and backward in 50% (n-2). In suicidal cases (n-3) head was involved in 66.67% (n-2) with all direction in backward, upward and towards left side.

Conclusions Country made firearms were involved in majority of cases. Multiple shots were present only in homicidal cases. Non contact entry wounds strongly indicate homicidal death. In homicidal death thorax was commonly involved and the direction of internal bullet path was towards the backward, downward and to the right side (B-D-R) in majority of cases. In all suicidal cases, the direction of fire was backward, upward and to left.

Key words: Firearm, Country made firearm, Site of entry wound, Range of fire, Direction of fire.

Introduction

Stabbing, mechanical asphyxia, blunt head injury and shooting are the most common methods of homicides, with firearm homicides on the increase throughout the world [1]. Indian national statistics reveal extreme variations across states and cities. As compared to other countries, firearm fatality rates in India are not particularly high. In 2008, India officially reported a national firearm murder rate of 0.36 per 100,000 people. Use of firearm for violent death is more common in Uttar Pradesh as compared to other states and firearm fatality rate in this city (Varanasi) was 3.1 per 1,00,000 population [2]. In India, in 2008 most of the victims of firearm murder are killed by unlicensed firearms (86%) [2] and use of unlicensed firearm increased in last
few years. As per national data, firearm were used in approximately 9% of homicidal deaths in India and only this region was accounted for 34.7% in the year 2012 [3]. Few studies have been published in other part of the world regarding internal bullet path pertaining to manner of death [4, 5]. Though in this region a number of studies are published on characteristics of firearm injuries [6, 7, 8], but direction of internal bullet path pertaining to manner of death were not investigated which can be also helpful for investigation of crime and reconstruction of event.

**Material and Method**

This prospective study was carried out on FFI cases brought to the mortuary of the department of Forensic Medicine, IMS, BHU, Varanasi, during period of 1st June 2009 to 30th March 2011. Before the start of the study, ethical clearance was taken from Ethical Committee of IMS, BHU. For the study, relevant questionnaires schedule were prepared.

Data relating to the study were collected by:

1) Examination of inquest report.
2) Interviewing the police personnel accompanying the cases
3) Interviewing the relatives, friends and eyewitnesses
4) Examination of photographs of scene of crime
5) Operative notes in case of hospitalized victims.
6) X-ray examination before autopsy in some cases.
7) Marking each gunshot wound on body diagram.

A large variety of features such as type of firearm, ammunition, number and site of entrance wounds, range of fire and direction of the internal bullet path were recorded.

The wound track was described in relation to planes of body relative to standing position:

(a) Frontal plane: From front to back or back to front.
(b) Sagital plane: From left to right or right to left.
(c) Horizontal plane: From above downwards (caudal) or from below upwards (cephalad).

Results were expressed in percentages. Chi-square and “P” values were calculated wherever applicable. P-value of <0.05 was considered significant.

**Findings**

Total 54 autopsies were studied due to fatal firearm injuries (FFI). Out of 54 case, 44 cases (81.48%) were victims of homicidal attacks, 5 cases (9.25%) were accidental and only 3 cases (5.55%) were suicidal, in 2 cases (3.7%) manner of death was undetermined. Overall unlicensed country made firearms was used in 37.03% FFI cases. Out of 44 homicidal FFI cases, country made firearm was used in 17 (38.64%) cases and was used in 3 out of 5 accidental FFI cases (Table-1). Pistol was preferred in suicidal cases.

A total of 69 entrance wounds were recorded in the 54 fatalities. Single entry wound was present in 79.62% (n=43) cases, two in 14.81% (n=8), three in 3.7% (n=2) and four in 1 case. Out of 44 homicidal cases single entry wound was found in 33 cases (75%) and multiple entry wound was present in 11 cases (25%). Interestingly Multiple entry wounds were present only in homicidal cases where as in accidental and suicidal cases only single entry wound was present (Table-2).

Total 59 entry wounds were recorded in homicidal cases, of which 36 (61.02%) were fired from close or near range and only 2 (3.39%) entry wounds were from contact range (Table-3). In accidental cases, 80% (n=4) was fired from close or near range and only 20% (n=1) was fired from distant range. In all suicidal cases range of fire was contact range (Table-3).

Anatomical site most commonly involved was the thorax (42.03%) followed by head (26.09%) and abdominal (17.39%) region (Table-4).

In homicidal cases, 44.07% of entry wound was present on thorax region followed by head (26.09%) and abdominal (17.39%) region (Table-4).

In accidental cases, 44.07% of entry wound was present on thorax region followed by head, neck and face region (33.9%). Limbs were involved only in homicidal cases. In majority of homicidal cases the direction of entry wound on vital anatomical region (Head, Neck, Face, Thorax and Abdomen) was backward, downward and left to right side (Table-5).

Among the non homicidal cases, 5 cases represent accidental death and 3 cases represent suicidal death. In accidental FFI cases abdomen was involved in 4 cases and thorax involved in a single case. Out of 3 suicidal
cases, head (right temple) was preferred region in 2 cases by using pistol and with long barreled shotgun abdomen was preferred in 1 case. In all suicidal cases, the direction of fire was backward, upward and right to left (Table-6). Direction of fire on vital anatomical regions (Head, Neck, Face, Thorax and Abdomen) involved in homicidal and non homicidal cases showed association ($\chi^2 = 3.8839$, $p$-value = 0.487). Direction of fire towards backward, downward and left to right in FFI cases represents homicidal injuries.

**Discussion and Conclusions**

**Manner of death and type of firearm:**

In our study, total 54 fatal firearm injury (FFI) cases were studied and this account for 1.54% of total autopsy cases. It was observed that maximum number of death were homicidal (81.48%) and rarely used for suicidal purpose (5.55%), this observation coincides with other studies conducted in India, similar result was reported in a study carried out in Edirne, Turkey, Egypt. However, some other studies conducted in developed countries like, Brescia (Northern Italy), Sweden, New Zealand reported that suicides accounted for the vast majority of firearm fatalities. We observed that unlicensed country made firearms were used in 37.03% FFI cases which is consistent with other studies conducted in India and other developing
countries. Firearms mainly used for homicides in developing countries, the reason could be easy and cheap availability of unlicensed country made firearms and they typically cannot be traced to any owner or by ballistic fingerprinting. These features make unlicensed firearms ideal for criminal use. In this country people rarely use firearm for suicide because people prefer more cheaper and more easily available methods like poisoning and hanging[15, 16]

The number of entry wound and manner of death:

We observed that in majority of cases (79.62%) single shot was fired. Similar observation was also found in Saudi Arabia by Magdy et al. [17], Druid H [5], A Kohli [9]. In 75%(n-33) of homicidal cases single entry wound was present as compared to 26-55% in other studies [5,10]. Interestingly we found in all non homicidal cases only single shot was present and multiple shots were present only in homicidal cases. In all accidental cases single gunshot injury was exclusively present in study by B.Karger et al [19] Myint Sithu et al [20] study also observed multiple entrance wound was common in homicidal cases. However some studies recorded multiple entry wounds in suicidal cases [12, 21]

Range of fire and manner of death:

The present study underlines that vast majority of homicide have close, near and distant range wounds, this consistent with other studies [4, 22]. In accidental cases contact wound was absent. In all suicidal cases only single contact wound was present and this findings are consistent with other studies in which contact or near contact wounds were present in more than 97% [22,23]. Only two cases of homicide were found to be discharged from contact range. Manner of death and range of fire showed significant association in our study. Non contact entry wounds strongly indicate homicidal death.

Anatomical site involved and direction of fire pertaining to manner of death:

Anatomical site preferred and direction of fire in homicidal, accidental and suicidal deaths is different. In homicidal cases, generally the victims are in motion either due to arguing with or opposing the assailant and the assailant generally prefer the large, vital and easy to target anatomical area to shoot. Contrary to this in suicidal cases, the person prefers comfortable position and most vital anatomical site for immediate death. While in accidental cases, the involvement of anatomical site and direction cannot be predicted and these cases totally depend on history of incidence.

In the current study, most common anatomical site of entrance wounds was thorax (n- 29, 42.03%), this result was consistent with other studies [10, 11]. Out of 59 entrance wound recorded in homicide, thorax (n-26, 44.07%) was most common targeted region followed by head, neck and face region (n-20, 33.90%) with the direction of internal bullet path towards backward, downward and to the right side (B-D-R) in majority of cases.

Out of 3 suicidal cases, head (right temple) was preferred region in 2 cases by using pistol because both persons were right handed, and in one case abdomen was preferred with long barrelled shotgun by using right great toe to pull a trigger. In all suicidal cases, the direction of fire was backward, upward and right to left (B-U-L). Similar observation was found by other studies [4, 5]

Epidemiological Profile of Snake Bites over 1-Year Period from Tertiary Care Centre in Maval Region of Maharashtra, India: Original Research Article

Rajesh Kharat¹, Rahul Kedare²

¹Associate Professor, Dept. of Forensic Medicine, Govt. Medical College, Shahdol (M.P.),
²Assistant Professor, Dept. of Pharmacology, MIMER Medical College, Talegaon (D), Pune

Abstract

Estimated death rate due to snake bites are more than 46,000 annually in our country. Ninety-seven to ninety eight percent bites occur in rural or remote areas. Snake bite is a one of common problem faced in rural India. It takes a high toll of lives mainly of working male of the family. The current prospective observational study was carried out to study the clinical and management by systematic approach of snake bites. The 245 cases of snake bite were hospitalized to Rural Hospital in a period of July 2017 to June 2018.

The present data showed that majority (91.43%) of cases were encountered from rural area, in the age group ranging from 21 to 30 years (24.90%). Majority were male patients (62.04%). Most affected were the agricultural laborers and farmers (56.33%). 60.82% of the cases were presented with bite over lower extremities. Most of the snake bite (75.97%) occurred during day time. July to October was the period in which most snake bite cases were observed. It was seen that syndromic or systematic approach was more effective in early diagnosis and treatment of snake bite. The average requirement of anti-serum venom (ASV) required for cobra bite was 16, krait bite 22, Russell's viper bite 12 and saw scaled viper bite 10. The total duration of treatment in hospital for cobra bite were 6, krait bite 8, Russell’s viper bite 4 and saw scaled viper 4 days.

Key words: Epidemiology, Snake bite, Anti-snake venom, Syndromic approach

Introduction

Snake bite is one of common medical emergency and an occupational hazard, more so in tropical region of India, where farming is a main or major source of earning. India has remained well known for its venomous snakes and the effect of their bites. Almost every year, 50,000 Indians died in 2,50,000 cases of snake bites, in spite of that India is not home for the largest number of venomous snakes in the globe, nor is there a shortage of anti-snake venom in the country. In the Maharashtra number of snake bite cases are highest i.e. 70 bites per 100,000 people and mortality of 2.4 per 100,000 per year. Main reason for high mortality and morbidity in any part of rural India is ignorance or negligence of the people. The initial approach to snake bite and treatment given by traditional village healers or non specific options, lack of transport facilities in rural India and sleeping habits of the villagers, difficult to access or unavailability of the doctor at Primary Health Centers most of the time, time taken by the doctors to identify the snakes, the signs and symptoms of envenomation in the patient. Important to note is that these are all preventable causes. In addition to the same is unavailability of ASV and endotracheal intubation and ventilation in neurotoxic envenoming. There are very few studies available from the Maval region of Maharashtra regarding the same.

Materials and Method

The current observational study was carried out in an Intensive Care Unit of Rural Hospital in Maval region of Maharashtra, India, in a period of July 2017 to June 2018. The aim of the study was to find out clinical profile, types of snakes and reasons to reduced decreased mortality rates at this center which may helpful to take
appropriate management approach and prompt treatment options or care be rendered in a rest of Maval region as well.

A total of 245 cases of snakebite were admitted during the said period. A written consent from patient or relative was taken, data was collected on a pre-designed proforma by interviewing the patient or close relatives and thorough clinical examination was done. Detailed information regarding the demographic and epidemiological parameters such as age, sex, occupation, site of bite, place of bite was noted. The type of snake was identified, if the snake was brought dead or identified by Syndromic approach.

Following syndromes were identified:

Syndrome 1 - Local envenomation (pain, swelling, ecchymosis); Bleeding/ clotting disturbances (haematuria, positive whole blood clotting test) = Russell’s viper and saw- scaled viper.

Syndrome 2 - Neuroparalytic symptom (ptosis, ophthalmoplegia, dysarthria); minimal haematuria and local swelling = Russell’s viper.

Syndrome 3 - Local envenomation (pain, swelling, blebs); Neuroparalytic symptom (ptosis, dysarthria); rapid progress towards respiratory arrest = Cobra.

Syndrome 4 - Neuroparalytic symptom (ptosis, dysarthria, dysphagia with respiratory arrest); no local swelling; history of severe abdominal pain and sleeping on floor = Krait.

Syndrome 5 - History of snake bite; no development of local or systemic symptoms; bite mark and mild burning present; observe till 12-24 hours; if asymptomatic = Nonvenomous snakebite(Rat snake, wolf snake; green keelback, trinket) orit may be a dry bite(Venomous snake). Subsequent data was collected i.e. total number of average ASV requirement, total duration in a hospital.

Inclusion Criteria

Patients of any age, sex and any locality of Maval region admitted with suspected or confirmed snake bite.

Exclusion Criteria

Patients brought dead with history of snakebite.

Patient with other insect bite

Observations and Results

A total of 245 cases were admitted in our hospital. Among them 152 (62.04%) were men and 93(37.96%) were women (Table No.1). The high incidence of snakebite was observed in the age group of 21-50 years (n=155, 63.27%) and low in the age group ≥51 years (n=38, 15.51%) (Table No.1). Most of the cases were from the rural area (91.42%, n=224) and rest of cases (8.58%, n=21) were from urban area (Table No.1). The most of the cases were bitten in the farms or field (n=171, 69.80%), followed by 61 (24.90%) in the houses or residences and 13 (5.30%) in public or common areas (Table No.2). Their occupational status 138 subjects (56.32%) were farm laborers, 42(17.14%) were farmers and 65(26.54%) were housewives, students (Table No.1). Large number of cases 149(60.82%) had site of bite on lower extremity followed by 87(35.51%) on upper extremity, 5(2.04%) on trunk and 4(1.63%) on head, neck and face (Table No.2). Regarding activities at the time of bite, 24 were sleeping on floor, 57 were handling debris or animal waste, 124 were working in the field or farms and 40 were doing or performing other field related activities (Table No.2). Majority of the patient of krait bite were sleeping on floor. The snake bites i.e. 186 (75.92%) occurred during daytime and 59 cases during night time. The common species was krait. Because of the seasonal variation maximum snake bite 127 (51.84%) were seen during rainy season (Table No.3). On further analysis of 245 snake bite cases, 153 cases were bitten by venomous snakes found in this region (The big four) and 92 cases were bitten by non venomous snakes. Of the venomous snakes 60 (24.48%) were Cobra bites, 41 (17.74%) were Krait bites, 45 (18.36%) were Russell's viper bite, 7 (2.86%) were bitten by Saw Scaled viper (Table No. 2). Regarding the identification of snake, 153 snakes were poisonous and they were identifies when they were brought dead or alive by the relatives or the snake friend (Sarpamitra) and by the Syndromic approach as per WHO guidelines while 92 snakes were non venomous snakes (Table No.2). In 245 cases of snake bite maximum patients had fear 240 (98%) as the prominent sign or symptom, 218 (89.04%) had pain at the same site followed by swelling in 186 (76%) and 32 (13%) of the patient had difficulty to open eyes and 39 (16%) had difficulty in breathing or respiratory distress, 44 (18 %) had bleeding from the site 29 (12%) had pain in abdomen and 22 (9%) had nausea and vomiting, on local examination bite marks, blister formation and necrosis were observed in 205 (83.46%), 23 (9.42%) and 12 (5.06%) cases respectively (Figure
Maximum cases causing rapid cellulitis were of Russell’s viper where as blister and necrosis were caused by Cobra, absence of bite marks was an important feature of Krait. In case of Russell’s viper 23.4 % cases had both neurotoxic as well as vasculotoxic symptoms. 10 patients had mild alteration or derangements of renal function test (acute renal failure) 16 % cases of cobra bite developed ulcers, all of which healed completely by regular dressings (Table No.5). The basic or first aid treatment given before admission in most of the cases was in the form of application of tourniquet (78.36%) proximal to the site of bite. Average ASV required for the cobra bite was 16, krait bite was 22, Russell’s viper bite was 12, and Saw Scaled viper bite was 10. Average total hospital stay for Cobra bite patients was 6 days, for krait bite patient was 8 days and Russell’s viper bite patients and saw scaled viper bite patient required total 4 days (Table No: 4). Overall mortality in 245 cases, one patient who died because of neurotoxic envenomation the patient was obese, diabetic and the other dying of hemotoxic envenomation had severe hypothyroidism with poor compliance.

Discussion

In the present study, most of the snakebite cases were in the age group of 21-50 years and from rural areas (91.42%) these factors have great impact on the psychosocial and economical status of the family. Loss of the earning family member, most commonly male (62.04%) has long lasting effect on the family status. Majority of cases were reported from the farms during their routine work. Similar observations were reported in earlier studies.5,6,7,8. It was noted that 62.44% cases were bitten by venomous snakes, found in this area. The venomous snakes identified were – Cobra, Krait, Russell’s viper and Saw scaled viper. Syndromic approach was found to be useful in identification of species of snake. Regional signs and symptoms or syndromes should be identified and syndromic approach should be applied. In this study, we discussed with physicians, intesivists, resident doctors and paramedical staffs about identification of snake and Syndromic approach. It was helped in early recognition and prompt management. The most common presenting symptoms include fear (98%), pain (89.04%), swelling (76%), difficulty to open eyes (13%), difficulty in breathing (16%), bleeding from the site (18%), pain in abdomen (12%) and vomiting (9%) of the observed cases. Bite marks were observed in 83.46% of the cases and bite marks were absent in Krait. Blister formation was seen in 9.42% cases, all of which were cobra bites. Tissue necrosis was found in 5.06% of the cases. The Most common site was lower extremities followed by the upper extremities this is consistent with the occupational exposure. The krait bites occurred during mid night and
while sleeping over floor. The preventive measures were discussed with people about the mode of bite of these poisonous snakes and recommended to sleep on a bed and avoid sleeping on the floor. Use of mosquito nets is an effective preventive measure for krait bites. Average ASV required were 16 for cobra bite cases, 22 for krait bites cases, 12 for Russell’s viper and 10 for saw scaled viper cases. The total hospital duration for cobra was observed to be 6 days, 8 days for krait and Russel’s viper and saw scaled viper to be 4 days. Similar findings were made by Kulkarni and Annes. The overall mortality was 2 in 245 total snake bite cases (0.81%). One patient who died because of neurotoxic envenomation the patient was obese, diabetic and the other dying of hemotoxic envenomation had severe hypothyroidism with poor compliance. Higher rates of mortality were observed by Kulkarni and Annes, Hansdak et al, and Punde. Lower mortality at our hospital could be attributed to the dedicated Intensive Care unit, trained staff and early recognition of envenomations by Syndromic Approach and early endotracheal intubation.

Conclusions

Snake bite is a one of common problem in rural areas of India, taking a high toll of lives mainly of working male of the family. In the present study 245 cases of snake bite were analysed who were admitted to Medical Intensive Care unit of Rural Hospital. The data showed that majority (91.42%) of cases were belong to rural area, in the age group of 21 to 50 (63.27%), out of total cases, majority were male patient (62.04%). Most commonly affected was the agricultural laborers (56.32%) and 60.82% of the cases had bite over lower extremities. Most of the cases (75.97%) occurred during day time in the month of July to October. It was observed that Syndromic approach was very effective in early diagnosis and treatment of snake bite. Average number of ASV required for cobra bite cases was 16, krait bite 22, Russell’s viper bite 12 and saw scaled viper bite 10. Average hospital stay in days for cobra bite was 6, krait bite was 8, russell’s viper bite was 4 and saw scaled viper was 4. All cause mortality was 1.67% for neurotoxic and 2.43% for vasculotoxic snakes.

Recommendations

1. It is strongly recommended to make snakebite a specific notifiable disease and should be formally recognized as an important occupational disease in Maval region.
2. As most snakebite occurred during the agricultural work, strict protective measures should be practiced by the farmers.
3. Sleeping on floor should be discouraged to prevent specially krait bite.
4. Anti-venom alone cannot be relied upon to prevent early death from respiratory paralysis. Artificial ventilation is essential in such cases. In this region more doctors should be trained to carry out endotracheal intubations, as it was found to decrease the mortality rate in neurotoxic envenomations.
5. Syndromic Approach should be followed for management of snakebite, when snake is not brought.
6. Training of Physicians, resident doctors and paramedical staff regarding Syndromic Approach is necessary.
7. Establishment of dedicated snakebite management units, at least at every district hospital, where the incidence of snake bite is high, as dedicated snakebite management units have positive impact on mortality rates.
8. Community education about snakebite is strongly recommended as the method most likely to succeed in preventing bites. Use of flip charts or videos related to awareness about symptoms of snake bite and first aid measures in schools and colleges will definitely help in sensitizing the people in rural area.

Conflict of Interest: There is no conflict of interest; the author does not have financial or other relationship with other people or organization that may inappropriately influence the author’s work.

Ethical Clearance: Research was approved by the institutional ethical committee.

Informed Consent in Clinical Practice and Research and Its Awareness among Under Graduate Medical Students

S.R. Saritha¹, C.S. Sreedevi²
¹Associate Professor, ²Professor and Head, Department of Forensic Medicine, Govt.T.D. Medical College, Alappuzha

Abstract

Consent denotes voluntary agreement, permission or compliance. Informed consent in medical practice is the grant of permission by a patient for an act to be carried out by a doctor, such as a diagnostic, surgical or therapeutic procedure. Informed Consent in research is the voluntary agreement to participate in the study.

The study was undertaken with the objective to assess the level of knowledge regarding informed consent among Second MBBS undergraduate medical students at the beginning of the class by a pretest and to demonstrate measurable gain in knowledge at the end of the class by a posttest using the same questionnaire.

This quasi-experimental study conducted in the Department of Forensic Medicine, Govt.T.D Medical College, Alappuzha, among 118 students using a structured and close ended, pretested questionnaire containing 13 multiple choice questions.

Statistical analysis done on average pre and posttest score and on difference in pre and posttest responses to individual questions; revealed measurable gain in knowledge at the end of the class, since p value was < 0.05.

Key words: informed consent, clinical practice, research, pre and posttest, gain in knowledge.

Introduction and Background

Consent denotes voluntary agreement, permission or compliance. It should be free, voluntary, informed, clear and direct. According to Indian Contract Act, 1872 two or more persons are said to consent when they agree upon the same thing in the same sense¹. As per Indian Medical Council (Professional conduct, Etiquette and Ethics) Regulations, 2002 that a physician, performing an operation without written informed consent, shall constitute professional misconduct rendering him/her liable for disciplinary action by MCI².

Informed Consent must be obtained for all types of human subjects research including; diagnostic, therapeutic, interventional, social and behavioral studies, and for research conducted domestically or abroad³. A doctor must give a patient adequate information to understand the various aspects of the proposed treatment such as: The nature and procedure of the treatment, purpose and benefits, likely effects and complications, alternatives if available, substantial risks and adverse consequences of refusing treatment².

Types of Consent⁴,⁵.

Implied consent: Seen in routine medical practice. Here the consent is implied in the mere fact that the patient comes to the physician with a problem or when a patient holds out his arm for an injection.

Expressed consent: May be written or oral. Any procedure beyond the routine physical examination, like operation, collection of blood, blood transfusion etc. needs expressed consent. Consent should be taken before the proposed act and not at the time of admission to the hospital.
Informed consent: In medical practice anything beyond routine would require informed written consent.

Blanket consent: It is a consent taken on a printed form that covers (like a blanket) almost everything a doctor or a hospital might do to a patient, without mentioning anything specifically. Blanket consent is legally inadequate for any procedure that has risks or alternatives.

The concept of informed consent is embedded in the principles of Nuremberg Code, The Declaration of Helsinki and The Belmont Report. Consent to participate in a research should be understood as a process rather than an event. In order for participants to give meaningful consent, they should be able to understand the intent of the research, be clear about what they are being asked to do and if any risks are involved, and know how their information will be used.

Informed Consent Document (ICD)

Before requesting an individual’s consent to participate in research, the researcher must provide the individual with detailed information and discuss her/his queries about the research in the language she/he is able to understand. ICD has two parts –

- Patient/participant information sheet (PIS)
- Informed consent form (ICF).

Information on known facts about the research, which has relevance to participation, is included in the PIS. This is followed by the ICF in which the participant acknowledges that she/he has understood the information given in the PIS and is volunteering to be included in that research. Adequate time should be given to the participant to read the consent form.

Special situations

1. Waiver of consent: The researcher can apply to the Ethics committee (EC) for a waiver of consent if the research involves less than minimal risk to participants and the waiver will not adversely affect the rights and welfare of the participants.

2. Re-consent or fresh consent: Re-consent is required in situations where new information pertaining to the study becomes available, a research participant who is unconscious regains consciousness, a child becomes an adult during the course of the study, research requires a long-term follow-up or requires extension, there is a change in treatment modality, procedures, site visits, data collection methods or tenure, and when there is possibility of disclosure of identity.

3. Assent: Assent is defined as a child’s affirmative agreement to participate in research. The assent process should take into account the children’s developmental level and capability of understanding and should be obtained from children of 7 to 18 years of age.

4. Electronic consent: Electronic media can be used to provide information as in the written informed consent. Hon’ble Supreme Court has issued direction that in all clinical trials, in addition to the requirement of obtaining written informed consent, audio-visual recording of the informed consent process also should be done. This is applicable to the new subjects to be enrolled in all clinical trials including Global Clinical Trials.

5. Gatekeepers: Permission of the gatekeepers, that is, the head/leader of the group or culturally appropriate authorities, may be obtained in writing or audio/video recorded on behalf of the group and should be witnessed.

6. Community consent: There may be situations when individual consent cannot be obtained as it will change the behaviour of the individual. In such situations community consent is required. When permission is obtained from an organization that represents the community, the quorum required for such a committee must be met. Individual consent is required even if the community gives permission.

7. Consent from vulnerable groups: Vulnerable persons are those individuals who are relatively or absolutely incapable of protecting their own interests and providing valid informed consent.

Informed consent is probably the most important concept flowing from the doctrine of autonomy. In the Indian context, informed consent was practically nonexistent till the Consumer Protection Act was made applicable to the medical profession. Now, both doctors and patients are becoming more aware about this concept, and patients are better informed of their rights.

This study was undertaken with the objective to assess the level of awareness regarding informed consent among Second MBBS undergraduate medical students at the beginning of the class by giving a pretest and to
demonstrate measurable gain in knowledge at the end of the class by a posttest using the same questionnaire.

**Materials and Method**

This quasi-experimental study was conducted in the Dept. of Forensic Medicine, Govt. T D Medical College, Alappuzha for one month period. One Hundred and Eighteen (118) Second professional MBBS students willing to participate in the study were included. Students who were absent on the day of assessment, did not participate both in pre and posttest and have given partly filled questionnaire were excluded. Domains included definition, types and components of consent, informed consent in medical and medicolegal practice, informed consent in research and special situations.

Study tool was structured and close ended, pilot tested questionnaire based on informed consent in clinical practice and research containing 13 multiple choice questions with five options and single correct response, covering key points. After obtaining informed consent, pretest questionnaire was given, then a lecture pertaining to the topic was delivered for about 40 minutes and the same questionnaire was given as posttest. For pre and posttest 10 minutes each was given.

Data entered in Microsoft Excel worksheet and analysis done using SPSS version 18.0. Correct answer was given score 1 and wrong answers were given score 0. Maximum achievable score was 13. Average score and standard deviation (SD) for pre and posttest were calculated and analysis done using Wilcoxon signed rank test for paired data. Responses to individual questions were also expressed as number and percentage and difference in responses were subjected to statistical analysis using McNemar’s test for paired samples. Gender wise distribution of students and its relation with score obtained was also studied.

**Findings**

Gender wise distribution of the students and score gained:

Among the students participated, 39 (33.1%) were males and 79 (66.9%) were females. Pre and posttest scores were categorised into two groups, those who scored ≤ 6 and who scored ≥7. These groups were cross tabulated with gender. Majority of male students scored less than or equal to 6 (19.5%) for pretest and more than or equal to 7 in posttest (28.0%). Majority of female students scored more than or equal to 7 in both (38.1% and 64.4% respectively). Only posttest values showed significant association with gender (p = 0.026 i.e. <0.05) (Table 1).

**Table 1. Showing association of gender of students and test score.**

Analysis for paired data:

Mean and standard deviation (SD) calculated for pre and posttest samples for all questions (1 to 13). Mean pretest score was 6.32 with SD 1.871 and mean posttest score was 9.57 with SD 2.154. Wilcoxon signed rank test for paired data revealed highly significant p value i.e. p=0.000 (p<0.05), so there is statistically significant difference between pre and posttest score (Table 2).

Domains were classified into informed consent in clinical practice including its essential elements, application in medical and medicolegal practices (questions 1 to 6) and informed consent in research
including informed consent document and special situations (questions 7 to 13). Mean and SD calculated for these sub groups also. For questions 1to 6, mean pretest score was 3.60 with SD 1.269 and mean posttest score was 4.74 with SD 0.910 and for questions 7 to 13, mean pretest score was 2.72 with SD 1.161 and mean posttest score was 4.83 with SD 1.635. Wilcoxon signed rank test revealed statistically significant difference between pre and posttest sub group values (for questions 1to6, p=0.000 and for 7 to 13, p=0.000) (Table 2).

a. Based on negative ranks.

Analysis based on response to individual questions:

Individual questions were analysed and difference in pre and posttest responses were expressed as number and percentage. Statistical analysis was also done using McNemar’s test, for comparison of responses in paired samples. All questions except 2 and 10 showed increase in frequency of correct response and statistically significant p value (Table 3).

Discussion

Didactic lecture is one of the most widely accepted methods among teaching and learning methodology. Because of time restriction and vast syllabus to be covered through lectures, feedback knowledge before and after the lectures to assess the extent of knowledge of learners gained provides the platform for feedback.

The pretest can be used as a feasible tool to get useful information about the knowledge of students, to shape group specific education programs, to use as a diagnostic tool for obtaining early feedback on the need for assistance and also to provide a benchmark for assessing teaching effectiveness.

Pre-post testing is valuable to teachers because it allows for real-time progress monitoring. Multiple posttest can be administered throughout a student’s enrollment, and thus educational gains can be monitored and instruction can be adjusted appropriately. In pre and posttest based learning method, the student will be actively involved in education. Pre and posttest can also be used as a powerful diagnostic tool to identify weak students, strongest students, topics students already know, topics students don’t know and the topics students have not leaned.

Disadvantages of pre and posttest includes, students may absorb knowledge just from taking the test and may attend more readily to the content and there may be a tendency to teach to the posttest.

A pre and posttest study conducted to evaluate whether formal communications skills training on informed consent improves the quality of written informed consent among untrained Post-Graduate Residents in the Department of Obstetrics and Gynaecology at a Medical College Hospital, Maharashtra revealed that the intervention had increased the mean scores in post-test (5.17 to 9.33) and the paired t test was highly significant with $t = -13.61$, $< 0.0001$. In the present study also statistical analysis done on average pre and posttest score and on difference in pre and posttest responses to individual questions; revealed measurable gain in knowledge at the end of the class, since $p < 0.05$.

Conclusion

Knowledge regarding informed consent is indispensable in medical practice and research and it is an integral part of medical curriculum. Measuring academic progress through appropriately administered pre-post tests can be a powerful tool in providing teachers feedback about how to better meet students’ academic needs.

Sexual Dimorphism in Mandibular Canine Crown Dimensions in Early Adolescents: A Hospital based Study

Kanak Priya¹, Poonam Agrawal², Dinesh Kumar Bagga³, Hiten Kalra⁴, Disha Sirohi⁵, Ritika Gupta⁵

¹Post graduate Student, ²Professor, ³Professor and Head, ⁴Professor, ⁵Senior Lecturer, Department of Orthodontics and Dentofacial Orthopaedics, School of Dental Sciences, Sharda University, Greater Noida, UP

Abstract

Determination of sex is valuable in forensic investigations. Forensic odontology plays a major role due to the hardness and chemical stability of teeth. This study was done to find out the utility of mandibular canine crown dimensions as a tool for sex determination in North Indian population. Crown length and mesiodistal width of right and left mandibular canines were measured on the 60 casts and analyzed to assess sex difference using Students ‘t’ test. The canine crown parameters as measured for males and females when compared were found to be statistically significant. However, when these parameters were compared between left and right sides for the same sex, they were found to be statistically insignificant.

Key words: Sexual dimorphism, canine, crown dimensions.

Introduction

“Sexual dimorphism” is variations in morphological features between males and females. Sex determination is important in the identification of unknown individuals especially when information relating to the person is unavailable. Sex determination can be done either by morphological or molecular analysis. Most anatomical methods for sex determination are based on pelvic and cranio-facial morphology. However, these bones are sometimes recovered as fragments, rendering sex estimation difficult especially in juvenile or sub-adult remains since dimorphic traits become apparent only after puberty. Morphology of teeth is potentially useful in sex determination because both primary and permanent sets of teeth develop before puberty. Mandibular canines are considered as the ‘key teeth’ for personal identification because they are least affected from periodontal diseases and are the last to be extracted. Nair et al (1999) found that the mandibular canines exhibit greatest sexual dimorphism among all teeth. The aim of this study was to find out the utility of mandibular canine crown dimensions as a tool for sex determination in North Indian population and to compare the crown dimensions of right and left mandibular canines.

Material and Method

A retrospective, hospital-based study was conducted in post graduate department of orthodontics and dentofacial orthopaedics, School of Dental Sciences, Sharda University, Greater Noida. Total 60 casts of completely erupted and caries free dentition of 12-15 yrs age group subjects (30 male and 30 female) were studied. Cast with partially erupted, restored, and attrited canine were excluded from the study. Type of malocclusion present was not taken into consideration. Sexual dimorphism was studied on the basis of comparison of mandibular canine crown length, mesiodistal width, and length:width ratio. The crown length and mesiodistal width of right and left mandibular canines were measured using a digital Vernier caliper. The measurements were recorded and statistical analysis using Students ‘t’ test was done to assess sexual dimorphism.

- Following measurements were taken in all the casts on an anatomically sound basis using a digital Vernier Caliper with a measuring range of 0–150 mm/0–6 inch, resolution: 0.01mm/0.0005 inch, repeatability: 0.01mm/0.0005 inch, accuracy: + 0.02 mm/0.001 inch. (<100 mm), + 0.03 mm/0.001 inch. (>100 – 150 mm), maximum measurement speed: 1m/s.

Corresponding author:
Poonam Agrawal
e mail: drpoonamajai@yahoo.co.in
Crown length of the mandibular canines on each side was recorded as the greatest distance on labial surface from the incisal line to cervical line parallel to the occlusal plane.

Width of the mandibular canines taken as the greatest mesiodistal width between the contact points of teeth on either side of jaw.

- Sexual Dimorphism in right and left mandibular canines was calculated using formula given by Garn & Lens (1967) i.e., Sexual dimorphism = (xm/xf) x 100 (where xm is mean value of male and xf is mean value of female).

**Results**

- The readings obtained were subjected to statistical analysis to derive conclusions and the results have been depicted in the tables 1-6. From the findings, it can be interpreted that the left canine is found to exhibit greater sexual dimorphism. The sexual dimorphism as computed for measurements on casts has been observed as follows.
  - Length
    - Sexual dimorphism in Right canine = 1.016%
    - Sexual dimorphism in Left canine = 1.022%
  - Width
    - Sexual dimorphism in Right canine = 1.059%
    - Sexual dimorphism in Left canine = 1.077%

Discussion

The present study establishes the existence of statistically significant sexual dimorphism in mandibular canines. The results are in consistence with a study on Saudi males and females of 13-20 year age group population by Hashim and Murshid (1993) who found that only the canines in both jaws exhibited a significant sexual difference. Lew and Keng (1991) obtained similar results in their study on ethnic Chinese population with normal occlusions. Garn & Lewis (1967) and Lysell & Myrberg (1986) established that the mandibular canine with 6.4% and 5.7%, respectively demonstrates the greatest sexual dimorphism amongst all teeth. Nair et al (1999) in their study on South Indian subjects concluded that the left mandibular canine (7.7%) shows the maximum sexual dimorphism followed by the right mandibular canine (6.2%). In the present study also, the left mandibular canine was found to exhibit greater sexual dimorphism.

In contrast, Mohd. Abdulla has reported a low degree of sexual dimorphism that is not statistically significant in Saudi population. Similarly insignificant sexual dimorphism was reported by Al Rifaiy et al, in Saudi Arabian population. A study of human fossil excavated at Ra’s Al-Hamra, Eastern Arabian Coast also showed statistically insignificant sexual dimorphism of mandibular canine teeth. Gabriel (1958) has stated that any measurement of teeth unaccompanied by age, race and sex must be treated with great reserve. Apart from sex the other significant findings that can be obtained from teeth are age, race, customs and habits.

This study concludes that human teeth are sexually dimorphic and although males and females exhibit overlapping dimensions, there are significant differences in mean values. Sexual dimorphism has been observed in both deciduous and permanent dentition, with more dimorphism exhibited by the permanent teeth. On an average, male teeth are slightly larger than female teeth, with canine showing the greatest difference. Microtomographic scans of the internal dental tissues have also shown significantly greater quantities of dentine in male teeth than in female. Researchers have attempted to use statistical techniques such as discriminant functions or logistic regression equations based on these sex differences to estimate sex, but the usefulness of such formulae is unsure as sexual dimorphism in teeth might vary between populations.

Since the present study has been conducted on both sexes in a definite age group in the North Indian population, it establishes the morphometric criteria of canine size for the North Indian population. The emerging field of forensic odontology in India relies a lot on inexpensive and easy means of identification of persons from fragmented jaws and dental remains. The present study measured by only linear dimensions because of its simplicity and low expenses. The practicing dentists and the dental students should be made aware of the available technologies and its use in forensic dentistry.
New researches have to be encouraged in the field of forensic dentistry which will pave way for incorporating newer technologies in establishing the human identity.

**Conclusion**

This study concludes that canine crown length, width, and length:width ratio as measured for males and females when compared were found to be statistically significant. However, these parameters for the same sex both in male and female, when compared between left and right, were found to be statistically insignificant. Further, the left canine is found to exhibit greater sexual dimorphism.

Rationale of Evaluation of Potency in Medicolegal Cases of Sexual Assault by Penile Color Doppler with Injection of Papaverine

Shilpa Domkundwar¹, Varsha V Jadhav², Sonal Khandelwal³

¹Professor & Head of Dept of Radiodiagnosis, Grant Govt Medical College and JJ Groups of Hospitals, Byculla, Mumbai, ²Associate Professor at Dept of Radiodiagnosis, Grant Govt Medical College and JJ gr of Hospitals, Byculla, Mumbai, ³Senior Resident at Dept of Radiodiagnosis, Grant Govt Medical College and JJ gr of Hospitals, Byculla, Mumbai

Abstract

Introduction: Impotency in male is inability to develop or maintain a sufficient penile erection to conclude the act of intercourse to orgasm and ejaculation. The question of potency arises in many lawsuits in civil and criminal courts. In India, potency testing which includes penile color doppler with injection papaverine is done for all accused of sexual assault as a blanket rule. Penile color doppler with injection papaverine has its own limitations and side effects. Our study therefore aims to analyze and ascertain the justification of subjecting each accused of sexual assault to penile color doppler with injection papaverine.

Aims and Objectives:

1. To analyse whether evaluating potency in every medico legal case of sexual assault referred to our department using color doppler with injection papaverine is justified.

2. To recommend changes based on our study.

Method: This study is a retrospective analysis of data of 166 accused of sexual assault, between the period of May 2015-April 2018. Baseline ultrasound and penile color doppler assessment of erection following papaverine injection was done.

Results: Procedure was performed on 166 accused of sexual assault, of whom the, 3 (1.80%) had arterial insufficiency. 6 (3.61%) accused on whom the procedure was performed developed priapism as complication. The rate of complications was found to be double than the positive result of the procedure.

Conclusion: We conclude from our study that, due to limited role and complications of penile doppler and change in the definition of rape and laws related to it, overburdened health infrastructure of our country, every accused of sexual assault should not be subjected to penile color doppler study.

Keyword: Erectile dysfunction(ED), Potency, Color Doppler, Papaverine

Introduction

Erectile dysfunction is described as inconsistent ability to generate or maintain an erection of sufficient rigidity for sexual intercourse.

A male is said to be impotent when there is inability to develop or maintain a sufficient penile erection to conclude the act of intercourse to orgasm and ejaculation.
In civil courts the question of potency arises in cases like adoption, disputed paternity, nullity of marriage and divorce. In criminal courts the potency is examined in cases of crime against women and children like rape, sexual assault, molestation, sodomy.

A number of medico-legal cases assert impotency in plea. In India, potency testing for all accused of sexual assault is done as a blanket rule despite of the fact whether or not the accused claims it. Such accused are subjected to penile color doppler with injection papaverine for establishing the potency. Penile color doppler with injection papaverine, although a minimally invasive tests has its own limitations and side effects.

There are many other screening tests available to screen for erectile dysfunction.

With the change in the current legislation, the new amendment of Section 375 IPC, implies, peno-vaginal intercourse is not necessary to commit rape.

Our study therefore aims to systematically analyze and ascertain the justification of subjecting each accused of sexual assault to penile color Doppler with injection papaverine.

Aims and Objectives

3. To analyse whether evaluating potency in every medico legal case of sexual assault referred to our department using color doppler with injection papaverine is justified.

4. To recommend changes based on our study.

Materials and Method

This study is a retrospective analysis of data of 278 accused (sec 375,377,376 IPC) referred to the Department of Radio-diagnosis, Sir JJ group of hospitals, Mumbai between the period of May 2015-April 2018. They were in the age group of 15-77 years. All those who consented for the procedure were included. In case of minors, informed consent was taken from the accompanying guardians.

Any accused who did not consent for the procedure were excluded from the study (110 cases). 2 of the accused had e/o local inflammation and hence the procedure was not carried out. Hence procedure was performed on 166 accused.

A base line study was performed initially. Patient was placed in supine position, preferably in a quiet cool place with penis in its anatomical position.

The penis was scanned in longitudinal and cross-sectional views using B mode high frequency linear transducer (7.5-9.0 MHz).

Cavernosa and tunica albuginea were analysed. The local area is cleaned and draped using all aseptic precautions.

Pre injection baseline diameters of the cavernosal arteries are recorded.

60 mg of papaverine (2 mL ampoule of 30 mg/mL diluted in 2 ml of distilled water) was injected intra-cavernosally using an insulin syringe under USG guidance avoiding the cavernosal artery. Precaution taken to avoid spill.

Post-injection measurements were taken at 5, 10, 15 and 20 minutes. The inner diameter of cavernosal artery, peak systolic velocity, end diastolic velocity, visual tumescence and erection were monitored.

Assessment of erection following papaverine injection:

Phase 1: sudden increase in both systolic and diastolic flow velocity in cavernosal artery with minimal tumescence

Phase 2: with further increase in intra-cavernosal pressure, there is a decrease in diastolic flow with a classical ‘dicrotic’ notch

Phase 3: as the intra-cavernosal pressure increases, diastolic flow reaches zero with further increase in tumescence

Phase 4: diastolic flow reversal occurs with maximum systolic velocity; this is associated with penile rigidity

Phase 5: decrease in the systolic flow velocity occurs; this is usually 15 minutes post-injection which is associated with reduction in tumescence and rigidity

Interpretation: In flaccid state, monophasic flow is seen with absent/minimal diastolic flow. With onset of erection, systolic and diastolic flow both increases. With further increase in pressure, ‘dicrotic notch’ appears with dip in diastolic flow. End-diastolic flow may go...
down to zero or reversal may be seen. Then monophasic flow is seen with sharp systolic peak.

Observations and Results

Out of the 278 accused of sexual assault, 110 did not consent for the procedure. 3 had Peyronies disease, out of which one had normal penile doppler study and in other two procedure was not performed due to local inflammation. Procedure was performed on 166 accused of whom the, 3 (1.80%) had arterial insufficiency. 6 (3.61%) accused on whom the procedure was performed developed priapism as complication.

The rate of complications was found to be double than the positive result of the procedure.

Fig:1. Total number of patients consenting for the procedure

Fig:2. The results of the procedure{positive:3(1.8%), complications:6(3.61%)}

Review of Literature

Physiologic process of normal erection begins with psychological factors (mental impulse) which cause transmission of parasympathetic motor impulses to the penis. This causes relaxation of smooth muscles in wall of cavernosal sinusoids, allowing sinusoids to expand and decreasing resistance to incoming blood flow. At the same time, cavernosal arteries dilate and carry increased blood flow into the penis. As the sinusoidal spaces start filling, the corporal veno-occlusive mechanism activates, and the fibrous tunica albuginea compresses the draining veins of the corpora, and rigid erection is achieved.2

Normal erectile function requires normal psychological health, normal endocrine balance, intact innervation to penis, normal cavernosal sinusoids, adequate arterial supply and normal venous occlusion with erection. Abnormalities of any of these systems may lead to erectile dysfunction.2

Erectile dysfunction is described as inconsistent ability to generate or maintain an erection of sufficient rigidity for sexual intercourse.

Etiology of erectile dysfunction:

I) Psychogenic- 10%

II) Organic-Neurogenic, Arteriogenic-30%, Venogenic-15%, Morphological, Drugs

To correctly diagnose/rule out impotency other than general physical examination, following Tests/investigations are needed to be performed-11

I) Blood test:

a. Serum testosterone and sex hormone binding globulin- to exclude endocrine causes.
b. Fasting glucose and glycated hemoglobin (HbA1c)- to exclude latent diabetes mellitus

c. Lipid profile- for deranged lipid profile

d. Thyroid hormones- for hypogonadal patients.

e. FSH- for patients with special clinical conditions.

II) Nocturnal penile tumescence.

III) Duplex ultrasonography.

IV) Intracavernosal testing with vasoactive substance.

V) Cavernosometry – used to test for venous leaks.

VI) Cavernosography – it is radiographic visualization of the cavernous penile tissues using contrast material in order to exclude structural abnormalities within the cavernous tissues. VII) Penile arteriography.

VIII) Spongiosography.

Priapism (an erection that lasts for more than 4 hours) is the most serious complication of the procedure which may lead to penile fibrosis. Other complications of penile Doppler with vasoactive stimulation include hypotension, pain, and hematoma.

Current legislation

Excerpts from section 375 IPC (Criminal Law (Amendment) ACT, 2013)  

A man is said to commit “rape” if he—

A.

Penetrates his penis, to any extent, into the vagina, mouth, urethra or anus of a woman or makes her to do so with him or any other person; or

B.

Inserts, to any extent, any object or a part of the body, not being the penis, into the vagina, the urethra or anus of a woman or makes her to do so with him or any other person; or

C.

manipulates any part of the body of a woman so as to cause penetration into the vagina, urethra, anus or any part of body of such woman or makes her to do so with him or any other person; or

D.

Applies his mouth to the vagina, anus, and urethra of a woman or makes her to do so with him or any other person, under the circumstances falling under any of the following seven descriptions.

Discussion

Vincenzo Mirone et al 4 in his study had proposed two tiered examination for evaluating erectile dysfunction. First level diagnostic tests included anamnesis, validated questionnaire, routine laboratory tests and hormonal profile. These tests were enough to make an etiological diagnosis of erectile dysfunction and to identify and remove any erectile dysfunction risk factors in most cases. First level tests should be performed, so that urologists can accurately diagnose erectile dysfunction and prescribe relevant treatment. Second level diagnostic evaluation included specialist instrumental exams helpful for accurate etiological diagnosis of erectile dysfunction. These exams, included Penile dynamic color-duplex Doppler ultrasonography, nocturnal penile tumescence recording, cavernosometry/cavernosography and neurological investigation. However, they proposed that these tests should be performed when first level diagnostic assessment was not clear, or an underlying organic pathology needed to be excluded in young patients with persistent ED, when veno-occlusive or neurogenic ED was suspected.

Martins FE et al 5 determined the role and validity of visual erotic stimulation as a more physiological and cost-effective diagnostic modality for primary noninvasive screening of psychogenic versus organic impotence. He reported that a positive response to visual erotic stimulation is strongly indicative of a predominantly psychogenic cause of erectile dysfunction and can be performed as an initial, minimally invasive test for cost-effective screening of psychogenic impotence.

There are other ways of screening like physical examination, psychometric evaluation, nocturnal penile tumescence, serum hormone levels blood chemistry and newer methods like visual erotic stimulation, which have no test related complications.

There are complications related to color Doppler study with intracavernous papaverine injection, most important is priapism. Penile Doppler with
intracavernous injection of papaverine induced priapism rate in different previous studies has been compared with our study in table 2.

Although maximum systolic velocity fairly correlates with arterial function of the penis, there are limitations to this diagnostic method. Patient’s anxiety may diminish the arterial response to vasoactive pharmacological agents to the point that maximum velocities fall below the normal range despite normal arterial function.²

A study conducted by Raheel M S et al.¹¹ concludes that since a person is assumed to be innocent by law unless proved otherwise, should be treated with dignity. They also oppose the trend of subjecting each and every accused of sexual assault to potency test without any rationale.

A similar study conducted by Ozkara H et al.¹² indicated that lawyers may abuse the assertion of erectile dysfunction in lawsuits for divorce and rape.

Although penile doppler ultrasound is extremely helpful in accurate estimation of erectile dysfunction it only caters to detection of arterial/venous/combined/morphological causes of erectile dysfunction. The psychogenic causes not being acknowledged. Potency unlike sterility is not permanent and depends on various factors. Person may be potent at the time of alleged rape but may be impotent at the time of medical examination or vice versa. This is mainly relevant, when accusation is brought up after considerable time gap. Person who is impotent towards one person may be potent to other person. Person impotent to one gender may be potent to other gender. So even after having normal result of Doppler study, which excludes organic cause, person may still be impotent at any particular situation or vice versa.

The new amendment of Section 375 IPC ¹, implies, peno-vaginal intercourse is not necessary to commit rape. This broadens the definition of abuse beyond the organic causes and hence further reduces the role of an invasive test as relevance in the accusation.

There is also involvement of a lot of specialised manpower (urologist, radiologist and para medical staff) who not only have to do the examination but also attend court summons in future. Also, the cost of the procedure is borne by the government. In India health sector already struggles lack of funds and manpower. There is no justification of diverting so many resources to one such issue when the study will not even have much impact on fate of the case.

Hence accused who is not asserting impotency should not be subjected to penile color doppler study and Penile color doppler with papaverine injection should be done in cases found impotent on screening.

**Conclusion**

We conclude from our study that, due to
- Limited role of penile Doppler in evaluation of causes of erectile dysfunction.
- Complications like priapism of the procedure.
- Change in the definition of rape and laws related to it.
- overburdened health infrastructure of India

Every accused of sexual assault should not be subjected to penile color doppler study

Based on our study we would also like to offer some suggestions:

1) Not all accused of sexual assault should be subjected to potency tests- only the accused asserting impotency should undergo potency test and color Doppler ultrasound.

2) Proper medical history with lab investigations
should be done.

3) Screening methods for impotency like visual erotic stimulation, NPTR (nocturnal penile tumescence and rigidity) should be done. Penile color doppler with papaverine injection should be done in cases found impotent on screening.

Determination of Stature from Anthropometric Measurements of Thyroid Cartilage in the Population of Punjab

Sunil Subramanyam¹, Dalbir Singh², YS Bansal³, SP Mandal⁴

¹Associate Professor, Department of Forensic Medicine, Pondicherry Institute of Medical Sciences, Ganapathichettikulam, Pondicherry, ²Professor, Department of Forensic Medicine, Adesh Medical College and Hospital, Kurukshetra, ³Professor & Head, ⁴Professor, Department of Forensic Medicine, Post Graduate Institute of Medical Education and Research, Chandigarh

Abstract

The astonishing task of determining the identity of an individual has been simplified, with the innovation of scientific technologies like DNA fingerprinting in the developed countries. Yet the application of such advanced technologies in developing countries is still a daunting task due to its complexity. Anthropometric analysis for the identification of unknown bodies is reasonably productive owing to its inexpensiveness. The aim of this study was to correlate the anthropometric measurements of the thyroid cartilage with the stature of the individual. Thyroid cartilages from 300 post mortem cases done in native population of Punjab were studied anthropometrically. A total of seventeen anthropometric measurements of selected parameters of thyroid cartilage were defined, measured, and statistically correlated with the body length of the individual. The variables which were significantly correlating with the body length were further analysed by regression analysis for derivation of a regression equation.

Key words: Anthropometric measurements, Regression analysis, Stature determination, Thyroid cartilage.

Introduction

One of the most important duties of any forensic expert is to determine the identity of an unknown deceased and establishing the same from any dismembered part of body. Stature of an individual is an essential requirement for establishing the identity of the individual. Most of the previous studies have relied on the anthropometric measurements of long bones for identifying the stature of an individual. The various well defined anatomical features of thyroid cartilage are not only quantifiable as anthropometric measurements (¹) but it also has an added advantage of being in a superficial anatomical location that negates the tedious removal and preparation process that must be done when utilising long bones for stature estimation. There are a few literatures (²-⁶) that estimates the stature of individual using anthropometric measurements of thyroid cartilage, which are done exclusively within a target native population. The aim of this study was to determine the stature from the anthropometric measurements of the thyroid cartilage in native population of Punjab.

Objectives:

1. To establish correlation between the anthropometric measurements of thyroid cartilage and the body length of the deceased.

2. To derive regression equation for estimation of stature from significantly correlating anthropometric measurements of thyroid cartilage.

Materials and Method

Materials used:

Portable anthropometer, Vernier caliper and Goniometer were used for the present study.

Method:
It is a prospective analytical study conducted from July 2012 to December 2013 on 300 cases autopsied in the department of Forensic Medicine of a tertiary care hospital in Chandigarh. Written informed consent from the legal heirs of the deceased were taken.

**Inclusion criteria**

- All cases above the age of 18 years.
- Residents of Punjab having at least two generation of ancestors from Punjab.

**Exclusion criteria**

- Cases with injury to thyroid cartilage.
- Known cases of Kyphosis
- Known cases of Scoliosis
- Acromegaly.
- Gigantism.
- Cretinism.
- Dwarfism.
- Congenital abnormalities of neck.
- Cases with advanced decomposition changes.

The recumbent length of the deceased was measured with the help of portable anthropometer after extending the neck, spine, and the lower limbs to overcome flexion due to rigor mortis. The body length was measured from vertex to the heel of the foot. To avoid inter observer error, the measurements were measured by three different observers and the mean value was taken. The thyroid cartilage was dissected out during autopsy, with great care as not to damage the superior and inferior horns in the process. The entire thyroid cartilage was then soaked in warm caustic soda solution until all muscular and ligamentous attachments sloughed off. After removal of all attachments, the dimensions of the thyroid cartilage were measured with the help of a thread, vernier caliper and goniometer. The recumbent body length and 17 parameters including the thyroid angle of thyroid cartilage were measured as per Table 1. All the parameters were measured by three observers and the mean value was taken as the final measurement to avoid inter observer error of measurement. All the analyses were carried out with the help of IBM SPSS Statistics package (version 20.0).

**Results**

A total of 300 samples of thyroid cartilages of the deceased belonging to Punjab population were collected and studied. Of these 300 samples, 238 were males and 62 were females. The length of body varied from 146 cm to 195 cm in males with a mean of 169.95 cm, mean standard deviation of 7.16 cm and standard error of 0.46. In females, body length ranged from 144 cm to 184 cm with a mean of 156.59 cm, mean standard deviation of 8.06 cm and standard error of 1.02. The length of body was compared and correlated with each of the seventeen variables using bivariate correlation analysis. A significant positive correlation was obtained between the body length of male and female with the length of both the sides of thyroid lamina with Pearson correlation value of \( r > 0.8 \) as shown in the table 2A, 2B, 2C.

In males:

- L RT L was correlating with the length of body with Pearson correlation of \( r = 0.908 \).
- L LT L was correlating with the length of body with Pearson correlation of \( r = 0.895 \).

In females:

- L RT L was correlating with the length of body with Pearson correlation of \( r = 0.959 \).
- L LT L was correlating with the length of body with Pearson correlation of \( r = 0.953 \).

Regression equation for prediction of body length of male and female was obtained from length of right and left thyroid lamina with standard error of estimate of 2.87 (male) and 2.89 (female)

**MALE:** Body length = 97.087 +7.481(L RT L) - 4.822(L LT L)

**FEMALE:** Body length = 93.119 +7.851(L RT L) - 4.919(L LT L)

Discussion
Various studies, which analysed the anthropometric measurements of thyroid cartilage of males and females, found a significant difference between them and established that sex can be determined from anthropometric measurements of thyroid cartilage (7-15). In the present study, the body length of the deceased was compared with various parameters of thyroid cartilage and it was found to be significantly correlating with length of right and left thyroid lamina for both gender. This finding was consistent with the studies conducted by Monica and Dhall (2) and Pierre Fayoux et al (3). The study conducted by Monica and Dhall (2) also found a significant correlation between body length of individual with height of arch of cricoid cartilage and transverse diameter of cricoid cartilage. In the present study those anthropometric parameters were not measured. The study conducted by Pierre Fayoux et al (3) done on 300 human larynxes also found significant correlation with thyroid alar width, and median anterior thyroid height. Whereas the present study didn’t find any correlation of body length with thyroid alar width and median anterior thyroid height. Too-Chung and Green (4) conducted a study in paediatric age group with 67 samples. They reported a linear correlation between body length with coronal and sagittal diameter at lower border of cricoid cartilage whereas the present study, the anthropometric parameters like coronal and sagittal diameter of lower border of cricoid cartilages were not evaluated. The study conducted by Schild (5) was conducted on human infant larynxes and found a linear correlation between crown rump length and the ventral thyroid height, but in the present study the parameter ventral thyroid height was not correlating with the body length. The study conducted by Ajmani et al (6) didn’t find any correlation between various anthropometric measurements of thyroid cartilage and the body length of the individual. The deviations of the above study results from the present study might be due to variation in the definition of parameters studied, differences in the number of samples and age range of samples studied from the present study.

Conclusion
Significant correlations were found between length of both sides of thyroid lamina and body length in both gender. Regression equation for prediction of body length from length of right and left thyroid lamina was derived for each sex. With a sample of thyroid cartilage of known gender, one can estimate the body length of the individual using the regression formula we have derived. This regression formula uses only the major parameters of thyroid cartilage namely length of right and left thyroid lamina, which are less prone to be damaged in the process of recovery from the body compared to other parts of thyroid cartilage. Further studies need to be conducted in different population to derive a standard regression equation for estimation of stature from anthropometric measurements of thyroid cartilage for a native population.

Abstract

210 autopsies (176 males and 34 females) aged between 2 to 70 years were studied. 12(6.81%) males, 8(23.5%) females total 20(9.52) were aged between 2-10 years 32 (18.1%) males, 4(11.7%) females total 36(17.1%) were aged between 11-20 years. 52(29.5%) males, 12(35.2%) female total 64(30.4%) were aged between 21-30 years. 31(17.6%) males, 3(8.82%) females total 34(16.1%) aged between 31-40 years 21(11.9%) males, 2(5.81%) females, total 23(10.9%) were aged between 41-50 years 15(8.5%) males, 3(8.82%) females, total 18(8.57%) were aged between 51-60 years 13(7.3%) males, 2(5.88%) female total 15(7.14%) aged between 61-70 years. The types of riders were, 17(8.09%) pedestrian 29(13.8%) cyclist, 103(49%) were riding two wheelers. 49(23.3%) travelling in car, 12(5.71%) were Lorry drivers / bus travelers. The types of injuries were 72(34.2%) had head injury 22(10.4%) had neck injury, 31(14.7%) had injuries to lower limb, 21(10%) abdominal injuries, 34(16.1%) had injuries to thorax, 13(6.19%) had injuries to upper limb 17(8.09%) had injuries to face. This pragmatic study will be quite useful to medico legal expert to assess the age group, region wise injury, types of riders because accident is an unexpected mishap which claims life, who are in hurry and disobey the traffic rules.

Key words – Accidents, injuries, Autopsies, Telangana

Introduction

Globally, the growth of transport system has been growing continuously and become a key element in economic development Due to industrialization and urbanization the transport system has been increased at leaps and bounds But in India. Bad roads, ignorant of traffic rules. Corruptive administration, law and orders ultimately leads to road accidents and deaths Every year Road traffic Accidents (RTA) claim 600000 and fifteen million get injure in RTA.(1)

The term accident has been defined as an occurrence in the sequence of events which usually produces unintended injury death or property damage(2) and majority of death occurs in age group between 5-44 was reported globally(3) It is surprise to note that, a person is killed or injured in every 4 minutes in Delhi traffic accidents in India(4) Hence attempt was made to study deaths in both sexes at different age, and different vehicles of Telangana state highways.

Material and Method

210 Autopsies (176 males and 34 females) aged between 2-70 years brought to osmania government collage hospital Hyderabad which is attached to Bhaskera medical college Yennukapally, Moinabhad Hyderabad

Information of age riding vehicles, or pedestrian were collected from police records. Majorities of autopsies blood / viscera traces of alcohol was found. Most of the accident took place during night time. The age group in both sexes, types of riders / pedestrian Region wise external injuries were classified with number and percentage

Duration of the study was 2010-2014 (four years)

Observation and Results

Table-1 classification age and sex in patterns of Road accidental deaths- 12(6.8%) males, 8(23.5%) of females total 20(9.52%) were aged between 2-10 years. 32 (18.1%) males 4(11.7%) females total 36(17.1%) aged between 11-20 years. 52(29.5%) males, 12(35.2%) female total 64(30.4%) were aged between 21-30 years. 31(17.6%) males, 3(8.82%) female, total 34(16.1%) were aged between 31-40 years. 21(11.9%) males,
2(5.88%) females, total 23(10-9%) were aged between 41-50 years. 15(8.5%) males, 3(8.82%) female total 18(8.57%) were aged between 51-60 years 13(7.31%) 2(5.88%) females total number 23(7.14%) were aged between 61-70 years.

Table-2 study of types of riders in patterns of injuries 17(8.09%) were pedestrian, 29(13.8%) cyclist, 103(49%) were two wheelers. 49(23.3%) were travelling in car, 12(5.71%) were lorry drivers / travelling in Bus

Table-3 study of injuries in road accidents. 72(34.2%) had head injury 22(10.4%) had neck injuries 31(14.7%) had lower limbs injuries, 21(10%) had abdominal injuries, 34(16.1%) had injury to thorax, 13(6.19%) had injuries to upper limb, 17(8.09%) had injuries on face.

Discussion

In the present study of patterns of injuries by traffic accidents in Telangana population. Classification of age and sex was 12(6.81%) in males, 8(23.5%) in female total 20(9.52%) in the age between 2- 10 years 32(18.1%) in males 4(11.7%) in females total 36(17.1%) in the age between 11-20 years 52(29.5%) in males 12(35.2%) in females total 64(30.4%) in the age between 21-30, 31(17.6%) males 3(8.82%) in females total 34(16.1%) in the age group of 31-4 years. 21(11.9%) males, 2(5.88%) female total 23(10.9%) ware in the age group between 41-50 years, 15(8.5%) males, 3(8.82%) female total 18(8.57%) were aged between 51-60, 13(7.3%) males 2(5.88%) females total 15(7.14%) were aged between 61-70 years. (Table-1) In the study of types of riders 17(8.09%) were pedestrian, 29(13.8%) were cyclist 103(49%) two wheelers, 49(23.3%) were travelling in car, / Jeep, 12(5.71%) were al- lorry / Bus (Table-2) In the evaluation injuries

During the autopsies 72(34.2%) had head injuries, 22(10.4%) had neck injury, 31(14.7%) had injuries to lower extremities, 21(10%) had injuries to abdomen, 34(16%) had injuries to thorax, 13(6.19%) had injuries to upper limb, 17(8.09%) had injuries to face. (Table-3). These different findings were more or less in agreement with previous studies(5)(6)(7)

Head injury includes, scalp injury in the form of contusions, lacerations, under scalp hematoma intracranial hemorrhages, comprising skull fractures(8) the tempo- regional injury was quite common. The neck injury include compression of spinalcord followed by fracture of vertebrae, fracture of larynx, laryngeal cartilages, laceration of common carotid and Jugalar vein.(9) Injury to thorx included fracture of ribs, with lung and heart injury was also noted. Injuries to upper limb and lower limb mainly included fracture of long bones followed by laceration blood vessels and musculature in addition to joint fractures. Moreover abdominal injury includes injury to vital organs rapture of spleen, intestinal perforation and bladder rapture(10) injury to spinal column was also noted. Most of the deaths due to severe bleeding injury to respiratory centres of brain, and involvement of nervous system and respiratory organ (cardio-vascular)

Summary and Conclusion

The present study of pattern of injuries in road traffic accidents in Telangana population is quite useful to medico legal expert, police and judiciary officials, Death or accidents in RTA is not only a Indian problem rather it is problem of the whole world where transport is functioning. The reasons are riders are un-aware or ignorant of traffic rules and consequent punishment. Disobedience of traffic rules and fearless consequences of punishments. Hence stringent law should be imposed and awareness of traffic rules in illiterates. Apart from this journey in night and during rainy seasons must be discouraged. Use of alcohol, non usage of helmet and belts in cars. Pedestrian should take particular caution when crossing the roads and look both ways before crossing walking on the road must be discouraged. Wide and neat roads, ban on old vehicles can prevent the major accidents. Above all, early slow driving self confidence will save our life and others too.

This research paper was approved by ethical committee of Bhaskara medical college yennukapally. Moinabad- Hyderabad (Telangana)

Abstract

Poisoning is a common day to day problem. Profile of poisoning in an area depends upon a variety of factors, ranging from access to and availability of poison, socio-economic status of the individual, cultural and religious influences, etc. A prospective study was carried out in the Department of Forensic medicine, Kempegowda Institute of Medical Sciences and Hospital Bangalore to study the socio-demographic profiling of deaths due to poisoning. Out of the 100 cases studied, incidence of poisoning was found to be more amongst the age group of 21 to 30 years in both sexes with mean age being 25.4 years and 25.4 years amongst males and females respectively. Poisoning is more in males (68%) as compared to females. In both the sexes, married (68%) outnumbered the unmarried in rural and urban community. This study shows that maximum number of poisoning cases were noticed among Upper Lower socio economic Class and in Nuclear families(61%). It was observed that majority of the victims were Graduate (28%). Financial constraints(22%) were the most common motive behind poisoning deaths.

Keywords: Poisoning Death, Autopsy, Socio-demographic profile, Motive

Introduction

Indiscriminate use of pesticides in agriculture, introduction of a variety of newer drugs for treatment, exposure to hazardous chemical products due to rapid industrialization, unhealthy dietary habits and increase in alcohol consumption have led to a wide spectrum of toxic products to which people are exposed nowadays. Profile of poisoning in an area depends upon a variety of factors, ranging from access to and availability of poison, socio-economic status of the individual, cultural and religious influences, etc.

Both suicidal and homicidal cases of poisoning are more common in India than in Western countries owing to the easy availability of poisonous substances on account of non stringent application of the laws of the land. Accidental poisoning is also on an increase because of the greater use of chemicals for agro industry and domestic purposes.

It is very difficult to draw a common report to say which kind of poisoning is more frequent as the nature of poisoning varies from one region to another depending upon the poison availability and the knowledge of local population regarding the properties of poisons. So this study has been aimed to determine the various parameters of poisoning such as mode of poisoning, type of poison, relation to occupation, marital status, religion status, motivation, vulnerable age group in South Bangalore.

Materials and Method

The present study has been carried out in the Department of Forensic medicine, Kempegowda Institute of Medical Sciences and Hospital Bangalore, during the period of Nov-2011 – May-2013. All the cases brought to the department for medicolegal autopsy with history of poisoning and cases that were diagnosed as poisoning after post mortem examination were selected. A sum total of 100 cases were selected by simple random sampling for this prospective study.

Ethical Clearance: Ethical clearance for the
present study was obtained from the institutions ethical committee, Kempegowda Institute of Medical Sciences, Bangalore.

**Method of Collection of Data:**

All cases with history of poisoning autopsied at Kempegowda Institute of Medical Sciences and Research Centre (KIMS), Bangalore were included in the study.

Detailed information of the deceased pertaining to the case was collected from the concerned police and relatives of the deceased by a questionnaire, Post mortem findings were analyzed with the chemical analysis reports. In treated cases information was acquired by perusal of hospital records. In cases of allegations, information was supplemented by either visit to the scene of crime or from the photographs of the scene of crime.

**Results**

In our study, the maximum number of poisoning in the study population are seen in the age group of 21 to 30 years (43%). In males it amounted to (42.65%) followed by 31 to 40 years (26.47%). Least number was noticed in the age group of 0 to 10 years and 11 to 20 years, accounting to (1.47%) each. In females, maximum number of poisoning occurred in the age group of 21 to 30 years accounting to (43.75%) followed by 31 to 40 years and 51-60 years of age group (15.63%) each. Least number was noticed in the age group of 0 to 10 years and 71 to 80 years, accounting to (3.13%) each.

Males outnumbered the females in the study population. In males it amounted to 68% and in females 32%. Poisoning is seen more among married people (68%) as compared to unmarried (32%). It is observed that poisoning cases were predominantly seen in urban areas (92%) as compared to rural areas (8%).

According to Kuppuswamy’s Socio-Economic classification, it is observed that the maximum number of poisoning cases were noticed among Upper Lower Class, followed by Upper Middle Class. Least is seen among the Upper Class group. Majority of victims were Hindus (86%) (n =86) followed by Muslim (10%) (n = 10) and Least were seen amongst the Christians (4%) (n=4). Incidence of poisoning is more among the Nuclear Family (61%) as compared to the Joint families (39%) in the present study population.

In the present study, it is observed that the incidence of poisoning were seen more amongst the Students comprising (25%), followed by House wives (16%), Domestic works (14%), Office work (13%), Professional (11), Unemployed and Salesperson (6%) each and Others (5%) who comprised of transport workers, retired persons and those whose profession were not clear. Least were seen amongst the Agriculture works (4%). It is also observed that majority of the victims were Graduate (28%) followed by High school certified (24%) and least were among profession (2%).

With respect to motive, most victims had financial constraints (22%) followed by Love Failures (15%), Ill Health (12%), Marital problems (10%), Educational problems and others comprised of (9%) each [others included death of dear ones, etc.], Family problems (7%) and the least accounted for Unemployment problems (6%). In (10%) of cases motive could not be ascertained.

**Discussion**

In our study it is observed that maximum number of poisoning is seen in the age group of 21 to 30 years (43%). In males it amounted to 21 to 30 years (42.65%) followed by 31 to 40 years (26.47%). Least number was noticed in the age group of 0 to 10 years and 11 to 20 years, accounting to (1.47%) each. In females, maximum number of poisoning occurred in the age group of 21 to 30 years accounting to (43.75%) followed by 31 to 20 years and 51-60 years of age group (15.63%) each. Least number was noticed in the age group of 0 to 10 years and 71 to 80 years, accounting to (3.13%) each. Similar findings were observed in the studies conducted by Adarsh Kumar1, Lan Zhou2, M. Shoaib Zaheer3, Kartik Prajapati4, Tejas Prajapati5, J.Gargi6, Shetty AK7 and Murari Atul8. It is not in accordance with studies by conducted by Margaret Warner9 and Deepak Pokhrel10.

Sex wise distribution of cases in this study showed the maximum number of cases were among males. Males outnumbered the females in this study. In males it amounted to 68% and in females 32%. Males being the main breadwinner in the family and the burden of earning for a livelihood are on them and the male ratio being more than the female, are the reasons for the incidence of poisoning more in males. Similar findings were observed in the studies conducted by Adarsh Kumar1, Kiran N11, M. Shoaib Zaheer3, Margaret Warner9, Heethal Jaiprakash12, Kartik Prajapati4, Chataut J13, Mizanur Rahman14, Tejas praajapati5, J.Gargi6, Shetty
AK and Murari Atul. It is not in accordance with studies by conducted by Deepak Pokhrel.

In the present study, poisoning is seen more among married people (68%) as compared to unmarried (32%). Similar findings were observed in the studies conducted by Kiran N, Heethal Jaiprakash and Kartik Prajapati.

In this study, it is observed that poisoning cases were predominantly seen in urban areas (92%) as compared to rural areas (8%). Similar findings were observed in the studies conducted by Kartik Prajapati and B. Maharani.

According to Kuppuswamy’s classification of Socio-Economic Status, this study shows that maximum number of poisoning cases were noticed among Upper Lower Class, followed by Upper Middle Class. Least is seen among the Upper Class group. Since the study involved the subjects residing more in urban setup, the annual income of the Upper Lower class could not suffice to meet the basic amenities resulting in disillusionment in life amongst them. Similar findings were observed in the studies conducted by Chataut J and Maharani.

Incidence of poisoning is more among the Nuclear Family (61%) as compared to the Joint families (39%) in the present study. Similar findings were observed in the studies conducted by Kartik Prajapati.

In the present study, it is observed that incidence of poisoning were seen more amongst the Students comprising (25%), followed by House wives (16%), Domestic works (14%), Office work (13%), Professional (11), Unemployed and Salesperson (6%) each and Others (5%) who comprised of transport workers, retired persons and those whose profession were not clear. Least were seen amongst the Agriculture works (4%). Similar findings were observed in the studies conducted by Adarsh Kumar and Kartik Prajapati.

In the present study it is observed that incidence of poisoning were seen more amongst the Graduates (28%) followed by High school graduate (24%) and least were among profession (2%). Similar findings were observed in the studies conducted by Adarsh Kumar and Kartik Prajapati. It is not in accordance with studies by conducted by Heethal Jaiprakash, Chataut J, Maharani and Tejas prajapati.

It is seen from the above study that financial constraints (22%) followed by Love Failures (15%), Ill Health (12%), Marital problems(10%) and Educational problems and others comprised of 9% each [others included death of dear ones, etc.], Family problems (7%) and the least accounted for Unemployment problems (6%). In (10%) of cases motive could not be ascertained. Among financial constraints the reasons were excessive debts, poverty, not able to pay the loan, extravagant lifestyle, engaging in activities in an urge to achieve instant richness were the prominent financial causes noticed. Among the ill health, in majority of cases evidence of chronic illness like gastrointestinal disorders, bronchial asthma, tuberculosis, diabetes, hypertension, and gynecological problems as procured through the history and hospital records, on autopsy corroborated with autopsy finding. Similar findings were observed in the studies conducted by Adarsh Kumar.

Conclusion

- Incidence of poisoning is more among the age group of 21 to 30 years in both sexes with mean age being 25.4 years and 25.4 years amongst males and females respectively.
- Poisoning is more in males as compared to females.
- In both the sexes, married outnumbered the unmarried in rural and urban community.
- Majority of the victims were Graduates (28%).
- Socio economic status of the present study among the deceased belongs to upper lower class and the least is among upper class.

Abstract

The study of the relative positions of astronomical objects and their movements is called Astrology. It is used as a means for deriving information about terrestrial planets and affairs of humans. The fear of the unknown is the primary reason for the current fascination with horoscopes. The beliefs are different among different cultures and every country has their own belief systems. Some of the beliefs and superstitions of Indians are seen to have been passed on from generation to generation. The Aim of the study is to co-relate the death with life line. Plotting the data against the age for correlation in scattered diagram it was observed that it did not reflect the life span of the individuals. Though people have belief in different aspects of astrology, this study proves that there is no scientific basis to the claims of palmistry.

Key Words: Astrology, Palmistry, Life line, Death

Introduction

In India 50% of the population is below the age of 25 years and the expected average age of an Indian will be 29 years by 2020[1]. India stands 165th in the life expectancy of the citizens with 69.09 years.[2] Hence the loss of life would affect the productivity of the state. This study is imminent, as it analyses the lifeline that could be used in predicting the death.

The study of the relative positions of astronomical objects and their movements is called Astrology. It is used as a means for deriving information about terrestrial planets and affairs of humans.[3] The origin of the word Astrology is from ‘Astrologia’ which is a Latin word ‘that means the account of the stars. Astrology is a language that symbolizes a form of art and ‘clairvoyance’. Astrology, all throughout the history of astrology, has been closely related to medicine, astronomy, thaumaturgy and meteorology.[4] The scientific value of astrology was questioned with the onset of the scientific revolution and it has been challenged successfully both on theoretical and experimental grounds. Certain studies have shown it not to have any scientific validity.[5] Thus Astrology is said to have lost its academic and conceptual standing, and the belief in it of people has seen a decline.[6]

The fear of the unknown is the primary reason for the current fascination with horoscopes. Some of the beliefs and superstitions of Indian are seen to have been passed on from generation to generation. The faith in Astrology stems from the objective that predictions given will help to protect them from evil spirits.[7]

Astrology is an integral part of Indian culture. In today’s time also, people prefer to start auspicious things such as taking the first step into a newly made home (Gruhapravesha), buying a new vehicle, its number, getting a marriage proposal fixed, selecting a marriage date, to begin a new business etc, according to their beliefs in astrology. Superstitions are seen not only in India, but it is present all over the world. The beliefs are different among different cultures and every country has their own belief systems. Though some believe these superstitions and follow them blindly, there are others, who do not believe in them and just ignore them.[7]

Palmistry is believed to have been originated from India, is more than 3000 years old. It includes studying
various aspects of the hand of an individual such as the shape and size of the hand, configurations and contours of the palm, finger shape, size and also features of the fingernails. It is said that at least a hundred signs or marks are there that could help predict qualities, events or supposed relations. The basic assumption is that every minute detail of the hand has information that could help predict the individual’s present or future.\textsuperscript{[8]}

The closest relationship that palmistry bears to science as conceived by many is the branch of dermatoglyphics, defined as the study of fingerprints. It has helped discover genetic correlation between particular patterns of fingerprint and certain human diseases.

Palmistry is said to have some branches such as

1) “Medical” palmistry, states that there is an association between the hand pattern and the emotional or physical states of the individuals.

2) “Psychotherapeutic palmistry” associates the hands, character, and personality giving the positive and negative aspects of the individual.

The lines of the palms are divided in two categories – the major lines and the minor lines. There are a minimum of 14 major lines that include the lifeline, head line, heart line, and lines of marriage, children, intuition, fortune, fate, intuition and spirituality. The lines are also studied in terms of their size, shape, length, so on and so forth. The lifeline is a line that indicates the constitution and physical well-being of the individual. In general it gives the vitality of the individual while its length indicates natural life expectancy\textsuperscript{[9]}

**Aim of the Study**

1. To measure the length of the life line in both hands of those who died

2. To co-relate the death with life line (palmistry)

**Materials and Method**

This cross-sectional study was undertaken between April 2017 and September 2018 at the Department of Forensic Medicine & Toxicology, SRMC & RI, and Chennai. Socio demographic and other data was collected from the deceased relatives, friends and Police/Investigating officer who were present during the autopsy of the deceased using standardized proforma developed for the purpose.

The lifeline was correlated with the age at time of death (longevity) obtained from the inquest report /FIR

Lifeline length was measured by a single observer in 100 cases brought to the Department of Forensic Medicine for autopsy. The lifeline lengths in both hands were measured by laying a stretched piece of thread or string along the line and then measuring its length using a ruler.

Cheiro was probably the first man to identify palmistry as seen in his work ‘Undisputed Doyen of Palmistry’. From his work on lifeline it is understood that it runs from a place at the meeting point of the radial end of the hand and distal end point of lifeline to the junction of proximal end of lifeline and palmar crease. This maximum lifeline length called the maximum potential lifeline was also measured as a control to account for the difference in hand sizes. The corrected life line ratio was thus calculated as the ratio of actual lifeline length to its potential maximum.

**Results**

In the theory of palmistry the length of life line in hand refers to longevity of a person. The life line extends from the corner of the palm above the thumb and travels towards the wrist in an arc. This lifeline in both hands were measured in all ages and compared with the actual life span of the deceased. The length of the lifeline in the left hand divided by the maximum length of left hand gave the left hand ratio. Plotting the data against the age for correlation in scattered diagram it was observed that it did not reflect the life span of the individuals. In the similar manner the right hand was analysed, which showed similar results.

**Left hand life line ratio: Chart– 1**
Discussion

From the time, Palmistry has been quoted in Indian and Chinese manuscripts, some 3000 years ago; the scientific validity of it has always been questioned. It gained peak popularity with intensive work done by society palmist Louis Hamon, known by his false name of Cheiro.\[10\]

Theoretically the length of life line in hand is related with the longevity of an individual in palmistry. The length of the life line is measured in both hands and it is compared with the actual life span of the deceased. The length of the lifeline in the left hand divided by the maximum length of left hand gave the left hand ratio. Plotting the data against the age for correlation in scattered diagram it was observed. In the similar manner the right hand was analyzed, in many cases which were studied had the same life line ratio but were of different ages and it was seen that left hand life line ratio and right hand life line ratio individually also had no correlation with longevity of a person.

This is contradicting the observations made by P G Newrick et al in their study which states that a strong statistical correlation exists between the life line length and the age up to which a person lived. This was particularly true for the correlation of the age at death and the right hand lifeline length.\[11\]

Conclusion

Though people have belief in different aspects of astrology, this study proves that the there is no scientific basis to the claims of palmistry.

In palmistry aspect the lifeline ratio of the subjects was found to have no correlation with the longevity of a person. This clearly disproves the claims in the palmistry.

Abstract

Agar-Paraffin double embedding technique is a simple technique that combines the advantages of both the embedding material. It preserves the minute tissue biopsies in orientation and holds them together from getting lost. Oral biopsies, being most commonly small incisional tissues, have to be preserved all through the processing and embedding to ensure optimal visualization of all the mucosal layers without compromise. In the present study, samples were divided into two groups: Group A: Agar-paraffin double embedding (APE) and Group B: conventional paraffin embedding (PE). Tissue samples collected were sectioned into two approximately equal sized bits. Both the bits were simultaneously processed, embedded in two different techniques (APE and PE method). Sections obtained were scored by an observer and analyzed using independent sample t-test (SPSS software version 21) to evaluate the efficacy of agar-paraffin double embedding technique in comparison to the conventional paraffin embedding technique. Agar paraffin embedded tissue was found to be well processed, firm and well preserved. Orientation was comparatively easier and the blocks yielded sections of good quality. They showed no interference with staining and cell morphology was of good clarity. Thus Agar-paraffin embedding technique represents a simple, reliable method that can greatly improve the quality of diagnostic information.

Key words: Agar-Paraffin, double embedding, oral biopsies

Introduction

Agar-Paraffin double embedding refers to the technique whereby the tissue is first impregnated with agar and subsequently blocked in Paraffin to combine the advantages of both the embedding media [1]. Use of Agar-Paraffin embedding for small specimens in routine surgical pathology was first reported in 1959, which was developed further by Herbert Z Lund in 1961 [2]. Agar-formalin solution to aggregate fragments of tissues prior to paraffin embedding was described by Cook and Hotchkiss in 1977 [3].

Oral mucosal biopsies, being the small incisional ones, in common instances poses frequent problem in appropriate orientation. Proper visualization of mucosal layers is most necessary to accurate diagnosis. Although Agar-Paraffin double embedding holds numerous advantages, it remains little used technique in oral pathology laboratory.

The present study aims to assess the efficacy of Agar-paraffin double embedding technique in comparison with conventional paraffin technique to emphasize the usefulness of the technique in handling small oral specimens.

Materials and Method

Ethical approval was obtained from the institution standard review board prior to the commencement of the study and oral mucosal biopsies were prospectively collected during gingivectomy and operculectomy procedures (Prospective experimental study). Each
specimen obtained was sectioned into two approximately equal sized bits (Figure 1b). One bit was given to Group A- agar-paraffin embedding group, APE and the other bit to Group B - conventional paraffin embedding group PE. Group A and B specimens were processed together and subsequently embedded in paraffin. Except for the difference that Group A specimens (eight samples) were embedded in 3% agar (type 1 bacteriological agar) prior to processing. Both the tissue sections were scored and analyzed by an observer who is blind to the choice of the procedure. All the data obtained were tabulated and statistically analyzed using independent sample t-test (software: IBM SPSS Statistics version 21).

Preparation of Agar-Paraffin (APE) blocks

3% Agar solution was prepared by adding 3gms of Type I agar (extra pure bacteriological grade Type I agar, GRM666 - HIMEDIA research lab, Mumbai, India) to 100 ml of distilled water in a conical flask and bringing to a boil on continuous stirring. Stirring was kept until the solution appeared clarified and no particle of agar was visible (Figure 1). The agar solution was slowly cooled to room temperature. Then using a dropper/ micropipette the solution was added slowly in the L-mold containing the fixed/unfixed minute oral specimen in correct orientation to cover the entire specimen. After cooling and solidifying the agar block (Figure 2) was (put for fixation if unfixed) processed in the usual way and subsequently embedded with paraffin. It was made sure at least 3mm of agar surrounds the tissue in all directions. The remaining agar are stored in a beaker and maintained in the laboratory refrigerator. As needed, sufficient quantities are re-liquefied by heating.

Fixation, Processing, Sectioning & Staining

Both the Group A and Group B tissue samples were fixed by leaving the tissues in 10% neutral buffered formalin overnight.

These samples were simultaneously processed without any difference in dehydrant (isopropyl alcohol), clearing (2 changes of xylene), infiltrated in molten paraffin wax and subsequently embedded in paraffin. 2-3 \( \mu m \) thick section of each block were taken, stained with routine hematoxylin and eosin and cover slipped with DPX mounting medium.

Results

Conventional oral biopsies as small as 0.2 to 0.5 cm were processed by this technique. These biopsies are further reduced in tissue volume and surface area to nearly half during formalin fixation and paraffin processing making it difficult to identify embedding surface. Agar paraffin Embedding technique has helped to overcome this problem as the fresh tissue has already been embedded in agar before processing. The colorless Agar block was easily viewed in liquid and gel forms, orientation of the biopsy was easily monitored. Agar had not interfered with the penetration of fixative or processing chemical reagents, thus all the APE tissues were well processed.

There were eight sections in each group [Group A-Agar paraffin embedded sections (APE) and Group B- Paraffin embedded sections (PE)]. The sections obtained from each group (Figure 4) were scored in observer score sheet based on quality of section, staining properties, optimal orientation and cell morphology. The results are summarized in the Table 1.

The mean score for section quality of APE sections was 1.63±.744 whereas those for PE sections was 1.50±.535 (p= 0.228). The mean score for staining clarity of APE sections was 1.88±.354 whereas those for PE sections was 1.38±.744 (p= 0.052). Both the APE & PE sections showed a mean score of 0.88±.354 (p= 0.052) for orientation. The clarity of the cell morphological characteristics of APE and PE sections were with average score of 1.5±0.535 and 1.38±0.518 respectively (p= 0.744).

Figure 1: a. Preparation of 3% agar solution, b. sectioning of oral biopsy specimen to equal sized bits, c. orientation of specimen bit held in L-mold around which molten agar poured.

Figure 2: Prepared Agar pre-embedded block along with the corresponding bit for conventional embedding.
Embedding involves enclosing properly processed, correctly oriented specimens in a support medium that provides external support during microscopy. Agar stabilizes the specimen by penetrating and replacing the intercellular fluid between the cells of the mucosa. It forms the cheapest source of embedding medium.

Agar is good choice for tissue embedding because of its property of hysteresis as it remains solid at 36°C±1.5°C, which remains firm even at 60-65°C thus holding the tissue firm and oriented in molten paraffin wax. Agar melts only at 87°C±1.5°C, a temperature range which tissue processing never reaches. Being a product of cell wall polysaccharides, Agarose and Agaropectin has an easy melting and good gel stability properties even at high temperatures. It is a common gelling agent used in various industries.

Improper choice of embedding medium can cause difficulty in section cutting resulting in poor quality of tissue sections. Among the faults in section cutting, crumbling of sections into fragments, wrinkling or folds are common. We found that Agar-Paraffin sections showed 25% more good quality sections compared to paraffin sections. This could be attributed to the strong penetration of tissue by dual materials, agar followed by paraffin, forming a homogeneous block from which sections could be cut easily. Improved cohesion of tissue layers and plasticity given by agar with facility of better ribboning characteristics offered by paraffin are combined to produce sections without inclusion of much of artifacts.

Staining processes are used to give tissue contrast and color before they are examined with the microscope. Presence and absence of embedding medium during staining not only manipulate sections but also result in coloration of the embedding media. The staining characteristics of APE were better than the PE sections by 37.5%. This data proves that the agar was better cleared away from the tissues unaffecting the senility and specificity of the stain used. Moreover agar does not generally stain with hematoxylin and eosin unlike media like gelatin.

In our study, we had used acrylic color paints (Faber-Castell 6 Fabric colors Acrylic paint PC: 1410501, Mumbai, India) to mark the margins of the specimens and found that inking on the specimens were well preserved all through out the processing by agar embedding whereas the inking materials over the specimen margins was lost during conventional processing as the specimen is passed through successive processing solutions. Thus it adds on the credit of using even the cheapest and easiest mode of inking, which can be preserved by the Agar- Paraffin embedding technique.

Improper embedding due to change in shape of the tissue during the processing can result in tangential sectioning which may interfere with reading or cause incorrect critical measurement such as thickness of the tumor. Often difficulty of identifying embedding surface on the minute oral specimens (~0.2-0.4cm) is produced due to shrinkage produced by formalin fixation and paraffin embedding. In the study, Agar held the specimen intact through the processing and since the orientation is also maintained which is accordance with previous studies, it yielded better quality of sections apart from saving the time for the pathology
technicians. Although, we found no significant difference between the tissue orientation achieved by Agar – Paraffin and conventional paraffin embedding, ease of orientation had been better with pre-embedding in agar.

The tissue processing procedure should preserve the underlying tissue architecture giving more comprehensive view of disease and its effect on tissues [4]. APE sections produced sections with well-preserved, discernable cell features- 12.5% more than that achieved by PE sections. Mechanical processing can distort the shape of the specimen due to action of the processing chemicals, which was prevented by agar block.

In the study, we had subdivided group A specimens (8 nos.) into two subgroups A1, A2 (4 no each). A1 group specimens were first embedded in agar followed which they were fixed in 10% neutral buffered formalin for a period of 24 hours whereas A2 group specimens were fixed (24 hours) prior to agar embedding. While the A1 group produced good quality sections with better staining characteristics, orientation and cellular morphology was better with A2 group [Table 2]. It was evident from the A1 sections that formalin had penetrated and fixed the tissue through the pores present in the agar. Cumulative intercellular tissue stabilization, removal with ease during de-waxing procedure and other physical characteristics of agar was responsible for section quality and staining character. The cellular morphology could have been compromised in A1 compared to A2 group due to probable imbibition of water from aqueous formalin solution or due to autolytic changes produced by the delay in the fixation during the process of agar embedding.

Certain slides of Agar-Paraffin showed edematous appearance of the cells showing the imbibition of water by agar. Agar blocks tend to hold more water even at high concentrations (due to imbibing action of agar). Increased duration in the dehydrating and infiltrating medium while tissue processing rectified the problem.

**Conclusion**

The Agar-paraffin embedding technique represents a simple, reliable user-friendly method that can greatly improve the quality of diagnostic information one can obtain from minute biopsies by improving tissue orientation, quality of sections and shortened turn around time. This study is the first comparative study to prove the efficacy of Agar-Paraffin double embedding over conventional Paraffin embedding.

Severity Grading, Management, Outcome and Epidemiological Profiling of Snakebite Victims in Tertiary Care Hospital in South India: 5 Years Retrospective Study

Smriti Sinha1, Sathyajith Karanth2, Avinash Kumar3
1 Assistant Professor, Department of Anaesthesiology, Kasturba Medical College, Mangalore, 2 Professor, HOD Anaesthesiology, SIMS&RC, Mangalore, 3 Associate Professor, Department of Community Medicine, Kasturba Medical College, Mangalore

Abstract

Objective: We conducted this study to do epidemiological and clinical profiling of the patients with snake bite in a tertiary care referral centre, situated in suburban area of Dakshin Kannada district, Karnataka, south India.

Materials and Method: This retrospective, record based study was done by analysing medical records of all the patients of snake bite admitted over 5 years from June 2015 to July 2019. It included demographic details and clinical profiling. Based on presenting complaint, clinical sign/symptoms and laboratory reports snake envenomation patients were divided into neurotoxic and hemotoxic group. The severity grading, amount of ASV used and outcome assessed in both the groups.

Results: Total 108 patient records were analysed, maximum of which were males (64.8%) in age group of 15-30 years (46.2%). In majority of the cases the species of snake was not identified (67.5%). Dry bites were reported in 40.7% cases, among envenomated cases, 68.7% presented with hemotoxic syndrome, 29.7% with neurotoxic syndrome and 0.9% had both the features. In all envenomated patients with increasing bite to needle time, the grade of severity, amount of used ASV, duration of hospital stay and complications were found to increase.

Conclusion: Snake bite is a neglected life threatening condition, which is a preventable disease. Tourniquet is still very commonly used first aid technique, which can be deleterious. The lack of education and awareness about snake bite management was evident and active mass education is clearly needed.

Key words: Snake envenomation, severity grading, Clinical profile and outcome

Introduction

There are almost 216 species of snakes in India and out of these only 60 are considered as poisonous. In India, there are mainly four species of snake majorly poisonous; cobras or Naja naja, krait or Bungarus caeruleus, Russell’s viper or Daboia russelli, and saw-scaled viper or Echis carinatus. All snake bite does not lead to envenomation, 70% of all snakes are non poisonous and poisonous snakes envenomate only in 50% of cases. Snake envenomation is a medical emergency. In 2009 WHO enlisted snake bite as neglected tropical condition. According to WHO report, maximum number of snake bite has been reported from South Asia, Southeast Asia, and sub-Saharan Africa. Every year highest number of mortality due to snake envenomation occurs in India, which ranges from 5,000 to 13,000 cases annually. The exact mortality due to snake bite may be even higher in India as many deaths go unreported in rural areas.
Clinico - toxicologically, nature of snake envenomation is categorized into hemotoxic, neurotoxic, and myotoxic syndromes\(^7\). We undertook this research for clinico-epidemiological profiling, and to find the risk factors which affects the outcome of different snake envenomation.

**Methodology**

The present retrospective, record based study was done in Srinivas Institute of Medical Science & Research Centre (SIMS&RC), on all the patients of snake bite admitted over a period of 5 years, from July 2015 to June 2019. It is the only tertiary care health facility in 20 km area, serving population of Mangalore city, suburban outskirts of Mangalore city, rural population of Udupi district, adjoining districts of coastal Karnataka and northern districts of Kerala.

Recorded information was entered in a pre-coded proforma which included demographic and clinical data. The data related to part of the body which was bitten, any first aid/ traditional treatment received, time to reach hospital after snake bite and time in receiving ASV after bite (bite to needle time) were collected for the entire patient. If snake species was identified at time of bite, that was also noted.

It is the hospital policy to admit all snakebite patients to Intensive care unit (ICU) and get done complete blood count, coagulation profile, renal function test, serum electrolytes including sodium, potassium and chloride. Patients were followed for 24 hours for “dry bite” confirmation and discharged after a day. In ICU, the 20 WBCT (whole blood clotting test) was done to assess venom induced defibrinogenation\(^8\) and used as a guide for further dosing of ASV in hemotoxic patients. Patients with signs of envenomation were administered ASV, which is known to cause allergic reaction, shock, anaphylaxis and serum sickness, these were also looked in the records.

Cobras and krait both belongs to elapid family and their envenomation leads to neurotoxic and cardiototoxic features\(^8\), local effects are supposed to be more common with cobra envenomation but by medical record evaluation it was difficult to differentiate both species. Russell’s viper and saw-scaled viper venoms are vasculotoxic\(^8\) and produce severe necrotising local effects. So for evaluation, all the patients of envenomation were majorly divided into two groups, neurotoxic group and hemotoxic group. According to the presenting complaints we tried to grade the severity of snake bite from grade 1 (mild) to grade 4 (very severe) in both hemotoxic and neurotoxic group, based on Kumar et al study\(^9\). The amount of ASV received according to the grade of severity also noted.

**Results**

A total of 108 patients of snake bite were admitted to the hospital during the study period. The maximum numbers of snake bite patients were reported in month of July-September and none in the months of January and February. Most of the patients were bitten during 6-11pm (77, 71.29%), at residence and roadside while walking (76, 70.37%) and in lower extremity (67, 62.03%).

One patient had reached hospital after 3 days due to cellulitis at the site of bite; she had earlier received ASV in some other centre, as all the information was present in the medical record so she was not excluded from the study. In majority of the cases the cause of delay was because of not considering it dangerous. Maximum patients did not receive any first aid and 2 (1.8%) patients arrived with immobilisation.

Dry bite was confirmed in 44 (40.74%) patients. Out of 64 cases of snake envenomation, 44(68.75%) were categorised as hemotoxic and 19(29.7%) were categorised as neurotoxic syndrome. One patient had presented within half an hour of Krait bite in hand which was sustained while cutting tree, two fang marks were present, profusely bleeding from the site of bite, tourniquet was tied, drooping of eyelid, difficulty in speaking, blurred vision and gait abnormality were present. On investigation, coagulopathy was present (INR 7.8). He left against medical advice in view of financial constrains.

Severity grading of hemotoxic envenomation, management and complications

Pain was found to be the most common presenting complaint in 41(93.1%) patients, followed by swelling in 29(65.9%), discolouration in 28(63.63%), local rise of temperature in 12(27.27%) and blisters in 4(9.09%) patients respectively. Bleeding from the fang wounds, hematemesis and hematuria were present in 5(11.36%), 4(9.09%) and 5(11.36%) patients respectively. Coagulopathy and cellulitis were reported to be the most common complication in 39(88.63%) and 24(54.54%) patients. Ulceration in the limb, renal failure, sepsis, necrotising fascitis and compartment syndrome were other complications noted in 10(22.72%), 8(18.18%), 8(18.18%), 5(11.36%) and 4(9.09%) patients respectively. All the cases of renal failure managed conservatively. Surgical interventions were needed in 11(25%) patients. Blood products were transfused in 27(61.36%) patients. No mortality recorded.

Severity grading of neurotoxic envenomation, management and complications

Ptosis was found to be the most common presenting complaint in 18(94.73%) patients, followed by external ophthalmoplegia in 11(57.89%), pain in 6(42.85%), swelling in 6(42.65%), abdominal pain in 4(21.05%), vomiting in 3(15.78%), discolouration in 3(15.78%), blisters in 3(15.78%), local rise of temperature in 3(15.78%), bulbar weakness in 3(15.78%) and gait
abnormality in 2(10.52%) patients respectively. Significant respiratory weakness was found in 2 patients, they were managed by endotracheal intubation. They improved after ASV administration and extubated after a day. Renal failure, cellulitis and gangrene were other reported complications in 4(21.05%), 4(21.05%) and 1(0.95%) patients respectively.

Neurotoxic group

| Amount of ASV used(mean) in patients with tourniquet | 15(n=1) | 20(n=2) | 40(n=3) | 25 |
| Amount of ASV used(mean) in patients without tourniquet | 12.5(n=6) | 16.25(n=4) | 28.3(n=3) | 19.01 |
The mean dose of ASV which was given for the neurotoxic snake bites was 21.5 vials (range 10-40 vials) and 20.92 vials (range 10-45) were given for the hemotoxic bites.

Allergic reactions to ASV were noted in 8 (12.63%) cases (pyrexial reaction in 6 cases, and urticarial reactions in 2 cases).

**Risk factor assessment**

Delay in presentation to hospital lead in increase in grade of severity. Application of tourniquet lead to increased requirement of ASV.

**Discussion**

The study was conducted in SIMS&RC, which is situated in suburban area of Mangalore, Dakshin Kannada district, Karnataka, South India. The Dakshin Kannada district is sheltered by Western Ghats on the east, which is the only remaining rain forest in India and home to several species of reptiles.

We explored medical records of 108 snakebite victims and found that mostly young males in age group of 15-30 years were victims bitten by the snake in the lower limb, which may be because ambulant population are at higher risk of snake bite. The maximum bites reported in months of July – September, which is the monsoon season and activity of snake increases during that season, which was in close agreement to previous studies. Most of the patients were bitten during the time of dusk and night at residence and roadside while walking, which was due to diminished vision and accidentally stepping on the snakes. Occupationally most of the victims were students and house wives, which were unlike other studies where agriculture was most common occupation. It may be the result of occupational difference in the population. Agriculture is not a major occupation of people in Dakshin Kannada.

Contrary to the major believe that all snake bite results in envenomation, we found that 40.7% patients were either bitten by non poisonous snakes or there was no envenomation (dry bite) in case of poisonous snake bites. The studies conducted in other states of India, like Kerala found 66% dry bite cases and in Himachal Pradesh it was found to be 43%.

In current study, maximum patients reported to hospital within 6 hours of bite and early arrival lead to lesser degree of severity. The amount of ASV used was found to be higher in severe grades and duration of stay was also longer due to development of complications. The direct correlation of early presentation and better outcome has earlier been demonstrated in other studies. There was no mortality reported in our study which could be because of early presentation of the patient to the hospital.

In current study, 29.6% patients came with tourniquet, in other studies conducted in South India almost 30-50% patients came with tourniquet application. The tourniquet is known to be potentially dangerous in snake bite cases as it leads to gangrene, increased fibrinolysis, bleeding in the occluded limb, peripheral nerve palsies and intensification of local envenomation. In current study it was found that the amount of ASV used in same grade of severity was more in the patients with tourniquet application in both hemotoxic and neurotoxic groups.

Maximum patients (73, 67.59%) did not receive any first aid. The knowledge to immobilise the bitten part of the body, as muscle contraction promotes venom absorption, was majorly lacking. Only 2 patients arrived with splint. The need of mass education about first aid of snake bite was obvious.

Hemotoxic syndrome was more common among envenomated patients that neurotoxic syndrome, which could be the result of more prevalence of Viper snakes in the region. This finding was in close accordance to studies conducted in neighbouring regions. The average ASV used was more in neurotoxic group, which may be because the elapid venom are small molecules, gets rapidly absorbed in the blood stream and needs higher dose of ASV for neutralisation.

In hemotoxic group, coagulopathy was most common complication followed by cellulitis, ulceration in the limb, renal failure, sepsis, necrotising fasciitis and compartment syndrome. These results were almost similar to other studies conducted on viper snake bite patients. In neurotoxic group; ptosis, external ophthalmoplegia, pain, swelling at the site of bite, abdominal pain, vomiting, discolouration, blisters, local rise of temperature, bulbar weakness and gait abnormality were presenting features, which were comparable to other studies done earlier.

To summarise, India is capital of snake bites so we need to focus on mass education about first aid and importance of early arrival in management of snake bite.
The amount of venom absorption can be decreased by immobilisation and early administration of ASV can cure the disease. The alternative treatment in any form can be deleterious and can make the prognosis poor.

**Limitation:**

It was a retrospective study so few data may be missing. Snake species identification was limited to very few cases so species specific severity grading could not be done. As neuroparalytic features were common to both Cobra and Krait, it was difficult to differentiate both the species based on medical record data evaluation, so both analysed together.

**Financial support and sponsorship:** Nil.

Study of Organo-Phosphorous Compound Poisonings with Blood Sugar Levels in Telangana Population

Jakaregari Srinivas
Associate Professor, Department of Forensic Medicine and Toxicology, IQ Medical College
Duragapur, (West Bengal)

Abstract
85 adult patients aged between 23 to 60 years of age were admitted at emergency wards were studied. These patients were known diabetic since 2 to 5 years, The clinical manifestation were 6(7.0%) had anxiety, 7(8.23%) had giddiness, 5(5.88%) had emotional liability, 7(8.23%) had slurred speech, 4(4.70%) had ataxia, 9(10.5%) had drowsiness, 5(5.88%) had confusion, 6(7.0%) had headache, 8(9.41%) had coma, 6(7.0%) had absence of reflexes, 12(14.1%) had dyspnea, 10(11.7%) had hypotension. The random blood sugar level in 48(56.4%) had 60-200 mg% and 37(43.5%) had > 200 mg%. This pragmatic approach to patients of oregano phosphorus patients who were diabetic and under anti diabetic treatment will be quite useful to physician and medico-legal expert to treat efficiently to avoid morbidity and mortality in Diabetic patients because diabetic mellitus is a silent killer and challenge to the clinicians globally.

Key words - Op = Organo-phosphorous compound DM = Diabetes Mellitus, Blood sugar, Telangana.

Introduction
Organo phosphorus (OP) Compounds have been widely used in agriculture for crop protection and pest control since few decades. Some of these compounds also has been used in the medical treatment of myasthenia gravis. These are DFP (diisopropyl phosphorofluoridate), TEPP (tetraethyl pyrophosphotetramide). Some of OP esters are also used to treat glaucoma (Ecothiopate). In addition to this veterinary medicine OP compounds such as tabun, sarin, soman and VX are used as nerve gases in chemical warfare. They are also used as stabilizers in lubricating and hydraulic oils flame retardants, and gasoline additives.

Acute poisonings with OP compound is quite common in India, generally with intention of suicidal ingestion. Because it is widely available for different uses. Mortality due to OP compound ranges from 4 to 38% in Indian studies. But in survival patients also suffer with health hazards. Hence attempt was made to study the OP compound poisonings in known diabetic patients.

Material and Method
85 patients aged between 23 to 60 years were admitted at emergency ward of Osmania government hospital which was attached to Bhaskera medical college, Yennukapally, Moinabad, Hyderabad. Due to consumption of organo phosphorous compound poisoning, as witnessed by the attenders. The history collected from the relatives (attendants) was that, they were under treatment of anti diabetic. As they had known history since more than 2 to 5 years.

Their physical examination was done, Ryle’s tube aspiration followed by ET tube with stomach wash was given. Before starting specific treatment with antidote atropine, oximes and I V fluids, Blood was drawn for random blood sugar levels, and calculated by glucose oxidase GOD-POD end point caloric metric method.

The patients consumed alcohol other poisons and under treatment of anti-psychiatric were excluded from the study. The ratio of male and female patients were 3:1.
The duration of the study was about 4 years (2010-2014)

**Observation and Results**

Table-1 clinical manifestations of patients consumed OP compounds poison – 6(7.0%) had anxiety, 7(8.23%) had giddiness, 5(5.88%) had emotional liability, 7(8.23%) had slurred speech, 4(4.70%) had ataxia, 9(10.5%) had drowsiness. 5(5.88%) had confusion. 6(7.0%) had headache, 8(9.41%) had coma, 6(7.0%) had absence of reflexes 12(14.1%) had dyspnea 10(11.7%) had Hypotension.

Table-2 Random sugar levels 48(56.4%) had 60-200 mg% 37(43.5%) had > 200 mg%

**Discussion**

In the present study OP compound poisoning with blood sugar levels in diabetic patients in Telangana population. 6(7.0%) had anxiety 7(8.23%) had giddiness, 5(5.88%) had emotional liability 7(8.23%) had slurred speech, 4(4.70%) had ataxia, 9(10.5%) had drowsiness – 85, 5(5.88%) had confusion, 6(7.0%) had headache, 8(9.41%) were in coma state, 6(7.0%) had absence of reflexes, 12(14.1%) had dyspnea, 10(11.7%) had hypotension (Table-1) Random blood sugar levels, 48(56.4%) had 60-200 mg% and 37(43.5%) had > 200 mg% (table-2) these findings were more or less in agreement with previous studies.\(^{(6)(7)(8)}\)

due to potent and appropriate antidotes and proper stomach wash and adequate ventilations no patient could develop ketoacidosis because it was reported that, post OP poisoning there was keto- acidosis in previous studies because hypoglycemia was confirmed in previous studies because of acute pancreatitis can occur with OP intoxication.\(^{(11)}\). It was also observed that, majority of the patients had mental- illness and depression which abated them to consume OP poison hence such patients were referred to psychiatric counseling.

**Summary and Conclusion**

The present study OP compound poisoning in diabetes will be concluded that, proper dosage of antidote, adequate ventilation, proper stomach wash can prevent the rise in blood glucose level and avoid further complication which may end in to mortality of the patients. Moreover diabetics patients having insomnia, depression must consult psychiatrist which might avoid such undue complication because exact complications of D.M is still un-clear

This research work was approved by ethical committee of Bhaskera medical college, Yennukappally Moinabad, Hyderabad- (Telangana)

Abstract

Personal identification is of paramount importance in the forensic odontology for ethical, humanitarian and criminal investigations. In forensic odontology, scientific methods using DNA is considered to be the gold standard method of identification; however, it’s expensive and time-consuming approach have circumvented the need for less expensive and faster methods of identification. The latest inexpensive approach of quantifying evidences for identification of suspect in crime is using lip print, fingerprint, palatal rugae & blood grouping and this has gained tremendous importance in the present days. Hence, the aim of the present study is to correlate and compare Cheiloscopy, Dactyloscopy and Palatoscopy with blood group and Rh factor. Method: A total of 200 dental students between the age group18 to 25 years were included in the study. Lip print, finger print and palatal rugae patterns with ABO blood groups were collected and compared using Chi square test. The data was analysed using SPSS version 10.0 statistical package. Results & Conclusion: Statistically significant correlation existed between lip print and ABO-Rh factors (χ²statistic = 37.56, p value <0.05) and between finger prints and ABO-Rh factors (χ² statistic = 30.6, p value < 0.05). No association was found between palatal rugae with ABO-Rhesus blood groups (χ² statistic = 17.71, p value >0.05).

Key words: ABO Blood groups, Cheiloscopy, Dactyloscopy, Palatoscopy, Personal identification, Rh factor.

Introduction

Proper identification enacts an important step in forensic odontology that is required for ethical, humanitarian and criminal investigations as well as in archaeology and paleo demographic support research studies.¹,²,³ Scientific methods using DNA are considered to be expensive and time-consuming approach, thus initiating the need for using less expensive and faster methods of identification. The methods using lip print, finger print and palatal rugae are considered to be unique to individuals and have gained tremendous importance in forensic odontology these days. Lip prints being unique to individuals, are formed by numerous elevations and depressions on the part of the lining mucosa called labial mucosa.³ The study of these lip prints is called as Cheiloscopy and was first noted in countries like Poland and USA.⁴ Fingerprint, on the other hand, once formed remain unchanged from birth till death. These raised portions of epidermis that are differentiated during 3rd or 4th month of embryonic life are best seen on palmer planter surface of human hands.⁵ Cummins in 1926 coined the term Dactyloscopy for study of these entities. ⁶ One more latest approach used for quantifying evidences of suspect in crime is studying the palatal rugae patterns present on the anterolateral aspect of hard palate. Due to its internal location in the head, these patterns usually, do not undergo any changes in one’s life, the only exception being its length. Yet another biological record that remains unchanged during the life time of a person is blood grouping. Considering all these points, we decided to conduct a study to correlate and compare Cheiloscopy, Dactyloscopy and Palatoscopy
with blood group and Rh factor.

**Material and Method**

A cross sectional study design was conducted among 200 dental students during the period of December 2015 to March 2017. The study was initiated after obtaining the ethical clearance committee approval from Krishna institute of medical sciences “deemed to be university”, Karad with ref no. KIMSDU/IEC/03/2015 dated 10/12/2015. All the participants belonging to age group of 18-25 years were included in the study design. The exclusion criteria were subjects with deformities of palate like cleft palate, traumatic injury on fingers, palate and lips, allergy to alginate impression material. Informed verbal consent was taken from the included participants. Convenience method of sampling was used for the purpose of randomisation to avoid any selection or performance bias.

For lip print

The lips of the subjects were cleaned and lipstick was applied on the lips. Lip imprints were recorded with usual rest position on A4 sheets (Royal Executive Bond, 85 gsm, premium white) and visualized using the magnifying glass (TAG 3TM, 50mm double reading glass optical graded lens with 5x and 10x magnifying capacity). The lip prints were classified according to Suzuki K and Tsuchihashi Y as type I, I’, II, III, IV, V. [7]

For finger print

The same subjects were asked to place his/her thumb over the stamp pad (CAMLIN COMPANY of size 157x 96mm). The finger prints were recorded on the A4 sheet by rolling their finger gently. Immediately after recording, the finger prints were interpreted using magnifying glass, based on Michael and Kucken’s finger print classification. [8]

For palatal rugae

Alginate (dentsply) impressions of maxillary arch was obtained and casts were made using dental stone (dentstone). The rugae patterns were traced on these casts using a sharp HP graphite pencil and patterns were explored on these casts using magnifying lens. The palatal rugae were classified by Kapali S et al as curved, straight, wavy and circular. [9] All the participants with known blood group were included for the study. Statistical comparison between lip prints, finger prints and palatal rugae impressions are as shown in Figure 1.

**Results**

Amongst, the total sample of 200 dental students the female (72.5%) participants were more in number than the males (27.5%). Majority of the participants belonged to the blood group B (40%). About 96% of individuals were Rh positive and only 4% were Rh negative.

Comparison between lip print and ABO blood group:

In the present study, vertical lip print was the most predominant pattern (37%) followed by intersecting (22%), branched (21.5%), reticular (11.5%) and undetermined (8%). The percentage distribution of most prevalent lip print pattern with ABO blood groups is as shown in Figure 2. There was no significant association between lip prints and ABO blood groups is as shown in Figure 2. There was no significant association between lip prints and ABO blood group (p > 0.05) (χ² statistic = 18.84, p = 0.093).

Comparison between lip print and Rhesus factor:

There was no significant association between lip prints and Rhesus blood group as shown in Table 1 (p > 0.05) (χ² statistic = 6.758, p = 0.149).

Comparison between lip print and ABO-Rhesus blood group:

There was significant association between lip print patterns and ABO-Rhesus blood group as shown in Table 1 (P < 0.05) (χ² statistic = 37.56, p = 0.0107).

Comparison between finger print and ABO blood group:

The highest incidence of occurrence of finger print pattern among the participants was loops (62.5%) followed by whorl (29%) and the least being arch type (8.5%). Composite type was not found in our study. The percentage distribution of most prevalent finger print pattern with ABO blood groups is as shown in Figure 3. There was significant association between finger prints and ABO blood group (χ² statistic = 23.02, p = 0.001). The highest incidence of occurrence of finger print pattern among the participants was loops (62.5%) followed by whorl (29%) and the least being arch type (8.5%). Composite type was not found in our study. The percentage distribution of most prevalent finger print pattern with ABO blood groups is as shown in Figure 3. There was significant association between finger prints and ABO blood group (χ² statistic = 23.02, p = 0.001).

Comparison between finger print and Rhesus factor:

There was no significant association between finger prints and Rhesus blood group as shown in Table 1 (P >
0.05) ($\chi^2$ statistic = 0.963, $p = 0.618$).

Comparison between finger print and ABO-Rhesus blood group:

There was significant association between finger prints and ABO-Rhesus blood group as shown in Table 1 ($P < 0.05$) ($\chi^2$ statistic = 30.6, $p = 0.006$).

Comparison between palatal rugae and ABO blood group:

The most predominant was wavy type (46%) followed by curved (38.5%) and straight type (15.5%). Circular type was not found in our study. The percentage distribution of most prevalent palatal rugae pattern with ABO blood groups is as shown in Figure 4. There was no significant association between palatal rugae and ABO blood group ($\chi^2$ statistic = 6.13, $p = 0.409$).

Comparison between palatal rugae and Rhesus factor:

There was no significant association between palatal rugae and Rhesus factor as shown in Table 1 ($P > 0.05$) ($\chi^2$ statistic = 0.466, $p = 0.792$).

Comparison between palatal rugae and ABO-Rhesus blood group:

There was no significant association found between palatal rugae and ABO-Rhesus blood groups as shown in Table 1 ($\chi^2$ statistic = 17.71, $p = 0.22$).

Comparison of finger print, lip print and palatal rugae with ABO blood group and Rh factor

In the present study, finger print, lip print and palatal rugae were compared with the ABO-Rhesus blood group as shown in Table 1 (Lip print: $\chi^2$ statistic = 37.56, $p = 0.10$, df = 28; Finger print: $\chi^2$ statistic = 30.6, $p = 0.006$, df = 14; Palatal Rugae: $\chi^2$ statistic = 17.71, $p = 0.22$, df = 14).

Discussion

In forensic identification, compilation of data from lip print, bite marks, fingerprint, blood groups in crime scenarios have played a benevolent role in identification of suspect in crime. However, no studies that compared and correlated all these parameters with blood groups. Hence, the present study is an attempt made to compare and correlate lip print, finger print and palatal rugae with blood group.

Lip print and blood group

Lip prints are unique to individuals and are present on the lining mucosa. The present study considered the basic pattern of lip prints given by Suzuki K and Tsuchihashi Y in 1971 as I, I’, II, III, IV, V. [7] In the present study, I and I’ are categorized as vertical lip print (type I); in accordance with study done by Nagasupriya A et al [10], where both partial and full vertical lip patterns were included under one category as vertical lip print (Type I). The present study showed that vertical pattern (37%) was the most predominant. These findings were in accordance with the study conducted by Patel S et al. [11] Karim B et al. [12] in 2013 among 122 subjects found that type II was predominant in A-ve blood group and type III with A+ve blood group which was in concordance with the present study. Verma P et al. [13] showed branched pattern was the dominant pattern, which was not similar to the results obtained in the present study. So, studying in depth and establishing further facts and truth in lip print will certainly help us, as useful evidence in forensic science. [14]

Fingerprint and blood group

The epidermal ridges of the fingers and palms as well as the facial structures like the lip, alveolus, teeth and palate are formed from the same embryonic tissues (ectoderm) during the same embryonic period. [15] In our study the finger prints were recorded based on Michael and Kucken’s finger print classification. [8] In the present study loop pattern showed the highest incidence of occurrence, followed by whorl and arch. These results were in accordance with the findings noticed by Mehta AA et al. [16] Sudikshya KC [17] conducted a study among 300 Nepalese, the study results revealed that whorls were more common in blood group B-ve which showed varied results when compared to the present study. In present study there was significant association between finger print patterns and ABO-Rhesus blood group (p<0.05).

Palatal rugae and blood group

Palatal rugae due to their unique features have been widely used in personal identification. The classification of palatal rugae was given by Kapali S et al. [9], based on the shape. Study conducted by Hunasgi S et al. on palatal rugae in two different population and their
correlation with the sex of the individual showed that the wavy and curved patterns were predominant in Karnataka population compared to Kerala. [18] Saraf A et al. conducted a similar study where curved pattern was more common in males than females. [19] Since, varying results were obtained, the present study was done to correlate palatal rugae with blood group and Rh. In the present study wavy palatal rugae pattern is most dominant pattern followed by curved that was in accordance with the findings reported by Abdellatif AM et al. [20] Our attempt to correlate all the three parameters with blood group is to assess their usefulness in the forensic science such as in mass disaster scenarios were identifying unknown victims becomes challenging. To authenticate these results, equivalent studies should be conducted by using these parameters.

Conclusion

The present study was conducted to correlate and compare Cheiloscopy, Dactyloscopy and Palatoscopy with blood group and Rh factor. Statistically significant association of lip prints and finger prints with ABO-Rh blood groups were found in the present study. Furthermore, we would like to conclude that future studies should be conducted with larger sample size to determine the validity of the results of present study.

Unnatural Female Deaths within Seven Years of Marital Life: An Autopsy based Study

Jeeveswararao Bagadi¹, Srinivasulu Pothireddy²
¹Assistant Professor; ²Professor & Head, Department of Forensic Medicine & Toxicology, Great Eastern Medical College, Srikakulam, Andhra Pradesh

Abstract

Unnatural female deaths pose a major challenge for society. The study was conducted on 644 unnatural female deaths during the calendar years from 2008 to 2012, in the Department of Forensic Medicine, Andhra Medical College. Women less than 29 years of age group, in the first three years of their marital life were the major victims in our study. Improving women literacy may give employment and thereby economical independency of women.

Key words: - Unnatural female death, Suicide, Burns.

Introduction

The complexity of “Unnatural female deaths within seven years of marital life” is so deep, as it involves study of human societies and cultures, marriage systems, customs of different religions of Indian society, civilization evolving through decades and psychology of Indian women. Population explosion, illiteracy and unemployment leading to poor socio economic status, fast urbanization with unequal opportunities for female and social dependency of women may be causing more women deaths after marriage. Sizeable sections of population still believe in the die-hard traditions of social customs in regards to dowry and caste. The statement made by Carl Marx “All the human relations are economical”¹ appears to be wise in respect to Indian marriages. In Indian society, ill adaptation of women to the changing social, economical and ethical environments increase the incidence of unnatural deaths when a female gets married and goes to her in-laws house. Failure to adapt to the husband, illegal affairs of spouses, new surroundings, and harassment from the in-laws often leads a married woman to extreme steps.

In Indian society the common methods adopted by women to commit suicide are burning by pouring inflammable liquids on the body, poisoning and hanging².

The incidence of unnatural married female deaths varied from place to place, time to time, season to season, one religion to other religion, in different circumstances and age groups with duration of married life. For the first time during the decade 2001 to 2011 that of the total of 217.70 million literates added, women (110.07million) outnumbered men (107.63million) (source: Ministry of Women and Child Development Government of India (XII th Five Year Plan)).³

From Manual labour stage, the twentieth century opened up new professional avenues for women entering into the Indian Administrative Services, soft ware and other educational services in increasing numbers.⁴ Even though educational and occupational opportunities are providing women with new roles outside the home, their social position in the family remains largely unchanged. They are still subordinate to husbands. Legal proceedings against the husband may mean her social ostracism as public opinion still places the man in the position of “LORD” for a wife.

The reports, statistical data, existing laws create an appearance that the position of women is better in India today. On close scrutiny one can find subordination and inequality of women still prevailing in society. The laws provide protection to women against injustice,
exploitation, dowry and discrimination. But in practice, in cases where the female deaths have not occurred, the crimes are being diluted in local scenario itself. An economical dependency and traditions bound wife can hardly take resource to law even if she has a valid ground for divorce. With the advent of new technology and development of personalized mobile phones, the privacy and intimacy between two persons has lead to the development of unlawful relations between male and female causing disturbance to the family life and leading to female deaths.

**Materials and Method**

A total of 8521 Medico legal Post Mortem Examinations were conducted during calendar years from 2008 to 2012, in the Department of Forensic Medicine, Andhra Medical College, Visakhapatnam. Out of 8521 cases, 644 cases were unnatural women deaths within 7 years after marriage. The statistics of these unnatural deaths were analyzed with available data like inquest report, autopsy report, suicide notes, panchanama report and dying declaration.

Age of the person, incident time, date, month, and period of survival, cause of incident, cause, manner and place of death were studied.

Survival period after the incident – Figure 1

Observations and Discussion

A total number of 8521 postmortems were conducted in the department of Forensic Medicine Andhra Medical College, Visakhapatnam. Among these, 644 cases of unnatural female deaths were recorded basing on the history given by the inquest report.

More number of unnatural female deaths were observed in the age group of <29 years (94.25%), among which 441 deaths were recorded in the age group of 20-29 yrs (68.47%) followed by <20 years (25.77%) and 30-39 years (5.74%). Post marital life pressure, financial problems; illegal affairs of either spouse in house may be responsible for more deaths in the age group of 20-29 years. Less number of deaths in 30-39 years can be explained on basis of adjustment of relation between husband and wife, better environment in in-laws house with time. Our study correlates with Naresh karukutla\textsuperscript{5} and Sandhya arora\textsuperscript{6} studies.

More number of unnatural female deaths occurred in in-laws and husbands place (86.18%) followed by victims parents residence (11.64%). As per Indian tradition staying with husband and in in-laws house is more common and coming back to victim’s parent’s residence is less. Our study correlates with Naresh karukutla\textsuperscript{5} study.

Fire, while cooking or lighting kerosene lamps accounted more deaths (43.01%) followed by Husband and in law’s harassment (31.52%). The other common predisposing causes were forced marriage (11.95%) and ill health (13.5%). This study correlates with Sandhya arora\textsuperscript{6} and contrasts with Rajesh kumar varma etal\textsuperscript{7}, Radhika R.H\textsuperscript{8}.

Death in most of the cases was during day time from 6am to 6pm (58.53%). After quarreling, husband may go out on work and house wife staying alone are vulnerable to unnatural deaths in day time which correlates with Madar ramchadra sane\textsuperscript{9} study.

In summer season more number of deaths were recorded (37.57%) followed by winter season (36.80%).
Among summer, May month recorded highest number (n=86) of deaths. More number of deaths in summer can be explained on basis of increased temperature causing more exhaustion, irritation, more family unions due to holidays, more friction in families due to discussion about dowry and financial issues.

Most of the victims (n=375) died within 72 hrs including 99 spot deaths. More fatality in early hours can be explained on basis of severity of injuries, disease and lack of proper health care facilities at village /mandal level implying the need to focus on patient care at early hours. This study correlates with Naresh karukutla etal 5 study.

Majority of the victims (81.52%) died after admission in to the hospitals followed by deaths at crime scene (16.30%). As explained earlier, Burns were the common cause of death where fatality is more common even in hospitals also. Services like 108 ambulances, arogyasri, are helpful to admit the victims in hospitals there by increased number of hospital admission and deaths. This study correlates with Naresh karukutla etal 5.

Maximum number of deaths occurred within first 3 years of marriage (51.08%). More deaths in first three years can be explained on basis of lack of awareness about marriage life, misunderstanding, financial problems, husband and in-laws harassment for dowry, ill adjustment in in-laws house, and extramarital affairs in early married life. Staying of newly married couple in female’s house for first 3 years may decrease the unnatural female deaths. Deaths in 4 to 7 years (n=315) of married life may be due to problems of infertility and husband bad behavior, forced female feticide. Decreased number of victims in 4-7 years (n=315) may be due to better adjustment of couple, for the sake of children and emotional bonding of family members .This study correlates with Naresh karukutla et al, 5 Rajesh Kumar varma et al 7, Radhika R.H et al 8, and contrasts with Rajesh c.dere 10 where more deaths occurred at 6-7 years of married life.

Most of the victims died from Burns (74.06%) followed by Poisoning (16.45%). Burns as the common cause of death, can be explained on the basis of daily cooking, easy availability of explosive materials like gas cylinders and kerosene. More fatality in burns can be ascertained to loss of skin resulting in decreased resistance of the body to the micro organisms leading to septicemia, shock, multiple organ failure etc., which explains burns as predominant cause of death. This study correlates with Naresh 5, Sandhya arora 6 Rajesh c dere 10, Kailash u zine 11, However M Ramachadra study 9 differs which states that Hanging was the most common cause of unnatural female deaths. Accidental Burns were common (56.18%) followed by suicides (39.20%).

Suicide is the most common manner of death (n=324) followed by accidental deaths (n=274).

Conclusions

1. <29 yrs of Age group is more vulnerable for unnatural female deaths.
2. Most of deaths occurred during the day time between 6:00am to 6:00 pm.
3. Summer recorded highest number of deaths, with peak incidence in May Month.
4. Deaths occurred mostly in first 3 years of marital life.
5. Majority of deaths occurred at husband and in-laws home.
6. Most victims died in hospital, after admission with period of survival <72 hours.
7. Burns were the major cause of death.
8. Commonest manner of death is suicide.

Suggestions and Recommendations:

1. Women protection cells have to be established in all mandal /district headquarters. They should collect the statistical data of all the new couples of their region and counsel the couple in immediate post marital life problems.
2. All marriages have to be registered mandatorily either at panchayath, municipal or at registrars’ offices wherever possible.
3. The society may be educated through audio-visual aids like T.V., Radio, Daily newspaper, Advertisements to prevent unnatural female deaths.
4. The Government should take personal protection measures for women to supply safety cooking devices, especially for low socio economical families.
5. Selling of pesticides and dangerous drugs should be stopped to women.
6. There is a great need for opening suicide prevention centers for prevention of suicides.

7. Improving women literacy may give employment and thereby economical independency of women.

8. Parents showing large gap of disparity between daughters and sons should be counseled to realize their responsibilities.

9. Educate the parents and counsel them to stop early marriages in girls.

Acknowledgement: I am thankful to Dr M Taquiuddin Khan, Professor and Head, Department of Forensic Medicine and Toxicology, Andhra Medical College, and other faculty for giving valuable suggestions during the study period.

Conflict of Interest: None

Study of Dimorphism of Humerus in Maharashtra Population

Mohammad Abdul Mateen
Associate Professor, Department of Forensic, Medicine and Toxicology, Jiu’s Indian Institute of Medical Science Warudi Badnapur (Taluk) Jalna (District) (Maharashtra)

Abstract

45 male and 45 females right and left dried, non pathological humerus were measured with vernier caliper and weighed with digital weighing machine. The vertical diameter of superior articular surface, transverse diameter of superior articular surface, circumference of superior articular surface, circumference of mid shaft in males and females of right and left humerus were studied and found highly significant P values in both sexes and right left humerus (P<0.01). These parameters will be quite useful to medico-legal expert, anthropologist because morphometric values of mesoderm are uncertain.

Key words:- vertical, transverse, circumference, articular, diameter vernier caliper

Introduction

humerus bone is named after sense of humours feels, when medial epicondyle is touched because it is crossed or in contract with ulna nerve, humerus is long bone of the arm forms should or joint and elbow joint. A biological profile which includes age, race or ethnicity and stature, sex when determined from the various human remains require certain parameter to determine with accuracy (1)(2). Many criteria are available to determine sexual dimorphism of human skeleton(appendicular and axial) (3)(4). But least data is available for sexual dimorphism of humerus. Hence attempt was made to differentiate male bones of humerus with females humerus with morphometric parameters in Maharashtra population, because skeleton of a particular individual or ethnic group is able to adopt to its owners life.

Material and Method

45 male and 45 females dried non-pathological humerus were selected for study humerus were available at Anatomy department and forensic department of IIMSC and R.C warudi– Jalna (Maharashtra) In addition to this, anatomy Department of Government Medical College Aurangabad.

Each bone was put in anatomical position and its metrical study was carried out by vernier caliper and weight of bones was carried by digital weighting machine. The obtained values were calculated by 2007 Microsoft computer (values of the males bones were compared with females bones)

The pathological, fractured bones were excluded from the study. The duration of the study was about three years.

Observation and Results

Parameters of right humerus

Table-1 – Comparison of vertical diameters of superior articular surface in male and females – Mean value of male humerus was 4.45cm(SD±0.12) and females was 3.53 Cms (SD±0.08) and t test was 42 (P<0.01) p value was highly significant

Table-2 – comparison circumference of superior articular surface of humerus Mean value of male was 3.53 Cms (SD±0.08) and t test was 42 (P<0.01) p value was highly significant

Table-3 - Comparison of mid shaft circumference of humerus mean value of male was 6.22(SD±0.20) and
females was 5.77 (SD±0.12) t test value was 13, and P value was highly significant (P<0.01)

Parameters of left humerus

Table-4 - Comparison of vertical diameters of superior articular surface. Mean value of male was 3.83 (SD±0.45) and females was 3.16(SD±0.20) t test value was 09 and P value was highly significant (SD±0.01)

Table-5 - Comparison of circumference superior articular surface. Mean value of male was 12.5 (SD±0.10) t test was 26 and P value was highly significant (SD±0.01)

Table-6 - comparison of mid-shaft circumference of humerus mean value was 5.73(SD±0.01) and female was 5.12 (SD±0.01) t test was 29 and P value was highly significant (P<0.01)

Discussion

In the present study of sexual dimorphism of humerus in Maharashtra population. In the study of right humerus the comparison of vertical diameter of superior articular surface. Mean value of male was 4.45 (SD±0.12) and females was 3.53 (SD±0.08) t test 42, p value was highly significant (P<0.01) (Table-1). Comparison of circumference of superior articular surface. The mean value of male was 13.8 (SD±0.37) and females was 12.4 (SD±0.13) t test was 25 and P value was highly significant (p<0.01)(Table-2). Comparison of mid-shaft circumference the mean value of male was 6.22 (SD±0.20), females was 5.77 (SD±0.12) t test was 13, p value was highly significant (P<0.01)(Table-3).

The parameter of left humerus (cms) comparison of vertical diameter of superior articular surface. The mean value of male was 3.83(SD±0.45) and females was 3.16 (SD±0.20) t test was 09, p value was highly significant (P<0.01)(Table-4). Comparison of circumference of superior articular surface of humerus. The mean value of male was 12.5 (SD±0.10) and females was 11.80 (SD±0.17) t test was 26, P value was highly significant (P<0.01)(Table-5). Comparison of mid-shaft value of male was 5.73 (SD±0.01) and female was 5.12 (SD±0.01) t test 29, P value was highly significant (P<0.01)(Table-6) These finding were more or less in agreement with previous studies(5)(6)(7).

These difference could be attributed a more variable life style and differential patterns of physical labour expected of males versus females (8). Moreover early maturity of females than males, giving two or more addition years to develop physically to males (9).

It has been also suggested that sexual dimorphism changes have strong genetic bases. It has been noted that population consuming very low or very high protein of demonstrated least amount of sexual dimorphism(11). Hence nutritional status also play vital role in sexual dimorphism

Summary and Conclusion

The present study of sexual dimorphism of humerus in Maharashtra population. Will be quite useful to medico- legal expert, anthropologist and anatomist. But this study demands further embryological, genetic nutritional, hormonal, biomechanical study because exact mechanism factors and duration of ossification is still unclear

This research paper was approved by ethical committee of jiui’a Indian Institute of medical science and research Warudi-Badnapur (Taluq) Jalna (Dist) (Maharashtra)

Perception of Students Regarding Gender based Violence

Muzaffar A1, Shenoy VK2, Vaswani VR3, Badiadika KK4
1Postgraduate Final Year, 2Assistant Professor, 3Professor and Head, 4Associate Professor,
Department of Forensic Medicine, Yenepoya Medical College, Mangalore, India

Abstract

Objectives: The study is undertaken to explore perception of students regarding violence against women with specific reference to domestic violence and sexual violence.

Methods: This is a descriptive cross-sectional questionnaire based exploratory study conducted in Mangalore, Karnataka, India. 220 participants consisting of age group between 18 to 25 years were included. Responses were obtained from the study participants through open and close ended questionnaires. Results: More than half (60%) of medical students and (56%) of engineering students disagree that in modern India women are enjoying equal rights to men. Three forth (77% male, 82% female) of students believe and disagree that it is alright for a man to beat his wife in order to make her obedient. Two forth (61%) of medical students and (63%) of engineering students agree that throwing acid on a woman to cause disfiguration is an example of gender based violence. Conclusion: The perception of medical and engineering students regarding gender based violence is quite similar. This study brought out issues of increased violence against women. A significant number still felt that dressing of a woman may be a factor for sexual assault. Women are still facing gender inequality and are not getting equal rights to men. Even though incidence of harassment, domestic violence are on the rise, women are not ready to report about their suffering because of social and family pressure. There is also need for awareness to be bought in gender mainstreaming for educating all sectors of the society.

Key Word: Sexual harassment, Crime against women, Domestic violence.

Introduction

Women are important part of our society and play vital roles in all aspects of life but their identity is restricted to being mother, sister, wife, or daughter1. In ancient Indian time’s as mentioned in Rigveda and other scriptures women held the most prestigious and honoured place in society2. The status of women in society over the period of time seems to be controversial, violence against women has been increasing and a universal concern too as men hold themselves superior and believes that women are mediocre. Women are given low status at work place and home. In last few decades there has been increase in the incidence of violence against women3. Globally violence against women has increased, it has been reported that more the one in three women (35.6%) have been subjected to sexual or physical violence by their friends or relatives and 38% of all murders are committed by their spouse4. 05% of murder of men is committed by their spouse. A woman has been subjected from verbal abuse, emotional abuse, physical and sexual exploitation leading to femicide. Worldwide 5000 murders in the name of honour killing and 25000 in the name of dowry death have been reported every year. There are also reports that the women are victim of sexual violence in wars and mostly prone to human right violation5. Unwanted pregnancy, child birth and child abuse may be a sign of violence against women. India is the second densely inhabited democratic country and seventh largest country in the world with 1.3 billion people, 48.4% are females and 51.6% are males6. Developing India is emerging as a global power but still women have to struggle for their position and status in the society. Women are subjected to violence irrespective of their cast, educational status, class and their subjugation adds to their suffering by physical, emotional, mental and economical deprivation7,8.

In India women have been subjected to violence and they are suffering from various causes such as
cheating, rape, torture, abduction, violent pornography, immoral trafficking and so on. A total of 3,27,394 cases of crime against women were reported in year 2015, 29.9% of sexual harassments, 10.4% physical assault, 7.6% stalking, 1.0% voyeurism, and 51.8% other cases. Human trafficking has increased from 0.4% in year 2014 to 0.5% in year 2015. According to NCBR “head wise percentage of crime against women” during year 2015 there were 34.6% cases of domestic violence, 25.2% cases of assault on women with intend to outrage her modesty, 18.1% cases of kidnapping and abduction of women, 10.6% of rape cases, 3.05% cases of dowry prohibition, 2.35% cases of dowry death, 2.7% cases of insult of modesty of women, 1.4% cases of attempt to rape, 1.2% cases of abetment of suicide by women, 0.7% cases of immoral trafficking of women, 0.25% other crimes.

Women have to suffer from gender violence throughout their life. As a child her father is in charge of her, as an adult her husband is in charge of her and after death of husband, her son takes over charge of her.

Rafique vs state of U.P 1980, Justice Krishna Iyer said “when a woman is raped, what is inflicted is not mere physical injury but a sense of some deathless shame” and judiciary response could not be muted to such grave human right violation. The implementation of preliminary measures gives a perception that the present criminal justice system India is not robust to protect women.

Women who suffer from sexual assault have physical and mental issues, poor sleep, irritable bowel, diabetes, post-traumatic stress disorder and various studies has shown that they were benefited with screening and discussing sexual assault with health care provider and all this helped in their recovery.

Gender based violence is a serious issue all the students undergoing medical education should be taught about the importance of the issue and how to address such cases.

The study was undertaken with the objective to explore perception of students regarding violence against women with specific reference to domestic violence and sexual violence.

Material and Method

This is a descriptive cross-sectional questionnaire based exploratory study conducted in Engineering and Medical Colleges of Mangalore, Karnataka, India. Questionnaire was externally validated by two subject experts. After obtaining institutional ethical clearance and due necessary permissions study was conducted and data were collected from the study area. The study was conducted in October 2018 to November 2018. 220 participants between ages 18 to 25 years were included. Responses were obtained from the study participants through close and open ended 25 items questionnaires. The data was analysed using SPSS version 20.0 software. Chi – square test was applied.

Result

In the present study, out of 220 participants, 110 (50%) were Medical students and 110 (50%) were engineering students of which 119 males and 101 females. There is no significant difference noted on various issues amongst the students from medical and engineering streams. 59.1% of medical students and 55.4% of engineering students did not agree that in modern India women are enjoying equal rights as men. Nearly half of medical and engineering students agreed that domestic violence in women is common and wide spread issue. More than 80% of medical and engineering students disagree that women feel safe while travelling alone and going out at night. More than 70% of medical and engineering students agree that vulnerable group such as minors and women with disabilities are more prone for sexual violence.

More than 70% of medical and engineering students agree that most of women hesitate to report about crime against them because of social and family pressure. Nearly 30% of male and 20% of females agreed that man can beat his wife to make her disciplined.

51% of medical students and 50% of engineering students (24% of male and 19 % female) believe that dressing style of a woman is be a factor for sexual assaults. More than 60% of medical engineering students agree that throwing acid on a woman to cause disfiguration is an example of gender based violence. 59.1% of medical students and 69.1% of engineering students agree that if a person with political background or influence is named as perpetrator of sexual violence, they are protected by investigating officer. 77.31% of medical students and 80% of engineering students agree that there is a stigma regarding sexual assault survivor in India. 78.2%
of medical students and 91.1% of engineering students agree that domestic violence is preventable.

Medical students perceive that percentage of perpetrators on violence against women are strangers 46.4%, family 30.9%, relatives 21.8%, friends 0.9% and engineering students report that perpetrators of violence on women are strangers 69.1%, relatives 20.9%, family 8.2% friends 1.8%. Medical students perceive that the place where women is commonly assaulted are public transport 44.55%, work place 30.0%, home 15.5%, market place 10%. Engineering students report that the place where women are commonly assaulted were public transport 60.9%, work place 30%, market place 6.4% and home 2.7%.

Medical and engineering students report that information on violence against women comes largely from Internet more than 50%, TV and Radio more than 40%, newspaper more than 10%, and others.

Medical students report that place where a victim of sexual assault more likely to visit is first to Primary health centre, second to Community health centre, then so on Secondary Hospital, District Hospital, Tertiary Hospital and engineering students report that place where a victim of sexual assault more likely to visit first to Primary health centre, second to Community health centre, then so on Secondary Hospital, Tertiary Hospital, District Hospital.

More than 90% of medical and engineering students agree that workshop and continued hands on training in Forensic Medicine is important to deal with cases in rural areas. 78.2% of medical students and 89.1% of engineering students agree that the attitude of people in India can be changed regarding sexual assault victim.

Discussion

In the present study, results did not indicate that Medical and Engineering stream students significantly differed in their perceptions regarding gender based violence. Mangali RN et al conducted a study in year 2007, women are considered lower compared then men in society and women suffer from gender discrimination in all aspects of life. Similarly, in the present study It was observed that more than half of total number of participants (m=60, e=56) disagree that in modern India women are getting equal rights to men.

Watts C et al in year 2002 reported that child sexual abuse is common and under reported because most of times they are threatened or the perpetrators is family member. Similarly, in the present study three forth of students (73%) believe that vulnerable group such as minors are more prone for sexual violence.

Imran M et al 2010, has reported crime against women is increasing, sexual violence cases are often under reported because of stigma and shame related to the survivor of sexual assault. Similarly, three forth of students (79%) believe that there is a stigma regarding sexual assault survivor in India. In the same study Imran in 2010 has reported that, domestic violence so common in our society, that six out of every ten husbands have beaten their wives. Sexual harassment is often not reported due to fear of family and fear of isolation from society. Similarly, in the present study majority of students (85%) believe that domestic violence is a wide spread issue and at least, one fourth of the students (26%) still believe that it is alright for a man to beat his wife in order to make her obedient. This is not only a perception prevalent in male (25%) but also shared by females (20%). This is a concerning fact as violence against women cannot be stopped if the belief by disciplining a woman by physical force continues. Similarly, if this is deep rooted in females, the inflicted violence on self gets justified and she may not access the health care or report to police.

Naskar G et al in year 2015, reports of wife battering and violence against widows are also on rise and legal measures should be taken for elimination of violence against women. The Indian cultural system is not open for wife reporting to the police of having been battered by her husband. Similarly, in the present study three forth (79%) of students believe that women hesitate to report about crime against them because of social and family pressure.

Nagindrappa M et al 2013, reports that women in India are not given equal rights to men irrespective of their cast, class, educational status. They are physically, socially, mentally and economically exploited since long. Bhawana D et al reported that various crime against women that occur in India such as sexual assault, kidnapping, abduction, dowry death, torture, molestation has been increased 59% since year 2011. Similarly, in present study three forth (78%) of students believe that violence against women in our society is common and
is on rise.

Waghamoda R.H 2013, conducted a study on domestic violence where women were the victims which is similar to the study by Badiadka 2017 where much of the public assault was on males and domestic violence in females. The World Human Rights Conference in Vienna, recognised gender based violence as human right violence in 1993. Article 14, 15 and 21 of Indian Constitution provides protection of women from domestic violence (domestic violence Act, 2005). There is cultural gender inequality, economic dependence on men, political under representation, less education and awareness among women and they are facing domestic violence by men because of all these reasons. Present study students perceived that domestic violence is preventable (85%).

T.K.K Naidu et al 2007, reported that Forensic Medicine has an important role in detection and help in administration of justice, forensic training must be given to Medical and Para Medical students to deal with cases in rural and semi urban areas. Proper Medicolegal investigation will help in solving of cases so that cases will not be undetected and unconvicted. Similarly, in present study majority (95%) of students reported there is requirement of specialized nursing training “Forensic nursing” as it is in developed countries and majority (93%) reported that workshop and continue hands on training in Forensic Medicine is important to deal with cases in rural areas.

Hossain N 2015, reported that gender based violence is a serious issue all the students undergoing medical education should be taught about the importance of the issue and how to address such cases.

Watts C 2002, reported that some of the most common and severe forms of violence against women by intimate partner are physical abuse, psychological abuse, acid throwing, sexual abuse, trafficking for sex, forced prostitution, exploitation of labour. Similarly, in the present study more than half (61%) of students agree that throwing acid on a woman to cause disfiguration is an example of gender based violence.

In the present study more than half of students believe that the perpetrators of violence on women are mostly strangers (58%). This is contrary to the study done by Madeswarana et al 2013, majority of cases perpetrators of violence on women were acquaintances such as family member, friends and relatives.

**Conclusion:** The perception of medical and engineering students regarding gender based violence is quite similar. This study brought out issues of increased violence against women. One third of the students still believe that it is alright for a man to beat his wife to make her obedient. More awareness programs should be conducted in gender mainstreaming. Women are still facing gender inequality and are not getting equal rights to men. Even though incidence of domestic violence is on the rise, it may not get reported because of social and family pressure. There should be sensitization program for every stream of students on gender related issues. Registered medical practitioner and Forensic nursing should be available so that when a woman accesses a health centre at any level, be it primary or tertiary, she gets appropriate care and medicolegal service. Investigating agencies, medical and paramedical staff should be sensitized and trained in this regard.

**Limitations of study:** Only medical and engineering students from select colleges are considered for study. They do not represent population of India.

**Conflict of Interest:** There is no conflict of interest.

**Ethical approval:** Institutional ethical committee (centre of ethics) approval has been obtained (Reference no-YEC198/2018)

**Source of Funding:** Self.

Legal & Intellectual Property Dimension of Health & Access to Medicines in India

M.Z.M. Nomani1, Alaa K.K. Alhalboosi2, Mohammad Rauf3

1Professor, Faculty of Law, Aligarh Muslim University, Aligarh (U.P./India), 2Research Scholar, Faculty of Law, Aligarh Muslim University, Aligarh (U.P./India), 3Assistant Professor, Faculty of Law & Islamic Studies, Maldives National University, Male (Maldives)

Abstract

Trade-Related Aspects of Intellectual Property Rights (TRIPS) Agreement, 1995 established synergy with human rights laws in realization of right to health, access to medicine and sustainable development. The Doha Declaration on Public Health, 2001; Sustainable Development Goals, 2015-2030 and United Nations Secretary-General’s High-Level Panel on Access to Medicines Report, 2016 promote innovation of health technologies in developing countries. It is estimated that 75 per cent of the world’s population is health deficient and medicine starved due to patenting requirement of pharmaceutical industries. India passed Patents (Amendment) Act, 2005 dealing with exclusive marketing right, product patent and process patent to protect the interest of the generic drugs in compliance of TRIPS Agreement, 1995 under public interest. In post Patents (Amendment) Act, 2005 phase India faced formidable challenge of the Swiss drug maker Novartis’ patent application for Gleevec in Madras High Court, 2006; Intellectual Property Appellate Board (IPAB) in 2009 and Supreme Court in 2013. The judicial exuberance struck a balance between patent right, health right and access to medicine in Indian socio-economic context. It is followed by spelling out of the National Intellectual Property Right (IPR) Policy, 2016 focused on enhancing access to healthcare as human right.

Key Words: TRIPS Agreement, Public Health, Access to Medicines, Pharmaceutical Industries, Exclusive Marketing Right, Novartis Judgment, IPR& Health Policy.

Introduction

Globally innovations in health technologies and access to medicine has dramatically improved and brought commendable health improvements but the majority of patients in developing countries constituting around 75 per cent of the world’s population are denied access to medicines due to patent by the pharmaceutical industry. The investment in research and development (R&D) of health technologies is ill-equipped to respond to diseases, such as Ebola and Zika, neglected tropical diseases (DTNs) and Antiretroviral (ARV) drugs related to HIV/AIDS.1 The World Health Organization Statistic, 2016 documented that prevention and treatment of AIDS, tuberculosis, malaria hepatitis, communicable diseases and neglected tropical diseases have not received the adequate attention.2 The legal and intellectual property dimension of health and access to medicines in India is governed by the TRIPS Agreement, 19953 and the Patents (Amendment) Act, 1970, Patents (Amendment) Act, 1999, Patents (Amendment) Act, 2002 and Patents (Amendment) Act, 2005.4 The innovation of health technologies in post TRIPS Agreement, 1995 and Indian slew of reform desiderates human rights to health and its links with intellectual property rights.5 The TRIPS Agreement,1995 flexibilities under the Doha Declaration on Public Health, 2001 addressed meaningfully to access to medicines as public health. This is supplemented by United Nations Sustainable Development Goals 2015-2030 which ensures healthy lives and well-being of all people of all ages.6

Access To Medicines: Promoting Innovation & Access To Health Technologies Which Review And Assess The Situations of Health Technologies Report, 2016 reveals ground realities asserting the millions of people lack of access to health technologies. Thus the legal and intellectual property dimensions needs a serious engagement to foster realization of access to medicine and human right to health in India.

Material & Method

The material and methods applied for the study include analytical method of legal research by undertaking the legislative survey and scrutiny of health and intellectual property laws at international and national levels. The comparative law methods applied for the statutory interpretation of Universal Declaration on Human Rights, 1948, International Covenant on Economic, Social and Cultural Rights, 1966 TRIPS Agreement, 1995, Doha Declaration on Public Health, 2001 and United Nations Panel On Access To Medicines and Access To Health Technologies Report, 2016. The Indian Patents Act, 1970, Patents (Amendment) Act, 1999, Patents (Amendment) Act, 2002 and Patents (Amendment) Act, 2005 is examined for harmonious construction of health and intellectual property legal framework. This study has analyzed the corpus of legal materials on international and national health and IP laws in the framework of Maxwell’s qualitative research design.7

Findings

The Universal Declaration on Human Rights, 1948 which mandates that everyone has the right to standard of living adequate for the health, medical care and wellbeing. This is buttressed by International Covenant on Economic, Social and Cultural Rights, 1966 by conferring enjoyment of the highest attainable standard of physical and mental health.8 The Inter-Ministerial Conference of the WTO adopted Doha Declaration on Public Health, 2001 on access to medicines in the context of the TRIPS Agreement, 1995.

WTO & TRIPS Agreement, 1995: The adoption of the WTO and TRIPS Agreement, 1995 ushered intellectual property norms and enforcement. Article 7 strikes the balance between the intellectual property rights holders and broader social interests and common good. Article 8 adopts measures to protect public health and nutrition, as well as to promote the public interest in sectors of vital importance to socio-economic and technological development.9 Article 27.2 restrict the patentability of inventions to save human life and health without prejudice to environment.10 Article 30 permits states to limit the exclusive privilege granted through patent rights in the interest of third parties, such as people suffering from HIV/AIDS diseases. It is further supplemented by Article 31, which sets out a regulatory framework for compulsory licensing with number of conditions. One of the strategies which have been debated in recent times is based on the implicit provision in the TRIPS Agreement, 1995 on the issue of parallel imports or the principle of exhaustion of rights of the patent holder under Articles 6 as a means of reduced prices and increased basket of access. However, negotiators included safeguards and flexibilities within the TRIPS Agreement, 1995 that could be used by signatories to tailor national intellectual property regimes so that countries could fulfill their human rights and public health obligations.11

Doha Declaration & Access to Medicines: The Doha Declaration, 2001 recognizes that the patent rights in health sector to protect the public health as obligations of WTO members to interpret the TRIPS Agreement, 1995 in public interest of medicinal access and drugs. It recommended exporting patented products and utilizing their compulsory licenses to needed drugs at affordable costs. It further enunciates that public health issues will supersede private interests in view of life threatening diseases such as tuberculosis, malaria and HIV/AIDS be issued under Article 31 of TRIPS Agreement, 1995.12 The Doha Declaration on Public Health, 2001 reaffirmed Article 31 of TRIPS Agreement, 1995 by empowering WTO members to utilize flexibilities available for the right to health and public health. However on the ground we find that the Median availability of essential generic medicines in developing countries generally reveals that only countries 37.7% in public sector whereas the in Private sector 70% found to be disturbingly very high.13 Despite these pronouncements, the sovereign right to issue compulsory licenses provided for by TRIPS Agreement, 1995 has been often stymied by threats of retaliation from governments and corporations.14

United Nations Health Technologies Report, 2016: The UN Secretary-General convened a High-Level panel to review and assess proposals and recommend solutions for remedying the policy incoherence between the justifiable rights of inventors, international human rights law, trade rules and public health in the context of health technologies in 2015. The Panel called for proposals that promote research, development, innovation and
increased access to medicines, vaccines, diagnostics and related health technologies to improve the health, wellbeing and sustainable development. The United Nations Health Technologies Report, 2016 penultimately replicated WHO Model List of Essential Medicines as a tool to advocate for access to priority medicines in all countries. It also calls for more transparency about the patent status of essential medicines and build domestic capacity to procure generic copies and develop Medicines Patent Pool to all disease.\textsuperscript{15}

**Health & Sustainable Development (SDG) Goal 2015-2030:** The SDG Agenda demonstrates unprecedented scope and ambition in the context of the current intellectual property system has created situations where new treatments are launched at increasingly high prices. The SDG Agenda creates affordability and sustainability issues for health systems even in high-income countries. The third SDG Agenda enunciates to ensure healthy lives and promote well-being for all at all ages in its own right. It institutionalizes the fact that the health significantly contributes to environment and sustainable development goals as reliable indicator.\textsuperscript{16} To usher these objectives the SDG Agenda enjoins WHO to play a strategic role public health, innovation and intellectual property.\textsuperscript{17} It also mandates to build capacities by providing an appropriate balance between affordability and maintaining incentives for investment in R&D. These endeavor’s will result in downsizing of rising burden of chronic non-communicable diseases (NCDs) and removal of barriers to access to medicines deficits.\textsuperscript{18}

**Discussion**

India’s obligation to faithfully comply with its commitments under international treaties and resulted to the status of the pharmacy of the world. It protects the interest of the generic manufacturers who have been manufacturing certain drugs patented elsewhere by providing the compulsory licensing regime. This mechanism encourages innovations as well as inventions in India to secure the effective working on a commercial scale. The combined impact of these attempts enlarged the ambit and scope of the public policy in health sector in the existing legal and intellectual property framework.

**Access To Medicines In India:** The Patents (Amendment) Act, 1970, Patents (Amendment) Act, 1999, Patents (Amendment) Act, 2002 and Patents (Amendment) Act, 2005 are to be seen in continuum of TRIPS Agreement, 1995 and Doha Declaration on Public Health, 2001 and the most progressive patent laws in terms of diagnostic, surgical and therapeutic methods of treatments. India extracted benefit of TRIPS Agreement, 1995 and introduced product protection on pharmaceuticals by Patents (Amendment) Act, 2005. By product patent protection India created supply of low-cost active pharmaceutical ingredients and investment in R&D. The shift in public policy dimensions under legal and intellectual property framework is evidenced an exponential growth in pharmaceutical R&D in post Patents (Amendment) Act, 2005 phase.\textsuperscript{19} Indian pharmaceutical companies increased the share of its revenues by focusing on building on their strengths by launching generic versions of big-selling drugs in the from the developed world. In 2003, India was granted 72 pharmaceutical patents in the United States. Although this is a small proportion of the total, it makes India the eleventh largest foreign source of United States patents in that category.\textsuperscript{20} Thus the new patent regime not only enabled better access to medicines at more affordable prices but foster the pharmaceutical industry R&D an upswing trend.

**Health & Public Policy:** The National IPR Policy, 2016 provides strong and effective IPR laws, which balance the interests of rights owners with larger public interest. The policy take away is a vibrant Intellectual Property ecosystem imbibed in public welfare of health care within the framework of the Doha Declaration on Public Health, 2001.\textsuperscript{21} The mission statement of the policy is to stimulate a balanced intellectual property system in India to foster innovation entrepreneurship and enhance access to healthcare as sectors of vital importance.\textsuperscript{22} A perusal of seven broad objectives of policy reveals the desire and direction of the legislative space and flexibilities available in international treaties to engage constructively in the negotiation of human right healthcare, access to medicine and drug as an inalienable entitlement. The National Health Policy, 2017 also expresses a firm commitment to Intellectual Property protection establishing a direct correlation between IPR and healthcare access. It has been observed that economies with the strongest IP protections are 60 percent more likely to provide environments conducive to innovation. And economies with IP protection in life sciences see an average of 13 times more biomedical investment than those lacking IP protection.\textsuperscript{23} The target of universal healthcare can sustain in a cohesive scientific, economic and policy ecosystem of medical
innovation.

**Novartis Judgment:** The impact of legal and intellectual property policies reached to culmination in Novartis Judgment when the patent application for Gleevec was rejected by the Indian Patent Office in 2006. It appealed to IPAB in June 2009 and Madras High Court challenging the denial of patent under Section 3(d) of the Patent Act, 1970. The Madras High Court rejected these appeals on the ground that ‘the domestic courts could not be asked to give an opinion regarding international treaties and obligations and that Novartis should take its complaint to the disputes settlement mechanism in the WTO.’ Novartis further appealed to Supreme Court through special leave petition in 2012. The Supreme Court merged three petitions in one popularly known as Novartis AG and observed that:

The Court was urged to strike a balance between the need to promote research and development in science and technology and to keep private monopoly (called an ‘aberration’ under our Constitutional scheme) at the minimum. The Court was reminded of its duty to uphold the rights granted by the statute, and the Court was also reminded that an error of judgment by it will put life-saving drugs beyond the reach of the multitude of ailing humanity not only in this country but in many developing and under-developed countries, dependent on generic drugs from India.

The Novartis judgment fortified the right to health and access to medicine in public interest than that of commercial interest. The Indian courts played seminal role in enforcing the right to life encompassing health access and affordability of medicine in to national interest.

**Conclusion**

With the adoption of TRIPS Agreement, 1995 and the introduction of pharmaceutical patents in developing countries to the development of Anti retroviral (ARV) drugs related to HIV/AIDS and other tropical diseases have become matters of great concern and posing continuous challenge. The intellectual property rights and human rights auditing demands that access to affordable drugs for realizing agenda of sustainable development goals. The TRIPS Agreement, 1995 flexibilities as approved by Doha Declaration on Public Health, 2001 and TRIPS Agreement, 1995- plus should foster public funded research prioritizing public health objectives among the pharmaceutical companies. The regime which denies product patentability in the field of health naturally leads to reduced access to drugs and derogation of human right norms. This is illustrated by the fact that one-third of the world’s population does not have access to basic drugs and pharmaceutical patents are hitting hard to disadvantaged people. It calls for human rights to place over intellectual property laws and all countries must freely be able to use flexibilities granted under TRIPS Agreement, 1995 to access affordable medicines. There is need to create cohesive legislative and policy framework for access to medicine and health care system.

Abstract

Aim & Objectives: To assess the awareness of patient’s dental record maintenance among BDS students and to evaluate their knowledge regarding the potential use of their maintained records in forensic identification.

Materials and Method: Data was collected by means of a self administered questionnaire consisting of 24 closed ended questions, addressed on the awareness about patient’s dental record maintenance and its importance in forensic needs among ³rd, ⁴th year BDS students and interns of a private dental college.

Results: 73.1% of the respondents were aware that dentists were legally bound to maintain records in India and 83.5% were aware that these could contribute towards forensic investigations. Most of the students were aware of how to maintain dental records in an institution. 67.4% of the study population felt the need to store records for a minimum of 5 years. 65-70% had knowledge regarding denture markers and role of implants in forensic identification. The most perceived barrier to good dental record keeping was lack of time according to most of the students.

Conclusion: The survey revealed awareness on the importance of dental records in forensic identification among BDS students. Few areas showed inadequate knowledge, thus mandating an utmost need to train dental students in this field. Newer methods like denture marking and Aadhar number in corporeartion in prostheses should be given importance.

Key Words: Aadhar number, Denture markers, Dental records, Forensic Odontology, Undergraduate dental students.

Introduction

Personal identification is of paramount importance in forensic investigations, and this can be done on the basis of the theory that “all individuals are unique and can be identified on the basis of individual characteristics.”¹ Variety of methods can be used to corroborate forensic identity, but the reliability of each of these methods varies and moreover, cannot be used in all sorts of cases. DNA profiling, dermatoglyphics, anthropometric data, use of dental records are the standard methods employed.²³ Since dental remains are usually the last ones to decimate post mortem, these can be of utmost importance in personal identification in mass disasters, natural or man-made. In addition to this, dental records can also help in identification of suspects in criminal investigations and in medico legal cases.⁴
Dental records comprise of clinical notes, radiographs, plaster models, treatment done including serial numbers of prosthesis. These records encompass an in-depth and continual documentation of the patient’s conditions and treatment, hence helping in diagnosis and patient care. These records also serve research, administrative, quality assurance, education purposes and can also be used as evidence in legal proceedings.

Thus, generating detailed accurate patient records, maintaining, storing and retrieving them should be a crucial part of practice and this habit should be inculcated during the professional training of dental students. Keeping all these facts in mind, this study was conducted to assess the awareness of patient’s dental record maintenance among BDS students, and also to evaluate their knowledge regarding the potential use of the maintained dental records in forensic human identification.

Materials and Method

This was a cross sectional study using descriptive qualitative methodology. The study population comprised of 3rd, 4th year students and interns of a private dental college in Bhubaneswar, Odisha. Data was collected by means of a self-administered questionnaire consisting of 24 relevant closed-ended questions addressed on the awareness about patient’s dental record maintenance and its importance in forensic needs. All the students were explained about the nature and purpose of the study and consent was obtained. The study protocol was approved by the Institutional Ethics committee.

Statistical Analysis

Pearson’s Chi-Square test was used to evaluate the association between interns, final and third BDS students regarding awareness on dental record maintenance and its forensic implications. P value of less than 0.05 was considered statistically significant.

Results

A total of 242 students responded to the survey, in which 82 were from 3rd year, 77 from 4th year and 83 were interns. Data regarding awareness of respondents about the medico-legal aspect of dental records and its contribution towards forensic investigations is charted in Table I. It also shows comparative results of the most effective and fastest method of forensic investigation among the students.

Table II shows awareness and knowledge of students regarding how to maintain dental records, how long records should be stored in institutions and the preferred method of maintaining and storing them. Table III displays knowledge of students regarding details to be included in personal information of patients, use of diagnostic aids and reports in patients file and their use as ante-mortem records.

Interns had better knowledge about recording treatment details, materials used and their use in identification of the deceased. Regarding denture markers and role of implants in forensic identification, percentage of knowledge ranged between 65-70% and did not show any statistical significant result. Awareness regarding use of records, dental anomalies, intraoral camera captures and photographs was found to be satisfactory among the three groups, wherein 72.3% of students believed dental anomalies could contribute towards personal identification. Around 70% of the study population believed that incorporation of “Aadhar Number” in dental records and prosthesis would help in identification of deceased individuals.

Table IV shows the most perceived barriers to good dental record keeping, students perception on attending CDE programs and workshops on Forensic odontology and their take on relevance of forensic odontology for a successful clinical practice.

Discussion

Production, maintenance and release of accurate, legible, comprehensive, organized records is the ethical and legal obligation of a dentist, and hence this practice must be inculcated during the period of professional training of students. Very few studies have been done to evaluate the awareness of importance of dental records among undergraduate dental students, and hence this study was undertaken to do the same.

Hannah et al performed a cross-sectional institution based survey among undergraduate dental students and evaluated their knowledge, attitude and practice of forensic odontology. They reported more than 80% of students had good knowledge about forensic odontology, 82% of their participants pointed their source of knowledge to be from lectures and workshops in college and 83% of their students were interested to undergo formal training in the field. On the contrary, 50.8% of our study population believed that they did not have adequate knowledge regarding the subject and its various methods. 57% of our study population had attended CDE and workshops on the subject, whilst 76% of our students believed they needed to know forensic odontology in detail to run an authentic clinical practice. Ignorance of forensic odontology during the undergraduate level may be responsible for students having comparatively lesser knowledge in this aspect.

Kutesa et al conducted a qualitative cross sectional study among 4th and 5th year undergraduate dental students to obtain information on the factors responsible for unsatisfactory state of dental records at the students clinic. Poorly designed clerking forms, inadequate storage space and poor maintenance of records were the factors attributed to this deficit, and according to them electronic system was deemed to be the ultimate solution to this problem. According to our study, lack of time was the most perceived barrier to good dental record keeping. In addition, factors like lack of experience, lack of training programme/CDE and increased work load were also responsible for this inadequacy. Our study also showed that interns and final years believed electronic dental records to allow faster accessibility and easy retrieval and hence had better understanding of dental record retrieval, a finding in accordance with the study of Kutesa et al.

Several studies have been done to assess the awareness of dental record maintenance among dental practitioners in India. Astekar et al conducted a cross sectional survey among practising dentists in Rajasthan, India and reported only 38% of the surveyed population maintained records. Preethi et al analyzed the knowledge, attitude and practice of forensic odontology among dental practitioners in Chennai and reported 21% of the practitioners did not maintain records in their clinics, while only 12% maintained complete records in which 93% did not maintain them for more than seven years, thus concluding inadequate knowledge, poor attitude and lack of practice of forensic odontology among the practitioners. Similar results were also reported by Harchandani et al and Sengupta et al from Pune and Ghaziabad respectively. On the contrary, Rahman et al reported an adequate level of knowledge, awareness and practice regarding forensic odontology among dental surgeons in Bhubaneswar, Odisha. Ramesh et al from their cross sectional questionnaire survey concluded that knowledge of forensic odontology among dental practitioners in Kanpur to be adequate, while lacking in the attitude and application of that knowledge.
undergraduate students go for clinical practice after their graduation, they should have adequate knowledge and right attitude to maintain dental records and thus should be inculcated during their training period.

Kannan et al assessed the knowledge and awareness on the application of prosthetics in forensic dentistry among dental practitioners in Chennai, and reported awareness amongst 62% of surveyed dentists. However, the acceptance and willingness was found to be very low. Our study revealed the percentage of knowledge regarding denture markers and role of implants to range between 65-70%. The field of forensic science could also benefit from the advent and incorporation of “Aadhar number - the unique identification number of Indian citizens”, in various prosthesis used in patient’s body and thus, help in the identification of an individual. Motivation and education on these grounds right from the training period of students are hence mandatory to promote their awareness, acceptance and application. Ours is the first study to explore the students knowledge in this context.

73.1% of the respondents in our study were aware that dentists were legally bound to maintain records in India, which could help in protection against any commercial, legal or medicolegal litigation. On the contrary, Astekar et al reported that none of the dentists in their study population were aware that it was legally mandatory to maintain records in India. However, the Indian Constitution under Article 51A(h) mandates the maintenance and preservation of medical, medicolegal and legal documents in the best interest of social and professional justice.

Patient records must formally document patient details, clinical findings, reports and treatment given, and these should be kept securely. Indian Law necessitates preservation of official records and documentation for a minimum of 8 years to avoid attracting penalties under Section 271 of Income Tax Act,1961. For legal suits, judicial records should be safeguarded for minimum 2 years in consumer cases, 3 years in civil cases and no time limit in criminal cases. The Indian Dental Association recommends that for practicability, a doctor may maintain records up to a minimum of 5 years to satisfy consumers and the judiciary, for protection against medical negligence and complications. According to 67.4% of our study population, dental records should be stored for a maximum of 5 years. But the Dental Council of India has not set any specific set of rules.

Conclusion

The result of the survey revealed the awareness on the importance of dental records in forensic human identification among BDS students. Few areas showed inadequate knowledge. Thus, there is an utmost need to train dental students to maintain good and adequate dental records as they are the future dental practitioners. Adequate time and guidance should be given to students for proper maintenance of records, so that the habit and attitude can be ingrained, which would prove to be beneficial in the longer run. Newer methods like denture marking and incorporation of Aadhar number in prostheses should be given importance.

A Study to Compare the Stress Patterns in the Edentulous Mandibular Bone around the Two Implant Retained Over Denture and the Prosthesis Restored with All-On-Four Concept Using the Three Dimensional Finite Element Analysis

Puneeth Hegde¹, Satish Shenoy², Shobha Rodrigues³, Thilak Shetty⁴, Umesh Pai¹, Sharon Saldhana¹, Mahesh M¹

¹Associate Professor, Department of Prosthodontics, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, Manipal; ²Professor & Head, Department of Aeronautical Engineering, Manipal Institute of Technology, Manipal, Manipal Academy of Higher Education, Karnataka, India; ³Professor & Head, ⁴Professor, Department of Prosthodontics, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, Manipal

Abstract

When we consider the rehabilitation of patients with the mandibular implant supported over denture, the influence of the implant number and the cantilever design on the stress distribution on the bone needs to be assessed precisely.

Purpose: The purpose of the simulation study was to compare the biomechanical behavior of the two implant supported over denture design with the All-On-Four Concept using the three dimensional finite element method thereby evaluating the Von Misses stresses induced on the implant under different loading simulations.

Materials & Method: Three dimensional models representing mandible restored with two implant supported prosthesis was compared with the models that were restored based on the ‘All-On-Four’ concept. The models were then subjected to four different loading simulations (full mouth biting, canine disclusion, load on cantilever, and load in the absence of cantilever). The maximum von Mises stresses were localized and quantified for comparison.

Results: Among the models, under all loading simulations, the maximum stress concentrations were along the neck of the implant. The stress levels for full mouth loading simulation was highest for two implant supported overdenture design and the least for All-On-Four overdenture design. In all the designs, the least stress was when the implants were loaded in a lateral direction. The stress levels for cantilever and non-cantilevered designs were nearly the same for all the simulated designs.

Conclusion: When tested under different loading simulations, both models showed similar location and distribution of stress patterns. Thus from the study it can be concluded that the All-On-Four Concept is a clinically applicable treatment option for the atrophic edentulous ridges and induces least amount of stresses on the edentulous ridges. Therefore the overall longevity of the prosthesis is greatly enhanced.

Key words: atrophic mandible, biomechanics, finite element analysis, implants supported prosthesis, tilted implants.

Introduction

Recent advancements in the field of oral implantology has greatly improved the options available for rehabilitation of edentulous patients with highly resorbed ridges. Other than enhanced retention and
stability the implant supported over denture design demonstrates lot of advantages like preservation of the alveolar ridges, increased comfort, chewing efficiency and overall improved quality of life when compared to the conventional complete dentures. A new concept named All-On-Four is now widely being applied for rehabilitation of completely edentulous arches with implant supported prosthesis.1,2,3,6.

According to this technique, the use of tilted implant permits cantilever reduction while warding off important anatomical structures. Poor planning and designing of the implant supported prosthesis can result in stress concentration and peri-implant bone loss. This eventually would lead to complete loss of implant. Hence an indepth understanding regarding the regions of stress concentration encountered by the implant and the supporting bone is essential for the long term success of the implant and the prosthesis.3,5,6.

Aim

To compare the stress patterns in the edentulous mandibular bone around two implant retained overdenture and the prosthesis restored with All-On-Four Concept using finite element analysis.

Objectives

To compare the biomechanical behaviour of the prosthesis restored with All-On-Four Concept with that of two implant supported mandibular overdenture using three dimensional finite element analysis.

To localize and quantify the Von Mises stresses induced on the implants under different loading simulations.

Material & Method

Armamentarium used for the study

- CT Scan of edentulous mandible
- Replace Select Tapered TiU NP 3.5 x 13mm (Nobel Biocare)
- The Profile Projector (METZ- 801)
- Cylindrical Retainer of 4mm diameter.
- ANSYS - 11 Workbench Software.

Preparation of FEM model of the Edentulous Mandible.

The computerized tomographic (CT) image of the human edentulous mandible was introduced into the Computer Aided Design (CAD) software. The ANSYS software was then used to simplify the CT image of the mandible into an arch shaped bone block with dimensions of 7.5mm thick and 15mm high. To simulate the type III bone which is commonly found in the mandibular posterior region, 1mm cortical bone layer was established overlying the entire mandible whereas the trabecular bone was used in the internal structure. After obtaining the computerized 3-Dimensional model, incorporation of the implant design into the model was planned.

Preparation of the FEM implant model

For a precise and more accurate analysis, the contour and design of the threaded implant is very important. However the shape and depth of the threads could not be evaluated and reproduced in the 3 dimensional model with the help of computerized tomography. Hence an instrument called ‘Profile Projector Optical System’ was used in the study. The values thus obtained were then used to design an accurate 3-D model of the threaded implant along with the retainer.

Profile Projector (METZ -801) Optical System

The profile projectors have the ability to display a two dimensional projection of a part rather than just simple linear dimension as in case of other gauging devices. The images are displayed in a viewing screen as an aid to precise determination of the dimension, form and physical characteristics.

This instrument creates work piece image on the projection screen at desired magnifications (10x, 20x, 50x) to provide accurate dimensional measurement as well as inspection of the contour and surface condition of the work piece. The accuracy of this instrument is known to be 0.001mm.

Preparation of the working model

Three dimensional working models were constructed using 3D computer aided design software (ANSYS). The models represented the mandible restored with 2 - implant supported prosthetic design and the design restored with the All On Four Concept. A rigid type III
For the 3-Dimensional two implant supported prosthesis model, the threaded implants were strategically placed vertically in the region of lateral incisors bilaterally.

For the 3- dimensional ‘All-On-Four’ model, two anterior implants were placed vertically in the position of the lateral incisors and two implants were placed bilaterally in the position of second premolars and tilted distally to 30º angle.

To evaluate and compare the distribution of stresses on the implant on the three models, four loading situations were simulated in each model using load values similar to those of functional bite movements from patients with implant supported prostheses.

- Loading 1: Full mouth biting – bilateral and simultaneous vertical static loads of
  - 200 N was applied on the occlusal surface of the first molars (Cantilevers)
  - 150 N on the occlusal surface of second premolars
  - 150 N on the occlusal surface of first premolars
  - 100 N on the distal of canines

- Loading 2: Lateral Load – Unilateral static load of 50 N applied in the region of left canine.

- Loading 3: Cantilever Load – Unilateral vertical static load of 200 N was applied on the left cantilever.

- Loading 4: Load without the cantilever - Unilateral vertical static load of 200 N was applied in the region adjacent to the left second premolar, simulating absence of cantilever.

The results of the numerical analysis are shown in Table - 2 for Von Mises stresses occurring for the FEM models.

The Graph 1 represents the biomechanical behavior of the two implant supported overdenture FEM modes when subjected to different loading simulations. The graph depicts maximum stress levels during full mouth loading simulation which was 2226.7 Mpa followed by cantilever loading simulation which was 813.09 Mpa and load without cantilever shown as 531.39 Mpa. The least stress for this model was found during the lateral loading simulation which was 64.76 Mpa.

Graph 2 illustrates the graphical representation of the biomechanical behavior of the FEM model simulating the prosthesis restored with the All-On-Four Concept. The maximum stress in this simulation was found during full mouth loading which was 253.37 Mpa followed by load simulating lateral load which was 88.01 Mpa and load simulating the cantilever load which was 85.22 Mpa. The least stress was found when load without cantilever was simulated which was 60.21 Mpa.

From the graphs it can be inferred that among the two models, the stress levels for full mouth loading simulation was highest for two implant supported overdenture design and the least for All-on-four overdenture design. For both designs, the least stress was when the implants were loaded in a lateral direction. The stress levels for cantilever and non-cantilevered designs were nearly the same for all the simulated designs.

Discussion

Bone remodeling is a constant process and continues throughout the life of an individual. However, despite having progressive medical and technological advancements, as age advances, the bone resorption pattern is faster and aggressive. This leads to a severely resorbed ridge thus compromising the function and esthetics when a conventional denture is delivered. Implant supported denture could be a good option but in patients with resorbed ridges, the amount of bone support might be compromised to assist in osseointegration and withstand masticatory load.

Among several techniques being used in rehabilitation of completely edentulous patients with implant supported prosthesis, the All-On-Four technique is considered to be the most successful and rewarding technique. A proper understanding of the load transfer and stress concentration under implant supported prosthesis is very essential before planning an implant supported prosthesis.

The finite element analysis is a very effective technique to obtain a detailed stress strain analysis at any location. The three dimensional finite element analysis has been used to evaluate the stresses around the various implant systems.

Keeping in mind the consequences of unwanted stresses, this study was an attempt to compare the Von Mises Stresses around the implant by different loading conditions, on two different finite element models. The models were simulated on the basis of implant number, position, angulation and the type of prosthesis which is a Type III gold bar.

Prosthetic Rehabilitation of Patient with Mixed Connective Tissue Disease Using Glove Type Silicone Finger and Toe Prosthesis

Thilak Shetty¹, Abhinav Sharma², Shobha J Rodrigues³, Vidya K Shenoy⁴, Umesh Pai⁵, Sharon Saldanha⁵, Mahesh M⁵

¹Professor, ²Postgraduate Student, ³Professor & Head, Department of Prosthodontics, MCODS, Mangalore, India, ⁴Professor, Department of Prosthodontics, A J Institute of Memorial Dental Sciences, Mangalore, India, ⁵Associate Professor, Department of Prosthodontics, MCODS, Mangalore, India

Abstract

The hand is a powerful tool and its loss causes a severe psychological and physical drawback. A considerable number of people each year suffer finger or partial finger amputations as a result of malignant disease, trauma, and congenital deformity.

Prosthetic restoration is usually considered difficult for the whole or a part of the finger and it worsens if multiple fingers are involved. Additionally in patients with mixed connective tissue disorders with overlapping clinical features of scleroderma and arthritis any undue pressure from the artificial rings or vacuum fit of the prosthesis might cause further vasoconstriction that could worsen blood flow to extremities. This clinical report describes a simple and economical method for prosthetic rehabilitation of a patient with mixed connective tissue disease following digital loss using a custom made prosthesis with medical grade tissue adhesive as retentive aid.

Keywords. Finger prosthesis, silicone, mixed connective tissue disorder

Introduction

Mixed connective tissue disease (MCTD) is a systemic disease of unknown etiology affecting as many as 1 person in 40, often with a predilection for the female sex and seen in a group of patients with overlapping clinical features of lupus, scleroderma, polymyositis, and rheumatoid arthritis.¹ A defining feature of MCTD is the presence of antibodies against the U1-ribonucleoprotein (U1-RNP) complex.¹ The prognosis for patients varies from a benign course to severe progressive disease.

In approximately one third of patients the clinical symptoms go into long-term remission. One third of patients have a severe, progressive disease course with the most severe clinical manifestation being pulmonary hypertension contributing to premature death.² Although in the benign variety most patients are unlikely to have life-threatening consequences, 25% report with digital necrosis which may be extremely debilitating and distressing, significantly reducing quality of life for the patient and his or her family.² Rehabilitation of patients with loss of digital substance can be accomplished either prosthetically or by plastic surgery. The method of rehabilitation depends upon the site, size, severity, age, and the patient’s wishes. However, age, general medical condition of the patient, anatomic complexity, appearance of the area to be rehabilitated, complexity of the surgical procedure, and the patient’s refusal to undergo further surgery may contraindicate surgical reconstruction, resulting in a visible defect. Prosthetic rehabilitation of such patients then has considerable

DOI Number: 10.37506/v14/i1/2020/ijfmt/192881
advantages, in that prosthesis offers the clinician and the patient the means to observe the health of the tissues, esthetic improvement, technical simplicity and inexpensive care.

For several decades, a number of biomaterials and techniques have been used in the fabrication of finger prostheses. Each material has its advantages and shortcomings. Methyl methacrylate resin has been used as a maxillofacial material because it is easy to work with, hygienic, durable, and economical. Also, it can be satisfactorily colored to match individual skin tone. However, its use is limited by its rigidity. Silicones are generally the preferred materials for fabrication because of its lightweight and life-like appearance. They are synthetic polymeric chains where silicone atoms bond to organic groups typically methyl groups.\(^3\) Silicones are grouped as Class I-IV according to their applications,\(^4\) with the Class II medical grade silicone commonly used for prosthetic fabrication. However, silicone materials fall short of an ideal maxillofacial prosthetic material as adhesives do not work well with silicones, they are difficult to polish, have low tear resistance, and have microbial growth-promoting characteristics. Their use is limited in transcarpal residual limbs, unstable residual limb volume with fluctuations of more than 5%, unhealed residual limb wounds and when the finger joint/wrist and residual limb end that are unable to bear weight.\(^5\) Although attempts have been made to greatly improve the properties of various maxillofacial materials, there is still no ideal material that resembles or duplicates human skin.\(^4,6\)

Success of the prosthesis depends both on the appearance and retention, active grasp with the prosthesis being a key determinant in patient acceptance. Finger prosthesis are challenging in terms of retention. The various methods to increase the retention of the prosthesis are well documented which include customized artificial rings, medical adhesives, creating vacuum fit, etc.\(^7-11\) Leow et al\(^11\) studied optimal circumference reduction of finger models and suggested that 5–7% circumference reduction in the finger showed superior results as compared to 1–3% and 8–9% of reduction.

Conventional retention aids should not be used in patients suffering from Raynaud’s phenomenon as any undue pressure from the artificial rings or vacuum fit might cause further vasoconstriction that could worsen blood flow to extremities.

Medical grade adhesives when used as retentive aids can provide excellent retention. However, disadvantage of medical adhesives is its maintenance. The prosthesis should be removed everyday so that underlying tissues can rest overnight to maintain the health of the tissues. Everyday removal of residual adhesive from under surface of prosthesis and skin can be cumbersome for some patients. In addition, in the post fitting review patients must be advised to clean their prosthesis with soap and water on a daily basis. Abrasives and bleaching agents need to be avoided and the delicate feather edge margins of the prosthesis must be dealt with care.

Technological advances have made available highly dexterous hand and I LIMB\(^{12-14}\) as well as digital technology to accurately replicate patient’s finger characteristics. However the cost of these advances limits their use in most patients.

This clinical report describes a simple and economical method for prosthetic rehabilitation of a patient with mixed connective tissue disease following digital loss using a custom made glove type of prosthesis with medical grade tissue adhesive as retentive aid.

**Case Report**

A 42-year-old female patient diagnosed with MCTD and symptoms of arthritis and Raynaud’s phenomenon reported to the Department of Prosthodontics, of this Institution, for the fabrication of a Fixed Partial Denture involving the left maxillary first premolar. On general examination, limited mouth opening was noted. In addition, the left index, ring, right index finger and right big toe was malformed and the left little finger was missing (Figure 1, 2). The patient was counseled to attend to this digital loss in addition to the missing teeth. Various modalities of prosthetic reconstruction were discussed with the patient and following informed consent, glove type silicone finger prosthesis was planned for the malformed fingers and the expectations of this prosthesis were discussed with the patient. The left little finger was not restored since there was no residual finger stump for adequate retention of glove type prosthesis. Implant supported finger prosthesis was also contraindicated due to the progressive arthritis that the patient was suffering from. Conventional retention aids were not used in this case considering the patient was suffering from Raynaud’s phenomenon. Any undue pressure from the artificial rings or vacuum fit might...
cause further vasoconstriction that could worsen blood flow to extremities. Hence, medical adhesive was used for retention of prosthesis.

The defective and donor hand and foot were lubricated with a thin layer of petroleum jelly and its boundary was boxed with modelling wax to confine the impression material. The impression was obtained in resting state with irreversible hydrocolloid (Imprint; Dental Products of India Ltd). In addition the impression of the individual defective fingers were also obtained and were all poured in Type III dental stone (Dentstone; Pankaj Industries). The impression of the donor appendages, however, was poured in modelling wax and used for characterization of their respective stump mold. The prosthesis was waxed to form and verified at the trial insertion appointment for acceptability. The wax pattern along with the mold stump was indexed, relieved of undercuts and invested in such a manner such that the dorsal and palmar surfaces of the fingers were separable. The wax was eliminated and the mold space (was packed in the presence of the patient with medical grade silicone (Silicone for Prosthesis; M P Sai Enterprises). The silicone was proportioned based on the skin tone at various regions of the finger. Basic skin tone color was formulated using intrinsic coloring pigments to the closest accuracy possible. The respective proportions of the silicone shades were layered on the regions of ventral surfaces and dorsal surfaces. The material was processed overnight as recommended by the manufacturer. The prosthesis was recovered after polymerization trimmed and finished using sharp scissors and finishing burs. The fit and shade was evaluated on the patient. The fingernail was processed using autopolymerising acrylic resin (DPI-RR; Dental Products of India Ltd) and pigmented to match the patient nails to further enhance aesthetics and to break the monochromatic appearance final coloration was achieved by extrinsic staining procedure. Retention in this case was obtained by using medical grade skin adhesive (M.D. Enterprises, Mumbai, India) and patient was educated about its daily use and cleaning technique. The prosthesis was inserted (Figure 3, 4) and the patient instructed on maintenance and home care.

The patient was scheduled for the first post-insertion adjustment 3 days after the insertion. At the first post-insertion appointment the malformed fingers were observed to ensure health of the tissues, to relieve the prosthesis for pressure areas on the tissues, to compensate for processing changes, and to emphasize hygiene and home care. In the post fitting review patients was advised to clean their prosthesis with mild antibacterial soap and water on a daily basis and to avoid wearing the prosthesis in case of inflammation or during sleep.[15] The patient was satisfied with prosthesis and was placed on a 3-month recall for evaluation and observation.

Figure 1 and 2. Preoperative view of the patient.
Figure 3 & 4. Post-treatment view of patient.

Figure 1 & 2 : Preoperative view of the patient

Figure 3 & 4 : Postoperative view of the patient

Summary

A convenient and affordable method of prosthetic rehabilitation of an amputated finger with room temperature vulcanizing silicone material has been presented. The custom made glove type finger prosthesis is esthetically acceptable and comfortable in patients with amputated or malformed fingers, resulting in psychological
improvement and personality.

Perception of Students Regarding Gender based Violence

Muzaffar A1, Shenoy VK2, Vaswani VR3, Badiadika KK4

1Postgraduate Final Year, 2Assistant Professor, 3Professor and Head, 4Associate Professor, Department of Forensic Medicine, Yenepoya Medical College, Mangalore, India

Abstract

Objectives: The study is undertaken to explore perception of students regarding violence against women with specific reference to domestic violence and sexual violence.

Method: This is a descriptive cross-sectional questionnaire based exploratory study conducted in Mangalore, Karnataka, India. 220 participants consisting of age group between 18 to 25 years were included. Responses were obtained from the study participants through open and close ended questionnaires. Results: More than half (60%) of medical students and (56%) of engineering students disagree that in modern India women are enjoying equal rights to men. Three forth (77% male, 82% female) of students believe and disagree that it is alright for a man to beat his wife in order to make her obedient. Two forth (61%) of medical students and (63%) of engineering students agree that throwing acid on a woman to cause disfiguration is an example of gender based violence. Conclusion: The perception of medical and engineering students regarding gender based violence is quite similar. This study brought out issues of increased violence against women. A significant number still felt that dressing of a woman may be a factor for sexual assault. Women are still facing gender inequality and are not getting equal rights to men. Even though incidence of harassment, domestic violence are on the rise, women are not ready to report about their suffering because of social and family pressure. There is also need for awareness to be bought in gender mainstreaming for educating all sectors of the society.

Key Word: Sexual harassment, Crime against women, Domestic violence.

Introduction

Women are important part of our society and play vital roles in all aspects of life but their identity is restricted to being mother, sister, wife, or daughter1. In ancient Indian time’s as mentioned in Rigveda and other scriptures women held the most prestigious and honoured place in society2. The status of women in society over the period of time seems to be controversial, violence against women has been increasing and a universal concern too as men hold themselves superior and believes that women are mediocre. Women are given low status at work place and home. In last few decades there has been increase in the incidence of violence against women3. Globally violence against women has increased, it has been reported that more the one in three women (35.6%) have been subjected to sexual or physical violence by their friends or relatives and 38% of all murders are committed by their spouse4,1. 05% of murder of men is committed by their spouse. A woman has been subjected from verbal abuse, emotional abuse, physical and sexual exploitation leading to femicide. Worldwide 5000 murders in the name of honour killing and 25000 in the name of dowry death have been reported every year. There are also reports that the women are victim of sexual violence in wars and mostly prone to human right violation5. Unwanted pregnancy, child birth and child abuse may be a sign of violence against women. India is the second densely inhabited democratic country and seventh largest country in the world with 1.3 billion people, 48.4% are females and 51.6% are males6. Developing India is emerging as a global power but still women have to struggle for their position and status in the society. Women are subjected to violence irrespective of their cast, educational status, class and

Corresponding author:
Shenoy VK

their subjugation adds to their suffering by physical, emotional, mental and economical deprivation\textsuperscript{7,8}.

In India women have been subjected to violence and they are suffering from various causes such as cheating, rape, torture, abduction, violent pornography, immoral trafficking and so on. A total of 3,27,394 cases of crime against women were reported in year 2015, 29.9\% of sexual harassments, 10.4\% physical assault, 7.6\% stalking, 1.0\% voyeurism, and 51.8\% other cases. Human trafficking has increased from 0.4\% in year 2014 to 0.5\% in year 2015. According to NCBR “head wise percentage of crime against women” during year 2015 there were 34.6\% cases of domestic violence, 25.2\% cases of assault on women with intent to outrage her modesty, 18.1\% cases of kidnapping and abduction of women, 10.6\% of rape cases, 3.05\% cases of dowry prohibition, 2.35\% cases of dowry death, 2.7\% cases of insult of modesty of women, 1.4\% cases of attempt to rape, 1.2\% cases of abetment of suicide by women, 0.7\% cases of immoral trafficking of women, 0.25\% other crimes.\textsuperscript{8}

Women have to suffer from gender violence throughout their life. As a child her father is in charge of her, as an adult her husband is in charge of her and after death of husband, her son takes over charge of her.\textsuperscript{9}

Rafique vs state of U.P 1980, Justice Krishna Iyer said “when a woman is raped, what is inflicted is not mere physical injury but a sense of some deathless shame” and judiciary response could not be muted to such grave human right violation\textsuperscript{10}. The implementation of preliminary measures gives a perception that the present criminal justice system India is not robust to protect women.\textsuperscript{10}

Women who suffer from sexual assault have physical and mental issues, poor sleep, irritable bowel, diabetes, post-traumatic stress disorder and various studies has shown that they were benefited with screening and discussing sexual assault with health care provider and all this helped in their recovery.\textsuperscript{12}

Gender based violence is a serious issue all the students undergoing medical education should be taught about the importance of the issue and how to address such cases\textsuperscript{13}.

The study was undertaken with the objective to explore perception of students regarding violence against women with specific reference to domestic violence and sexual violence.

**Material and Method**

This is a descriptive cross-sectional questionnaire based exploratory study conducted in Engineering and Medical Colleges of Mangalore, Karnataka, India. Questionnaire was externally validated by two subject experts. After obtaining institutional ethical clearance and due necessary permissions study was conducted and data were collected from the study area. The study was conducted in October 2018 to November 2018. 220 participants between ages 18 to 25 years were included. Responses were obtained from the study participants through close and open ended 25 items questionnaires. The data was analysed using SPSS version 20.0 software. Chi – square test was applied.

**Result**

In the present study, out of 220 participants, 110 (50\%) were Medical students and 110 (50\%) were engineering students of which 119 males and 101 females. There is no significant difference noted on various issues amongst the students from medical and engineering streams. 59.1\% of medical students and 55.4\% of engineering students did not agree that in modern India women are enjoying equal rights as men. Nearly half of medical and engineering students agreed that domestic violence in women is common and widespread issue. More than 80\% of medical and engineering students disagree that women feel safe while travelling alone and going out at night. More than 70\% of medical and engineering students agree that vulnerable group such as minors and women with disabilities are more prone for sexual violence.

More than 70\% of medical and engineering students agree that most of women hesitate to report about crime against them because of social and family pressure. Nearly 30\% of male and 20\% of females agreed that man can beat his wife to make her disciplined. 51\% of medical students and 50\% of engineering students (24\% of male and 19 \% female) believe that dressing style of a woman is be a factor for sexual assaults. More than 60\% of medical engineering students agree that throwing acid on a woman to cause disfiguration is an example of gender based violence. 59.1\% of medical students and 69.1\% of engineering students agree that if a person with political background or influence is named as perpetrator of sexual violence, they are protected.
by investigating officer. 77.31% of medical students and 80% of engineering students agree that there is a stigma regarding sexual assault survivor in India. 78.2% of medical students and 91.1% of engineering students agree that domestic violence is preventable.

Medical students perceive that percentage of perpetrators on violence against women are strangers 46.4%, family 30.9%, relatives 21.8%, friends 0.9% and engineering students report that perpetrators of violence on women are strangers 69.1%, relatives 20.9%, family 8.2% friends 1.8%. Medical students perceive that the place where women is commonly assaulted are public transport 44.55%, work place 30.0%, home 15.5%, market place 10%. Engineering students report that the place where women are commonly assaulted were public transport 60.9%, work place 30%, market place 6.4% and home 2.7%.

Medical and engineering students report that information on violence against women comes largely from Internet more than 50%, TV and Radio more than 40%, newspaper more than 10%, and others.

Medical students report that place where a victim of sexual assault more likely to visit is first to Primary health centre, second to Community health centre, then so on Secondary Hospital, District Hospital, Tertiary Hospital and engineering students report that place where a victim of sexual assault more likely to visit first to Primary health centre, second to Community health centre, then so on Secondary Hospital, Tertiary Hospital, District Hospital.

More than 90% of medical and engineering students agree that workshop and continued hands on training in Forensic Medicine is important to deal with cases in rural areas. 78.2% of medical students and 89.1% of engineering students agree that the attitude of people in India can be changed regarding sexual assault victim.

Discussion

In the present study, results did not indicate that Medical and Engineering stream students significantly differed in their perceptions regarding gender based violence. Mangali RN et al conducted a study in year 2007, women are considered lower compared then men in society and women suffer from gender discrimination in all aspects of life17. Similarly, in the present study It was observed that more than half of total number of participants (m=60, e=56) disagree that in modern India women are getting equal rights to men.

Watts C et al in year 2002 reported that child sexual abuse is common and under reported because most of times they are threatened or the perpetrators is family member16. Similarly, in the present study three forth of students (73%) believe that vulnerable group such as minors are more prone for sexual assault.

Imran M et al 2010, has reported crime against women is increasing, sexual violence cases are often under reported because of stigma and shame related to the survivor of sexual assault19. Similarly, three forth of students (79%) believe that there is a stigma regarding sexual assault survivor in India. In the same study Imran in 2010 has reported that, domestic violence so common in our society, that six out of every ten husbands have beaten their wives. Sexual harassment is often not reported due to fear of family and fear of isolation from society18. Similarly, in the present study majority of students (85%) believe that domestic violence is a wide spread issue and at least, one fourth of the students (26%) still believe that it is alright for a man to beat his wife in order to make her obedient. This is not only a perception prevalent in male (25%) but also shared by females (20%). This is a concerning fact as violence against women cannot be stopped if the belief by disciplining a woman by physical force continues. Similarly, if this is deep rooted in females, the inflicted violence on self gets justified and she may not access the health care or report to police.

Naskar G et al in year 2015, reports of wife battering and violence against widows are also on rise and legal measures should be taken for elimination of violence against women. The Indian cultural system is not open for wife reporting to the police of having been battered by her husband. Similarly, in the present study three forth (79%) of students believe that women hesitate to report about crime against them because of social and family pressure.

Nagindrappa M et al 2013, reports that women in India are not given equal rights to men irrespective of their cast, class, educational status. They are physically, socially, mentally and economically exploited since long7. Bhawana D et al reported that various crime against women that occur in India such as sexual assault, kidnapping, abduction, dowry death, torture, molestation has been increased 59% since year 20112. Similarly, in present study three forth (78%) of students believe that
violence against women in our society is common and is on rise.

Waghamoda R.H 2013, conducted a study on domestic violence where women were the victims which is similar to the study by Badiadka 2017 where much of the public assault was on males and domestic violence in females14. The World Human Rights Conference in Vienna, recognised gender based violence as human right violence in 1993. Article 14, 15 and 21 of Indian Constitution provides protection of women from domestic violence (domestic violence Act, 2005). There is cultural gender inequality, economic dependence on men, political under representation, less education and awareness among women and they are facing domestic violence by men because of all these reasons3. Present study students perceived that domestic violence is preventable (85%).

T.K.K Naidu et al 2007, reported that Forensic Medicine has an important role in detection and help in administration of justice, forensic training must be given to Medical and Para Medical students to deal with cases in rural and semi urban areas. Proper Medicolegal investigation will help in solving of cases so that cases will not be undetected and unconvicted15. Similarly, in present study majority (95%) of students reported there is requirement of specialized nursing training “Forensic nursing” as it is in developed countries and majority (93%) reported that workshop and continue hands on training in Forensic Medicine is important to deal with cases in rural areas.

Hossain N 2015, reported that gender based violence is a serious issue all the students undergoing medical education should be taught about the importance of the issue and how to address such cases13.

Watts C 2002, reported that some of the most common and severe forms of violence against women by intimate partner are physical abuse, psychological abuse, acid throwing, sexual abuse, trafficking for sex, forced prostitution, exploitation of labour17. Similarly, in the present study more than half (61%) of students agree that throwing acid on a woman to cause disfiguration is an example of gender based violence.

In the present study more than half of students believe that the perpetrators of violence on women are mostly strangers (58%). This is contrary to the study done by Madeswarana et al 2013, majority of cases perpetrators of violence on women were acquaintances such as family member, friends and relatives20.

Conclusion

The perception of medical and engineering students regarding gender based violence is quite similar. This study brought out issues of increased violence against women. One third of the students still believe that it is alright for a man to beat his wife to make her obedient. More awareness programs should be conducted in gender mainstreaming. Women are still facing gender inequality and are not getting equal rights to men. Even though incidence of domestic violence is on the rise, it may not get reported because of social and family pressure. There should be sensitzation program for every stream of students on gender related issues. Registered medical practitioner and Forensic nursing should be available so that when a woman accesses a health centre at any level, be it primary or tertiary, she gets appropriate care and medicolegal service. Investigating agencies, medical and paramedical staff should be sensitized and trained in this regard.

Limitations of Study: Only medical and engineering students from select colleges are considered for study. They do not represent population of India.

Conflict of Interest: There is no conflict of interest.

Ethical approval: Institutional ethical committee (centre of ethics) approval has been obtained (Reference no-YEC198/2018

Abstract

Background: Identification of the suspect, living or dead with the help of physical characteristics play a vital role in forensic science. Improved methods of gender determination and personal identification are important in solving criminal cases. Cheiloscopy and dactyloscopy have been proved to be of use in personal identification. The present study aims to evaluate correlation of Cheiloscopy and Dermatoglyphics in gender determination.

Materials and Method: The study was carried out from January 2017 to January 2019 on 2112 individuals (1056 males and 1056 females) aged from 15 to 60 years in KMCT Dental College, Calicut. For lip print analysis Suzuki and Tsuchihashi classification was followed. For finger print analysis impression of all the fingers were taken. For analysis, the images were cropped and abode photoshop software was used.

Results: Type 1 and 1’ lip groove patterns were found to be predominant among males. Type 4 and Type 5 lip groove patterns were found to be predominant among females. Loop finger print patterns were found to be predominant among males. Whorl finger print patterns were found to be predominant among females. Positive correlation (+0.80) was found between loop finger print pattern and Type 1’ lip print pattern in males which is statistically significant (p=0.003). Positive correlation (+0.75) was found between whorl finger print pattern and Type IV lip groove pattern in females which is statistically significant (p=0.005).

Conclusion: There was definite correlation of Cheiloscopy and Dermatoglyphics in gender determination.

Keywords: Cheiloscopy, Dermatoglyphics, Gender determination.

Introduction

Forensic science plays a vital role in the identification of the suspected victim or victimizer of a crime, with the help of physical characteristics. Physical evidence is important to solve criminal cases. Improved methods of gender determination and personal identification are gaining importance in recent years.[¹,²]

Lip patterns and finger print patterns remain the same throughout life and are uninfluenced by environmental changes and diseases. Cheiloscopy is a forensic investigation technique that deals with identification of humans based on lip traces. A lip print at a crime scene would throw light on many areas of the investigation like the number of people involved, the gender and the behavior pattern of the crime. Edmond Locard was the first scientist to recommend the use of lip prints in personal identification.[¹]

Dermatoglyphics is the term specified to the scientific study of fingerprints. The term “fingerprint” predominantly means an impression of the epidermal ridges of the fleshy distal portion of a finger. It was first given by Harold Cummins in the year 1926.[³]

Cheiloscopy and dactyloscopy are used in personal identification.[⁴,⁵] The present study aims to evaluate
the uniqueness of lip prints and thumb print patterns and to establish a correlation between them for gender determination.

**Methodology**

The study was carried out from January 2017 to January 2019 on 2112 individuals (1056 males and 1056 females) aged from 15 to 60 years in KMCT Dental College, Calicut. The study protocol and objectives were thoroughly explained to the participants and informed consent was taken from them. The ethical approval was obtained from Institutional Ethical Committee of KMCT Dental College.

Individuals with normal transition zone between the mucosa and skin of both lips and fingers were selected. The Excluded criteria were persons with lip scar, Lip congenital deformities, active lesions on fingers or lips and persons with hypersensitivity to lip sticks.

Materials used to record the lip groove patterns and finger prints were: red coloured lip stick (Lakme, India), cellophane tape, ink (Kores, extra dark pad), white paper and magnifying lens. Costa and Caldas technique was used to record the lip groove pattern, Kucken technique was used for the finger print pattern.

The individuals’ lips were cleaned with wet tissue before starting the procedure. The lip stick was gently applied to the upper and lower lips and the individual was asked to roll the lips in a uniform manner from centre to the corner of lips.

The individual was asked to stop moving the lips during the procedure and to keep the lips in relaxed state. The lip groove patterns were lifted by cellophane scotch tape on upper lip from one side to another; following which the tape was pasted on a white bond paper as a permanent record. The same process was repeated for lower lips. The obtained lip groove patterns were carefully examined under the magnifying lens.

Finger print recording was done by asking the subjects to ink all their finger pads, both right and left hands, and the impression was recorded on a white bond paper. Only one impression was made to avoid artifacts. Then the finger print pattern was studied with the help of magnifying lens and the predominant pattern of 10 finger pads (in each subject) was quantified tabulated and analysed statistically.

Lip groove patterns were categorized into four regions predominantly by dropping a perpendicular from the philtrum of lips; Upper Right (UR) region, Upper Left (UL) region, Lower Right (LR) region and Lower Left (LL) region. The analysis was done as per the Suzuki and Tsuchihashi classification. The classification is as follows: Type I: clear cut grooves running vertically across the lips; Type I’: grooves are straight but disappear halfway instead of covering the entire breadth of the lip; Type II: grooves fork in their course; Type III: grooves intersect; Type IV: grooves are reticular; Type V: grooves do not fall into any of the Type I to IV and cannot be differentiated morphologically.\(^6,^7\) (fig.1)

The finger prints were categorized as follows: Ridge count of thumb, index, middle, ring and little fingers of both hands, Right hand total finger ridge count (TFRC), Left hand total finger ridge count (TFRC), Absolute finger ridge count (AFRC). The finger prints were qualitatively categorized as Arch (simple arch, tented arch), Loop (ulnar loop and radial loop) and whorl (simple, spiral, double pocket, composite) patterns.\(^3\) (fig 2)

---

**Fig 1: Armamentarium: Cheiloscopy**

**Fig 2: Armamentarium: Dermatoglyphics**
Statistical analysis

Obtained data was tabulated and statistically evaluated using IBM SPSS Statistics for Windows, Version 20.0. Armonk, NY: IBM Corp. Normality of the data was assessed by Kolmogrov-Smirnov Test. If data follows normal distribution, Independent ‘t’ test was used. If data follows non-normal distribution, Mann-Whitney ‘U’ test was used. Chi square test: for association of qualitative variables. Pearson’s Correlation was used for assessing the correlation between cheiloscopy and dermatoglyphics.

Results

Type 1 and 1’ lip groove patterns were found to be predominant among males. Type 4 and Type 5 lip groove patterns were found to be predominant among females (Table 1 and 2).

Loop finger print patterns were found to be predominant among males. Whorl finger print patterns were found to be predominant among females (Table 3-6).

Positive correlation (+0.80) was found between loop finger print pattern and Type 1’ lip print pattern in males which is statistically significant (p=0.003). Positive correlation (+0.75) was found between whorl finger print pattern and Type IV lip groove pattern in females which is statistically significant (p=0.005)(table 7).

Table 1: Lip Groove patterns among males. A total of 2112 lip regions among 1056 males were assessed for the lip groove patterns and the variables of upper lip and lower lip are compared.

Discussion

Forensic science plays a definite role in criminal investigation. The victimizers of the infamous Nirbhaya gang rape case (2012) were identified by forensic records. The woman who was part of the hit squad during the Paris attack (2017) was identified by finger prints. Many more such cases were proved by forensic records.

The current research revealed the predominance of Type IV ,Type V patterns among females and Type I’, Type I patterns among males. Costa and Caldas and Kumar et al stated that lip groove patterns can be used as a potential aid in gender determination which is in accordance with the results of current research.[5] Lip groove patterns varies in different parts of lips and it reiterates the fact of uniqueness of lip groove patterns. [8, 9,10, 11]

In our study the Loop finger print patterns were found to be predominant among males and Whorl finger print patterns were found to be predominant among females. The study results were in accordance with tendon et al. [12]
The predominant pattern of finger print and lip print also show regional variations. In Iranian sample population, (96 individuals) Type V lip groove patterns was found predominant pattern. [11] In saudi population (150 individuals), males showed Type III pattern and females showed Type I pattern as the predominant type. [8] In our study, Loop finger print patterns with type 1 lip print were found to be predominant among males. Whorl finger print patterns with type 4 lip print were found to be predominant among females. Similarly Gaba et al found that lip prints were unique to an individual and the patterns varied among males and females and concluded that lip print analysis can be used for forensic analysis and gender determination. [15] Our results are in association with Metgad et al results, who found that correlation between lip prints and finger prints for gender identification was statistically significant. [16] From our study it can be observed that there is various in lip print and finger print form one person to other and among gender hence it can be used for identification of gender in forensic medicine. Further long term studies are required on larger sample size with other variables for gender determination.

**Conclusion**

Most studies on lip prints and thumb prints have limited samples. [13,14] The current study was done on a larger sample of population, however more studies in different geographic areas with larger populations are needed to establish cheiloscopy and dactyloscopy as distinct branches with wider scope in forensic science.

A Study to Compare the Stress Patterns in the Edentulous Mandibular Bone Around the Two Implant Retained Over Denture and the Prosthesis Restored with All-On-Four Concept Using the Three Dimensional Finite Element Analysis

Puneeth Hegde¹, Satish Shenoy², Shobha Rodrigues³, Thilak Shetty⁴, Umesh Pai¹, Sharon Saldhana¹, Mahesh M¹
¹Associate Professor, Department of Prosthodontics, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, Manipal, ²Professor & Head, Department of Aeronautical Engineering, Manipal Institute of Technology, Manipal, Manipal Academy of Higher Education, Karnataka, India, ³Professor & Head, ⁴Professor, Department of Prosthodontics, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, Manipal

Abstract

When we consider the rehabilitation of patients with the mandibular implant supported over denture, the influence of the implant number and the cantilever design on the stress distribution on the bone needs to be assessed precisely.

Purpose: The purpose of the simulation study was to compare the biomechanical behavior of the two implant supported over denture design with the All-On-Four Concept using the three dimensional finite element method thereby evaluating the Von Misses stresses induced on the implant under different loading simulations.

Materials & Method: Three dimensional models representing mandible restored with two implant supported prosthesis was compared with the models that were restored based on the ‘All-On-Four’ concept. The models were then subjected to four different loading simulations (full mouth biting, canine disclusion, load on cantilever, and load in the absence of cantilever). The maximum von Mises stresses were localized and quantified for comparison.

Results: Among the models, under all loading simulations, the maximum stress concentrations were along the neck of the implant. The stress levels for full mouth loading simulation was highest for two implant supported overdenture design and the least for All-On-Four overdenture design. In all the designs, the least stress was when the implants were loaded in a lateral direction. The stress levels for cantilever and non-cantilevered designs were nearly the same for all the simulated designs.

Conclusion: When tested under different loading simulations, both models showed similar location and distribution of stress patterns. Thus from the study it can be concluded that the All-On-Four Concept is a clinically applicable treatment option for the atrophic edentulous ridges and induces least amount of stresses on the edentulous ridges. Therefore the overall longevity of the prosthesis is greatly enhanced.

Key words: atrophic mandible, biomechanics, finite element analysis, implants supported prosthesis, tilted implants.

Introduction

Recent advancements in the field of oral implantology has greatly improved the options available for rehabilitation of edentulous patients with highly resorbed ridges. Other than enhanced retention and stability the implant supported over denture design demonstrates lot of advantages like preservation of the
alveolar ridges, increased comfort, chewing efficiency and overall improved quality of life when compared to the conventional complete dentures. A new concept named All-On-Four is now widely being applied for rehabilitation of completely edentulous arches with implant supported prosthesis \(^1,^2,^3,^6\).

According to this technique, the use of tilted implant permits cantilever reduction while warding off important anatomical structures. Poor planning and designing of the implant supported prosthesis can result in stress concentration and peri-implant bone loss. This eventually would lead to complete loss of implant. Hence an indepth understanding regarding the regions of stress concentration encountered by the implant and the supporting bone is essential for the long term success of the implant and the prosthesis \(^3,^5,^6\).

**Aim**

To compare the stress patterns in the edentulous mandibular bone around two implant retained overdenture and the prosthesis restored with All-On-Four Concept using finite element analysis.

**Objectives**

To compare the biomechanical behaviour of the prosthesis restored with All-On-Four Concept with that of two implant supported mandibular overdenture using three dimensional finite element analysis.

To localize and quantify the Von Mises stresses induced on the implants under different loading simulations.

**Material & Method**

**Armamentarium used for the study**

- CT Scan of edentulous mandible
- Replace Select Tapered TiU NP 3.5 x 13mm (Nobel Biocare)
- The Profile Projector (METZ-801)
- Cylindrical Retainer of 4mm diameter.
- ANSYS - 11 Workbench Software.

Preparation of FEM model of the Edentulous Mandible.

The computerized tomographic (CT) image of the human edentulous mandible was introduced into the Computer Aided Design (CAD) software. The ANSYS software was then used to simplify the CT image of the mandible into an arch shaped bone block with dimensions of 7.5mm thick and 15mm high. To simulate the type III bone which is commonly found in the mandibular posterior region, 1mm cortical bone layer was established overlying the entire mandible whereas the trabecular bone was used in the internal structure. After obtaining the computerized 3-Dimensional model, incorporation of the implant design into the model was planned.

**Preparation of the FEM implant model**

For a precise and more accurate analysis, the contour and design of the threaded implant is very important. However the shape and depth of the threads could not be evaluated and reproduced in the 3 dimensional model with the help of computerized tomography. Hence an instrument called ‘Profile Projector Optical System’ was used in the study. The values thus obtained were then used to design an accurate 3-D model of the threaded implant along with the retainer.

**Profile Projector (METZ-801) Optical System**

The profile projectors have the ability to display a two dimensional projection of a part rather than just simple linear dimension as in case of other gauging devices. The images are displayed in a viewing screen as an aid to precise determination of the dimension, form and physical characteristics.

This instrument creates work piece image on the projection screen at desired magnifications (10x, 20x, 50x) to provide accurate dimensional measurement as well as inspection of the contour and surface condition of the work piece. The accuracy of this instrument is known to be 0.001mm.

**Preparation of the working model**

Three dimensional working models were constructed using 3D computer aided design software (ANSYS). The models represented the mandible restored with 2 - implant supported prosthetic design and the design restored with the All On Four Concept. A rigid type III gold prosthetic bar, 6mm thick and 4mm high and in the shape of an arc was then designed and joined to the abutments.\(^1\)
For the 3-Dimensional two implant supported prosthesis model, the threaded implants were strategically placed vertically in the region of lateral incisors bilaterally.

For the 3-dimensional ‘All-On-Four’ model, two anterior implants were placed vertically in the position of the lateral incisors and two implants were placed bilaterally in the position of second premolars and tilted distally to 30º angle.

To evaluate and compare the distribution of stresses on the implant on the three models, four loading situations were simulated in each model using load values similar to those of functional bite movements from patients with implant supported prostheses.

- **Loading 1**: Full mouth biting – bilateral and simultaneous vertical static loads of
  - 200 N was applied on the occlusal surface of the first molars (Cantilevers)
  - 150 N on the occlusal surface of second premolars
  - 150 N on the occlusal surface of first premolars
  - 100 N on the distal of canines
- **Loading 2**: Lateral Load – Unilateral static load of 50 N applied in the region of left canine.
- **Loading 3**: Cantilever Load – Unilateral vertical static load of 200 N was applied in the region adjacent to the left second premolar, simulating absence of cantilever.
- **Loading 4**: Load without the cantilever - Unilateral vertical static load of 200 N was applied in the region adjacent to the left second premolar, simulating absence of cantilever.

The results of the mathematical solutions were later converted into visual results and expressed in colour gradients, ranging from shades of red, orange, yellow, green and blue, with red representing highest stress values. The stress values in the two models were collected and compared, with the points of greatest magnitude identified by the Von Mises equivalent stress levels.

**Results**

The results of the numerical analysis are shown in Table - 2 for Von Mises stresses occurring for the FEM models.
Discussion

Bone remodeling is a constant process and continues throughout the life of an individual. However, despite having progressive medical and technological advancements, as age advances, the bone resorption pattern is faster and aggressive. This leads to a severely resorbed ridge thus compromising the function and esthetics when a conventional denture is delivered. Implant supported denture could be a good option but in patients with resorbed ridges, the amount of bone support might be compromised to assist in osseointegration and withstand masticatory load.

Among several techniques being used in rehabilitation of completely edentulous patients with implant supported prosthesis, the All-On-Four technique is considered to be the most successful and rewarding technique. A proper understanding of the load transfer and stress concentration under implant supported prosthesis is very essential before planning an implant supported prosthesis.  

The finite element analysis is a very effective technique to obtain a detailed stress strain analysis at any location. The three dimensional finite element analysis has been used to evaluate the stresses around the various implant systems.

Keeping in mind the consequences of unwanted stresses, this study was an attempt to compare the Von Mises Stresses around the implant by different loading conditions, on two different finite element models. The models were simulated on the basis of implant number, position, angulation and the type of prosthesis which is a Type III gold bar.

Assessment of Needle Stick Injury in an Institutional Set up: A Retrospective Analysis

Shobha Rodrigues¹, Thilak Shetty², Umesh Pai³, Sharon Saldanha³, Mahesh M³, Puneeth Hegde³, Mandakini Mohan⁴

¹Professor & Head, ²Professor, ³Associate Professor, Department of Prosthodontics, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, ⁴Senior Lecturer, Division of Clinical Dentistry, International Medical University, Kuala Lumpur, Malaysia

Abstract

Purpose: Occupational exposure to blood borne pathogens with needle stick or other sharp tool injuries is a serious but preventable problem. this study will be conducted to investigate the incidence of Needle stick injury (NSI) among the Dental health care providers (DHCP) of Manipal College of Dental Sciences, Mangalore.

Method: The NSI incidence, demographics, contributing factors, and follow up following NSI report were reviewed.

Results: Six, eleven, seventeen and nineteen needle stick injuries were reported in 2010, 2011, 2012 and 2013 respectively. Most injuries were experienced by students and least by the Faculty.

Conclusion: Based on the results and within the limitations of this surveillance study it is concluded that occupational exposures can be reduced and reporting of all exposures is vital. The institution of appropriate PEP, psychological support and counselling of affected HCWs and stringent follow-up are all needed to reduce the burden of occupationally acquired infections in HCWs.

Keywords: Needle stick injury (NSI), Health care worker(HCW), dental students

Introduction

Occupational exposure to blood borne pathogens with needle stick or other sharp tool injuries is a serious but preventable problem. Health care workers (HCWs) are at a risk of occupational acquisition of human immunodeficiency virus (HIV) infection and other viral infections (HCV and HBV) due to accidental exposure to infected blood and body fluids.¹ The reporting of such injuries is a critical step in initiating early prophylaxis.²

Needle stick injury (NSI) is a significant problem in general dental practice and exposes personnel to a serious risk of infection from blood-borne transmissible agents. Dental students are exposed to various oral infections or lesions, which may be due to manifestations of AIDS. As dental students lack knowledge, experience and skill, they are vulnerable to accidental exposure to blood and other body fluids when performing clinical activities. Even if there are timely and effective post exposure prophylaxis, such as for HBV and HIV, there can be serious psychological and economic consequences following NSIs. Also, unsafe practices such as not wearing gloves and the resheathing of needles predispose dental students to NSI. There should be a well-formulated coordinated approach for the provision of information support, and referral from healthcare workers who sustain occupationally related management of occupational exposures varies between institutions and often reflects the level of staff education.

and previous experience in areas of infection control and transmission of blood-borne diseases. Despite published guidelines and training programs, needle stick injuries remain an ongoing problem. All patients should be considered to pose a potentially high risk of infection; also, recommended precautionary measures should be followed at all times. An effective and multifaceted management plan must be prepared for prevention and management of needle stick injuries in healthcare workers. After an occupational exposure, the healthcare worker should be counseled about the degree of risk associated with the type of exposure: needlestick injuries pose a greater risk than splashes, and those from a hollow-bore needle are a greater risk than from a solid needle.

As dental students lack knowledge, experience and skill, they are vulnerable to accidental exposure to blood and other body fluids when performing clinical activities. This places them at the potential risk of blood-borne diseases such as hepatitis B virus (HBV), hepatitis C virus and human immunodeficiency virus (HIV). Even if there are timely and effective post exposure prophylaxis, such as for HBV and HIV, there can be serious psychological and economic consequences following NSIs. Also, unsafe practices such as not wearing gloves and the resheathing of needles predispose dental students to NSIs.

There are various approaches and differences in the program curricula of various dental schools to prevent NSIs among medical students. One preventive strategy is to enhance training programmes on infection control, including the prevention of NSIs, while another is to improve students’ knowledge of the management and reporting procedures following an NSI. An effective and multi focused training programme is essential, as its implementation can decrease the overall rate of NSIs in hospitals. Dental students are oriented about infection control during the course as part of the measures taken to reduce the incidence of NSIs among medical students. There are also standard operating protocols on measures to be taken and injury notification available at this Institution.

While there is a declining trend for the incidence of NSIs, there has been so such study performed in our Institution. In light of the above findings, this study will be conducted to investigate the incidence of NSI among the Dental health care providers (DHCP) of Manipal College of Dental Sciences, Mangalore.

Materials and Method:

Reports of NSI occurrences of DHCP originating from MCODS, Mangalore that were entered in Adverse Event Reporting System, Kasturba Medical College, Attavar during the period from May 2010-November 2013 were the source of information. The NSI incidence, demographics, contributing factors, and follow up owing NSI report were reviewed. A standard operating protocol was introduced in January 2013 to help reduce the incidence of NSI. The incidence of NSI before and after introduction of this protocol was also reviewed. The results was then subjected to a descriptive analysis and areas of improvement in the current training system will be suggested.

Discussion

Prevention and management of occupational exposures has been a thrust area of the hospital infection control committee since the last several years. Continuing education and training for HCWs has been very successfully carried out at our institute for many years. There has been a decline in sharps injuries from garbage bags, needle recapping and during injection administration, over the years due to constant awareness programs conducted at our hospital on infection control.

Regular education is also very important to discourage practices like needle recapping and encourage responsible storage, use and disposal of sharps. Only constant surveillance can ascertain exactly what interventions are wise to make and whether they will result in a positive change. Most of the NSI injuries were experienced by students. This may be because of the inexperience of the students.

In the study by Yang et al, 8 trainee nurses were exposed to NSIs about 2-4 times more frequently than other nurses.

Similarly, data presented in this study corroborates with other publications.9

The fact that NSIs were detected at lower rates among doctors may have been owing to less reporting of the injury in this group.

It is a known fact that not all NSI cases are reported. It is also known that the awareness of the identity of the source and the status of bloodborne infections causes a false sense of security after exposure and decreases the report frequency of reports.10 The percentage of unreported NSIs in the literature ranges from 22%-82%.11-13 Voide et al11 conducted a questionnaire survey about NSIs among health care professionals. They found that although the most frequent injuries occurred among doctors (49.2%), the group that least reported NSIs was also doctors.

The results emphasize the risk of needle stick injuries in HCWs. The reporting date of needle stick injury is varied by job categories. In a study from United States, nurses accounted for 68%, interns for 35%, and resident doctors for 31% of BBF exposures.14 Another study conducted in Mumbai, India, observed that the incidence of occupational exposure due to infected blood and body fluids were highest among resident doctors (76%), followed by nurses (11%), and interns (5%).15

Since students in our hospital have more patient contact there are more frequent uses of needles by them than other HCW’s, and therefore they report a higher incidence of needle stick injury. These findings suggest the need for improved continuing education programs which verify competency of HCWs, especially students about standard precautions and risk of needle stick injuries.

The first aid is a crucial factor to decrease the risk of infection from NSI. Washing the wound immediately and thoroughly with soap and water is the most important management. It is ensured that unsafe work practices such as recapping needles are avoided, used needles are disposed of promptly in an appropriate sharp instrument disposal container. Finally, efforts are being made to improve the surveillance systems for needle stick injuries and collected data are analyzed to develop and assess methods to decrease the risk to HCW exposure.

Safe use of dental equipment, provision of education, Implementation of institutional protocol, and their reflection on outcomes and behaviors have seen a decreasing trend in NSI.

Conclusion

Based on the results and within the limitations of this surveillance study it is concluded that occupational exposures can be reduced and reporting of all exposures is vital. The institution of appropriate PEP, psychological support and counselling of affected HCWs and stringent follow-up are all needed to reduce the burden of occupationally acquired infections in HCWs.

Root Canal Morphology of Mandibular Second Molars Using CBCT

Mohamad Qulam Zaki Bin Mohamad Rasidi¹, Mahesh Ramakrishnan²

¹Under graduate Student, Department of Pedodontics and Preventive Dentistry, ²Reader, Department of Pedodontics and Preventive Dentistry, Saveetha Dental College and Hospitals, Saveetha Institute of Medical and Technical Sciences, Chennai, India

Abstract

Background: A thorough knowledge of root canal system, anatomy and variation in morphological plays an important role in all scopes of endodontic treatment. The practitioner should have a great understanding of the detailed morphological anatomy of root canal system in order to utilize the proper technique and method during the endodontic treatment especially in mandibular second molar.

Aim: To evaluate root canal morphology of mandibular second molars using Cone Beam Computed Tomography (CBCT) in Chennai Population based on Vertucci’s classification.

Materials and Method: The CBCT scans of patient age between 20 years to 40 years were retrieved from Department of Oral Medicine and Radiology, Saveetha Dental College, Chennai, India from September 2018 to January 2019. The teeth were observed for the root canals system using Vertucci classification, and other parameters. The comparison between males and female were made.

Results: Generally the parameter values are more in females when compared to males and the most prevalence root canal configuration are Type 4, followed by Type 2 in mesial and distal roots for both gender.

Conclusion: The study indicates the significant values to certain extend and can serve as aids to utilize the proper technique and method during the endodontic treatment especially in permanent mandibular second molar.

Key words: Root canal; Morphology; Second Mandibular Molar; CBCT; Chennai population

Introduction

A thorough knowledge of root canal system, anatomy and variation in morphological plays an important role in all scopes of endodontic treatment. The practitioner should have a great understanding of the detailed morphological anatomy of root canal system in order to utilize the proper technique and method during the endodontic treatment. The proper technique of the treatment will increase the success rate of the treatment.¹

The anatomical variations of the root canal morphology are the most important aspect in the endodontic treatment.² The untreated missing root canal may lead to the abnormal pain caused by the contamination of microorganism colonies and production of necrotic tissue inside the canal. These condition will lead to the apical pathosis development.³

The study of the root canal anatomy and their variations has been reported in various research articles from the past and more recent update. Hence, it is show the importance of the morphology of root canals which dictates the final results of the root canal procedures.⁵
Few types of root canal system morphology has been proposed by various authors. The different root canal systems classification of human permanent including the Weine’s classification, Vertucci’s classification, and Gulabivala classifications. Vertucci’s classification is considered the most widely used and includes eight categories: Type I (1), Type II (2-1), Type III (1-2-1), Type IV (2), Type V (1-2), Type VI (2-1-2), Type VII (1-2-12), and Type VIII (3).  

The methods that have been utilized to investigate the root canal system morphology can be divided into in vitro and in vivo methods. Methods in the in-vivo consist of clinical evaluation during root canal treatment, retrospective examination of patient records, conventional assessment of radiographic imaging, and advanced radiographic techniques such as CBCT. The methods in the in-vitro are canal staining and tooth clearing, root sectioning, microscopic examination, examination of conventional radiographs, and using three-dimensional modalities such as microcomputed tomography.  

The CBCT methods has the ability to examined and precise detection of root canal morphology same as the root canal staining and the clearing techniques, which in the past were considered as the advanced to conventional methods of studying root canal system because its ability to shows 3-dimensional views and details on complete morphologic.  

The CT application in the endodontic treatment had been reported at earliest by Tachibana and Matsumoto in 1990. The advantage of CT is can shows the 3-dimensional views and facilitates the root canal system reconstruction. The recent introduction of CBCT has provide dentistry with advanced practical. The CBCT is a practical radiographic tools which is less invasive and provide 3D reconstruction imaging that can be used in endodontic and morphologic study.  

The radiographic images generated by CBCT were processed and analysed for these parameters of current research. The pattern of the root canals was evaluated and classified according to Vertucci’s classification shown in Figure 1. There are 6 types of root canals system based on Vertucci’s classification. The types of root canals system was observed in mesial and distal roots of the mandibular second molars. The mesial and distal root length, the distance between occlusal pit and pulp chamber, the distance between pulp floor to furcation, were observed by using the digital system. Later, the the descriptive analysis of all parameters were analysed in term of mean values, standard deviation and their significance of result. The comparison between descriptive values were done between males and females.
Result

A total of 83 teeth were examined by using the CBCT scans in the current study. Out of the total, 28 are males and 22 are females. The result for both genders can be seen as mean value and standard deviation, p-values and its significance of result. The p-value less than 0.5 shown the significant value.

The descriptive analysis of permanent mandibular second molar root canal types in males can be seen in Table 1. Out of 50 teeth examined and assessed, the most common root canal morphology in males are Type 1 and Type 4 morphology, which are 46% and 20% respectively. Both Type 1 and Type 4 are dominant in the mesial root and distal root of mandibular second molar. There are no finding of Type 7 and Type 8 during the examination in mesial roots and distal roots.

In females, out of 33 mandibular second molar teeth examined and assessed, the descriptive analysis of root canal types shown that Type 1 and Type 4 are the most dominant root morphology in distal roots and mesial roots with total percentage of 53% and 19.6% respectively [Table 2].

The result of the descriptive analysis of mesial root length for permanent mandibular second molar in males and females are shown in Table 3. The mean value of mesial length for males is 11.9468mm meanwhile for females is 12.6313mm. This shown that females having longer length of mesial roots compared to males. Both the values collected from males and females sample having significant value of p-value which are less than 0.5.

The result of the descriptive analysis of distal root length for permanent mandibular second molar in males and females are shown in Table 4. The mean value of distal root length for males is 11.1636mm meanwhile for females is 11.8147mm. This shown that females having longer length of distal roots compared to males. Both the values collected from males and females sample having significant value of p-value which are less than 0.5.

The result of the descriptive analysis of distance between occlusal pit and pulp chamber for permanent mandibular second molar in males and females are shown in Table 5. The mean value of distance between occlusal pit and pulp chamber for males is 4.165mm meanwhile for females is 4.262mm. This shown that females having more distance between occlusal pit and pulp compared to males. Both the values collected from males and females sample having significant value of p-value which are less than 0.5.

The result of the descriptive analysis of distance between pulp floor to furcation for permanent mandibular second molar in males and females are shown in Table 6. The mean value of distance between pulp floor to furcation for males is 2.5977mm meanwhile for females is 2.5993mm. This shown that there is no significant differences between males and females for distance between occlusal pit and pulp. The standard deviation between both genders also shown slight differences. Both the values collected from males and females sample having significant value of p-value which are less than 0.5.

**Discussion**

The study of the root canal morphology of mandibular second molars using CBCT had been studied in various research papers previously. The CBCT is a practical radiographic tools which is less invasive and provide 3D reconstruction imaging that can be used in endodontic and morphologic study.\(^\text{14}\)

In the current study in Chennai population, 83 permanent mandibular second molars were examined and assessed by using CBCT. In this study, Type 4 and Type 2 root canals configuration was the most common in mesial and distal roots, both males and females. The finding of this current study is consistent with other research result in few previous studies.

The study done in 850 south-eastern Turkish population by Bil Gulsum Nur et al. shown that Type 4 configuration was the most prevalent which were 89% in females and 93% in males for mesial roots. Type 4 canal configuration was the most common in the mesial roots, whereas type 1 canal configuration was the most common in the distal roots. Moreover, type 2, type 3, and type 5 canal configurations were also observed in mesial and distal roots, and the incidences of varying root canal configurations did not statistically differ between females and males with p-valued more than 0.05 (\(P>0.05\)), with the exception being the mesial canal of the left mandibular second molars with its p-values less than 0.05 (\(P<0.05\)).\(^\text{15}\)

The study done by Zaatar et al. and al-Nazhan et al. shown that type 2 were the most common root canals configuration followed by Type 4 configuration. In their studies, only one female patient had a Type 8 root canal configuration in the mesial root.\(^\text{3, 16}\)

The present study shown the contrast with the previous study done by Vertucci and Williams in a Caucasian population. In their studies, they observed Type 1 as the most common root canal configuration in both males and females for mandibular permanent second molars.\(^\text{17}\)

In the previous study by Marwan et al. between 2005 and 2007 where he investigated four hundred and thirty-six mandibular molars in an Egyptian Ismailia population shown that most common root canals configuration of mandibular second molars was Type 2 (57.71%) in the mesial roots and Type 1 (95.02%) in distal roots. He also concluded that there are not gender roles in determination of any root canals configuration.\(^\text{18}\)

The study by Gulabivana et al. in 2002 in Mongoloid traits shown the same results as in the Korean population. The author had concluded that the root and canal morphology of mandibular second molars also can be used in tracing the racial origins of populations.\(^\text{20}\)

In the current study, there are few limitations that may affect the precision of result in an evaluation of root canal morphology of mandibular second molars by using CBCT. The specific technique and methods need to be used during the handling of CBCT software. Technical defect may contribute in wrong evaluation of canal configuration.

**Conclusion**

The study concluded that the root canal morphology of mandibular second molars using CBCT in Chennai Population based on Vertucci’s classification shows significant result in certain extend. . There is a significant difference which can be differentiated between the genders. Generally the parameter values are more in females when compared to males and the most prevalence root canal configuration are Type 4, followed by Type 2 in both gender. Therefore the study indicates that the study can serve as aids to utilize the proper technique and method during the endodontic treatment especially in permanent mandibular second molar.

Comparative Evaluation of Effect of Auxillary Grooves on Retention of Complete Cast Crowns in Molar Teeth – An In-Vitro Study

Thilak Shetty¹, C T Anand², Sharon Saldanha³, Shobha J Rodrigues⁴, Umesh Pai³, Mahesh M³, Puneeth Hegde³

¹Professor, Department of Prosthodontics, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, ²Private Practitioner, Thilagar Dental Clinic, South Car Street, Sivakasi, ³Associate Professor, ⁴Professor and Head, Department of Prosthodontics, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education

Abstract

Aim: The aim of this study is to compare and evaluate the effects of auxillary grooves on retention of complete cast crown on molars. Method: Thirty mounted teeth were divided randomly into three groups of 10 each and grooves are placed using NOF104R diamond point. In group A, no groove is placed – control, group B, one groove is placed proximally in the centre of mesial surface – Test group. In group C, two groove is placed proximally, each in centre of mesial surface and distal surface - Test group. Castings were prepared luted and retention was checked using a Universal Testing machine Results were subjected to one way ANOVA and Student T Test. Results: Auxiliary retentive features produces a significant increase in retention of complete cast crowns. Incorporation of two proximal grooves on the mesial and distal side produces the most retention as compared to one groove or conventional tooth preparation Conclusion: Retentive features produces a significant increase in retention of complete cast crowns

Key words: auxillary grooves, complete cast crowns, tooth preparations, mandibular molar

Introduction

A full complement of natural dentition plays an important role in mastication, speech and aesthetics. Conditions like dental caries, periodontal problems, congenital abnormalities, neoplasm, trauma affects the dental health causing loss of teeth, which results in loss of function and aesthetics. Restorative materials are used to re-establish form and function of teeth.

Different modalities of tooth replacement are removable dental prosthesis, fixed dental prosthesis, & Implant supported prosthesis, and among them the most frequently done is fixed dental prosthesis. Complete coverage restoration are the commonly fabricated restoration to regain the morphology, function and contour of the damaged tooth structure caused by caries, trauma and for protection of root canal treated teeth as well as retainers for fixed partial dentures. They are also indicated for establishing occlusal rest and guide planes in removable partial dentures.

Teeth preparation is defined as the mechanical treatment of dental diseases that restores tooth to original form. Tooth preparation must follow certain mechanical, biological and esthetic principles. Retention prevents removal of restoration along the path of insertion or along the tooth preparation. Retention depends on taper, height, surface area and texture of tooth preparation.

Sometimes we come across tooth with inadequate crown height which results in reduced crown retention causing dislodgment of the crown by masticatory or para-functional forces.
Clinically a short crown requires crown lengthening, which is a periodontal surgical procedure before crown preparation which adds to the cost and complexity of treatment. Other modalities for inadequate crown height to improve retention are incorporation of grooves, boxes, pins & ledges. The aim of this study is to compare and evaluate the effects of auxiliary grooves on retention of complete cast crown on molars.

**Materials and Method**

Thirty extracted mandibular first molars, of equal dimensions mesiodistally, buccolingually and cervico-incisally were selected for the study. The roots of teeth were notched for anchorage and mounted vertically in auto polymerizing acrylic resin block 2mm below the cementoenamel junction. A dental surveyor is used to position the long axis of the tooth. These mounted teeth were divided randomly into three groups of 10 each and grooves are placed using NOF104R diamond point.

In group A, no groove is placed – control group

In group B, one groove is placed proximally in the centre of mesial surface – Test group

In group C, two grooves are placed proximally, each in centre of mesial surface and distal surface - Test group.

The groove were placed parallel to the path of insertion and minimum of 3mm long. Groove should be terminated 0.5mm above the chamfer finish line and are parallel to each other with the axial walls converging towards the occlusal surface. Size of groove should be half the diameter of the diamond point with buccal and lingual walls diverging from each other.

**Tooth Preparation:**

Tooth preparation was done with a high speed airotor handpiece attached to vertical arm of surveyor using a lockable joint. A custom made paralleling device is used to attain parallelism of axial walls and constant taper for each crown preparation. All teeth were then photographed (at an image size of 4:1) for facial and/or lingual aspect as well as mesial and/or distal aspect. A protractor was used to measure the degree of taper. A constant taper of 10 + /- 1 degree was obtained for all the preparations. A uniform chamfer finish line of 0.5mm width is established at the cemento-enamel junction. All preparations are refined using SF-102R diamond point. Teeth are prepared to constant height of 3.5mm as measured at the mid-buccal surface.

**IMPRESSION TECHNIQUE:**

Impressions of the prepared teeth were made with multiple mix single step technique with polyvinyl siloxane impression material. and cast is poured in type IV die stone following manufacturer’s instructions taking care to see mix is free of any defects or air bubbles by mixing with a vacuum mixer.

**PREPARATION OF WAX PATTERNS:** The dies are painted with three coats of die spacer 1mm short of finish lines. Die lubricant (Isolit) is painted on the master die and excess of lubricant is removed with a gentle stream of air. Wax copings of 1mm is prepared by using blue inlay wax(BEGO), carved with PKT wax instrument simulating a cylinder axially and flat occlusally. A 2mm sprue wax is made as loop and attached to the centre of occlusal surfaces of wax pattern for testing in a universal testing machine. Wax patterns are designated with a code number for convenience of identifying it for corresponding prepared tooth. These wax patterns are sprued and invested with phosphate bonded investment. Burn out is done by lost wax process.

**Casting And Finishing:**

Test copings are cast using nickel chromium alloys (Wirolloy Bego, Germany) in electronic centrifugal induction casting machine (Gallioni). These castings are retrieved from investments and sprues are cut using high speed grinder (Speed Master). Minor adjustments to seat the casting are done with a small round bur mounted on a laboratory hand piece. Internal surface of the castings are air abraded with 100-150 um Aluminium oxide particles at 40 psi and fit of casting are verified on the preparation. All the casting are cleaned with ultrasonic cleaning unit (USG 4000 Ultrashall, Dentarum) for 15 minutes.

**Cementation:**

Teeth and crowns are thoroughly cleansed and dried with filtered compressed air before cementation. All these teeth are cemented with Type I glass ionomer cement according to manufacturers recommendation. Each casting is filled with sufficient luting cement to evenly cover the inner surface, seated with digital pressure on the tooth taking care to see that excess cement is flown all around. An explorer is used to carefully remove the excess cement.
To verify the complete seating of casting, micrometer measurements are made before and after cementation. Each casting is seated on tooth without cement and the distance from the bottom margin of the acrylic resin base is measured. Measurement is repeated after cementation and two readings are compared. Tests specimens are stored for 24 hours at 37 degree at 100% relative humidity.

**Measurement Of Retention:**

Crowns are subjected to vertical dislodgement force until failure on a universal testing machine at a cross head speed of 5mm/ min. Castings are pulled along the apicoronal axis of each tooth using a “J” hook attached to the upper member of the testing machine. Force of dislodgement and debonding are recorded in Megapascals and tabulated. Intergroup comparison was done using ANOVA. Level of significance was set at $p \leq 0.05$.

**Results**

Results are presented in Table 1 and 2.

**Discussion**

Full cover restorations are required to restore teeth with minimal remaining coronal tooth structure or when fixed partial denture is fabricated. A steadily increasing demand for restorations of edentulous regions with fixed partial dentures has directed attention to the effectiveness of retention of fixed partial denture on abutment teeth. Several factors affect the retention of the crowns. They are geometry of preparation, type of luting agent, occlusal forces acting, position of crown and tensio-frictional resistance offered by the dentin. Loss of retention of a full coverage restoration may be due to poor geometrical preparation of the crown, dissolution of the luting agent and improper occlusal contacts.

This study demonstrated that clinically compromised complete coverage tooth preparation including reduced occluso cervical dimension, increased TOC, and a reduced occluso cervical –to buccolingual dimension ratio offered greater retention with grooves. Thirty freshly extracted mandibular molars are used. These teeth were divided into three groups. Group A had teeth prepared in a conventional manner, group B had teeth prepared with one proximal groove & group C had teeth prepared with two proximal grooves. Tooth occlusal convergence is one of aspect of preparation of complete cast crowns. Retention of crown is determined at various TOC angles by applying a tensile force to cemented crown. Maximum tensile retentive values are recorded at 5 degree TOC. Wilson and Chan in 1994 reported maximal retention occurred between 6 to 12 degrees. Occlusal views were used to clinically assess TOC but of limited value, hence during tooth preparation mouth mirror has been recommended so that facial and lingual view of prepared tooth is established as effective means of assessing TOC.

Mandibular teeth are generally prepared with greater TOC compared to maxillary teeth, hence axial grooves are routinely incorporated in preparation of mandibular molars for fixed partial dentures. Also FPD abutments are prepared with greater TOC compared to individual crowns.

Woosley and Matisch determined that proximal grooves provided complete resistance to faciolingual forces, whereas facial or lingual grooves provided only partial resistance to faciolingual dislodgment. Proximal grooves increase the resistance and retention of restoration. Ayad et al in a study found a marked difference between the degree of taper of full crown
preparation of 18-22 degree and that of boxes and grooves in the axial surface of preparations as shorter distance between walls allows dentist to prepare more precisely. Also Woosley and Matich reported that proximal grooves on short 15 degree dies provide complete resistance to faciolingual horizontal displacement.

The results showed highly significant amount of separation force required to dislodge casting between one groove (Group B) and no grooves (Group A)  \( p \leq 0.047 \) and very highly significant forces required to dislodge castings with two grooves \( p \leq 0.001 \). This suggests incorporation of proximal grooves improves the retention of cast crowns. The increased retention may be attributed to the fact that the lateral walls of the grooves will help in the tensiofrictional resistance and will limit the freedom of displacement. This results are in confirmation with previous studies done by Kishimoto et al and, Omar et al 2,3

**Limitations :**

Unidirectional forces were applied for dislodgement of crowns in this study. Masticatory forces are multidirectional. In addition only one luting agent that is Type I glass ionomer was under consideration. This study was an invitro study and did not consider the role of saliva which has an influence of the physical properties of the luting agent.

**Conclusion**

1. Auxiliary retentive features produces a significant increase in retention of complete cast crowns

2. Incorporation of two proximal grooves on the mesial and distal side produces the most retention as compared to one groove or conventional tooth preparation

Risk Assessment, Risk Management, and Risk Communication of Welding Work at PT Dok and Perkapalan Surabaya (Persero)

Aditya¹, I Made Muliatna², Abdul Rohim Tualeka¹

¹Department of Occupational Health and Safety, Faculty of Public Health, Airlangga University, Surabaya, East Java, Indonesia; ²Engineering Department, Faculty of Technic, Surabaya State University, Surabaya, East Java, Indonesia

Abstract

PT Dok dan Perkapalan Surabaya Is one of the manufacturing industry sectors in which operational activities can cause accidents and work-related illnesses such as the activities of joining the ship’s hull parts, namely the welding process. The risk of welding work needs to be done risk management to determine the prevention of possible work accidents through Risk Assessment activities which are then communicated to all parties. The purpose of this study is to identify hazards, conduct risk assessments and study risk control on welding work. This research is a descriptive study with an observational approach. From the results of the risk assessment of the 3 stages with 7 job descriptions, the percentage of risk categories was obtained, namely high risk 43% and medium risk 57%, and there was no low risk category Control carried out as part of risk management went well but residual risk remained so need a strong commitment from human resources or management and awareness of the workers on the use of personal protective equipment in every work. Risk communication is carried out through coaching or training, conducting safety induction, safety talk, Safety campaigns such as the activity of installing banners, posters, conducting meetings of the Health and Safety Guidance Committee at the end of each month to discuss the problems that occur and make improvements.

Keywords: Risk Assessment, Risk Management, Risk Communication, Job Safety Analysis (JSA), Welding

Introduction

In the current era of globalization, it is necessary for advanced technology to meet human needs as a whole, sometimes without us realizing the absence of good control causes harm to humans themselves. In the use of technology it is unavoidable that in the current era of industrialization the transformation process in technology cannot be prevented from developing. With the use of advanced technology, it will affect the increased use of materials that have potential hazards according to current industrial needs. In the use of advanced technology, it will provide convenience for users, but it will also have an unavoidable impact, namely the increase in the number of hazard risks and the variety of sources of accidents for technology users themselves¹.

The East Java Manpower and Transmigration Office claims that there were 21,631 cases of work-related accidents in 2017. That number rose around 200 cases compared to the previous year. While at PT Dok dan Perkapalan Surabaya every year there are still work accidents. In 2010 to 2015 there were a total of 36 occupational accidents with a risk rating of occupational deaths to minor risks².

PT. Dok and Perkapalan Surabaya (Persero) is one of the processing industries (manufacturing) of BUMN with international standards, and has main activities including: ship building, steel structure fabrication,
design & engineering, offshore construction and ship repair & conversion which in each production uses equipment or machinery that has the potential to cause accidents and there are also other potential dangerous and toxic accidents that can cause occupational diseases. As for its operational activities, it covers: welding, cutting steel plates or ship material, lifting iron or heavy equipment ships, assembling ships, installing pipes in ships and other operational activities.

The activity of uniting ship blocks is inseparable from welding activities. Welding is the connection of two or more materials based on the principles of the diffusion process, so that a part of the material is joined together. This welding process is very important because to join the hull parts of the ship. Where in the welding process there should not be the slightest mistake whether it is a crack, over heat, and so on. This welding process is a very vital part of the ship building process. The types of hazards that occur due to welding are exposed to ultraviolet and infrared radiation, inhaled fumes that exist in welding, fires, electrocuted. Therefore, to find out what hazards there are in the welding activity and control.

The problem faced by companies in this modern era is that there is no comprehensive analysis of all hazard factors in the company so that the control of each hazard factor is often done partially. Thus, to look at the problems in the company in a comprehensive manner, the company’s problems must be analyzed in the risk risk analysis. Risk analysis is an effort to analyze all hazard factors in the company based on risk assessment, risk management and risk communication. Risk Communication is an interactive process that involves exchanging information and opinions about risk, both Risk assessment and risk management. Risk Management is an effort to manage occupational health and safety risks with its implementation component including hazard identification, risk assessment and risk control. Risk assessment is an attempt to calculate the magnitude of a risk and place whether the risk is recognized or not. Before conducting a risk assessment, first identify the hazard. One of the hazard identification techniques is Job Safety Analysis (JSA).

One way to prevent accidents in the workplace is to establish and arrange work procedures and train all workers to implement efficient and safe work methods. Compiling work procedures that are correct and safe is one of the advantages of applying Job Safety Analysis. Job Safety Analysis is one method for identifying hazards which in its implementation emphasizes the identification of risks from hazards that arise at each stage of the work or task. This is in line with the approach to the cause of work accidents that starts from the condition or action that is not safe when carrying out an activity. Therefore, by identifying hazards for each type of work, appropriate and effective preventive measures can be taken. Positive things that can be obtained from the implementation of JSA, are:

1. As an effort to prevent accidents
2. As a safety contact tool for new workers
3. Review the job procedures after an accident
4. Provide pre job instruction on a new job
5. Providing personal training to employees

The Law of the Republic of Indonesia Number 1 of 1970 is the legal basis for Occupational Safety in Indonesia. This law discusses labor rights and obligations, as well as work safety requirements that must be applied in each company. Another related law is Law No. 13 of 2003 concerning Labor, article 86 in this Law states that every organization must implement occupational safety and health efforts to protect the safety of workers, while article 87 in this Law states that each company is required to have a Occupational Health and Safety Management System that is integrated with the management of other companies. To comply with the law in Indonesia and to minimize workplace accidents in the company, efforts are needed to identify potential hazards in the company. Identification of potential hazards and control can also use the Job Safety Analysis method.

The purpose of this study is to identify hazards, conduct risk assessments and study risk control on welding work at PT. Dock dan Perkapalan Surabaya with Job Safety Analysis method, so that later it will be communicated to workers.

**Material and Method**

This type of research is a descriptive study with an observational approach. This research was conducted by interview and direct observation. This research was conducted at PT Dock and Shipping Surabaya, Surabaya, East Java. The type of welding process that
will be identified is SMAW. SMAW (Shield Metal Arch Welding) is an arc welding electric flame protected by using an electric arc as a heat source for melting metal. The risk assessment method uses the JSA with the following risk assessment steps:

1. Select the place to be analyzed
2. Explain the stages of work
3. Identify the various hazards and risks that occur at each step of the work, and identify the various possibilities that have the potential to become accidents;
4. Risk assessment (likelihood and severity)
5. Categorize risk (risk assessment matrix)
6. Provide control recommendations

In its implementation, risk assessment looks at the workplace to identify equipment, situations, and processes, which can cause damage especially to humans. After identification is made, the risk of the possibility and severity of the risk must be evaluated, then determining the effective steps to prevent or control the loss.

Risk Assessment shows the level of risk acceptable or unacceptable. Low risk categories range from grades 1-4, moderate risk 5-14, while 15-25 are high risk categories. Risk assessment matrix is used as the basis for carrying out further actions, so that the level of risk received can be reduced to a level that can be tolerated. Determining risk control measures is an effort to reduce or eliminate hazardous exposure in the work environment. Activities in the control are: elimination, substitution, technical engineering, administration, and finally personal protective equipment.

**Findings**

### A. Risk Assessment

In the welding process Using the type of welding SMAW (Shield Metal Arch Welding) there are 3 stages with 7 job descriptions. The first stage begins with preparation, where there are steps to assemble a welding
device, adjust the amount of electric current as needed, and install the filler on the holder. At the preparation stage the potential hazards are electrical hazards such as electric shock, burning wires, and short circuit. There are 2 risk levels for the High Risk category and 3 Medium Risk categories.

The Second Stage is Implementation. At this stage is the welding process or the stage of the workpiece merge. The dominant danger present at this stage is the physical chemical hazard of toxins such as metal fume fever. Fume is a solid particle that is toxic, collects, and forms bonds with larger molecules. Fume particle size ranges from 0.001-0.1 microns which can endanger health problems\(^{11}\). Other hazards at this stage are cataract eye irritation, visible light and sparks from UV-B radiation and infrared. All risks at this stage fall into the High category.

The third stage is Finishing. At this stage is the activity of cleaning workpieces after welding, using both grinding machines and hammers. At this stage there is the risk of noise, burns, injury to the eyes due to grinding of work materials and sparks of welding material. At this stage all risks fall into the medium category.

B. Risk Management

From the results of the risk assessment, the percentage of risk categories is high risk 43% and medium risk 57%, and there is no low risk category, meaning that the welding work at PT Dok and Perkapalan Surabaya is included in the work that requires control measures to prevent accidents from occurring.

PT Dok dan Perkapalan Surabaya implemented one of the global occupational health and safety management systems that is in effect OHSAS 18001.2007. In the OHSAS 18001.2007 concept, risk management is a core element mentioned in clause 4.3.1\(^{10}\).

Based on the results of Hazard identification and Risk Assessment in the welding section, there are several forms of control applied by PT Dok dan Perkapalan Surabaya, such as using a respiratory protective device type cartridge respirator to prevent the risk of inhalation of fume particles through inhalation and using a face shield to prevent risk of eye irritation and eye fatigue for exposure to UV-B radiation and infrared at the high-risk stage of the welding process.

Other controls applied by PT Dok dan Perkapalan Surabaya in the welding process are based on the control hierarchy, including engineering control. This is to create a footing board for road access when the work area is wet, installing a safety line in a hazardous work area flammable work equipment, tidy up scattered cables so as not to interfere with road access. Control which includes administrative control on welding is a warning sign installed in the work area, carried out safety talk before doing work, communication with fellow workers, coordination with the Health Safety and Environmental Officer, work permit for welding in hazardous places, standard operating standards (SOP) on each job, selection of employees to do certain jobs, conducting patrol safety and field inspection training on certain jobs, maintenance of work equipment, calibrating work tools.

Control by using personal protective equipment. The forms of personal protective equipment provided by the company are: safety helmet, safety belt, safety shoes, gloves, safety harness, ear plug / ear muff, mask and respiro mask, safety spectacles, goggles, face shields.

However, all of these control methods do not necessarily reduce danger and risk at zero, meaning that workers are still more likely to be exposed to hazards at work. Research conducted by Wahyu, P.D and Tualeka, A.R., 2013 in one of the welding industries in East Java, Indonesia explained that there is still residual risk despite risk control. So that residual risk assessment needs to be done so that it can further determine additional risk control recommendations\(^{12}\). For this reason, we need a strong commitment from human resources or management and the awareness of the workers on the use of personal protective equipment in every work.

C. Risk Communication

The results of risk assessment and risk management in the form of Job Safety Analysis Sheet must be communicated so that it can be known by all parties including workers. Communication must be easily understood by all parties so that it needs to be designed in accordance with the desired goals\(^{5}\).

Risk Communication carried out at PT Dok dan Perkapalan Surabaya is through occupational health and safety development aimed at socializing and raising awareness of all workers about safety culture in the work environment for example: conducting safety induction is intended for new workers and transfer workers to enter
the welding activity area talk is held every Monday and Friday at the time before the start of an activity that contains informs of potential hazards at work. Safety campaign is an activity to install banners, posters that contain appeals for work safety, it is hoped that with these posters the workers are interested in reading and implementing their work, and conducting meetings of the Occupational Health and Safety Management Committee at the end of each month to discuss issues that occur improvement. Through the findings of patrol safety and inspection.

**Conclusion**

From the results of the risk assessment of the 3 stages with 7 job descriptions, the percentage of risk categories was obtained, namely high risk 43% and medium risk 57%, and there was no low risk category, meaning that welding work at PT Dok dan Perkapalan Surabaya included work requiring control to prevent accidents. Control carried out as part of risk management is going well but residual risk still exists so that it needs a strong commitment from human resources or management and the awareness of the workers on the use of personal protective equipment in every work. Risk communication is carried out through coaching or training, conducting safety induction, safety talk, Safety campaigns such as the activity of banner installation, posters, conducting meetings of the Worker Health and Safety Advisory Committee at the end of each month to discuss the problems that occur and make improvements.

Abstract

Background: Benzene was a dangerous chemical compound which was one of the products of gas stations and one of the chemicals contained in gasoline and it was carcinogenic. To reduce and eliminate toxin of benzene from human body, could be used the detoxification process. One of the detoxification process approach was using foods. The aim of this research was to calculate the foods intake containing CYP2E1 enzyme, sulfation, and glutathione to improve benzene detox.

Method: The type of research was descriptive study. The subjects was 15 workers. Location of this research was in gas station Pancoranmas Depok. Variables were body weight, duration of work, working time perweek, working time perday, and benzene concentration. After getting all variables above, breathing rate and intake non-carcinogen per respondent can be calculated. Then, effective doses of foods containing CYP2E1 enzyme, sulfation, and glutathione would be obtained.

Results: All respondents were at workplace shows benzene concentration below the TLV. The highest effective dose of foods containing CYP2E1 enzyme was cow brain, sulfation was tuna, and glutathione was carrot.

Conclusion: The level of adequacy of enzyme of each respondent was different. Effective dose of each respondent depending on body weight, duration of work, and benzene concentration at workplace. Every respondent could choose foods depending on their needs and taste.

Keyword: Benzene, CYP2E1, Detoxification, Glutathione, Sulfation

Introduction

According to the Central Bureau of Statistics, the number of vehicle users such as private cars has reached almost 15 million, for private motorbike users reaching 105 million in 2016. The use of the vehicle certainly requires fuel. One of the efforts to obtain fuel is through a Gas Station (SPBU). Every day, gas stations will refuel. The odor can cause a smell that is quite stinging so that it can be inhaled into the workers’ body. The smell of this fuel contains organic compounds, namely benzene.

Benzene is a colorless and sweet-smelling liquid, evaporates very quickly in the air but difficult to dissolve in water. Based on the results of the NCI (National Cancer Institute) and CAPM (Chinese Academy of
Preventive Medicine) studies, it was stated that fopoiotic malignancies lymphohema and hematological disorders in 74,828 benzene-exposed workers in 672 factories in 12 cities in China, increased the risk of all types of ANLL leukemia (Acute Nonlymphocytic Leukemia) and a combination of ANLL and precursor MDS (Myelodisplastic Syndrome)\[^{1}\] (Travis et.al, 1994). If workers are exposed to benzene it will cause a variety of negative things such as dizziness, nausea, kidney and liver problems, even if in long-term exposure and in a long duration it will cause cancer to cause death. Body receptors that will interact with toxins namely cells, enzymes, DNA/RNA, oxygen transport. The interaction between benzene and the receptors above causes work-related diseases.

Regulation of Indonesian Ministry of Manpower and Transmigration Number PER13/MEN/X/2011 and American Conference of Government Industrial Hygienists (ACGIH) in 2007, set the threshold limit value (TLV) for benzene exposure at workplace is 0.5 ppm (1.6 mg/m\(^3\))\[^{2-3}\]. Benzene included as a carcinogenic group in humans. National Institute for Occupational Health and Safety (NIOSH) in 2005, set the recommended exposure limit for 8 hours of work at 0.1 ppm (0.32 mg/m\(^3\))\[^{4}\]. While according to Agency for Toxic Substance and Disease Registry (ATSDR) in 2007, set the minimal risk levels (MRLs) for benzene exposure is 0.009 ppm (0.02 mg/m\(^3\)) per day which for acute effect and 0.003 ppm (0.009 mg/m\(^3\)) per day for chronic effect\[^{5}\]. The most vulnerable population to the accumulation of benzene exposure is gas stations workers. This is because SPBU workers work every day at the place so that continuous exposure can occur which over time accumulates the concentration of benzene can become quite high in the workers’ body.

Previous research, states that the benzene concentration at gas station Pancoranmas Depok is 0.02 ppm (0.06 mg/m\(^3\)) at both administration and operational units\[^{6}\]. That means it is still below the threshold limit value (TLV) according to Regulation of Ministry of Manpower and Transmigration Number PER13/MEN/X/2011 and American Conference of Government Industrial Hygienists (ACGIH) in 2007. This concentration value also below the TLV based on manual calculation of safe concentration at gas station Pancoranmas Depok is 0.03 ppm (0.09 mg/m\(^3\)). But this concentration value is above the TLV of minimum risk level (MRL) according to ATSDR\[^{5}\].

Although the benzene concentration in the gas station Pancoranmas Depok is below TLV, solution is needed to reduce negative impact of benzene exposure for gas station workers. One way is detoxify toxin from the body. One detoxification method that can be used is detoxification using food. Before toxins can be detoxified from the body, a biotransformation process is needed in the body. The purpose of biotransformation is to convert non-polar to polar, then to become hydrophilic so that it can be excreted out of the body. Biotransformation occurs in two phases. The first phase is the functional phase where the functional group matches the oxidation, reduction and hydrolosis reactions. Then the second phase is the conjugate reaction phase involving several types of endogenous metabolites in the body in the endoplasmic reticulum\[^{7}\] (Tualeka, 2013).

Research using foods approach as benzene detoxification is still very limited. Foods containing CYP2E1 enzyme such as cow liver, cow brains, and salmon \[^{8-9}\]. Foods containing sulfation such as egg, chicken, and tuna, and foods containing glutathione such as broccoli (Forman et al, 2010), carrot, and tomato \[^{10-11}\] (Dhivya, 2012). But there has never been a research that explains how much intake of these foods is needed to improve benzene detoxification, especially in populations that exposed to benzene in the long time. Based on the background above, the aim of this research is to calculate the intake of foods (effective doses) containing CYP2E1 enzyme, sulfation, and glutathione to detoxify benzene at gas station workers in Pancoranmas Depok.

**Method and Materials**

The type of research was descriptive study. Subjects were workers in gas station Pancoranmas Depok. The inclusion criteria were workers who had worked in this industry for 10 years or more and willing to be used as research respondents. The sample of was 15 respondents.

Variables calculated were body weight, duration of working (years), working time per week (days), average of working everyday (hours) of respondents, benzene concentration at 2 locations in this gas station. Measurement of respondents weight using manual measurement method with body scales. Measurement of duration of work, working time per week, and average of working everyday were obtained with indepth interview with respondents. Then, measurement of benzene concentration at environment using
measurement method of NIOSH 1501 (2003) with aromatic hydrocarbon sampling method [4]. Air samples were taken using a calibrated personal sampler pump. The filter used to absorb toluene vapour was a charcoal tube SKC 226-01. Air samples were analyzed using Gas Chromatography-Flame Ionization Detector (GC-FID). Willingness to participate in research was made in writing through informed consent and this study had received prior ethical approval by the Ethics Committee of the Faculty of Public Health, Airlangga University with ethical number 516 KEP-K.

After getting all variables above, can be found breathing rate and intake non-carcinogen of benzene per respondent. Then, effective dose of foods containing CYP2E1 enzyme, sulfation, and glutathione would be obtained by manual calculating, use the formula below:

\[ \text{Intake nc (non-carcinogen)} = \frac{C}{R} \times Dt \times fE \times tE \times Wb \times C_{\text{enzyme}} \]

**Explanation:**

- \( C \): Benzene concentration (mg/m^3)
- \( R \): Breathing rate (m^3/hour)
- \( Dt \): Duration of working (years)
- \( fE \): Working time per week (days)
- \( tE \): Average of working time per day (hours)
- \( Wb \): Weight (kg)
- \( C_{\text{enzyme}} \): Concentration of enzyme in 100 grams of food

**CYP2E1 enzyme**

\[ C_{\text{CYP2E1}} = 0.0000088 \text{ mmol/ml} \]

**Sulfation**

\[ C_{\text{Sulfation}} = 0.0001 \text{ mmol/ml} \]

**Glutathione**

\[ C_{\text{Glutathione}} = 0.00000099 \text{ mmol/ml} \]

**A** = Content of enzyme in 100 grams of food

- **CYP2E1 enzyme**
  - Cow liver: 5.6 mg
  - Cow brain: 1.8 mg
  - Salmon: 6.6 mg

- **Sulfation**
  - Egg: 1.477 g
  - Chicken: 0.801 g
  - Tuna: 0.755 g

**Results**

**Distribution of Benzene Concentration at Workplace**

In Figure 1 shows that all respondents are at workplace with benzene concentration below the threshold limit value (TLV). The TLV of benzene concentration in the air is 0.5 ppm (1.6 mg/m^3). While, there is no respondent who is at workplace with benzene concentration above TLV. Measurements of benzene concentrations are carried out at administration and operational units. The benzene concentration in both units are 0.02 ppm (0.06 mg/m^3).

**Effective Dose of Foods Containing CYP2E1 Enzyme to Benzene Detox**

- Egg: 1.477 g
- Chicken: 0.801 g
- Tuna: 0.755 g
- Broccoli: 7.8 mg
- Carrot: 5.9 mg
- Tomato: 10.9 mg

![Figure 1. Distribution of Benzene Concentration at Workplace](image)

![Figure 2. Effective Dose of Foods Containing CYP2E1 Enzyme to Benzene Detox](image)
In Figure 2 shows that the effective dose of cow brain has the highest dose, while salmon has the lowest dose from foods containing CYP2E1 enzyme. The highest effective dose of cow liver, cow brain, and salmon are 25.08 mg, 78.05 mg, and 21.28 mg (respondent 11). While the lowest effective dose of cow liver, cow brain, and salmon are 15.36 mg, 47.8 mg, and 13.03 mg (respondent 12).

Effective Dose of Foods Containing Sulfation to Benzene Detox

In Figure 3 shows that the effective dose of tuna has the highest dose, while egg has the lowest dose from foods containing sulfation. The highest effective dose of egg, chicken, and tuna are 53,093 mg, 97,901 mg, and 103,866 mg (respondent 11). While the lowest effective dose of egg, chicken, and tuna are 32,346 mg, 59,644 mg, and 63,278 mg (respondent 12).

Effective Dose of Foods Containing Glutathione to Benzene Detox

In Figure 4 shows that the effective dose of carrot has the highest dose, while tomato has the lowest dose from foods containing glutathione. The highest effective dose of broccoli, carrot, and tomato are 0.09 mg, 0.12 mg, and 0.06 mg (respondent 11). While the lowest effective dose of broccoli, carrot, and tomato are 0.05 mg, 0.07 mg, and 0.04 mg (respondent 12).

Discussion

Distribution diagram analysis between benzene concentration and the threshold limit value (TLV) shows that all respondents are at workplace with benzene concentration below TLV according to Regulation of Ministry of Manpower and Transmigration Number PER13/MEN/X/2011 about The Threshold Limit Value of Physical and Chemical Factors at Workplace [2]. Detoxification is very important to be done in order to remove harmful chemicals in the body. Many toxins are spread on this earth such as in the sea, rivers, food, drinks, and objects around us. Detoxification can be done uses food approach. Food-based nutrition be involved in the detoxification process. Several publications that had used cells, animals and clinical studies show that food-based components and nutrients could modulate the process of conversion and excretion of toxins from the body [13].

CYP2E1 enzyme catalyzes the oxidation reaction of benzene to benzene oxide which is in balance with benzene oxepin. Then metabolized to phenol (the main metabolite product of benzene). Phenol is then oxidized with CYP2E1 catalyst to catechol or hydroquinone, which is then oxidized by the enzyme myeloperoxidase (MPO) to be a reactive metabolite 1,2- and 1,4-benziunon. Catechol and hydroquinone can be converted to metabolites 1,2,4-benzenetriol with CYP2E1 catalysts [14-15]. Food sources of CYP2E1 enzyme like cow liver, cow brain, and salmon [8-9]. Specific foods and nutrients can induce metabolic enzymes, such as sulfation. Sulfation can be catalyzed by enzyme sulfotransferase. This enzyme can be found in the liver, intestines, adrenal glands, brain, and skin. The sulfating process is a detoxification process that can reduce the toxicology of a chemical. The decline in the function of this enzyme can be caused by genetic or certain chemicals. The activity of the sulfotransferase enzyme depends on inorganic sulfate reserves. Food sources of sulfation-containing compounds such as egg, chicken, and tuna [9]. Enzyme that responsible for metabolizing glutathione is the glutathione s-transferase enzyme. Involving antioxidant responsive elements and xenobiotic responsive elements. Many foods to be
upregulation of this enzyme, including garlic, fish oil, black soybean, broccoli, carrot, tomato, curcumin, etc. Genetic variances, gender, and maybe body weight can play a role in the effects of dietary factors on GST enzymes [9].

Based on the results of data analysis, the effective dose of cow liver, cow brain, and salmon that the body needs to remove benzene out of the body as shown in Figure 2-4. The effective dose of each food is different depending on the physical of individual. The higher concentration of benzene in the body, the higher detox mass of cow liver, cow brain, and salmon needed. Also with detox mass of egg, chicken, tuna, broccoli, carrot, and tomato. This is consistent with the formulation that has been made in previous studies which states that it has a synergistic relationship with substance concentration [16]. Maximum consumption mass of foods containing CYP2E1 enzyme like cow liver is 26.08 mg, cow brain is 78.05 mg, and salmon is 21.28 mg. Maximum consumption of foods containing sulfation and glutathione like egg is 53.09 g, chicken is 97.9 g, tuna is 103.86 g, and broccoli is 0.09 mg, carrot is 0.12 mg, and tomato is 0.06 mg. Foods in the diagram can be chosen by each respondent needs and tastes. If the respondent does not like the cow liver and cow brain, he/she can consume salmon according to the effective dose of salmon needed, and vice versa. Also with foods containing sulfation and glutathione. The consumption of each food can be regulated by each respondent, can be divided into several days.

**Conclusion**

All of respondents were at workplace with benzene concentrations below the threshold limit value (TLV). Intake of foods that contain CYP2E1 enzyme (cow liver, cow brain, and salmon), sulfation (egg, chicken, and tuna) and glutathione (broccoli, carrot, and tomato) were expected to increase detoxification of benzene. The effective dose was required by the respondents depending on body weight, duration of work, and benzene concentration at workplace. The higher the benzene concentration, the higher the needs for foods containing CYP2E1 enzyme, sulfation, and glutathione that the body needs. Body weight and duration of work could also be another factors in differences of individual intake. Every respondent could choose foods depending on their needs and tastes.

Determination of Safe Benzene Concentration at Ciputat Gas Station

Cut Suci Almadiana¹, Abdul Rohim Tualeka¹
¹Department of Occupational Health and Safety, Public Health Faculty, Airlangga University, Surabaya

Abstract

Benzene is a simple cyclic organic compounds whose concentrations are found usually low dilikungan. Benzene is often used in the industrial world, both home industry and the oil and gas industry. Benzene can enter into the body through the lungs, it can be through inhalation, gastrointestinal tract, and through the skin. If someone exposed to benzene at high concentrations, the levels of benzene into the lungs roughly half of the levels of benzene is absorbed, so that the incoming kealiran blood. This research is descriptive. The population in this study is a gas station worker Ciputat region totaling 10 people. The results of the study then analyzed quantitatively to determine the concentration secure benzene for workers obtained from the data concentration of benzene in the workplace, height workers, the weight of workers, heavy mice, respiration rate workers, time spent working, the surface area of the worker’s body surface area the body of laboratory mice, the highest dose of the toxin no effects in animal experiments (NOAEL), Km factors in animals (animal Km), Km factors in workers (Human Km), and the safe limit for workers toxin dose (SHD). The results of measurement of the concentration of benzene in petrol stations in the region Ciputat is 0.58mg/m³ (0.18 ppm), which means it is still below the Threshold Limit Value (TLV) according Permenakertrans 13 / MEN / X / 2011, the year 2011 is equal to 0.5 ppm. In contrast to the NAB which have been set at 0.18 ppm, based on manual calculations for safe concentration limit of benzene obtained value of 0.02 ppm.

Keyword: Benzene, Safe Concentration, Gas Stations, Workers

Introduction

In the era of the fastest growing technology, transportation is a very necessary thing humans in performing daily life. Means of transport is a tool that has a main component of a machine that needs fuel to run, usually referred to by fuel oil (BBM). In Indonesia alone type of fuel oil used on a variety of vehicles, such as gasoline and diesel.

There are various kinds of chemical substances contained in the fuel dinataranya benzene, toluene, xylene, ethylene, etc. which is certainly harmful to human health. The nature of the chemicals benzene, namely colorless liquid with a sweet odor. Benzene evaporates into the air very quickly, slightly soluble in water but soluble in fats, and flammable. Benzene can be found in air, water, and soil. Benzene is a chemical that is harmful and carcinogenic to humans and is a colorless liquid and volatile. Benzene is widely used in the rubber industry, oil refining, shoe factories, chemical plants and other industries related to oil including age refueling stations (gas stations).

Indonesia itself has created rules limit benzene exposure in the work environment specified in the Threshold Limit Value (TLV) of benzene of 0.5 ppm in accordance with the Regulation of the Minister of Manpower and Transmigration Republic of Indonesia number PER / 13 / MEN / X / 2011 on the Threshold Limit Value Physical and chemical factors in the Workplace.

Acute benzene exposure would have an impact like that cause disturbances in the nervous system, lack of oxygen supply to the brain, dizziness, rapid heart
rate, headaches, tremors, confusion and fainting. While chronic benzene exposure can cause decreased production of red blood cells causes anemia. Benzene can also get to the bone marrow and impair the production of blood cells so that persons exposed to benzene can suffer diseases related to decreased production of blood cells in the bone marrow. Some studies indicate a relationship between the quantity of benzene exposure by inhalation to the trans, trans-Muconic Acid (ttMA) as a biomarker of exposure to benzene. trans, trans-Muconic Acid (ttMA) is a minor metabolite of benzene that can be used as biological indicators of exposure to benzene. The occurrence of abnormalities in the hematopoietic system caused by exposure to benzene is a major concern. Examination and laboratory testing conducted on workers at risk of benzene exposure include a Complete Blood Count (CBC) with leukocyte count, hematocrit, hemoglobin (Hb), red cell count, erythrocyte indices (MCV, MCH, MCHC), and platelet counts.

Based on previous studies of benzene in the workplace, there is very little research on the safe concentration (C safe) in the work environment that have exposure to benzene. Area gas stations as a working environment that has a high exposure to benzene, should the concentration of benzene in the safe limits so as not to cause health problems for workers. Therefore, based on the explanation above, the writer will measure the safe concentration limit of benzene in the area of the pump.

This study aims to determine safe concentrations of benzene in petrol stations in the region namely Ciputat. The results of this study are expected to be on filling stations in protecting workers from exposure to benzene.

Material and Method

This research is descriptive. The population in this study were gas station workers who worked at number 1 and point 2, totaling 10 people. The collection of primary data that the air concentration of benzene in the workplace, the duration of working time, and the weight of workers. It also conducted a secondary data collection on laboratory animals, namely the weight of mice.

The variable in this study is the concentration of benzene in the workplace, height workers, the weight of workers, heavy mice, respiration rate workers, time spent working, the surface area of the worker’s body, body surface area of mice, the highest dose of the toxin no effects in animal experiments (NOAEL), Km factors in animals (animal Km), Km factors in workers (Human Km), the safe limit for workers toxic dose (SHD), and the concentration of benzene in the air that is safe for workers (C safe).

Findings

A. Characteristics of Animals Try and Try

Animal Body Surface Area (Rats)

The toxicity of compounds in general can be interpreted by the potential chemicals that cause damage when it entered into the human body. In the implementation of toxicity tests using experimental animals are mice. In general, the human response to toxicant is qualitatively similar to the response of the animals, so that this fact is the basis of extrapolation from animal data to humans.

Based on data from white rat body weight, it can be calculated body surface area white mice using the following formula:

\[ BSA \text{ hewan} = 0.09 W^{0.67} \]

Information:

- BSA : Body Surface Area / body surface area (m2)
- W : Weight / Weight (kg)

B. Characteristics of Workers, Body Surface Area Workers and Workers Respiratory rate

Characteristics of workers in this study include the weight and working time of 10 respondents working
in the area of gas stations in Region Ciputat. Based on Table 2, the highest known weight 67 Kg, 44 Kg lowest weight, and average weight of 51.4 kg. Long time working day is 8 hours. As for the height using the average value of height of an adult male Indonesia is 159 cm. Based on data from trade body weight and height workers, can be calculated body surface area workers and workers breathing rate using the following formula.

1. Full Body Surface Area

\[ BSA = \sqrt{\frac{W \times h}{3600}} \]

Information :

BSA : Body Surface Area / body surface area (m²)

W : Weight / Weight (kg)

h : Height / Height (cm)

2. Respiratory rate of Workers

\[ BR = \frac{5.3 \times \ln W - 6.9}{24} \]

Information :

BR : Breathing rate / respiratory rate (m³ / h)

W : Weight / Weight (kg)

<table>

</tbody>
</table>

Based on Table 2, the highest known weight of workers at gas stations Ciputat region that is 67 kg, while the lowest body weight 44 kg. The length of time worked in a day is all of 8 hours and height using the average value of height of an adult male Indonesia is 159 cm.

The results of the analysis of body surface area calculation and respiratory rate workers according to table 2 shows that the average worker’s body surface area is 1.59 m² and the average worker respiratory rate is 0.57 m³ / h.

C. Benzene concentration

The results of measurement of the concentration of benzene in the workplace stations in Ciputat area is either at point 1 and point 2 equals that is 0.58 mg / m³ (0.18 ppm)
Table 3. Distribution of Benzene concentration at the pump stations in Region Ciputat

</tbody>
</table>

Based on the results of measurements taken, the concentration of benzene in the working environment Ciputat Regional gas station is 0.18 ppm. The benzene concentration is below the Threshold Limit Value (TLV) of 0.5 ppm in accordance with the Regulation of the Minister of Manpower and Transmigration No. PER.13 / MEN / X / 2011 on the Threshold Value Factor of Physical and Chemical Factors in the Workplace. However, the benzene concentration is above the Minimum Risk Level (MRL), inhalation of benzene exposure levels set by ATSDR, namely for acute exposure (≤14 days) = 0.009 ppm, exposure to moderate (15-364 days) = 0.006 ppm, and chronic exposure (≥365 days) = 0.003 ppm.

D. Animal and Human Km Km

The determination of safe dose limit for workers toxin begins prior to the calculation of Animal and Human Km Km.

1. Animal Km

\[ Animal \ Km = \]

Information:

Animal Km: Km factors in animals

\( W \) : Weight of experimental animals (rats)

BSA : Body Surface Area of experimental animals (rat White)

Animal Km ditunjukka calculation results in Table 4, with an average of Animal Km on white rats is 5.81.

E. NOAEL

One objective of the research activities in the field of Tiksiologi is to be able to evaluate the safety of a substance. To determine the safety limit concentration of a chemical substance toxicity test begins with the
determination of the highest dose without effect on animal or No Observed Adverse Effect Level (NOAEL). The research results Swaen et al. (2010) states that benzene NOAEL was 3.0 mg / m³, equivalent to 0.022 mg / kg obtained from the following calculation formula.

\[
\text{Benzene NOAEL (mg / m³)} = 0.022 \text{ mg / kg}
\]

**F. Safe Human Dose**

Safe Human Dose safe dose limits for workers or Safe toxin Human Dose (SHD) found begin using the formula from Shaw et al. (2007) below.

\[
\text{SHD} = \text{NOAEL}
\]

Information:

- **SHD**: Safe Human Dose (mg / kg)
- **animal Km**: Km factors in animals
- **Human Km**: Km factors in human / workers

Based on this equation, the calculation results obtained from the SHD NOAEL value, average animal Km, and the average human Km are:

\[
\text{SHD} = 0.022 \times
\]

\[
= 0.003 \text{ mg / kg}
\]

**G. Safe limit concentration of Benzene**

Determining the safety limit concentration of benzene in the workplace (filling station) using the formula (William, 1985; Soemirat, 2003; Davis, 1991) the following:

\[
\text{C aman} = \frac{\text{mg}}{\text{m}^3}
\]

To convert the units of mg / m³ to ppm use the following formula.

\[
\text{C aman} = \times 24.5 \text{ ppm}
\]

Information:

- **C safe**: The concentration of toxins in the air that is safe for workers (mg / m³)
- **SHD**: Safe Human Dose (mg / kg)
- **W**: Weight (kg)
- **\(\delta\)**: % Of the absorbed substances lungs

Based on the formula above, the result of calculation of a safe concentration of benzene in petrol stations Ciputat region derived from SHD value, the average weight of workers, the percentage of absorption of the average worker respiratory rate and the average length of working time is:

\[
\text{C safe (mg / m³)} =
\]

\[
= 0.067 \text{ mg / m³}
\]

\[
\text{C aman (Ppm)} = \times 24.5 \text{ ppm}
\]

\[
= 0.02 \text{ ppm}
\]

The result of the calculation of the safety limit in the air that is safe for workers above can be used for (William, 1985 in Tualeka, 2013): predict the concentration of toxins in the air a safe working environment for the workers when there has been no determination of the Threshold Limit Value (TLV), and for comparison with NAB which has been established by various agencies both by Manpower, the National Standardization Agency, ACGIH, NIOSH and OSHA.

**Conclusion**

The results of measurement of the concentration of benzene in petrol stations in the region Ciputat is 0.58 mg / m³ (0.18 ppm), which means it is still below the Threshold Limit Value (TLV) according Permenakertrans 13 / MEN / X / 2011, the year 2011 is equal to 0, 5 ppm. In contrast to the NAB which have been set at 0.18 ppm, based on manual calculations for safe concentration limit of benzene obtained value of 0.02 ppm. While based on the Minimum Risk Level (MRL) set ATSDR 2007, the concentration of 0.009 ppm benzene every day can give the effect of acute and 0.003 ppm daily for chronic effects, so as the concentration of benzene in petrol stations work environment has the potential to provide health effects for workers.

Thus the necessary control measures so that workers are protected from the adverse effects of benzene on health. Control recommendations are to consume the
enzyme CYP2E1 contained in beef liver and salmon which serves to reduce the levels of benzene in the body, use of personal protective equipment appropriate in the form of half-mask respirator with organic vapor cartridge for meminimalisir exposure to benzene, and planted a number of plants that can absorb and lowering the concentration of benzene such as Boston and Golden Phothos 14.

Forensic Implications of Saliva: An Overview

Debesh Nilendu¹, Arjun Kundu¹, Avaish Chand¹, Abraham Johnson²

¹Postgraduate Student, ²Assistant Professor, Laboratory of Forensic Odontology, Institute of Forensic Science, Gujarat Forensic Sciences University, Gandhinagar, Gujarat, India

Abstract

Over past years, investigators and researchers have been repeatedly attracted by possible applications of saliva related evidence in forensics. It is specifically looked for in cases of sexual assault, drug abuse, driving while intoxicated, and in cases involving animal bites. Oral fluid has a role in linking suspects or victims to a crime scene, as well as in profiling of the unknown individual. Collection of salivary evidence should thus be given deserved importance and should be carried out using scientific methods, considering the progression of time, type of case, sequence and type of analytical methods to be performed, nature of surface etc. This review emphasizes the comprehensive use of saliva in forensics.

Key words: Identification, Investigation, Forensics, Analysis, Oral Fluid, Saliva

Introduction

Mandel in 1990 quoted that “saliva lacks the drama of blood, the sincerity of sweat and the emotional appeal of tears”. [1] An exocrine secretion from the salivary glands, saliva is the predominant secretion in the oral cavity. With an average secretion of about a litre per day, and a slightly alkaline pH, it has a multifunctional role. [2] Having a range of molecules in content, saliva has an indispensable role in forensic odontology. [3]

Although with few solutes, saliva is has a varied scope in drug detection, identification, DNA fingerprinting, cases of abuse, analysis of psyche, and so on. Saliva can be collected from bite-marks on skin and edible items, from stains in surfaces, and from various items like utensils, straws, phones, cigarette butts, stamps etc. [4]

In the past, forensic investigations have revealed saliva in lip-prints, bite-marks, and other objects, helping in identification to a greater extent. [5] As saliva enters the oral cavity, it coalesces with blood cells, oral microflora, food, and upper airway secretions. This increases the chance of saliva containing information about a person. [6]

The current article will summarise on the use of saliva in various context of forensics.

Presence of Saliva at the Crime Scene

In numerous crimes, saliva is stored in ‘nibble marks’. [7] The advantages of using saliva its ease of access, ease of handling, its non-invasive collection, and economical analysis. [3] On the other hand, oral fluid deposited on substrate can’t be specifically submitted to extraction procedures. [8]

Recovery and Detection:

• Visual Examination: As dry colourless stains, saliva is difficult to identify in a crime scene. However with the use of alternate light sources and ultraviolet lights, discovery becomes easier. Under ALS, ranging 415–490nm (using orange/red goggles) [9], quartz arch tube or argon ion laser, saliva presents soft edged white spots, less intense than other stains. [4] Saliva stains will appear bluish-white under an ultraviolet light. However, it degrades the DNA in the sample. [10]

• Presumptive tests: Due to lack of solutes, there are no confirmatory tests for saliva. [8] The presence of saliva stains can be detected through test for amylase, present in high concentrations in saliva, pancreatic

Corresponding author:
Dr. Abraham Johnson,
Assistant Professor, Laboratory of Forensic Odontology, Institute of Forensic Science, Gujarat Forensic Sciences University, Gandhinagar, Gujarat, India, Phone: +91-8849130278
Email: drabrahamjohnson4000@yahoo.com
fluid, and faeces. Detection of amylase is particularly important in cases involving fellatio.\textsuperscript{[11]}

Test for saliva involves starch and Florence iodine solution (~1:100), with the sample. Starch and iodine form a deep blue complex. Amylase hydrolyses starch and the colour fades (time: 15 mins, temperature: 37°C). However, albumin, gamma-globulin, semen, etc. may give a false positive result.\textsuperscript{[10]} Elevated amylase levels may also be from oral sex/fellatio or from vaginal cavity.\textsuperscript{[9]}

The method has limitations and variable sensitivity depending upon the age of the stain and quantity of deposit.\textsuperscript{[9]}

- **Collection:** Collection involves three aspects: the crime scene, the victim and from suspect(s). The classical technique is using a single wet cotton swab/filter paper laid passively on the surfaces.\textsuperscript{[4]}

  Sweet et al developed the double swab technique, to provide a better yield through rehydration of the saliva traces by swabbing with a sterile swab, wetted in nuclease free water with moderate pressure in a rolling motion for about ten seconds, followed by a second dry swab.\textsuperscript{[4, 12]}

  Stimulated saliva can be collected from the suspect using paraffin or citric acid crystals, and non-stimulated saliva by simple rinse with mouthwash. While these samplings are considered as diluted saliva, whole saliva is directly milked from the opening of Stenson’s duct. Commercial kits like Oragene are also available, when salivary DNA is required.

  FTA cards (Fritz Technology Associates) are useful for the collection and storage of DNA from body fluids, including saliva.

  **Laboratory analysis:** Amylase mapping is performed for saliva stains on samples of larger area [Figure-1].\textsuperscript{[9]}

  \begin{itemize}
  \item Amylase substrate is sprayed on a sheet of filter paper
  \item Substrate-containing paper is placed over the area to be tested
  \item The orientation of the filter paper is marked to aid in locating the stain
  \item The filter paper is dampened by spraying with water and plastic wrap is placed on top to prevent the paper from drying.
  \item Brown colour indicates a positive reaction
  \end{itemize}

**Figure 1: Procedure for amylase mapping**

A radial diffusion assay has been used to distinguish sources of AMY1 (amylase found in saliva, breast milk, perspiration) and AMY2 (amylase in the pancreas, semen, and vaginal secretions) [Figure-2]
**Immunological methods:** ELISA is not widely used. α-amylase is detected using a horseradish peroxidase conjugate combined with monoclonal antibodies. The Phadebas1 test reagent, used in tube and press tests, with sensitivity up to 1:12810, incorporates procion red amylopectin.

**Detection of Chemicals:** Dried saliva stains can be identified with soluble phosphatase, starch and amylase resulting in a red precipitate. Nitrites and thiocyanates can also be detected. Tryptophan also helps recognize dried oral fluid, giving a trademark emanation range on fluorescent spectroscopy.\[13\]

Near-infrared (NIR) Raman spectroscopy has been used to measure spectra of pure dried human saliva samples, showing its heterogeneity.\[14\]

The RSID (Rapid Stain Identification) test, specific for human salivary α-amylase, has been very useful and quick to identify saliva. It is similar to a pregnancy test (parallel stream immuno-chromatography) and is the principal high sensitivity specific non-enzymatic test for amylase.\[12\]

Investigation of Drugs of Abuse in Saliva

Oral fluid is second only to urine for checking medications.\[15\] Medications enter the salivation by the passive exchange.\[16\] Most illicit and addictive drugs of abuse can be distinguished in saliva.\[17\] Radioimmunoassay (RIA) has also proved useful.\[1, 18\] Recently, Drug wipe, an immunochemical based test strip has been introduced to detect medications of mishandle in the fluid.\[19\]

Peel et al. discovered quantifiable amounts of medications in salivation removed with methanol and broke down by immunoassay and gas chromatography/mass spectrophotometry, which can be adjunct to serological testing.\[20\]

Deoxyribonucleic Acid Profiling/Fingerprinting

DNA analysis is of great dependency when traditional identification methods fail.\[21\] In spite of affecting the security of human DNA dirt and microscopic organisms don’t pose much threat as the tests utilized for profiling are particular to person only.\[22\]

Saliva contains leukocytes and exfoliated epithelial cells as a useful DNA source.\[23\] Since secretory genes are present, saliva can also be used for blood grouping.

Saliva yields a very small amount of DNA. However, DNA tests are intensified by polymerase chain response for DNA writing utilizing short tandem repeats (STRs), unique, lifelong and durable markers consisting of repeated DNA sequences. STRs are suitable for maternity/paternity assurance and scientific examination, requiring only 0.5ng of DNA template.\[26\]

Mitochondrial DNA (mtDNA) is present in cells found in saliva, which has a high copy number proves useful when nuclear DNA testing fails, due to degradation.\[27\] mtDNA is maternally inherited\[28\], thus, distant maternal relatives can be used as a reference source for identification.\[29\]

Methylation and telomere shortening, has been observed in salivary DNA to estimate age.\[32\]

Salivary DNA lasts even after about fifteen days.

**Sex Determination from Saliva**

The peeled epithelial cells present in salivation have expanded the likelihood of sex assurance of the culprit. Even in degraded samples, sex chromatin like Barr bodies (in females) and F bodies (in males) can be observed; and sex hormones detected using fluorescent dyes or radioimmunoassay.\[22\]

**Salivary Biomarkers**

Salivary nucleic acids and proteins contain vital information. Saliva biomarkers have been used in diagnosis of various diseases but they have wider role in forensics. Markers for any particular disease can be matched and on tracking that disease to hospital visits, positive identification can be achieved.\[6\]

**Determining Psychology**

Different hormones in saliva helps in deciding the mind of a person.\[11\] Salivary level of steroid hormones reflects the free, unbound circulating fraction,\[30\] helps in determining mind-set of a person. High testosterone in spit has demonstrated people as rough, less consistent and related with individual mischief.\[11\] Low salivary cortisol could likewise be related with fierce criminal conduct.\[31\]

**Conclusion**

Rarely, people think of saliva, as a convenience,
Practicing dentists find it’s a nuisance, to be sponged, evacuated or dammed. However, over the years, the need and importance of saliva as an investigative body fluid is increasing rapidly in forensics. With constant examination, and a communitarian work in serological and odontological fields, salivation is developing as a fundamental device for scientific examination. A careful learning of what at a dentist faces each time he/she works in a mouth, may increase the significance of an odontologist in a criminal examination group by manifolds. One can only ponder what more is behind each drop of spit in the mouth.

Risk Management by Implementing Hazard Identification, Risk Assessment and Determinant Control (HIRADC) Method in the Research Center of the University in Surabaya, Indonesia

Ade Titis Kurniawati1, Putri Ayuni Alayyannur1, Dani Nasirul Haqi1, Tri Martiana1, Shintia Yunita Arini1, Allin Wahyudiono F1

1Department of Occupational Safety and Health, Faculty of Public Health, Universitas Airlangga, Campus C, Mulyorejo, 60115, Surabaya, East Java, Indonesia

Abstract

The Research Center of the Faculty of Dentistry, Universitas Airlangga is one of workplaces that have various risks to cause occupational accidents. The use of various chemicals, specimens, and special instruments at the Research Center has potential to cause various risks that can threaten workers, assets, and environment. To prevent and control every hazard with potential negative risks, a risk management using HIRADC method must be implemented. This study aims to implement Hazard Identification, Risk Assessment and Determinant Control (HIRADC) method in the Research Center of the Faculty of Dentistry, Universitas Airlangga. This study is descriptive research with a cross-sectional design. Data collection was done through direct observation in the workplace and interview with a laboratory worker at the Research Center. The Research Center of the Faculty of Dentistry, Universitas Airlangga has a moderate risk. The research results showed that of the 5 work activities, there were 20 potential hazards with 20 risks identified. Based on the risk assessment, there are 1 extreme risk, 1 high risk, 11 moderate risks, and 7 low risks. The extreme risks identified are explosion, fire, and death caused by LPG. The high risks identified are explosion, poisoning, and death caused by CO2 gas. Based on the determinant control, there are 15 controls implemented including substitution control, engineering control, administration control, and wearing personal protective equipment. However, there are still 5 controls that have not been implemented. Further recommendations are needed for 5 controls that have not been implemented in every activity conducted in the Research Center of the Faculty of Dentistry, Universitas Airlangga.

Keywords: HIRADC, Hazard Identification, Risk Assessment, Determinant Control, Research Center, Laboratory

Introduction

Every job has its own potential hazards depending on the production type, machines and instruments used, materials used, environment, and management and worker quality. Hazards are everything including situations or actions that have the potential to cause occupational accidents or injuries to humans, damage or other disturbances(1). If a hazard is linked to the likelihood of occurrence of an accident and the severity it causes, it becomes a risk. Uncontrolled risks that are not managed effectively have potential to cause occupational accidents to workers.

According to data from the International Labour Organization (ILO) (2017), as many as 2,780,000 workers die each year due to occupational accidents and occupational diseases. About more than 380,000 (13.7%) of work deaths were caused by occupational accidents. In addition to causing high number of deaths of workers, occupational accidents also cause losses. Estimates of
losses due to occupational accidents reach 3.94% of global Gross Domestic Product (GDP) each year\(^{(2)}\). In Indonesia, the number of occupational accidents is also quite high. According to data from the Ministry of Health of the Republic of Indonesia (2015), from the number of occupational accident cases in Indonesia during 2011-2014, the highest number occurred in 2013 with 35,917 cases. Therefore, it is known that every hour as many as 4 workers die due to occupational accidents\(^{(3)}\).

The Research Center of the Faculty of Dentistry, Universitas Airlangga is one of workplaces that have various risks to cause occupational accidents. The Research Center of the Faculty of Dentistry, Universitas Airlangga is a research center that aims to facilitate basic research, applied and innovative research for prevention of various diseases in oral cavity based on science and technology. The Research Center has five laboratories in it, which include immunology laboratory, molecular biology laboratory, karyotype laboratory, microbiology laboratory, dental biomaterial laboratory and stem cells.

The large number of work activities carried out at the Research Center has potential to cause various risks that can threaten workers, assets, and environment. The use of various chemicals, specimens, and special equipment at the Research Center also has potential to cause explosions, fires, occupational accidents such as being cut off, slashed, poisoning, exposed to chemicals, and also occupational diseases such as contact dermatitis, infertility and cancer. To prevent and control every hazard with potential negative risks, a risk management using HIRADC method must be implemented.

Hazard Identification, Risk Assessment and Determinant Control (HIRADC) method is a system for conducting risk analysis consisting of 3 stages, including hazard identification, risk assessment and determinant control. The output of risk management using the HIRADC method is to minimize any risk that can cause occupational accidents in the workplace\(^{(4)}\). Therefore, the objective of this study is to implement Hazard Identification, Risk Assessment and Determinant Control (HIRADC) method at the Research Center of the Faculty of Dentistry, Universitas Airlangga.

**Material and Method**

This study is a descriptive research, which is a study conducted to describe or explain a phenomenon that occurs\(^{(5)}\). This study is an observational study with a cross-sectional design. The population in this study was a laboratory worker at the Research Center of the Faculty of Dentistry, Airlangga University. This study uses the total population as respondents. This study was done during October 2018. The data collected in this study is primary data through direct observation in the workplace and interview with a laboratory worker. The variables that will be used in this study are hazard identification, risk assessment and determinant control.

Hazard identification completed through direct observation in the workplace using the HIRADC form and interview with a laboratory worker at the Research Center using an interview sheet. Based on the results of hazard identification, the potential hazards and risks in each work activity carried out are known. Then, the level of likelihood and severity at each risk are determined using risk assessment matrix of Australian Standard / New Zealand Standard 4360:2004 (AS/NZS 4360:2004) \(^{(6)}\). The results of multiplication between likelihood and severity level scores will result in total risk. Based on the total risk, the analysis is carried out using a risk assessment matrix to determine the level of risk. After knowing the level of risk, then determinant controls were given in accordance with the level of risk.

Findings

Hazard Identification

Hazard identification is a systematic process carried out to identify all circumstances and events that have potential to cause occupational accidents and occupational diseases that may arise in the workplace\(^1\). Hazard identification method in this study is a proactive method using Job Safety Analysis (JSA). There are 5 work activities identified at the Research Center, including research in immunology and histology laboratory, research in microbiology laboratory, research in molecular biology laboratory, research in stem cell laboratory, and cleaning of research medium used.

When carrying out work activities in each
laboratory at the Research Center, there are various potential hazards that can threaten workers health and safety. Based on the results of the hazard identification, it is known that from 5 work activities carried out at the Research Center of the Faculty of Dentistry, Universitas Airlangga there are 20 potential hazards with 20 risks that can occur. Potential hazards identified at the Research Center include physical hazards, chemical hazards, biological hazards, electrical hazards, and ergonomic hazards. Physical hazards identified at the Research Center are illumination, syringe, and fire. Chemical hazards identified at the Research Center are formalin, acids, dental paint, CO\(_2\) gas, and LPG. Biological hazard identified at the Research Center is bacteria. Electrical hazard identified at the Research Center is electricity. Ergonomic hazard identified at the Research Center is long sitting positions while conducting research.

In addition, the risks that identified at the Research Center of the Faculty of Dentistry, Universitas Airlangga are eye fatigue caused by inadequate illumination; finger puncture wound caused by using syringe; fire caused by using fire; suffering from cancer and gas poisoning caused by formalin exposure; skin and eye irritation caused by exposure to acids; stains marks that are hard to remove on the hands caused by dental paint exposure; explosion, poisoning, and death caused by CO\(_2\) gas; explosion, fire, and death caused by LPG; disease from residual organisms in research activity caused by bacteria; mild electric shock in workers caused by electricity; Musculoskeletal Disorders (MSDs) caused by long sitting positions while researching.

Risk Assessment

After all potential hazards and risks were identified, a risk assessment was then carried out. Risk assessment method used in this study is a qualitative method. Risk assessment includes 2 stages, namely risk analysis and risk evaluation. Risk analysis is carried out to determine the total risk that is the result of multiplication between the level of likelihood and the severity at each risk. Meanwhile, a risk evaluation is carried out to assess whether the risk is acceptable or not, compared to the applicable standards or the ability of the organization to face a risk\(^{(1)}\). Risk assessment is done by finding the value of relative risk using risk assessment matrix of AS/NZS 4360:2004\(^{(6)}\).

According to AS/NZS 4360:2004, the risks included in the low risk category is risks with a relative risk score of 1-4, the moderate risk category is risks with a relative risk score of 5-9, the high risk category is risks with a relative risk score of 10-19, and the extreme risk category is risks with a relative risk value of 20-25\(^{(6)}\). Based on the results of the risk assessment, in the risk analysis it is known from 5 work activities carried out at the Research Center of the Faculty of Dentistry of Universitas Airlangga, there are 20 risks consisting of 1 extreme risk, 1 high risk, 11 moderate risks, and 7 low risks.

In the risk evaluation, it is determined whether the risk is acceptable or not which determines the prioritisation of risk. Based on ALARP concept (As Low as Reasonably Practicable), the risks included in the category of high risk and extreme risk are unacceptable risks. Because these risks cannot be accepted or tolerated, risk controls must be taken so that the risk level can decrease to an acceptable level\(^{(1)}\). In work activities carried out at the Research Center, the risk that included in the extreme risk is explosions, fires, and deaths caused by LPG, and the risk that included in the high risk category is explosion, poisoning, and death caused by CO\(_2\) gas.

On the results of the risk assessment of LPG hazard potential, the likelihood level is 4 and the severity level is 5, so the total risk is 20. Based on the results of observations and interviews, it is known that the likelihood of LPG exposure when conducting cleaning activities is likely. The likelihood of hazard in a particular circumstances and the frequency of the occurrence is almost 100%. The severity it causes included to the catastrophic category, which can result in human death. Therefore, the risk of explosion, fire, and death due to LPG included to the extreme risk category.

On the results of the risk assessment of CO\(_2\) gas hazard potential, the likelihood level score is 2 and the severity level is 5, so the total risk is 10. Based on the results of observations and interviews, it is known that the likelihood of CO\(_2\) gas exposure when conducting research is unlikely. The likelihood usually not happens, is unlikely and the frequency of the occurrence is annual. For the severity it causes included to the catastrophic category, which can result in human death. Therefore, the risk of explosion, poisoning, and death due to CO\(_2\) gas included to the high risk category.

Based on the results of the risk assessment, it is known that all hazards at the Research Center must be given determinant controls to minimize the occurrence
of work accidents, especially for extreme risks and high risks. Determinant control is also needed to reduce the impact on worker health and safety.

Determinant Control

After the assessment of all existing risks, the next step is to determinant control. Determinant control aims to minimize or reduce the level of risk to the lowest or tolerable level\(^{1}\). Based on the results of the risk assessment, then control is determined according to the level of risk that has been analyzed. The determined control is adjusted to the risk control that has been implemented at the Research Center of the Faculty of Dentistry, Universitas Airlangga.

Based on the results of determinant control, there are 15 controls that have been implemented including substitution control, engineering control, administration control, and wearing personal protective equipment. The controls that have been implemented at the Research Center for potential hazards of bacteria are assistance by laboratory workers when conducting research, use of disposable gloves, hand washing with alcohol before and after conducting research, collecting in jerry cans, and washing autoclave 2 times with detergent. For potential hazards of illumination is use of bright colors on the ceiling and wall paints in laboratory, and adjusting use of lighting.

For potential hazards of formaldehyde, risk controls have also been implemented are storing formalin in tight specific places and controlled use of formalin when conducting research. For potential hazards of a long sitting position while conducting research is use of movable seats that can be used for stretching the body. Then, for potential fire hazards are the provision of small fire extinguishers in laboratory and use of fire as sterilization method only carried out by laboratory workers. For potential hazards of dental paint, risk controls have been implemented is washing the stains of dental paint on the hands slowly for several days. For \(\text{CO}_2\) gas hazard potential are the provision of backup electricity in the form of generators and UVS in the laboratory, and assistance by laboratory workers when conducting research.

Most of controls have been implemented to every activity carried out at the Research Center of the Faculty of Dentistry, Universitas Airlangga. However, there are still 5 controls that have not been implemented, including potential hazards of syringes, potential electrical hazards, potential hazards of acids, and potential hazards of LPG.

Conclusion

Based on the results of this study, it can be concluded that the Research Center of the Faculty of Dentistry, Universitas Airlangga has a moderate risk. The research results showed that of the 5 work activities, there were 20 potential hazards with 20 risks identified. Based on the risk assessment, there are 1 extreme risk, 1 high risk, 11 moderate risks, and 7 low risks. The extreme risks identified are explosion, fire, and death caused by LPG. The high risks identified are explosion, poisoning, and death caused by \(\text{CO}_2\) gas. Based on the determinant control, there are 15 controls implemented including substitution control, engineering control, administration control, and wearing personal protective equipment. However, there are still 5 controls that have not been implemented to some activities carried out at the Research Center of the Faculty of Dentistry, Universitas Airlangga.

Further recommendations are needed for 5 controls that have not been implemented in every activity conducted in the Research Center. For research activities with potential hazards of syringes, it is recommended to provide temporary waste shelters around the Research Center area. For potential electrical hazards, it is recommended to provide without a small electric current voltage and the installation of protective equipment for laboratory equipment on the outside that is made of metal. For potential hazards of acids, it is recommended in the form of making Material Safety Data Sheets. For potential hazards of LPG, it is recommended to store and put LPG cylinders in a well-ventilated place.

Conflict of Interest: None.

Source of Funding: This study was sponsored by Universitas Airlangga.

Ethical Clearance: Ethical clearance was obtained from the Ethics Committee of the Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia.

Evaluation to Identify Benzene Safe Concentration in Oil and Gas processing Facility in East Java Area Due to Process Fugitive Emission

Ahmad Muslih Bambang Sugiharta1, Aditya1, Abdul Rohim Tualeka2

1Students Department of Occupational Health and Safety, Public Health Faculty, Airlangga University, Surabaya, 2Department of Occupational Health and Safety, Public Health Faculty, Airlangga University, Surabaya

Abstract

Benzene is an organic chemical compound with the chemical formula C6H6. The benzene molecule is composed of six carbon atoms joined in a ring with one hydrogen atom attached to each. Acute benzene exposure can cause central nervous system depression. Longterm exposure can result in depression of the blood-forming system and may increase risks associated with anemia and leukemia. The purpose of this research is to identify benzene safe concentration in crude oil processing plant in east java area due to process fugitive emission. Sample is taken from 20 workers include work duration and weight of the worker also crude oil plant air quality monitoring is measured using direct-measure benzene detectors.

In the benzene measurement on the crude oil plant in east java area, 2 spot sample is taken with resulting data 0.96 mg/m3 or 0.30 ppm and 0.86 mg/m3 or 0.27 ppm, and according to final manual calculation for safe benzene concentration with the result 1.12 mg/m3 or 0.35 ppm, all of those number are still below safe concentration limit by refer to minister of man power No.13 / MEN / X / 2011 regulation and The Occupational Exposure Limits (OELs) which have been adopted globally as a company standard which is 0.5 ppm as an eight hour time-weighted average (TWA8) and 1.0 ppm as a Short Term Exposure Limit (STEL) (averaged over fifteen minutes). But according to Minimum Risk Level (MRL) ATSDR 2007, those value already above threshold which is 0,009 ppm daily exposure for acute effect and 0,003 ppm daily exposure for chronic effect, Recommendation to control and reduce fugitive emission which resulting in number of benzene is by reviewing engineering design for equipment causing fugitive emission, and since this company regulation for respirator usage in benzene case are 0.5–5.0 ppm must use Half-face mask with organic vapor cartridge, 5.0–25.0 ppm use Full-face mask with organic vapor cartridge, and Greater than 25 ppm use Self-Contained Breathing Air (SCBA) then need to re asses all area which has an obligation to wear personal protective equipment (Half-full / full mask with organic vapor cartridge or Self contain breathing apparatus) by not only based on benzene level but also considering the exposure duration.

Keywords: Benzene, safe concentration, Crude Oil Plant, Fugitive emission, engineering design.

Introduction

Oil and gas processing facility is place to separate raw oil from water, sediment, and unwanted gas. According Agency for Toxic Substances and Disease Register (ATSDR), dangerous chemical substances in the crude oil proprietary is benzene, toluene, xylene, ethylene, TPH (Total Petroleum Hydrocarbon), and Polycyclic Aromatic Hydrocarbon (PAHs). From six of them, benzene has the highest carcinogen effect to which can cause high severity harmful effect to the body.

Airborne benzene is the most common route of exposure. Even at low doses of airborne benzene (<1 parts per million (ppm)), As a result of inhalation
exposure, lungs are the major site of benzene metabolism (Arnold et al., 2013)\(^3\). Worker in here continually exposed by benzene from process fugitive emission which come from process fugitive emission on the oil and gas processing facility\(^4\).

The results of the measurement of benzene at two points in the Oil and Gas processing plant Industry in East Java are 0.96 mg/m\(^3\) or 0.30 ppm and 0.86 mg/m\(^3\) or 0.27 ppm. These results are still below safe concentration limit according to minister of man power No.13 / MEN / X / 2011 and The Occupational Exposure Limits (OELs) which have been adopted globally as a company standard which is 0.5 ppm as an eight hour time-weighted average (TWA8) and 1.0 ppm as a Short Term Exposure Limit (STEL) (averaged over fifteen minutes)\(^5\), but workers who are exposed to benzene will still have a carcinogenic effect. A similar study at the Pancoranmas Depok gas station by Abdul rohim (2012), even though benzene concentrations at the site had yields below the safe concentration limit, but workers at the exposed area had a risk of carcinogenic effects at the duration of the lifetime exposure\(^6\).

The authors will measure the limits of the safe concentration of benzene in different areas, namely in the Oil and Gas Industry processing plant in east java region.

**Material and Method**

This type of research is an observational, cross sectional and descriptive study. The population in this study are all production operators in oil and gas company workers in the East Java region. The sampling technique is the total population, so the sample is 20 workers.

The research variables is benzene concentration in the workplace, worker body weight, worker height, respiration rate of ayworkers, length of day working, body surface area, weight of white mice, body surface of white mice, highest dose of toxin without effect on experimental animals NOAEL, Km factor in animals (Animal Km), factor Km in workers (Human Km), safe dose limit for toxins for workers (SHD), and safe benzene concentration in the air (safe C).

Data analysis in this study was carried out by using quantitative data analysis manually to determine the safe concentration of benzene for oil and gas company workers in the East Java region.

**Findings**

A. **Characteristics of Try Animals and the Surface Area of Try Animals (White Mice).**

According to Saridewi and Tualeka, the implementation of a toxicity test using experimental animals which is white rats\(^6\). In general, the human response to toxicity is qualitatively similar to the response of animals, so this fact forms the basis of extrapolation from animal to human data.

In table 1, the characteristics of experimental animals in the form of white rat body weight are displayed on below table.

Based on the data of white rat body weight, the body surface of the white mouse can be calculated using the following formula\(^7\).

\[
\text{BSA Animal} = 0,09 \cdot W^{0,67}
\]

Explanation:

- BSA : Body Surface Area (m\(^2\))
- W : Weight (kg)

Based on data on worker weight and height of workers, the body surface area and the rate of respiration of workers can be calculated using the following formula.

1. Worker Body Surface Area

\[ BSA = \sqrt{W \cdot h/3600} \]

Explanation:

BSA : Body surface area (m²)

W : Weight (kg)

h : Height (cm)

2. Workers Breathing Rate.

\[ = 5.3 \ln - 6.9/24 \]

Explanation:

Table 2 shows that the average body surface area of workers is 1.80 m² and the average respiration rate of workers is 0.66 m³ / hour.

B. Benzene Concentration.

The measurement results of the concentration of benzene at two points in the Oil and Gas processing plant Industry in East Java are 1.44 mg / m³ or 0.45 ppm and 1.18 mg / m³.

Table 3. Distribution of Benzene Concentration in oil and gas processing plant in East Java region.

<table>
<thead>

</tr>
</tbody>
</table>

Those benzene concentration is still below the threshold limit value of 0.5 ppm in accordance with the provisions of the Minister of Manpower Regulation No.13 / MEN / X / 2011 concerning Occupational Safety and Health at the Work Environment. However, the concentration of benzene is above the Minimum Risk Level (MRL), the level of benzene inhalation exposure determined by ATSDR which is for acute exposure (≤14 days) = 0.009 ppm, moderate exposure (15-364 days) = 0.006 ppm, and chronic exposure (≥365 days) 8

C. Animal Km dan Human Km

The first step to determine safe dosage of toxin for workers is by calculating Animal Km and Human Km.

1. Animal Km

\[ \text{Animal Km} = \frac{W_{\text{animal}}}{BSA_{\text{animal}}} \]

Keterangan :

Animal Km : Animal Km Factor.

W : Weight of research animal (White Mice).

BSA : Body Surface Area (White Mice).

The results of the Animal Km calculation are shown in table 4. The average Animal Km in the experimental animal is white rats which are 5.81.
Table 4. Result of Animal Km for Research animal (white mice).

D. NOAEL

One of the objectives of toxicology research is to be able to evaluate the safety limit of a substances in order to determine the safe concentration limit of a chemical begins with a toxicity test to determine the highest dose without causing effects on research animal or No Observed Adverse Effect Level (NOAEL).

There was a research from Swaen et al. (2010) revealed that benzene NOAEL is 3.0 mg/m³ (0.94 ppm) or equivalent with 0.022 mg/kg which come from below calculation.9

\[
\text{NOAEL benzene} = \frac{3 \times 0.00013 \times 12}{0.1405} = 0.022 \text{ mg/kg}
\]

F. Safe Human Dose

\[
\text{SHD} = \frac{\text{NOAEL}}{\text{Human Km}} \times \frac{W \text{ human}}{BSA \text{ human}} \times 0.1405
\]

According to above formula then from the SHD calculation which come from NOAEL value, average from animal KM and human KM are:

\[
\text{SHD} = \frac{0.022 \text{ mg/kg}}{0.1405} = 0.0398 \text{ ppm}
\]

G. Benzene safe concentration limit.

Below formula (William, 1985)9 is used to determine benzene safe concentration limit in process area of oil and gas processing plant in east java region.

\[
C \text{ aman} = \frac{(\text{SHD})(W)}{(\delta)(BR)(t)} \text{ mg/m}^3
\]

And to convert unit of mg/m³ to ppm can use below formula.

\[
C \text{ aman} = \frac{\# \text{ mg/m}^3}{(MW)} \times 24.5 \text{ ppm}
\]

Explanation:

C Safe: safe toxin concentration in the air for worker (mg/m³). SHD: Safe Human Dose (mg/kg). W: Weight (kg). \(\delta\): % absorbed substances in lungs. BR: Human breathing rate (m³/jam). t: Working time duration (jam). MW: Molecular Weight.

The results of calculating the benzene safe concentration in the oil and gas process area in east java region are obtained from the SHD value, the average body weight, the percentage of absorbed substances, the average workers breathing rate and the average working time duration are:

\[
C \text{ aman} = \frac{(0.0398)(74.05)}{0.1405} = 0.729 \text{ mg/m}^3
\]

\[
C \text{ aman} = \frac{0.729 \times 24.45}{78.11} = 0.35 \text{ ppm}
\]
Discussion

The risks of benzene are caused by the increasing accumulation of benzene exposure in the body through inhalation. It is also in line with the research of Maryiantari et al (2016), enter the duration exposure workers with a high level of exposure has adverse effects against the risk of developing health problems\(^\text{11}\).

In this study involving 20 outside operators who work on the detected benzene area. Under normal condition, outside operators will stay on the benzene exposed area for doing routine job, but there will be potential higher benzene exposure where the activity in abnormal state (equipment failure, equipment under preparation for maintenance, pigging pipeline, or other breaking containment job).

OHSAS 18001 (2007) provides specific control guidelines for Occupational Health and Safety Hazards through elimination, substitution, technical, administrative and personal protective equipment approaches. The approach of elimination and substitution at oil and gas processing plant in east java will require big project means will demand high cost. For the technical approach can be done by making sure the preventive maintenance to minimize equipment failure, and continue re assessing area which producing harm benzene value and providing personal benzene detector to increase awareness when time to use benzene respirator protection as a personal protective equipment approach.\(^\text{12}\)

Conclusion

In the benzene measurement on the crude oil plant in east java area, 2 spot sample is taken with resulting data 0.96 mg/m\(^3\) or 0.30 ppm and 0.86 mg/m\(^3\) or 0.27 ppm, those number are still below safe concentration limit according to minister of man power number No.13 / MEN / X / 2011 and The Occupational Exposure Limits (OELs) which have been adopted globally as a company standard which is 0.5 ppm as an eight hour time-weighted average (TWA8) and 1.0 ppm as a Short Term Exposure Limit (STEL) (averaged over fifteen minutes), and also according to final manual calculation for safe benzene concentration with the result 1.12 mg/m\(^3\) or 0.35 ppm, but according to Minimum Risk Level (MRL) ATSDR 2007, all of those value already above threshold which is 0,009 ppm daily exposure for acute effect and 0,003 ppm daily exposure for chronic effect, then control action needed to protect workers from benzene harm effect to worker occupational health. Recommendation is reviewing engineering design for equipment causing fugitive emission (review type of gasket on flanges, change to double seal on the pumps or compressors, and re-routing hazardous gas vent), and since this company regulation for respirator usage in benzene case are 0.5-5.0 ppm must use Half-face mask with organic vapor cartridge, 5.0-25.0 ppm use Full-face mask with organic vapor cartridge, and Greater than 25 ppm use Self-Contained Breathing Air (SCBA) then need to re assess all area which has an obligation to wear personal protective equipment (Half-full / full mask with organic vapor cartridge or Self contain breathing apparatus) by not only based on benzene level but also considering the exposure duration\(^\text{4}\).

Abstract

Introduction: Drug usage is a prevalent social and health problem in most countries. The highest prevalence of drug abuse has been reported among people aged 30-40 years old. The purpose of this study was to determination of the types of drugs and the methods of drug usage in Iran in a systematic and meta-analysis study.

Methods: This study was performed based on the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. Databases of SID, Iran Doc, ISI, Cochrane library, Science direct, PubMed/Medline, and Scopus were independently searched by two researchers using MeSH keywords. Articles published between 2004 and 2018 were recruited. Data was analyzed using random effects model using STATA-SE12 software. Heterogeneity among studies was investigated using, T² and I²statistical indices.

Results: Initial search retrieved 90 articles from which 7 articles with desirable quality were finally analyzed. Opium was the most common in used narcotic50 %(95% CI: 35-66%) followed by opium extract44%(95% CI: 5-83%), and heroin 19%(95% CI: 12-26%). Using more than one narcotic was observed in 9% (95% CI: 4-15%). The inhalation was the most common method of usage72 %(95% CI: 61-83%) followed by oral consumption 32%(95% CI: 9-54%) and injection 14%(95% CI: 05-24%).

Conclusion: Drug abuseis a common phenomenon in Iran. It is amenable to reduce the tendency to using drugs by providing appropriate training, informing the risks of drug abuse, and identifying and educating high-risk groups.

Keywords: Drug usage, Meta-analysis, Iran

Introduction

Iranian scientists, have been aware of the beneficial and detrimental impacts of opium and had used it as an antidote (¹, ²) Besides other major crises including nuclear threats, environmental pollution and poverty, drug addiction has turned into an acute problem of the today’s world. Addiction to drugs has also boosted in Iran in recent years. The primary official statistics have estimated that around 2 million drug addicts and abusers are present in the country (³, ⁴). In addition to the direct economic burden, serious health threats such as respiratory illnesses, AIDS, hepatitis, tuberculosis etc., as well as numerous socio-economic complications

Corresponding Author: Walieh Menati
MSc of Epidemiology, Student Research Committee, Ilam University of Medical sciences, Ilam, Iran. Email: Waliehmenati@yahoo.com.
and problems such as increased drug-related crimes shrinkage the country’s large material capital (5-6).

This is while most professionals specify that familial support, as well as social support can be key contributors to increase the effectiveness of pharmaceutical treatment. In fact, social support can boost the therapeutic efficiency of pharmaceutical treatment through him parting information related to addicts’ health, encouraging healthy behaviors and preventing risky health attitudes, as well as providing access to psychological facilities to augment social capital and social support (7, 8).

Previous studies have reported the rates of drug usage recurrence as 50% to 80% in the first year after quitting (10, 9). Therefore, it is very important to identify the factors responsible for reusing drugs to prevent this phenomenon by implementing appropriate controlling policies and measures, (11-12). The chemicals in the drug have different effects (35). Therefore, the purpose of this study was to determine the types of drugs and the methods of drug usage in Iran.

Method

This was a systematic review and meta-analysis. The data of this review was acquired from studies conducted around the world. Articles published in SID, Iran doc, Science direct, PubMed/Medline, Scopus, ISI, and Cochrane library within 2004-2018 were recruited. MeSH keywords encompassing the type of drugs and the methods of drug usage in Iran were applied.

Selection of studies and data extraction: All the articles related to drug usage in Iran were collected. A checklist of abstracts of the found articles was initially prepared. Then all articles that mentioned the type of drug and the method of usage in their titles were recorded in the checklist. Studies mentioning merely suggestions or recommendations on drug usage were excluded.

Next, the required information from each study including author’s name, article title, year and location of study, sample size, number of women and men, the type of substance, and age groups were recorded into a secondary checklist.

Statistical analysis: Given that the types of narcotics and sample sizes had been extracted from each study, binomial distribution was used to calculate the variance of each study. Weighted mean was used to combine the frequencies reported indifferent studies. Each study was inversely weighted according to its variance. Due to the great heterogeneity in frequencies reported by different studies and statistically significant heterogeneity index (I²), the random effects model was used to conduct meta-analysis. The rate of heterogeneity in this study was 94.5% falling into the category of studies with high heterogeneity (i.e. I² indices < 25%, 25-75%, and >75% represent low, moderate, and high heterogeneities respectively) (13-14). Meta-regression was used to evaluate the trend of drug abuse in Iran in terms of the year of study and sample size. Meta-regression was also used to investigate the cause of heterogeneity between results. Subgroup analysis was performed to investigate the rate of drug abuse in Iran based on contributing factors and age groups. The data was analyzed using STATA software (version 12).

Results

The initial search yielded 90 articles related to the topic. Two independent researchers reviewed the titles and abstracts. If the title or abstract was relevant, the related full text was prepared for further reviewing. During screening, 25 duplicated and 25 irrelevant articles were excluded. Also, 33 studies were omitted because of providing insufficient information. Finally, 7 articles with adequate quality entered the systematic review process.

The rate of heterogeneity in this study was 94.5% representing a high heterogeneity (I² indices of < 25%, 25-75%, and >75% indicate low, moderate, and high heterogeneities respectively) (13-14). The total sample size was 6375 rendering the average sample size of 911 per study. Table 1 shows the characteristics of each included study.

The Forest plot of opium consumption frequency showing the rate of 50% (95% CI: 35-66%). The Forest plot of the frequency of opium extract consumption representing the prevalence of 44% (95% CI: 05-83). The Forest plot of the frequency of heroin usage representing the prevalence of 19% (95% CI: 12-26%). The Forest plot of the frequency of using more than one narcotic. The overall frequency was obtained as 9% (95% CI: 4-15%). The Forest plot of inhalation method of drug consumption representing the frequency of 72% (95% CI: 61-83%). The Forest plot of oral consumption of narcotics representing the prevalence of 32% (95% CI: 9-54%). The Forest plot of the rate of drug injection showing the overall prevalence of 14% (95% CI: 05-24).

The meta-regression analysis of drug usage based on sample size and the year of study publication indicated that the rate of drug consumption decreased in more recent studies and increased in studies with larger sample sizes (Figure 3, P<0.001). The mean age of drug users was 34.5 (95% CI: -25-44) years old.

Figure 1a. Meta-regression analysis of drug abuse based on the year of study conduction
Discussion

The review studies provide various evidence to the researchers\(^{(32-34)}\). Also considering the impact of drugs on mental health\(^{(3,4)}\) and the importance of paying attention to mental health\(^{(35,34)}\), For this reason, this review study was conducted. The tendency for using narcotics has increased especially in adults of 30-40 years old. The aim of this systematic review and meta-analysis was to determine the types of drugs and the methods of drug usage by Iranians. The highest drug consumption was observed in >35-year-old age group which was in line with the report of the Iranian Drug Control Headquarter that reported the highest prevalence of drug abuse in the 20-29-year-old age group\(^{(22)}\). However, in the study of Sadeghiyeh Aberiet al, the highest rate of drug abuse was observed in individuals around 40 years old\(^{(15)}\). As people usually raise a family in this age group\(^{(20-29)}\), providing occupation opportunities to provide their family’s expenses may help them to avoid drug abuse.

The present study showed that the most consumed substance was opium with 50% frequency (95% CI: 35-66) followed by opium extract and heroin with frequencies of 44% (95% CI: 5-83) and 19% (95% CI: 12-26) respectively. In addition, consuming more than one type of drug was observed in 9% (95% CI: 4-15). It seems that higher tendency to consume opium and opium extract roots in their faster and easier availability, as well as their cheaper prices than other narcotics. Over the past two decades, policies such as intense monitoring of Eastern borders to prevent drug trafficking, arresting drug dealers, establishing rehabilitation centers, and producing and distributing advertising videos and posters to illustrate the negative consequences of drug abuse have been followed in Iran. Nevertheless, drug abuse and its subsequent health problems continue to be serious challenges in the country\(^{(16, 23)}\). Measures such as training life skills through mass media, increasing public awareness of the adverse effects of drug abuse, emotional support for susceptible individuals, and educating on drug resistance of narcotics have been effective in reducing drug consumption\(^{(16, 24)}\). In addition to the aforementioned actions, focusing of families on educating their children and controlling their relationships, providing appropriate environment for routine activities and healthy entertainments, and informing community and families about the consequences of narcotics can be effective to prevent drug abuse\(^{(16, 23, 24)}\).
A study by Bagheri et al in Qazvin found that the most common used substances were opium and heroin (25). Also, Abbasi et al. reported that opium constituted the most common in used narcotic in Gorgan (26). In the study of Ahmadipour et al in Kermanshah, heroin was the most popular drug among addicts, while the lowest frequency was related to hashish (27).

Nevertheless, Di et al. stated that drug injection was on the rise (28) in people working in various occupations including health care professions (29). This is critical as if drug abused disseminates among health care personnel, their activities and functioning are disrupted endangering patients’ lives and increasing occupational violence (30-31).

**Conclusion**

Drug abuse is a common phenomenon in Iran. It is amenable to reduce the tendency to using drugs by providing appropriate training, informing the risks of drug abuse, and identifying and educating high-risk groups.

Abstract

Pesticide sale circumstances in Paser District through measuring cholinesterase enzymes by the laboratory of the Paser District on the blood of pesticide traders found 37.5% experienced organophosphat group pesticide toxicity. This research aim to analyze risk factors related to the level of pesticide toxicity in pesticide traders namely age, nutritional status, educational level, length of work, work period and use of personal protective equipment. The study design used was observational with a cross sectional approach. The number of samples is 42 people taken by simple random sampling. Measurement data using observation and examination sheet cholinesterase levels in the blood of respondents using Tintometer tool brands in ScienPro Pest 100. The data were analyzed using Chi-square and multiple logistic regression. Pesticide traders who experienced pesticide toxicity were 42.9%. Result of Chi-Square test shows three variables that have a significant relationship with the incidence of pesticide toxicity. Risk factors for pesticide toxicity were age (p=0.021; OR=6.250; 95% CI=1.511-25.860), length of work (p=0.038; OR=6.769; 95% CI=1.268-36.139) and work period (p=0.043; OR=4.900; 95% CI=1.238-19.399). Multiple logistic regression showed that the most dominant factor associated with the incidence of pesticide toxicity namely the length of work and work period. Risk factors associated with the incidence of pesticide toxicity are age, length of work and work period where is the last two are the dominant factors.

Keywords: pesticide, toxicity, age, length of work, work period

Introduction

Pesticides are toxic and dangerous materials, if not managed properly it will have a negative impact on health. One of the places that manages pesticides is the pesticide management sites. Scope of supervision of pesticide management sites, namely pesticide factories, plantations, shops, or Village Unit Cooperatives. The place to pesticides selling that are not properly managed will cause pollution to the surrounding environment and can cause health problems for the surrounding community or its management whether acute or chronic.¹

Based on data from the Agriculture Office East Kalimantan Province in 2016, the number of pesticide sellers in East Kalimantan was 228, spread across 10 municipal Districts. Use of chemical pesticides for the delivery of plant pests and disease vectors tends to increase constantly. High use of pesticides increase to the health risks faced by both pesticide operators and the community at large. Health risks experienced by users of pesticides (industrial workers, formulators, applicators) usually related to the security method, storage, and use of pesticides. While the health risks experienced by the wider community are generally due to contamination of pesticides that enter the food chain, and poisoning of pesticides due to ingestion, inhalation and direct contact with the skin.²,³,⁴
Previous studies in Subang concluded that, 66.1% of workers working at pesticide sales sites experienced organophosphate group pesticide toxicity. Likewise, 78.8% of pesticide sales people in the city of Bengkulu experienced pesticide toxicity. The same was shown in the Pasamanan sub-District where nearly 50% of pesticide management workers experienced pesticide toxicity.5,6

Data from the Paser District Health Laboratory (2018), which states that 37.5% of pesticide traders were identified as organophosphate group pesticide poisoning with an average age of 39 years. The data also states that the people who are poisoned are male, with an average work period of 8 years and a long working average of 8 hours per day. In addition, 25% of traders have poor nutritional status, with 75% of traders having high school education, and 100% of pesticide traders not using Personal Protective Equipment (PPE) when managing pesticides.

This research was conducted to find out the relationship between pesticide toxicity in pesticide traders in Paser District, especially the relationship between age, nutritional status, education level, length of work, length of service, and use of PPE.

**Materials and Method**

This study was an analytic observational study with a cross sectional design. The population in this study are all traders or workers who work in pesticide shops as many as 97 people. Sampling technic by simple random sampling, the sample size is determined by the formula of Lemeshow is 42. Sources of data from the primary data were collected using observation and interview sheets and blood sampling of respondents. Data taken includes data on pesticide toxicity, age, nutritional status, education level, length of work, work period, and use of PPE, as well as reference books related to research. Analysis using univariate, bivariate analysis using Chi-square test and multivariate analysis using the Logistic Regression Test.

Age

The results of Chi-square test with p-value 0.021 (p<0.05) with OR 6.25 which means that there is a significant relationship between the age of the trader and the incidence of pesticide toxicity. The farmers aged 40 years are more likely to suffer from pesticide poisoning. The age of pesticide traders over 35 years is more likely to experience pesticide toxicity compared to under 35 years of age. People who are older, they get more experience and exposure. Their metabolic function will decrease and result in a cholinesterase activity so that it will facilitate pesticide toxicity. Age is also related to immunity the body in overcoming the level of toxicity of a substance, the older the age of a person, the effectiveness of the immune system in the body will decrease.

Nutritional status

The results of Chi-square test obtained p-value 0.162 (p<0.05), which means that there is no significant relationship between the nutritional status of traders and the incidence of pesticide toxicity on traders. The number of pesticide traders who have good/normal nutrition is 58.1% compared to pesticide traders who have poor nutritional status. There are no relationship between nutritional status and the incidence of pesticide toxicity in the pesticide trader in Subang and West Lombok District, Wonosobo and Magelang District farmers.

Respondent with a poor category of nutritional status 69.23% is a pesticide trader who experiences overweight, this can result in toxic substances that can be stored in body fat tissue, so that the effects of poisoning cannot be detected. There is a positive relationship between the percentage of body fat and respondent’s cholinesterase levels, meaning that the higher the body fat percentage, the more the number/dose of pesticides needed for the occurrence of low cholinesterase levels.

Education Level

The results of statistical analysis using the Chi-square test with p-value 0.119 (p <0.05) which means that there is no significant relationship between the level of education with the incidence of pesticide toxicity in pesticide traders. There is no relationship between education level and pesticide toxicity on traders.

The formal education received by respondents does not necessarily indicate the actual level of knowledge about pesticides, a lot of knowledge about pesticides is actually obtained through education and training activities specifically for this matter, and especially for traders of pesticides that this can be done by the agency agriculture, health services and agents of pesticide brands.

Length of Work

The results of statistical analysis using the Chi-square test obtained p-value 0.119 (p<0.05) with OR 6.769 which means that there is a significant relationship between the length of work of traders and the incidence of pesticide toxicity at pesticide traders. There was a relationship between the length of work and the incidence of pesticide toxicity in farmers in the Jambi and Brebes Muaro.

Respondent who has more than five hours of work per day with a working period of more than 5 years as much as 40.5% where the respondent who works more than five hours with a larger work period is 8.85 years compared with respondents with working time of less than 5 hours which has an average working period of 6.76 years. This shows that the longer people work, the more likely they are to be exposed to dangerous substances. In addition, respondents who work more than 5 hours per day and also work long periods of time will cause continuous and repeated exposure to pesticides which causes a very high risk of pesticide toxicity. The main factors causing toxicity are the length of exposure, concentration/dose of exposure and thickness in individuals affected by age, nutritional status, sex and others.

Work Period

The results of statistical analysis using the Chi-square test obtained p-value 0.019 (p<0.05) with OR 4.900 which means that there is a significant relationship between the length of work of traders and the incidence of pesticide toxicity at pesticide traders. There was a relationship between the length of work and the incidence of pesticide toxicity in farmers in Tomohon and Brebes. There are significant differences in toxicity due to pesticides among farmers with employment <5 years and ≥ 5 years.

Work period is one of the factors that influence the level of cholinesterase in the blood of the respondent, where the longer the period of work, the lower the level of cholinesterase in the blood of the respondent so cause the risk of pesticide toxicity. The length of work as a pesticide trader influences the incidence of poisoning.
because exposure to pesticides in a short time can lead to toxicity in traders. Chronic organophosphate poisoning symptoms arise due to inhibition of cholinesterase and will mene tap for 2-6 weeks, resembling mild acute poisoning. But, when exposed again in a small number of severe symptoms may arise.

**Use of PPE**

Influence personal protective equipment (PPE) at the pesticides sale sites has no relationship. The results of this study indicate that the proportion of pesticide traders does not use complete personal protective equipment (PPE), so statistical analysis cannot be done. Although the results of the study showed no association between the use of PPE and the incidence of poisoning in traders but it is necessary to recommend the use of PPE when mixing/repacking pesticides because of the potential for the most contact to occur at that time.

**Dominant factors**

Based on the results of logistic regression analysis, the variables have p-value <0.05 is the length of work p-value 0.028, OR 9.587 and work period p-value 0.044, OR 6.005. The calculation of probability for the incidence of pesticide toxicity in pesticide traders can be predicted based on influential variables, P = 0.725 or 72.5%. So, pesticide trader with a service period of> 5 years; length of work per day> 5 hours have probability for pesticide poisoning of 72.5%.

The length of work and working period is a strong determinant of the incidence of pesticide toxicity in farmers.13 Both of these risk factors (length of work and working period) reinforce each other based on multivariate analysis. Results of research shows that the longer the life of the farmer, the lower the enzyme activity of blood kolinesterase explain that vegetable farmers who have been exposed for a long time or are persistent are at risk of getting poisoned at the next level. This is made worse by all pesticide traders in Paser regencies who make contact with pesticides, which are not used to wearing personal protective equipment (PPE), even if wearing does not meet the requirements. Length of work and work period with pesticides must be wary, because the longer the contact pesticide, the greater the exposure to pesticides in the sale.16

**Conclusion**

As many as 18 respondents (42.9%) experienced pesticide toxicity and 24 others (57.1%) did not experienced. There is a relationship between age, length of work and working period with the incidence of pesticide toxicity in pesticide traders in Paser Regency, while the results of the study show that all respondents did not use personal protective equipment in a complete manner so that they were more at risk of experiencing pesticide toxicity. The need to conduct counseling or training for managers and workers at the pesticide sale sites on how to properly manage pesticides and mitigate the negative effects of hazards caused by pesticides which include the management of appropriate pesticides, the use of personal protective equipment, the practice of handling pesticides, health labor aspects, how to repack pesticides, work environment sanitation as well as ways of dealing with poisoning. As well as for traders to conduct medical check-up every 6 months and provide PPE for workers and themselves.

Determination of Safe Benzene Concentration in Tank Car Crew at PT Pertamina Patria Niaga

Bella Oktavia¹, Farhana Syahrotun Nisa Suratna¹, Abdul Rohim Tualeka¹

¹Department of Occupational Health and Safety, Faculty of Public Health, Airlangga University, Indonesia

Abstract

Benzene is a compound that can cause carcinogenic effects in humans. The purpose of this study was to determine the level of health risk due to exposure to benzene through inhalation on tank car crews at Pertamina Patra Niaga. This type of research is a descriptive, observational and cross sectional study. The population in this study were all the Tank Car Crew (AMT) who worked in Pertamina Patra Niaga, amounting to 8 people. The sampling technique is the total population, so the sample is 8 workers. Data analysis used quantitative data to determine the safe concentration of (C) benzene in workers from animal body weight of white rats (W animals), body surface of experimental animals (BSA animals), body weight (W), height of workers (h), worker body surface area (BSA), worker respiratory rate (BR), working time (t), benzene (C) concentration, animal km. Human km, NOAEL and safe dose toxin limit (SHD).

The results showed measurements of benzene concentration at PT. Pertamina Patra Niaga is 0.26 mg / m³ (0.08 ppm), which means the concentration of benzene is still below the Threshold Value (NAB) according to Minister of Manpower Regulation No. 13 / MEN / X / 2011 at 0.5 ppm. Based on the calculations that have been done, the safe limit value is 0.02 ppm. This value if according to the Minimum Risk Level (MRL) of 2007 ATSDR exceeds that which is set at 0.009 ppm daily for acute effects and 0.003 ppm daily for chronic effects, so that control efforts are needed to be protected from the adverse effects of benzene on the health of workers. Control recommendations are to consume CYP2E1 enzyme contained in beef liver and salmon which serves to reduce benzene levels in the body, use Personal Protective Equipment (PPE) in the form of mask respirators and plant a number of ornamental plants that can absorb and reduce benzene concentrations such as Boston and Golden Photos¹

Keywords : Benzene, safe concentration, workers of PT Pertamina Petra Niaga

Introduction

Industrial progress and development requires the availability of adequate transportation so that it can meet economic needs and development. According to data from the Central Statistics Agency (BPS) since 2014-2016 there has been an increase in the number of vehicles in Indonesia by 5-6% per year.²

Increasing the number of vehicles will support the economy of the community, but on the other hand it can cause air pollution and energy needs which continue to increase every year.³

PT Pertamina Patra Niaga is one of the motorbike fuel terminals which is in charge of distributing fuel in Central Java. In fuel distribution activities, workers called the Tank Car Crew (AMT) must come in contact with benzene.

Benzene is a compound that can cause carcinogenic effects in humans. Benzene can enter the human body through 3 pathways, namely breathing, inhalation and skin. Prolonged exposure to benzene in the work environment such as fuel terminals can cause an increased risk of nervous system disorders, blood pressure, headaches and loss of consciousness.⁴
Based on observations made at Pertamina Patra Niaga, it was found that tank crews did not use personal protective equipment (PPE) such as masks and gloves to protect themselves from exposure to gasoline vapors containing benzene and many workers who smoke also added to the risk of benzene exposure.

Based on the background described, the researchers wanted to conduct a study that aimed to determine the level of health risk due to exposure to benzene through inhalation on tank car crews at Pertamina Patra Niaga.

**Research Method**

This study was a descriptive, observational and cross sectional study. The population in this study were all the Tank Car Crew (AMT) who worked in Pertamina Patra Niaga, amounting to 8 people.

The research design begins with the collection of secondary data related to work processes which include chemicals in the work area and the number of workers involved. Furthermore, primary data collection was carried out related to the concentration of benzene in the workplace air, length of work time, and worker body weight. In addition, primary data collection was also carried out on experimental animals, namely the weight of white mice. Data on the concentration of benzene in the air was obtained by direct measurement using Coconut shell charcoal and analyzed by Gas Chromatography (GC), referring to the NIOSH 1501 method.

The research variables were benzene concentration in the workplace, worker body weight, worker height, respiration rate of workers, length of day working, body surface area, weight of white mice, body surface of white mice, highest dose of toxin without effect on experimental animals (NOAEL), Km factor in animals (Animal Km), factor Km in workers (Human Km), safe dose limit for toxins for workers (SHD), and benzene concentration in safe air for workers (C is safe).

Data analysis in this study was carried out by using quantitative data analysis manually to determine the safe concentration of benzene for tank car crews at PT Pertamina Patra Niaga.

**Findings**

A. Characteristics of Try Animals and the Surface Area of Try Animals (White Mice)

In general, the toxicity of compounds is interpreted by the potential of chemicals that can cause damage when it enters the human body. In general, the response of the human body qualitatively to toxic substances is similar to the response of animals, so this becomes the basis of extrapolation from animal to human data.

Table 1 shows the characteristics of experimental animals in the form of white rat body weight.

Based on the data of white rat body weight, the body surface of the white mouse can be calculated using the following formula:

\[ BSA_{\text{animal}} = 0,09 \ W^{0,67} \]

Description :

BSA: Body Surface Area / body surface area (m²)

W: Weight / weight (kg)

B. Worker Characteristics, Worker’s Body Surface Area and Worker’s Respiratory Rate

The surface area of the worker body

\[ BSA = \sqrt{W.h/3600} \]

Description : 

BSA: Body surface area (m2)

W: Weight / weight (kg)

h: Height / Height (cm)

C. Occupational respiratory rate

\[ BR = 5,3\ln W - 6,9 / 24 \]
Description:

BR: Breathing Rate (m³/hr)

W: Weight (kg)

The characteristics of the workers in this study included the body weight and working time of 6 workers in the Tank Car Crew area at PT Pertamina Patra Niaga. Based on Table 2, it is known that the highest body weight is 79 Kg, the lowest weight is 50 Kg, and the average weight is 65.62 Kg. The duration of work in a day is 8 hours. Whereas the highest height is 171 cm, the shortest is 155 cm with an average height of workers that is 163.5 cm. The results of the analysis of the calculation of body surface area and worker respiratory rate according to table 2 show that the average body surface area of workers is 1.72 m² and the average respiration rate of workers is 0.63 m³/hour.

Based on the results of air measurements of the workplace environment at PT Pertamina Patra Niaga where the results of these measurements showed a concentration of Benzene of 0.08 ppm or 0.26 mg/m³. Based on the Minister of Manpower and Transmigration Regulation No. Per.13 / MEN / X / 2011 concerning the threshold values of physical factors and chemical factors in the workplace for 0.5 ppm Benzene concentration so that benzene concentrations in the Tank Car Crew at PT Pertamina Patra Niaga Benzene concentration values below NAB.

**E. Animal Km dan Human Km**

Determination of safe dosage of toxin for workers begins with the calculation of Animal Km and Human Km.
Animal Km and Human Km.

1. Animal Km

\[ \text{Animal Km} = \frac{W_{\text{animal}}}{\text{BSA}_{\text{animal}}} \]

Description:
Animal Km = Km factor in animals
W = experimental animal body weight (white mouse)
BSA = Body surface area can be tried

<table>
<thead>
<tr>

</tr>
<tr>
<td><strong>Average</strong></td>
<td><strong>37.98</strong></td>
</tr>
</tbody>
</table>

The results of the Human Km calculation are shown in table 5, with an average Human Km in labor force of 37.98.

F. NOAEL

One of the objectives of research activities in the field of toxicology is to be able to evaluate the safety of a substance. To determine the safe limit of the concentration of a chemical begins with a toxicity test determining the highest dose without causing effects on experimental animals or No Observed Adverse Effect Level (NOAEL).

NOAEL Benzena (mg/m³) = \( \frac{3 \times 0.00013 \times 8}{0.1405} \)
= 0.022 mg/kg

Swaen et al. (2010) research results state that benzene NOAEL is 3.0 mg / m³ or equivalent to 0.022 mg / kg obtained from the calculation of the formula above.

G. Safe Human Dose

Safe dosage of toxin for workers or Safe Human Dose (SHD) is found to be initiated using the following formula from Shaw et al. (2007):

\[ \text{SHD} = \frac{\text{NOAEL} \times \text{Animal Km}}{\text{Human Km}} \]
\[ = \frac{0.022 \times 5.82}{37.98} \]
\[ = 0.003 \text{ mg/kg} \]
H. Safe Limit for Benzene Concentration

Determination of safe limits of Benzene concentration in the working environment of the Tank Car Crew uses the following formula:

\[
C_{\text{safe}} = \frac{(SHD)(W)}{(\delta)(BR)(t)} \text{mg/m}^3
\]

Description:
- C safe: concentration of toxin in the air that is safe for workers (mg / m³)
- SHD: Safe Human Dose (mg / kg)
- W: Weight (kg)
- δ: % of substances absorbed by the lungs
- BR: Human respiratory rate (m³ / hour)
- t: Working time (hours)
- MW: Molecular Weight / Molecular Weight

Based on the above formula, the results of calculating the safe concentration of benzene at PT Pertamina Patra Niaga are obtained from the SHD value, average worker weight, percentage of substance absorption, average worker respiratory rate and average length of work time is:

\[
C_{\text{safe}} = \frac{(0.003 \times 65.62 \times 0.50 \times 0.6 \times 8)}{2.4} = 0.07 \text{mg/m}^3
\]

\[
C_{\text{safe (ppm)}} = \frac{0.07 \times 24.5}{78.11} = 0.02 \text{ppm}
\]

The results of the calculation of safe limits in the air for workers above can be used to predict the concentration of toxins in the air of a safe work environment for workers if there is no determination of the Threshold Limit Value (NAV), and to be compared with the NAV determined by various institutions either by Ministry of Manpower and Transmigration, National Standardization Agency, ACGIH, NIOSH and OSHA.

CONCLUSION

The results of the measurement of benzene concentration in PT Pertamina Patra Niaga were 0.26 mg / m³ (0.08 ppm). Based on Permenakertrans No. 13 / MEN / X / 2011 Threshold Value The benzene limit is 0.5 ppm. From the measurement results when compared to the NAB, it is still below the set threshold value.

While based on the 2007 ATSDR Minimum Risk Level (MRL), daily benzene concentration of 0.009 ppm can have an acute effect and 0.003 ppm every day for chronic effects, so that the concentration of benzene in the work environment of PT Pertamina Patra Niaga
has the potential to provide health effects for workers. Thus control efforts are needed so that workers are protected from the adverse effects of benzene on the health of workers.

Control recommendations are to consume CYP2E1 enzyme contained in beef liver and salmon which serves to reduce benzene levels in the body, use the appropriate Personal Protective Equipment in the form of half mask respirator with organic vapor cartridge to minimize benzene exposure, and plant a number of ornamental plants that can absorb and reduce the concentration of benzene such as Boston and Golden Phothos.

Abstract

The most common facial malformation in all populations and ethnic groups is Cleft lip and palate (CB/L). Various factors cause nonsyndromic cleft lip and palate abnormalities (CB/L NS) such as interactions between environmental and genetic factors, so that CB/L embryopathy is not clear. Deficiency of Zn with certain severity in pregnant women can be a risk factor for CB/L. The purpose of this study was to analyze the relationship of polymorphism of rs7526700, rs2278651, and rs611386 of the gene SLC30A1 mother with a group of deficiency events of Zinc maternal. The type of this research is an observational study through cross sectional approach with the research subjects are mothers and newborns diagnosed with CB/L NS in the Perinatology Department of Dr. Hasan Sadikin Hospital Bandung and other Network Hospitals. The research was conducted in September 2016 to June 2017 with 34 groups samples. Data were analyzed using fisher’s exact test and correlation test. The results showed that the majority of mothers who became the research respondents aged 25-29 years were 34% and the majority of infants who became the respondents were female as much as 60%, and most types of lip and palate disorders experienced by infants who became the respondents was Unilateral CB/L which is as much as 66%. Furthermore, the results of statistical tests indicated that there was no significant relationship between polymorphism of rs7526700, rs2278651, and rs611386SLC30A1 maternal gene with levels of Zinc maternal.

Keywords: Polymorphism, rs7526700, rs2278651, rs611386, SLC30A1, Zinc, Mother

Introduction

Most common facial malformations in all populations and ethnic groups are the cleft lip and palate (CB/L) reported from all anomalies in the head and neck around 65%. CB/L prevalence is quite high in Asian populations and American-Indian, of which there is around 1 in every 500 births. In Indonesia, the number of CB/L incidence is not yet known certainly. According to Kembaren L (2012), people with cleft lip disorders in Indonesia have increased by an average of 7,500 people per year.1,2

Failed unification of central facial skeleton part in the fourth to the tenth week of pregnancy is the cause of cleft lip and palate since the embryo experiences development and growth of facial skeleton at the end of the fourth week and the end of the eighth week of pregnancy. The process of fusion of the palate ends at the end of the tenth week of pregnancy.3,4

Various factors cause nonsyndromic cleft lip and palate abnormalities (CB/L NS) such as interactions between environmental and genetic factors so that CB/L of the embryopathy is not clear.4 Both have complex

genetic traits, environmental factors have a role in the pathogenesis of CB/L NS and genetic factors are still difficult to understand. Some genes become candidate genes related to CB/L NS events such as transforming growth factor beta 3 (TGFβ3) gene, orofacial cleft (OFC1) gene, the transforming growth factor alpha (TGFα) gene, the methylene tetrahydrofolate reductase (MTHFR) gene, drosophilamsh homebox homolog-1 (MSX1) gene, alpha retinoic acid receptor (RARα) gene, orofacial cleft 2 (OFC2) gene, and orofacial cleft 3 (OFC3) gene. 

Micronutrient Deficiencies are found in developing countries, especially in Indonesia, especially deficiency of Zinc (Zn) and folic acid. Women in modern times like today consume a lot of food but experience less nutrient. The cause of micronutrient deficiency is due to the lack of food intake and consumption of Zn and iron which usually present together in food sources. Oysters, beef, turkey, chicken, cereals, and processed nuts are examples of foods containing Zn and iron.

Zinc is a micronutrient belongs to the category of essential minerals, in which about 3 - 10% of genes encode proteins in humans having a domain of binding Zinc. Zinc ions cannot pass through the cell membranes, thus the Zinc transportation requires a Zinc Transporter. The biological functions of Zn in cells are divided into 3 categories, those are catalytic, structural and regulatory systems. The catalytic system of more than 300 human body enzymes requires Zn to function properly. In structural system, Zn plays an important role in protein synthesis, both at the cellular and molecular stages. In the molecular level, Zn acts as a catalyst for DNA replication enzymes, gene transcription, RNA synthesis and protein. In cellular level, Zn is important to maintain cell survival, affecting the signal transduction, transcription and replication. The regulatory system of Zn’s role is very broad, among others, as a counterweight to the levels of a number of hormones, bone metabolism, neuropsychiatry, immune system, taste and olfactory sensation systems. 

Zn deficiency with certain severity in pregnant women can be a risk factor for CB/ L. Research in mice shows the role of Zinc transporters (ZnT) in fetal development. Zn transporters are classified as family solute-linked carriers 30A (SLC30A / ZnTs) and SLC39A (ZiPs). The SLC30A1 gene is one of the genes in which ZnT is known to be actively expressed in developing mouse embryos and this expression depends on the mothers’ intake of Zinc. SLC30A1 and SLC30A5 proteins have an essential function in the process of transporting zinc from mother to fetus.

The purpose of this study was to analyze the relationship of polymorphism of rs7526700, rs2278651, and rs611386 of SLC30A1 maternal gene with the incidence of Zinc maternal deficiency.

Research Method

This research was an observational study with a cross sectional approach in which the research subjects are mothers and newborns diagnosed with CB/L NS in the Perinatology Department of Dr. Hasan Sadikin Hospital Bandung and the Network Hospital, among others: RSUD of Bandung City of Ujung Berung, Cibabat City Hospital of Cimahi, Special Hospital for Women and Children in Bandung City, and those who came to the Foundation for Lip and Palate Disease Foundation (YPPCBL) Bandung conducted in September 2016 to June 2017. The research subjects were selected based on inclusion criteria including new mothers who gave birth to babies diagnosed with CB/L NS, newborns diagnosed with CB/L NS, mothers and babies diagnosed with CB/L NS from the Deutero Melayu tribe, as well as mothers and babies diagnosed with CB/L NS who were in good health and good general condition, selected through consecutively Sampling. The sample size in this study was 34 people per group.

The variables in this study were level of zinc maternal and infant suffered from CB/L NS as the dependent variable and polymorphism of rs7526700, rs2278651, and rs611386 of the SLC30A1 gene for mothers as the independent variables. Clinical examination was carried out to determine the diagnosis of cleft lip and palate (CB/L NS) and maternal blood taking from CB/L NS infants and CB/L NS infants whose Zn plasma level was examined and continued by genetic analysis (DNA isolation, PCR and RFLP and Sanger Sequencing). Data were analyzed through statistical test which was fisher’s exact test. If the result did not meet the requirements but normally distributed, Pearson correlation test was performed. Meanwhile, if the data were not normally distributed, the Spearman correlation test rank was used.

Table 1 shows that the majority of mothers who became respondents and aged 25-29 years old were 34% and the majority of infants who became the respondents were female, which was 60%.

Figure 1 Distribution of Respondents by type of cleft lip and palate

Figure 1 shows that most types of lip and palate disruption experienced by infants who were respondents were Unilateral CB/L which is as much as 66% of the respondents.

2. PCR and Sequencing of rs7526700 polymorphisms

PCR products produced polymorphisms of rs7526700 for SLC30A1 gene by 352 bp. A single band of 352 bp indicated that the PCR technique has been optimized. The PCR results were then sequenced to analyze the polymorphism of rs7526700. Taq1 was primarily used in this study. From 70 samples, it was found in the mother and baby.

3. PCR - RFLPs / MboI Digestion polymorphism rs2278651 Digestion

Process along with enzymes MboI carried out for 4 hours at 37°C produces a PCR product of 566 base pairs, rs2278651 truncated produces a PCR product of 566 base pairs, rs2278651 truncated homozygou homozygot produces base pieces 345 base pairs and 277 base pairs, while those that do not produces base pieces 345 base pairs and 277 base pairs, while those that do not the result was 566 base pairs. RFLP results were then confirmed by using the sequencing method.

4. PCR - RFLPs / MboI Digestion polymorphism rs611386

The digestion process along with the enzyme MboI which was carried out for 4 hours at 37°C produced a PCR product of 679 base pairs. rs611386 truncated homozygou produces base pieces of 572 base pairs and 121 base pairs, while uncollected results are 679 base pairs. Only normal (variants wild type) and heterozygous were found in this fragment.

5. Relationship of polymorphism rs7526700, rs2278651, and rs611386 gene SCL30A1 mother with group events deficiency Zinc mother

Relationships polymorphism rs7526700, rs2278651, and rs611386 gene SCL30A1 mother with group events deficiency Zinc mother can be seen in Table 2.

*Fisher’s Exact

Table 2 shows statistical analysis results of the rs7526700 gene polymorphism in mothers which is not significantly related to Zinc maternal level (p = 1.00 or p > 0.05), which means that there was no differences in levels found Zinc maternal between the polymorphism and non-polymorphism of rs7526700. In addition, gene polymorphisms of rs2278651 also did not have any significant relationship with Zinc maternal level (p = 0.69 or p > 0.05) or there were no differences in Zinc maternal level between the polymorphisms and non-polymorphisms of rs2278651.

Discussion

Based on the respondents’ characteristic with lower zinc level in infants compared to mothers in this study, the results of experimental studies and human epidemiological case reports indicate that severe Zn deficiency can cause fetal malformations including cleft lip and palate. In this study, the clinical manifestations of CB/L NS are mostly unilateral CB/L. This is consistent with previous research, in which the incidence of cleft lip and palate is the largest, amounting to 45%, ceiling slit was 30%, and lip slit was only 25%. However, the results of this study is different from bilateral CB/L which has more severe clinical manifestations compared to unilateral CB/L and appear less frequently. Cases of CB/L and CL are considered to be two different effects and each has a different genetic etiology.

The results showed that polymorphism can disturb the balance of transporting Zn from mother to baby. Polymorphism in the mother directly influences the levels of Zn in the mother’s body or in the baby’s body. This assumption raises the hypothesis that gene polymorphism of SLC30A1 in mothers can affect the levels of Zn in mothers and infants, but the results of research and statistical analysis showed that the three polymorphisms of SLC30A1 genes in mothers do not affect levels of Zn in mothers. This happens because polymorphism in the mother influences levels of Zn from the beginning of embryogenesis to the second trimester, thereby increasing the occurrence of CB/L during fusion between the maxillary process and the medial process. This will not be observed in this study because the measured level is the level of Zn in the serum of babies who have been born (~ 9 months).

The results of genetic studies in humans showed a significant relationship between the gene expression profile for Zn Transporter in chronic diseases (diabetes, asthma) and carcinogenesis. Since craniofacial malformations arises from tissue misregulation which is usually coordinated during early embryogenesis. Another interesting aspect is the aspect of Zn Transporter’s function with the possible involvement of this protein in
Genetic and environmental factors, including maternal nutritional status, are known to take part in the process of orofacial gaps including CB, CB/L and CL. Some previous studies have shown that nutritional deficiencies, such as folic acid, cholesterol, multivitamins and micronutrients such as Zinc in mothers, can increase the risk of developing orofacial gaps in infants. In contrast, fortification of food by adding folic acid to pregnant women has been shown in several studies to reduce the risk of developing orofacial gaps in infants.

**Conclusion**

Most of the mothers who were respondents were aged 25-29 years and most of the babies who were respondents were female. Most types of cleft lip and palate disorders experienced by infants who were respondents were Unilateral CB/L, and there was no correlation between polymorphism of rs7526700, rs2278651, and rs611386SLC30A1 mother gene with Zinc maternal levels.

Conventional Detection of Resistance of *Aedes aegypti* Larvae as DHF Vector in Kediri District Against Temephos

**Demes Nurmayanti¹, Marlik¹, Nurhaidah¹**

¹Health Polytechnic of Surabaya, Indonesia

**Abstract**

Dengue Haemorrhagic Fever (DHF) becomes health problem in the world. The most number of DHF sufferers in Kediri District in 2016 were in Pare Subdistrict, Ngasem Subdistrict, and Kunjang. However, controlling technique of DHF vector is such as fogging by using active substance of melathion for adult stadium of mosquito and larvasidation by using active substance of temephos for larvae stadium of mosquito. Moreover, resistance of vector against insecticide is global phenomenon, particularly for program management of infectious disease controlling vector and as a singular barrier in the success of vector control chemically. The vector resistance detection can be conducted by using Detection Conventionally through WHO standard method of Susceptibility test in impregnated paper. This research aimed at analyzing detection conventionally the resistance of *Aedes aegypti* as DHF vector in Kediri District against Malathion and Themepos. This research was True Experiment research and temephos was scattered to the larvae with concentration of 0.01 mg/l, 0.02 mg/l, 0.03 mg/l, and 0.04 mg/l in contact time of 15, 30, 45, and 60 minutes. Data analysis included determination of resistance status by referring to category standard from WHO and analyzing the difference of biota test mortality by using statistical different test of Anova. The result of this research was *Aedes aegypti* larvae in Kediri District was resistant against temephos with concentration in 0.01 mg/l, 0.02 mg/l, 0.03 mg/l, 0.04 mg/l and there was a significant influence of contact time against the death of *Aedes aegypti* larvae. Furthermore, suggestion for Health Office in Kediri District was the use of temephos as larvacide was needed in concentration of more than 0.04ml/l. Besides, it was also needed resistance test of *Aedes aegypti* larvae with concentration of temephos in more than 0.04 mg/l.

**Keywords:** resistance, *Aedes aegypti*, temephos

**Introduction**

DHF is infectious disease that is caused by dengue virus from *Falvivirus* genus. Until nowadays, DHF still becomes main health problem in the world. Geographical distribution of DHF case is found to be scattered in either tropical area or subtropical area. Based on¹, since 1968 until 2009, World Health Organisation (WHO) noted that Indonesia was the highest country with DHF case in Southeast Asia. DHF case in Surabaya in 1968 was 58 people who were infected and the 24 people died. Afterwards, DHF disease scattered to all areas in Indonesia and attacked all people, particularly children, as well as for DHF case in Kediri District.

In 2016, Kediri District had been occurred DHF case with 993 people (IR = 64.19/ 100,000 population) with total of mortality in 18 people (CFR = 1.8%). If it was compared with the case total in 2015, it had been occurred a tremendous increase in which total of DHF case was 702 people with total of mortality in 7 people. Meanwhile, the case total in 2014 was 221 people, but there was no mortality case. Case total in 2013 was 832 people with total of mortality in 11 people and in 2012 was 492 people with total of mortality in 7 people. Among 38 Districts/Cities in East Java, Kediri District was one of the districts that was categorized as Outbreak area of DHF because in 2015, it was occurred more rather than in 2014. The most number of distribution of DHF sufferers’s domicile in Kediri District in 2016 was in Pare Subdistrict with sufferer total in 107 sufferers. Then, it was in Ngasem Subdistrict with 90 sufferers.
and it was followed by Kunjang Subdistrict with 74 sufferers.\(^{(2)}\)

Efforts that had been done in preventing and controlling DHF in Kediri District in 2015 were such as: socializing how to prevent and control DHF; monitoring and training the group of control worker (Pokjanal) in eradication of Mosquito Nest (PSN-DBD) at Subdistrict level, countryside level, and school; training for the mosquito larva monitor for conducting periodic check; fogging focus if it was known that there was transmission of DHF case around sufferer’s house, PSN 3M plus, fishization and larvasidation.\(^{(2)}\)

Technique to control DHF vector was such as: fogging by using active substance of malathion for adult stadium of mosquito and larvasidation by using active substance of temephos for larva stadium of mosquito. Both of the active substances were organophosphate insecticide. Furthermore, this insecticide was used in Indonesia since 1970, but until nowadays, DHF case was still more reported. The condition made question whether it had been occurred the resistance of \textit{Aedes aegypti} as DHF vector against Malathion and Temephos or not, particularly in Kediri District which was an endemic area of DHF.

Temephos is one of larvasidations from organophosphate class that is more used by Health Office or non-governmental organization for controlling population of \textit{Aedes aegypti} larvae. The use of temephos was began since the government proclaimed abatitation in 1980 for determining DHF transmission chain by distributing abate powder to the society. This program was conducted continuously throughout the year without any larvicidal rotation by proposing to avoid the epidemic. Resistance of insect against an insecticide would be occurred if it was used intensively for 2 until 20 years and continuously throughout the year.\(^{(3)}\)

The resistance of temephos and malathion in 0.8\% had been occurred to \textit{Aedes aegypti} in West Jakarta, East Jakarta, and South Jakarta.\(^{(4)}\) \textit{Aedes aegypti} larvae was resistant against temephos in 0.02 mg/l at Plosokerep Village, Sumobito Subdistrict, Jombang District, East Java-Indonesia.\(^{(5)}\)

Concerning with the use of temephos had been used in Kediri City for more than 20 years as an effort of preventative and chain breake of DHF transmission when it was occurred the outbreak or infectious disease epidemic of dengue. Hence, it was needed to be conducted a determination of the susceptibility status of \textit{Aedes aegypti} larvae against temephos at three Subdistricts of endemic DHF.

This research aimed at detecting conventionally the resistance of \textit{Aedes aegypti} larvae as DHF vector in Kediri District against temephos.

**Methods**

This research was true experiment research and the sample was 3\textsuperscript{rd} descent (F3) of \textit{Aedes aegypti} larvae stadium that was bred in laboratory of Department of Environmental Health, Health Polytechnic of Surabaya, from parental that came from trapped egg in ovitrap in DHF endemic area in Pare, Ngasem, Kandat, and Kunjang, Kediri District, East Java Province, Indonesia. Temephos was scattered to larvae with concentration in 0.01 mg/l, 0.02 mg/l, 0.03 mg/l, 0.04 mg/l with contact time in 15, 30, 45, and 60 minutes. Data analysis included determination of resistance status in Kediri District by referring to category standard from WHO and analyzing the difference of biota test mortality by using statistical different test of Anova.

**Findings**

Result of Conventional Resistance test which scattering 20 \textit{Aedes aegypti} larvae that came from Kediri District for 60 minutes by using temephos with either concentration in 0.01; 0.02; 0.03; or 0.04 mg/l, for control group, it used etanol 1 cc. Every 15 minutes, it was conducted an observation. Result that was obtained in either first 15 minutes, second 15 minutes, third 15 minutes, or fourth 15 minutes was there was no dead \textit{Aedes aegypti} larva, except for concentration in 0.03 mg/l, the percentage average of \textit{Aedes aegypti} larva death was in 0.83%. However, \textit{Aedes aegypti} larva was dead that was caused by residual temephos with concentration in 0.01; 0.02; 0.03; and 0.04 mg/l and also etanol 1 cc for 24 hours (1440 minutes) was in 1.25%; 0.42%; 1.25%; 0.42% ; and 2.08%.

\textit{Aedes aegypti} larva in Kediri District was resistant against temephos with concentration in 0.01 mg/l, 0.02 mg/l, 0.03 mg/l, and 0.04 mg/l (Table 1).

### Discussion

*Aedes aegypti* larva from Kediri District that was scattered by using temephos with concentration in 0.01; 0.02; 0.03; and 0.04 mg/l until 60th minutes, there was no dead *Aedes aegypti* larvae. In certain concentration, *Aedes aegypti* larvae died because as the effect of residue from temephos with concentration 0.03 mg/l. As we know that temephos is the substance of organophosphate insecticide which is effective to be used in water and to be able to kill mosquito larvae. This substance is substance from *abate* that is often used by the society. How to use this temephos insecticide is by hindering enzyme in the insect nervous system, thus, it is not able to have normal function. Larvae of *Aedes aegypti* mosquito in Kediri District which was almost all in varied concentration did not undergo death and this was caused by the concentration that was used was perhaps too small. Similar research was conducted by Merty, et al.\(^6\) in Proceedings of Medical Education who researched resistance of Malathion in 0.8% and Temephos in 1% to adult *Aedes aegypti* mosquito and larvae in Bandung City. Observation was conducted during these two weeks for *Aedes aegypti* larvae that was still sensitive with insecticide of temephos 1% with percentage average of death in 100%. However, the difference with recent conducted research was the concentration that was used in this research was in mg/l, meanwhile, in conducted research by Merty et al.\(^6\) used percent. Concentration and similar units which were conducted by Ridha, et al.\(^7\) who researched by using insecticide of temephos 0.02 mg/l to *Aedes aegypti* larvae in Generation F1 in Banjarbaru City, that the average percentage of death for larvae in the area was in 95%.

Insecticide that was used by society commonly was *abate*, which another name of *abate* was temephos. Dosage of *abate* use in society was 10 gram/100 liter, thus, dosage of *abate* that was used by society was 10%. In this research, the substance of *abate* that was used was temephos with concentration in 0.02 mg/l. Result of the research was all larva of *Aedes aegypti* mosquito in Kediri District was resistant in concentration 0.01; 0.02; 0.03; and 0.04 mg/l. This was caused by toxicity that was given to larva was too small.

Similar research was conducted by Handayanji\(^8\) who used temephos with concentration in mg/l. Her research by using concentration 0.625; 0.31; 0.15; 0.078; and 0.039 mg/l concluded that larvae in perimetry area was in tolerant category with mortality rate in 96%, meanwhile, in buffer area was in resistant category with mortality rate in 68%. Another conducted research by Sinaga, et al.\(^9\) used concentration 0.0025 mg/l; 0.005 mg/l; 0.02 mg/l; 0.01 mg/l; 0.02 mg/l; 0.04 mg/l; and 0.08 mg/l. Mortality percentage of *Aedes aegypti* larvae reached 100% in concentration 0.08 mg/l.

All in all, the use of *abate* continuously will make larvae to be able to adapt with the environment around, hence, it causes larvae will be resistant with chemical substance. This condition is proved from several areas where have endemic for DHF and always use *abate* as one of mosquito controls. Giving *abate* with concentration...
0.02 mg/l that is conducted continuosly causes larvae is resistant, thus, it needs higher concentration. Controlling by using abate must be noticed more. Furthermore, abate cannot be given continuosly. It can be conducted periodiically in order to avoid resistant mosquito larvae against chemical substance. However, the main mosquito control is through controlling mosquito population in the environment. One of the most effective ways in controlling the mosquito is through draining, closing, and burying, which in Indonesian.

Analysis result showed that there was a significant influence between contact time and larva death, but concentration of temephos and interaction of contact time with temephos did not have any significant influence against death of Aedes aegypti larvae. It meant that larvae will die with longer contact time. The influence of several dosages of bacillus thuringiensis var israelensis Serotype H14 against Aedes aegypti larvae in West Kalimantan was a conducted research by Perwitasari. In her research, she stated that the use of insecticide in Bacillus thuringiensis type with dosage based on WHO that was 0.02 ml/l could kill Aedes aegypti larva of LT50 with contact time in 5,046 hours, meanwhile, in contact time of 24.68 hours, larva population was dead (95%). Furthermore, temephos is insecticide in organophosphate which is insecticide category from organic substance that is added by phosphate substance. Phosphate is non-toxic acid type. Characteristic of this acid will impede growth process from mosquito larvae. The larvae can be alive in pH 5.8-8.8. If pH of the water under 5.8, larva will die. However, controlling larvae through insecticide must be kept and controlled well. Safe use for killing larvae is by using insecticide concentration from organophosphate, which is in small concentration in quite long exposure time. Giving insecticide is not allowed continuosly, but it can be given periodically and insecticide substance, is always evaluated.

Conclusion

Aedes aegypti Larvae in Kediri District was resistant against temephos with concentration in 0.01 mg/l, 0.02 mg/l, 0.03 mg/l, 0.04 mg/l and there was a significant influence between contact time and larva death.

The use of temephos as larvacide was needed with concentration in more than 0.04 mg/l. Giving abate was needed to be done periodically and also evaluated every time. Moreover, it needed resistance test for larvae by using other insecticide substance besides from organophosphate type. In addition, it needed to be conducted monitoring of vector resistance periodically in different area.

Abstract

Indonesia is known as an agrarian country, should rely on the agricultural sector as an economic source as well as supporting development. In addition to the economic aspects, the progress of agriculture is also very important for the provision of nutrients for the maintenance and improvement of public health. This study uses the Location Quotient method to obtain a base subsector in the agricultural sector, so that the results can be used as material for consideration of export specialties. This study uses East Java GRDP data and as a comparison using Indonesia’s GRDP in 2010-2016. The results in this study indicate that the food crop and livestock sub-sector has an advantage compared to other sub-sectors and becomes a subsector of the base, so that these two sub-sectors can be used as export products for East Java.

Keywords: Location Quotient, Agriculture, East Java

Introduction

Background: The economic growth of a region can be seen from the increase in Gross Regional Domestic Products (GRDP).¹ Sector in GRDP is agriculture, mining and excavation, processing industry, electricity, gas and water sector, building sector, trade, hotel and restaurant sector, transportation and communication sector, financial sector, leasing and business services, and services sector.² A region is said to be agrarian if the role of the agricultural sector is very dominant in its GDP, and vice versa is said to be an industrial area if the dominant sector is the industry.

The existence of agricultural potential in an area does not have meaning for the agricultural growth of the region if there is no effort to utilize and develop the potential of agriculture optimally. Therefore, the utilization and development of all potential agricultural potentials must be a top priority to be explored and developed in implementing regional agricultural development as a whole.³

Address: Pucang Jajar Tengah-56, Surabaya-Indonesia

Indonesia is known as an agrarian country, should rely on the agricultural sector as an economic source as well as supporting development. In addition to the economic aspects, the progress of agriculture is also very important for the provision of nutrients for the maintenance and improvement of public health. The role of the agricultural sector in economic development is very important, because most members of Indonesian society depend their lives on the sector. If the planners really pay attention to the welfare of their people, then the only way is to improve the welfare of most members of their community who live in the agricultural sector.⁴ The agricultural sector is still a part of potential development resources to be used as a strategic sector of current and future development planning, both at the national and regional levels.⁵

The percentage of East Java’s agricultural sector to East Java GRDP during 2010-2017 averaged 14% with an increase every year. The Agriculture, Animal Husbandry, Hunting and Agricultural Services sub-sector has the largest contribution compared to the lack and logging and fisheries. Food crops have the largest contribution to the subsector of Agriculture, Livestock, Hunting and Agricultural Services and always increase every year.⁶ The potential of East Java province with
agricultural and non-agricultural land resources reached 4,598,266 Ha at the end of 2016, with donations of 1,176,650 hectares of rice fields, 2,477,669 hectares of non-rice fields, and 943,946 hectares of non-agricultural land.\(^{(7)}\)

The Agricultural sector has a forward and backward relationship that is relatively strong with the manufacturing industry sector; construction; trade, hotel and restaurant; transportation and communication; and services. This relatively strong forward link means that output from the agricultural sector is widely used as input by these sectors, the relatively strong backward link means that these sectors need a lot of raw materials from the agricultural sector.\(^{(2)}\)

Economic growth is an important part that is inseparable from achieving economic development. Therefore, an analysis of the region that is the mainstay of the leading sector is needed to encourage economic growth in the East Java province. So that economic development planning can be realized in a structured manner based on its sectoral potential. If viewed from the regional GRDP sector value, the agricultural sector has a large role in increasing East Java GRDP. Nevertheless, it cannot be ascertained that the agricultural sector is the basis of the East Java Province, because comparisons with the wider area are needed. In this case, East Java Province is a comparison of the value of the East Java Regency GRDP sector. Calculation of Location Quotient (LQ) value is needed to find out the base and non-base sectors owned by East Java Province. LQ calculation can be used to find a Leading sector so that with industrial development it will spur and lift the development of other sectors, such as the agricultural sector. Rapid industrial growth will stimulate the growth of the agricultural sector to provide raw materials for industry.\(^{(8)}\)

**Purpose**

Identification of the agricultural subsector which is the base sub-sector of East Java Province as the A Reference for Law and Policy on Economics, Nutrition and Public Health.

**Method**

**Location Quotient (LQ)**

LQ techniques are widely used to discuss economic conditions, leading to the identification of specialization of economic activities or measuring the relative concentration of economic activities to get a picture in determining the leading sectors as a leading sector of an industrial economic activity.

Commodities that produce LQ> 1 are normative standards to be determined as superior commodities. However, when there are many commodities in an area that produce LQ> 1, while only one is sought, then the one that must be selected is the commodity that gets the highest LQ. Because the higher the value of LQ in an area shows the higher the potential for superiority of the commodity. Thus, the LQ analysis method or location quotient can be used easily and efficiently if you want to calculate a leading sector somewhere. Deficiencies encountered in the field can be reduced carefully and diligently in collecting data. The results obtained later are accuracy and leading sectors that can be empowered and developed by all communities in a particular region.

Based on GRDP data, sectoral contributions and economic growth rates in East Java and Indonesia, calculations can be made using the Location Quotient (LQ) method to find the comparative advantage possessed by East Java Province towards Indonesia by identifying the base and non-base sectors. The data used is data on the basis of constant prices.

With the aim to see economic developments in real terms whose growth is not affected by changes in prices or inflation / deflation. Sectors included in the base sector indicate that the sector has a comparative advantage. With the increase in the number of base activities in a region, the income inflows will increase due to export activities. On the other hand, non-base activities cause the outflow of income from the region to the monetary outflow caused by the region importing shortages in demand in the sector to meet needs within the region.

Base and Non-Base Sectors According to Arsyad\(^{(8)}\) economic base theory states that the main determinant of economic growth in a region is directly related to the demand for goods and services from outside the region. Economic base theory essentially differentiates base sector activities and non-base sector activities. Base sector activity is the growth of the sector that determines the overall development of the area, while the activities of the non-base sector constitute the city polowing sector, which means that it depends on developments that occur from comprehensive development.
Economic base theory seeks to find and recognize the activity of the basis of a region, then predict that activity and analyze the additional impact of the export activity. The key concept of economic base theory is that export activities are the engine of growth. Whether or not a region grows is determined by how the region’s performance is against demand for goods and services from outside.

Furthermore, in economic base theory analysis, the theory can be used to determine potential sectors and sub-sectors in East Java Province based on Gross Regional Domestic Product (GRDP). If the potential sector can be developed properly it certainly has a significant influence on the economic growth of a region, which in turn can increase regional income optimally. According to this theory an area can be differentiated into a mainstay area and not a mainstay, which is subsequently modified into a potential economic sector / subsector and not a potential economic sector / sub-sector.

### Discussion

Table 1 is the data on GRDP of the Agriculture, Forestry and Fisheries sector of East Java Province and Indonesia’s GRDP in billion Rupiah as comparative material for the analysis of the agricultural sector location quotient. In the agricultural sector including the subsector of agriculture, livestock, hunting and agricultural services (food crops, agricultural crops, plantation crops, livestock and agricultural and plantation services), forestry and logging and fisheries. Based on GRDP, the eastern subsector of agriculture, animal husbandry, hunting and agricultural services has a greater contribution to East Java’s GRDP compared to the forestry subsector and logging and fisheries.

The following are the results of East Java Agricultural sector LQ Calculation for the 2010-2017 period.

Table 2. LQ Processing Results

LQ >1 and consistent from 2010-2017, it is the food crop subsector and livestock, with the highest LQ value being the livestock subsector. The two sectors can be interpreted as the provisional sector base of East Java while the non-base sector is the subsector of Horticulture Plants, Plantation Plants and Agricultural Services and Hunting.

In the Food Crop sub-sector, the following information about the results of the calculation of Food Crop LQ value in East Java Province in 2010-2017: In 2010 the Food Crop sector has a LQ value of 1.26 >1 with a GRDP amounting to 46010.30 (Billion Rupiah) for one year. In 2011 the food crop sector had an LQ value of 1.28 >1 with a GDP value of 46435.30 (Billion Rupiah) for one year. In 2011, the value of LQ did not experience a significant change from 2010 to 2011 with an increase in the value of GDP that was also not too high. There is no significant change to the LQ value because this occurs when the economic growth rate in the Indonesian sector is greater than that of the East Java Province.

In 2012 the food crop sector had a LQ value of 1.24 >1, the LQ value in 2012 decreased compared to the LQ value in 2011 with a GDP value of 47585.50 in billion rupiah. In 2013 the food crop sector value of LQ dropped back to become the number 1.23 >1, with a GRDP value of 48241.20. In 2014 the LQ value rose again to 1.26 >1 with a GDP value of 49679.10. However, in 2015-2017 the value of LQ has decreased continuously, namely 1.23 1.22 and 1.16 with a GDP value of 51233.80 in 2015, 52136.80 in 2016 and 51001.70 in 2017 in billion rupiah.

In the subsector of livestock, the value of LQ has continued to decline from 2010 to 2017. In 2010 the value of livestock subsector LQ was 1.73 with a GRDP value of 26996.40 in the rupiah bill. In 2011 the LQ value decreased by 1.71 with a GRDP value of 28126.70 in billion rupiah. And in 2012-2017 livestock subsector LQ values were 1.67 1.60 1.52 1.49 1.47 1.47 with a GDP value of 29055.80 in 2012, 29365.60 in 2013 29704.60 in 2014, 30302.80 in 2015, 31357.80 in 2016 and 32579.10 in 2017 in billion rupiah.

East Java Province has great potential in the food and livestock sector, including Malang and its surroundings. The food crop sector is the sector that has the largest increase in output as a result of changes in the demand for the end of East Java Province. Capital support is considered very much needed in both sectors. The
shift in the structure of the economy from agriculture to the industrial sector is feared to have an impact on the state of economic stability, where the agricultural sector also contributes to the food sector. Food security and increased regional income can be achieved through maximization and optimization in the agricultural sector. Land use and use of machinery are expected to increase agricultural productivity in East Java, so that sustainable development in the agricultural sector can work.\(^{(10)}\)

The contribution of the food and livestock sector in East Java to GDP is the second largest after trade. Malang Regency is the largest producer of beef cattle in Indonesia.\(^{(11)}\) Livestock subsector has a very important role in supporting the achievement of national food security. This is because livestock is a provider of animal food from livestock through increased production of various commodities, as well as providers of raw materials for industry. In addition, livestock indirectly plays a role in alleviating poverty, because livestock is a process that uses production factors from the community so as to provide remuneration to the community that will affect their income, as well as an alternative energy source for environmental sustainability life (Zulkifli et al., 2015).

**Conclusion**

Based on the analysis of the agricultural sector location quotient in East Java, the food crop and livestock sector can be regarded as a base sector, both sectors have LQ >1. So that both sectors can be used as leading sectors to specialize in exports. Livestock has a greater LQ value compared to the food crop sector, this is because East Java is more precisely in Malang Regency, the largest producer of beef cattle in Indonesia. Food security and increased regional income can be achieved through maximization and optimization in the agricultural sector. As it is understood that food security in turn is a source for nutritional needs and improving public health.

Association between Soluble ST2 Basal and Global Longitudinal Strain 2D-Speckle on Tracking Echocardiography with Left Ventricle Remodeling after an Acute Myocardial Infarction

Fani Suslina Hasbuan¹, Muhammad Aminudin¹
¹Department of Cardiovascular, Faculty of Medicine, Universitas Airlangga - Dr. Soetomo General Hospital, Surabaya 60131, Indonesia

Abstract

Background: Left ventricle remodeling (LVR) is an important prognosis post acute myocardial infarction (AMI). Soluble ST2 is a novel biomarker for myocardial fibrosis and left ventricular remodeling. Global Longitudinal Strain (GLS) which is a reflection of the longitudinal layer of cardiac muscle can be detected in the early ischemia phase, and has been proven to predict the occurrence of left ventricular remodeling post AMI. Objective: To identify the association between soluble ST2 basal and GLS with LVR post AMI. Method: This research was conducted from August to December 2015. This is an analytic observational study with one group pretest and post test design. Soluble ST2 and GLS examinations were performed twice (2-5 days after AMI and 12 weeks after therapy). The results were analyzed using Spearman’s correlation test. Result: The sample size was 45 respondents (82.2% males, average age of 55.47 ± 10.13 years, 84.4% STEMI). There was a strong correlation between high ST2 basal levels with LVR (p = 0.0001 r = +0.723) and ΔST2 with LVR (p = 0.0001 r = 0.639). The association of low GLS with LVR was p = 0.015 and r = + 0.362. Conclusion: A significant LVR was found post-AMI, the high soluble ST2 basal and low GLS basal may be a factor for predicting LVR.

Keywords: Left Ventricle Remodeling, Soluble ST2 basal, GLS, Acute myocardial infarction

Introduction

Heart disease is the main death leading cause worldwide. In the United States, acute coronary syndromes occur every 34 seconds resulting death in every minute¹. Indonesia’s Health Profile 2009 released by the Health Ministry of the Republic Indonesia reported that in 2008, vascular system disease took the highest place (11.06%) of all death causes in hospitals².

Acute myocardial infarction (AMI) causes myocardial regional damage leading to systolic dysfunction, after an infarction then left ventricular remodeling (LVR) occurs. LVR is associated with high cardiovascular cases including heart failure. The characteristics are progressive left ventricular dilatation (LVESV) >15% or >20% (LVEDV). Several epidemiological studies and clinical studies suggested that heart failure was a 30-40% complication of AMI. The incidence of left ventricular systolic dysfunction (LVSD) after myocardial infarction was still poorly documented, but LVSD appeared in 25-60% of AMI, and 50% of patients with LVSD would have heart failure³,⁴.

Echocardiography is an affordable screening tool and can be used to study the regional and global functions of the left ventricle on AMI. Left ventricular ejection fraction (LVEF) measured by Simpson biplane method at the time of hospitalization is a well-known marker for left ventricular global function and predicting short-term or long-term morbidity and mortality of AMI patients. 2D Speckle Tracking Echocardiography (2D-STE) is a new non-invasive method of ultrasonic imaging capable...
of quantitatively and objectively assessing the global and regional function of myocardium in both systolic and diastolic function. This modality is considered more sensitive and accurate in predicting or detecting the presence of coronary heart disease. The change of regional function occurs earlier than the global damage, and can be detected by 2D STE. Examination with 2D STE is done by the per segmental strain and strain rate.

Longitudinal strains disturbed earlier at the time of ischemia. Studies in AMI patients found that longitudinal strains were associated with peak level cTt and extensive infarction. Longitudinal strains measurement after reperfusion is a very good predictor of LV remodeling, heart failure and mortality. Another study showed a Global Longitudinal Strain (GLS) examination before reperfusion could also predict LV remodeling and complications in STEMI patients.

Biomarkers become an important thing in improving the accuracy of diagnosis and providing disease information therefore it can determine the appropriate treatment options. The soluble ST2 (Interleukin 1 like receptor) is part of IL-1 receptor (IL-1R) consisting of ST2 transmembrane (ST2L) and dissolved (sST2). The soluble ST2 has no transmembrane or intracellular domains and is thought to have a function as a bait receptor neutralizing IL-33, known as the ligand of ST2 transmembrane. IL-33 has a function of inhibiting hypertrophy effect on cardiomyocytes and otherwise on the soluble ST2 giving excessive intracardiac pressure on marmots. The data showed that cardiac protection role was from IL-33/ST2 signal pathway.

SST2 biomarkers for myocardial fibrosis had been included in the ACC/AHA guideline for monitoring heart failure patients. Increased soluble ST2 in AMI patients suggested that a good myocardium acquired additional hemodynamic pressure as compensation for the necrotic area. An increase of baseline sST2 >35 μg/L was an independent predictor of mortality, sudden death and heart failure within 30 days and demonstrated sST2 biomarker’s role in providing prognostic information of acute coronary syndromes patients. SST2 role studies in ST Elevation Myocardial Infarction (STEMI) patients showed an increase of initial SST2 level indicating mortality risk and heart failure in patients treated with both fibrinolysis and percutaneous coronary intervention (PCI).

Analysis of echocardiographic characteristic difference obtained from not normally data distribution was used by Mann Whitney U Test. There was an increase of LVEDV from $76 \pm 29.69 \text{ ml/m}^2$ to $98.11 \pm 36.84 \text{ ml/m}^2$ of subjects undergoing LVR compared to non LVR ($p = 0.003$), LVESV was increased from $40.89 \pm 23.89 \text{ ml/m}^2$ to $51.96 \pm 26.43 \text{ ml/m}^2$ ($p = 0.006$) The basal value of soluble ST2 was much higher in LVR 34 (12-71) ng/mL ($p = 0.0001$). The basal value of GLS was lower in those with LVR -10.0 (-20-3) compared to non LVR ($p = 0.017$; Table 2).
Based on the type of AMI the most subjects who experienced LVR were patients with NSTEMI (6 people), then inferior STEMI (6 people), anteroseptal STEMI (4 people), broad anterior STEMI, anterior, inferior VR posterior (2 people), and the rest was STEMI inferior and anteroseptal inferior (1 person).

Statistical analysis of not normally distributed data using Spearman correlation showed no correlation between LVEF and LVR \((p = 0.44; r = 0.117; \text{Table 3})\). Statistical analysis using Spearman correlation obtained significant correlation between soluble ST2 and LVR \((p = 0.0001; r = +0.723; \text{Table 4})\). It also obtained significant correlation between \(\Delta\) soluble ST2 in 12 weeks with LVR \((p = 0.001; r = 64\%; \text{Table 5})\). The analysis showed correlation between basal level of GLS with LVR \((p = 0.015; r = +0.362; \text{Table 6})\).

**Discussion**

In this study, the incidence of LVR was 27 people (60%), more than in the previous study, probably it caused by the subjects used were all primary PCI and PCI, and aggressive antiremodelling drugs, whereas in this study most of them received conservative therapy because most of the AMI patients came more than 24 hours, thus passing the onset of doing reperfusion either mechanically or pharmacologically \(^{14}\). In addition, not all patients wanted to do reperfusion for cost reasons. In the study found 29/93 patients who experienced remodeling (31\%) \(^{15}\).

An increase of LVEDV >20% from basal or an increase in LVESV >15% from the basal were the criteria used in LVR such as in the previous study \(^{14,16}\). LVEDV values after 12 weeks were increased, it was higher in LVR compared to non LVR. This was consistent with previous studies either associated with GLS or soluble ST2 \((p = 0.003)\), as well as LVESV after 12 weeks \((p = 0.006)\). This was similar to the previous study, there was an increase in LVEDV and LVESV after 90 days on AMI patients treated with PPCI. Basal level of soluble ST2 and GLS were also significant in LVR \((p = 0.0001\) and \(p = 0.017\) respectively) \(^{14}\). In the study there was an increase in LVEDV after 8 weeks from \(36 \pm 6\) to \(56 \pm 22\) with \(p <0.05\), and LVESV from \(20 \pm 5\) to \(33 \pm 18\) with \(p <0.05\) \(^{17}\).

NSTEMI and inferior STEMI were the most infarct type of LVR in the study, It was similar with this study, most of them were NSTEMI and inferior STEMI patients \(^{14}\). Literature states that infrak areas often experience remodeling if the infarction is widespread or spreading to LAD, but it is also said that diabetes, smoking, and previous infarction also often lead to LVR after AMI \(^{18}\).

This study found a significant correlation between basal level soluble ST2 and LVR \((p = 0.0001; r = +0.723)\). The previous study found an increase in basal soluble ST2 was associated with a change in LVEDV after 24 weeks that was measured by Cardiac Magnetic Resonance (CMR) proving that the increase in basal ST2 soluble was associated LVR. In the study basal soluble ST2 was also associated with lower basal LVEF after AMI. Changes in ST2 after 12 weeks (\(\Delta\)ST2) were also associated with \(\Delta\)LVEDV after 24 weeks \(^{15}\).

Study of ST2 roles in STEMI patients showed an increased of initial ST2 level indicating mortality and heart failure risk in patients treated with both fibrinolysis and PCI \(^{19}\). GLS basal had weak correlation \((p = 0.015 r = +0.362)\). This was similar to previous research that obtained a correlation between GLS and LVR \(^{14}\). Many studies using STE to predict LVR, either with GLS, torque or circumferential \(^{14,16,19}\). STEMI patients treated with PPCI found that the GLS examination at the time before the patient was repatriated was a novel examination to predict the occurrence of LVR. In patients with decreased GLS, LVR was obtained after 3 months and 6 months \(^{20}\). A study obtained a low basal GLS \(-11.05 \pm 4.1\) in LVR compared to non LVR \(-15.2 \pm 3.2\) with \(p <0.001\) \(^{21}\). This study only used GLS because of measurement limitation of echocardiography in Dr. Soetomo General Hospital Surabaya.

Generally, longitudinal LV mechanics, which are influenced largely by subendocard region, are the most vulnerable components of global LV mechanics because they are very sensitive to the presence of myocardial disease. Single longitudinal mechanical assessment is more adequate in early myocardial disease or has not shown significant abnormalities. The subendocardium region is the most remote area of perfusion therefore it is susceptible to hypoperfusion and ischaemia \(^{4,5}\).

**Conclusion**

There was a positive correlation between basal soluble ST2 and LVR after AMI and there was a negative correlation between basal GLS and LVR after AMI.

Gynecomastia Treatment by Liposuction with Gland Excision and H.H. Method

Haider Ali Muslim AL Ramahi
Assistant Professor, College of Medicine –Waist University, Iraq

Abstract

Background: Gynecomastia (GM) is benign enlargement of male breast (glandular enlargement with fat accumulation). We classify in 6 grades depend on size and shape of breast. All cases were treated surgically as combine of gland excision and liposuction and added new method HH (Haider and Husam) method which is specific for grade 5 and 6 GM.

Method: From 2013 to 2018, a chart review was performed for 300 patients. Preoperative examination included endocrine and urological examination and exclusion of other pathological conditions. The surgical technique consisted of liposuction through small incision in lateral side of breast, combine with gland excision by sub areolar incision and sometime HH method depend on grade of gynecomastia.

Results: Total number of patient 300 cases all of them under want combination of liposuction and gland excision with drain keep for about 8 hours. Recurrent rate very rare and complication like infection or areolar necrosis also rare and 9 case only suffering from early postoperative bleeding and 22 cases develop seroma within 2 weeks.

Conclusions: This analysis data that include treatment of GM grade 1-6 is performed by liposuction combined with subcutaneous resection of the glandular tissue by sub areolar incision the procedure had low rate of complications and excellent patients’ satisfaction about the results. Preoperative fellow up is important to rule out and prevent specific complication of procedure and to exclude diseases or malignancy causing the GM as all gland sent to histopathology.

Keywords: Gynecomastia, HH method, liposuction, gland excision, surgery, combine treatment.

Introduction

Gynecomastia (GM) is a common condition but with variable severity that occurs in men at all ages and refers to a benign condition of breast enlargement with benign glandular proliferation of various causes. It can be found at autopsy in 40-55% of all men [1 - 5]. GM most often presents bilaterally, although it can occur asymmetrically. Patients with GM most frequently present suffering from aesthetic or psychological symptoms [6].

Three peaks in the prevalence of palpable GM are described: The first one occurs in infants, caused by high materno-placental estrogen levels, and regresses in the first weeks after birth [7]. The second peak appears during puberty between the ages of 13 and 14 years, with a high rate of regression before the 17th year of life [8 - 10]. This transient form is related to the hormonal changes during puberty, which shows an earlier peak of estrogen before testosterone reaches its peak levels. The third peak occurs in men between 50 and 80 years of age related to diverse conditions [4]. Besides physiological categories, GM can be categorized by the triggers (25%) persistent pubertal GM, 10-25% drug induced, 8% cirrhosis or malnutrition, 10% male hypogonadism, 3% testicular tumors, 1.5% hyperthyroidism, 1% chronic renal insufficiency, 25% idiopathic [11]. GM results from an increased volume of glandular tissue or adipose tissue (pseudogynecomastia) or a mixture of both. All causes share an imbalance of androgens and estrogens with a decreased testosterone-to-estradiol ratio, which directly affects the breast tissue [12]. Altered ratios of androgens and estrogens or increased sensitivity of breast tissue to normal circulating estrogen levels gives rise to ductal...
hyperplasia, elongation and branching of the ducts correlated with proliferation of fibroblasts and neovascularization\textsuperscript{[13 & 14]} which altogether form the clinical appearance of GM.

Figure 1: Male patient with enlargement beast (A). patient after gland excision and liposuction (B)

Gland of breast

Figure 2: Same Male Patient, before bilateral gland excision (A). After bilateral gland excision and a bilateral liposuction were performed (B). Glandular tissue and adipose tissue from breast (appearance of GM) after removal from the patient(C)

All pictures show the same patient before and after in all cases, a bilateral gland excision and a bilateral liposuction were performed.

The classification of GM

- Type 1: puffy look of the nipple coin like.
- Type 2: more extreme amount of glandular tissue and fat. As, fatty feeling in the outer zones.
- Type 3: includes breast sagging.
- Type 4: excess breast tissue sags below the chest fold, and the breasts look like a woman’s breasts.
- Type 5: A more extreme degree of sagging, under armpits, and may extend toward the back.
- Type 6: the nipple appearing at the bottom of a large amount of saggy breast tissue.

Most often used\textsuperscript{[15]}. Its groups patients into categories according to the size of the GM. Group (I) is characterized by minor but visible breast enlargement without skin redundancy. Group IIA features moderate breast enlargement without skin redundancy. Group IIB shows moderate breast enlargement with minor skin redundancy. Group III is characterized by gross breast enlargement with skin redundancy that simulates a pendulous female breast. Patients in groups I and II do not require skin excision during potential surgery, but the breast development associated with group III is so marked that excess skin must be removed Figure (2). Therapy of GM depends on several factors including its duration, grade, etiology, and the presence or absence of clinical symptoms. Treatment options include drug therapy and surgical removal of breast glandular tissue\textsuperscript{[16 & 17]}. After a persistence of 12 months or longer, GM is likely to have reached the fibrotic status, in which conservative treatment is not effective.

The aim of this study was to analyze the surgical strategies in GM grade I-II, their clinical outcome and, based on this data, the development of an algorithm for surgical treatment.
**Patients and Method**

Between 2013 and 2018, we surgically treated 300 patients with GM.

All patients underwent presurgical workup like a physical examination, and investigation and sometime ultrasound to breast. If any abnormalities, we found so send the patient to MRI to breast and some time to abdomen or fine needle aspiration from the testis and other laboratory workup about hormonal assessment of the patient.

**Surgical Technique**

Subcutaneous fatty tissue area of the breast was infiltrated with normal saline 0.9% solution 500 cc with one ampule of adrenaline[18]. Under guide monitoring of anastasis for any arrhythmia of change in cardiac condition[19]. One stab incision in lateral side near anterior axillary line for infiltration then for liposuction the breast by vesper or traditional method, complete clear the area and also below the gland to be dissected easy without use cattery unipolar figure (1).

This procedure for all grade of gynecomastia.

After finishing the liposuction then sub areolar incision to excision the gland very gentle release of the gland with secure homeostasis without need for bipolar and routinely. we put corrugate drain from the side of liposuction cannula for about 6-8 hours.

The size of liposuction cannula it’s about 4 -6 mm.

For grade 4 GH we do small skin excision below the areola look like <> on both side of areola.

For grade 5 and 6 we do my method name HH method (Haider, Husam) by which we do liposuction as usual then supra areolar incision look like inverted - U shape to elevate the areola up to 4 intercostal area; slightly lateral to mid clavicular line and also we put corrugate drain from side of liposuction cannula then the wound closed by 3/0 PDS and drain was keep for about 8 hours to avoid any hamartoma.

In all procedure we advice the patient to wear chest corsea for about 4 to 8 weeks to avoid redundant skin appear and also to avoid any seroma.

**Results**

Clinical data from 300 patients all cases bilateral gynecomastia mean age was 34 years (rang from 14 to 55) and mean body mass index about 25 – 35% all of the patients under want liposuction and gland excision under general anaestasia for about one to one and half hour and discharge to home in the same day on in the next day after drain remove and sure no any collection of haematoma.

Postoperatively no pain only parastesia remain for about 3 to 8 weeks.

9 cases suffering from immediate haematoma after 2-4 hours and immediate evacuation was done.

33 cases were suffered from seroma after 10 days and aspiration was done for one time only with covering antibiotic and compression of chest by coarsa.

Only one case develop areolar necrosis on one side only treated conservatively.

All glands after excision sent to histopathology no any case of malignant report

And no any case of wound infection.

**Discussion**

Surgery is the best way to treatment of gynecomastia in man start from grad one to grad six the procedure include combination of liposuction and gland excision or subcutaneous mastectomy[20] the duration of operation about one hour and drain routinely was keep for a few hours follow by compression of breast to avoid any collection of fluid like blood or serous[21] the postoperative complication are rare as infected wound or bleeding or areolar necrosis and recurrent[22] some time asymmetrical of right and left breast occure postoperatively in 3-4 weeks so need to simple liposuction under local anesthiasia or mesotherapy lipolysis injection it benefit[23].

The conservative treatment may be trail in early stage of GM combine with psychological support[24]. Some time we do operation to early stage of GM duo to aesthetic cousce[25].

The operation cost it’s not expensive it slightly depend on stage of GM.

Again we strongly recommended to do sub areolar gland excision to all stage of GM combine with liposuction.
Patient with drags that cause GM should be stop these drags or change to other type of medication [26]. Nowadays with elevated the body awareness will raise the discussion and curve toward surgical treatment of GM and will be raise more in future.

Abstract

Obesity is a major metabolic illness that results from increased body fat and leads to negative health consequences. Obesity increases the prevalence of various diseases, including diabetes mellitus, hypertension, coronary heart disease, sleep apnea, CVA, GERD disease, gall bladder disease, certain types of malignancy, and non-alcoholic fatty liver disease. Moreover, it is also a major avoidable health detriment. Current therapeutic approaches to obesity are lifestyle changes, pharmacologic treatment, and bariatric surgery. Materials and Method: Twenty-seven patients visited our obesity clinic in Al-Dewaniyah Teaching Hospital from September 2016 to September 2017 and selected for intra-gastric balloon insertion after discussion with the patients, all current bariatric operative options beside the discussion to choose different balloon types. Air filled balloon was chosen. Results: female to male ratio 3.1:1, with mean age 34±6.1 and mean body mass index 40.48 ± 5.16 had excess body weight 38.93 ± 8.44 Kg, all patients had been received IGB heliosphere 720 ml as treatment of their obesity. Each patient has been followed up 6 months and weight loss patterns observed. Mean weight loss after six month 9.6 ± 4.8 Kg. Conclusion: In regards of patient selection to the procedure, Patients should be selected according to their commitment to the recommended diet and life style modification, this would largely affect the outcome.

Introduction

Obesity is a major metabolic illness that results from increased body fat and leads to negative health consequences. Obesity increases the prevalence of various diseases, including diabetes mellitus, hypertension, coronary heart disease, sleep apnea, CVA, GERD disease, gall bladder disease, certain types of malignancy, and non-alcoholic fatty liver disease. Moreover, it is also a major avoidable health detriment. Current therapeutic approaches to obesity are lifestyle changes, pharmacologic treatment, and bariatric surgery. Although intensive lifestyle modification was reportedly associated with only limited weight reduction when it is combined with weight-loss drugs approved for long-term use, an additional weight reduction of 3%-9% can occur within 1 year. Such drugs are said to improve several cardio-metabolic risk factors, but they are also related to harmful adverse effects. Although new obesity medications have recently been approved and introduced, they are associated with issues of safety and high costs. Weight-loss surgery provides the most sustained and effective therapeutic choice for obesity. Accessible methods include the adjustable gastric band, Roux-en-Y gastric bypass, or sleeve gastrectomy. Regardless of its proven effectiveness, only 1% of obese patients eligible for the surgical procedure choose to undergo it. The major issues with surgery are difficult accessibility, high costs, patient non-preference, and significant morbidity and mortality. Although its associated mortality has decreased considerably, the complication rate in the early and late stages of the bariatric procedure persist at 17% (95%CI: 11%-23%)9. However, several adverse events were associated with its use, including small bowel obstruction associated with spontaneous deflation and gastric mucosal injury. Although the GEBG is no longer used, considerable advancements to its design have led to the development of a more effective and safer intra-gastric balloon. It is now being used in numerous countries. The increased prevalence of obesity has motivated experts...
in bariatric medicine to advance minimally invasive endoscopic treatment for obesity management as well as innovative techniques that address important features of treatments, such as their efficiency and safety. A new meta-analysis showed that endoscopic obesity treatment could be effective and of substantial value if combined with a multidisciplinary and comprehensive treatment plan. Intra-gastric balloon is placed in the stomach using endoscopic procedures under mild sedation in an outpatient setting. Intra-gastric balloons allow patients to sense fullness and ultimately reduce their food intake. It is hypothesized that the intra-gastric balloon facilitates satiety peripherally by being an obstacle to food consumption, decreasing intragastric volume, and delaying gastric emptying. Additionally, signals transmitted centrally through the vagal nerves by activated gastric stretching receptors could affect satiety. The intragastric balloon permits an early feeling of satiety, which is thought to be a consequence of gastric distention. The mechanical intragastric distention to a meaningful volume during mealtime significantly decreases the amount of food eaten. This study aimed to evaluate the role of Intragastric Balloon insertion to decrease body weight in obese patients.

**Materials and Method**

Twenty-seven patients visited our obesity clinic in Al Dewania Teaching Hospital from September 2016 to September 2017 and selected for intra-gastric balloon insertion after discussion with the patients, all current bariatric operative options beside the discussion to choose different balloon types. Air filled balloon was chosen. Heliosphere IGB 720 cc positioning was performed, the manufacturer’s instructions were followed in positioning the device, after diagnostic endoscopy, under unconscious sedation. After placement, the balloon was slowly inflated with room air to the final volume of 720 ml. All patients were discharged on the same day of insertion with omeprazole (po 20 mg/d), ondansetron (po 8 mg/d) and butyl scopolamine bromide (po 20 mg t.i.d.).

All patients from day 3 after placement began liquid diet and were on a 1000 kcal diet (carbohydrate 146 g, lipid 68 g, protein 1 g/kg ideal weight). The patients were followed monthly, and complications and their treatment, post-placement symptoms, BMI and %EWL were recorded. After 6 months, the Heliosphere Bag was removed. Data were analyzed by SPSS 18.

**Results**

Twenty-seven patients enrolled in these study, female to male ratio 3.1:1, with mean age 34±6.1 and mean body mass index 40.48 ± 5.16 had excess body weight 38.93 ± 8.44, all patients had been received IGB heliosphere 720 ml as treatment of their obesity. Each patient has been followed up 6 months and weight loss patterns observed.

The table (1) shows the difference in excess body weight and body mass index with gender. In male the excess body weight were 44.45±10.58 while in female 36.38±15.2 the difference not statistically significant. The BMI in male were 43.52±4.89 and in female were 39.2±5.914 which is not significantly difference between them.

During the follow up period many patients had developed complication after insertion of intragastric balloon, 49% had vomiting, 42% had only nausea, 56% feel epigastric discomfort and 11% patient need admission, 3.75 develop gastric perforation as show in figure 1

![Figure 1: shows percent of each complication](image)

Intra-gastric balloon placement can be performed through a simple endoscopic method and is easily reversible. This simplicity offers an expansive role in obesity treatment based on the degree of obesity.

Intra-gastric balloon treatment might produce only short-lasting effects in obesity treatment. Thus, it is important to maintain weight loss following intra-gastric balloon removal. Long-term management for weight reduction after intra-gastric balloon removal can also comprise intensive lifestyle modification, alone or with pharmacotherapy, and could be suggested to protect against weight regain

According to our results, maximum weight loss achieved, was in the first two weeks of IGB insertion. In this period, nausea and epigastric discomfort were maximum, soon later when patients started to tolerate these symptoms, the weight loss achievement decreases and oral feeding becomes more tolerable.

The cornerstone of obesity management is patient compliance. It is crucial and vital. One of our patient who lost only 4 kgs after 6 months, said he was dividing sweet food into pieces so can ingest them without difficulty and without inducing nausea and epigastric cramps.

Three patients developed severe abdominal cramps and they asked to retrieve the IGB, we responded by readmission and prescribing more analgesia and IV fluid without improvement in their symptoms and final decision of retrieval of the IGB was taken, based on patients request.

All our patients received IGB insertion as their definitive obesity treatment but with possible second line bariatric surgery based on patients' weight loss achieved, all our patients have been informed that IGB could be their definitive therapy if the commit to the diet and life style modification. This was our goal to achieve maximal patient compliance. To encourage the patients to commit to the diet and life style modifications, we informed the patient that the IGB could be their final bariatric intervention.

This point is against most of studies that suggest IGB as bridge to bariatric surgery. One patient developed acute abdominal pain and tenderness 12 hours after
insertion with air under diaphragm. At Laparotomy, we found tiny pin point fundal gastric perforation and was repaired with primary closure and drainage of sub phrenic space with nasogastric suction tube patient recovered well and discharged home on the sixth postop day without complication. Such complication was not reported till the date of writing this paper as we did extensive online researches. This was life threatening complication and need urgent intervention. Thus, close clinical follow up is indicated in the first 24 hours after insertion. We recommended adding such complication to the informed consent.

The results of our study support most of the studies that recommend intra-gastric endoscopic bariatric interventions and concluded that it is promising procedure. the average of our patient BMI decreases to below 35 % where surgery is not indicated at such level, a part from the higher BMI in those studies, all other variables included, were the same. However no one of these studies BMI decreases below 35 %, due to the higher Baseline BMI 16,17,18.

**Conclusion**

In regards of patient selection to the procedure, Patients should be selected according to their commitment to the recommended diet and life style modification; this would largely affect the outcome. Larger scales and volume studies are needed particularly those studies that divide patients into groups according to the compliance and commitment to the diet and behavioral and life style changes they need to achieve the ideal body weight beside IGB insertion, those patients who understand that any bariatric procedure is not the only needed to lose weight. Incidence of life threatening complication was 3.7 %, Close follow up is indicated in the first 24 hours to detect gastric perforation .Material and safety issues regarding the intra-gastric balloon should be further investigated. More research should be performed to investigate a pathophysiologic pattern of obesity, the uncertain role of gut hormones, potential predictive factors for the efficacy of the intra-gastric balloon in obesity treatment, and individualized treatment-induced changes.

Abstract
Decreased ovarian reserve is considered as one of the main causes of infertility. It is about the availability of preovulatory oocytes in the ovaries. With increase age, ovarian reserve decreases. Nowadays, “ovarian reserve” assessment became a strategy to assess female infertility.

Objective: The current study aims to find the relationship between age and infertility type with measures of ovarian reserve (FSH, AMH and AFC) in infertile patients.

Material and Method: The cross-sectional study design was used for this study and a survey was conducted among 100 infertile women.

Result: Results revealed that Relationships between age and ovarian reserve indicators show a highly significant negative correlation with AFC (p= 0.001) and AMH (p= 0.007) level while positive correlation is found with FSH level (p= 0.001). The relation between age and FSH was moderate (rs=0.38, p<0.0001) and revealed that AMH and AFC level decreases while FSH level increases with age.

Conclusion Study of AMH level is the most reliable source to measure age-specific changes.

Key words: Female infertility, ovarian reserve, anti-mullerian hormone.

Introduction
In the modern world, the determination of the strategy to manage female infertility by assessing ovarian reserve has become necessary. Traditionally, ovarian reserve used to be evaluated by age and ultrasound investigation of Follicle stimulating hormone, Antral follicle count, and estradiol levels at the early follicular phase [1]. AMH (Anti-Mullerian Hormone) or Mullerian inhibiting substance is promising marker for ovarian reserves. It is a dimeric glycoprotein and involved in growth and differentiation. It is gonadal factor causes Mullerian duct regression and precursor of female reproductive tract. Plasma level of AMH is detectable at birth, gradually increases till puberty and then decreases until undetectable at menopause1. For evaluation of low ovarian reserve, FSH and E2 levels were considered to be determining biochemical markers for several years. However, it has been recently found that high level of FSH is associated with decreased functioning of ovary. Moreover, evaluation of AFC at later stages are considered to be more reliable in the assessment of ovarian reserve. High-resolution sonographic systems help obtain follicle count quickly, but there are certain difficulties in assessing correct AFC such as anatomical variations and high inter-observer differences 2 . AFC is considered the first choice to determine ovarian reserve by several health care professionals because it predicts poor response effectively when compared to basal FSH. Recently, it has been suggested that Anti-mullerian hormone are essential in the evaluation of ovarian response. It is a Mullerian inhibiting hormone which is a dimeric glycoprotein. This hormone belongs to the family of transforming growth factor – β. In women of reproductive age, AMH is produced in the ovary by granulosa cells and is secreted by small antral follicles 3 . The primary function of AMH in the ovary is resisting the accumulation of primordial follicle and reducing pre-antral and small antral follicles sensitivity to FSH in the ovary. There are certain advantages of AMH when compared with other tests in the assessment of ovarian reserve.
reserve. One of the significant advantages is AMH levels can be evaluated at any day of the menstrual cycle as they are stable throughout the cycle. Moreover, they are not affected by variations in any other hormone as well as the use of oral contraceptives. Bentzen et al. have suggested in a recent study that makers of ovarian reserve are lower in women who use contraceptive methods involving steroids.

On the other hand, AMH cannot be detected in women until they reach puberty and reaches its highest level at the age of 24-25 years, while it cannot be detected after menopause. With increasing age, AMH level, as well as the quality of oocytes, reduces. According to recent studies, depletion of follicles doubles when the amount of primordial follicle reaches approximately to the value of 25,000. Women reach at this critical stage at about 37-38 years, after which ovarian reserves sharply reduced. The normal AMH level value with female age is 5.4, 3.5, 2.3, 1.3 and 0.7ng/ml in 25, 30, 35, 40 and >43 years respectively (fertility, 2019). These changes in ovarian reserves are not only associated with age; hence, a woman’s age alone is not sufficient to evaluate ovarian reproductive potential. This enables the need for implementation of individual biological age-specific ovarian reserve determining tests. These tests can be highly reliable in determining ovarian reserves and reproductive potential of a woman at the early stages of infertility. According to recent studies, AMH can be a good predictor of ovarian reserves and the success rates of in vitro fertilization.

On the other hand, some other studies have shown that pregnancy can also be achieved even at low levels of AMH. Evaluation of ovarian reserves by identifying AMH levels is a modern method, and the data obtained are contrasting, implementation of further studies and collecting more data in the field are deemed to be reasonable. Hence, this study aimed to explore the relationship between different age groups and type of infertility with measures of ovarian reserve (FSH, AMH, and AFC) in infertile women.

## Material and Method

This was a cross-sectional study which consisted of the study population of 100 infertile women. Patients were recruited from outpatient’s private clinics during the period from June 2017- March 2019. These women were divided into two groups by age above and below 45-years old and by type of infertility into primary and secondary infertile groups. All patients underwent detailed fertility assessment including history, physical examination, laboratory and radiological (transvaginal ultrasound) investigations. AFC and serum FSH and AMH were measures and compared between groups. The study was approved by the Ethics Committee of University of Babylon. All patients consented to participate in the study. Statistical analysis was performed using SPSS v.24 (IBM, USA).

## Results

The study population was distributed based on age as follows: group I comprises of female of age less than 45 years (83%) and group II comprises of female of age more than 45 years (17%). There were 48% (n=48) primary infertile patients and 52% (n=52) secondary infertile patients. Table 1 and 2 show the values for AMH, FSH and AFC, respectively, according to the study groups. All of the three indicators of ovarian reserves in both age groups differed significantly from each other (AMH: p=0.007; FSH: p=0.001; AFC: $\chi^2=15.45, p=0.001$). These indicators varied according to age. Results are expressed as mean± SD.

### Table 1. AMH and FSH levels in women with age below and above 45 years

Normal AFC count was observed in secondary infertility in nulliparous and multiparous women (51.9%) while decreased AFC count was observed in primary infertility in nulliparous and multiparous women (66.7%) with p-value: 0.07

**Discussion**

Results from the current study revealed that assessment tests of ovarian reserve reflected age-specific changes in both age groups. As an ovarian reserve marker, AMH is useful to estimate the reproductive lifespan of healthy young women and to predict the ovarian response to stimulation for in vitro fertilization (IVF), namely poor and hyperresponses. Reduction in AMH and increased in FSH level is associated with age increase while there is no significant association among age and AFC level. No clear link between infertile women age and AMH, FSH values with infertility type and there is no association between primary and secondary infertilities and AFC values is evident from current study. AFC and AMH serum level decreases with age. MH levels vary in both age groups, AFC levels significantly higher in women below 45 years, while FSH levels were higher in women above 45 years. AMH value is more reliable in assessing age-specific changes when compared to other indicators. Relationships between age and ovarian reserve indicators show difference between indicator levels. The relation between age and FSH was moderate and revealed that AMH and AFC level decreases while FSH level increases with age. Above mentioned trends are also confirmed by other researchers. Similar results were found by different studies. We found a significant difference existed in the mean FSH of fertile and infertile women. There is a significant difference in AMH between fertile and infertile women. There was a negative correlation between FSH and AMH in both fertile and infertile, stated that the plasma AMH levels were significantly higher in women with the polycystic ovarian syndrome. The significant association was seen between FSH and AFC with AMH. However, no significant association was observed between AMH levels with age, BMI, ovarian volume and type of treatment protocols.

It is cleared from current and previous studies that observed AMH value was significant in all age groups, while AFC value was significant in women above 45 years. Hence, we conclude that age-specific changes are better reflected by considering AMH values. Study of AMH level is the most reliable source to measure age-specific changes. This correlation is also confirmed by other researchers.

**Conclusion**

Among ovarian reserve evaluation tests that are used in modern practice, the serum levels of AMH
should be considered more authentic. Measuring serum AMH levels along with AFC levels may enhance the evaluation of ovarian reserve for assessing fertility potential and examining infertility treatment. Study of AMH level is the most reliable source to measure age-specific changes.

Evaluation of Risk Factors and Outcome of Incarcerated Inguinal Hernia in Pediatric Age Group

Ibrahim Tariq Ameen¹, Raid Hamid Abdul-Ghafoor², Bilal Hamid Abdul-Ghafoor³
¹Specialist in pediatric surgery, Al-Ramadi Hospital for Maternity and Children, Department of pediatric surgery, (Anbar/Iraq), ²Specialist in internal medicine, Al- Ameriya Hospital, (Anbar/Iraq), ³Consultant in pediatric surgery, Child Central Teaching Hospital, Department of pediatric surgery (Baghdad /Iraq).

Abstract

Background: Incarcerated inguinal hernia is one of emergency conditions in children. It results from entrapment of bowel or other viscera within the hernia sac. High incidence of incarcerated inguinal hernia occurs in young age and preterm. The incidence of incarcerated hernia is variable and ranges from 12–17%. The aim is to evaluate the risk factor / or factors and outcomes for patients with incarcerated inguinal hernia.

Patients and method: This prospective study directed in department of pediatric Surgery, Central Child’s Teaching Hospital, Baghdad, Iraq. Fifty-five patients with incarcerated inguinal hernia were managed for 10 months. They were evaluated for history and sent for investigations. All patients initially treated by manual reduction. Later on they treated by elective operation. Overall outcomes were evaluated in all patients.

Results: The patient’s age range from 17 days to 5.5 years. There was male predominance with male: female ratio was 10:1. The frequency of right side incarcerated inguinal hernia was more than the left. Fourty (72.7%) patients were under first year. Thirty-two (58.2%) patients were preterm. Fourty-four (80%) patients have successful manual reduction and eleven (20%) patients were failed and underwent emergency surgery. Intestinal resection done to 4 patients and rate was 7.3%, and orchiectomy done to 3 patients and rate was 5.4%.

Conclusion: Premature and younger age patients are risk factors for incarcerated inguinal hernia. Incarceration increases the rate of overall complications. Any patient, especially young patient and preterm, with reducible hernia should be treated as soon as possible.

Key words: Incarcerated inguinal hernia; Risk factors; Outcomes.

Introduction

Indirect inguinal hernias are fundamentally the result of failure of closure of the processus vaginalis (¹, ²). Incarcerated inguinal hernia can result from entrapment of bowel or other viscera within the hernia sac (¹). Approximately 1–5% of all children will develop an inguinal hernia and a positive family history is found in about 10%, while the male-to-female ratio was 5:1, and right-sided hernias were twice as common as those on the left. The mean age at diagnosis was 3.3 years. The overall incidence of inguinal hernia in premature infants is estimated to be 10–30%, whereas term newborns have a rate of 3–5 % (³, ⁴). Younger age and prematurity are risk factors for incarceration (⁵).

Incarcerated hernia

Inguinal hernias that are difficult to reduce are “incarcerated. A strangulated hernia happens once there’s vascular compromise of the entrapped viscera. This results from constriction by a tight internal or external ring. Most children can progress speedily to strangulation if the hernia isn’t reduced. This method will take as very little as a pair of hours. If this process is unchecked, this will lead to gangrene and perforation of the bowel or other viscera. Incarceration and strangulation can also damage the testicle by compromising the blood supply to the testis (¹).
Clinical presentation

Incarceration symptoms are often manifested as a fussy or inconsolable child with intermittent abdominal pain and vomiting. A tender and at times erythematous irreducible mass is noted within the groin. Abdominal distention may be a late sign; as are bloody stools. Peritoneal signs indicate strangulation. Incarceration may be the presenting sign of the hernia, especially in an infant (3). The diagnosis of incarcerated inguinal hernia is usually made on clinical grounds. Abdominal x-rays may occasionally show bowel gas within the lump in the groin and confirm the diagnosis (6). In uncertain cases ultrasound can be useful to distinguish bowel from hydrocele fluid or a testicular torsion (1). Differential diagnosis for incarcerated hernia is the primary distinction to be made is between an inguinal hernia and a hydrocele. Femoral and direct inguinal hernia are rare but should be kept in mind; a retractile or undescended testis may mislead the unwary, and in young children, an inguinal lymph node may be situated close to the external inguinal ring (7).

Treatment

If the patients without obvious signs of shock or peritonitis, non-operative management is first tried (1). The incarcerated hernia should be reduced by taxis. Taxis is a manipulative trick, not a matter of force, and if necessary may be attempted several times. As long as the necessary monitoring is available, a distressed child may be sedated with midazolam or opiate analgesia. Taxis is successful in over 90% of cases, with virtually no chance of complication by en masse reduction (7). If positive, the hernia contents can steadily disappear into the internal ring. To be certain it is reduced; compare it with the contralateral side (1). Once an incarcerated hernia is reduced, a delay of 24 to 48 hours to allow resolution of edema is reasonable (3, 8).

Complications

The risk of recurrence after an elective inguinal hernia repair is less than 1% in several large series. Injury to the spermatic cord or testis is a rare occurrence in elective hernia repairs. Also the infection and hematoma can occurs in 1–3% of cases. Moreover loss of domain due to a huge hernia is another problem more frequently seen in adults, but it can occur in infants or children and may require staged repair or other measures. The iatrogenic cryptorchidism from failure to replace the testis in normal anatomic position is a rare occurrence (<1%). Bladder injury in infants in whom the medial wall of the sac contains urinary bladder is also a rare complication. While Mortality directly related to inguinal hernia or its repair is exceedingly rare (<1%) (3).

Patients and methods:

Fifty five patients with incarcerated inguinal hernia were evaluated in term of risk factors and outcome at surgical department of Central Child’s Teaching Hospital in Baghdad from 1st October 2015 to 2nd August 2016. The information’s been collected from the patients according to special data sheet and collected data involved:

1- History included: name, age, gender, maturity, presenting symptoms and sings with duration, side, and history of reducible hernia.

2- Investigations involved: plain erect abdominal x-ray, U/S (abdomen and inguinal), and preoperative routine investigations.

3- Treatment by taxis: reduction by taxis followed by elective operation and failed reduction followed by emergency operation.

4- Post-operative complications for elective and emergency operation.

5- Operative time and hospital stay.

The diagnosis depended mainly on clinical examination. Erect abdominal X-ray was taken to all patients. U/S of abdomen and inguinal was taken for some patients. Blood sample was taken and sent for preoperative routine investigations. Manual reduction by taxis was tried to all patients as they didn’t have contraindication. For elective patients who succeeded by manual reduction, formal herniotomies through inguinal approach were done later on with high ligation of sac. Patients were followed in term of wound infection, hematoma, recurrence, and testicular atrophy.

Statistical Analysis

Statistical package for social sciences version 22 (SPSS v22) was used for data input and analysis. Discrete variables presented as numbers and percentages and continuous data presented as means. Chi-square test for independence was used to test the significance of association between discrete variables. Findings with P values less than 0.05 were considered significant.
Results

The study includes fifty five patients with incarcerated inguinal hernia. Age range from 17 days to 5.5 years and mean age was 11 months. It consists of 50 males (90.9%) and 5 (9.1%) females with ratio male: female ratio is 10:1. In term of age distribution; 28 (50.9%) patients were less than 6 months, 12(21.8%) patients were between 6-12 months, 10 (18.2%) patients were between 12-24 months, and 5(9.1%) patients were more than 24 months. About 2/3 (72.7%) of patients were less than one year old which showed in table1.

The overall post-operative complications of these patients with incarcerated hernia were 7 (12.7%) patients. For elective operation, only 2 (4.5%) of 44 patients had post-operative complications including: 1 (2.25%) patient had hematoma and 1(2.25%) had wound infection. For emergency operation, 5(45.4%) of 11 cases had complications including: 1(9.1%) hematoma, 1(9.1%) recurrence, 2(18.2%) wound infection, and 1(9.1%) testicular atrophy as showed in table 5.

**Discussion**

The incidence of hernia incarceration is variable and ranges from 12–17 % (3, 4). In this study, 28 (50.9%) patients were less than 6 months, 12(21.8%) patients were between 6-12 months, 10 (18.2%) patients were between 12-24 months, and 5(9.1%) patients were more than 24 months. About two third of patients (72.7%) were infants as in Kayode T. Bamigbola etal (9) study and Mohammed Zamakhshary etal (10) study which assume that two third of incarcerated hernia were infants. With higher incidence among infants, this is due to narrow rings which easily trap the herniating loops of bowel or other viscera. Mean age of occurrence was 11 months with age range from 17 days to 5.5 years, common in male 50(90.9%), and in right side.

In this study preterm infants were 32(58.2%), and 23(41.8%) were terms. prematurity considered as risk factor for incarceration and this is mentioned by Rowe MI etal (4) study, EinSH etal (8) study, and Hughes K etal (11) study.

Regarding clinical presentation, 51(92.7%) of patients presented with irritability (pain) and/or excessive crying. Other presentations were poor feeding in 44(80%), vomiting (bilious or non-bilious) in 37(67.2%), constipation in 17(30.9%), abdominal distension in 12(21.8%), and bleeding per rectum in 1(1.8%). No signs of peritonitis were presented. Examination of swelling demonstrates tenderness in 44(80%), and redness in 8(14.5%). The most common symptom was irritability (pain) and/or excessive crying and the most common sign of swelling was tenderness which is comparable with Wael Mohammed etal (12) study.

Thirty two (58.2%) patients presented less than 24 hrs. duration and twenty three (41.8%) patients were more than 24 hrs. duration. Total manual reduction rate of incarcerated inguinal hernia by taxis succeeded in 80% of patients followed by elective herniotomy later on. Less 24hrs duration, 96.8% (31 of 32 cases) had succeeded by manual reduction, this rate decreased to 56.5% (13 of 23 cases) between 24-48 hrs. duration and only 16.6%(1 of 6) above 48 hrs. The total successful rate of manual reduction is less than Puri P. etal (32) study, and Ein SH etal(8) study which range from 90-95%. This is a result of the high rate of delayed presentation with 41.8% of cases presented after 24 hrs.

Eleven patients had emergency operations because of failed manual reduction. During operation, the sac must be opened and content examined. Bowel necrosis occur in 4 patients and give rate of 7.3% and the rate equal to Kayode T. Bamigbola etal (9) study which is 7.3%. Frankly gangrenous testis was 3 and give rate of 5.4%. This rate is less than Kayode T. Bamigbola etal (9) study which is 14 % and this may be due to high operation rate in neonate due to high failure of manual reduction in his study but near to 2.6-5% as mentioned in Arnold G. Coran etal (1). The overall complications rate was 12.7% and this is comparable with reports in studies of Niedzielski etal (13), Meier AH etal (14), Chen LE etal (15), and Ameh EA (16) with rate range between 11 and 31%. Complications rate of emergency operations was 45.4% and it is comparable to 51.7% in Sadik H Kadhem etal (17) study.

Mean operative time for patient with incarcerated hernia treated emergently was 55 minutes range from 35 – 100 minutes while mean time was 22.7 minutes with range of 15-30 minutes for patients who were treated electively. Mean post-operative hospital stay was 2.7 hours range from 2-4 hours for elective patients and 63.1 hours (2.7 days) range from 30-140 hours for emergency operations. So, there is prolonged operative time for emergency treated patients that will increase risk of anesthesia and complications. And there is prolong hospital stay which means more cost on hospital and more cost on patients.
Conclusion

Younger age and prematurity are risk factors for developing incarcerated inguinal hernia. Longer duration and younger age will decrease rate of manual reduction and increase rate of testicular and intestinal necrosis. Overall complications in incarcerated hernia will be higher than those with reducible hernia and especially high in emergently operated patients. Incarcerated inguinal hernia is more costly for patient and hospital than reducible hernia, as there is prolonged operative time and hospital stay.

Conflict of Interest: Authors have no conflict of interest.

Source of Funding: The current study which was directed at Central Child Teaching Hospital, Department of Pediatric surgery in Baghdad, where personal finance was adopted by the authors.

Ethical Clearance: The information’s been collected from the patients according to special data sheet and collected data. All patients were joining up in the study after signing a written informed consent, and their selection follows the above criteria’s.

Harmonic Scalpel Vs Conventional Cautery Use In Hemorrhoidectomy

Khalid K. Hussein

General surgeon, clinical lecturer, Department of surgery, Tikrit university college of medicine, Salah Aldin, Tikrit, Iraq

Abstract

Introduction: The evidence-based literature emphasizes the requirement of prioritizing harmonic scalpel haemorrhoidectomy over the conventional surgical interventions in the context of minimizing the intra-operative and post-operative complications in the treated patients.

Aim: The presented research study evaluated the significance of the harmonic scalpel (HS) as compared to the conventional electrocautery in the context of facilitating safe and effective haemorrhoidectomy in the selected patients. The study question focusses on analysing the potential of HS haemorrhoidectomy in terms of minimizing the post-operative complications in the patients affected with grade III and IV hemorrhoids. The study hypothesized beneficial treatment outcomes of HS haemorrhoidectomy as compared to the conventional electrocautery-based haemorrhoidectomy.

Methodology: The prospective cohort study shortlisted 20 candidates for HS and electrocautery-based haemorrhoidectomies. Initial 10 patients underwent the conventional haemorrhoidectomy; however, the other 10 received HS haemorrhoidectomy.

Result: The research findings categorically revealed limited post-operative pain and bleeding in the harmonic scalpel group as compared to the conventional electrocautery group. HS haemorrhoidectomy substantially reduced the extent of collateral thermal damage in the treated patients.

Conclusion: The study findings affirmed the effectiveness of HS haemorrhoidectomy over traditional intervention in terms of minimizing postoperative complications including bleeding, pain, urinary incontinence, fecal incontinence, anal stricture, and anal abscess.

Keywords: Harmonic scalpel, Electrocautery, Haemorrhoids, Bleeding, Collateral thermal damage

Introduction

Harmonic scalpels (HS) include the ultrasonic scalpel instruments that effectively incorporate automatic vessel-sealing systems for undertaking the surgical intervention including hemorrhoidectomy. These scalpels include the hemostatic, electrothermal, and bipolar devices that systematically utilize pressure and radio frequencies in the context of coagulating and dissecting the vessels of 0.7cm diameter. Utilization of harmonic scalpels leads to minimal tissue charring and limited thermal spread that reduce the risk of intraoperative hemorrhage. Harmonic scalpels increase surgical field visibility during hemorrhoidectomy. The concomitant undertaking of hemostasis and resection by the harmonic scalpels results in the reduction of mucosal tissue damage and post-surgical infection. Furthermore, harmonic scalpels’ use minimizes the risk of surgical site pain and post-hemorrhoidectomy bleeding in the treated patients. Contrarily, the hemorrhoidectomy through conventional cautery is performed in two distinct stages. The first stage facilitates the damage of blood vessels and mucosal tissues during hemorrhoidal resection.
The second stage is based on hemostasis and suturing at the resection site. These facts affirm the significance of harmonic scalps in terms of reducing the intra-operative hemorrhage as well as operation duration.

The analysis by Bulus et al. advocates the significance of the harmonic scalpel in terms of effectively treating the Grade III/IV hemorrhoids and associated complications. Various research studies affirm the safety of HS-based hemorrhoidectomy in comparison to the conventional operative interventions. Patients who undergo harmonic scalpel hemorrhoidectomy rapidly resume their work as compared to other patients who receive conventional hemorrhoid excision interventions in the operative settings. However, evidence-based findings regarding the effectiveness of harmonic scalpel hemorrhoidectomy over conventional techniques, lack scalability. Some of the significant studies do not report any reduction in postoperative pain intensity, bleeding and other postsurgical complications through the prioritized use of an ultrasonic scalpel over conventional hemorrhoidectomy techniques. The analysis by Homayounfar et al. reveals similar thermal injury and greater extent of necrosis under the impact of the ultrasonic scalpel as compared to the conventional monopolar electrocautery. Similarly, the findings by Khan et al. do not reveal the claimed benefits of HS hemorrhoidectomy over traditional electrocautery-based hemorrhoidectomy. These findings radically reveal the limited generalizability of the harmonic scalpel (safety/efficacy-related) findings in the scientific community. This necessitates the requirement of prospective interventions to comparatively analyze the safety and efficacy of HS-based hemorrhoidectomy in comparison to the conventional cautery method.

The analysis by Bilgin et al. affirms the potential of a harmonic scalpel (HS) hemorrhoidectomy in terms of reducing the recurrence of hemorrhoids in the treated patients. The assessment affirms the capacity of the harmonic scalpel in facilitating fast and safe hemorrhoidectomy. The study findings advocated the use of HS hemorrhoidectomy over the conventional staple hemorrhoidopexy. However, harmonic scalpel-based reduction in the initial postoperative complications, including the post-surgical pain and intra-operative bleeding substantiates the prioritization of this technique in comparison to conventional hemorrhoidectomy approaches. Postoperative pain is the major complication experienced by the treated patients following the administration of hemorrhoidectomy. Harmonic scalpel-based technique is more advantageous as compared to other conventional interventions, including cryotherapy, photocoagulation, sclerotherapy, electrocautery, and rubber band ligation. This is majorly because of limited postoperative pain and decreased lateral thermal trauma (0.5 – 1.5mm) under the impact of harmonic scalpel utilization. The assessment by reveals no rational evidence of the systematic utilization of the harmonic scalpel in hemorrhoidectomy. The study findings also relate the post-operative pain with the extent of thermal injury in the treated patients. Monopolar cautery leads to the thermal injury (up-to 15mm) to the porcine small bowel mesentery during hemorrhoidectomy. This injury substantially elevates the intensity of post-operative pain in the treated patients. Contrarily, the analgesic effect of the harmonic scalpel reduces these outcomes to a considerable extent.

Harmonic scalpel utilizes sound waves that effectively induce vibrations at 55, 000/second in the context of coagulating the medium/small size blood vessels during hemorrhoidectomy. Utilization of conventional electrocautery increases the risk of perianal pain-related post-operative complications including constipation and urinary retention. This eventually elevates patients’ treatment burden and length of their hospital stay during the post-operative period. Contrarily, no such clinical complications are reported after utilizing harmonic scalpel during hemorrhoidectomy. This resultantly reduces the operative time and risk of blood loss-related clinical complications in the treated patients. In summary, the HS hemorrhoidectomy is a closed and suture-less intervention that not only saves the operative time, but also increases patient safety to a considerable extent. The reduction in intra-operative and post-operative complications through the utilization of HS technique justifies its benefits over the conventional electrocautery technique in the hemorrhoidectomy-based surgical settings. We hypothesized that the Harmonic scalpel use in hemorrhoidectomy reduces the intra-operative and postoperative complications in comparison to the conventional electrocautery intervention. The presented research study accordingly evaluated the safety and outcomes of HS hemorrhoidectomy while comparing them with the conventional hemorrhoidectomy results.

**Methodology**

The prospective study selected 20 subjects affected with grade III/IV internal hemorrhoids. These candidates underwent hemorrhoidectomy in the year 2017 in
a private hospital in Tikrit city. Indeed, 10 patients received the conventional monopolar electrocautery-based hemorrhoidectomy. However, the other 10 of them underwent HS hemorrhoidectomy in the operative setting. The medical records of the selected patients were effectively retrieved from the hospital database. The study participants included 9-females and 11-male patients. The entire subjects had to undertake pre-operative lab interventions prior to hemorrhoidectomy. Saline enema was administered to each patient one night before surgery. Administration of prophylactic antibiotics was effectively undertaken before the initiation of surgical hemorrhoidectomy. 15 patients received general anesthesia for hemorrhoidectomy. However, 5 patients (including 2 female subjects) received spinal anesthesia prior to surgery. The surgical field acquisition was performed through anoscope. Forceps were utilized for lifting the hemorrhoidal stems from the anal sphincter.

The conventional hemorrhoidectomy was performed in the selected group through monopolar electrocautery in accordance with the Ferguson’s closed hemorrhoidectomy method. The anal sphincter and hemorrhoidal tissue were sequentially excised through the monopolar electrocautery device. The hemorrhoid mucosal resection was followed by hemostasis and closure of the surgical wound by Vicryl 3-0 surgical sutures. Contrarily, the ultrasonic scalpel was utilized for excising the hemorrhoidal pedicle and tissue up-to-the apex region. Vascular forceps were used in the context of minimizing the internal sphincter injury during the intra-operative period. Coagulated blood vessels and hemorrhoidal mucosa were subsequently excised through harmonic scalpel. 3-0 vicryl was used for placing the mucosal sutures.

Acetaminophen (2-tables TDS) were prescribed to each patient for post-operative pain management. Patients underwent ‘sitz bath’ three times a day during the post-operative tenure. VAS (visual analog scale, 0-10) was utilized for recording the post-defecation/resting pain, urinary retention, and hemorrhage. The occurrence of fecal incontinence, anal structure, and anal abscess was effectively monitored during the post-operative period. Indeed, 0-10-points on a VAS scale indicated no-pain to severe pain. Major bleeding was identified by the requirement of intensive medical interventions (including close-monitoring, reoperation, blood transfusion). Contrarily, minor bleeding was indicated by the minimal bleeding pattern during defecation that did not require consistent monitoring.

**Results**

The findings of the prospective study revealed limited post-defecation pain in the patients who received the harmonic scalpel intervention. The pain pattern was marked between the range of 1-2 on VAS scale. However, subjects of conventional electrocautery reported post-defecation pain on the VAS scale of 5-6. Major bleeding was not reported in both study groups. However, electrocautery-based subjects reportedly experienced elevated bleeding as compared to patients who underwent HS hemorrhoidectomy in the surgical setting. The subjects who received electrocautery-based hemorrhoidectomy encountered greater tissue injury that caused increased bleeding and anal pain as compared to the other treatment group. The elevated pain and tissue injury at the surgical site resulted in the clinical complications including fecal incontinence, anal abscess, and urinary retention in the initial treatment group. These postoperative complications variably impacted the study subjects in accordance with the extent of their tissue injury and immunity level. However, the other group did not experience these complications (except minimal anal pain/post-defecation bleeding) to any level during the post-operative period. Therefore, the study findings revealed the safety and efficacy of HS hemorrhoidectomy over the conventional electrocautery-based hemorrhoidectomy in the selected patients.

**Discussion**

The study findings effectively concord with the evidence-based outcomes that emphasize the effectiveness of HS hemorrhoidectomy over conventional electrocautery intervention in terms of minimizing the hospital stay duration, post-operative pain, blood loss and surgery time. Similarly, the systematic review by Mushaya et al. affirms the efficacy and safety of harmonic scalpel hemorrhoidectomy in terms of enhancing the quality of life and minimizing post-operative pain in the surgically intervened patients.

Numerous research interventions advocate the single-handed utilization of the harmonic scalpel method in comparison to the conventional electrocautery technique. Some studies also emphasize the requirement of the harmonic scalpel with other devices and techniques including the cushion suspension clamp, electric knife, and Milligan–Morgan hemorrhoidectomy for treating stage III/IV hemorrhoids. These mixed
method interventions also generate better outcomes as compared to the conventional electrocautery-based Ferguson’s closed hemorrhoidectomy. The analysis by Lohsiriwat\textsuperscript{14} emphasizes the effectiveness of non-conventional hemorrhoidectomies over the traditional methods in terms of limited convalescence duration, reduced postoperative pain, and shorter operative time. However, the findings do not indicate the greater effectiveness of non-conventional techniques (related to the long-term outcomes) as compared to the conventional hemorrhoidectomy methods.

The findings of the presented study revealed the reduction in post-hemorrhoidectomy pain under the sustained impact of pain-relieving medication and as well as minimally invasive harmonic scalpel-based intervention. These findings lack generalizability because of the small sample size. However, the findings still prove to be credible in the context of the systematic methodological approaches that the presented study utilized effectively for retrieving the desired outcomes. The findings of the presented study revealed minimum post-defecation pain in patients who underwent harmonic scalpel hemorrhoidectomy in comparison to the conventional technique. These findings effectively concord with the evidence-based outcomes that advocate the effectiveness of Harmonic Scalpel Hemorrhoidectomy in terms of minimizing the risk of sphincter lesions and associated fecal incontinence\textsuperscript{15}. Eventually, the absence of post-hemorrhoidectomy continence disorders minimizes the risk of post-defecation pain in the treated patients.

Undoubtedly, the harmonic scalpel-based hemorrhoidectomy offers the scope of the concomitant utilization of other non-conventional methods with the core objective of reducing the extent of the lateral thermal injury and resultant postoperative complications. The study by Abo-hashem, et al.\textsuperscript{16} revealed similar findings that indicated the reduced risk of excessive lateral thermal injury through the utilization of the harmonic scalpel while undertaking non-conventional hemorrhoidectomy. Similarly, the findings by Ababaikere, et al.\textsuperscript{17} reveal the limited risk of thermal injury to the subjacent tissues and resultant postoperative bleeding through the administration of harmonic scalpel-based hemorrhoidectomy. The findings also reveal the effectiveness of harmonic scalpel technique for minimizing the risk of postoperative mucous discharge.

The findings of the presented study revealed the absence of postoperative urinary retention and anal abscess in patient groups who received harmonic scalpel-based treatment. This occurred under the impact of minimal collateral thermal damage during the operative process. Evidence-based research literature substantially affirms these findings while indicating the minimal lacerating impact of harmonic scalpel-based ultrasound waves on the adjacent healthy tissues\textsuperscript{18}. The harmonic scalpel-based technique precisely dissects and coagulates the targeted hemorrhoidal tissues, while minimizing the surgical site complications. This eventually reduces the risk of fecal incontinence, urinary retention, and anal abscess during the post-operative period. The conventional electrocautery-based hemorrhoidectomy fails to minimize this post-operative complications that eventually lead to the extended hospital stay and reduced quality of life of the treated patients. These findings categorically support the authenticity of the outcomes of our prospective cohort study that advocates the use of HS hemorrhoidectomy over conventional monopolar electric cauterity in the surgical units.

Conclusions

The presented research study effectively authenticated the potential of HS hemorrhoidectomy in terms of minimizing the post-operative complications in the treated patients. The findings revealed a substantial reduction in postoperative bleeding, anal pain, urinary retention, and fecal incontinence through the utilization of the harmonic scalpel as compared to the conventional electrocautery during hemorrhoidectomy. The findings advocate the scalable utilization of HS hemorrhoidectomy for minimizing the post-surgical complications. The findings prove to be a milestone for healthcare professionals and the scientific community in terms of improving the safety and efficacy of hemorrhoidectomy methods for the treated patients. However, the study did not perform a cost-benefit analysis to evaluate the economic implications associated with HS hemorrhoidectomy as compared to the conventional treatments in the operative settings. This substantiates the need for organizing prospective studies to understand the economic implications of HS hemorrhoidectomy in the healthcare sector.

Ethical Clearance: The blood was collected from the a private hospital in Tikrit city after their investigation. Oral consent was taken before enrolled the patients in the study.

Abstract

The computer laboratory of the Faculty of Public Health, Universitas Airlangga is used as a research site, measurement or scientific training for about 15,000 students. There are various types of activities which are at high risk, especially in the use of electricity, which can cause short-circuit and leads to fire. The objective of this study was to apply the Hazard Identification, Risk Assessment and Determining Control (HIRADC) methods in the computer laboratory as an effort to prevent occupational accidents and illness of the user. This study was an observational research using cross sectional design. The observation was conducted on the source of hazard and control efforts on the computer laboratory. Interview was conducted on the lecturers and administrative staff who are in charge of the computer laboratory. The results of the hazard identification indicated that there were 17 hazard sources that can cause 18 risks. Based on the risk assessment conducted on a activities practicum, there are 18 risks classified into 2 risk levels, those are 3 risks with moderate risk level and 15 risks with low risk level. The three level of moderate risks include taking off the shoes in standing position which can cause sprains, there is no first aid box and using electric current which can cause short circuit, electric shock and fire risk. The control that can be carried out by management laboratory to reduce the three moderate risk are by giving advice to taking off the shoes in sitting position, covering the socket which has risky placement by using duct tape to avoid the risk of electric shock as well as the provision of a light fire extinguisher for fire risk and the last providing first aid kits to treat the accidents that occur in the laboratory as soon as possible.

Keywords: HIRADC, risk, computer laboratory

Introduction

The management of Occupational Health and Safety (OHS) risk is the effort to manage hazard which has a potential risk to the workers’ safety and health. The aim is to prevent accidents and illnesses caused by the occupation in the workplace comprehensively, planned and structurally in a good system. The magnitude of the potential risk is determined by the accident and its severity which is possibly caused (¹). According to OHSAS 18001, organization must establish procedures and make efforts in terms of Hazard Identification, Risk Assessment and Determining Control or known as HIRADC (²).

Correspondance:
Putri Ayuni Alayynnur
(+6281331068808), email: putri.a.a@fkm.unair.ac.id

HIRADC is an essential element in the occupational safety and health management system because it is directly related to the prevention and control of hazards used to determine OHS purposes and plans (¹). The OHS Management System in Indonesia refers to the Government Regulation Number 50 of 2012 on the Implementation of Occupational Health and Safety Systems. HIRADC is a part of the implementation of OHSS. The regulation in appendix II point 2.1.2 states that as the OHS strategy, the identification of potential hazards, as well as the assessment and control of OHS risks plan needs to be implemented by competent officers (³).

The computer library of the Faculty of Public Health is one of the largest laboratories at Universitas Airlangga. This laboratory is used as a research site,
and scientific measurement or training for about 15,000 students. The hazards which can occur in such place can be in the form of electric shock, tripping of cables, low back pain interference and fire or short circuit. The computer laboratory practicum are usually done 5 days a week. This laboratory is also supervised and protected by the Department of Biostatistics, Faculty of Public Health. This laboratory has not implemented the OHS Management System in spite of the number of thousands students participated in the laboratory which is potentially can cause hazards. Therefore, this place has bigger risk of accidents.

Based on the preliminary observation, hazard of electric shock or short circuit is a major hazard which has a high risk of causing fire. Power sources come from various types of cables connected to the computer and electric socket next to the computer desk. In addition, this laboratory has some rules which prohibited the students to wear any shoes or footwear and bring food or drink into the laboratory.

The objective of this study was to apply the Hazard Identification, Risk Assessment and Determining Control (HIRADC) method in the computer laboratory of the Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia.

**Material and Method**

Based on the analysis characteristics and system, this research is a descriptive research. Based on the length of time this research was conducted, this research belongs to a cross sectional study. In addition, based on the research site, this study is an observational study since the data is obtained through observation and interviews. The population of this research is the computer laboratory staff which consists of two people. The sample was taken using total sampling method. The research was conducted for one month in July 2018.

This study was completed by implementing HIRADC method. The first step was doing hazard identification which include analysis of work activities, sources of hazards and risks. The second step was doing risk assessment by considering the likelihood and severity of risk. The assessment process is done by multiplying the likelihood value and severity value. Furthermore, multiplication results are used to determine the level of risk with Low (L), Moderate (M), High (H), or Extreme (E) risk categories. And the last step is determining the controls that have been carried out by management and giving the recomendation.

The category level of Likelihood, Severity, and Risk Matriks accordance with AS/NZS 4360 standard (1,4).

### Findings

The activities conducted in student practicum in the computer laboratory of the Faculty of Public Health consist of seven activities, including taking off shoes before entering the laboratory, putting the bag into the laboratory’s locker, sitting on the seat, the lecture gives lectures using wired microphone, practicum preparation which include checking the computer equipment, the implementation of the computer practicum and the closing of computer practicum. According to the identification results, there are 17 potential hazards from all of the activities which can lead to 18 risks. After the hazards were identified in the practicum activities, the next step is to carry out the risk assessment. Based on the risk assessment conducted on all work activities, there are 18 risks classified into 2 risk levels, those are 3 risks with moderate risk level and 15 risks with low risk level. The three level of moderate risks include taking off the shoes in standing position which can cause sprains, there is no first aid box and using electric current which can cause short circuit, electric shock and fire risk. Then, the management’s existing control were giving advice to taking off the shoes in sitting position, covering the socket which has risky placement by using duct tape to avoid the risk of electric shock as well as the provision of a light fire extinguisher for fire risk and the last providing first aid kits to treat the accidents that occur in the laboratory as soon as possible.

### Hazard Identification

Hazard identification is a process that can be done to recognize the whole situation which potentially can cause occupational accidents and illness in the workplace. This research used the proactive method. Proactive methods are the best method for identifying hazards.

Laboratory regulations prohibit footwear from entering the computer laboratory, therefore students must take off their shoes and put them in the locker. The students usually take off their shoes in a standing position, which makes their body unbalanced and can cause their legs to dislocate. In a certain time, the floor in the front of the laboratory is sometimes slippery which can cause risks to the students.

The activity sitting on the chair was found a source of hazard, in which the sitting position which was less ergonomic for a long time can cause a low back pain disorder. According to Sumekar’s research (2010), a good sitting position caused 27 out of 65 respondents (41.5%) experienced low back pain, while in a bad sitting position, 11 of 12 respondents (91.7%) also experienced low back pain with a risk of 15,481 times.

The source of hazard in the computer practicum preparation activity was turning on the computer that can cause electric shock. The electric shock hazard during plugging in or removing an electronic cable can cause electric shock and weakness. Then, the second source of hazard is the use of electric current sources in the form of a socket which can cause a short circuit leading to fire and electric shock. This is due to the type and the placement of the socket which is appropriate. The third source of hazard is in the form of the sparks of the electrical cables installation which is unknown by the people since it is covered by the plywood, so that it can cause a fire. The fire extinguishers must be near the workplace to help extinguish the fire. The fourth source of hazard is the noise of a damaged computer that can cause hearing disorder. This has been
experienced by the students when they are operating a damaged computer. The fifth source of hazard is the unavailability of first aid kits in the laboratory. Based on the Law Number 1 of 1970 article 3 paragraph 1, one of the requirements for occupational safety is to provide first aid kits \(^9\). The absence of this equipment can make the injury occurred becomes worse.

The computer practicum implementation activity have two sources of hazard, those are ultraviolet (UV) radiation and cold temperatures in the laboratory. A long exposure to UV radiation from a monitor screen can cause eye disorders, which can lead to a disorder of Computer Vision Syndrome (CVS). When Computer Vision Syndrome is not treated well, it can decrease one’s daily work productivity, increase the level of error in work, and decrease the job satisfaction \(^10\).

The source of hazard in the form of cold temperatures in the laboratory can cause unbalance fluid or water on body (mild dehydration) with the symptoms of dry and cracked skin, sleepy, dry mouth as well as reduced saliva.

**Risk Assessment**

Risk assessment is the process of evaluating risks caused by hazards, taking into account the adequacy of controls owned, and determining whether the risks are acceptable or not \(^2\). This study used a qualitative risk assessment method according to AS/NZS 4360:2004 standard which consists of likelihood and severity criteria \(^4\). This method uses a risk matrix that describes the level of likelihood and severity of an event that is expressed in the form of a range from the lowest to the highest risk. The danger of taking off the shoes in standing position, there is no first aid and using electric current gets likelihood 2 value and severity value 3. If multiplied then gets a total value of 6. Value 6 is included in the moderate risk category in the risk matrix.

The danger of sitting less ergonomic for a long time get likelihood value of 3 and a severity value of 1. If multiplied then gets a total value of 3. The danger of turning on the computer get likelihood value of 2 and a severity value of 2. If multiplied then gets a total value of 4. This means that risk is included in the low risk category. The danger of sparks on electric cables under plywood get likelihood value of 1 and a severity value of 4. If multiplied then gets a total value of 4. The danger of damaged computer causes noise get likelihood value of 1 and a severity value of 3. If multiplied then gets a total value of 3. And the last, the danger of laboratory temperature is quite cold and ultra violet radiation from monitor screen gets likelihood value of 3 and a severity value of 1. If multiplied then gets a total value of 3. This means, all of the total values above are included in the low risk category in the risk matrix.

Work activities with *moderate risk* requires action to reduce risks including prevention costs that are needed to be carefully calculated and limited and measurement of risk reduction needs to be implemented properly and correctly \(^4\). Work activities with *low risk* does not require additional control measures, but requires monitoring actions to ensure that controls are maintained and implemented properly and correctly \(^4\).

**Determining Control**

Risk control plays a role in minimizing or reducing the level of risk to the lowest level. There are five hierarchies of risk control including elimination, substitution, engineering, administration and the use of personal protective equipment \(^2\). The determining controls carried out by the laboratory management were adjusted to the existing hazards, including:

For moderate risk, the determining controls were the student should taking off the shoes in sitting position to avoid sprains, covering the socket which has risky placement by using duct tape to avoid the risk of electric shock as well as regularly checking the socket to avoid the hazard risk of circuit and fire and the last providing first aid kits to treat the accidents that occur in the laboratory as soon as possible.

For low risk, the determining controls were chair design is adjusted to the computer desk to avoid musculoskeletal disorders on the student, giving a warning to carefully contact with the electrical appliance and attaching warning stickers to prohibit the students to bring food and drinks into the laboratory room to avoid the risk of electric shock and short circuit, checking the condition of the cable installation under the plywood and the provision of a light fire extinguisher for fire risk, do not operate the damage computer to avoid hearing disorders, and giving attention to rest their eyes for a moment after long facing the computer screen to avoid computer vision syndrome.

**Conclusions**

The computer laboratory of the Faculty of Public
Health, Airlangga University is used as a research site, measurement or scientific training for about 15,000 students. There are various types of activities which are at high risk, especially in the use of electricity, which can cause short-circuit and leads to fire. Based on HIRADC analysis, there are three level of moderate risks include taking off the shoes in standing position which can cause sprains, there is no first aid box and using electric current which can cause short circuit, electric shock and fire risk. Then, the management’s existing control were giving advice to taking off the shoes in sitting position, covering the socket which has risky placement by using duct tape to avoid the risk of electric shock as well as the provision of a light fire extinguisher for fire risk and the last providing first aid kits to treat the accidents that occur in the laboratory.

Abstract

Nursing managers have paid special attention to quality assessment as an important management tool for improving nursing performance and the quality of nursing care. This study aimed to evaluate the aspects and factors involved in the quality of nursing cares for dying patients in ICUs in 2016-7. This descriptive and analytical study was conducted in ICUs of Imam Khomeini Hospital Complex and Shahid Rajaei Cardiovascular Medical & Research Center, Tehran. In total, 191 working nurses were selected via convenience sampling. Data collection tool was quality patient care scale (QUALPACS). In addition, data analysis was performed in PSSS version 20 using descriptive and inferential statistics. The mean score for end-of-life care was 83.62±8.62 in the psychosocial, 85.36±7.74 in the communication and 92.23±10.88 in the physical aspects. According to the results, a significant relationship was observed between passing educational courses related to end-of-life care and quality of end-of-life care in the physical (P=0.002), psychosocial (P=0.02) and communication (P=0.01) aspects. According to the results of the study, the quality of care for dying patients was higher in the physical aspect, compared to other aspects. However, the quality of nursing care was poor in the psychosocial aspect.

Keywords: Quality, End-of-Life Care, Nursing Care, Intensive Care Unit

Introduction

Today, with the advancements in technology and new therapies in recent decades, we are faced with a high incidence and long-term hospitalization of critically ill patients in intensive care units (ICUs), which is accompanied with the suffering of the patient and the family without hope for improvement and, on the other hand, imposing heavy financial and mental burdens on the patient, the family and the health system. Helping patients in the final stages of life involves a period of the imminent death of patients. In this regard, the great number of demands and needs of patients and companions and stressful situations prevent participation in care decisions, caregivers' dissatisfaction, disregard for care details, and poor quality of care for patients.

Similar to other countries, with regard to the advances made in the field of medical and paramedical sciences, we are faced with a higher number of people in need of special care due to chronic diseases or problems caused by life-threatening and incurable diseases in Iran. Recently, national attention and focus have been on the provision of end-of-life care, where palliative care is the center of attention and includes a range of management of physical, mental, and social sufferings associated with health status for which the treatable cure is not a remedy.

In the field of modern medical ethics, special attention has been paid to the rights of patients (6). All over the world, numerous differences are observed in end-of-life treatment methods for dying patients considering the ethical principles (7). While the goal of end-of-life care is death with dignity and respect, its concept is vague in articles and has no comprehensive definition (8).

Nurses and physicians in intensive care units (ICU) are a group of professional healthcare providers, who deal with problems related to end-of-life care on a daily basis (1). While nurses all over the world share many commonalities in terms of different physical, psychological, and social needs of patients, there are differences in patterns of end-of-life care that are rooted primarily in the culture and beliefs of the community (9).

Since nurses are the largest group of medical staff in the hospital to provide care services (10, 11), Quality is a multi-dimensional concept with mental, social, and spiritual aspects (12). The quality of care provided is an important factor in the satisfaction of patients and their families and even the job satisfaction of nurses in the health system and is recognized as a priority of the health care system, especially in the field of nursing. In most countries, including Iran, a hospital’s grading and accreditation are influenced by the quality of nursing care provided and is assessed along with other validation measures (13, 14). In Iran, Haghighi and Khoshkhoo (2004) confirmed the validity and reliability of this scale in a research conducted to assess the quality of nursing cares from the perspective of nurses and patients hospitalized in training healthcare centers affiliated to Tabriz University of Medical Sciences, Tabriz, Iran (16).

In addition, the scale was used in studies by Akbari Kaji and Farahmini (2009) and Neyshabouri et al. (2010) (17, 18). In the present study, the reliability of this tool was confirmed at 0.82 using the split-half method. Data analysis was performed in SPSS version 20 using Chi-square, correlation bivariate, and Pearson’s correlation to assess descriptive and inferential statistics. Moreover, P-value of less than 0.05 was considered statistically significant.

Results

In this study, the majority of nurses (54.5%) were within the age range of 30-40 years. In addition, 74.3% of the participants were female, whereas 51.3% of the subjects were married. In terms of work experience, 58.1% had less than 10 years of work experience. Moreover, 59.7% of the nurses had permanent contracts, and 136 subjects were working in special surgical sections, including heart surgery, transplantation, neurology, cancer, and gynecology. Furthermore, 87.4% of nurses had a BSc degree, and 66.5% of the subjects were highly interested in working in ICUs.

Statistical tests demonstrated a significant relationship between the physical aspect and type of employment (P=0.01), the experience of the death of a family member or close friend (P=0.005), passing critical care courses (P=0.03), and gender (P=0.02). (Table 1).

The quality of end-of-life care for dying patients showed an undesirable level (46.1%=low) considering the overall score of end-of-life care areas, which was favorable (53.9%=moderate). In addition, the mean score of end-of-life care in the psychosocial aspect was 83.62±8.63 (%37.7 favorable and 62.3% lower), whereas the same mean in the communication aspect was 85.36±7.74. In addition, the mean score of end-of-life care in physical aspect was 92.23±10.88 (Table 2). Moreover, the score of psychosocial aspect of end-of-life care in ICUs of Imam Khomeini and Shahid Rajaei Cardiovascular Medical Center of Tehran was reported to be 82.61±8.52 and 85.42±8.59, respectively.

According to correlation bivariate analysis, the level of correlation between psychosocial aspect with the physical aspect (R=0.7, P=0.001) and between psychosocial aspect with the physical aspect (R=0.6, P=0.001) was significant and direct. On the other hand, a reverse association was found between the physical aspect and psychosocial aspect (R=-0.7, P=0.001) (Table 3).

Discussion

The results showed that the total mean quality of end-of-life care provided by nurses in ICU was desirable while the quality of nursing care was undesirable in the psychosocial aspect and desirable in the communication and physical aspects. Similar results showed that the quality of care in the psychosocial aspect was desirable from the perspective of 31.6% patients and 92.6% nurses. In the communication aspects, quality of care was favorable from the viewpoint of 24.7% of patients and 56.8% of nurses. In the psychosocial aspect, 73.5% of patients stated that nurses would rarely introduce themselves to patients. Moreover, 77.9% claimed that new patients were rarely introduced to patients. In the communication aspect, 42.5% of patients stated that they were rarely assured of the confidentiality terms (19).

Although various studies conducted in Iran have demonstrated attention to functional and care aspects, studies have shown that lack of time and fatigue, and any factor that leads to a negative attitude and emotional stress in nurses, can result in emotional and physical withdrawal of nurses from patients, and in many cases, neglecting the emotional needs of patients and ignoring the aspects of care quality (20,15). Meanwhile, nurses are legally and morally responsible for the quality of care they provide and must be aware that both psychosocial aspects, as well as their expertise and skills in providing care, are effective in understanding the quality of care by patients.

Since nurses primarily aim to meet the basic needs through communication, intervention and assisting in treatment, these communications must be increased and
appropriate and accurate care must be provided so that patient satisfaction could be ultimately achieved (21). By better identification of the quality of nursing care for dying patients (in the face of death), we can provide evidence-based care and reduce the severity of illness in the final stages of life. Convincing evidence has shown that the inadequate association between the ICU group and the family members of patients is common, which can have serious consequences. When ICU staff are not well-trained in this aspect, families often regard communication with ICU personnel as a major concern. Accurate, sensitive, and inclusive communication is the key to the success of the discussion and the problems that arise in end-of-life care (16).

Statistical tests showed that the correlation between psychosocial aspect and the physical aspect was direct and significant since the increase in social psychosocial score was associated with an increased score of the physical aspect. In this respect, Izadji et al. (2013) marked that the highest priority of caring behaviors by nurses was related to a relationship based on trust and emotional and physical well-being of patients, whereas the availability and anticipation of the needs of patients was the last care priority, which could reduce the quality of care (22). According to the results of the present research, end-of-life care had a higher quality in the physical aspect, compared to communication and psychosocial aspects. In addition, the professional attitude of nurses toward the subject of death affected caring for dying patients. Therefore, discussion of attitudes toward death, including the inevitability of death and fear of death, must be included in the education of these individuals.

**Ethical Clearance:** This article is the result of a research project (a master’s thesis critical care nursing) approved by the in Shahid Rajaei Cardiovascular Research and Academic Center. After the necessary coordination and receiving the relevant licenses, the researcher met with the subjects at their working hour in the hospital to introduce himself, explain about the objectives of the research, and obtain oral and written consents prior to the research. Moreover, the participants were assured of the confidentiality terms regarding their personal information since the questionnaires would be completed anonymously.

**Conflicts of Interest:** None declared

**Funding:** This study was conducted without the financial support of the committee or organization.

Effect of Crude Bacteriocin Isolated from Locally *Lactococcus lactis* on Cancer Cell Lines

Mariam T. Abbdul -Kaliq¹, Khetam H. Rasool¹ and Rajwa Hasen Essa¹

¹Department of Biology, College of Science, Mustansiriyah University, Baghdad-Iraq

Abstract

*Lactococcus lactis* is a Gram-positive bacterium used widely in the production of cheese and buttermilk, but has moreover become well-known as the first genetically modified organism to be used alive for the treatment of human diseases. This study was designed to display the efficacy of lactococcus lactis, which was isolated from raw cow’s milk isolated by using the liquid MRS agar, culture, and microscopically was tested moreover, chemically was also tested to check the presence of (catalase, oxidase, protease production, gelatinease, clot formation). The isolates were confirmed using molecular diagnosis. The Bacterial isolates were developed on the M17 liquid medium at 30 °C for 24 hrs to obtain the raw bacteriocin after separation by centrifuge. The toxicity and bacterial susceptibility was tested as well the effect of Bacteriocin on *E.coli*, *P.aerugionsa*, *staph.areus*. The results showed a clear inhibitory effect of bacteriocin on pathogenic bacteria. The toxic effect of crude bacteriocin was investigated and its effect on cancer cell lines of breast cancer cells (MCF-7) lymphoid cell line (CCL-119) using different concentrations of the extract. The toxic effect was also examined on normal liver cell lines (WRL) with a 72 hrs incubation period. The results show a clear and high-significant effect of crude bacteriocin on cancer cells. It was also observed that the severity of toxicity increased with the increases of concentration with no effect on normal cell lines.

Keywords: lactococcus lactis, cow milk, bacteriocin, cancer cell lines.

Introduction

Lactic Acid Bacteria (LAB) are beneficial microorganisms and contribute to develop people fitness. These beneficial bacteria are alive microorganism which is necessary for mammalian healthiness. Probiotic bacterial strain comprise of bacteria belongs to *Bifidobacterium*, *Lactobacillus* groups, these group are varied include numerous kinds of bacterial strain, the probiotic term refers to nutritious matters. That benefit bacteria can grow above benefit strain and have ability to produce bacteriocin that found in raw caw milk, heterogenous group of bacteriocins with anti-microbial activity. Bacteriocins are protein that have different spectrum of activity mode of action, biochemical properties, genetic origin, and molecular weight. Probiotic bacterial strain can be isolated and identified from this diet product, LAB is one of the greatest groups of probiotic organisms (¹, ²).

*lactococcus* are helpful bacteria that inhibit the growth of pathogen, stimulate digestion, improve immune function and rise resistance to infectious diseases, in addition to its physiological aids in eliminating carcinogens. In spite of development in care, medication, recognition and the presence chemotherapeutic treatment, the disadvantage of cancer treatment remains non-specific in damaging the normal body cells, beside that cancer cell during the course of treatment has ability to improve resistance to chemotherapy, as a result, it’s difficult to treat cancer cell by using usual anticancer drugs, therefore, the request for different anticancer therapy is very necessary to develop a unique biological control methodology (³-⁵).

Bacteriocin is a complex protein produced from LAB and used therapeutically; it is rapidly digested by the protease enzyme and have an inhibitory effect on Gram-positive bacteria by directing the (cell envelope-associated mechanisms), several types of bacteriocins such as antibiotics and some class II bacteriocins target Lipid II found in the middle in the biosynthesis of peptidoglycan in the envelope of the bacterial cell in this way they are capable to inhibit peptidoglycan synthesis, other bacteriocins have the potential to destroy the target
cell by inhibiting gene expression (6).

The bacteria products that contain toxins, several proteins, bacterial enzymes, diverse peptides with low molecular weight products also have anticancer properties though, merely a rare of these peptides considered as anticancer, these peptides are modified by bioengineering technique (7, 8).

In this study the researchers display the efficacy of lactococcus lactis, which was isolated from raw cow’s milk isolated and was tested against microbes and breast cancer cell lines (MCF-7).

**Material and Method**

**Lactic acid bacteria Isolation and Identification**

Thirty sample of goat and cow milk were collected from different barn in Baghdad. The lactation period was under sterile conditions in hygienic cap and was transferred to Graduate Laboratory, treated within 1 hr. Milk sample was diluted with distilled water, after that a serial of dilution and culture on M17 and MRS media. All colonies cultures were purified by subculture on the same media and incubated at 30 °C for 24 hrs. Cultures were tested its morphology, physiological, biochemical features and molecular characteristics up to the genetic level.

**Identification of lactococcus bacteria by sequencing of the 16S rRNA gene**

The genomic DNA was isolated from the isolate. Amplification of the 16s rRNA gene was performed using the universal primers. Sequence analysis was carried out using NCBI online tools. DNA extraction from bacteria using G- Spin DNA extraction kit, intron biotechnology, Cat. No. 17045.

**Sequencing and Sequence Alignment**

The Polymerase Chain Reaction (PCR) products were alienated on a (2%) agarose gel electrophoresis and U.V spectrum at 302 nm after staining, gene sequencing was done by National Instrumentation Center for Environmental Management (NICEM) online at, biotechnology lab, machine used for DNA sequence was 3730XL, similar search was directed using Basic Local Alignment Search Technique (BLAST) which is available at the National Center Biotechnology Information online at (http:// www.ncbi.nlm.nih.gov).

**Screening and identification of bacteriocin producing strain**

The first step to detect the bacteriocin production was to assess the inhibitory effect of the isolated bacteria through microbiological tests by using disc diffusion test.

**Indicator bacteria used in the study**

Indicator pathogenic bacteria and biofilm formation belong to the different genera were used in capping plate method, and agar well diffusion method for selection bacteriocin activity, Gram positive bacteria *Staphylococcus aureus* and two strains of Gram negative bacteria *Pseudomonas aeruginosa*, *Escherichia coli* were collect from Medical City Hospital-Baghdad.

**Bacteriocin production media**

MRS and M17 modified media was prepared to increase bacteriocin production composed from:

Effect of bacteriocin on CCL-119 and MCF-7 cancer cell line used in this study

*(MCF-7) cancer cell line*

Brest cancer cell was derivative from the pleural effusion from female 69 year old Michigan—cancer-foundation, (MCF-7) regret from a breast adenocarcinoma.

*(CCL-119) cancers cell line*

(ATCC No. CCL-119™) cell line collected from tissue peripheral blood type of T lymphoblast cancer occurred in patient with acute lymphoblastic leukemia.

*(WRL-68) normal cell line*

Hepatic cell line was gathered from human body (WRL 68) that exhibit morphology like to hepatic primary cultures and hepatocytes and, cells have been revealed to secrete alpha-feto protein ,albumin , and precise liver enzymes such as (alanine amino transferase) (9). Cytotoxicity influence crude bacteriocin that was
isolated from L. lactis and was carry out by via (MTT) protocol by using ready kit:

Contents of Kit:

a. Solution MTT (1 ml x 10) vials.

b. Solubilize solution (50 ml x 2) bottle.

Detection Caspase (9) Assay in CCL-119 and MCF-7 Cell Line (10).

This assay is a standardized glowing assay that measures activity of caspase-(9) that play a key role in the (intrinsic apoptotic pathway) of animal and human cells.

Contents of kit:

a- CaspaseGlo9 (Buffer1 × 10mL).

b- CaspaseGlo9 Substrate lyophilized.

c- (MG 132) Inhibitor 30 μL.

Result and Discussion

L. lactis Cultural Characteristics

Cultural for bacterial isolates carried on when isolated bacteria grown on MRS agar and M17 agar plates. On M17 agar, L. lactis colonies were seemed with distinctive features as a pure white colony, the size of the colony was small (2-3 mm). After that, identification of the isolates was carried out by measuring its ability to form clot on both skim milk, and lysis skim milk.

Molecular identification of L. lactis subsp.lactis

After genomic extraction of the DNA from L. lactis which was carried out via (PCR) and gel electrophoresis and recognize the L. lactis using 16S RNA, PCR was accomplish on an unpolluted DNA template to every bacterial isolates particularly for intensification of (16S RNA) by using (oligonucleotide primer), which increase the existence of DNA.

Thermo stable polymerase with (Mg ions) in a buffer solution was added to PCR, denaturation was used to separate both strand, and then temperature was lowered to start the primer annealing. The initial temperature was around (72 °C) which is ideal for the polymerase to extend the primer with the incorporation of (dNtp), the results indicate the bacterial isolates were L. lactis subsp. lactis . The primer that was use produced (1250 bp) and was appear in electrophoresis gel and was measured using a (100 bp) of DNA ladder.

It was found that the greatest number of the isolates can prevent the growth of *S. aureus*, *p. aeruginosa* and *E. coli* (11). Consuming raw cow milk and fermented products can assist human health, fitness and defend the body against probiotic infection (12).

Raw camel milk analysis usually shows the presence of *L. pentosus*, *L. plantarum*, and *L. lactis* as probiotic lactic acid bacteria (13) and it could be a source to isolate probiotic (LAB) strains, furthermore it can be considered as an antimicrobial against pathogenic bacteria due to the presence of bacteriocin production (13).

**Bacteriocin cytotoxicity on normal and cancer cell lines using MTT assay**

MTT assay was achieved to determine the (IC$_{50}$) for crude bacteriocin on human breast cancer cell line (MCF7), lymphoblast leukemia (CCL 119), and normal embryonic liver cell line (WRL-6).

Data analysis carried out in ($\mu$g/ml) and the log value ($\mu$g/ml) and plotted in graph cushion prism using log Inhibitor against regularized response curve. Greatest values were selected for the maximum significant (IC$_{50}$) values. Cell viability at each time-point was firm by MTT colorimetric assay.

Figure 1 shows crude bacteriocin was potent cytotoxic effect CCL-119 cells and the (IC$_{50}$) concentration. The value of crude bacteriocin after 24 hrs of incubation at 37 °C was 322.8 µg /ml.

Table 1 shows the diameter of inhibition zone of crude bacteriocin on pathogenic biofilm formation bacteria with different ammonium sulfate saturation

**Table 1: Inhibition zone diameter with different ammonium sulfate**

<td>E.coli</td>
<td>15</td>
</tr>
</tbody>
</table>

Figure 2 shows that the crude bacteriocin has moderate cytotoxic effect on MCF7 cell line, and the IC$_{50}$ after 24 hours of incubation at 37 °C was 614 µg/ml.

Figure 3 show that the crude bacteriocin has little cytotoxic effect on WRL-68 cells and the IC$_{50}$ after 24 hrs and 37 °C (1486 µg/ml).

From above, it is clear that the CCL-119 cells has high sensitivity toward crude bacteriocin than MCF-7 and human liver WRL-68.
The cell wall proteins of *L. lactis* have an obvious cytotoxic effect in growth inhibition of *Acute* myeloid leukemia cell line as well as Human Epithelial type 2 tumor cell lines *in vitro* depending on both concentration and time (14). Similar results recorded by (Vajihe Akbari, 2017), he found that bacteriocin produced by *lactococcus lactis* have cytotoxic effect on MCF7 breast cancer cell lines and slight cytotoxic effect on Human umbilical vein endothelial cells (HUVECs) normal cell line (15). Polysaccharides show less cytotoxic effect toward normal kidney (16).

The exact mechanism of anti-cancer effect of NISIN (Substance which is a mixture of related polypeptides) remains to be unexplained, studies have suggested several mechanisms including cell membrane disruption and pore formation that cause the altering to the level of intracellular ions, which lead to the changing in the trans membrane potential, and induct the cell cycle arrest and leads to cell apoptosis (17).

New Bio-Therapeutic Candidate for Pancreatic Cancer

Marwah Saad Joudah¹, Basma Talib Al-Sudani², Inam Sameh Arif³

¹College of Pharmacy, Branch of Toxicology, Mustansiriyah University, Iraq,
²College of Pharmacy, Branch of Clinical Laboratory Sciences, Mustansiriyah University, Iraq

Abstract

SIRT1 is NAD⁺-deacetylases, several histone and non-histone proteins which their involvement in metabolic processes, cell growth, apoptosis, and senescence are well known. Several Sirtuins targets are implicated in cancer. SIRT1 is both an oncogene and tumour suppressor, and it can act in this capacity depending on the kind of tissue and the cancer etiology. Subsequent studies in this field are going to make evident the exact function of SIRT1 at the cancer site and it is hoped that new chemotherapeutic functions of SIRT1 activators are going to be determined. In accordance with this, it is suggested that very selective ligands such as aptamer was created and investigated in various pancreatic cancer cell lines for the regulated activity of SIRT1. This study seeks to establish the therapeutic impact of the activator SIRT1 aptamer as a pharmacological model of pancreatic cancer by evaluating the impacts of activators SIRT1 (aptamer) on the growth of a series of human pancreatic cancer cell lines (AsPC-1, Capan-2, BxPC-3). Results gotten from in vitro cytotoxicity assays revealed that circular aptamer BAS inhibited the growth of pancreatic cancer cell lines [BxPc-3 (80%), Capan-2 (83%) and Aspc-1 (82.8%)] at 72h with IC₅₀ 0.55, 0.5, 0.76 µM respectively. Importantly, circular aptamer showed no reduction of cell viability on the non-pancreatic cancerous H6c7 cell line, implying it might be safe to non-cancerous tissue. Our results indicate that the SIRT1 activated by aptamer could a promising targeted therapeutic approach for pancreatic cancer.

Keywords: aptamer, pancreatic cancer, SIRT1.

Introduction

Pancreatic cancer is considered as a deadly tumor with no improvement in its prognosis regardless of the recent progress in cancer interventions. Many of the interventions for pancreatic cancers are associated with disappointing results. Though curative surgery is associated great benefits, it is hard to achieve in most advanced pancreatic cancers. Interventions such as conventional chemotherapy, radiation therapy, and even targeted chemotherapy have shown disappointing results. Therapies for target tumors by using monoclonal antibodies are the most thriving cancer therapies ¹; however, there are different limiting factors. These limiting factors include high costs and low penetration to tissue ². There is a need for the development of more efficacious and cost-effective targeted interventions. Aptamer (ssDNA, RNA or peptide oligomers) have been extensively studied for their therapeutic properties ³. Al –Sudani, 2017 was selected a circular aptamer against SIRT1 as used to treated many of cancer cell by activation of SIRT1 ⁴. Deacetylation of histones and non-histones proteins is by SIRT1. These histones and non-histone proteins are implicated in a variety of biochemical activities. These biochemical activities include metabolism, cell growth, apoptosis, and senescence ⁵. The function of SIRT1 in tumorigenesis and cancer advancement is not fully understood but it was stated that its function could be tissue-type and context specific ⁶. Pancreatic adenocarcinoma up-regulated factor (PAUF) is known to induce a swift spread of pancreatic cells by up-regulating b-catenin. This is based on the postulation that b-catenin could be a target molecule for pancreatic cancer therapy with a speculation that whether there is SIRT1 suppression of b-catenin in pancreatic cancer cells that express PAUF (Panc-PAUF). It is suggested that evaluation of such suppression could result in inhibition of the proliferation of these cells. The amounts of b-catenin protein and its transcriptional role in Panc-PAUF cells are (SIRT1 activator) siRNA improves b-catenin expression and transcriptional activity. Through the down-regulation of cylin-D1, activation of SIRT1 leads to inhibition of the growth of Panc-PAUF cells. Cyclin-D1 is a
target molecule of b-catenin. This project aimed to evaluate the therapeutic effect of the activator SIRT1 aptamer (BAS aptamer) as a pharmacological model for pancreatic cancer cells.

**Methodology**

**Cell culture**

Human pancreatic cancer cells: AsPC-1, Capan-2, and BxPC-3 were gotten from American Type Culture Collection ATCC (Middlesex, UK). Human pancreatic normal cells: H6c7 were bought from Kerafast (Boston, USA). Capan-2 cells was preserved in McCoy’s 5A Medium, AsPC-1 and BxPC-3 cells were stabilized in Roswell Park Memorial Institute-1640 (RPMI-1640) medium, all media were enhanced with 10% fetal bovine serum FBS and 1% L Glutamine as well as to 1% Penicillin-Streptomycin-Amphotericin B 100X as an antiseptic. H6c7 cells were maintained in Keratinocyte SFM + EGF + bovine pituitary extract (Invitrogen). Then they were supplemented with 1x antibiotic-antimycotic (Gibco). Cells were cultured in 75cm² flasks and incubation carried out in 5% CO₂/95% humidified air at 37°C. Once the cells reached 90% confluency, flasks containing Capan-2, BxPC-3, and AsPC-1 were kept under sterile conditions. The cells were subjected to washing with 5 ml of phosphate buffered saline solution (PBS) and then incubate for 2 min in trypsin solution at 37°C to permit cells to separate from the bottom of the flask. Addition of an equal volume of complete growth media was done, and the cell suspension was moved into a 50ml conical tube. Centrifugation of the cells was performed at 1200 rpm for 3 min. Separation of the supernatant was done, and the cell pellet underwent re-suspension in fresh supplemented growth media. Cells were counted under the microscope on a haemocytometer and use as required. The cells were stored at -80 °C for 24hrs and then were stored under liquid nitrogen.

**Cell viability by MTT assay**

The MTT assay was used assessing the effects of aptamer on pancreatic cancer cell viability. A 100 μl from all cells suspensions (Capan-2, BxPC-3, AsPC-1 and H6c7) were dispense into 96-well flat-bottom tissue culture plates at concentrations of 5 x 10³ cells per well and were incubated 24h under standard conditions; 4 x 10³ cells/well for 48h incubation, and 3 x 10³ cells/well for 72h incubation. After 24 h, the cells would have treated with 2.5 μM circular aptamer (BAS). After a recovery period 24h, 48h and 72h, the cell culture medium was removed and cultures was incubated with medium containing 30 μl of MTT solution (3 mg/ml MTT in PBS) (3-(4,5-Dimethylthiazol-2-yl)-2,5-Diphenyltetrazolium Bromide) for 4h at 37°C. After 4h this medium was done with by gentle inversion and tapping onto paper. Control wells receive only 100 μl growth media. 100 μl of dimethyl sulfoxide (DMSO) was added to all wells, the plates were then kept at room temperature in the dark for about 15-20 min. The absorbance of each well was measured by multi-scan reader at a wavelength of 540 nm and correcting for background absorbance using a wavelength of 650 nm. IC₅₀ was evaluated by MTT assay at 72h after the cells exposure to aptamer. The concentration range used for circular aptamer (BAS) are, 0.0078, 0.0156, 0.0312, 0.625, 0.125, 0.25, 0.5, 1.00 μM.

**Immunofluorescence microscopy**

The seeding of the cells was performed at roughly 10,000 cells per well in 96-well clear bottom imaging tissue culture plates. Eighteen hours later, cells were treated with 1μM circular aptamer (BAS) and incubation done in 5% CO₂/95% humidified air at 37°C overnight, after that the washing of the cells was done thrice in PBS, fixing for 5mins at room temperature with Formalin 4%, washing 2 times in PBS, then will be permeabilised by 0.5% Triton X-100 for 5mins, washing 3 times with PBS; nonspecific binding was obstructed with 3% FBS for 1h at room temperature, then the blocking solution was removed, followed by an addition of 100 μl/well of Anti-Sirtuin1 antibody to the cells. After that incubation was done overnight at 4°C in a wet tray. The following day, cells will be washed thrice in PBS, and incubated for 2h in dark at room temperature with 1:2000 Alexa Fluor 546 goat anti-mouse IgG (AF546)/1% FBS in PBS. Thereafter the washing of the cells was done thrice in PBS. At the end, the preparation was treated with 10 μl mounting medium containing DAPI for staining cell nuclei. It was left for 1hr before the microscopic examination using fluorescence microscopy.

**Results**

**Cell viability by MTT assay**

The cell viability of circular aptamer, at 2.5μM concentration shows it is extremely active on the different pancreatic cancer cells up to a period of 72 hours. As demonstrated in figure 1, BxPC-3,Capan-2 and Aspc-1 cells demonstrated to be highly sensitive with an increase response dependent on time (cell death around
80%, 83% and 82.8% at 72h, respectively). Importantly, circular aptamer showed no reduction of cell viability on the non-cancerous H6c7, implying it might be safe to non-cancerous tissue. The IC50 of circular aptamer was very low concentration (0.55, 0.5, 0.76 µM) in BxPc-3, Capan-2, and Aspc-1 cells respectively.

Figure 1: Cell viability studies on different pancreatic cancer cell lines, at 24, 48 and 72h of incubation. All samples were run in triplicate, control is expressed as 100% viable cells. Cells were challenged with circular aptamer at 2.5µM. At 24h the cell viability was as: 79%, 28, 37, and 67 for Aspc-1, BxPc-3, Capan-2, and H6c7 respectively. At 48h the cell viability was as: 89%, 24, 19, and 56 for Aspc-1, BxPc-3, Capan-2, and H6c7 respectively. At 72h the cell viability was as: 88%, 20, 17, and 17.2 for Aspc-1, BxPc-3, Capan-2, and H6c7 respectively.

Determine the Location of Circular Aptamer by Fluorescence Microscopy

To determine the location of the circular aptamer, fluorescence microscopy was used in this experiment. The circular aptamer was labelled with green fluorescent, DAPI (4’, 6-Diamidino-2-Phenylindole, Dihydrochloride) was utilized for locating the nuclei and a Texas Red (sulfonyl chloride) antibody for SIRT1. The cells were dosed with circular aptamer at a low concentration to avoid cell death depending on their IC50. Thus, figure 2 showed that fluorescence microscopy is very useful tool for studying the location of circular aptamer in cancer and non-cancer cell lines. Cells treated with circular aptamer were brightly fluorescent and over-expression of SIRT1 as showed in figures 2. In contrast, there was no observable fluorescence signal from control H6c7 cells treated with the circular aptamer.

As a figure 2 shown the localization of SIRT1 in BxPc-3 and Capan-2 cells in the cytoplasm of these cells, while in AsPC-1 and H6c7 cells, the SIRT1 was localized in the nucleus. These results strongly suggested that this aptamer is highly affinity and selectivity binding with SIRT1 as the results of fluorescent imaging shown that when the aptamer present in this cancer cells it could be activated and increased the expression of the SIRT1 enzyme.

Figure 2: Fluorescence microscopy analysis of circular aptamer binding to SIRT1 enzyme in BxPC-3, Capan-2, AsPC-1 and H6c7 cell lines. Cells pretreated with 1 µM circular aptamer. Circular aptamer was labelled with green fluorescent, nuclei were stained with DAPI (Blue) and a Texas Red antibody for SIRT1 (Red). Fluorescence intensity were measured by luminometer microplate Readers, fluorescence measurement system with an excitation wavelength of 395, 359 and 596 nm and an emission wavelength of 509, 461 and 615 nm of GFP, DAPI and Texas Red respectively. Images were taken at a magnification of 100X.

Discussion

This study investigated oligonucleotide aptamer and its usefulness for anticancer drug discovery. Our study has provided information concerning the usage of MTT assay in assessing the inhibitory effect of SIRT1-aptamers on viability of BxPc-3, Capan-2, and Aspc-1 cell lines and non-cancer cells (H6c7). Our experiments using Aspc-1, BxPc-3, and Capan-2 cancer cell lines demonstrates that circular aptamer BAS has a growth suppressor characteristics. Kabra, (2010) was found that knockdown of SIRT1 raises the percentage of tumour advance by promoting cell spread, whereas over-expression of SIRT1 decreases tumour induction and expansion in nude mice 8. This result is in agreement with our suggestion that the pharmacological activation of SIRT1 by aptamer causes reduction of the rate of cell viability in Aspc-1, BxPc-3, and Capan-2 cell lines as shown in figure 1. Our results indicate that SIRT1 works as a context-dependent tumour suppressor. Also activation of SIRT1 causes suppression of tumour initiation and promotion of cell death. The anti-apoptotic role of SIRT1 is well known and it is rooted in the assumption that SIRT1 acts as an oncogene. However, it was revealed that transgenic mice over-expressing SIRT1 decreased the progress of neoplasia in the intestine caused by ApcMin mutation, this suggests a tumour inhibitory function of SIRT1 9. Many studies have pointed out that
SIRT1 could behave as an oncogene. This is possible because of the higher association of normal expression of SIRT1 level in specific tumors than normal tissue. In contrast, Kabra, (2010) established that SIRT1 levels are uneven in various phases of colon cancer tumours. It has been reported that SIRT1 has both oncogenic and tumour-suppressive functions. The expression of SIRT1 at high levels shows that SIRT1 is effective in inducing G1 arrest. Indeed, our results confirmed these previous suggestions that activators of SIRT1 by circular aptamer could have therapeutic potential as an anti-cancer target. Another condition is that activators of SIRT1 could affect cancer blocking impacts by promoting the growth-inhibitory impact of SIRT1 in cancer cell line, and revealed the decrease level of intracellular ROS production. Through direct deacetylation the inactivation of the p65 subunit of NF-κB is caused by SIRT1. Inhibition of NF-κB causes suppression of the iNOS (inducible nitric oxide synthase are a family of enzymes catalysing the production of nitric oxide (NO) from L-arginine) and thus could decrease the cellular ROS load. To advance our study the role of SIRT1, circular aptamer was used to study the activity of SIRT1 in (BxPc-3, Capan-2, and Aspc-1) cells. The results observed in this study are consistent with several research groups have reported that resveratrol which activator SIRT1 was inhibited much more cancer cells proliferation such as Caco-2, MCF-7, A549, U2OS, MDA-MB-468 and HepG2. Interestingly, it has been demonstrated that there is not effect to used SIRT1-aptamers on H6c7 cells viability, which indicating that circular aptamer have actively killing cancer cells without affecting normal cells. The IC_{50} of circular aptamer was very low concentration (0.55, 0.5, 0.76 µM) in BxPc-3, Capan-2, and Aspc-1 cells respectively. This low concentration of IC_{50} is very good results because the low dose of circular aptamer can suppress the spread of cancer cells. To study the localization of SIRT1 in these cells, fluorescence microscopy was used and the results were showed the different location of SIRT1 between cytoplasm and nuclei depending on the type of cells. As a figure 5 shown the localization of SIRT1 in BxPc-3 and Capan-2 cells in the cytoplasm of these cells, while in AsPC-1 and H6c7 cells, the SIRT1 was localized in the nucleus.

In Conclusion, the results provided here indicate that circular aptamer could be effective in treating pancreatic cancer because its properties of a growth suppressor for specific killing of the tumor cells only avoiding unpleasant side effects from damage to the rest of the body. Additional research works are required, for instance, the cellular mechanisms of action of SIRT1 in aptamer-mediated apoptosis still needs a lot of study.

Acknowledgment: The authors show their appreciation to the Mustansiryiah University (www.uomustansiryiah.edu.iq), Baghdad-Iraq for assistance rendered. We also show our gratitude to the Salford University for allowing us to use their laboratory for our selected aptamer.

Infanticides in Dakar: Medico-Legal Aspects

Mohamed Maniboliot Soumah1, 2, Peace Renée Senami Akokbegan3, Mor Ndiaye1
1Forensic Medicine and Occupational Health Service, Faculty of Medicine, Pharmacy and Odontology, University Cheikh Anta Diop, Dakar, Senegal, 2General Hospital of Grand-Yoff, Dakar, Senegal, 3University Elhadji Ibrahima Niasse/ Saint Christopher School of Medicine, Senegal

Abstract

Infanticide is a crime that evokes emotion and misunderstanding in the general population. The overall objective was to assess the current situation regarding the killing of new-born children in Dakar. This is a cross-sectional, descriptive study spread over a 12-year period from 1 January 2004 to 31 December 2015. The study population was women accused of infanticide incarcerated in the prison and correctional facility of Liberté 6 and who had either been tried or who were awaiting trial during the study period. The 46 cases tried concerned 47 newborns and one mother having killed both her babies. The victims were found especially in the mother’s home (28 cases) For all women in our sample, the murder was motivated by personal, social and economic factors. The average age of the mothers was 25.5 years with the youngest being 17 years old and the oldest 41 years old. These detention periods ranged from 2 to 6 years. The average length of pre-trial detention was 3.26 years, The preventive strategies put in place in some countries are proof that prevention against these acts remains possible.

Keywords: murder, newborn, pregnancy, asphyxia

Introduction

Infanticide is a crime that evokes emotion and misunderstanding in the general population. Our desire to better understand this issue of maternal child murder stems from the magnitude of the phenomenon. The overall objective was to assess the current situation regarding the killing of new-born children in Dakar. The specific objectives were to describe the epidemiology of infanticides in the general population of the Dakar department; The aim was also to describe the socio-demographic, economic, cultural and psychopathological factors involved in the occurrence of this phenomenon and to propose strategies to prevent such acts.

Material and Method

The study took place in two sites in Dakar: The Court (Palais de Justice) and the Detention and Correctional Facility (Maison d’Arrêt et de Correction) of Liberté 6. As of 27 April 2016, there were about one hundred prisoners, including 26 women suspected of infanticide, who agreed to answer our questions. This is a cross-sectional, descriptive study spread over a 12-year period from 1 January 2004 to 31 December 2015. The study population was women accused of infanticide incarcerated in the prison and correctional facility of Liberté 6 and who had either been tried or who were awaiting trial during the study period. We included in this study women convicted of infanticide whose criminal records are exploitable and women accused or detained for infanticide at the Liberté 6 Detention and Correctional Facility and who responded to our questionnaire. The data was collected on the survey sheet. Data entry and analysis were respectively performed on Epidata Entry version 3.1 and Epidata Analysis software.

Results

The results which follow concern both convicted women and women accused (pre-trial detention) of infanticide. We identified 70 cases of infanticide over the period January 2004 to December 2015 in the Dakar region. Of the 70 cases recorded, we have a group of 46...
women who have been tried and sentenced and another group of 24 women who are in pre-trial detention or awaiting trial. In the latter group, the women concerned were incarcerated in the penitentiary establishment of Liberté 6. Due to the secrecy of the investigation, the study of the group of accused persons concerned only demographic, socio-economic and cultural data. The study of the convicted group covered demographic, socio-economic, cultural and forensic data. The 46 cases tried concerned 47 newborns and one mother having killed both her babies.

The facts were brought to the attention of the police authorities by denunciation of individuals in 35 cases and by judicial reporting of a hospital structure in 11 cases of which 8 of these were due to an immediate postpartum haemorrhagic complication and 3 due to suspicious death reports.

Of the 46 files available, almost all victims were found. In two cases, the bodies of the new-borns were never found. The victims were found especially in the mother’s home (28 cases), in a variety of places (closets, bedroom, backyard of the house), in garbage sites near the home (dustbins, rubbish bags or garbage dumps) in 8 cases, in deserted places (forest, bush) in 4 cases, and 4 bodies were discovered in the hospital after suspicious death reports.

The new-born’s found had been disposed of in a number of ways. Most victims were placed in plastic bags (88.6%) or wrapped in a cloth (9.1%). In one case, the victim was found naked.

In almost all cases, the women had confessed to their actions (95.7%). Only two of them did not recognize their act.

In the majority of the 44 cases, the women implicated admitted that they had acted alone. The complicity of family members was mentioned in two cases. The mother of one of the perpetrators was identified as an accomplice in one case and in the other, it was the father and the mother-in-law.

For all women in our sample, the murder was motivated by personal, social and economic factors. It was motivated by fear of dishonour in 25 cases (35.7%), despair in 14 cases (20%), social isolation in 10 cases (14.3%), extramarital paternity in 6 cases (8.6%), abandonment of the father in 8 cases (11.4%), social insecurity in 6 cases (8.6%) and for reasons not specified in 1 case (1.4%). None of the women in our sample had been previously arrested.

The average age of the mothers was 25.5 years with the youngest being 17 years old and the oldest 41 years old. The median was 25 years old, with a standard deviation of 5.3. At the time of the incident, 37 women (52.8%) were single and 20 women (28.6%) were divorced. Eleven women were married (15.7%) and 2 were widows (2.9%).

The women in our sample had a generally low level of education. The majority of these women - 51 cases (72.8%) - were uneducated. None of the women in our study sample had received sexual education. A very low level of knowledge about contraception was found in 2 women (2.9%) and 68 women disregarded contraceptive techniques.

Of these, 57 women were working as domestic workers (81.4%). 8 women (11.4%) were self-employed (food seller, shopkeeper, telecentre manager, seamstress). One woman was employed in the public service (garbage collector) (1.4%). Two women were students (2.9%) and two others were housewives (2.9%) at the time of the incident.

At the time of the incidents, 3 women were living alone (4.3%). Twenty-eight women lived with their children (40%) and they were not in a relationship. Other women lived with extended families (47.1%), or in couples (10%). For the latter, the husband was present in 3 cases (4.3%) and for the other 4, the husband had emigrated.

The women involved were almost all (67 cases) from economically disadvantaged backgrounds (95.7%). Only 3 of them came from an average economic background (4.3%).

The women involved had had an unhappy childhood marked by emotional deficiencies, a lack of communication and a climate of loneliness. They all came from unskilled families.

In the majority of cases, 68 female respondents had an unstable relationship (97.1%) with the alleged father of the victim at the time of the incident.

For the majority of women (n=54) in our sample, the pregnancy was the result of an extra-marital relationship (84.3%). Pregnancy occurred in marriage for 11 cases (15.7%), including 5 pregnancies attributed to the legal
spouse (7.1%) and 6 pregnancies resulting from an adulterous relationship (8.6%). The majority of women (n=65) had not informed their family or father about their pregnancy.

It was the first pregnancy and childbirth for 21 of the women (30%) and the other 49 women had already been pregnant at least once (maximum 6 pregnancies) and had at least 1 child alive at the time of the incident.

The majority of women (n=44) did not have any psychiatric disorders before the event. Two of them (4.4%) had in the past been followed for psychiatric disorders. One presented a table of a stabilized acute psychosis while for the other the mental pathology had not been diagnosed.

Regarding the notion of addictive behaviours, none of the women in our sample presented an addiction to any substance.

Of the 46 accessible files, age was not specified in 2 files and in the in 2 files where the bodies were not found, the age was not determined. As for the 43 cases where identification was possible, 41 cases (95.3%) were neonaticides and 2 cases were infanticides (4.6%). The sex remained undetermined in some victims (6 cases) due to the advanced state of decomposition of some bodies (2 cases), the fact that victims were never found (2 cases), and the fact that the sex was not specified in two cases. Among the victims whose sex was known (41 cases), it was more often than not a girl (24 cases) rather than a boy.

Childbirth occurred in almost all cases in the mother’s home (89.1%), either in the mother’s bedroom (52.2%) or in the toilet (30.4%). Rarely had it taken place outside: outside the mother’s bedroom (veranda, backyard of the house) (6.5%), in the hospital (4.3%) or in a deserted place (6.5%).

Death occurred most often in the mother’s home (89.2%), particularly in the mother’s bedroom (60.9%), in the toilet (28.3%) and rarely outside in a deserted place (10.9%).

Of the 46 accessible files, an autopsy had been performed in 25 cases. In the other 21 cases, it could not be done, 7 cases due to the advanced state of decomposition of the bodies and in 2 cases because the bodies of the newborns were never found. Almost all of the victims (23 cases) were viable and had breathed because the hydrostatic docimasia was positive. In 2 cases, the victims were declared non-viable. A congenital malformation anomaly with a type of transposition of large vessels was noted in 1 case. In the other victim, it was reported that the child probably did not breathe and that it was stillborn.

The cause of death was known in 22 of the 25 cases. Most deaths were due to asphyxia (12 cases) by suffocation: manual (1 case), in a plastic bag (2 cases), with a loincloth (1 case) or by burial in the ground (1 case). Manual strangulation (4 cases), or attachment to a piece of cloth (1 case) was also used. Submersion took place in cesspools (2 cases). The other causes of death were related to combined mechanisms (5 cases) by association between polytrauma and internal bleeding (2 cases), internal and external bleeding (2 cases) and internal bleeding with strangulation (1 case). Finally, death rarely occurred as a result of fatal injuries (1 case).

All women in the study either accused or awaiting trial had been subjected to pre-trial detention. Among the 46 cases that were judged, variations in the length of detention were noted.

These detention periods ranged from 2 to 6 years. The average length of pre-trial detention was 3.26 years, the median was 3 years with a standard deviation of 0.855. None of the women involved in our investigation had been placed in a psychiatric centre.

The final decision regarding the women involved in our study population was as follows: of the 46 women involved, 41 were sentenced to prison terms, while the other 5 were dismissed and the charges against them dropped. Sentences ranged from 6 months to 7 years. The most common sentence was 5 years of hard labour (31 cases).

**Discussion**

This typical profile is contrasted in our study. We found women with similar profiles but with certain specificities. Indeed, the young age reported as one of the common characteristics is neither validated in recent studies nor in our cases. Shelton et al and Tursz and Cook had found an average age of between 21.7 and 26 years, and in our study the average age was 25.5 years. In addition, Beyer et al have shown in their work that there are both young women and women in their 30s and 40s. The same is true for our cases. These women were in contrasting couple situations. As in our
study, these women had already had previous children or pregnancies and were predominantly employed as domestic workers.

The women involved in our study, as well as those described in a number of studies had no psychiatric history themselves, nor in their parent’s generation, and had no criminal record. As for the psychopathological profile of these women, it remains unknown in our cases because no expertise was carried out. But it is noted, with considerable consensus, that a psychiatric disorder affects only a minority of women who have committed an infanticide (neonaticide). Several authors reported in their work that the women concerned did not have an obvious psychopathological or psychopathic profile at the time of the crime.

In the literature, the common characteristic concerning women who commit this crime was an unwanted pregnancy hidden from close family and friends. This is the case in our study. This could be explained by the fact that these pregnancies occurred under conditions subjectively disadvantageous for these women. Tillier in his historical study reported that the women concerned buried the body or threw it into the bush. Neonaticide was traditionally considered in a sociological context but it is still relevant today. In the literature, as in our study, the neonaticide act was dominated by psycho-social factors associated with socio-cultural and economic constraints (fear of dishonour, despair, fear of social rejection, abandonment of the father, extramarital paternity, social insecurity).

Despite the introduction of new reforms, prolonged pre-trial detention continues to be a reality in prisons in Senegal. In neonaticide cases, very few studies focus on criminal decisions. The sentences for infanticide have varied widely throughout history and continue to do so, ranging from the greatest tolerance to the greatest rigour. Much more, juries and the court show leniency towards mothers who acknowledge the facts.

Many preventive strategies have been used around the world to reduce the number of neonaticides. Legislation is evolving slowly but not always in the direction of decriminalization of abortion.

Conclusion

Early infanticide is a crime that has existed since ancient times. In the Senegalese social context, particularly in Dakar, this crime appears to be the act of distress of a woman from a physically, economically and culturally vulnerable environment. She is faced with the stigmatization of an illegitimate birth against the backdrop of a lack of education, the inaccessibility of contraception, as well as the prohibition of abortion.

In our study, 70 cases were identified during the study period but only 46 trial cases were available. With regard to the social profile of these women, there is no typical, classical profile as described in the Anglo-Saxon literature. Despite the difficulties that neonaticide presents in terms of forensic liability, it is a largely avoidable tragedy. The preventive strategies put in place in some countries are proof that prevention against these acts remains possible. Multidisciplinary coordination between health and justice professionals as well as social actors would be necessary to set up preventive strategies and avoid such tragedies in the future.

Changes in Some Urinary Variables After Potassium Citrate Therapy In Patients With Recurrent Urinary Stone Disease In Tikrit City, Iraq

Mohammed Mohsin Abdul-Aziz1, Nihad Nejres Hilal2, Mohanned Hussam Mohammed Saeed Alkumait3
1Assistant Professor of Urology, Tikrit University, College of Medicine, 2Assistant Professor of Chemical Pathology, Tikrit University, College of Medicine, 3Assistant Professor of Urology, Tikrit University, College of Medicine

Abstract

Objective: to determine the effect of oral potassium citrate (k-citrate) on urinary calcium, magnesium, volume, and pH in patients with recurrent stone disease.

Patients & Method: Interventional clinical trial study was implemented from June 2016 to February 2019 in Tikrit city, Iraq. 94 patients with recurrent urinary stone disease were enrolled in this study. Oral k-citrate therapy was given to patients in a dose of 15 meq three times daily for 2 weeks. Patients instructed for 24 hours urinary collection before and after therapy. Urinary calcium, magnesium, volume, and pH were measured before and after therapy to examine the effect of k-citrate.

Results: mean age was 38.5 (SD 17.4) years. Male patients were 64% while 36% of patients were females. Mean urinary calcium level decreased significantly after k-citrate therapy, p value < 0.001. Mean urinary volume and pH increased significantly after therapy, p value < 0.01 and < 0.05 respectively. No significant change was identified in mean urinary magnesium level after therapy, p value = 0.14. No adverse effects related to k-citrate therapy were reported by patients during study period.

Conclusion: Urinary volume and pH increased significantly in patients after potassium citrate therapy. Also k-citrate therapy significantly produced marked decrease in urinary calcium level. No change was observed in mean urinary magnesium level before and after k-citrate therapy. No adverse effects related to k-citrate therapy were reported by patients during study period.

Keywords: Urinary calcium, Urinary magnesium, Urinary volume, Urinary pH, Potassium citrate.

Introduction

Renal stones have affected human beings since the earliest civilization. The etiology of stones remains hypothetical. Developments in the surgical treatment of urinary stones have overtaken our understanding of their causes. For patients, it is important to ensure complete metabolic evaluation that results in proper medical therapy and lifestyle changes to help decrease recurrent stone disease. Lacking such follow-up and medical involvement, stone recurrence rates can reach 50% within 5 years. [1]

The life time prevalence of renal stone disease is evaluated at 1% to 15%, with the likelihood of having a stone is different according to age, gender, ethnicity, and geographical location. [2] Hypercalciuria, hypocitraturia, hyperoxaluria, and hyperuricosuria are major metabolic disorders observed in patients with calcium containing stones. [3]

Potassium citrate is one of the most important therapies on the way to alkalinization of the urine and management of hypocitraturia. Potassium citrate is an
oral agent that increases urinary pH actively by 0.7–0.8 pH units. Classic dosing is 10-60 meq in three or four divided doses per day. Most studies support the reduction in stone recurrence rates for patients receiving citrate treatments. [4, 5]

Certain mechanisms are presumed for k-citrate to decrease stone formation. Citrate attaches calcium ions in the urine, creating a stable complex. It was suggested that this mechanism decreases accessible urinary calcium, consequently inhibiting calcium and oxalate precipitation. [6] Citrate as well diminishes the spontaneous nucleation of calcium oxalate. [7] The inhibitory action of magnesium is gained from its attachment with oxalate, which decreases oxalate and calcium oxalate supersaturation. [2]

Some randomized controlled trials of oral k-citrate have identified a drop in stone formation in patients with recurrent stones taking a variety of citrate medications. [4, 8, 9] In another one more study, no difference was found in stone recurrence. [10]

The aim of this study is to assess the consequence of oral k-citrate on urinary parameters like volume, pH, calcium, and magnesium in patients with recurrent stone disease in Tikrit city, Iraq.

Patients and Method

This interventional clinical trial study was performed during the period from June 2016 to the end of February 2019 in Tikrit city in Iraq. 100 patients with recurrent attack of urinary stone, recruited from Tikrit teaching hospital and private clinic, were included in this study. At the end of the study, 94 patients completed the study treatment, and 6 patients were lost to follow-up.

Patients with severe urinary tract infection, borderline renal function, diuretic therapy, patient with single functioning kidney, and pregnant women were excluded from this study. Patients instructed for 24 hours urinary collection before k-citrate therapy to get baseline measurement of urinary volume, pH, calcium, and magnesium. Oral k-citrate therapy was given to patients in a dose of 15 meq three times daily. Patients were encouraged to discontinue all medication during the study time. After 2 weeks of therapy, patients were instructed to collect urine for 24 hours for final assessments.

Urinary calcium was determined by semi-auto chemistry analyzer (expected values in 24 h in urine is 100-300 mg/24h, detection limit is approximately 0.16 mg/dL). Urinary magnesium was measured by semi-auto chemistry analyzer (expected values in 24 h in urine is 73-122 mg/24h, detection limit is 0.05 mg/dL). Urinary pH was estimated using a pH Meter.

All patients signed an informed consent to take part in the study, and the study was approved by ethical committee of Tikrit University, College of Medicine. All data were presented as mean and SD. Statistical analysis was implemented with paired student’s t test. A P value of less than 0.05 was regarded significant. Analysis was performed by IBM SPSS Statistics for Windows, Version 23.0.

Results

A final number of 94 male patients completed the study. The mean age was 38.5 (SD 17.4) years. Male patients were 64% and female patients were 36%. Table 1 shows that mean urinary calcium level decreased significantly after k-citrate therapy, p value <0.001. Mean Urinary volume and pH increased significantly after k-citrate therapy. No significant statistical difference was observed in mean urinary magnesium level before and after k-citrate therapy. No adverse effects related to k-citrate therapy were reported by patients during study period.

Discussion

Renal stone development is often regarded as nutritional or environmental disease, on the other hand hereditary or anatomic factors are substantial. Nearly 5% to 10% of the people of the western countries are believed to have formed a minimum one kidney stone by the age of 70 years, and the occurrence of urinary stones is escalating. For most stone categories, there is a male predominance. The mechanisms in charge of multiple recurrences of renal stones in only certain people are not completely explained. Reasons involved consist of urine flow that depends on fluid consumption, excretion of large amounts of stone constituents, the lack of a constituent or substances in the urine that prevent stone development, and urinary pH. [11]

The cornerstone of therapeutic approach for renal stone disease management was potassium citrate for many decades. The main mechanisms by which k-citrate inhibits stone formation are to make the constituents in urine more soluble, and increase inhibitory action against development of calcium containing stone. Potassium citrate causes marked increase in urinary levels of both potassium and citrate. [12] Urinary citrate is a potent inhibitor for stone formation. [4]

In this study, it was observed that urinary calcium level reduced significantly after potassium citrate therapy. Same result was reported by other studies [4, 5]. This result can be explained by the binding that occur between citrate and calcium in urine. Citrate and calcium in urine make stable complex that decrease the amount of urinary calcium needed for stone formation. [2] No significant change in urinary magnesium after potassium citrate therapy was identified in this study. This result can be attributed to the nonexistence of chemical interaction between potassium citrate and urinary magnesium.

Urinary volume of patients with recurrent stone disease was significantly increased after k-citrate therapy in this study. This finding is similar to the result of Robison and his followers in 2009 [13]. The increase in urinary volume can be explained by the suggested diuretic effect of potassium citrate that increased urinary volume in patients with recurrent renal stones.

Urinary pH was significantly increased in this study after the administration of potassium citrate therapy for patients with recurrent stone disease. Whitson and his followers in 2007 [14] found that no relation existed between potassium citrate therapy and urinary pH, and change in urinary pH was mainly caused by change in patients diet. The increase in urinary pH in this study can be explained by the increase in alkaline load caused by potassium citrate therapy.

Conclusion

Urinary volume and urinary pH increased significantly in patients with recurrent stone disease after potassium citrate therapy. Also potassium citrate therapy significantly produced marked decrease in urinary calcium level in patients with recurrent stone disease. No change was observed in mean urinary magnesium level before and after k-citrate therapy. No adverse effects related to k-citrate therapy were reported by patients during study period.

Synthesis and Characterization of Some Bis-Nitroaryl Pyrazolones and Estimation of Their Anti-Bacterial and Anti-Fungal Activities

Muath Jabbar Tarfa Al-Abbasse1, Hamid J. Mohammad2, Mawlood K. Mawlood1

1Chemistry Department, College of Education, University of Samarra, Iraq, 2Chemistry Department, College of Applied Sciences, University of Samarra, Iraq

Abstract

A simple and efficient one-pot synthesis of bicyclic nitro pyrazolone derivatives in traditional alcoholic solvents under refluxing conditions, The chemical structure of the synthesized derivatives was substantiated by FT-IR, 1H NMR, 13C-NMR and CHNS analysis, All of these compounds of the series have been tested in vitro as antibacterial and antifungal agents against four types of organisms. The minimum and maximum inhibitory concentrations were determined against each organism.

Keywords: pyrazolone, one-pot synthesis, nitroaldehyde, antibacterial activity, antifungal activity.

Introduction

Pyrazoles are five membered ring compounds, containing three carbon atoms in addition to two adjacent nitrogen atoms. The keto (=O) derivatives of pyrazoles are called pyrazolones.1 Chemically, pyrazoles are known as 1,2-diazole and are becoming a desirable topic by reason of their diverse applications.2 Pyrazolone is a substantial group of compounds obtained from pyrazole. It possesses a five membered ring in addition to a lactam functional group and occurs in two isomeric forms: 3- and 5- pyrazolone.3

In recent years, the synthetic work of functionalized pyrazolones has caught the attention of organic chemists, by reason of their potent bioactivities.4

Compounds derived from pyrazolone have taken a major part in the pharmaceutical chemistry and have been used as important pharmacophores in the design of drug dosage forms too,5 as antitumor,6 antimicrobial, anti-inflammatory,7,8,9,10 anti-oxidant,11 antidepressant, anticonvulsant,12 analgesic,13 antihistaminic14,15,16,17 and so on.

pyrazolones are prepared by lengthy and often tedious methods because of the tautomerization that affects the pyrazolone ring.18 A special effort has been put into preparing this important moiety, a general procedure for the synthesis involves the condensation of hydrazine hydrate with ethylacetoacetate in commonest mixed solvents.19 The archetypal pyrazolone synthesis involves the condensation of a b-ketoester, such as ethylacetoacetate, with a hydrazine.20

The composition of a bicyclic pyrazolone via a previously synthesized pyrazolone ring is not usually a feasible method because of the tautomerization that affects the pyrazolone ring. Therefore, we contrived a step that is capable of generating both rings intramolecularly in a one-pot reaction.

Our continuous work in this field led us to plan a one-pot method to get combined bicyclic pyrazolone moieties in a good yield. In this paper, we hope to declare our comprehensive results in preparing bicyclic pyrazolone derivatives.

This paper describes in vitro screening results of the compounds in question for their antimicrobial activity, minimum and maximum inhibitory concentrations. Herein, we provide information about the synthesis and pharmacological assessment of bis pyrazolones.
Experimental

Apparatus measurements

The used of chemicals were synthesis of analytical reagents grade. Melting points was uncorrected and were taken throughout open capillaries, TLC used to check purity of compounds, (Shimadzu Infrared Spectrophotometer Fourier Transform FTIR-8400S) using KBr pallets were used to record IR Spectra,The recorded NMR peaks were on NMR bruker500 MHz; which recorded on δ scale (ppm) against TMS. The utilized solvent was DMSO (3.33-3.35). The elemental analysis was done by Euro Vector EA 3000A Italy.

Organic Preparations

Synthesis of 3-methylpyrazole-5-one (I)

Hydrazine monohydrate (80 % 6.25 g, 100mmole) in methanol-water mixture (1:1) in (20 mL) completely dissolved and in an ice bath was cooled to 0-5 C°. To the mixture in question, ethyl acetoacetate was added (13 g, 100mmole) dropwise with continuous magnetic stirring and the temperature was kept at 0-5 C° by external cooling. Then, (in 5-20 minutes) a white crystalline deposit separated. The solution was left to stand further at 5-15 C° for 30-40 minutes to complete the crystallization. The mixture is then filtered under vacuum system pump, washed by ice-cold water. Recrystallization by absolute ethanol gave short needles, melted at 220-222 C°. The ratio was 9.15 g, 93%. [21]

General procedure for the synthesis of pyrazolone derivatives (II-IV)

(2 mmole, 0.392 g) of pyrazolone derivative (I) with (1 mmole, 0.302 g) of nitro-derivatives benzaldehyde was put under reflux using ethanol (within 3 hr). until the completion of the reaction, the gained solid compound was extracted out, dried,recrystallized by absolute ethanol to get the products. The physical properties and yield are listed in Table 1, The TLC was used for monitoring reaction progress (ethyl acetate 3: 1 n-hexane). [22]

Biological activity

Examination the antibacterial and antifungal activity of synthesized compounds were conducted in plates method.

Standard solutions

Preparing a stock solution by solubilizing anappropriate amount of the USP Standard Reference of the used antibiotic, where appropriate in the specified solvent as in Table 2; and diluted to obtain the required concentrations. Stored at 2o-8o , and use within the period indicated. Stock solution raisegradually in concentrations, often in the ratio of 1:1.25. see table (2).

Results and Discussion

First, we obtained apyrazolone scaffold as the starting materials by tandem condensation and cyclization.[23] as depicted in Scheme 1.

Scheme (1) synthetic pyrazolones (I-IV)

The cyclization of ethylacetoacetate by hydrazine hydrate and bicyclic formation may proceed by the following mechanism. [24]

FT-IR Spectra

Pyrazolone (I), the starting material of this research, was synthesized by cyclic condensation which is characterized by TLC, melting points, FT-IR stretching bands indicated the appearance of the (N-H) at 3389 cm\(^{-1}\) and aliphatic (-C-H) at 2931 cm\(^{-1}\) and (-C=O) at 1680 cm\(^{-1}\) and (-C=N) at 1583 cm\(^{-1}\). The FT-IR spectrum of bicyclic pyrazolone (IV) shown appear of (NH) stretching absorption band at 3413 cm\(^{-1}\) and absorption band for aliphatic (-C-H) at 2920 cm\(^{-1}\) and (-C=O) at 1690 cm\(^{-1}\) and (-C=N) at 1585 cm\(^{-1}\) and absorption band for nitro group at (1489, 1309) cm\(^{-1}\).[25]

1HNMR and 13C-NMR spectra

The 1HNMR spectrum of compound (I), (in DMSO as a solvent) revealed the following distinguished chemical shifts: a singlet signal at \(\delta\) (2) ppm refers to aliphatic CH\(_3\) protons, singlet signal at \(\delta\) (3.2) ppm refers to methylene protons of the pyrazolone ring, the characteristic singlet signal at \(\delta\) (8.4) ppm refers to NH
proton. [25]

1H NMR spectrum for derivative (IV), revealed a singlet signal at δ 1.8 ppm, refers to aliphatic CH₃ protons, α-carbonyl protons of the rings as doublet at δ 3 ppm, the characteristic triplet signal of linker carbon protons at δ 4 ppm, singlet signal at δ 5 ppm refers to NH proton, the doublet of doublet signal between δ (8-9) ppm refers to para-substitution nitro group ring protons. [25]

13C-NMR spectrum for derivative (I) revealed C=O at δ 178 ppm, C=N at δ 144 ppm, methylene of the ring at δ 67 ppm and methyl group at δ 25 ppm. [25]

13C-NMR spectrum for derivative (II) revealed C=O at δ 177 ppm, C=N at δ 145 ppm, C-NO₂ of benzene ring at δ 135 ppm, the carbon cited as (1) at δ 133 ppm, the carbon cited as (2) at δ 131 ppm, the carbon cited as (3) at δ 128 ppm, the carbon cited as (4) at δ 121 ppm, the carbon cited as (5) at δ 120 ppm, the carbon flanked at α-carbonyl of pyrazolone ring at δ 55 ppm, the carbon of methyl group at δ 35 ppm, and the linker carbon at δ 27 ppm. [25]

13C-NMR spectrum for derivative (III) revealed C=O at δ 164 ppm, C=N at δ 150 ppm, C-NO₂ of benzene ring at δ 148 ppm, the carbons cited as (1) at δ 141 ppm, the carbon cited as (2) at δ 125 ppm, the carbon cited as (3) at δ 122 ppm, the carbon cited as (4) at δ 115 ppm, the carbon flanked at α-carbonyl of pyrazolone ring at δ 72 ppm, the linker carbon at δ 32 ppm and the carbon of methyl group at δ 26 ppm. [25]

4. Biological activity

In our study, new series of heterocyclic derivatives showed moderate to significant antibacterial activity when compared with standard drug Neomycin and powerful antifungal activity.

The minimum inhibition for synthesized compound (I) was (11 mg/mL) against Staphylococcus aureus (picture 1) while the maximum inhibition for synthesized compound (I) was (14 mg/mL) against Bacillus subtilis (picture 2) and the maximum inhibition for synthesized compound (I) was (16 mg/mL) against candida albicans (picture 3). The minimum inhibition for synthesized compound (II) was (11 mg/mL) against Staphylococcus aureus (picture 4) while the maximum inhibition for synthesized compound (II) was (12 mg/mL) against Bacillus pumilus (picture 5) and the maximum inhibition for synthesized compound (II) was (18 mg/mL) against candida albicans (picture 6). The minimum inhibition for synthesized compound (III) was (11 mg/mL) against Staphylococcus aureus (picture 7) while the maximum inhibition for synthesized compound (III) was (16 mg/mL) against Bacillus subtilis (picture 8) and the maximum inhibition for synthesized compound (III) was (17 mg/mL) against candida albicans (picture 9).

In general, all the synthesized compound revealed moderate to good antibacterial activity concerning fungi, all the synthesized compound revealed good activity against candida albicans in all testified concentrations. See table (4).

Conclusion

New gained compounds (I,II,III,IV) were obtained by simple refluxing, short reaction time, ease of working and good yield. All of the produced derivatives were detected by TLC, melting points, FT-IR, 1H-NMR, 13C-NMR and elemental analysis. Thesesynthesized derivatives (I-IV) were evaluated to test their antibacterial and antifungal activities by cylinder-plate method against various Gram positive bacteria and fungi (Candida albicans). All synthesized compounds have shown significant activity against Bacillus subtilis and Bacillus pumilus and against Candida albicans too, whilst towards Staphylococcus aureus they showed comparable activity with the standard drug (Neomycin) at the concentrations used.

Assessment of the Correlation between the Salivary Flow Rate and Dental Caries Experience among Children with β-Thalassemia Major

Mudhafar Fadhil Jaddoa¹, Alhan Ahmed Qasim²

¹M.Sc. Student, Department of Pediatric And Preventive Dentistry/ College of Dentistry/Univ. of Baghdad, Iraq, ²Assistant Prof., Department of pediatric and preventive dentistry/College of Dentistry/Univ. of Baghdad, Iraq

Abstract

Thalassemia constitutes a group of congenital blood disorders which characterized by a defect in synthesis of one or more globin chains of human hemoglobin molecule and the resultant microcytosis and hypochromia of the RBCs. It is of two main divisions, α- and β-thalassemia and several other subdivisions. The study group composed of 40 patient years previously diagnosed with β-thalassemia major attending the thalassemia center in Thi-Qar province/Iraq. The control group, matching the age and sex of the study group, and consisted from 40 child selected from a number of primary schools. Unstimulated salivary samples was taken from each subjects under standardized conditions. The mean value of flow rate of saliva was lower among β-thalassemias (0.466±0.024) than for controls (0.829±0.048). The (mean±SE) for the primary teeth (dmfs) in β-thalassemias (1.450±0.324) was higher than that for controls (1.250±0.808), this difference was not significant (P> 0.05). The (mean±SE) of the caries experience (DMFs) in β-thalassemias (6.850±0.782) was higher than for the control group (3.600±0.489).

Keywords: β-Thalassemia major, Salivary flow rate, Dental caries experience (dmfs/DMFs).

Introduction

Thalassemia is a very worldwide common autosomal and recessive genetic disorder with a large geographical incidence difference, it is a so severe and incurable disease because prevention is the only way to evade the disease [¹], Thalassaemias are caused by markdown or complete absent in the synthesis of one or more of the globin chains that constitute the hemoglobin (Hb) unit [²,³]. About 60,000 to 70,000 newly born children are born yearly with a severe form of thalassaemias around the world [⁴], and unfortunately most affected children are those who born in areas of low sources of income [⁵]. β-Thalassemia major is the most severe type of thalassemia and occurs due to a defect in the synthesis of β-globin chain [⁶].

Beta-homotetramers in α-thalassemia are more stable than alpha- homotetramers in β-thalassemia; therefore, in beta thalassemia α-homotetramers tend to precipitate priorly in the RBCs life span, producing marked RBCs haemolysis [⁷]. Few of the pro-erythroblasts beginning their maturation and can survive [⁸,⁹], the resultant few RBCs will bear an inclusion bodies that identified in the spleen, shortening the RBC lifespan and producing severe haemolytic anaemia [¹⁰]. The produced anaemia stimulates the production of erythropoietin stimulating hormone from the kidney and liver with a compensatory erythroid hyperplasia, but the marrow response is disrupted by ineffective erythropoiesis. [¹¹]. Later on, massive bone marrow expansion will happened and the end result is skeletal deformities [¹²].

In thalassemias, high caries index, pallor of oral mucosa, atrophic glossitis, sialadenitis, retained deciduous teeth, shortened and spiked roots of teeth and thinning of the lamina dura could be seen [¹³]. Oral health, on the other hand, can also affect child’s personality, knowledge, and social relationships [¹⁴].
Dental caries is a chronic disease resulted from a complex intercommunication of a mass of cariogenic oral microorganisms which grow on the teeth surfaces within the dental [15]. Dental caries is widely spread and can affecting all ages. The experience of dental caries could be modified by several important factors, including diet, age, gender, socioeconomic level and some medicines [16].

Saliva is a heterogeneous mixture of fluids mainly produced via the major and minor salivary glands and contains oral bacteria and food debris from the gingival crevicular fluid [17,18]. Saliva have an important role in the maintenance of a healthy oral environment through a variety of physicochemical and biological properties. Unstimulated (resting) saliva includes secretions that enter the mouth without any exogenous stimuli [19,20].

Flow rate is the most important salivary parameter affecting oral health status and it represents the rate of salivary secretion and it is expressed in milliliters per minute [21]. Flow rate is very important protective factor against dental caries throughout its washing and buffering effect [22], any minimization in the normal salivary flow rate can results in establishment of dental caries [23]. Al-Jobouri and Al-Casey [24] and Kataria et al. [25]

## Materials and Method

The total sample included in this study was (80) subjects. The study group was consisted of a (40) child suffering from β-thalassemia major and aged (11-12 years old). The control group, the non-thalassemic children, matching the age and gender of the study group, and consisted of a (40) child selected from the primary schools. An ethical approval was firstly obtained from the Ministry of Health and the Ministry of Education to perform the clinical examination and laboratory biochemical analysis. Also, a written consent form as well as patient information sheet were provided to each participant for gaining the acceptance of the child’s parents or his/her caregiver. Children having other diseases whose known to affect the experience of dental caries or the characteristics of saliva such as diabetes mellitus, were excluded.

The oral examination was performed under standardized conditions of oral health surveys (WHO 1997). During examination, a suitable chair is used with noticing that it supports the head of the child. Clinical examination was performed using plane mouth mirror and dental probe. The reported caries experience was based on the criteria suggested by Manjie et al. [26]. Unstimulated salivary samples was taken from each subjects under standardized conditions suggested by Navazesh and Kumar [27]. Statistical analyses were done using SPSS computer programme, version 21. Descriptive statistics including (the mean and SE) of each clinical variable were determined for all the subjects. Student t-test was used to compare the caries experience between the study and control groups. Pearson’s correlation coefficient (r) was used to assess and compare the correlations among the variables. (P>0.05) was considered statistically not significant. (P≤0.05) was considered statistically significant and (P≤0.01) was considered to be statistically highly significant.

## Results

Table (1) illustrates the results showed that the (mean±SE) in β-thalassemias (1.450±0.324) was higher than that for the control group (1.250±0.808), This difference was not significant (P> 0.05).

*NS = Not significant

Discussion

In the present study, the mean value of salivary flow rate was founded to be lower among β-thalassemias (0.466±0.024) than in their control subjects (0.829±0.048). This result was also documented previously by Norri [28] and by Al-Jobouri and Al-Casey [24]. This minimization in the salivary flow rate among the study group might be attributed to the fact that the salivary glands function in thalassemic patients can be affected directly by the excessive iron deposits,
and the resultant painful inflammation of the salivary glands, with either regular or diminished salivary flow [23]. However, Siamopoulou et al [29] concluded in their study that the difference in salivary flow rate between the two groups is not significant. These results were in disagreement with Luglie et al. [30] and Greenberg et al. [31] whose showed in their studies that salivary flow rate was similar in both study and control groups.

The present study also concluded that the mean value of caries experience by surfaces in primary dentition (dmfs) among β-thalassemias was higher than that recorded in their controls. This result was corresponding with Gomber et al. [32], Kaur et al. [33], Dhote et al. [34]. On the contrary, this result was disagree with Scutellori et al. [35], Qureshi et al. [36] and Arora et al. [37] who were concluded that there is no difference between the two groups.

Furthermore, the results of the present study revealed that the mean value of caries experience by surfaces in permanent dentition (DMFs) among β-thalassemias was higher than that recorded in their controls. This results was in agreement with Hattab et al. [38], Al-Raheem et al. [39] and Al-Hadithi [40], while it was in disagreement with the results of Scutellori et al. [35] and Arora et al. [37] who were founded a similar mean value between the two groups.

In present study, there was a negative correlation between salivary flow rate and caries experience. Salivary flow rate may play an important role in relation to dental caries in which the flow rate of saliva exert cleansing activity which is critical in the clearance of food remnants and bacteria [41]. It was documented that the caries experience is obviously increased when salivary flow rate is stunted and this fact sign that the chronic decrease in flow rate is a risk factor for dental caries initiation and progression [42]. In thalassemic patients, reduced salivary flow rate can help in colonization of cariogenic S. mutans, which may have a role in the higher caries experience. Al-Zaidi [43] has documented an indubitable correlation between oral mutans streptococci and dental caries in β-thalassemia patients.

However, the higher caries experience in β-thalassemias than the normal controls can be related to factors other than a reduced salivary flow rate. This could be explained on the idea that these patients are less concern with their oral health, their parents are more worried about the serious physical condition, they paying less care to the oral health care, and seeking professional oral care just when the child experience severe pain [23, 44].

Al-Wahadni [45] and Gomber and Dewan [32] concluded in their studies that skeletal changes as enlargement in maxillary arch that occur in thalassemias in could result in protrusion of anterior segment, increased space between upper and lower teeth, over-bite or open-bite which all could predispose to dental caries.

**Conclusion**

Dental caries experience was higher among beta thalassemias compared to the control group. The salivary flow rate among β-thalassemias was lower among β-thalassemia patients than for their control subjects. The reduced salivary flow rate detected in β-thalassemia major patients could be considered as a modifying factor for the increased experience of dental caries in these patients.

Application of Risk Management Using HIRADC Method in Analytical Chemical Laboratory of University in Indonesia

Muhammad Bagus Fachrudin1, Dani Nasirul Haqi1, Putri Ayuni Alayyannur1, Noeroel Widajati1, Yenni Rohma Wijaya1

1Department of Occupational Safety and Health, Faculty of Public Health, Universitas Airlangga, Surabaya, 60115 East Java, Indonesia

Abstract

The analytical chemistry laboratory is one of laboratories at Universitas Airlangga which is often used in conducting analytical chemistry practicum activities and research for lecturers and students. In this analytical chemistry laboratory there are various chemicals and activities that are at high risk of causing danger, especially the exposure to toxic chemicals that can lead to risk of poisoning in students and laboratory staff. The purpose of this study was to apply the HIRADC method as an effort to prevent the risk of accidents and work-related illness in laboratory users. This research method is observational by observing the source of danger and the control efforts that have been made. From the results of the identification of hazards that have been made it is known that there are 10 potential hazards that can cause 10 risks. After doing the risk assessment, it is known that there are 4 low risks, 2 medium risks, 2 high risk, and 2 extreme risks. Control efforts have been made to minimize any risks. The recommendations that can be given from this study are the provision of personal protective equipment (PPE) that is in accordance with the hazards in the laboratory as well as training on how to use the PPE.

Keywords : HIRADC, analytical chemistry laboratory, risk.

Introduction

Risk is a combination of the possibility and severity of an event. In the aspect of occupational safety and health (OHS), the risk is usually negative, such as injury, damage, or disruption of the operation. Risk management is an effort to manage hazards that have the potential to pose a risk to occupational safety and health to prevent accidents and illnesses caused by unwanted work in a structured and well planned manner1. HIRADC is one of many methods that hold an important part because it deals with prevention and control of hazards that are used as a reference in determining OHS program objectives and plans.

Government Regulation Number 50 of 2012 concerning the Implementation of Occupational Safety and Health System has explained that in preparing policies and formulating an OHS plan strategy, employers must at least conduct an initial review of OSH conditions which includes identification of potential hazards, assessment and risk control2. In OHSAS 45001: 2018 it is stated that organizations must establish, make, implement and maintain procedures for identifying hazards, assessing risks, and determining the control of hazards and risks required3.

According to the 2013 International Labor Organization (ILO) data, there are more than 250 million cases of workplace accidents every year and more than 160 million cases of work-related illness. From a number of these cases, there were 1.2 million workers who died from workplace accidents and work-related illness or were sick at work4. Based on data from the BPJS (Social Security Agency) on Employment, the number of occupational accidents in Indonesia is still high even though it has decreased every year. Meanwhile, until August 2017 there were 80,392 work accident cases5.

Workplace accidents can occur everywhere, including laboratories in educational institutions.
Some examples of accidents that have occurred in the laboratory include the fire that occurred at the Chemical Engineering Laboratory, Patras, Egypt on August 27, 2005, which was caused by short circuiting in the laboratory equipment. Another case was the accident that occurred at the Texas Tech University chemistry laboratory on January 7, 2010 due to violating the procedure for using a mixture of nickel hydrazine perchlorate chemicals in conducting research which resulted in one student losing three fingers, perforating the eyes, and experiencing burns in several body parts.

**Material and Method**

Based on the method of retrieval of data, this study is observational, the data is obtained by making observations and there is no treatment of the object of research during the study. Based on the analysis, this research is descriptive, namely describing the process without analyzing relationships between variables.

The population of this study was all laboratory assistant at the analytical chemistry laboratory of Science and Technology Faculty Universitas Airlangga, which amounted to 2 people. Sampling in this study uses the total sampling method, namely the sample used in the study is all members of the population. Variables in this study included hazard identification, risk assessment, and determining control. Data collected in this study only primary data obtained through interviews with laboratory assistants responsible for the analytical chemistry laboratory and observations.

**Findings**

Work activities at the analytical chemistry laboratory at Universitas Airlangga consist of two activities, namely practicum by students and preparing and cleaning practicum equipment by laboratory staff. The first stage in HIRADC is doing hazard identification. Hazard identification was using the Job Safety Analysis (JSA) method. Based on the results of identification of hazards that have been carried out, obtained the potential or source of danger that exists in practicum activities by students as well as preparation and cleaning of practicum equipment by laboratory assistants are 10 sources of danger that can cause 10 risks.

After identifying hazards from work activities in the laboratory, the next step is to carry out a risk assessment. The risk assessment includes risk analysis and risk evaluation. Risk analysis is carried out by qualitative methods by assessing aspects of opportunity or likelihood and the consequences or severity then evaluating the level of risk. Qualitative risk analysis refers to the Australian Standard / New Zealand Standard (AS/NZS 4360:2004).

Based on the results of the risk assessment carried out on all work activities there are 10 risks including 4 low risk level, 2 moderate risk level, 2 high risk level, and 2 extreme risk level. The results of the risk assessment carried out on activities in analytical chemistry laboratories will be used as a basis in determining appropriate risk control efforts.

The next step is to determine risk control efforts. In this stage, the hazards and risks that have been identified are analyzed to formulate the control strategies based on each risk category. The determining control used in this research refers to OHSAS 45001:2018 that contains elimination, substitution, engineering manipulation, administrative, and PPE.

**Hazard Identification**

Hazard identification is the process of checking each area and work activity to identify all possible hazards. Hazard identification can be done by several methods, including passive, semi-active, and proactive. In this study hazard identification is carried out by using a proactive method that is carried out as a preventive and repairing effort before the loss arises due to danger at work. One technique in the proactive method, namely by making a Job Safety Analysis (JSA) conducted by analyzing potential hazards in each work activity in an analytical chemistry laboratory.

In practicum activities by students there are several potential hazards, firstly there are fragments of laboratory equipment made of glass. Most of the tools used for practicum in chemical laboratories are made of glass because they have several beneficial properties, including translucency, are not easy to react with chemicals, and have a high boiling point so that it doesn't melt at heating below 100°C. However, equipment made of glass risks breaking when it falls and will cause a lot of broken glass scattered and can injure students and laboratory staff.

The second potential danger is the sitting position of students when recording and doing labs that are less...
ergonomic. The incompatibility between the dimensions of the chair and the size of the anthropometry of the user can lead to unnatural posture and risk of causing musculoskeletal disorders (MSDs). Chairs in the laboratory use chairs that are upright, small in size, and without backrest so that they don’t interfere with student mobility but with a chair like that can reduce comfort and make the posture less ergonomic.

The third potential danger is lighting in an inadequate laboratory room. The standard of lighting in the laboratory is 500 lux. Lighting in analytical chemistry laboratories that are less or more than 500 lux can risk causing eye fatigue in students. The fourth is the electricity source. The presence of an inadequate source of electricity and errors when using it can run the risk of short-circuiting and fire.

The fifth potential hazard is the chemicals used in the practicum are corrosive. In analytical chemistry labs, students often use H2SO4 (Sulfuric acid) and HCl (Hydrochloric acid). These materials can enter the body through inhalation pathways and contact with skin and eyes and will have an effect on health. If corrosive chemicals are inhaled it can risk causing irritation to the nose and throat and can interfere with lung function. When in contact with the skin it is at risk of causing damage to the skin and painful sores. When in contact with the eyes, there is risk of causing blindness.

The sixth potential hazard is inadequate laboratory temperature. The temperature of the room that is too high when practicing can cause the body to sweat a lot and will reduce comfort and concentration when doing practicum. In addition, health problems can occur such as the appearance of white spots (milia) in the area of the nose, eyes, and forehead. The temperature of the room in the laboratory is tried between 23-26°C and there is adequate ventilation and wide windows to provide healthy environment.

The seventh danger potential is the presence of nitrogen gas (N2) tube which is not given a protective chain to prevent from collapsing. Gas cylinders in a lab that are heavy and easily dropped when touched can risking the feet of laboratory workers and students causing injury to the legs. The eighth potential danger is the heat that comes from the heating process using methylated spirits fire. In the chemistry practicum, most of the heating process of materials or chemical solutions uses fire from methylated spirits that can be at risk of being touched by the hand when doing lab work and causing burns.

The second activity is to prepare and clean lab equipment by laboratory staff. In these activities there are two potential hazards, those are the presence of corrosive chemicals, such as H2SO4 and HCl. Corrosive chemicals can enter the body through inhalation pathways, contact with the skin, and eyes. Next is exposure to various chemicals continuously. Some chemicals can have a direct or short-term effect when exposed and some chemicals do not have a direct effect, but continuous exposure to various chemicals through inhalation and skin contact can risk negative effects on long-term health.

Risk Assessment

Risk assessment is the process of assessing the risk of each potential hazard that has been identified. In this study, risk assessment was carried out with a qualitative risk assessment method that refers to the AS / NZS 4360: 200412. In qualitative risk assessment a scale of risk level categories will be generated, namely extreme, high, medium and low risk. The purpose of risk assessment is to determine whether the risk is still at an acceptable level or not and requires risk control.

</table>
The results of the risk assessment conducted on all work activities have 10 risks including 2 extreme risk level, 2 high risk level, 2 moderate risk level, and 4 low risk level. Based on an experiment in pharmacy laboratory, spilled by chemicals such as HCl, Nitric acid, and Sulfuric acid become high-ranking risk and dangerous.

**Determining Control**

Risk control is the process of taking action to eliminate health and safety risks to the extent that they can be implemented fairly or rationally. According to OHSAS 45001: 2018 a risk control hierarchy is carried out by eliminating, substituting, engineering, administrative control, and using personal protective equipment (PPE).

At this laboratory, efforts have been made to control any risks, including substitution efforts by replacing several detached plugs with new electrical terminals to temporarily reduce short circuiting and fire risk. Technical engineering efforts by installing local and general exchanger to reduce the risk of discomfort and health problems due to excessive sweating due to hot rooms.

Administrative control is carried out with neat storage facilities and supervision by lecturers and laboratory assistants to reduce injury risk due to glass fragments, there are wooden seats to reduce the risk of MSDs, ceilings and walls painted in bright colors and adjustable lighting to reduce the risk of eye fatigue, and provided a heat-resistant clamp for the heating process to reduce the risk of getting heat from heating spirits. Control with PPE is done by providing medical masks and medical gloves to students and laboratory assistants to reduce the risk of irritation of the nose and throat, disruption of lung function, damage and injury to the skin, and blindness as a result of the danger of corrosive chemicals used in practicum. Meanwhile, the risk of injury and damage to the floor due to being crushed by a nitrogen gas tube has not been controlled.

**Conclusion**

Hazard identification has been done on activities in analytical chemistry laboratory. We can conclude from the average results that this laboratory contain low-risks activities. But although risk control efforts in analytical chemistry laboratories have been carried out, there are still risks with extreme and high categories, so that control efforts are deemed less effective and need improvement.

1. Extreme category risks can be done by provision of PPE in the form of acid resistant gloves and respirators, policy making about using PPE when in the laboratory, requiring students to have a personal respirator, and conducting hazardous socialization of each chemical by lecturers or laboratory assistants and for laboratory assistants are given training in the use of PPE and instill the importance of using PPE on laboratory.

2. High category risks can be done by replacing all electrical plugs that are detached to prevent the electrical wires from being pulled out and providing electrical terminals for each device that has high electrical power. In addition, refer to health risks of laboran due to continuous exposure to chemicals can be carried out periodically medical check-ups.

3. Medium category risks can be done by optimizing the existing exhauster and adding air conditioner to prevent hot temperature, also providing a protective chain tube and put nitrogen tubes in a safer place to prevent N2 tube become falling.

4. Low category risks can be done by giving first aid kit due to Minister of Manpower and Transmigration Regulation Number 15 of 2008. The MSDs risk can be done by providing a standardized seat in the laboratory and providing cushioning on the seat to reduce pain in the sitting bones. The eye fatigue risk due to inadequate lighting can be controlled by turning on all lights in the laboratory room when practicing and immediately replacing a damaged or dead lamp. And the risk of burned out when warming up with spirits can be monitored by the laboratory during the heating process and use gloves to reduce the risk of being exposed to fire heat.

Study of Epidemiological Factors According to the Positive Response of IgG of Patients Infected With Blastocystis Hominis in Diyala Province, Iraq

Muna Hameed Ahmed Alazzawi¹, Nabaa Ali Jasim², Masar H. Ismail³
¹Directorate of General for the Education of Diyala, Iraq, ²Department of Community Health, Baquba Technical Institute, Middle Technical University, Iraq, ³Department of Biology, College of Sciences, Diyala University, Diyala, Iraq

Abstract

Background: Blastocystis hominis (B. hominis) is the most common intestinal parasite in humans and many other animals. Infections with the organism are spread worldwide and some of them have been asymptomatic, acute symptomatic and chronic.

Materials and Method: 100 blood samples were collected from patients with B. hominis which were reviewing to some Hospital and health center in Diyala province during the period from October 2018 to March 2019. To determine the extent of IgG antibody responses in serum patients infected with B. hominis for depending on the chromatic changes resulting from the association of antigens with antibodies.

Results: The results of the current study showed the percentage of infection among males was (56.25%), which is higher than that of females (43.75%), and the age group (3-6) years among males showed the highest rate of infection (33.34%) and the lowest in age groups less from one year and (9-12) years groups at (11.11%). The rate of infection in the age groups (1-3) years and (6-9) years was (22.22%) and in the age group of (1-3) years was the highest incidence among female groups (42.86%), while the age group (3-6) years showed less than that (28.57%) and significant differences at the level of probability less than (0.05). The percentage of B. hominis infection increased among the rural population by (56.5%), male infected, (57.14%) female, while the proportion of males among the urban population was (44.44%) and females reached (42.86%), with a standard deviation of (1.600 ± 0.495) and (1.480 ±0.505) respectively.

Conclusions: The presence of immunoglobulin IgG in serum patients has been shown to stimulate the cellular immune response and be indicative of long-term immunity against pathogenic antigens.

Keywords: Blastocystis hominis, diagnosis, parasite, infection, patients.

Introduction

B. hominis is one of the most common protozoa intestinal parasitic diseases worldwide and a common infected among humans and animals [1]. It isolated from stool specimens appear as unicellular and it has multiple shapes, such as vacuolar, granular, and amoeboid [2]. It was considered as harmless yeast, but it is now getting acceptance as an agent of human intestinal disease especially under immunosuppressive conditions [3]. The extent research on B. hominis is transmission mechanisms, incubation period, epidemiology, and treatment options [4]. Its status as a true pathogen is controversial - while it has been found in patients with gastrointestinal symptoms with diarrhea or severe abdominal pain. Symptoms associated with human papillomavirus infection include: diarrhea, nausea, colic, abdominal distension, fever and chills. It is not proven to be the cause and many carriers are asymptomatic [5].

Diagnosis of B.hominis is used by clinical diagnosis of diarrheal symptoms and dehydration of the patient and laboratory methods. Direct microscopy of stool and cystic phase observation overlap with other causatives of diarrhea specially [6,7]. These data indicate that
B. hominis induces as well as modulates the immune response in intestinal epithelial cells, and we conclude that different pathophysiological events may occur during B. hominis infection \[8\]. The spread of disease is associated with poor hygiene, exposure to animals and the consumption of contaminated food or water \[9\].

Iraq has seen widespread outbreaks of gastrointestinal diseases. The Iraqi Ministry of Health and contributed many factors in the spread of the disease; including displacement of people to other places and water pollution. There are several studies that showed prevalence in different Iraqi governorates of the country. The rate of infection was recorded in 2013 (5.08\%) for (31) children in Dohook in northern Iraq suffers from gastrointestinal symptoms \[10\]. 28 (4.1\%) was infected with B. hominis from a total of 861 reviewers \[11\]. While in Muthana province in southern Iraq, the infection rate was 58 (45.67\%) out of 127 patients infected with B. Hominis \[12\].

The aim of the present study is to investigate the most important immunological changes in infected patients by measuring the IgG level, determining positive response rate, age and genders, and setting up patients.

**Materials and Method**

**Collection of samples**

The present study collected 100 cases with Blastocystis hominis within the period from October 2018 to March 2019, of 50 male and 50 female, ranged in age less one year to 12 years. It has diagnosed the disease process and determined by dermatologists at some Hospital and health center in Diyala province and the injury was diagnosed based on the clinical symptoms and distinct phenotypic traits of infections.

**Serological diagnosis**

Serological diagnosis was performed by measuring the IgG level in the serum of patients with B. hominis to determine the response of the positive in the body of the infected patients. Blood samples were collected from patients. Was withdrawn 5 ml of venous blood for each of the infected persons, therapists and control the use of a syringe, put blood samples in test tubes and let the blood to clot at room temperature (20-25) minutes and then the separation of the serum Centrifuge device speeds of (3000) rpm and then it is kept freeze-preserved models when (-20°C) until the subsequent immunological tests.

To find out the most important immunological changes associated with infection in patients with B. hominis, the study has included measuring levels of certain cellular dynamics in the serum of infected by and based on the principle of color change resulting from the correlation of quality IgG antibodies and measured color change resulting mediated.

**Statistical analysis**

Statistical analysis of the results of the current study using the Statistical Package for Social Sciences conducted (SPSS) metadata. Test was used T-test, variance analysis ANOVA, Chi-square, percentage, standard deviation and standard error in the present study to find moral differences between groups with infection Blastocystis hominis and there were significant differences (P < 0.05).

**Results**

The present study included 100 patients with B. hominis, 50 males and 50 females. The positive response rate of IgG for males was higher than that of females, which recorded positive response rate of (56.25\%) at (1.820±0.388) .While the percentage of response to the antibiotic in the serum infected females (43.75\%) at (1.860±0.351). Hence, the statistical analysis of this increase indicates that there isn’t a significant difference of statistical significance at the level the probability is less than 0.05 as shown in Table 1.

Table 2 shows that the injuries spread within a wide range of age groups. The age of those infected was less than 1 to 12 years. In males recorded age groups the (3-6) year age group had the highest IgG response rate at (33.34\%) and followed by tow the age groups (1-3) years and (6-9) years (22.22\%) and less than at (11.11\%) in tow groups less one year and (9-12) years age groups. Compared to the female group, the (1-3) years age group had the highest incidence of IgG infection and response 42.86\%.The lowest response among the age group of females was 0.00\% in the age group less than one year, so that no percentage is recorded. This is due to the visitors who visit the health centers at the time of collecting samples. While the age group 3-6 years by 28.57\% and less than the age groups (6-9) and (9-12) years by (14.29\%). Differences between the proportions of m and their response to IgG were statistically significant at the probabilistic level the level the probability is less than 0.05 as shown in Table 2.

The patients’ place of residence showed a clear
difference between their urban and rural residence, but did not constitute a significant difference of statistical significance at the probability of \( p > 0.05 \). The prevalence of IgG immunoglobulin was significantly higher among urban than in rural areas as Table 3 showed. The proportion of males was 55.56\% of respondents 5 patients of the total number are 20 cases, while females registered 57.143\%, with 4 patients of the total number of 26 cases. The response rate in the urban group of infected males was 44.44\% with 4 patients of 30 cases, less than 42.857\% in urban areas, with 3 patients of the total 24 cases.

Discussion

B. Hominis is a protozoan intestinal parasite disease that caused by the emergence of various symptoms, including diarrhea, nausea, abdominal cramps, bloating, excessive gas, and anal itching. The timescale of infection with the parasite can range from weeks to years [13]. The present study showed an increase in IgG and positive response rate in males, with (56.25%) infection rate and (43.75%) female infection as in the table (2). This may be due to the number of hospital-reviewed cases and some male health centers more than females, and therefore dependent on individual immunity. This is consistent with the findings of Nayef et al. (2011) which indicated the percentage of male (23.99%) height on females (16.27%) and attributed the reasons for this to the above, attributed the reasons to as exposure to the infection increases with the top of nutrition and increased funding [14]. The percentage of infection between females and males does not make any significant difference at the probability level (0.05), which is consistent with the results of Mahmood and Khudher (2016) indicating that there is no significant difference between the rates of infection of males and females and accounted for the percentage of infection B. hominis in Sammara city - Salah Al-Deen province was (9.09%) [15].

The study showed the effect of the age group in the incidence of B. hominis, whose age ranged between (> 1-12) years with a significant difference of (P < 0.05). As it was the highest rate of infection in both genus and is attributed to the lack of development of the immune system in the younger age groups compared to the large age and this is consistent with what Salman (2015), who pointed to a significant difference at level (P <0.05) between different age groups ranging from 6 months to over 61 years out of a total of (177) patients with B. hominis [16]. The main cause of diarrhea is B. Hominis among other pathogens, as explained by al-Kaissi and Majdi (2009), the highest proportion of who were 82 cases with B. Hominis isolated from 200 patients suffering from diarrhea by 41% [17]. Where the current study recorded the age group (3 – 9) years is the highest response rate positive for IgG among males infected with B. hominis, which amounted to (33.34 %) and the lowest was in the two age groups less than one year and (9-12) years is (11.11%). While the age group (1-3) years among females infected with the highest rate of (42.86%) and less than in the categories of age (6-9) years and (9-12) years is (14.29%), while the category less than a year does not register any case among females and this is due to patients reviewing hospitals and centers when collecting samples as showed in table (2).

The current study indicates that the housing factor has a difference in the percentage of IgG positive response for patients with B.hominis for both sexes but does not register any significant difference at the probability level (P >0.05). The positive response rate for patients with B. hominis who live in rural areas is higher than that of urban dwellers. This is due to the pollution of the environment and the environment of the rural inhabitants of B. hominis. They may be directly related to the reservoir stocks such as sheep, cattle, cats, dogs and other domestic animals. For rural males (55.56%) of respondents (5) patients of the total number is (20) cases, while females registered (57.143%), with (4) patients of the total number of (26) cases. The response rate in the urban group of infected males was (44.44%) with (4) patients of (30) cases, less than (42.857%) in urban areas, with (3) patients of the total (24) cases as showed table (3).

Conclusions

The present study conclude that the disease’s ability to stimulate the cellular immune response leading to the production of IgG that observed height in patients groups.

Risk Analysis of Occupational Disease and Accident in Environmental Health Laboratory

Naomi Cimera¹, Dani Nasirul Haqi¹, Putri Ayuni Alayyannur¹, Y.Denny Ardyanto¹, Nur Laili Rizkiawati¹
¹Department of Occupational Safety and Health, Faculty of Public Health, Universitas Airlangga, Surabaya, 60115 East Java, Indonesia

Abstract
Risk analysis is a process to identify hazards by calculating the size of the risks and determining whether a risk is acceptable or not. The purpose of this study is to do hazard identification and risk assessment in environmental health laboratories at Faculty of Public Health at Universitas Airlangga. This study was included in an observational and cross-sectional study based on the time of his research. Primary data is obtained through laboratory observations and interviews with reports presented in the form of tables and diagrams then analyzed descriptively. The results of this study indicate that in environmental health laboratories Faculty of Public Health Universitas Airlangga there are 10 potential hazards with 12 risks out of 4 activities. Based on the results of the risk assessment, from 12 risks there are 5 types of risks with low risk category, 4 types of risk for with moderate risk category, and 3 types of risk with high risk category. The conclusion of this study is that the greatest risk level in environmental health laboratories is low risk category of 41.67%. While for the moderate risk category was 33.33% and the high risk category was 25%. Risks with high risk categories include power failure, fire, and explosion at a time caused by the flow of electric current and chemical reactions carried out in the laboratory.

Keywords: environmental health laboratory, hazard identification, risk assessment

Introduction
The laboratory is a place for conducting scientific research, experiments, scientific measurements or training. Environmental health laboratories are usually used to test food safety, solid waste, wastewater treatment, environmental exposure assessment, drinking water quality, radiation exposure assessment, and biomonitoring.¹ One of the aims of this laboratory is to provide services to the community related to provide information about the quality of the natural environment that is beneficial for citizens as well as their own natural environment.² Activities in the laboratory may have chance to cause work accidents and work-related diseases such as sampling, pipetting, pouring and mixing of materials for experiments. Occupational health and safety risks that can occur when conducting an activity in an environmental health laboratory are exposure to the use of chemicals, exposure to biological hazards such as microbes and experimental organisms, physical hazards such as non-ergonomic positions when conducting research, scratched materials and research equipment, fires, electrical zips and explosions.³

Based on accidental survey statistics in the laboratory at the junior high school laboratory in Hong Kong during the 2014/2015 there were 241 cases of accidents that occurred to students and 10 cases occurred to employees and a total of 280 cases of accidents in the laboratory such as scratches, burns on hands, heat burns, eyes spattered from outside materials, and exposure to chemicals.⁴ According to other data from the Berkeley Laboratory the number of accident cases occurred from October 2017 to May 2018 as many as 70 injury cases recorded and first aid were given, accidents in Berkeley’s laboratory such as non-ergonomic working positions when moving the material, loss of hearing function, transportation accidents, exposure to chemicals, splashes in the eyes, and falling objects.⁵ Other cases also occurred at the Laboratory of High Schools in the

suburbs of Nashville, United States in 2018 as many as 17 people including students along with teachers who were teaching science experiments were experiencing fires due to the reaction of chemicals used.\(^{(6)}\)

Actually these work accidents can be prevented by risk analysis of activities carried out in environmental health laboratories. The identification activities and risk assessment are able to determine the various risks so that control efforts can later be carried out to reduce these risks so that accidents or health problems will not occur.\(^{(7)}\) Same as determined in ISO 45001, laboratories as workplaces that have potential hazards must be controlled so accidents will not occur. It is one of the international standards in occupational safety and health management systems that provides a framework for an organization to manage risks and opportunities to help prevent work-related injury and ill health to workers. The outcome of this system is to improve and provide a safe and healthy workplace. One of the provisions in ISO 45001 in clause 6, the company is required to do hazard identification and assessment of risk and opportunities proactively.\(^{(8)}\)

Therefore, based on the potential hazards that can occur in environmental health laboratories the authors are interested in conducting research related to Risk Analysis of Occupational Disease and Accident in Environmental Health Laboratory at the Environmental Health Laboratory of Universitas Airlangga. The general objective of this study is to identify the hazards, assess the risks and determine the level of risk at the environmental health laboratory of the Faculty of Public Health, Universitas Airlangga.

**Material and Method**

This study use an observational and cross-sectional research design then conduct interview with related party to Faculty of Public Health Universitas Airlangga environmental health laboratories. This research is included in descriptive research because this study does not make comparison or relation between variables and only describes a situation objectively. This research was conducted at the Environmental Health Laboratory, Faculty of Public Health, Universitas Airlangga. The variables to be examined in this study are hazard identification, risk assessment and risk level determination at Faculty of Public Health Universitas Airlangga Environmental Health Laboratory.

The data collected in this study are the primary data obtained through observation and interview which are used to find out the activities in the laboratory, the potential hazards that exist, the magnitude of the risks and the condition of the work environments. Data processing and analysis techniques are carried out based on data from observation and interview. Based on the data we will know potential hazards and the value of likelihood and severity, then they are analyzed using the risk assessment matrix table based on AS/NZS 4360:2004 Risk Management.\(^{(9)}\) The results of the analysis can determine level of risk of potential hazards with low, moderate, high, or extreme risk categories.

**Findings**

The environmental health laboratory is included in one of the laboratories owned by the Faculty of Public Health, Universitas Airlangga. It is functioned to support the learning process of public health study program. Environmental health laboratories have various potential hazards that can cause safety and health risks for laboratory users, workers and people in the vicinity of laboratory. Activities carried out at this place include the use of electrical power equipment and roll cables while the learning process, lectures and lab activities, the cleaning of the room after lab activities. In addition, there are several source of danger potentially cause harm to occupational health and safety such as electricity that is not in accordance with the MCB used, cable roll circuit, noise and hot temperature from outside, chemicals that are in direct contact with the skin and respiratory tract, eyes that exposed to foreign objects, sitting position, equipment and part of the room that can cause injury, chemical interactions/reactions, and blockages in water installations.

Based on the results of the study, it is known that there are three levels of risk that may occur in this laboratory, namely there are 3 high risks category, 4 moderate risks category and 5 low risks category. Activities that have a high risk are the use of equipment with electric power and excessive use of cable while the learning process with the risk of power failure and fire at any time as well as interactions or reactions between chemicals during lectures or labs which also pose a risk of explosions and fires in the laboratory that will cause harm to people in the location. The total risk of high risk category at this place is 10. Control can be done to reduce the level of risk is to minimize electricity use, manufacture cable lines/electrical installations, arrange the layout of chemicals in accordance with the MSDS,
obtain appropriate work procedures and use of adequate personal protective equipment (PPE).

**Hazard identification**

There are four main activities carried out in this environmental health laboratory, each of which has the potential to cause disruption to health and safety for example the use of equipment with electric power when the learning process takes place with a source of electrical hazards not in accordance with the MCB used causing the electricity failure and fire at any time, excessive use of chlorine cables during the learning process with hazardous sources of cable roll circuits that causing tripping and the occurrence of fire. Lecture
and practicum with sources of danger of noise and hot temperatures from outside of the room which is disrupting the concentration learning process. Direct contact with chemicals that can be inhaled and irritate the skin, respiratory tract and eyes. Sitting position which has a risk of causing symptoms of MSDs, equipment/parts of the room that can cause injuries that risk the body part of being scratched and slashed when using equipment, and the reaction between chemicals with a risk to irritate the skin, eyes and respiratory tract and cause an explosion as well as fire. Cleaning the room after practicum by laboratory assistant with a source of danger of blockages in water installations that cause waste disposal in water installations to irritate the skin and respiratory tract.

Risk Assessment

The risk assessment carried out at the environmental health laboratory is by determining the likelihood and severity based on the AS/NZS 4360:2004 risk management category.(9) The biggest risk is electricity failure and fire at a time with a source of danger of electricity that is not in accordance with the MCB used, fire due with the source of danger of a series of roll cable that is too much and irregular, explosions and fires due with the source of chemical reactions with the probability of each occurring is 2, the possibility of occurring is rare or the frequency of occurring is annual. The severity of 5 is causing death, very large financial losses, damage to equipment that causes the cessation of the activity. On all three risks, the total value of the risk that causes electricity to fail, fire, and the occurrence of an explosion of 10 with a high risk category requires control measures and consideration of resources to reduce the risk.

MCB(Mini Circuit Breaker) functions to disconnect electric current when the electricity network is overloaded. MCB is one of the safeguards so that the risks and dangers caused by excessive use of electricity do not occur. But if the use of the MCB is not in accordance with the standard of use are able to trigger a short circuit and even a fire at a time, if the use of the MCB is in accordance with the standards then there will be an electricity failure.(10) The use of a roll cable that exceeds the usage capacity has potential to cause electrical short circuit and fire. Whereas for explosions and fires due to the danger source of a chemical reaction can be caused by a reaction between chemicals with one another whose use is not accordance to material safety data sheet, certain chemicals cannot be used together or placed in the same place.(11) 

Risk control

Risk control can be done so that the risk level can decrease so that the risks for the occurrence of occupational health and safety disturbances can be minimized when conducting activities in an environmental health laboratory(12), namely by applying appropriate and established laboratory work procedures, minimizing electricity use by using electricity as needed, make grooves of roll cable that will be used from the front of the room to the back of the room, arrangement of layout and use of chemicals material safety data sheets (MSDS), in addition also provides a special place for chemical storage and fume hoods that are eligible for activities that related to chemical reactions and the use of PPE in accordance with the designation.

Applying appropriate and established laboratory work procedures aims to ensure that activities are carried out in accordance with the standards, organizational goals, and the effectiveness and efficiency of an activity. The existence of work procedures can be used as work guidelines for various interested parties and to determine work control measures as precisely as possible.(13) Minimizing the use of electricity with the necessary use so as not to exceed the load capacity that can risk triggering electrical short circuit and fire, in addition to make the cable roll grooves is aimed to arrange the cable neatly, not blocking the people, and minimizing the potential short circuit. The arrangement of the layout and use of chemicals is applied for the chemical according to the MSDS in order to avoid unwanted reactions that have the potential to harm people around the laboratory(11)

Conclusion

The hazards identified in the Faculty of Public Health Environmental Laboratory Universitas Airlangga are 10 potential hazards with 12 risks out of 4 activities which include the use of electrical power equipment during the learning process, lectures and practices, using roll cables during the learning process, and cleaning the room after practicum activities by laboratory staff. Based on the results of the risk assessment, there were 12 risks in 4 work activities with 5 types of risk in the low risk category, 4 types of risk for the moderate risk category, and 3 types of risk for the high risk category. Control measures that can be taken to reduce risk are by implementing work procedures, minimizing the use of electricity, arranging the cable neatly and not blocking the people, minimizing the potential short circuit,
arranging the layout and use of chemicals and applying MSDS and the use of PPE in the laboratory.

Abstract

Hartmann pouch is a dilatation of the wall of the gallbladder at the region between neck and the cystic duct, It is inconstant feature found as an anatomical variant and considered a frequent site for gall stone impaction and mucocele formation as a complication. Knowledge about anatomy of the pouch is important while performing surgery for cholecystectomy to avoid serious complications.

Objective: To identify the incidence and nature of Hartmann’s pouch in human gallbladder and the relation with gallstones for the growing importance and use of various invasive surgical techniques for gallbladder and extrahepatic biliary diseases.

Material and Method: The study was carried out in the department of Forensic Medicine at Basrah city, from Jan 2018 to Jan 2019. Two hundred fourteen gallbladders were obtained from cadavers that were under examination in the morgue. The gallbladders were examined morphologically to show Hartman pouch and gall stone existence and biopsies from the pouch were taken for histopathological examination.

Results: In the present study Hartman pouch was found in 4.7%, usually at older age group (> 40 yrs.). It was slightly higher in male than female and no significant association between Hartman pouch and gall stone presence. Histological picture showed normal histology of the three layers as seen in normal gallbladder

Conclusion: Hartman pouch is inconstant feature, more in male with no significant relation to gall stone, exist as an anatomical entity in our area of study.

Key words: Hartmann pouch, gallstones and percentage

Introduction

The gallbladder is a hollow pear shaped end diverticulum which stores and concentrates bile. It lies on the visceral surface of the right lobe of the liver and anatomically formed of neck, body and fundus [1,2]. Variations in the shape and size of the gallbladder is not uncommon [3,4] and should have attention through ultrasonic investigations and during laparoscopic cholecystectomy because the related Injuries may elevate the risk of morbidity and mortality[5-9].

One of these variations is Hartmann’s pouch, which was named after Henri Albert Hartmann who first described it in 1891 [10]. He recognized it as a dilatation on the ventral aspect in the junction of neck and cystic duct, has inconstant feature, variable in size and described it as a normal variant [11-14]. The Hartmann’s pouch may cabin the gallstones as common site [15]. A big Hartmann’s pouch may hide the cystic duct and the Calot’s triangle, which poses a major trouble during cholecystectomy [16-18]. It may also be complicated in associated pathological conditions responsible for adhesion between the neck and cystic duct. In addition, it
may cause chronic infections, which promote malignant changes later on [19].

Recently, Hartmann’s pouch is recognized more as an outcome of pathology in the form of dilatation or presence of stones, when the gallstones lodged within the Hartmann’s pouch result in mucocele formation [20]. Different data about the incidence of the pouch and gallstone relation were obtained from many articles, which makes the knowledge of relevant anatomy important for safer cholecystectomy.

**Aim**

To clarify the disagreements with regard to the incidence, nature and gallstones relation to the Hartman pouch and to obtain our own reference data because of inadequate information of this type of variant in our population of Basrah city which gives value to the present study.

**Material and Method**

The study was conducted from Jan 2018- Jan 2019. Two hundred fourteen human gallbladders were collected during routine postmortem examination in the morgue of the department of Forensic Medicine at Basrah city. Both gender were taken and age ranged from 10 to 79 years. The Ethical Review Committee at Health institute in Basrah city approved the study.

A Morphological examination was carried out on all gallbladders among the studied samples of unidentified bodies. Abdominal surgery for Crush injury to the abdominal organs specifically liver, biliary system dysfunction and suspected cases of poisoning were excluded. Specimens were divided in two groups, those with Hartmann’s pouch and those without. Gallbladders were opened for the presence of gallstones. (Fig 1 a and b ). The samples were divided according to age groups as in Table 1.
Table 1: Age distribution and Numbers

Three millimeter thickness tissue samples from Hartmann pouch were preserved in 10% NBF for routine histopathological processing to obtain sections of 4 micrometer thickness then stained with hematoxylin-eosin and examined under the light microscope by using Elica camera for photomicrography. Data analysis were done using SPSS v.20, and P value < 0.05 is considered significant with 95% confidence interval.

Results

1. Morphological study:

A total of 214 gallbladders underwent morphological examination, age range from 3 - 79 years with mean age 36.22 ± 14.94, Male / Female ratio = 2.3 / 1.

Hartmann Pouch was observed in 10 out of 214 specimens (4.7% incidence), while gallstones were found in 14 out of all gallbladders (6.5% incidence) as shown in Fig 2.

Regarding the relation of Hartman pouch to age groups. The pouch was detected mostly in the 40-60 years old age group (n=6) followed by the (> 60 years) group (n=3) with significant statistical difference (P=0.03) in comparison to the other age groups as shown in Figure 3.

![Figure 3: Relation of Hartmann pouch to age groups.](image)

In relation to gender, Hartmann pouch was significantly more in males than in females (P=0.032), but gallstones presence did not differ significantly between the studied male & female cases (P=0.919). (Fig 4).

![Figure 4: relation of gender to the incidence of Hartmann pouch & gallstones.](image)

In relation to the pouch presence, the incidence of gallstones was slightly but not significantly greater (P=0.0707) as shown in table 2.

<tr>
<th>Presence of Hartmann pouch and gall Stones</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gallstones</td>
</tr>
<tr>
<td>present</td>
</tr>
<tr>
<td>absent</td>
</tr>
</tbody>
</table>

2. Histological study:

Histological examination to the neck area of the pouch reveals three layers: the mucosal layer in form of
villi lined with simple tall columnar cells, faint stained cytoplasm and basely placed nuclei; the lamina propria with loose connective tissue and diffuse lymphatic tissue. The fibromuscular layer and smooth muscle layer interspersed with layer of loose connective tissue rich in elastic fibers. The outer layer is a wide perimuscular loose connective tissue having numerous blood vessels, lymphatics, and nerves. The serosa is seen outside. This histological picture resembles the normal histology of gallbladder (Fig 5).

Fig 5: Different histological sections of Hartmann pouch showed layers of mucosa (M), lamina propria (LP), connective tissue (CT) with blood vessels (BV), muscular layer (ML) and serosa (S), (10X, 40X),
Discussion

Brunicardi 2010 [21] found a developmental curvature at the neck region of the gallbladder, which may enlarge to form the Hartmann pouch. Standring 2008, Moore and Dalley 2006 [22, 23] detected a dilatation located at the junction of the neck of the gallbladder and the cystic duct, which is identified as Hartmann’s pouch. This anatomical variation of the biliary system and its associated choleithiasis may result in serious intra operative and postoperative complications [24, 25].

The present study found Hartmann pouch in 10 out of total 214 gallbladders (4.6%) which agrees with many other articles regarding the incidence like Leena et al 2015 who gave 4% of Hartmann pouch over total specimen examined in south Keralites, Another study by Nuran et al 2012 identified the pouch in 4 cases out of 70 (5.7%) in Dhaka, Bangladesh while Raj et al 2017 found an incidence of 8-9%. These studies consider Hartmann pouch from anatomical point of view as infrequent feature but it disagree with Van Eijck et al 2007 who detected 51 Hartmann pouch out of 98 (52%) gallbladders examined which was much higher than the present study. he also considered Hartmann’s pouch as a morphological entity. Khan et al 2014 [26] registered also higher prevalence (72.5%) of population of Dhaka (Bangladesh). In addition, Hartmann pouch was observed in a slightly higher proportion (81%) in a group of chronic calculous cholecystitis patients. The current study noticed also that the pouch tend to be more frequent with increasing age (40-60 & above 60 years) which may be due to data sample (more adults and older patients than young). Slight significant difference regarding gender and Hartman pouch distribution was detected in this study (male have slightly elevated ratio which could be due to data sample distribution). These findings disagree with Futura and Kinifu 2001 [27] who noticed a significantly higher prevalence of kinking of the gallbladder and Hartmann’s pouch in the female subjects more than male subjects.

The gallstone formation is frequent worldwide and presented as a common clinical problem faced usually in daily clinical practice in Basrah city. Majority of biliary diseases are a complication of gallstones, in form of acute and chronic cholecystitis, obstructive jaundice, gallbladder empyema, acute cholangitis, acute pancreatitis, malignancy, etc [28]. Lakshmi [29] found a significant association between Hartman pouch and presence of stone which differ from the current results (No significant relation), it could be asymptomatic but it may present with clinical manifestation which increases as the pathology of adhesions between the cystic duct and the neck of the gallbladder exist.

The Hartmann pouch could be congenital or acquired, the true (congenital) diverticula may or may not be involved in the pathology within the gallbladder but it include all three histological layers of normal gallbladder. While the acquired type may result from a disease process and has little or no smooth muscle in the wall of gallbladder [30, 31]. This study found normal histology of Hartman pouch as that present in normal gallbladder. These findings distinguish Hartmann pouch as an anatomical entity in our area of study.

Conclusion

This study provides facts of the Hartmann pouch prevalence and nature, which is of value in clinical-surgical events to manage invasive procedures, therapeutics and diagnostics in this region. It is inconstant feature with low proportion in our population, found more at older age, may lodge gallstones and tend to be anatomical more rather than pathological. A good anatomical knowledge of these structures is required, especially when performing emergency room procedures. Further recommendation is to study the Hartman pouch by imaging ultrasound in population with larger sample size.

Evaluation of Root Canal Morphology of Permanent Maxillary Canine Using CBCT – A Cross-sectional Study

Nor Masitah Mohamed Shukri1, Mahesh Ramakrishnan2
1Undergraduate Student, Saveetha Dental College, 2Department of Pediatric Dentistry, Saveetha Dental College and Hospital, Saveetha Institute of Technical Sciences, Chennai, India

Abstract

Background: A clear understanding and thorough knowledge of anatomy of human teeth is the utmost of importance to all dental procedures especially in endodontic and orthodontics treatment. This includes the study of root canal anatomy and its variations according to the race and gender.

Aim: The scope of the research was to determine the root and canal morphology of the maxillary canine in Indian population by analyzing cone-beam computed tomography (CBCT) images.

Material and Method: Forty-six CBCT images consisting of 20 males and 26 females were examined in this study and a total of 88 maxillary canines were analyzed. The root anatomy of each tooth was evaluated for the following parameters: the root canal patterns, the shape of the access cavity, the mesiodistal width of the crown and the distance from occlusal pit to the pulp chamber. The data was analyzed and compared and p-value of the data was considered 0.05 statistically.

Result: It can be concluded that a higher prevalence of maxillary canines have Type I root canal pattern in both gender. The most common shape of access cavity in male subjects was oval. Round access cavity was the most frequently observed in female subjects. Maxillary canine in male population also had greater mesiodistal crown diameter than female population.

Conclusion: The present study reported the normal anatomy and variations of maxillary canines in Indian population. The incidence of root canal morphology differed with gender.

Keywords: CBCT, maxillary canine, root canal morphology, Vertucci’s classification.

Introduction

Complete mechanical preparation of the root canal system plays an important role of a successful endodontic diagnosis and treatment. Nevertheless, many roots possess accessory canals and a wide variations of canal configurations which some are considered unusual1.

Universally, canines are referred as the cornerstone of the human teeth with the canine eminence on their labial portion of the teeth. This is because canines help in normal facial appearance at the corners of the mouth and also functionally, they are important for determination of intercuspal position through the canine guidance in dental occlusion2. Maxillary canines typically present with a single root and a single canal. The root is oval in cross section containing an oval cross-section canal. However, root canal configurations in maxillary canines may vary according to the race, sex and population. There are many studies from past to the recent on root canal morphology and configurations have been reported which varies with the respect to the race, gender and ethnicity. All these demonstrated the complexities of the entire root canal space and frequently reported that a single root canal exists as a single foramen3,4,5,6.
As the root canal morphology varies from tooth to tooth and its classification is much needed for communication, diagnosis and treatment planning, numerous classification for root canal morphology and its modifications have been proposed over the years which figures the total number of root, the number of canal in every root and the course of canal which confines the root. The earliest classification of root canal morphology was given by Weine FS et al in 1969 and followed by Vertucci FJ in 1984. Vertucci FJ demonstrated configuration for three canals, after he studied the root canal morphology of maxillary first premolar using clearing technique. His classification contains eight types of root canal system and is the most commonly used in most of the studies. Aminsobhani et al reported a significance number of mandibular canines had more than one root canal in Iranian population. Caucasian population was identified with only Type 1 canal in maxillary canines and additional canal configuration (1-3-4-1) was found in Turkish population.

It is well known that there are many methods can be done to study the root and canal morphology, which includes computed tomography (CT) scanning, cone beam computed tomography (CBCT) canal staining and tooth clearing techniques, conventional radiography techniques, contrast medium-enhanced radiography and sectioning. Cone beam computed tomography (CBCT) has become a successful tool to examine the root canal anatomy and has been widely used nowadays. It had been introduced in dentistry since the year of 1990 for endodontic purpose. CBCT works in the cone-shaped beam of radiation in a single 360° rotation and it is more advantageous than CT scanning due to its improved accuracy, low radiation dosage and lesser scanning time. Neelakantan et al. also supported that this technique is considered as the gold standard of identification root canal morphology. This study aims to determine the root and canal morphology of the maxillary canine in Indian population by analyzing cone-beam computed tomography (CBCT) images.

**Material and Method**

**Sample Collection**

The sample size was determined based on the G Power analysis. It was calculated by using prevalence of 0.05% and the precision (d) is 0.05. The power analysis indicated that 76 sample size were required. In order to increase power of this study, 86 maxillary permanent canines were examined.

\[
\text{Sample size} = \frac{Z_{1-\alpha/2}^2 \cdot p(1-p)}{d^2}
\]

Here

- \(Z_{1-\alpha/2}^2\) is the standard normal variate. As in majority of studies p values are considered as 0.05 so, 1.99 is used in formula
- \(p\) is the expected proportion in a population based on previous studies and the value is 0.05
- \(d\) is the absolute error or precision and it is 0.05

\[
\text{Sample size} = \frac{1.99^2 \times 0.05(1-0.05)}{0.05^2} = 76
\]

A total sample of 46 CBCT images consisting of 20 males and 26 females were examined in this study and a total of 86 maxillary canines were analyzed. The root anatomy of each tooth was evaluated for the following parameters: the root canal patterns, the shape of the access cavity, the mesiodistal width of the crown and the distance from occlusal pit to the pulp chamber. The criteria selections are presence of erupted maxillary permanent canines, complete formed root apices and those with free of deep caries, fracture and root canal fillings.
Scanning Procedure

CBCT images were obtained in the Saveetha Dental College, Department of Oral and Maxillofacial Radiology and the software used was SICAT Galileo Viewer version 1.9. Tomography sections of 0.3 mm axial planes and magnification was 1 : 1 were created. Serial axial CBCT images were examined by carefully rolling the toolbar from the pulp chamber to the apex.

The shape of access cavity at cementoenamel junction (CEJ) was evaluated in cross sectional view and Jou et al.’s classification was used15. The root canal pattern of maxillary permanent canines was classified based on Vertucci’s classification. Mesiodistal width of crown structure in mesiodistal planes was measured based on three levels; incisal third, middle third and apical third. The distance between occlusal pit and pulp chamber was also measured in this study.

Results

Root Canal Pattern

According to the present study, the most prevalent root canal configuration of maxillary canine in both gender were Type I (male 75% and female 79.2%). Maxillary canines in male patient had 15% of Type II and equally 5% of Type III and Type V. In female patients, their other root canal patterns were Type IV (8.3%), Type V (8.3%) and Type VI (4.2%). Both gender did not have root canal morphology Type VII and VIII. Present results are tabulated in Table 1 and Table 2 shows comparison with earlier studies on maxillary canines.

Shape of Access Cavity at CEJ

In male patients, a relatively highest percentage of the shape of the access cavity was oval (40%) and other shapes include; round (35%), long oval (20%) and flattened (5%). The most common shape of access cavity of maxillary canines in female patients was found to be a round shape (54.2) and the least was long oval (8.3%).

Mesiodistal Width of Crown

The average of mesiodistal width of crown structure in male patients was higher than female patients with the respect of incisal third, middle third and apical third.

Distance Between Occlusal Pit and Pulp Chamber

Present study showed maxillary canines in male patients (mean = 4.67) had longer distance between occlusal pit and pulp chamber than in female patients (mean = 4.17).

Figure 1: Vertucci’s classification of root canal system [16]
Discussion

Most of the methodologies to study root canal anatomy in the past such as periapical radiographs, clearing and demineralizing method and surgical operating endoscopy are invasive procedures as they are able to alter the actual canal morphology of the root. Based on a test done by Nguyen, it was proven that CBCT is an accurate measurement tool that can be used for measuring mesiodistal diameter of unerupted teeth. Neelakantan et al. also said in his study that CBCT is the gold standard in the determination of root canal configuration since its technology overcomes some drawbacks of conventional radiography as relatively high-resolution, very thin and high contrast that is able to eliminate distortion, superimposition and artifacts of the imaging.

For centuries, a great number of researchers have been studying the morphology of root canal especially in human teeth and they occasionally concluded that the system of root canal morphology have always been varies in regards to the ethnicity, gender and also population. Most reported earlier studies include the population of America, Sudan, Chinese, Sri Lanka, Uganda and Turkey. The variation of root canal morphology extremely is challenging in endodontic and orthodontics management. Endodontists bear huge responsibilities to clean these canals from any microbial biofilms with a proper mechanical preparation and use of irrigants. All these can only be achieved with a thorough knowledge and comprehension of the root canal anatomy thereby reducing the number of post treatment failures.

In the current study, the most common root canal pattern in both male and female Indian are Type I (75 % and 79.2 % respectively). Similar findings were found by Vertucci (100 %), Sert and Bayirli (91 %) and Pineda (100 %) in maxillary canines (Table 2). The second most common root canal in the maxillary canine of male was a Type II (15 %), followed by Type III and Type V, both in 5% of the samples. In the present study, the second most commonly occurring canal pattern in maxillary canines of female population was Type IV and Type V at 8.3% and followed by Type VI in 4.2% of the samples. Previous study10,11,19 did not report the presence of Type V and Type VI canal morphology in...
the maxillary canine, but in the present study both types of canal pattern were seen in both gender.

The various shape of access cavity of maxillary canine is tabulated in Table 3. In maxillary canine of male population 14 teeth had round access cavity, which is at 35% of the samples. 16 teeth had oval access cavity, which makes up the most commonly (40%) occurring shape of access cavity in male population. Other shape include long oval access cavity at 20% and the least was flattened access cavity at 5%. In female population, the most commonly found was round access cavity at 54.2% (26 teeth), followed by 20.8% of flattened access cavity. Based on the report of Somalinga and Raghu20, the most common shape of the access cavity was oval, found in 94 teeth with the percentage of 37.6%. 66 teeth of maxillary canine had flattened access cavity, amongst which 59% of the teeth had more than one canal. Somalinga and Raghu also reported that a flattened shape of access cavity might have more than one canal pattern in both maxillary and mandibular canine.

Based on the result of present study, male population (mean value = 4.67mm) showed a greater distance between occlusal pit and pulp chamber than female population (mean value = 4.17mm). Precaution should be taken into notes during access opening preparation of canals in order to prevent perforation. The average measurements of crown diameter of male and female subjects at incisal third were 6.73mm and 6.6mm respectively. In male subjects, it was 6.79mm at middle third and 5.7mm at apical third. Meanwhile, the average crown diameter of female population was 6.13mm at middle third and 5.18mm at apical third. For this study, comparison was made and one can differ that male subjects highly has greater mesiodistal width than female subjects. This is very helpful in replacement of prosthetic teeth in the cross section of population.

**Conclusion**

The present study reported the normal anatomy and variations of maxillary canines in Indian population. The incidence of root canal morphology differed with gender. CBCT is truly a useful device for endodontic diagnosis and treatment. It can be concluded that a higher prevalence of maxillary canines have Type I root canal pattern in both gender. The most common shape of access cavity in male subjects was oval. Round access cavity was the most frequently observed in female subjects. Maxillary canine in male population also had greater mesiodistal crown diameter than female population.

Relationship between Radiographic Evaluation with Age and Gender – A Radiographic Study

Nor Syakirah Binti Shahroom¹, Gheena.S²
¹Undergraduate Student, Saveetha Dental College, ²Reader, Department of Oral Pathology, Saveetha Dental College, Saveetha Institute of Medical and Technical Science, Saveetha University

Abstract

Background: Forensic odontology plays an important role in identification of man-made or natural disasters event which restricts identification through conventional methods. Various approaches have been specified which helps in the identification of the post-mortem remains. One such is the identification of the morphological features of the human skull and mandible. These features may help in sex differentiation. The aim of this study is to evaluate the relationship between radiographic evaluation with age and gender.

Materials and Method: A retrospective study was done with a total of 250 panoramic radiograph image. The images of 150 males and 100 females were selected with the range of age from 20 to 70 years old and divided into group 1 (20-45 years old) and group 2 (46-70 years old). Three parameters were evaluated from the panoramic radiograph which were gonial angle, antegonial angle and mental foramen against the age and gender. Statistical analysis was done for hypothesis testing.

Results: The results of this study suggests that there is no significant difference seen in the gonial angle and antegonial angle with relation to the age (p≥0.05). However, the relationship between age and mental foramen is highly significant (p≤0.01). With regards to gender, all the three parameter shows highly significant results with (p≤0.01).

Conclusion: In conclusion, the three parameter assessed in this study can be used for gender differentiation but not for age estimation which were highly significant. As for age estimation, the distance of mental foramen and tangent line of inferior border of mandible can be assessed.

Keywords: Antegonial angle, gonial angle, mental foramen, panoramic, radiographic evaluation

Introduction

An event which causes total destruction to the human body may require a group of specialist which deals with post-mortem identification. This team would include a forensic odontologist. Forensic odontology is a branch of dentistry which in the interest of justice, deals with the proper handling and examination of dental evidence, and with the proper evaluation and presentation of dental finding (1). This specialised branch of dentistry helps in identification of human remains if the other conventional method such as fingerprints and visual recognition are not possible (1).

The skeletal remains play an essential role in identification of gender. Most common skeletal parts used in the previous study were the skull and mandible. However, mandible which is the almost dimorphic, largest and strongest bone contributes to the significant difference in identifying gender among the human remains (2, 3). Mandible is made up of compact bone which makes it durable and highly resistant to fracture(4).
Apart from that, chronological age assessment is also an important factor in identifying human remains. Several factors may affect the morphological changes in the mandible which are the dental status and age. Some anatomical structure which might be affected are gonial angle, antegonial angle, condyle and ramus.

Dentofacial radiographs plays a significant role in identifying anatomical landmarks of the maxilla and mandible. Various intraoral and extra oral radiographs are available. However, the most commonly used radiograph in the assessment of anatomical landmarks in the mandible are the orthopantomography (OPG) or panoramic radiograph. This radiograph shows a whole view of the dentofacial tissues of the maxilla and mandible (5). Besides, the use of OPG in forensic anthropology which helps in the comparison of ante-mortem and post-mortem radiographs is one of the cornerstones of positive identification of human remains(4).

The aim of this study is to evaluate the relationship between the radiograph evaluation with age and gender. The radiographic evaluation includes the gonial angle, antegonial angle and mental foramen.

**Materials and Method**

This retrospective study was conducted in Department of Oral Medicine and Radiology at Saveetha Dental College and Hospital, Chennai, India. This study was approved by the institutional ethical committee of the college and informed consent was taken from all patients who were included in the study. A total of 250 panoramic radiographs were taken from the department. A few inclusion and exclusion criterias were assessed before including the radiographs in this study. The inclusion criteria was a clear radiographic image showing the anatomical landmarks of the gonial angle, antegonial angle and mental foramen. The exclusions criteria were any fractured mandible, mixed dentition, blurred radiographic images and micrognathia.

In this present study, three parameters were assessed which were the gonial angle, antegonial angle and mental foramen. Gonial angle is the angle between the distal ramus of mandible and lower border of the mandible. The angle can be determined by tracing two line intersecting from the distal ramus of mandible and lower border of mandible. Next, antegonial angle is an angle formed at the deepest antegonial notch at the lower border of the mandible. It can be measured by tracing a line parallel to the antegonial region. Third parameter was the mental foramen. It was measured by drawing a line tangent to the lower border of the mandible and a perpendicular line from the inferior most mental foramen was drawn along the tangent.

The panoramic radiographs were divided into two category: age and gender. For the first category, the age was divided into two groups. Group 1 consists of patient age from 20-45 years old and group 2 consists of patient age from 46-70 years old. Based on gender, the patients were divided into male and female. Statistical analysis was done by using t-test to test the hypothesis.

**Results**

Table 1 shows the result of this study which suggests that there are no significant differences seen in the gonial angle and antegonial angle in relation to the age (p≥0.05). However, the relationship between age and mental foramen is highly significant (p≤0.01). In regards of gender, all the three parameter shows a highly significance results with (p≤0.01) as shown in Table 2.

</tbody>
</table>
The relationship between age and the radiographic evaluation shows that as the age increases, the more obtuse the gonial angle become. There is slight increase of gonial angle in group 2 with 123.15 ± 8.92 compared to group 1 with 122.38 ± 7.27. Meanwhile, there is no significance difference seen in the antegonial angle in both age groups. As for mental foramen, the distance is greater in group 2 compared to group 1 (11.33 ±1.08 and 10.60 ± 1.79).

</tbody>
</table>

This present study shows that male has a smaller gonial angle compared to female (121.05 ± 8.74 and 124.89 ± 6.28). To compare the antegonial angle, female has a greater antegonial angle compared to male (167.04 ± 5.44 and 164.60 ± 7.99). However, for the distance of inferior border of mental foramen to the tangent line of inferior border of mandible shows a slight differences between male and female (11.09 ± 1.62 and 10.61 ± 1.51).

Discussion

Based on the results of this study, there was no statistically significant difference between age and gonial angle. However, there was increase in gonial angle as the age increase. In the study done by Upadhyay et al, there was a significant decrease in the mean gonial angle as the age advances but the results were not statistically significant to be reliable (6). Meanwhile, in the study done by Bhardwaj et al., Kasat V et al., and Shendakar AT et al., suggested that there were changes of the gonial angle from more obtuse to less obtuse and become more obtuse as the age advances (7-9). Apart from that, another study done by Sicher H et al, suggested that edentulous patient will have a greater gonial angle due to the disuse atrophy and tooth loss (10). In the study done by Carolina et al, there was significant difference between age and gonial angle in which the gonial angle decreases and stop from 21 years old onwards (11).

According to gender, many studies suggested that the gonial angle were greater in female compared to male which was similar to this present study (≤0.01). In the study done by Burak Apaydin et al. and Revant H. Cole et al. a statistically significance difference were found between male and female patients (p≤0.05) in which female has greater gonial angle than male (12, 13). However, in the study done by Upadhyay et al., Raustia AM and Salonen mam and Ceylan et al, there were no statistically significance between gender and gonial angle (6, 14, 15). Usually, male will have a greater mean angle of 3°-5° due to the large anatomical mandible (16). Nevertheless, the reason why female has a greater gonial angle is due to the masticatory forces act on the mandible (7). On average, male will have a greater masticatory forces which results in smaller gonial angle. The rotation of the mandible which is different between male and female may also affect the gonial angle. Female will have a downward and backward rotation of the mandible whereas male will have a forward rotation of mandible (12, 17).

The next parameter assessed was the antegonial angle. This study suggested that the antegonial angle in female was greater than male with a statistically significant result (≤0.01). The result was comparable with the study done by Bhardwaj et al and Burak Apaydin et al which showed that antegonial angle was greater in female which was highly statistically significant (≤0.01) (7, 12). Antegonial region is situated at the lower of mandible which is exposed to bone resorption which in turn decrease the antegonial angle and antegonial depth. The reason of the differences between male and female may be due to the hormonal changes. Testosterone and oestrogen affecting the bone metabolism of male and female respectively (7).

The relationship between the age and antegonial angle in this present study was not statistically significant (≥0.05) which was comparable to the study done Ghosh et al. Only a slight changes seen between group 1 and
Mental foramen is an anatomical landmark which is usually seen in the second premolar and first molar region. In this study, there was a statistically significant changes seen in the distance of mental foramen from the tangent line of the inferior border of the mandible (≤0.01) in relation to age and gender. As the age increases, the distance increases. Usually in the adults, the mental foramen is nearer to the inferior border but as the age advances, the mental foramen moves upward closer to the alveolar border due to tooth loss and bone resorption (19). In the study done by Bhardwaj et al, Amorin M et al, Kasat V et al and Shendarkar et al suggested that there were no statistically difference between ages (7-9). However, with regards of gender, this study showed that the distance from mental foramen to the tangent line of inferior border of mandible is higher in male than female (≤0.01) which is consistent with the study done by Burak Apaydin et al and Thakur et al (12, 20). Meanwhile in the study done by Prabhu et al, there was no statistically significant between mental foramen and gender (≥0.05) (21).

**Conclusion**

In conclusion, the three parameter assessed in this study can be used for gender differentiation but not for age estimation as gender differentiation alone was highly significant. As for age estimation, the distance of mental foramen and tangent line of inferior border of mandible can be assessed. Further study should be done using advanced modalities device to reduce the limitation of this study.

Corrosion of Orthodontic Metallic Brackets Immersed in Solutions of Salt and Spices in Artificial Saliva

Nurul Afiqah Amani Binti Zaaba¹, Harish Babu²
¹Graduate Student, ²Department of Orthodontic, Saveetha Dental College, Saveetha University, Chennai, India

Abstract

Background: Orthodontic treatment is commonly use to treat dental malalignment, especially orthodontic braces as it help to realigned teeth to the normal position as well as for aesthetic purpose. As orthodontic braces is a choice of orthodontic treatment various kind of orthodontic braces had been invented based on the material used, adhesives systems as well as their strengths to bring about tooth movement. As it is placed in the oral cavity, the aggressive environments of the oral cavity, will lead to corrosion of the orthodontic brackets. This may affect it physical properties and clinical performance.

Aim: To study the corrosion of orthodontic brackets that immersed in the solution of artificial saliva and spices.

Materials and Method: Stainless steel orthodontic brackets were used for this studies. Each bracket was placed in the container contain artificial saliva and other agents. Several types of aqueous solutions were prepared for this study by using different agents (spices). They were pure artificial saliva, salt (sodium chloride), black pepper, turmeric and mixture of all of the spices along with salt. After 24 hours, surface changes was seen under the optical microscope.

Results: Based on the study, orthodontic brackets surface immersed in the controlled medium, revealed that more corrosion was seen in the salt medium when compared to pure artificial saliva. More pitting also was seen in the salt medium of the controlled group. Based on the surface analysis of the orthodontic brackets in the studied groups, demonstrate that more corrosion and pitting was seen in the aqueous solution of mixture of artificial saliva with salt and spices and less pitting and corrosion was seen in the turmeric solution.

Conclusion: Based on the study, the finding suggest that the corrosion behaviour of the orthodontic brackets is influenced by the presence of a salt (NaCl) and other spices. Salt and black pepper are responsible for the corrosion of the orthodontic brackets, while turmeric capable in reduction or slowing the process of corrosion.

Keywords: Corrosion of brackets, spices, orthodontic treatment

Introduction

Orthodontic treatment is commonly use to treat dental malalignment, especially orthodontic braces as it help to realigned teeth to the normal position as well as for aesthetic purpose. Early approach for orthodontic treatment will help to provide a better outcome. As orthodontic braces is a choice of orthodontic treatment various kind of orthodontic braces had been invented based on the material used, adhesives systems as well as their strengths to bring about tooth movement. This will help to provide a good results and also patient comfort and aesthetic through the dental treatment. Example of dental brackets include metal brackets, titanium brackets, ceramic bracket and plastic brackets (aesthetic) [1].

Among these brackets, metal brackets is commonly used for orthodontic treatments due to their strong shear strength and also its successful results in clinical orthodontic study. However, when orthodontic brackets are placed inside the oral cavity, pitting and corrosion may occur as they are exposed to the components of the saliva as well as the food that accumulate in the oral cavity. Generally, saliva composed of inorganic salts which mainly chlorides and phosphates, along with other components like organic acids, enzymes, bacterial and also gastric secretions [2]. These mixture of saliva along with the food intake (especially spices), will create an aggressive environment for the orthodontic braces, which in return may results to degradation. Even though, they are manufacture to become resistant against the mechanical stress and also degradation cause by the active forces and corrosive environment [3].

This aggressive environments of the oral cavity, will lead to corrosion of the orthodontic brackets. Variety of dietary sources like spices, common salt; sodium chloride (NaCl), fruit juices and carbonated drinks also could be one of the factors which promote the corrosion of the brackets [4]. therefore, diet plays an important role in causing the corrosion of the metal appliances that placed in the oral cavity [5]. Corrosion of this dental materials in oral cavity tend to cause tooth discolouration, local pains or allergic reactions due to released of the metals ions into the organisms present in oral cavity [3,6]. Apart from that, corrosion of the metal parts can also affect their biomechanical properties along with the appliance efficacy [7].

On the orthodontic brackets surfaces, pitting corrosion are commonly seen. It is the most destructive type of corrosion which seen in the orthodontic appliances placed in the oral cavity [8]. It caused localised type of corrosion which can be scattered, isolated or closed together in forms of holes or pits within the metal. It will result to rough like appearance on the surface of the appliance. This pitting usually occur primarily within the crevices or other protected areas on metal surfaces that exposed to ward the corrosive agents or environment [4]. Therefore, this study was done to evaluate the relationship between the corrosion of the orthodontic brackets in artificial saliva with salts and spices.

### Materials and Method

#### Artificial Saliva

Materials that bring used in the study were mainly orthodontic brackets, artificial saliva and also spices. Orthodontic brackets used for the study are stainless steel (Libral Traders). The artificial saliva used was Wet mouth ICPA, which is manufactured artificial saliva for wetting purposed. It commonly indicated for the xerostamia patient or patient on oral therapy. It composed of water, glycerine, cellulose gum, sodium saccharin, parabens and also flavouring agents.

#### Salt and Spices

Several types of aqueous solutions were prepared for this study by using different agents (spices). They were pure artificial saliva, salt (sodium chloride), black pepper, turmeric and mixture of all of the spices along with salt. Salt which is sodium chloride (NaCl) was used as the promoter of corrosive agent in this study, while numeric act as inhibitor of the corrosion. The chemical compositions of the spices used in this study were showed in Table 1.

Surface analysis study

Initially, this study was conducted by preparing the aqueous medium, followed by immersing the orthodontic brackets in the prepared aqueous solutions as shown in Figure 1. The orthodontic brackets was placed in the closed container for about 24 hours. After 24 hours, surface analysis was done in order to identify the rate of corrosion of the orthodontic brackets immersed in the artificial saliva with salt and other spices solutions. Surface analysis was done by using the optical microscope.

Results

Artificial saliva and artificial saliva with sodium chloride medium were controlled variables of the study, which used as reference mediums. Whereas, turmeric, black pepper and mixture of the spices were used as the studied solutions. Based on the visual observation of the orthodontic brackets surface immersed in the controlled medium, it revealed that more corrosion was seen in the salt medium when compared to pure artificial saliva. More pitting also was seen in the salt medium of the controlled group.

Based on the surface analysis of the orthodontic brackets in the studied groups, demonstrate that more corrosion and pitting was seen in the aqueous solution of mixture of artificial saliva with salt and spices as shown in Figure 6. Figure 3 reveals less pitting and corrosion was seen in the turmeric solution. The corrosion and pitting of the orthodontic brackets were arranged in the ascending order as mention below.

1. Turmeric
2. Artificial saliva
3. Salt
4. Artificial saliva and black pepper
5. Mixture of artificial saliva, salt, turmeric and black pepper

Discussion

Variety of spices used in food have lots of benefits and medical used. In general, both tumeric and black pepper are having anti oxidants property, which allowed them to scavenge the free radicals produced inside the body. However, when they are consumed in a large amount it may cause corrosion to the orthodontic appliances which placed inside the oral cavity due to their aggressive nature especially the black pepper. Salt is also one of the ingredients which commonly used in food, as flavour enhancer. However, high intake of salty food should be avoided especially during the orthodontic treatment, as it can promote the corrosion of the orthodontic brackets, due to formation of acid. This acid is formed due to release of chloride ions from the salt with all available hydrogen ions in the oral cavity.

Released of the chloride ions from the salt also cause negative effect on the formation of the passive layer on the metal surface. Passive film is a protective film that formed on the orthodontic alloy which can be spontaneously forms or reformed in air or under the wet conditions, in the presence of oxygen. Oxygen allow this film to form and maintain it consistency. However, in the presents of acidic or chloride ions, it may cause alterations on the passive film, which can promote corrosion of the orthodontic brackets. This chloride ion will combine with a metal ion to form metal chloride, which lead to dissolution and propagation of the latter in autocatalytic manner. As the release of this metal ions increased, this will result to increase in the pH of the saliva, which in turn increase the rate of corrosion of the orthodontic brackets.

Other spices like black pepper and chilly powder also may cause corrosion of the orthodontic brackets, due to their aggressive nature. Adding of the black pepper to the artificial saliva enhance the aggressive property of the artificial saliva also through chloride ions, which promote corrosion of orthodontic brackets. Pitting is one of the common localised corrosion which seen on the surface of the metallic orthodontic brackets. It usually form due to the chloride ions, which break down the protective thin oxide film and cause rapid dissolution of the underlying metal and result to localise pitting formation. Thus, it may cause formation of holes, if the solution are too aggressive. Therefore, mixture of artificial saliva with salt and black pepper show the most corrosion in compare to other aqueous solutions.

Although, some spices can cause corrosion of the orthodontic brackets, some spices may inhibit or slowing the process of corrosion of orthodontic brackets like turmeric and coriander. The components of turmeric may have favoured in delayed of the corrosion of the orthodontic brackets. They will allow for prevention of adsorption of chloride ion, which is the responsible agent to cause pitting and corrosion of the orthodontic brackets. Therefore, aqueous solution of turmeric show the least corrosion on surface analysis min compare to other mixtures.

Thus, a proper diet should be educate to patient undergone the orthodontic treatments, as corrosion of the orthodontic appliances may affect the physical properties and its mechanical performance for a success orthodontic treatments.

Conclusion

Based on the study, the finding suggest that the corrosion behaviour of the orthodontic brackets is influenced by the presence of a salt (NaCl) and other spices. Corrosion can cause weakening of the orthodontic brackets and leading to mechanical failure of the orthodontic treatment, as it may affect the physical and chemical properties of the materials. Salt and black pepper are responsible for the corrosion of the orthodontic brackets, while turmeric capable in reduction or slowing the process of corrosion. Therefore, a proper diet should be instructed to patient undergone orthodontic treatment, in order to prevent failure of the treatment and also promote the success of the treatment.

Cheiloscopy: The Study of Lip Prints in Sex Identification between Indian and Malaysian Population

Nurul Afiqah Amani Binti Zaaba¹, Gheena.S²

¹Graduate Student, ²Department of Oral Pathology, Saveetha Dental College, Saveetha University, Chennai, India

Abstract

Background: The study of lip prints, is commonly applied in forensic odontology and it is known as cheiloscopy. The term cheiloscopy was derived from Greek words, in which “cheilos” means lip and “scopy” means to examine. In general, cheiloscopy is define as a method of identifying an individual based on the arrangement of lines seen on the red part of the lips or a science dealing with the various line appearing on the red part of the lips. The pattern of wrinkles and grooves that are present on the lips has distinct characteristic features of an individual which are almost similar to the fingerprints. It also will not change throughout the life. Therefore, it can be used for personal identification and sex determination.

Aim: To investigate lip print pattern in males and females and to evaluate them between Malaysian and Indian population.

Materials and Method: There were 40 participants of both gender. 20 of them are from the Malaysian population and another 20 people are from the Indian population. Each participant was instructed to clean their lips with a clean white cloth, before taking the lip print. This was followed by the application of dark coloured lip stick on lips by using the lip stick applicator. Cellophane tape was used to take the negative impression of the lip pattern. The glued portion of the cellophane tape was placed on the lips by giving a light pressure beginning from the centre of the lips till the corner of the mouth. Then, the impression was transferred to a clean white paper and seen under the magnifying glass.

Results: Type I lip pattern was commonly seen in Indian population, followed by type III, II and IV. Whereas for Malaysian population, type III was most common followed by type I, II and IV. There was significant difference between both population. In this study, it showed that type I was the most common lip print pattern seen in both Indian and Malaysian population for females. Whereas for male, type III was more common in Malaysian population, and both type III and IV were more common in Indian population.

Conclusion: There was no significant difference in both population according the general distribution of lip print pattern. There was no correlation or similarity of lip print patterns between each participants in both population. Thus, cheiloscopy can be used for sex determination and also personal identification.

Keywords: Lip prints, Cheiloscopy, Malaysian population and Indian population

Introduction

Each of every human beings is very unique, as each of the individuals have different personality along with their facial and body features. These special features can be used to distinguish one individual from another. Generally, fingerprints and DNA coding are commonly used in personal identification especially in the forensic field, as this information can be easily obtained and
different for each individual. This is also similar to the lip prints. The pattern of wrinkles and grooves that are present on the lips has distinct characteristic features of an individual which almost similar to the fingerprints [1]. It also will not change throughout the life [2]. Even though, inflammation, trauma or disease like herpes may occur, there is possibility for the pattern on the lips to recover to normal pattern [3].

In fact, smoking and age factors also does not influence the alteration or changes of lip pattern [4]. Therefore, it can be used for personal identification and sex determination. However, under certain circumstances like genetic deformities, surgical marks or maybe due to their occupation like blowing musical instruments [5], alteration on the lip patterns may occur. It is also similar to fingerprints which can be lose due to works or injury to the finger. Thus, it may be a disadvantage in certain cases and in those cases under unavoidable circumstances, where other alternative like DNA is required for further investigations.

The study of lip prints, is commonly applied in forensic odontology and it is known as cheiloscopy. The term cheiloscopy was derived from Greek words, in which “cheilos” means lip and “scopy” means to examine [6]. In general, cheiloscopy is define as a method of identifying an individual based on the arrangement of lines seen on the red part of the lips or a science dealing with the various lines appearing on the red part of the lips [7,8]. This involves the examination of the normal lines and fissures in the forms of wrinkles and grooves present in the transition area in between the inner labial mucosa and the outer skin of the lips [9]. The wrinkles and grooves that form on lip, contribute to different type of lip patterns, which differs for each individual.

In a crime scene investigation, a study of lip prints is very useful as they can be used for crime analysis and can be used to identify and rule out the suspect of the crime. Even the sex of the suspect can be analysed and determined. The lip prints evidence obtained from the crime scene should be preserved and the lip prints of suspects should be obtained to ruled out the criminal. For personal identification, cheiloscopy is useful as the lip prints may have been preserve in photograph, which can be applied in individual identification. This proves that Cheiloscopy has an equivalent value for personal identification and sex determination in forensic similar to other types of forensic evidences [10]. Therefore, this study was conducted to investigate lip print pattern in males and females and to study between Malaysian and Indian population.

Materials and Method

The study was conducted based on Indian and Malaysian populations of both populations with the average age values of 19 to 22 years old. There were 40 participants involved in this study, in which 20 of them are of Indian population and remaining 20 participants are Malaysian population of both sex. Consents of individuals were obtained for this study. During this study, the lips of the participants should be free from any injuries or deformities which may alter the lip print patterns during the study. Cracked or chapped lip also should not be seen on the lip of the participants, as it may result to distortion of lip print pattern. Therefore, the lip should be smooth with no other irregularities seen on the lips.

Each participants was instructed to clean their lips with a clean white cloth, before taking the lip print. This was followed by the application of dark coloured lip stick on the participants lips by using the lip stick applicator for a smooth and a proper coverage of the lips. Cellophane tape was used to take the negative impression of the lip pattern. The glued portion of the cellophane tape was placed on the lips by giving a light pressure beginning from the centre of the lips till the corner of the mouth. Then, the impression was transferred to a clean white paper and seen under the magnifying glass. The lip prints obtained were kept, with respect to name and sex of the participants in each population. Each lip print impression was recorded and analysed for the sex determination and comparison between Indian and Malaysian population.

The classification of lip pattern was analysed according to the classification of lines on lips which was proposed by Suzuki and Tsuchibashi in 1970 [11,12]. They were divided into six types based on the shape and grooves presence on the lips. The lips were examined based on the majority of lines or grooves seen on the entire part of the lips.

- Type I: Clear-cut vertical grooves or line that run across the entire lips.
- Type I’: Straight groove that disappear half way into the lip, instead of covering the entire part of lip or similar to type I, but do not cover the entire lip.
• Type II: Grooves that fork in their course or branched grooves (branching Y-shaped pattern).
• Type III: Criss-cross pattern or intersected grooves
• Type IV: Reticular grooves.
• Type V: Grooves that do not fall into any of the categories and cannot be differentiated morphologically (Undetermined).

Next, for the sex of the individuals other types of classification was used, which was introduced by Vahanwala et al [13,14]. The sex determination based on the lip prints was done as follows. The results were tabulated and analysed.
• Type I, I’ pattern dominant: Female
• Type I and II patterns are dominant: Female
• Type III pattern present: Male
• Type IV showing varied patterns: Male

Results

The study revealed that there were no two lip prints matched or identical with each other, which approved the uniqueness and differentiation of lip print of each individual. Based on the Table 1, type I (40%) lip pattern was commonly seen in Indian population, followed by type III (25%), II (20%) and IV (15%). Whereas for Malaysian population, type III (40%) was most common followed by type I (35%), II (20%) and IV (5%). There was significant difference between both populations.

According to Vahanwala et al classification of lip print pattern, sex determination was done in general for both population. It was found that 19 individuals were correctly diagnosed as females (Type 1 and 2) and 17 individuals were correctly identified as males (type 3 and 4), based on the lip prints obtained. Only one participant was misdiagnosed as females and three participants were wrongly identified as males, as shown in Graph 1. This proved that type I and type II of lip prints were common in females, while type III and IV were common in males.

Next, based on Table 2, it showed the classification of lip print pattern based on sex of each populations. It showed that type III (70%) was more common in Malaysian population, while in Indian population both type III (40%) and IV (30%) were more common. However for females type I was the most common lip print pattern seen in both Indian (70%) and Malaysian (50%) population. Although, there was no significant difference in sex identification for both populations, the use of lip print pattern in sex determination was proven and can be applied for any situation where lip print pattern is available and can be used. There was also no significance difference based on the distribution of lip print pattern of both populations.

**Discussion**

Lip prints are considered to be one of important tools for personal identification as well as sex determination, as it has an equal value as the finger prints. In some cases it also can be used for finger prints or bite prints replacement or as supportive evidence. This study was carried out based on the cheiloscopy method, to describe the diversity of lip print patterns and its application in sex determination. Through the application of lip print
classification by Suzuki and Tsuchibashi as the standard classification, the results obtained showed compliance based on proposed groups by them. However, in general the lip print pattern was not focusing on a single type or group, but it is a combination of different types [15], which made the lip pattern appear different and unique for each person.

On top of that, the way the lip muscles relax to produce a particular pattern also give uniqueness to the lip print, as stated by Sivapathasundharam et al in 2001 [16,17]. Even for twins, although their lip print pattern may appear similar, but they are not exactly identical to each other [18]. Therefore, lip print can be used for personal identification, and even can be used to differentiate people in different populations.

In a crime scene, lip prints are usually found and can be easily collected as evidence for crime analysis. If the lip prints are invisible, it can be visualised by making impression over the pattern by using different type of powder like aluminium powder to give a clear visibility of the lip print. However, a lipstick print is more visible and can be easily traceable. This type of lip print shows distinct features and is difficult to be removed. Thus, they are known to be the persistent lip prints [19].

In addition to this, presence of minor salivary glands and sebaceous glands at the vermilion borders and edges of lip, along with hair follicles and sweat glands in between also will lead to secretion of oils and moisturization, which result to formation of latent lip print. This will enhance the formation of lip print pattern on objects such as glasses [20]. Hence, lip print pattern can be acknowledged for personal identification and also sex determination.

In this study, it showed that type I was the most common lip print pattern seen in both Indian and Malaysian population for females. Whereas for male, type III was more common in Malaysian population, and both type III and IV were more common in Indian population. The results obtained in our study was found similar with studies of Vahanwala et al [13], Preethi et al [19] and Shilpa et al [21]. However, the result obtained was opposite with the study done by Kiran et al [14], as they stated that type II pattern was common in both males and females, which was also obtained from study by Deepa et al [15]. There, were no lip print pattern similar or identical with each other observed in the study. This was also proven in another study.

Conclusion

In conclusion, type I was the most common lip print pattern seen in both Indian and Malaysian population for females. Whereas for male, type III was more common in Malaysian population, and both type III and IV were more common in Indian population. There was no significant difference in both population according the general distribution of lip print pattern. There was no correlation or similarity of lip print patterns between each participant in both population.

Ethical Clearance: The lip prints results were obtained with individuals consent from students of Saveetha Dental College, Saveetha University Chennai, India

Type 2 diabetes mellitus (T2DM) is one of the metabolic diseases characterized by hyperglycemia and includes individuals who have relatively insulin deficiency and insulin resistance. Helicobacter pylori (H. pylori) is a spiral-shaped bacterium, infects 50% of the world’s people, and inhabits in the human gastric epithelium, causing many diseases. It has been suggested that H. pylori infection is more frequent among T2DM patients. Aim of this study is to evaluate the levels of interferon gamma (IFN-γ) in Iraqi patients with type 2 diabetes mellitus infected by H.pylori bacteria. Anti-H.pylori IgG and IFN-γ concentrations were measured by enzyme-linked immunosorbent assay (ELISA). The study includes 140 patients, divided into 3 groups, which are a group of patients infected by T2DM and H.pylori (T2DMHp+ve), a group of patients infected by T2DM but not by H.pylori group (T2DMHp-ve), and the third group includes patients infected with H.pylori only (Hp), in addition to apparently healthy control group (AHC). Our study revealed significantly decreasing in serum IFN-γ in both T2DMHp+ve group (P˂0.05) and T2DMHp-ve group(P˂0.01), compared with an apparently healthy control group(AHC). Also, this study shows decreased IFN-γ level in patients with Hp group compared with healthy control but without significant difference. Also, the concentration of IFN-γ in T2DMHp+ve is slightly more than that in T2DMHp-ve group.

Key words: T2DM, Anti-H. Pylori IgG, IFN-γ

Introduction

Diabetes mellitus (DM) is one of the metabolic diseases characterized by increased blood sugar (hyperglycemia) due to defects in insulin secretion, insulin action, or both (1). By the year 2030, DM will be the 7th principal cause of death according to the World Health Organization (2). Some pathogenic processes are associated with the development of diabetes. These processes include destroying the beta cells (β-cells) of the pancreas with subsequent insulin deficiency, and others that cause resistance to insulin activity (3).

Type 2 diabetes (T2DM), accounts for about 90–95% of all diabetes cases. This form includes individuals who have relatively insulin deficiency and peripheral insulin resistance (4). T2DM is the primary cause of death in only 13% of mortality cases, whereas the rest 87% is due to diabetes-associated complications—including infections (5).

Patients with diabetes are found to have a reduced cytokine response to acute infections, and the immune system induces inflammation in type 2 diabetes mellitus (T2DM) and triggers insulin resistance along with diabetic complications (6, 7).

Helicobacter pylori (H.pylori) is a microaerophilic, gram-negative and spiral-shaped bacillus. It infects 50% of the world’s people, although most infected individuals have no clinical symptoms (8, 9).

H. pylori are capable to attack the stomach lining, and causes gastritis, peptic ulcer, gastric lymphoma, and gastric adenocarcinoma. It is adapted to survive in the acidic and harsh nature of the stomach which has an ability to change the stomach pH so they can survive (10, 11). It is indicated that the worsen glycemic and metabolic control rises the rates of H. pylori infections and in the same time, this pathogen is considered as one of the common problems of diabetic patients with
Interferon-gamma is a key immunoregulatory protein which plays a major role in both innate and adaptive immune response. The biological effects of IFN-γ are widespread. IFN-γ although may be implicated in protection versus H.pylori infection but in a long-term infection, IFN-γ may play a vital role in gastric inflammation (13).

The aims of the current study is to evaluation of IFN-γ concentrations in diabetic patients infected by H.pylori, diabetic patients non-infected with H.pylori, non-diabetic patients infected by H.pylori, in comparison with apparently healthy control.

Materials and Method

Samples Collection

Ninety eight blood specimens were collected from suspected individual’s revealed positive result by using H.pylori IgG rapid test. ELISA IgG test indicated that only (92) patients have H.pylori infection. 3 ml of venous blood were taken from patients and control group using 5 ml disposable syringes under sterile condition. The specimens were collected in gel tubes and left for 30 minutes until clotted at room temperature. The tubes were centrifuged at 3000 rpm for 5 minutes, and then the serum is divided into 3 equal parts in Eppendorf tubes and stored in (-40°C) until it was used.

Rapid Anti-H.pylori Test

Helicabacter pylori rapid test is a lateral flow chromatographic immunoassay based on the principle of the double-antigen sandwich technique.

Diagnosis of Anti-H.pylori IgG by ELISA

The human body produces IgG when infected by H.pylori. This test was performed according to Human H.pylori ELISA Kit (14).

Method principle

The surface of microplate wells is coated with a target protein and incubated with a primary antibody to the target protein, followed by a (secondary antibody) versus the primary antibody. After washing, the microplate well-bound enzyme activity is estimated with the microplate reader at 450 nm.

Interferon Gama (IFN-γ) Determination

Determination of Interferon Gama (IFN-γ) was performed according to the protocol of Human IFN-γ ELISA Kit (15).

Principle of the assay

This kit is based on the sandwich technique. Anti IFN-γ monoclonal antibodies were coated on microtiter well. Calibrators and samples react with the capture monoclonal antibody and with a monoclonal antibody labeled with HRP (sandwich formation). After incubation and washing, the bound enzyme-labelled antibody is measured through a chromogenic reaction by added TMB solution.

Results and Discussion

Distribution of the groups

This study includes 140 individuals divided into 3 groups including patients with diabetes mellitus type 2 infected by H.pylori (T2DMHp+ve) were 45 cases, patients with diabetes mellitus Type 2 not infected by H.pylori (T2DMHp-ve) were 48 cases and non-diabetic patients infected by H.pylori (Hp) were 47 cases. In addition to these groups, there is an apparently healthy control group (AHC) were 20 cases. According to the Specialized Center for Endocrinology and Diabetes-Baghdad/Al-Rusafa, diagnosis of T2DM was performed, while infections with H.pylori were determined initially by antibody rapid test as a screening test, then followed by ELISA as a confirmatory test.

Serum Anti H.pylori IgG levels

A. Rapid test

Ninety eight from 140 individuals gave positive results in rapid anti-H. pylori IgG as screening and qualitative test, and when confirmed by using ELISA method, only 92 of individuals gave positive result while all negative results in the rapid test were corresponding to ELISA results. So, the sensitivity of Anti- H.pylori rapid test were 100%,and the specificity was 87.5%, as shown in table 1. IgG Ab against H.pylori typically appears approximately 21 days after infection and can remain for a long period beyond eradication (16).

The low specificity of the immunoassays is may be due to cross-reaction between prepared crude antigen containing proteins with antibodies directed against
other bacteria (17).

B. Using ELISA method

Table 2 revealed a highly significant difference (P<0.001**) of serum anti-H. pylori IgG in T2DMHp+ve group were 41.6980±4.85127 and Hp group were 45.0590 ± 5.132 AU/mL in compared with a control group were (3.12 ± 0.211). Also, this study showed non-significant differences between T2DMHp-ve and healthy control group.

AHC: apparently healthy control; T2DMHp+ve: a group with type 2 diabetes mellitus infected by H. pylori; Hp: group infected with H. pylori; T2DMHp-ve: type 2 diabetes mellitus non infected by H. pylori; M±SE: Mean ± Standard error; ** highly significant P<0.01; N.S: Non-significant P>0.05.

The ELISA is an easy, cheap, effective and reliable immunological test, an alternative to UBT (Urea breath test) for detection of H. pylori infection (18, 19). Also, this study agreed with Mansour (2) who confirmed elevated the immunoglobulin (IgG) during infection with H. pylori. The immune system of the host produces antibodies (Abs) against H. pylori immediately after bacterial gastric colonization. The immunologic tests developed for detection of immunoglobulin g (IgG) antibodies that specific for H. pylori in the serum of patients.

The types of ELISA are more suitable for diagnosis of H. pylori infection in epidemiological studies of peoples. Different antigen preparations have been prepared in coating ELISA wells, in these methods: crude antigens, such as (whole cell extracts, glycine extracts, sonicated cell extracts), heat-stable antigens and recombinant antigens. Antibody levels remain in the blood for a long time. The best performance of these tests is dependent on specificity for detection of (local) H. pylori strains in each country by choosing antigens for coating the (ELISA) wells. Serological tests are recommended in many studies for epidemiological studies, and they based on the many reasons: rapid, inexpensive, availability, and easy in use, but it is not recommended for the confirmation of H. pylori elimination after treatment (20).
Comparison of IFN-γ levels among the study groups

The level of IFN-γ in patients in the study groups (T2DMHp+ve, Hp, T2DMHp-ve, and healthy control group) were (2.83 ± 0.29, 3.85 ± 0.65, 2.65 ± 0.28, and 4.07 ± 0.58 IU/mL) respectively.

Data in the table 3, revealed decreased significantly in serum IFN-γ in both T2DMHp+ve group (P<0.05) and T2DMHp-ve group(P<0.01) in compared with an apparently healthy control group(AHC).

Also, this study shows decreased IFN-γ level in patients with Hp group compared with healthy control but without significant differences between them. Also, it has demonstrated that the concentration of IFN-γ in T2DMHp+ve is slightly more than that in T2DMHp-ve group.

</tr>
</tbody>
</table>

AHC: apparently healthy control; T2DMHp+ve: a group with type 2 diabetes mellitus infected by H.pylori; Hp: H.pylori infected group; T2DMHp-ve: type 2 diabetes mellitus non infected with H.pylori; M±SE: Mean ± standard error; *significant; ** highly significant P<0.01; N.S: Non-significant P>0.05.

Type 3 diabetic patients obviously had a decreased capacity of IFN-gamma production by a down-regulated production of cytokine molecules in the endoplasmic reticulum of both (CD4 and CD8) T-lymphocytes compared to healthy individuals (21). Many studies agreed with our result that decreased IFN-γ in T2DM patients (22-25). But disagree with Amin and his co-workers (26), who found elevated IFN-γ concentration in T2DM and that indicates T-cells activation against infection.

IFN-γ may be suppressed by H.pylori as a strategy to escape immune destruction through interference with IFN-γ signaling and that may cause permanent infection by H.pylori in gastric epithelial cells (27). The expression of cholesterol-α-glucosyl transferase (cgt) by H.pylori reduces cholesterol concentrations in infected gastric epithelial cells which result in blocks IFN-γ signaling, allowing H.pylori to escape the inflammatory response of the host (28).

In 2015, Yang and his coworkers (29) agreed with this study who found non-significant differences of IFN-γ in H.pylori infected persons compared with the control group. In contrast, different studies disagreed with this study (30, 31) who revealed that raised production of lipopolysaccharides, may trigger innate inflammatory processes which associate with increased inflammatory cytokines, also Abdollahi (13) and Bimczok(32) showed increased IFN-γ concentration in H.pylori infected patients and that indicates T-cells activation against infection ,and the IFN-γ maintains mucosal inflammation and may stimulate disease development to gastric ulcer.

Conclusions

1. Concentrations of serum interferon gamma (IFN-γ) decreased significantly in type 2 diabetic patients whether infected or non-infected by H.pylori. Also, slightly decreased IFN-γ level in H.pylori infected patients who are non-diabetic.

2. Anti-H.pylori IgG rapid test is important for the primary diagnosis of H.pylori infection, although ELISA IgG gives more sensitivity and specificity for confirmation of this infection.

Detection of ESBLs CTX-M Gene of *E. coli* Isolated from Clinical Cases in Maysan Province

Rabab Naeem Alag¹, ZahidSa’doon Aziz¹

Department of Biology, College of Science, University of Misan, Maysan, Iraq

Abstract

The antimicrobial resistance are a worldwide increasing and important problem in health care domain. ESBLs represent a main group of β-lactamases enzymes that mostly produced by gram negative bacteria, and give resistance to β- lactam antibiotics, thus the detection of these enzymes are very important for optimal care of patients. The aim of this study was to determine the antibiotic profile with the prevalence of CTX-M gene producing *E. coli* isolates which recovered from clinical cases by phenotypic and genotypic methods. A total of (291) clinical samples (urine, wound swabs, blood and seminal fluids) were included in this study. All bacterial isolates were subjected to the cultural, microscopical, and biochemical examinations methods, confirmed by API 20E and Vitek 2 system. Where the results revealed that 105 of isolates were identified as *E. coli*. Antibiotic sensitivity was performed by using disk diffusion methods. Investigation of extended spectrum β-lactamase(ESBL) production for isolates was performed using Initial screening and double disc synergy method(DDST). The results showed that most isolates showed high resistance to β-lactam and Cephalosporins antibiotics and vast majority of isolates were resistant to a minimum of three classes of antibiotics, which indicate that identified *E. coli* were multidrug resistant and ESBLs producer. While all isolates were sensitive to Imipenem and Amikacin. PCR technique was performed to detect ESBLs blαCTX-M gene, the results revealed that (100%) of *E.coli* isolates carried this gene.

**Keyword:** *Escherichia coli*, Antibiotic Resistance, ESBL, CTX-M gene.

Introduction

β-lactam antibiotics are the most common agents used for treatment of many bacterial infections caused by Gram-negative bacteria, but resistance versus these antibiotic groups occurred rapidly worldwide.[1] Extended spectrum beta-lactamas(ESBLs) are defined as enzymes produced by certain bacteria that are able to hydrolyze extended spectrum cephalosporin, they are therefore effective against beta-lactam antibiotics such as ceftazidime, ceftriaxone, ceftaxime and oxyiminomonobactam.[2]ESBL-producing organisms are mostly resistant to other classes of antibiotics.[3] Therefore Patients who infected with ESBL producing organism not only have an increased risk of treatment failure and some times lead to death, but also require more health-care resources.[4]The CTX-M enzymes are belong to group of class (A) ESBLs that in general exhibit much higher levels of activity against cefotaxime and ceftriaxone than ceftazidime.[5]Additionally, the CTX-M enzymes have been recognized as the most prevalent among *Enterobacteriaceae* especially in *E.coli*.[6]

Materials and Method

Bacterial samples collection and identification:

A total of 291 samples, were collected from different clinical cases (urine, wound swabs, blood and seminal fluid) from main Hospitals in Maysan Province during the period from October 2018 to the end of September 2018. Clinical samples immediately transferred to laboratory and culture according to the standard methods, the positive culture were identified by conventional techniques and confirmed by using API 20 E system and using VITEK®2 GN kit (BioMe’rieux, France) then the identified *E. coli* stored for molecular
Antimicrobial susceptibility testing

Susceptibility testing was determined by the agar disk diffusion method, and interpreted according to CLSI guidelines. The following antibiotic disks were used: Ampicillin 10 μg, Pipracillin 100 μg, Amikacin 30 μg, Amoxicillin + Clavulanic acid 20/10 μg, Oxacillin 1 μg, Imipenem 10 μg, Ciprofloxacin 5 μg, Ceftazidime 30 μg, Cefotaxime, 30 μg, Ceftriaxone 30 μg, Sulfamethoxazole+Trimethoprim 1.25/23.75 μg, Cefpodoxime 10 μg, Aztreonam 30 μg, Gentamicin 10 μg, Norfloxacin 10 μg, Nitrofurantoin 300 μg, Cefepime 30 μg, Cefoxitin 30 μg, (Bioanalyse, Turkey).

Phenotypic detection of ESBLs

All β-lactamase producing bacterial isolates were tested for ESBL production by initial screening test according to CLSI. The isolates showing resistance to one or more 3rd generation cephalosporins (3GCs) were tested for ESBL production by Double Disc Synergy Test (DDST).

Extraction of Bacterial Chromosomal DNA

DNA extraction was done toward all E. coli isolates according to Presto™Mini gDNA Bacteria Kit protocol (Geneaid, Taiwan). The integrity of extracted DNA was tested using Agarose Gel Electrophoresis. The chromosomal DNA then subjected to monoplex PCR.

Molecular detection of bla_CTX-M Gene Using PCR Technique

The protocol used depending on manufacturer’s instructions (Bioneer, South Korea). The specific primer for bla_CTX-M gene have been chosen according to[10,11] where F: CGCTTTGCGATGTCAG, R: ACCGCGATATCGTTGGT, which yield a product 550bp. PCR Program was performed as following: (1) cycles of (5 min.) initial denaturation at (94°C), followed by (34) cycles of denaturation at (94°C), (1 min.) annealing at (55°C), (1 min.) extension at (72°C), (1 min.) and a final extension step of (5 min.) at(72°C), then 5μl of amplified PCR product were loaded to the agarose gel wells with standard molecular weight of DNA ladder (Bioneer, South Korea) and the Electrophoresis were ran as described by[12].

Results and Discussion

Isolation and identification of Bacterial Isolates

The results of this study showed that among 291 clinical samples 235 gave positive growth and 105 (44.7%) were identified as E.coli. As compared with other studies, our findings were compatible with study[13] where the result was (44.8%), also in India by[14] and in Southwestern Uganda by[15] who obtained results very similar to our results that were (44%) for both. While the results were contrary to the findings of many researchers as[16,17] E.coli is the most gram negative bacteria found in clinical laboratories samples including the majority of urinary, wound, blood and peritoneal isolates.[18]

The antibiotic susceptibility pattern

The resistance patterns of E.coli towards various antibiotics were determined using disc diffusion method. Data in (Figure 2) exhibited that isolates of E. coli have the highest level of resistance to Ampicillin where up to (98.1%) were resist to this antibiotic, followed by (96.2%) for Pipracillin and (93.3%) for Ceftazidime, Cefpodoxime and Oxacillin, and (92.4%) for Cefepime, and the resistance to Cefotaxime was (94.3%), while to Amoxicillin/Clavulanic acid the percent of resistance was (90.5%). The resistance to the Ceftriaxone was (87.6%), (86.7%) for Cefoxitin, Aztreonam (81.9%) and (68.6%) for Trimethoprim/Sulfamethoxazole while the resistance was (53.3%) for Gentamicin. Whereas the resistance to antibiotic is less than a half for Norfloxacin, Nitrofurantion and Ciprofloxacin (46.7%), (35.2%) and (34.2%) respectively. Moreover this study recorded that all isolates (100%) were sensitive to Imipenem antibiotic followed by (90.5%) for Amikacin. Where these results were corroborated with findings of previous reports[19] which concluded that E. coli showed high resistance to Ampicillin and Pipracillin, also study conducted by[16] showed high resistance rates of E.coli to aztreonam, amoxicillin-clavulanic acid, which compatible with present study. Whilst[20] showed high resistance to third generation (Cephalosporins). The observed high resistance rates in most antibiotic may be due to uncontrolled consumption, consequence of easy access to inefficient and cheap antibiotics moreover could be justified by insufficient adherence to guidelines for infection control as well as inappropriate use of antibiotics. The members of Enterobacteriaceae has many mechanisms of resistance to β-lactam antibiotics.
like loss of porin and efflux pumps etc, however, β-lactamases enzyme most common and clinically significant mechanism of resistance to β-lactam antibiotics among these bacterial family. The most effective β-lactam antibiotics against E. coli was Imipenem where (100%) of E. col were susceptible to this antibiotic, followed by Amikacin. Similar pattern of results were obtained by which appeared high degree of effectiveness of these antibiotics against E. coli, also corresponded with the recent study for who considered the antibiotic Imipenem and Meropenem should be preferred drugs for E. coli infection isolated from clinical samples.

**Phenotypic Detection of ESBLs**

ESBLs have been found worldwide and they are considered a leading causer of drug resistance in many Enterobacteria. One hundred and five of E.coli isolates in present study were examined phenotypically and genotypically for ESBL production. The findings of screening test concluded that (82.9%) of E. coli were suspected to be ESBLs producers whereas the results of Double disk synergy test was (21.8%) as showed in figures (3 and 4). The results of screening test were similar to local studies of who found that screening test was positive in (100%) of E. coli. The high occurrence of ESBLs producing E. coli obtained in this study was probably due to the consumption of large amount of third-generation cephalosporins, trend of self-medication and the extensive prophylactic misuse of antimicrobials by Iraqi patients and physicians. Additionally a number of previous studies have showed the low prevalence of ESBLs producing E. coli when used confirmatory test which in concordance with present study such as the study implemented by where the results were (23.8%) and (29.8%) respectively. Many researcher such as concluded in their studies that there is incompatible between the results of the phenotypic observation and genotypic analysis and showing that the presence of ESBL-associated β-lactamase genes may be undetected when using the conventional phenotypic approach and mutation in these unexpressed genes may be the leading cause to ESBL antibiotic resistance, suggesting that the unexpressed and undetected genes may serve as reservoir for ESBL genes, therefore phenotypic screening should not be used as monitoring of ESBLs because there had been studies showing the discrepancy in the phenotypic and genotypic detection.

**Molecular Detection of ESBL Genes**

The CTX-M type β-lactamases constitute a novel group of enzymes that have a typical ESBL resistance phenotype, are capable of hydrolyzing broad-spectrum cephalosporins and are inhibited by clavulanic acid, They also confer a high level of activity against ceftazidime. As shown in figure (5) the results of molecular study revealed that (100%) of E. coli carry the CTX-M gene with amplified product 550 bp. The findings were directly in line with previous studies as who reported that majority of CTX-M ESBL producers were E. coli. The CTX-M was considered as a common type of ESBLs that detected at Asia, Europe, North and South America among multidrug-resistant E.coli. The important reason for the prevalence of CTX-M β-lactamases gene in Maysan Province may be due to the use of certain
third generation cephalosporins which led to high resistance in our study. Whereas, the results of current study went beyond previous reports\cite{19,32,33} that results were\( (56.7\%)\), \( (28.9\%)\), \( (10\%)\) respectively.

**Conclusion**

In this study isolated *E.coli* showed high levels of resistance to most antibiotics especially Beta-lactam group and considered as multidrug resistant bacteria. Furthermore, *E. coli* produced CTX-M in high rate of occurrence reached to \( (100\%)\). This terrifying situation with the spread of ESBL isolates highlights the need to adopt strict antibiotics using in internal hospitals to assess the effect of high resistance in bacteria and to take steps to reduce this resistance.

**Acknowledgment:** We would like to thank the staff of Al-Sader Teaching, Birth and Child, and Al-Zahrawi Hospitals for helping us in collection of specimens, and also thank to Heart disease center for facilitating our work.

**Financial Support and Sponsorship:** Nil.

**Conflict of Interest:** The authors declare that there is no conflict of interest.

**Ethics of Experimentation:** Permission to conduct this study was issued by the Health institutional committee at Al-Sader Teaching, Birth and Child, and Al-Zahrawi Hospitals, Maysan province; and the samples were taken from patients under the supervision of professional health care workers.

Abstract
The research aims at finding the effects of electronic games on the behavior of children and finding the relationship between the demographic information and the impact of these games on their behavior and educational achievement. A descriptive and analytical study of the effects of electronic games on the behavior of 60 children in the schools of Mosul city, conducted for the period from Feb.2019 to March 2019. (Non-probability) The sample was chosen according to us of phone or computer and other smart devices for the purpose of playing. Boys and girls equally chosen after fill a questionnaire which was used with a semi-guideline for collecting information. Results of the study revealed that time taken by the students to play a daily or intermittent basis is less than two hours, at 45.7%, and that higher than who spend one to two hours are 32.6% and those who spend more than two hours are 21.6%. Students playing electronically at the age of 3-6 are 19.5%at 7-8 years at 43.5% and, at 9 years are over 37.0%.

Yes, No, sometimes are answers of questionnaire.χ² value was less than p<0.05. The study showed differences between males and females in use of games. The study recommends Ministry of Higher Education, with assistance and participation of Ministry of Education, should develop an educational program for parents about electronic games and their harm to children.

Key words: Effect of electronic games on children, Damage electronic games.

Introduction
Children often have an inclination to play instinctively; definition play is an important and necessary activity in their lives because it reveals my inner self and personality, as well as emotional and other hidden aspects. Through play, personality is formed, and their emotional, social, The studies and psychologists have confirmed that play enhances the personality of the child, as well as is one of the basic means of learning in the present time, especially in the past, the concept of play was related to physical and motor activities only [1]. Today and the scientific and technological are developed in way that has been accompanied by changes in the concept of play than it was in the games, which attracted the attention of all age groups in the community [2].

On the other hand, these games helped the child how to deal with modern font engineering science such as computing machine internet and electronic devices, and other modern and modern applied science introduced child technology cosmos and virtual world [3]. It also brands him more determination to achieve success and win and achieve ambition his victory in Plot and his insistence on win generate. This will achieve success and win, which affect his ambitions for hereafter and his finding to achieve his goals and planning, liveliness [4]. This is what we explored through this study often parents do not want video games for their children because they think its wasting time. Some experts believe that these games are possible to have been spoiled by the brain [5, 6]. Violent media also play a role and easily blame violent video games as the reason why some teens turn violent or engage in aggressive anti-social behavior [7]. “According to the survey of national institute on media and family in the United States, find that 92% of children and adolescents between 2-17 old playing video games” [5]. Terri K. and Susan C (2013) said that because of the different types of electronic games that children engaged in various forms, such as television and electronic games
on the Internet, video and computer, iPod, movies, magazines, newspapers. The media has a big role that does not affect the children negatively or positively, according to the pictures displayed and the information contained therein which are not useful to children or always in their interest [6].

AL-Gamidy A.,(2010) state Some evidence of video games that reduce the size of boys and girls, or among researchers who participated in the US Senate, “found violent video games to increase violent behavior by 13% -22% for awareness”. A study by Stanford University researchers found that it is time to reduce violence with violent games and television programs that encourage violent behavior to 50 hours a week, reducing physical violence to 40% in third and fourth grade. The objective of the study is finding effect of electronic games on children’s behavior and Discover association between children’s behavioral problems and the educational level in school. The effects of the electronic games among school age children on health status [2].

Methodology

A descriptive and analytical study on behavior of children in the schools of Mosul city was conducted for the period from February 2019 to Murch 2019. A sample (non-probability) was chosen of 60 students for the schools from which the sample was taken. For boys and AbiDharGhaffari and for girls in the city of Mosul left coast. The sample was chosen according to the controls: children who use the phone or computer and other smart devices for the purpose of playing boys and girls equally after taking their consent and help them fill out the questionnaire for the specific research. A questionnaire was used in the study with a semi-guideline for collecting information. The for data collection is used as a tool questionnaire, which includes the following: Part 1: This part contains information about biographical data which is consisted of 6 items which include Age, sex, educational level, the number of student in same classroom, the number of students in the school, the sample size and the date of test done.

Part 2: This part consisted of 19 questions about electronic games, how they are used, the times, periods, and effects that these games cause on children’s health, their educational level, and the behaviors used by children using these games.

Statistical analysis

The research data were analyzed by descriptive statistical analysis using SPSS p<0.05

Results

Results of statistical analysis of the questionnaire (the impact of electronic games on the behavior of children and their academic achievements).

Section One

Conduct descriptive statistics on students’ information such as age, duration of student play, and duration of the electronic games.

Table 3 shows the frequency and percentage of respondents’ responses to the questionnaire (the effect of electronic games on children’s behavior and educational attainment). The first paragraph, which states: “Are you subjected to violence and beating by parents at home?” With an average of 2.33 and a standard deviation of 0.732 of 17 answers (no) and 22 answers (sometimes) out of 60 which corresponds to the answer (no) and low level as in table (2) and came last in the paragraph that states 1.24 and a standard deviation of 0.524 at a high level, which corresponds to the yes (in the Lycert triangular scale of Table 2). This indicates that the majority received tips for leaving the electronic games altogether.

The weighted mean weight of the entire questionnaire was 1.948 and a measurement deviation.

(0.1446), which corresponds to the answer (sometimes) by reference to the scale. This indicates that the reality of the effect of electronic games on children’s behavior and achievement is average for the target population in the study. The following figure shows the averages of the sample around the sections of the questionnaire.

Section three:

Know the relationship between respondents’
responses to the questionnaire and the gender variable (male and female).

I used the $\chi^2$ of independence to determine the extent of a statistically significant relationship between two variables. This type of test is applied if both variables have class data representing the community.

Table (4): Results of the Kay box test to identify the relationship between respondents’ answers and sex variables

Table 4 shows the responses of male and female students and the value of the tables and the significant value of the questionnaire. The table shows a statistically significant relationship between the answers of male and female students to the following questions: Do you play electronic games on the phone or computer? During this period, you feel heavy in the head and headache after you finish playing.

Do you feel the pain in the back or the muscles, do you prefer the electronic games wrestling and fighting, do you cheat colleagues in the class and the moral value of the test of $\chi^2$ in these questions less than the value of moral = p value 0.05 and the value of $\chi^2$ less than the value of the scale at df 2. The reason for this is that most children who use electronic games affect the concentration and attention and length of play cause them fatigue and head pain because of the length of play while the responses of male and female respondents did not record any statistical significance. The reason for this is that most males prefer violent electronic games such as wrestling and fighting, which develop aggressive behavior and harm their peers or close relatives without cause. Males are more than females at 19.49%. 

Discussion

This study deals with The impact of electronic games on the behavior of children and their academic achievement in schools table (1) Frequency, percentages and averages of study data table shows the majority that 79% of males play: approximately half of boys toys 45% of them play and spend one to two hours by 32.6% and for more than two hours by 21.6%, as opposed to females. In my opinion the type of games and parents life style have a very significant impact on the behavior of the child used for those games. “It is important to emphasize how video games affect children’s learning processes and adolescents, as well as their effects on the educational process in general. First thoughts on this subject in the United States as early as 1978, the line was established Look for learning-driven, including”[1]. This is Research spread somewhat in the 1980s, especially in the late 1990s. That time continued, scientific Search may already be links between video games and different worlds of the human began to examine the links between playing video games and Complex social processes that, in contemporary [5], so video games, as any other technological device, are simply media through which children people engage in numerous activities. Or, seen from another land site, they are no more than another feature with symbolic, economic, and technological attribute in a complex residential district circumstance that is constantly subjected to an intense and accelerated process of change[6].

“Kids who regularly play videogames are at slightly increased risk for developing attention problems at school”[8]. In my opinion this result due to; most sample playing games was boys and they use electronic games more than girls and it effect on their behavior.

The study found that most children have been advised to leave the electronic games and this indicates the desire of the people to leave these games because of the negative impact on them. The results showed that the majority of children are exposed to violence in their own way by parents as well as have knowledge about the damage to the games on their health and school level. We also have a large percentage of students who are fighting their friends because of the games and this is evidence of the growing aggressive behavior they have. This indicates that the effect of electronic games on children’s behavior and achievement is average for the target population in the study [9].

I used the $\chi^2$ of independence to determine the extent of a statistically significant relationship between two variables. The study said that current research has no clear evidence continuously links exposure to violence in video games. Aggression or violence in societies, but other studies and research are necessary to assess impacts on vulnerable subgroups that are at risk as children [3].

The study has shown that prolonged eye sight on the small screen affects the health of the eye as well as prolonged use of the computer has a negative impact on the health of the joints because of the length of the sitting period for playing Do you feel the pain in the back or the muscles, do you prefer the electronic games
wrestling and fighting, do you cheat colleagues in the class) results was less than the value of the scale at the df \[2\]. The reason for this is that most children who use electronic games influence the concentration, attention and length of play cause them fatigue and head pain due to the length of the playing time, while the responses of male and female respondents did not record any statistical significance. The reason for this is that most males prefer violent electronic games such as wrestling and fighting, which develop aggressive behavior and harm their peers or close relatives without cause [10&4]. We also have a large percentage of students who are fighting their friends because of the games and this is evidence of the growing aggressive behavior they have. We also note the differences between boys and girls in playing electronic games, as boys were more likely to be counted boys are more than girls. Two major trends can be observed towards the impact of electronic games; these games expose children to serious risks and these risks include injuries arising from repeated stress obesity, social isolation and visual stress, and in the long term caused the destruction of psychological and emotional growth mental health of children. The results showed that students have difficulty in studying and understanding when playing for long periods during the day and this is evidence of the impact of these games on the level of academic achievement with some differences between females and males [11] And that the majorities who play the games suffer from headaches in the muscles pain if they sit for long periods [7].

The second trend is that electronic games have a positive impact on learning and education, It helps develop image reading strategies and increases the use of attention and speed strategies in processing Information and effectiveness in problem solving, and this shows the argumentative hypothesis posed by many researchers in science Psychology, sociology, and educational science on the impact of these games on behaviors in children [9].

Overall the boys more effects electronic game usage compared to girls. Statistically significant difference was also observed for electronic game addiction and age groups the results showed that the duration of the children’s play has a negative impact on their health and that the majority feels a lack of concentration and attention. Also, the majority of them have been advised to leave these games. The growing aggressive behavior in some was due to violence by parents at home. While the responses of boy and girl respondents did not record any statistical significance. The reason for this is that most males prefer violent electronic games such as wrestling and fighting, which develop aggressive behavior and harm their peers or close relatives without cause. Males are more than females that the majorities who play the games suffer from headaches in the muscles pain if they sit for long periods. This is evidence of the impact of games on health, behavior and learning achievement.

The authors think that the Ministry of Higher Education, with the assistance and participation of the Ministry of Education, should develop an educational program for parents about electronic games and their harm to children. As well as, monitor their children constantly and identify specific times during the day without affecting their studies and social relationships.

Abstract

Risk management is a system owned by every organization, including university laboratory, to prevent losses. Amongst the methods of risk management that are usually applied is HIRADC method, which is a systematic stage to identify hazards, to assess and analyze risks, and to plan controls measures according to the existed risks. This research is observational research which aims to describe the phenomena. There are several stages in this method, namely hazard identification, risk analysis, and determining control. The data is collected by conducting observation before doing data matching with laboratory worker. The research results indicate that from five activities performed in the Laboratory of Histology Anatomy at Faculty of Medicine Universitas Airlangga, such as experiments by the medical students, dry cadaver shaping, new cadaver shaping, cadaver maintenance and the goods burning by the laboratory worker, there are 16 hazards discovered, with two extreme-risk hazards and three high-risk hazards. The controls and recommendation provided are giving socialization about the importance of wearing PPE (rubber gloves, safety goggles, and laboratory coat), providing explanation about the work to the worker as well as explanation about the laboratory SOP and providing the fire extinguishers.

Keywords: Risk Management, HIRADC, Laboratory

Introduction

Every workplace, including university laboratory, carries its own hazards and risks of occupational accidents. Based on the book authored by Ramli (2010) entitled “Pedoman Praktis Manajemen Risiko dalam Perspektif K3 OHS Risk Management”, hazard is all that includes problems or actions that lead accidents or damages to humans or other disturbances\textsuperscript{(1)}. According to ILO (International Labour Organization), every year the number of occupational accidents reach more than 250 million accidents at work and 160 million workers suffer from occupational illnesses\textsuperscript{(2)}.

Risk management must be owned by every organization, including university to protect it from all things that can cause accident, injury or losses. As mentioned in ISO 45001, risk can be explained as the terms of a combination of the severity caused by the events and its likelihood of adverse events. Risk management can be defined as the total procedure related with identifying an existing hazard, assessing the risk, arranging control measures, and reviewing the outcomes\textsuperscript{(3)}.

HIRADC (Hazard Identification, Risk Assessment, Determining Control) in ISO 45001 is listed in the planning section, as a procedure resolve the risks which consists of several stages of activity, specifically hazard identification, risk assessment, and determining control\textsuperscript{(4)}. Hazard identification is a process of identifying the hazards that may occur in a workplace. The types of hazards are physical, chemical, biological, psychosocial, or ergonomic hazards and also be caused by the workers, which also known as at-risk behavior.

Risk assessment as referred from ISO 45001 is an activity to assess the level of the risk from identified hazards as well as to review the effectiveness of the existing control program. Risks that are assessed by the results of the likelihood and severity will be matched to the risk matrix to determine the level of each risk and to priorities identified hazards.

Determining risk control usually uses the hierarchy of control to establish priority order for the types of action to be used to minimize or control risks. There are five stages in Hierarchy of Control ANSI Z10: 2005 in Djatmiko (2016): (5):

1. Elimination is the most effective way to control the risk, to eliminate potential hazards.
2. Substitution to replaces hazardous materials, process or equipment to become more harmless.
3. Engineering Control by modifying machine/equipment or workplace to become safer.
4. Administrative Control to secure workers from exposure by implementing SOP, training, working hours, etc.
5. Personal Protective Equipment (PPE) such as helmet, safety glasses, mask, gloves, earplug, work shirt and safety shoe is the most ineffective way to control and reduce the impact of hazards.

Material and Method

This research is an observational research and then the data are analysed descriptively, which is aimed to delineate a phenomenon. The method of risk analysis applied in this research is HIRADC method in accordance with AS/ NZS 4360: 1999 and ISO 45001: 2018. There are several steps mentioned in this research before, namely hazard identification, risk assessment, and determining control. The data collected is qualitative data in form of description, words or behaviour that were observed. Researchers completed the data collection from hazard identification by making an observation in the Laboratory of Histology Anatomy in Faculty of Medicine, Universitas Airlangga. Then, the researchers give the score in the risk assessment based on the likelihood and severity level. After that, the researchers match and check it with the laboratory worker. After completing a risk assessment, the researchers start to plan the control activity to reduce the risks that are likely to occur in the laboratory.

Findings

Hazard Identifications

Hazard identification is determined by the activities conducted in the Laboratory of Histology Anatomy. The Laboratory of Histology Anatomy contains five main activities, such as experiments conducted by the students, dry cadavers shaping by the laboratory worker, the used goods burning, new cadavers shaping and cadaver maintenance by the laboratory worker. The chemical substances used in cadaver handling that are likely to be hazard sources are 70% alcohol, formaldehyde, and glycerin.

In the Laboratory of Histology Anatomy, risks identified is mostly related to chemicals and psychology because of the cadaver. The two extreme-risk level risks found caused by the exposure of formaldehyde in a new shaping of cadaver and cadaver maintenance by the laboratory worker. There are three high-risk level risks identified, namely fire that used for goods burning, inconvenience and scare that affect laboratory psychology in new cadavers shaping and cadaver maintenance. Eight moderate-risk level risks are fingers injuries from sharp laboratory equipment, Musculoskeletal Disorders (MSDs) because of the sitting position, blisters from boiled water, skin and eyes irritation caused by 70% alcohol, glycerine in new cadaver shaping and cadaver maintenance, and skin diseases from Candida sp. and Epidemophyton sp., fungi while making new cadavers and maintaining cadavers. And three low-risk hazards are injuries by glass-made laboratory equipment, diseases transmission and eyes fatigue.

In fact, formaldehyde as the primary chemical substance is often used in cadaver handling (new cadaver shaping and cadaver maintenance). The students and the laboratory worker can expose by the chemical substances to the respiratory, eyes or skin and they can experience the inconvenience because of the cadaver during the laboratory activities.

Experiments Conducted by the Medical Students

Based on the findings in Laboratory of Histology Anatomy, the experiment usually uses the cadaver. Formaldehyde is a main chemical substance that can potentially cause any issue on Occupational Safety and Health in laboratory. The students can easily smell the formaldehyde in the air when entering the laboratory because of the cadaver. They may be exposed continuously to the formaldehyde for 2-3 hours in the laboratory and they feel the pain in the throat and shortness of breath and formaldehyde has an odor that makes many students feel unpleasant during the anatomy experiments. Moreover, the effect of formaldehyde exposure to the students are likely possible to irritate the
According to the previous finding by Raja & Bahar (2011), it was affirmed that during the gross anatomy dissection, the main exposure to formaldehyde vapor and contact with formaldehyde can cause several effects. The common effects of exposure to formaldehyde are skin disorders, congenital malformations, ocular irritation, cancer risk, ingestion-related gastrointestinal effects, inhalation-related upper airway irritation and bronchial asthma (6).

Cadaver Handling (Dry Cadaver Shaping, New Cadaver Shaping and Cadaver Maintenance) and The Goods Burning by the Laboratory Worker

From the research in Laboratory of Histology Anatomy, the laboratory worker is continually exposed to the chemical substances during the cadaver handling and the goods burning activity. The hazards from this activity can be classified to chemical, psychology and biological hazards. The chemical hazards in Cadaver Handling are alcohol 70 %, formaldehyde, and glycerin. The use of formaldehyde which is the fundamental substance to shape new cadavers and to maintain the existed cadavers surprisingly becomes the main hazard source in the Laboratory of Histology Anatomy.

Additionally, the potential hazard that may occur during the existed cadaver maintenance is extreme due to the fact that the maintenance is a routine activity every two weeks and also the shaping of a new cadaver is done once every two or three months. The manual handling process of formaldehyde may increase the risk of formaldehyde spill and spark to the skin or eyes. And when handling the cadaver, the laboratory worker doesn’t wear PPE properly. The laboratory worker experienced discomfort in breathing, eye and nose nerves irritation, and sore throat which known as the symptoms from formaldehyde exposure.

Formaldehyde is a colorless, flammable gas with a pungent odor used as a preservative and a corrosion inhibitor that are highly irritating to the nose and toxic if swallowed. If the skin contacts with formaldehyde, it can cause severe injury accompanied by drying, cracking, and scaling (7). The International Agency for Research on Cancer (IARC) has classified formaldehyde in Group 1 as a carcinogenic agent for human and someone is exposed formaldehyde will suffer from nasopharynx cancer (8).

This is in accordance with the research initiated by Jalles Dantas de Lucena, et al. which also took place in a Laboratory of Anatomy. In result, they discovered that 70.3% of the respondents were in discomfort due to unpleasant and disturbing smell from the use of formaldehyde. Furthermore, the formaldehyde exposure is followed by the symptoms, such as excessive lacrimation, red eyes, nasal congestion, and respiratory disorder which continuously happen in the laboratory (9).

Other potential hazards in the Laboratory of Histology Anatomy are having a nightmares and stress due to the works with the dead body that can affect laboratory worker’s psychology because of the inconvenience and scare. Afterwards, other activity is burning the goods with fire that carried out inside the laboratory and without providing fire extinguishers. This can be a high-risk level since the severity and impact can cause enormous losses both for laboratory and university.

Risk Assessment

The risk assessment is arranged to present the risk analysis and suggestions for the evaluation stage, which later will be considered by the organization to decide what control measures that effectively control the risk. In this stage, the assessment by giving scores to hazard ratings is needed by the Likelihood (the possibility of the risk occurrence) and the Severity (the consequences of the risks) in accordance with AS/NZS 4360 standard (10).

There are two extreme-level risks on Laboratory of Histology Anatomy that caused by cadaver handling. The exposure of formaldehyde in new cadavers shaping has the level of likelihood of 4 and in cadaver maintenance has the level of likelihood of 5 which means that the possibility of hazard occurrence will probably and expected to occur in most circumstances. This happens because formaldehyde is a main chemical used in cadaver handling activities. In this two cadaver handling activities the Severity level of 5. This can be said so due to the fact that formaldehyde may cause toxic release with detrimental effect to the respiratory tract, eye and skin.

In risk assessment process, it is noticed that the total risk of the exposure of formaldehyde in new cadavers shaping is 20 and 25. Based on the result of the risk assessment, the exposure of formaldehyde is categorized as extreme risk. It means that the control and consideration of resources are immediately needed to
reduce risks based on the priority in controlling the risks.

And three high-level risks on Laboratory of Histology Anatomy which also need to be noticed are fire on goods burning, inconvenience and scare that affect laboratory psychology in new cadavers shaping and cadaver maintenance. The fire risk of goods burning has the level of likelihood of 2 which means could occur at some time and the severity of 4 means can cause extensive injuries, loss of production capability, major financial loss with the total risks is 8. Both in new cadavers shaping and cadaver maintenance, psychology hazard has the level of likelihood of 3 which means might occur at some time and severity level of 3 means medical treatment required with the total of the risk is 9. Based on the result of the risk assessment, the exposure of fire and psychology hazards are categorized as high risk that need to be controlled so the risk not become more dangerous or change to extreme-risk level risks.

**Risk Control**

Determinant control is performed to reduce risk level to minimize the risks that can affect Occupational Safety and Health when conducting activities in the Laboratory of Histology Anatomy Universitas Airlangga. In accordance with hierarchy of control, risk controls need to be carried out to decrease the occurrence of occupational accidents in laboratory based on the hazards and risks that have been identified are analyzed to arrange the control measures by the priority of each risk level.

Moreover, the authors provide several recommendations to reduce the extreme-risk the engineering control which can be applied is by increasing the number of the ventilation. Laboratory worker needs to check the smell and temperature in the laboratory and open the ventilations immediately when strong formaldehyde odor was found. The next control is by giving socialization about the importance of wearing Personal Protective Equipment (PPE) while handling the cadaver or chemical substances, such as rubber gloves and laboratory coat, safety goggles and mask to avoid direct contamination with hazardous substances that can cause irritation and burns. And providing fire extinguishers when burning the goods in the laboratory. Therefore, the risk of psychological hazard while handling the cadavers can be done with adapting to the work, providing further explanation regarding the job and undertake the work together while handling the cadaver shaping at least with 3 people in a team. Providing the explanation about the laboratory SOP to the students and academicians who are involved in the laboratory activities and also providing the fire extinguishers when burning the goods in the laboratory.

**Conclusions**

Based on the research that has been done, it can be concluded that at Laboratory of Histology Anatomy has a low to extreme-risk potential. There are 16 risks found with two extreme-hazard from formaldehyde exposure and three high-risk hazards that need to be controlled. The controls and recommendations that can be provided are giving socialization about the importance of wearing PPE (rubber gloves, safety goggles, and laboratory coat), providing the explanation about the work to the worker as well as explanation about the laboratory SOP to the academicians who are involved in the laboratory activities and providing the fire extinguishers.

Investigating Relationship between Positive Organizational Behaviors and Organizational Commitment among Nurses at Emam Khomeyni Hospital in Jiroft, Iran, in 2017: A cross Sectional Study

Saadat Salari¹, Fereshteh Daneshi², Motahare Pilevarzadeh¹

¹Department Nursing Education, Lecturer of Nursing Midwifery Faculty, Jiroft University of Medical Sciences, Jiroft, Iran; ²Department of Pediatric Nursing, School of Nursing and Midwifery, Jiroft University of Medical Sciences, Jiroft, Iran

Abstract

Introduction: One of the most important indicators of development and excellence of an organization is the presence of committed and loyal manpower. Thus, this study aims to investigate the relationship between positive organizational behaviors and organizational commitment among nurses working at Emam Khomeyni Hospital of Jiroft, Iran in 2017.

Method: This study is correlative-descriptive. The statistical population consisted of all the nurses working at Jiroft Hospital and they were all selected as samples. The data were analyzed using SPSS v25. Independent t-tests were applied to investigate the relationships between demographic specifications, organizational behavior, and organizational commitment, while correlation coefficient was employed to study the relationship between the main variables and Regression test and Pearson Correlation Coefficient were used to examine the relationship between organizational commitment and organizational behaviors and its dimensions.

Results: the results indicated that there was an inverse and significant relationship between organizational behavior and organizational commitment in general (p<0.001) and in emotional dimension (p<0.001) and normative dimension (p<0.01) in particular. Moreover, a positive and significant relationship was observed between positive organizational behavior and organizational commitment (p=0.03).

Conclusion: since positive behaviors are of great importance for performance evaluation systems among nurses and, at the same time, can affect a variety of their attitudes, including organizational commitment, it is suggested to improve nurses’ understanding of positive organizational behavior and organizational commitment to allow them to have better opportunities to better provide services in their workplace.

Keywords: Positive Organizational Behavior, Organizational Commitment, Nurses

Introduction

Formerly, approaches of many organizational behavior psychologists were focused on employees’ weaknesses and their behavioral pathology to introduce suitable solutions to reduce the weaknesses, with their abilities and positive aspects not being considered to a considerable degree. But, with the emerson of psychology movement, this approach was reoriented toward positivism and emphasis on positive behavioral aspects, bringing up positivist organizational behavior approaches [1-3].

The new approach believes that individuals’ strengths and desirable qualities can be considered by avoiding leaders’ continuous focus on weaknesses and weak performances of individuals to improve their positive behaviors, thereby improving individual and
organizational performance \cite{4, 5}. Positive physiologic approach is a term that covers the study of positive emotions, positive individual characteristics, and healthy and strong organizations, including family \cite{6, 7}. The goal of such approaches is to identify the structures and methods that finally result in human wellbeing. Hence, factors that provide individuals’ with compatibility to their lives’ pressures and threats as much as possible are the most fundamental structures of the approaches. Relying on individuals’ strengths, positive psychology helps them improve their individual and organization performance \cite{4, 8}. Pundits and experts have proposed various components investigating positive psychology but four of them were the most agreed by them: 1) optimism, 2) self-efficacy, 3) tolerance, and 4) hope \cite{9}.

Organizational commitment is a concept that attempts to achieve the nature of attachment created by individuals in an organization. In fact, organizational commitment reflects the extent of an individual’s compatibility and attachment to the organization \cite{10}. Organizational commitment is the link between individual and the organization, which is shown by three factors: strong belief and accepting the organization’s objectives and values, high willingness toward the organization, and high willingness to stay at the organization. In view of some psychologists, commitment is a complicated multidimensional structure. Hence, a variety of definitions have been proposed by experts for commitment \cite{11}.

Meyer and Allen defined organizational commitment as a physiologic state that indicates willingness to, requirement for, or necessity of providing a service in an organization. They introduced a 3-dimensional model of organization commitment, which is composed of emotional commitment, continuous commitment, and normative commitment \cite{12}. Organizational commitment can be a good indicator to show the effectiveness of an organization. Authorities must indicate high interest in an individual and not consider them as an organization member but respect them as an individual because they will have better performance if they are viewed as humans and unique identities \cite{13}.

Given the importance of organizational commitment among nurses, this study attempts to investigate and identify problems that create responsibility, loyalty, and commitment toward an organization among the staff. Identifying factors influencing organizational commitment, better performance is enabled by making modifications and changes to create commitment.

Method

This study is descriptive-correlational aiming to investigate the relationships between psychologically positive organizational behaviors and organizational commitment components among nurses working at Emam Khomeyni Hospital of Jiroft, Iran in 2017. The statistical population consisted of all the nurses at the hospital. To collect data, demographic specifications questionnaire was used. At the same time, the questionnaire in Lutanz et al. (2007) was employed to measure positive organizations behaviors and the questionnaire introduced by Allen and Meyer in 1990 was used to measure organizational commitment.

The standard questionnaire proposed by Lutanz et al. (2007) consisted of 20 questions, 8, 2, 4, and 6 questions of which were concerned with self-efficacy, tolerance, optimism, and hope, respectively. Each question was evaluated on 5-point Likert scale. Lutanz et al. (2007) reported the reliability of the questionnaire to be 90%. Hoveyda et al. \cite{1}(1) reported the validity of the questionnaire as 70%.

The questionnaire introduced by Allen and Meyer in 1990 consists of 8 questions that measure emotional, continuous, and normative dimensions \cite{12}.

To control the validity of the positive organizational behaviors and organizational commitment questionnaires, they were given to a number of experts to make some modifications. Cronbach alpha was used for reliability. Alpha was obtained to be 86%, 91%, 63% for self-efficacy, hope, and tolerance. It was also calculated to be 82%, for the total of the organizational commitment questionnaire (87%, 78%, and 96% for emotional commitment, continuous commitment, and normative commitment, respectively). The data were analyzed using SPSS v25. Amount, mean, standard deviation, and percentage were employed for the descriptive section. After the normality of the data distribution was ensured, independent sample t test was performed to investigate the relationships between the demographic specifications, organizational behavior, and organizational commitment. At the same time, correlation coefficient was used to explore the relationship between the main variables and regression test and Pearson correlation coefficient were applied to study the relationships between organizational commitment, organizational behavior, and its dimensions. A significance level of 0.5 was considered for all the tests.
Results

210 nurses participated in this study. Individual information of the nurses, including age, gender, marital status, educational degree, and work expertise, is given in Table 1.

The mean score of the study units in the organizational commitment questionnaire was 71.81 of 115. Given the confidence level of 95% for the obtained mean score, the number of the study units was between medium and high. To determine to which dimensions the study units were more committed, repeated measure analysis and paired sample t test were employed. It was found that emotional commitment, continuous commitment, and normative commitment were significantly different (p<0.05). Paired sample t test revealed that emotional commitment and continuous commitment were almost the same among the participants, while there was a significant difference between emotional commitment and normative commitment (p<0.05) and between continuous commitment and normative commitment (p>0.05). Considering the mean scores obtained for each organizational commitment dimension, it can be said that normative commitment was lower than emotional commitment and continuous commitment (see Table 2).

The mean score obtained from the organizational behavior questionnaire was 48.88 of 100. Considering the confidence level of 95% for the mean scores, the commitment of the respondents was between medium and high (see Table 3).

The results showed that the mean score of organizational behavior for the respondents has no significant difference based on the demographic specifications (p<0.05). The mean score of organization commitment of male respondents was significantly higher than females (p=0.01). But no significant difference was observed based on other demographic specifications (p> 0.05) (see Table 4).

The obtained Pearson correlation coefficient revealed that there was a significant relationship between organizational behavior and organizational commitment in general, and between emotional dimension and normative dimension in particular. The relationship between organizational commitment and organization behavior in continuous dimension was positive and significant.

Discussion

Today, given the extensive role of organizations in social lives of humans, manpower has become more salient than before. Concerning the first three objective of the study, results are provided in tables. Regarding the relationship between organizational commitment and psychologically positive organizational behaviors, demographic information only indicated a significant relationship between organizational commitment and gender, with no significant relationships being revealed for other items. The mean organizational commitment was higher among the males than among the females. This result was consistent with Jahangir et al. [14]. Moreover, mean emotional commitment in Sajedi et al. was higher among males than among females, which was statistically significant.

In Bahri et al. [15], no significant relationship between organizational commitment and gender was observed, but there was a significant relationship between organizational commitment and marital status, which is not consistent with our results. The higher organizational commitment obtained for males was perhaps due to the fact that males are often responsible for their families’ financial requirements. Thus, it is more important to them to keep their job and promote, ensuring their income. This responsibility is mostly focused on workplace and they rarely consider their home management, while women are more responsible in home. Hence, men are more responsible toward their organizations. Indeed, more studies with more male and
females respondents are required to approve it. In the current study, organizational commitment was obtained to be 71.81% in general and 24.97%, 26.17%, and 20.67% in emotional dimension, continuous dimension, and normative dimension, respectively, which is at a medium level. There are many studies consistent with this study. For example, Sajedi [14], Jahangir [16], and Mahmoudi [17] reported organizational commitment among nurses to be at a medium level. An overview on statistical analysis results shows that the effects of positive psychological capacities on organizational commitment are very high. In other words, there is a positive and significant relationship between psychologically positive capacities and organizational commitment. But, as the multiple regression results indicate, the role of hope in increasing staff organizational commitment is more salient and significant. These findings are in an agreement with Joseph et al. (2007) who studied the relationship between psychologically positive capacities and work-related outcomes and concluded that hope and tolerance, among the other psychologically positive capacities, have increasing role in the emergence of organization commitment [4]. This is also consistent with Luthans study [4].

With respect to the relationships between hope and the three organizational commitment dimensions, the relationship between hope and emotional commitment is more significant than with the other two dimensions. This is consistent with Joseph study [4]. Concerning the relationships between optimism and the three organizational commitment dimensions, our results are consistent with Hodge study [18].

These findings demonstrate that continuous commitment plays a more salient role than the two other organizational commitments in individuals’ optimism. For the relationship between tolerance and the three organizational commitment dimensions, it was observed that tolerance can take a more effective step toward organizational commitment, which provides individuals’ with more compatibility to different conditions and meets their organizations requirements. This finding is consistent with other studies [4, 18, 19].

**Conclusion**

In overall, a higher efficiency and effectiveness of organizations depend on their manpower efficiency and effectiveness. Hence, it is a priority for organizations to move their staff toward hope, optimism, and tolerance, thereby increasing organizational commitment among them.

Alcoholic Extract of Shilajit as Anti Protein Denaturation, Anti Blood Hemolysis, and Anti Microbial

Saba Hadi\textsuperscript{1}, Sundus Hameed Ahmed\textsuperscript{1}, Noor Talib\textsuperscript{1}, Hassan Abdul Hussein\textsuperscript{1} and Isam Hussain T. Al-Karkhi\textsuperscript{2}

\textsuperscript{1}Mustansiriyah University/ College of Science/ Biology Department, \textsuperscript{2}Former Associate Professor, University of Baghdad, Iraq

Abstract

Shilajit is a natural material found mostly in the Himalayas (India), formed by the slow decomposition of certain plants by the action of microorganisms. It is an effective and extremely safe dietary supplement, and potentially able to prevent several diseases. Shilajit alcoholic extract was prepared by dissolving 10 grams of it in 200 mL of 95% ethanol. FTIR and other chemical procedures were used to detect the presence of Phenols, Alkaloids, Terpenoids, Tannins, Proteins Carbohydrates and, Steroids. Different concentrations of the extract were prepared and antimicrobial activity against several positive and negative gram stains, anti-protein denaturation and anti-blood cell hemolysis. Investigation results show that the nanoparticles were effective in inhibiting protein denaturation of albumin. Proteins denaturation refers the cause of inflammation, while the maximum inhibition of albumin was 87% observed at 300 μg/ml of Shilajit alcohol extract compared with aspirin at the same concentration. The results of inhibiting hemolysis at 300μg/ml in comparing with standard drug Diclofenac sodium 300μg/ml resulted in good protection against the damaging effect of heat solution

Keywords: Shilajit, anti blood hemolysis, phenol, alkaloid, anti protein.

Introduction

Shilajit is a brownish-black powder from high mountain rocks, particularly in the Himalayans Mountains (India), Russia, Tibet (China), Afghanistan, and recently in South America (Chile). Shilajit has been known and used for centuries as medicine, and as anti-aging compound. Lately, additional properties was found in Shilajit that is, to increase physical ability and to support human health\textsuperscript{(1-3)}. It is also used to treat chest problems, diabetes mellitus, nervous disorders, immune disorders, obesity, kidney disorders, asthma, gall stones, painful and bleeding piles, liver, fermentative dyspepsia, worms, renal and bladder calculi, nervous debility, sexual neurasthenia, hysteria, fainting, female infertility, joint pains, wounds, ulcers and skin diseases\textsuperscript{(4, 5)}.

Shilajit has demonstrated good inhibition against viral enzymes and anti HIV activity it is available in tablet form in medicines such as Abana, Cystone and Diabecon. It is also available in syrup form as Evecare and Geriforte. Variation in the quality of shilajit humus (both chemical and biological) and the factors that cause variations in shilajit humus are: (i) altitude and the nature of shilajit-bearing rocks; (ii) atmospheric conditions (e.g. alternate wetting and drying); (iii) pH and moisture content of the rock source; and (iv) activity of the rhizospheric microorganisms and their exo-enzymes\textsuperscript{(7)}.

Current knowledge on the phytochemical screening and antimicrobial activity of shilajit is sparse and thus there remains a wide gap in our knowledge of it and thus it needs to be explored\textsuperscript{(8)}.

In this article researchers Shilajit alcoholic extract was prepared. FTIR and other chemical technique were used to detect the presence of Phenols, Alkaloids, Terpenoids, Tannins, Proteins Carbohydrates and, Steroids. Different concentrations of the extract were prepared and antimicrobial activity against several positive and negative gram stains, anti-protein denaturation and anti-blood cell hemolysis. Investigations were carried out.
Materials and Method

Alcoholic extract

10 grams of the shilajit powder were add to 200 ml of 95% ethanol; stirred well on hot plate for 15 min, and kept for ten day at 28 °C, then filtered, dried and was kept at 4 °C (8).

Detection of Terpenoids

Terpenoids content was determined as was described by Oyagi and his co-workers (11). Peel extract powder (0.5 g) was mixed with 10 ml 90% methanol then 2 ml of chloroform and 3 ml of sulphuric acid were added and mixed well. Reddish brown color indicates the presence of terpenoids.

Detection of Tannins

Tannins were measured according to procedure mention by Oyagi and his co-workers (11) by adding (0.5 g) of peel extract to 10 mL distilled water then 2% of FeCl₃. A blue-green color appeared indicated tannins.

Detection of Proteins

Protein content was measured by an assay as described by Oyagi and his co-workers (11). Violet color appearance suggests the presence of amino acids and proteins.

FTIR spectroscopy

The spectra of Fourier transform infrared generated by the radiation of electromagnetic absorption in the frequency range 500 to 4000 cm⁻¹. The absorption and intensity of different active functional group indicate geometry features of these groups. FTIR spectra were taken using Shimadzu model.

Antibacterial activity assay

The antibacterial activity was determined by agar disc diffusion Oyagi and his co-workers (12). Agar plates were inoculated with 0.1 ml broth culture of tested organisms and was spread with sterile an L-shaped rod glass spreader. Whatman No. 1 filter paper of 5 mm diameter were impregnated with different concentration of crude extracts and dried in a hot air oven at 60 ºC for 5 min. The disc in the center of agar plate which impregnated with sterile distal water was used as control.

Denaturation inhibition of albumin

Human albumin (1%) was incubated at 37 °C for 20 minutes, heated at 51 °C and then the albumin was cooled. The turbidity was measured at 660 nm by UV Visible Spectrophotometer. Denaturation percent was determined according to the following equation:

Detection of membrane RBCs stabilization

Human blood cells centrifuged by 3000 rpm for
(10) min, washed the precipitate with normal saline then re-suspended to (10%) v/v in normal saline, the suspension was incubated at 56 °C by water bath for 30 min, centrifuged at 3000 rpm for five minutes, and the absorbance was measured at 560 nm. The Percentage of haemolysis inhibition calculated using the following formula:

**Statistical Analysis**

Data were expressed as a mean values ± SD by the statistical software package SPSS (version 16).

**Results and Discussion**

Shilajit consist of different groups of active components, Table 1 shows Shilajit components.

**Table 1: Shilajit active component**

Flavonoids are secondary metabolites, it protect cell from degradation, stress, and act as anti-cancer and anti-viral molecule. Phytoalexins, detoxifying agents, reduce toxic effects and stimulants. Recent research indicated that active components can be nutritionally helpful by triggering the production of natural enzymes that fight disease, such as cancers, heart disease, and age-related degenerative diseases (13).

**FTIR**

The band at 1181 cm\(^{-1}\) can be attributed to C=O stretching indicating the presence of polysaccharide or polysaccharide like compounds, at wavenumber 1411 cm\(^{-1}\) (O-H) bending indicating the presence of alcohols or carboxylic acid. A peak at 2930 cm\(^{-1}\) stretch is referred to aliphatic (C-H). The peak at region of 1613 cm\(^{-1}\) (aromatic C=C double bond) figure 1.

**Figure 1: FTIR spectra**

Table 2 shows that different bacterial species exhibited different sensitivities towards the extract of shilajit. The sensitivities of bacterial species against phenolic compounds showed more activity against gram positive bacteria compared to gram negative bacteria under this study. These variations in inhibition may be because of differences in the composition and structure surface between Gram positive and Gram negative bacteria (14).

Maximum inhibition of albumin was 87% observed at 300 μg/ml of shilajit alcohol extract compared with aspirin (which exhibit 91%) at the same concentration figure 2. Each value represents the mean ± SD. All values showed significant results when it compare with control p<0.01. This result investigated that nanoparticle was effective in inhibiting protein denaturation of albumin. Proteins denaturation refers to cause of inflammation (15).
In this study, protein denaturation was used for detection mechanism of the anti-inflammatory activity.

A Stereomicroscopic Analysis of Dentinal Micro Cracks after Root Canal Preparation Using Four Different Rotary Instruments

Samar Abdul-Hamed1, Rasha H Jehad1, Zainab M. Abdul-Ameer1, Jacob Al-Hashemi2

1Department of Restorative and Esthetic Dentistry, College of Dentistry, University of Baghdad, Baghdad, Iraq.
2Department of Conservative Dentistry, College of Dentistry, Al-Mustansiriyah University, Baghdad, Iraq

Abstract

A variety of single-engine driven files and kinematics have been introduced to improve the clinical performance of NiTi rotary files. The purpose of this in vitro study was to measure and compare the incidence of dentinal defects after root canal preparation with different single file systems.

Keywords: Root canal preparations, Root canal instrumentation, Tooth cracks

Introduction

During and after chemomechanical root canal preparation with rotary instruments that aimed to remove infected soft and hard tissue through the enlarged root canal; [1] the root canal wall can be harmed with the development of dentinal defects in the form of dentinal cracks or craze line which serves as localized sites of increased stress. [2]

Through the application of repeated tension via occlusal forces or when further clinical procedures are required such as post placement, these dentinal defects may have the potential to develop into vertical root fracture (VRF).[3,4,5]

Most shaping systems are categorized as to whether the file has active or passive cutting edges, a fixed or variable taper along its active portion, or a more traditional or unique cross-sectional design [6]. In addition to that whether the file has benefited from heat treatment that improves flexibility and the resistance to cyclic fatigue [7]. Also described whether it has a centered or offset mass of rotation, works with a rotary or reciprocation, whether the clockwise (CW) and counter clockwise (CCW) angles are equal or unequal [8,9,10]. A single file technique in conjunction with a novel reciprocating movement of unequal bidirectional angles that complete a full forward rotation of 360 degrees after four 90-degree cutting cycles of reciprocation can start and fully complete the preparation of a canal to a perfect shape [11].

It operates at 350 rpm speed in 170ºCCW and 50ºCW direction and completes 360º, torque 5 Ncm in 3 cycles, also it has parallelogram cross-section with two cutting edges at apical end [12].

F 6 Sky Taper (Komet Brasseler GmbH and Co., Lemgo, Germany) is a NiTi system that performs root canal treatment with continuous clockwise rotation, speed 300 rpm and torque 2.2 Ncm. It is available in five different sizes (20, 25, 30, 35 and 40) with a constant taper of 0.06 with S-shape section [13].

When using this instrument alone. It performs root canal preparation with continuous rotation at speed 800 rpm and torque 1 Ncm [14].

AF Blue R3 (Shanghai Fanta Dental Materials Co., Ltd ) is a rotary AF- R wire- 3- files- system suitable for curved canals, it performs root canal preparation with a reciprocating motion. It operates at 300 rpm speed, torque 2.6 Ncm in 150ºCCW and 30 º CW direction with 06 taper design and improved file flexibility while still retaining the cutting efficiency [15].

Root sectioning at different levels and inspection through a digital stereomicroscope allows direct inspection of dentinal defects on the root surface and provides information regarding the extension pattern and direction of cracks [16, 17].

To the best of our knowledge, little information has been found regarding the incidence of dentinal defects
resulting from the use of AF Blue R3, and F6 Sky Taper systems. Thus, the purpose of this study was to measure and compare the incidence of dentinal root defects after root canal shaping with four automated file systems: Wave One Gold, AF Blue R3, F6 Sky Taper and XP-Endo Shaper. The null hypothesis was that there would be no significant difference in dentinal defects amongst the studied groups.

**Materials and Method**

Seventy-five freshly extracted human mandibular premolars with approximately similar bucco-lingual and mesio-distal. The teeth were disinfected in a 0.1% thymol solution at room temperature for 24 h and were kept in purified filtered water until they were used [19]. Savannah, GA USA) under copious water coolant approximately 17mm from the apex to the facial CEJ [20]. The patency of the canal was ensured before and after instrumentation [21]. All the roots were imbedded in its simulated socket in impression materials [22].

Seventy-five root samples were randomly divided into five groups.

**Group I:** Specimens were instrumented by Wave One Gold (25 \ 0.07), length 25mm in a reciprocating movement.

**Group II:** Specimens were instrumented by AF Blue R3 (25\0.06), length 25 mm in a reciprocating movement using endodontic micromotor (speed: 300rpm, torque: 2.6Ncm).

**Group III:** Specimens were instrumented by F6 Sky Taper (25\0.06), length 25 mm in a rotation movement at WL with gentle in-and out- motion using endodontic micromotor (speed: 300rpm, torque: 2.2Ncm).

**Group IV:** Specimens were instrumented by XP-Endo Shaper (30\0.04), length 25 mm in a rotation movement at WL with gentle in-and out- motion using endodontic micromotor (speed: 800 rpm, torque: 1Ncm).

**Group V:** Specimens without instrumentation (control group).

The glide path was performed using size #15 K-file (DentsplyMaillefer) up to the working length,. A total amount 12 ml of 1% NaOCl was used per canal [23, 24].

A final flush of 5 ml of distilled water was administered to the prepared specimens to remove the remnant debris and irrigating solutions inside each canal. All root canals were dried with a sterile paper points to ensure that a complete instrumentation was achieved [25].

All the root samples were sectioned perpendicularly to the long axis in 3, 6, and 9 mm slices from the root apex [26, 27] using diamond disc (0.1 mm) under water cooling to avoid heating and to minimize smearing [28].

‘Defect’ was defined if any craze lines, microcracks, or fractures were present in root dentin or extending to outer root surface [18].

**Results**

**Discussion**

During the root canal instrumentation using engine driven instruments, high stress concentration in the wall of the root canal system is applied. This may increase the risk of dentinal damage predisposing the tooth to vertical root fracture [29].

Dentinal defects and then root cracking are a complex procedure because it is affected by many factors such as the design feature of the file used and its kinematics in addition to the alloy from which the instrument was manufactured. Since the primary aim of chemomechanical root canal preparation is to decrease the bacterial load and prepare the root canal for obturation, at the same time; the preservation of tooth structure and increase its resistance to fracture that lead to a long-term survival rate to the tooth [30]. The length of the canal and lower overall stresses, also to facilitate comparison of the results with several previous studies in which similar teeth had been used [27,31].

Adorno et al., found that apical cracks occurred in 50% of mandibular premolars after root canal preparation [32].

The teeth samples were selected from young adult patients because aging result in changes in the dentinal microstructure which in turn change the mechanical behavior of dentin resulting in average reduction of its strength predisposing it to crack growth and dentinal defects [33, 34]. Unlike the use of SEM that requires section treatment which may change the actual status of the tissue [35].

Although high resolution micro CT scans method is conservative and non-destructive, it is a complex procedure that lasts for an hour or more, this may increase dehydration of the samples resulting in spontaneous cracks in dentin [36].

The control group after sectioning was not shows any dentinal defects. This finding comes in line with several studies [4,18].

The largest number of dentinal defects promoted by Wave One Gold instruments may be related to its high level of flexibility due to the heat treatment of NiTi alloy and its parallelogram-shaped cross section [37]. During root canal preparation [40], which agrees with previous reports [16, 18]. However; reciprocating movement could prevent the continuous rotary force and constant torque that are applied to the walls of the canal [41].

The occurrence of dentinal defects is independent on the kind of the instrument used. The experimental groups varied in their design, cross section, tip design and taper but similar only in size (#25) of the tip, therefore; the null hypothesis of the present study has been partially accepted.

**Conclusions**

Within the scope of this in vitro study, it can be concluded that Wave One Gold system generated the significantly higher incidence of dentinal defects in mandibular premolars compare to the other tested file systems. While XP-EndoShaper system generates the lowest incident of defects in the rotating file systems compare to F6 SkyTaper file systems. The highest incidence was at the apical level in all of the tested groups. Additional researches may be required to assess these instruments on crack propagation and the fracture
resistance of the root canal treated teeth.

Studying Effective Factors on Overweight and Obesity in High School Students in Erbil

Sarhang Qadir Ibrahim¹, Tariq S. Al-Hadithi², Kameran Hassan Ismail³

¹Bsc, Msc in Public Health, College of Medicine, Auvergne University Clermont Ferrand1, France, ²Professor at College of Medicine, Hawler Medical University, Erbil, Kurdistan region, Iraq, ³Assistant Professor of Community Medicine, College of Medicine, Hawler Medical University, Erbil, Kurdistan region, Iraq

Abstract

Introduction: Overweight and obesity are explained as excessive fat depositions in human body. They have become one of the serious public health problems of the twenty-first century in low income countries. The prevalence of overweight and obesity in children is increasing worldwide, and currently 1 child in 10 is overweight or obese. The aim of this study was to assess overweight and obesity and associated factors in high school students in Erbil.

Method: It was a cross-sectional study in which 1,000 students in the age range 16-18 years of Erbil, Iraq in 2016-2017 were randomly selected. Data were gathered by a questionnaire. Data were analyzed using SPSS version 22 by appropriate statistical tests.

Results: Our results showed that some effective factors such as Computer games, watching TV, and irregular sleep (P-value<0.05) were the known factors affecting obesity/overweight in this study.

Conclusion: This study revealed that there are many factors involved in emerging over weight, such as overeating, eating snacks just before bedtime, and eating between meals especially between dinner and bed time, having lunch/dinner outside at restaurants and eating rice frequently, taking a nap during the day and watching TV/play video games/computer games.

Key words: overweight, obesity, high school, students

Introduction

Overweight and obesity can be explained as excessive and abnormal fat depositions in human body. They are major risk factors for several diet-based non-communicable diseases like dyslipidemia, cardiovascular diseases (CVD), and type II diabetes mellitus. About 2.8 million deaths and 35.8 million (2.3%) of global Disability Adjusted Life Years (DALYs) are caused by overweight or obesity.

The prevalence of overweight and obesity in children is increasing worldwide, almost 1 child in 10 is overweight or obese. Results of a study in United State suggest that obese adolescents are likely to stay obese into adulthood, and among individuals who were obese as adolescents, incident of severe obesity was 37.1% in men and 51.3% in women.

In lower- to middle-income countries, obesity co-exists with under nutrition where most overweight and obese children being concentrated in urban areas and presents serious social and psychological impacts. The prevalence of overweight in Iraq is experiencing a shift from underweight to overweight along with rapid socioeconomic and nutritional transition particularly in their area population. While, Africa is experiencing a shift from underweight to overweight along with rapid socioeconomic and nutritional transition particularly in their urban population. This transformation comes with increased access to energy-dense foods and less...
strenuous jobs resulting into many people having a positive energy balance and hence becoming overweight or obese.\textsuperscript{8,9}

It should be noted that 44\% of the diabetes burden, 23\% of the ischemic heart disease burden and between 7\% and 41\% of certain cancer burdens are attributable to overweight and obesity\textsuperscript{10,11}.

According to increase prevalence of overweight in high school children, the aim of this study was to assess the overweight in high school students and its relationship with lifestyle for the first time in Erbil, Iraq.

**Method**

It was a cross-sectional study which was conducted from the 20\textsuperscript{th} of September 2016 to the 10\textsuperscript{th} of March 2017. Target population were the students of grade 10, 11 and 12 of public schools (between 16-18 years of age) in Erbil city of Kurdistan region of Iraq.

The sample was collected by multistage cluster sampling technique. Schools were divided into 6 groups according to the municipalities of Erbil city, to cover all quarters of the city. Schools were randomly selected according to the number of students in each region. The total number of selected schools was 32 distributed in the 6 municipalities. Of the 36,777 students in these schools, 1,000 students were randomly selected. From each school a single class was selected randomly; For Data collection from each class was attended by the counseling specialist of the school.

**Questionnaire Design:**

A questionnaire which was designed by the Centers for Disease Control and Prevention (CDC) was modified and used as data collection\textsuperscript{9}. The questionnaire had three parts including demographic information, habits and life style of the students and socio-economic status (SES) that was calculated taking into consideration age, education and occupation of the father, car ownership and house ownership, according to the formula designed by Omer and AL-Hadithi \textsuperscript{10} and They were asked to choose between low SES, middle SES, and high SES which is one of the best types of descriptions. For better understanding; the questionnaires were adapted to each school’s language of instruction (local Kurdish and also to Arabic language).

After collecting the questionnaires, Data were examined using statistical package for social sciences (SPSS) version 22 (SPSS Inc. Chicago, IL) for windows. Data were analyzed through the use of simple descriptive statistical data analysis approach and inferential data analysis approach. Chi-square test of association was used to assess the association between the prevalence and several risk factors and Fisher’s exact test was used instead of the Chi square test when the expected count of more than 20\% of the cells of the table was less than 5. P value of ≤ 0.05 was considered as statistically significant.

**Ethical Consideration**

This study followed the tenets of the Declaration of Helsinki and written informed consent was obtained from all patients. All students were assured that their participation in the study was voluntary; they were informed about the purpose of the study; their anonymity and confidentiality were assured. Also an official permission from Erbil General Directorate of Education and from schools’ administrations to collect data was obtained. The study was approved by the Ethics Committee of the college of medicine of the Hawler medical university.

**Result**

This cross sectional study was done on 1000 high school children. Among them were 572 women and 428 men with an average age of 16.94±0.79. The tables of 1 to 5 show the prevalence of overweight and obesity by different factors.

Discussion

Our study showed that the overweight and obesity was significantly more in the age 16 and female students who were almost in class 11. A study by Taresa Kisi Beyen showed that More than half of the respondents 423 (53.5%) were females. The sex specific prevalence of overweight was similar with findings from Nigeria of which 0-8.1% males and 1.3-8.1% females were overweight. Ghana and Uganda (10.4% girls, 3.2% boys were overweight while 0.9% females and 0.5% males were obese) and Raichur district, India of which 6.17% of students were overweight in the year 2007. Our finding was in line with study done in South Africa, Jordan. The possible reason for this could be; girls spent most of their time at home and their movement from place to place are much restricted due to cultural influence than boys which result in more sedentary life.

The results showed that the students had history of such disease in their family: Diabetes mother and Overweight brother. Another interesting result was that most of them did not think that they were overweight or obese.

Family history is a consistent and independent risk factor for many common chronic diseases, and professional guidelines usually include the use of family history to assess health risk, initiate interventions, and motivate behavioral changes. Family history is a consistent and independent risk factor for many common chronic diseases, and professional guidelines usually include the use of family history to assess health risk, initiate interventions, and motivate behavioral changes.
between children and adults may lead to different manifestations of the disease.\textsuperscript{19}

Early onset of severe obesity increases the risk of long-term obesity and metabolic complications.\textsuperscript{20-23} Overweight and obesity from childhood to adulthood have been related to an increased risk of T2DM, AH, dyslipidemia, and carotid-artery atherosclerosis.\textsuperscript{24} Therefore, an early, multidisciplinary approach (pediatric, endocrinological, nutritional) in overweight and obese children is necessary to reduce the development of metabolic complications. IR, previously considered a problem in adulthood, becomes a serious issue also in children.

We concluded that there are many factors involved in emerging overweight, such as family history of diabetes and obesity and unawareness of being obese.

Removing Methods of Ultracide Residues in Imported Apple Peels in Iraqi Local Markets

Sedik A.K. Al-Hiyaly¹; Saba Riad Khudhaier ²; Jazzer, A. J. Al-Temmemi³ and Ahmed S.A. Al-Tae¹

¹Environmental Research Center, University of Technology, Baghdad- IRAQ, ²Department of Biology, College of Science, Mustansiriya University, Baghdad, Iraq, ³Al-Karkh University of Science, Baghdad- IRAQ

Abstract

The residues of ultracide insecticide used in controlling apple insects may have public health problems. This work was designed to find much effective method that capable of removing as much as possible of such residues from imported apple peels available in local markets. Imported apple samples were collected during winter 2018 from different local markets and divided into four subsamples as physical treatments where the first was left unwashed apple, the second was washed by tap water, the third was washed with saline solution and finally apple sample washed by tap water with acetic acid. Apple peels of all examined samples were left to dry in an oven at 85°C for 24 h and then powdered. 2.5 g from each sample was received 12.5 ml distil water to estimate the insecticide residues by using gas chromatography. It has been found that unwashed apple peels had the highest ultracide insecticide level followed by that washed by tap water while the peels washed by saline water was obviously free from the insecticide residues.

Key words: Ultracide residues, apple peels, tap water, saline water, acidic water.

Introduction

Crop plants may severely suffer from many diseases that are induced by different kinds of organisms such as viruses, fungous, herbs, insects, rodents and other organisms. Such crop diseases would cause significant reduction and economic losses. From early ages, farmers have tried to prevent such diseases and improve crop growth by using other biological species that can control plant pathogens [1-3].

In modern agriculture, biocides in general and pesticides in particular are very efficient materials to control crop diseases and enhancing agricultural production and therefore it is used worldwide. However, such insecticides particularly those contain phosphorous and intensively used with vegetables and fruits are concerned the most toxic material that may cause severe health problems to infants and teenagers [4-6].

The randomly use of various insecticides by farmers without scientific and official surveillance in terms of trade name, type and recommended doses suggested by producing companies may lead to real public health troubles since most of these insecticides are very toxic for both the health and the environment [7,8] where such disaster related to the fungicide was occurred in Iraq during seventeenth of last century with wheat grains treated with organ mercury [9].

Organophosphorus compounds are very toxic (LD50-25) especially ultracidine pesticide which affects cholinesterase due to increasing exposure and causes reducing of the enzyme level in the blood resulting in syndromes of muscarinic, nicotinic and central nervous system damage [10,11].

The application of such compounds as agricultural insecticides being very effective in protecting various edible plant crops from different insect species [12,13] where such edible plants have large surface area capable of taking significant quantities of these insecticides [14] such as peach, apple, cherry, ground berries, grape, spinach, potato, lattice and other vegetables.

Most of these oregano phosphorene insecticides such as parathion, malathion, dipterex and ultracide may form significant public health and environmental threats where several studies have reported the inhibition of choline enzyme at higher doses [15,16].

However, handling and removing such pesticide residues was received much attention being very
significant public phenomena \[17-21\] which needs to be investigated thoroughly and to find a proper removing method that should be accessible particularly at every home.

This work was designed to find a usable way to remove the residues of ultracide insecticide from imported apple where apple samples were collected from local markets and subjected to lab tests.

**Material and Method**

Imported apple samples were collected from local markets during winter 2018 and these samples were divided into four subsamples and subjected residues removing test where the first sample was left unwashed while the second was washed thoroughly by only tap water. The third sample was washed by diluted saline water at concentration of 1% for one minute and the forth sample was by acidic water which was tap water mixed with acetic acid at concentration of 1%. However, each treatment was replicated three times.

All apple samples after being treated as explained above were peeled and the peels placed in electric oven at 85 C° for few minutes then moved out and left to cool under room temperature. Dried peel apple samples were grinded by electric grinder and 2.5 g from each peel powder was placed in 250 volumetric flasks and received 12.5 ml distil water (1:5) and shacked for 30 min. Ultracidine pesticide residues was isolated by using chromatography/Mass Spectrometry-GC/MS following the method of previous study \[22\].

**Results and Discussion**

All obtained results were presented for unwashed, tap water, saline water and acetic acid water washed respectively of examined apple samples (Figures of analysis not shown).

It has been found that the residues of ultracidine insecticide in apple peels of unwashed sample had highest sharp peak by the value of 87.376 among other treatments. Also, there is another peak with a value of 62.621 due to reactions of unknown materials.

The residues of organophosphorin compounds in apple peels may be accumulated in human body up to lethal dose causing severe damage of various tissues and organs and also affect cell divisions \[18\].

In case of apple sampled washed by tap water, it was found the ultracidine insecticide residues were less than those left unwashed and had two peaks where the first peak was highest sharp peak was 12.23 while the second peak was 86.77

Again, the residues of such phosphoric compounds may be accumulated up to the lethal dose having severe effects as explained previously. the ultracidine insecticide residues in apple peel after being washed by saline water.

Apparently, there was no insecticide residues in the apple samples washed by saline water but there was a small peak due to unknown material reaction. However, it seems that saline water has totally destroyed all toxic phosphorene compounds.

Finally, the ultracidine insecticide residues were totally removed from apple sample washed by acidic water (acetic acid and tap water).

The obtained results suggest that the better effective methods of removing any quantity of residues of the ultracidine insecticide are washing such apples by using either saline water or acidic water that are available at all homes.

Several previous works examining similar pesticide residues removing methods were carried out worldwide. Previous work \[23\] has used dissolved ozone to get rid of four pesticides from vegetable which were methyl-parathion, parathion, diazinon and cypermethrin and found that low level (1.4 mg/l) of dissolved ozone was capable to oxidize up to 90% of all these pesticides except parathion within 5 minutes. Similar method (dissolved ozone) was followed by a work \[24\] carried on by using low concentration of dissolved ozone to remove four residues of four pesticide species and recorded a removing rate up to 99% within 30 minutes but it has reported that such removing rate was affected by temperature, concentration of applied ozone gas and preparing dissolved ozone concentration. In another study \[25\], five species of solutions were applied to remove blended organophosphorus pesticide residues from chines cabbage such as glycyrrhiza-mung bean, garlic juice, sods-salt, tap water and washed rice water and reported that soda-salt solution was the best removing solution while washed rice water showed very poor effects. Another study \[26\] has examined the impacts of using four washing methods (tap and ozone waters, ultrasonic cleaning and boiling) on 16 pesticide residues.
from raw strawberries and found that within less than 5 minutes, boiling technique had the highest removing rate followed by ultrasonic cleaning and ozonized water while tap water had the lowest removing rate which were 92.9 %, 91.2%, 75.1% and 68.1% respectively.

Apparently, it seems that several solutions can be used to remove pesticide residues from fresh fruits and vegetables where some of them such as ozonated, saline and acidic waters are capable of removing rate up to 90%. Nevertheless, such ability may be affected by certain variable such temperature, solution concentration and pesticide residues quantity as suggested by previous study [24]. So, the current results are supported by those of other works mentioned above but it necessary to examine other variables particularly temperature that may have significant effect on these methods used in this study.

Evaluation of Benzene Threshold Value in Benzene Exposed Work Environment: Case Study at Ciputat Gas Station

Shinta Arta Mulia1, Zikri Fathur Rahman1, Ahmad Muslih Bambang Sugiharta1, Lili Susanti1, Abdul Rohim Tualeka2

1Students, 2Department of Occupational Health and Safety, Public Health Faculty, Airlangga University, Surabaya

Abstract

Benzene is dangerous chemical compounds from products General Fuel Filling stations (gas stations) and is one component in gasoline with 1-5% carcinogen content. The purpose of this study was to determine the limits of safe concentration for benzene in the work environment of gas stations in Ciputat. This type of research is an observational, cross-sectional and descriptive study. The population in this study were all workers at one gas station in the Ciputat region. The sampling technique is the total population, so the sample is 27 workers. The design of the study begins with the collection of secondary data related to work processes which include chemicals in the work area and the number of workers involved. Furthermore, primary data collection was carried out related to the concentration of benzene in the workplace air, length of work time, and worker weight. In addition, secondary data was collected in experimental animals, namely the weight of white mice. The type of data in this study is primary data, obtained through questionnaires and observations as well as measurements of benzene in the air of the respondent’s workplace.

The measurement results of the concentration of benzene in the gas station in Ciputat in point 1 and point 2 are 0.58 mg / m3 or 0.18 ppm so that the concentration is still below the Threshold Value (TLV) according to Minister of Manpower Regulation Number 5 of 2018. Based on the manual calculation for safe limits of benzene concentration obtained 0.085 mg / m3 or 0.026 ppm. Control recommendations are to consume the CYP2E1 enzyme contained in beef liver and salmon which serves to reduce the level of benzene in the body, use the appropriate Personal Protective Equipment (PPE) in the form of half mask respirator with an organic vapor cartridge, and plant a number of ornamental plants that can absorb and reduce benzene concentrations such as Boston and Golden Photos 1.

Keywords: Benzene, safe concentration, workers gas stations.

Introduction

Benzene (C6H6) is an aromatic compound in the form of clear liquid at room temperature. This compound has a double bond and a saturated bond in the group with a resonating structure2. Benzene is one of the most applicable chemicals. Many uses of benzene are very useful for everyday life. The most important use of benzene is as a solvent and as a raw material for making other aromatic compounds which are benzene derivative compounds3.

Benzene is widely used in the rubber industry, oil refining, shoe factories, chemical plants and other oil-related industries including age fueling stations (gas station). The General Fuel Filling Station (gas station) is a facility or place that provides and sells various types of fuel oil for all types of vehicles. According to the Agency for Toxic Substances and Disease Register (ATSDR), hazardous and toxic chemicals contained in the oil content are benzene, toluene, xylene, ethylene, TPH (Total Petroleum Hydrocarbon), and Polycyclic Aromatic Hydrocarbon (PAHs). Of the six chemicals, benzene exposure has a very serious health impact.4
Individuals at risk of being exposed to benzene directly are workers at the gas station itself. Benzene exposure in gas station workers is mainly through inhalation or respiratory pathways. Gas station workers are continuously exposed to benzene because they are in the environment that emits benzene originating from the fuel pump engine when refueling, the fuel storage warehouse and the exhaust from the vehicle during the refueling queue.

Benzene has acute and chronic effects for exposed individuals. Acute toxic symptoms of benzene are suppression of the exposed central nervous system. While chronic and recurring chronic benzene exposure, even in low concentrations, can cause a variety of blood disorders from anemia to leukemia, a malignant disease that is irreversible and fatal. This chronic poisoning can result in non-cancerous effects and the effects of cancer.

In Hayat’s (2012) study, the results of benzene measurements at two points in the Ciputat region gas station were 0.58 mg/m³ or 0.18 ppm. The results are still below the threshold value (TLV) of 0.5 ppm (Minister of Manpower Regulation 5 of 2018). Although the concentration of benzene in the Ciputat region gas station is below the NAV, however, gas station workers exposed to benzene will still have a carcinogenic effect. A similar study at the Pancoranmas Depok gas station by Salim (2012), benzene concentrations at these sites had yields below the TLV but the gas station workers had a risk of carcinogenic effects at the lifetime duration of exposure.

In Hayat’s (2012) study, the results of benzene measurements at two points in the Ciputat region gas station were 0.58 mg/m³ or 0.18 ppm. The results are still below the threshold value (TLV) of 0.5 ppm (Minister of Manpower Regulation 5 of 2018). Although the concentration of benzene in the Ciputat region gas station is below the NAV, however, gas station workers exposed to benzene will still have a carcinogenic effect. A similar study at the Pancoranmas Depok gas station by Salim (2012), benzene concentrations at these sites had yields below the TLV but the gas station workers had a risk of carcinogenic effects at the lifetime duration of exposure.

Saridewi and Tualeka conducted research on safe (C safe) concentrations in the gas station area. The results of the study obtained a value of 0.03 as a safe concentration of benzene. Based on the research, the author will determine the limits of the safe concentration of benzene in different gas station areas, namely in the Ciputat gas station. In this study also the determination of RFC was also based on the conditions of workers in the study area which included weight and height.

**Material and Method**

This type of research is an observational, cross-sectional and descriptive study. The population in this study were all workers at one gas station in the Ciputat region. The sampling technique is the total population, so the sample is 27 workers. The design of the study begins with the collection of secondary data related to work processes which include chemicals in the work area and the number of workers involved. Furthermore, primary data collection was carried out related to the concentration of benzene in the workplace air, length of work time, and worker weight. In addition, secondary data was collected in experimental animals, namely the weight of white mice. The type of data in this study is primary data, obtained through questionnaires and observations as well as measurements of benzene in the air of the respondent’s workplace.

The research variables were benzene concentration in the workplace, worker body weight, worker height, respiration rate of workers, length of day working, body surface area, weight of white mice, body surface of white mice, highest dose of toxin without effect on experimental animals (NOAEL), Km factor in animals (Animal Km), Km factor for workers (Human Km), safe dose limit for workers (SHD), and benzene concentration in safe air for workers (C is safe).

Data analysis in this study was carried out by using quantitative data analysis manually to determine the safe concentration of benzene for workers in the Ciputat region gas station.

**Findings Experimental**

**A. Characteristics of Try Animals and Surface Area of Animals (White Mice)**

Toxicity is the ability of a chemical substance or compound to cause damage when it comes to sensitive internal parts or surfaces. According to Saridewi and Tualeka, the implementation of a toxicity test using experimental animals is a white mouse. In general, the human response to toxicity is qualitatively similar to that of animals, so this fact forms the basis of extrapolation from animal to human data.

In table 1, the characteristics of experimental animals in the form of white rat body weight are displayed.
Table 1. Distribution of Characteristics of Try Animals (White Mice)

<table>
<thead>
<tr>
<th>Try Animals (White Rat)</th>

</tbody>
</table>

Based on the data of white rat body weight, it can be calculated the body surface area of white mice using the following formula

BSA animal = 0.09 W^{0.67}

Description:

BSA : Body Surface Area / body surface area (m²)

W : Weight / weight (kg)

B. Characteristics of Workers, Worker’s Body Surface Area, and Worker’s Respiratory Rate

The characteristics of workers in this study include body weight and working time from 27 workers in the area Ciputat regional gas station. Based on Table 2, it is known that the highest body weight of workers in the Ciputat area gas station area is 80 kg, the lowest weight is 44 kg, and the average body weight is 57.73 kg. The duration of work in a day is 8 hours. Whereas for height use the average value of Indonesian adult male height which is 159 cm.

Based on data on workers’ body weight and worker height, the body surface area and the respiratory rate of workers can be calculated using the following formula.

1. The surface area of the worker body

BSA = \sqrt{W \cdot h / 3600}

Description:

BSA : Body surface area (m²)

W : Weight (kg)

2. Worker’s respiratory rate

BR = 5.3 ln - 6.9 / 24

Description:

BR : Breathing rate (m³/ hour)

W : Weight (kg)

</table>
The results of the analysis of the calculation of body surface area and worker respiratory rate according to Table 2 shows that the average body surface area of workers is 1.62 m² and the average respiration rate of workers is 0.61 m³/hour.

C. Benzene Concentration

The results of the measurement of benzene concentration at both points in the Ciputat region gas station showed the same results, namely 0.58 mg / m³ (0.18 ppm)

Table 3. Distribution of Benzene Concentration in Ciputat Regional Gas Station

Based on the results of measurements carried out, the concentration of benzene in the working environment of the Ciputat gas station is 0.58 mg / m³ or 0.18 ppm. This benzene concentration is below the threshold value of 0.5 ppm in accordance with the provisions of the Minister of Manpower Regulation Number 5 of 2018 concerning Occupational Safety and Health at the Work Environment. However, the concentration of benzene is above the Minimum Risk Level (MRL), the level of benzene inhalation exposure determined by ATSDR, i.e. for acute exposure (≤14 days) = 0.009 ppm, moderate exposure (15-364 days) = 0.006 ppm, and chronic exposure (≥365 days) = 0.003 ppm.

D. Animal Km and Human Km

The first step to determine the safe dosage of toxin for workers is by calculating Animal Km and Human Km.

1. Animal Km

\[ \text{Animal Km} = \frac{W_{\text{animal}}}{BSA_{\text{animal}}} \]

Description:
Animal Km: Km factor in animals
W: Experimental animal weight (white mouse)

2. Human Km

\[ Km = \frac{W_{\text{human}}}{BSA_{\text{human}}} \]

Description:
Human Km: Km factor in human/worker
W: worker weight
BSA: Body Surface Area worker

The results of the calculation are Human Km shown in Table 5. Based on Table 5, the Human average Km for Ciputat region gas station workers is 36.70.

E. NOAEL

one objective of the research activities in the field of toxicology is to be able to evaluate the safety of a substance. To determine the safe limit of the concentration of a chemical begins with the toxicity test determining the highest dose without causing effects on experimental animals or No Observed Adverse Effect Level (NOAEL).

The results of the research by Swaen et al. (2010) state that benzene NOAEL is 3.0 mg/m³ or equivalent to 0.022 mg/kg which is allowed from the calculation of formulas as follows.

\[
NOAEL \text{ benzene} = \frac{3 \times 0.00013 \times 8}{0.1405} = 0.022 \text{ mg/kg}
\]

F. Safe Human Dose

\[
SHD = NOAEL \times \frac{W_{\text{human}}}{BSA_{\text{human}}}
\]

Based on this formula, the calculation of SHD obtained from the NOAEL value, the average animal Km, and the average human Km is:

\[
SHD = 0.022 \times \frac{\text{data}59.89}{36.7} = 0.003 \text{ mg/kg}
\]

G. Limit Safe Benzene Concentration

Determination of safe limits of benzene concentration in the working environment of Ciputat region gas stations using formulas (William, 1985; Soemirat, 2003; Davis, 1991) the following.

\[
C_{\text{safe}} = \frac{(SHD) (W)}{(\delta) (BR) (t)} \text{ mg/m}^3
\]

To convert units of mg/m³ to ppm the following formula is used.

\[
C_{\text{safe}} = \frac{# \text{ mg/m}^3}{(MW)} \times 24.5 \text{ ppm}
\]

Description:

C is safe: concentration of toxin in the air is safe for workers (mg/m³)

SHD: Safe Human Dose (mg/kg)

W: Weight (kg)

\(\delta\): % of substances absorbed by the lung

BR: Human respiratory rate (m³/hour)

t: Duration of working time (hours)

MW: Molecular Weight / Molecular Weight

Based on the above formula, the results of calculating the safe concentration of benzene in the gas station in Ciputat region obtained from the value of SHD, average body weight, a percentage of substance absorption, average respiration rate of workers and the average length of work time are:

\[
C_{\text{safe}} = \frac{(0.003) (59.89)}{(50\%) (0.61) (8)} = 0.085 \text{ mg/m}^3
\]

\[
C_{\text{safe}} = \frac{0.085 \times 24.45}{78.11} = 0.026 \text{ ppm}
\]

The results of calculating safe limits in the air for workers above can be used to predict the concentration of toxins in the air a safe work environment for workers if
there is no determination of the Threshold Value (William, 1985 in Tualeka, 2013), and for comparison with NAV which has been determined by various institutions both by the Ministry of Manpower and Transmigration, the National Standardization Agency, ACGIH, NIOSH and OSHA.

**Conclusion**

The results of measuring the concentration of benzene in the gas station in Ciputat in point 1 and point 2 were 0.58 mg/m³ or 0.18 ppm so that the concentration was still below the Threshold Value according to Minister of Manpower Regulation Number 5 of 2018. Based on manual calculations for safe limits benzene concentration is obtained 0.085 mg / m³ or 0.026 ppm. TLV evaluation is a comparison of the results of the above calculation with TLV Benzene. According to Minister of Manpower and Transmigration Regulation Number 5 the Year 2018 which is 0.5 ppm. Based on manual calculations, safe limits benzene concentration in Ciputat gas station was bellow the TLV. So that the benzene threshold value is not feasible and needs to be revised.

Control recommendations are to consume the CYP2E1 enzyme contained in beef liver and salmon which serves to reduce the level of benzene in the body, use the appropriate Personal Protective Equipment (PPE) in the form of half mask respirator with an organic vapor cartridge, and plant a number of ornamental plants that can absorb and reduce benzene concentrations such as Boston and Golden Phothos.

A Complete Perusal of Polluter Pays Principle “Incorporation and Application In India”

Shyamantak Misra¹, Hiranmaya Nanda²
¹Assistant Professor, ²Assistant Professor, Faculty of Legal Studies, Siksha ‘O’ Anusandhan University, Bhubaneswar, Odisha, India

Abstract

Since long it’s a common practice to pay for the destruction and management of destruction caused by one, may it be destruction to property, life, nature etc. However for each kind of destruction there are specific laws and regulations enacted by the parliament. Apart from the laws there are few fundamental truths that act as the base or foundation for a system or in other words some theorems that have numerous special applications across a widespread area which are otherwise known as principles. Polluter pays principle is one of such preventive and remedial theorem applied to people causing environmental damage. This research work focuses on how the polluter pays principle was incorporated in India and emphasizes on its judicial application in various perspectives in India only. This paper starts with the introduction of the principle by “OECD (Organization for Economic Cooperation and Development)” in 1972 and further tracing its movement through the extended version of the principle, being enshrined under principle 16 of the Rio Declaration (UNCED) in 1992, being adopted by the European Community, being adopted as an extension of the rule of Absolute Liability in Torts and finally coming to how it started being applied to, by the Indian Judiciary. This article analyses the judgments pronounced in various cases by the Indian Courts relating to Polluter pays principle.

Keywords: OECD, UNCED, Torts, Absolute Liability, Strict Liability, Sustainable Development, EAP (Environment Action Program).

Sustainable Development and Polluter Pays Principle:

Today India has a variety of legislative measures, executive policies and programs to deal with environmental prevention and protection. In 1992, government of India adopted the well settled Polluter Pays Principle and the Doctrine of Sustainable Development as policy programs on matters relating to control of pollution. One of the major doctrine of sustainable development is the “Polluter Pays Principle, which recognizes that the polluter should pay all the environmental damage created and the burden of proof in demonstrating that a technology or process or product is safe for environment should lie with the developer not the general public.” As culled out from the Bruntland report named “our common future” the major features of the sustainable development includes polluter pays principle.

In Bruntland Commissions Report[1]:

The “World Commission on Environment and Development” or the “Bruntland Commission” in its report “Our Common Future” suggested that, the environmental costs of economic activity can be paid in an internalized manner by the enterprises. Which meant the payment may be in the form of investment made by the enterprises in order to prevent the damages caused or to restore the unavoidable damages like rehabilitation of man, afforestation, rehabilitation of land, or compensating the victims of the damage caused by such enterprises etc.

Corresponding author:
Shyamantak Misra¹
Assistant Professor, Faculty of Legal Studies, Siksha ‘O’ Anusandhan University, Bhubaneswar-751003, Odisha, India, Email-Id: shyamantak@soa.ac.in,
Mob: 7978707612
OECD (Organization for Economic Cooperation and Development) in 1972: OECD introduced the Polluter Pays Principle in 1972 and “the Guiding Principles Concerning International Economic Aspects of Environmental Policies under OECD stated that the polluter is to be held responsible for the environmental damage and pollution caused by such polluter.”

**EXTENDED VERSION OF POLLUTER PAYS PRINCIPLE:**

- **OECD IN 1989:** OECD suggested to extend the polluter pays principle to include the costs of accident prevention and for internalizing the damages caused by such accidents.

- **OECD JOINT WORKING PARTY ON AGRICULTURE AND ENVIRONMENT:** The OECD, Joint Working Party on Agriculture and Environment stated, extended version of polluter pays principle as: “…the polluter should be held responsible for environmental damage caused and bear the expenses of carrying out the preventive measures or paying for damaging the environmental state where the consumptive and productive activities causing the environmental damage are not covered by property rights.”

**RIO DECLARATION (UNCED) IN 1992:** In 1992 the guidelines for sustainable development were laid down in the Rio Declaration which aimed at utilization of the resources by the present generation without compromising the needs of the future generations. In furtherance of such aim the Rio Declaration enshrined the polluter pays principle under “Principle 16 of the Rio Declaration” which stated that the polluter should bear the cost of pollution.

**EUROPEAN COMMUNITY IN 2002:** In 2002 the European Community adopted the first EAP(Environment Action Program), thus following the Polluter Pays Principle of Organization for Economic Cooperation and Development.

**POLLUTER PAYS PRINCIPLE IN TORTS:** In this case of M.C.Mehta v.Kamal Nath and Ors[2], the court held that, “pollution is a civil wrong and thus it’s a tort committed against the community and any such person who is guilty of causing pollution has to bear the damages or compensation in order to restore the environment.” In torts the principle of Strict Liability or the rule in Rylands v. Fletcher[3] stated that, “any person in the course of non natural use of land is deemed to be responsible for the accumulation on it of anything that is likely to cause harm if it escapes and is liable for the interference with the use of land of another which results from the use of such thing that escapes from his land. However this principle of strict liability is subject to exceptions(plaintiffs fault, Act of God, Act of Third Party, Consent of the Plaintiff, Act done by Statutory Authority).” Whereas the principle of Absolute Liability is not subject to any exceptions and is thus considered to be the improvement of the principle of strict liability since in M.C.Mehta v. Union of India[4] the court held that “the rule in Ryland v. Fletcher laid down in 19th century did not meet the needs of the modern industrialized society therefore the need to recognize a new rule was necessary and the rule of absolute liability was laid. Under this rule of Absolute Liability the court pointed out the duty is absolute and non-delegateable and the enterprise cannot escape liability by stating that he has taken all reasonable care and that no negligence was there on his part. The polluter pays principle is said to be an extension of the principle of absolute liability since the rule of absolute liability is invoked regardless of whether or not reasonable care was taken in the dangerously inherent activity taking place due to the escape of the hazardous thing and such person is liable to compensate the victims of such dangerous activity,adding to it in polluter pays principle the polluter is also liable to pay the cost of repairing the damage caused to the environment.”

It can be said that the strict liability, absolute liability and polluter pays principle are interlinked with each other.

**FEW REMARKABLE DOCTRINES AND PRINCIPLES PROPOUNDED BY THE INDIAN JUDICIARY:** Below given are the list of the major doctrines and principles propounded by the Supreme Court of India and the corresponding case law in which it was propounded:
DOCTRINE AND PRINCIPLES: | CASE IN WHICH IT WAS PROPOUNDED:
---|---
1. DOCTRINE OF ABSOLUTE LIABILITY (laid down in M.C.Mehta Case) | BHOPAL GAS LEAK CASE (UNION CARBIDE CORPORATION V. U.O.I AIR 1990 SC 273) (1st applied here; laid down in M.C.Mehta Case)
4. PUBLIC TRUST DOCTRINE | M.C.MEHTA V. KAMAL NATH & OTHERS (1997) 1 SCC 212.

Polluter Pays Principle and The Indian Judiciary:

- **Indirect Recognition And Application of Polluter Pays Principle (M.C.Mehta v. Union of India)[8] (Oleum Gas Leak Case):** The Supreme Court of India declared that “we need to evolve new principles and lay new norms which could adequately deal with the new arising problems in a highly industrialized economy.” This case was also popularized because in this case the court formulated the principle to measure the liability of industries that are involved in hazardous or inherently dangerous activities. It was stated that in order to measure the liability in such cases “the larger and more prosperous the enterprise, the greater must be the amount of compensation payable by it for the harm caused on account of an accident in the carrying on the hazardous or inherently dangerous activity by the industry or enterprise.” In this case the industry (Shri Ram Food and Fertiliser Corporation of Delhi) was asked to deposit a sum of rupees 35 lakh in a bank and guarantee of rupees 15 lakh in the court so as to be paid as compensation to the persons who claim and prove to be the victims of the Oleum Gas Leak Case. Thus this innovative remedy evolved in this case which was considered to be the indirect recognition and application of the Polluter Pays Principle.

- **Case where the Polluter pays principle was first applied and defined (Indian Council for Enviro Legal Action v. Union of India)[6]:** In this case it was stated that, “the polluter is liable to pay the cost of the individual sufferers as well as the cost of redemption of the damaged environment which is considered to be a part of the sustainable development[7]. Thus here the polluter pays principle means the absolute liability for harming the environment which shall extend to compensating the victims of such pollution caused as well the costs incurred for restoration of the environmental degradation caused.”

- **Vellore Citizens Welfare Forum v. Union of India (AIR 1996 SC 2715):** Here the Supreme Court declared two principles as part of the environmental jurisprudence of India namely: The Precautionary Principle and The Polluter Pays Principle.

- **A.P.Pollution Control Broard v. Prof. M.V. Nayadu (AIR 1999 SCW 434.[8]:** In this case the Supreme Court declared that, “the polluter pays principle and the precautionary principle have become a part of the environmental law of the country.”

- **Taj Trapezium And Polluter Pays Principle, M.C.Mehta:** In this case “the court gave its order based
on the precautionary principle and the polluter pays principle as was defined in the vellore citizens welfare forum case and also stated that the poluter pays principle is an essential feature of Sustainable Development.”

**Conclusion**

As we found that more and more principles are being created to mitigate the lacunas that remained unseen in the previous principles or doctrines, similarly the polluter pays principle came up to mitigate the damage being caused to the environment which wasn’t compensated for in strict or absolute liability. However the measurement of the damage caused to the environment has no absoluteness due to lack of an imposed mechanism to measure such damages caused. Thus the amount of compensation charged for restoration of the environment remains inadequate at times and are in requirement of some more effective provisions to be beneficial in the long run.

**Ethical Clearance:** Not required, as the research article is based on environmental pollution and its protective principles. The research is doctrinally undertaken.

**Source of Funding:** Self

**Conflict of Interest:** Nil

Risk Assessment, Risk Management, and Risk Communication at Drug Industries PT. Kimia Farma (Persero) Tbk. Plant Bandung

Suherdin¹, Noeroel Widjati¹, Ratna Dian Kurniawati², Abdul Rohim Tualeka¹
¹Department of Occupational Health and Safety, Faculty of Public Health, Airlangga University, Indonesia, ²Bachelor Programme in Public Health, Bhakti Kencana Institute of Health Science Bandung, Indonesia

Abstract

There have been many accidents and occupational diseases caused by weak risk management efforts. Risk management can be carried out by starting with a risk assessment. Risk assessment is an important aspect of occupational health and safety. The pharmaceutical industry has a high risk of occupational health and safety. This study aims to identify the level of occupational health and safety risks and provide control recommendations. This research is descriptively using the Job Safety Analysis (JSA) method. The results of the identification show that from 19 work steps 10 of which include high risk, 8 including moderate risk and 1 low risk. The hazards identified include chemical, physical, ergonomic and fire hazards. High risks include hazards originating from chemicals as raw materials for making drugs. Several control measures have been taken, but to ensure worker health and safety, additional efforts should be made such as noise suppression personal protective equipment, special masks for use in chemical hazards and work accident emergency response procedures. Risk communication at the drug company is going well.

Keywords: Risk Assessment, Risk Management Risk Communication, Job Safety Analysis, Drugs Industries.

Introduction

In Indonesia, the number of accidents due to work is still fluctuating, recorded the number of work accidents from 2011-2014 the highest number of accidents occurred in 2013 with 35,917 cases of work accidents (in 2011 there were 9,891 cases; in 2012 there were 21,735 cases, and 2014 occurred 24,910 case). The provinces with the highest number of work accident cases in 2011 were Banten and Central Kalimantan. In 2012, Jambi and Maluku Provinces. In 2013 the provinces of Aceh and North Sulawesi. In 2014 were the provinces of South Sulawesi and Riau¹.

Whereas in the case of Occupational Diseases (PAK) from 2011-2014 the trend has decreased even though in 2012 and 2013 it has increased. In 2011 the number of PAK in Indonesia reached 57,929 cases, in 2012 60,322 cases and in 2013 increased again to 97,144 cases, then in 2014, it began to decline to 40,696 cases. The provinces with the most PAK prevalence in 2011 were Central Java Province, in 2012 North Sumatra, South Sumatra and West Java, 2013 Banten Province, and in 2014 were the Provinces of Bali, East Java, and South Sulawesi. The data shows that efforts to prevent accidents and occupational diseases are still not optimal¹.

Efforts to prevent work-related accidents and diseases can be carried out with a number of approaches, namely, approaches to weaknesses in the human element, such as the selection of employees properly and knowledge building or training. Approach to weaknesses in hardware or production equipment through the design, maintenance of production equipment and planning of the work environment. Approach to all levels of management by conducting equitable distribution of tasks, and determining the implementation of risk assessments².

Risk assessment is a systematic effort to identify opportunities for accidents and occupational diseases. Through risk identification efforts we can find out the characteristics of risks from hazards so that it is easier to make security efforts to avoid accidents. One method that can be used to identify risk is the Job Safety Analysis (JSA) method. JSA is a risk identification method by
reviewing and assessing the risk of each stage of the work performed.

Job Safety Analysis (JSA) is a process of identifying hazards and risks based on each stage in a work process that has the potential to cause serious harm before an accident occurs. Determine how to control hazards or reduce injury rates and make written documents that can be used for hazard information.

Benefits of Using JSA

1. Provide individual training in safety and efficient work procedures.
2. Provide information about hazards in the workplace.
3. Hazard information is described based on work stages so that it is more detailed.
4. Provide risk control alternatives based on the results of risk identification in the workplace.
5. Accurate absences, workers compensation becomes cheaper and increases productivity.

The risks identified must be immediately controlled, risk control efforts are known as risk management. Risk management is a systematic effort to determine the best actions in conditions of uncertainty. Risk management is an activity which contains elements: systematic identification, analysis, improvement, monitoring, and communication against risks.

The exchange of information between interested parties about the circumstances, magnitude, and importance of risk control. risk communication itself is included in the risk analysis process.

PT. Kimia Farma (Persero) Tbk. Plant Bandung, is one of the State-Owned Enterprises (BUMN) engaged in the production of drugs or pharmaceuticals. In an effort to guarantee the supply of drugs on the market, this company provides 3 parts of the production. Particularly for production I, producing solid drug preparations in the form of tablets and caplets.

Based on the visits made to the production section I, there are some potential hazards that can lead to accidents and occupational diseases. During the production process, workers make physical contact either through inhalation or dermal with chemicals as raw material for making drugs. The chemical ingredients for the manufacture of drugs, namely ethyl alcohol, dextrose anhydrous, amyllum maydis, and microcrystalline cells have the potential to cause health problems such as irritation, respiratory disorders, and nervous system disorders.

The purpose of this study is to conduct occupational health and safety risk assessments in the Production Section I of PT. Kimia Farma (Persero) Tbk. Plant Bandung using the Job Safety Analysis (JSA) method.

Material and Method

This study used a descriptive observational research design. The danger is a potential hazard, risk refers to actual danger. Risks can be identified through direct observation at the production site.

The study was conducted in the Production Section I of PT. Kimia Farma (Persero) Tbk. Plant Bandung. The risk assessment method uses the JSA with the following risk assessment steps:

1. Select the place to be analyzed
2. Describe the stage of work
3. Identify the various hazards and risks that exist in each step of the job, and identify various possibilities that have the potential to become accidents;
4. Risk assessment (likelihood and severity)
5. Categorize risk (risk assessment matrix)
6. Provide control recommendations

Risk Management is carried out by selecting control options that are in accordance with the characteristics of the risk. Evaluation of available controls, so that it can provide additional control recommendations. Data on risk communication is obtained by direct observation at PT. Kimia Farma (Persero) Tbk. Planting Bandung. Risk communication can generally be observed through the media, company management meetings with workers and local stakeholders.

Findings

a. Risk Assessment

There are 9 stages of work then clarified into 19 job descriptions. The first stage is the weighing of raw materials carried out at the weighing center. The weighing process has 3 job descriptions, opening drums containing medicinal raw materials, weighing drug-making materials and manual lifting process. The risks identified are, workers inhale the raw materials of drugs that can cause shortness of breath. Workers sitting too long can cause Lob Back Pain (LBP), lifting the manual can cause LBP and Thoracic Outlet Syndrome (TOS). All work descriptions at this stage are included in the high risk.

The second working stage is a wet granulation process, in this stage described into 4 job descriptions. Climb the ladder of the granulation machine, insert the solvent of water or organic alcohol into the machine, hold the granulation results into a plastic barrel and there are operators as supervisors. The risks identified include, workers can experience injury, dizziness, shortness of breath and eye irritation. Two job descriptions are included in the high-risk level and the other 2 are moderate risk levels.

The third working stage is the drying process, there are 2 job descriptions in the drying process. Enter the raw material into the dryer with the average temperature of the 70°C machine and the manual lift process. The risk identified at this stage is that workers can become dehydrated due to exposure to a hot work climate, and workers can experience fatigue, LBP, TOC due to the position of non-ergonomic apes. The level of risk in this stage is included in the low and moderate levels.

The fourth working stage is sieving, there is one job description in this process. Workers enter mixtures that have previously been dried into the sieving machine. The risk identified in this process is LBP due to work position when overseeing the sieving process for too long sitting and not ergonomic. The level of risk in this job description is included in the level of moderate risk.

The fifth working stage is dry granulation, in this stage, there are 3 job descriptions. Workers put the mixture into a dry granulation machine, pour additives in powder or liquid form and bring the results of dry granulation to the drug printing section. The risks identified are workers can experience LBP, shortness of breath nervous system disorders, fatigue, and TOS. Two work descriptions are included in the level of moderate risk and 1 other is high-risk level.

The sixth working stage is drug printing, in this stage, there are two job descriptions. First Enter the ready-made material into the printing press. The risks identified are the risk of shortness of breath and nervous system disorders due to workers being too close to the reach of the dust collector. The level of risk in this job description includes high risk. Both operators process to monitor printing machines. The identified risks are workers experiencing varicose veins and fires from electrical installations. The level of risk includes high risk.

The seventh working stage is in coating the drug, there is one job description at this stage. Workers put drugs into the coating machine. The risks identified are workers at risk of experiencing varicose veins due to too long standing when watching the machine. Included in the median risk level.

The eighth stage is the primary packaging. There are 2 job descriptions at this stage. First, the workers send the drug into the engine, the identified risks are that workers can experience hearing loss due to noise produced by the primary packaging machine. Second, workers control the packaging results. The risks identified include that workers can experience PBP as a result of too often sitting in a non-ergonomic position. This risk is included in the level of moderate risk.
The ninth working stage is secondary packaging. There is one job description where the worker enters the drug into the box. The risk identified is that workers can experience varicose veins due to too long standing when packing. The level of risk in this job description is included in the high-risk level.

b. Risk Management

Based on the risk assessment above, it shows that of the 9 work stages and 19 job descriptions, 10 descriptions or 52.6% are at high risk for Occupational Safety and Health. The weighing and printing stage is a part of which all work descriptions are high risk. The remaining 8 descriptions or 42.1% are medium risks and 1 description or 5.3% low risk of Safety and Occupational Safety.

Referring to the results of the risk assessment that there are several job descriptions that have a high risk, the activities may not be carried out until the risk has been reduced or controlled. The purpose of risk control is to avoid workers from the worst consequences that can cause loss of work time and worker productivity.

Some stages of the production run the risk of causing health problems. Identified ergonomic risks such as errors in manual handling, excessive physical loads, and posture incompatibility with work stations, risk causing muscle disorders.9

Research conducted by Wahyu, P.D and Tualeka, A.R., 2013 in one of the welding industries in East Java, Indonesia explained that there were still residual risks despite risk control. So that the residual risk assessment needs to be done so that it can further determine additional risk control recommendations10.

PT. Kimia Farma (Persero) Tbk. Plant Bandung has carried out several efforts to control identified risks. The effort is a combination of technical control, administrative and use of personal protective equipment. controls that have been carried out between, providing masks, making Standard Operating Procedures, providing chairs for workers, working rooms equipped with refrigeration equipment, providing lightweight fire extinguishers, and efforts to maintain workers’ fitness with gymnastics every morning.

Such control is still not enough to reduce some of the identified risks. Some controls must also be carried out, such as conducting safety talk, safety inspections, stretching work intervals, giving awards and reprimands, providing accident and fire emergency response procedures, exchanging with colleagues who are already tired and weak and providing earplugs.

c. Risk Communication

PT. Kimia Farma (Persero) Tbk. Plant Bandung applies OHSAS 18001: 2007 as work safety and health management system. One form of implementation of the system is communication, participation, and consultation11.

Risk communication is the exchange of information about the magnitude of health risks in the work environment. The forms of application of risk communication carried out in the company include, meetings between the entire corporate structure include workers in communicating occupational health and safety policies. Risk communication media are installed such as posters and banners. In addition to these efforts, PT. Kimia Farma (Persero) Tbk. Plant Bandung routinely holds meetings with workers on the National Occupational Health and Safety commemoration. This meeting was held so that there was an exchange of information between workers and managing the company.

Conclusion

Based on the results of the study it can be concluded that of the 9 work stages and 19 job descriptions, 10 descriptions are at high risk for Occupational Safety and Health. 8 description is the moderate risk, and 1 description low risk. Risk management has been carried out, but additional control is needed so that the risk of illness and occupational accidents can be reduced. The process of risk communication works well, risk communication involves management and workers. Communication media have been installed, and information exchange with routine workers is carried out.

Work Safety Risk Assessment at Container Load Unloading Jobs at PT. Pelabuhan Indonesia II (Persero) Palembang Branch 2017

Tedi Levinrariant1, Zikri Fathur Rahman1, Abdul Rohim Tualeka1
1Department of Occupational Health and Safety, Faculty of Public Health, Airlangga University, 60115 Surabaya, East Java, Indonesia;

Abstract

Loading and unloading of container goods is carried out using cranes and truck containers as a means of transportation besides facilitating activities, which can also lead to the risk of workplace accidents. In 2014 there was a work accident in Kuningan Jakarta, workers were crushed by a container during the loading and unloading process. Container loading and unloading is a routine activity carried out at PT. Pelabuhan Indonesia II (Persero) Palembang Branch. This activity involves tools that can cause accidents such as being hit by a container and hit by a truck head, therefore a risk assessment is carried out on container loading and unloading work. The purpose of this study was to analyze occupational safety risk assessments on container loading and unloading work. This study uses a qualitative research design, using Job Safety Analysis (JSA) for the risk identification process, the US / NZ 4360: 1999 semi-quantitative risk assessment table for risk analysis and semi-quantitative risk level Cross (1988) for risk evaluation. The results of the study indicate that container loading and unloading work consists of the preparation stage, the operation phase of the QCC and the stage of moving containers. The risks identified based on the stage of work are overtaken by containers, falling from heights, collisions between head trucks, falling lifts, hit by a lock lock, getting hit by a truck head, falling into the river, collisions between QCCs and electric shock. The hazards included in the acceptable risk category include being crushed by repair equipment, hands pinched, tripping, slipping lubricants and head banging. The suggestion of this research is that all activities in the field should be carried out in accordance with the applicable regulations and supervision should be carried out more specifically in the use of PPE and conduct periodic health checks on workers.

Keywords: Risk Assessment, Container Loading and Unloading, Job Safety Analysis.

Introduction

Occupational Health and Safety (K3) is a compulsory program that exists in every workplace. Its implementation has spread widely in almost every industry sector, its main goal is to reduce the number of accidents, and reduce the risk of being dangerous1.

Correspondence Author:
Abdul Rohim Tualeka,
Department of Occupational Health and Safety, Faculty of Public Health, Airlangga University, 60115 Surabaya, East Java, Indonesia. e-mail: inzut.tualeka@gmail.com or abdu-r-t@fkm.unair; Handphone: +6281333519732

The number of occupational accidents in the world is in quite alarming conditions, every year two million people die and 270 million people are injured due to workplace accidents that occur throughout the world2. The development of workplace accidents in developing countries is also very high, including Indonesia, this is because developing countries have many labor-intensive industries, so that more workers are exposed to potential hazards3.

Workplace accidents are unwanted events that have an impact on someone or material damage, which are the result of contact with kinetic, electrical, chemical, heat and other sources4. Most (85%) accidents are caused by human factors with unsafe actions. Unsafe action is an action that can endanger the workers themselves
and others who can cause accidents that can be caused by various things such as not using PPE, not following work procedures, not following work safety regulations and not working carefully, where out of every 300 unsafe actions, there will be 1 (one) accident resulting in the loss of workdays.

The port is one of the workplaces that have a high risk of work accidents. Every year accidents caused by lifting at the port occur. Based on the statistics of the Marine Industrial Accident, the Hong Kong Maritime Department in 2016 had occurred as many as 76 cases of workplace accidents in the loading and unloading section port. The work accident consisted of 60 minor accident cases, 15 serious accident cases and 1 fatal accident case.

One of the work accident incidents that occurred during loading and unloading was the breaking of the RTG wayer trolly while carrying out container loading and unloading from the ship which caused the death of the RTG operator assistant on October 21, 2017. In addition, in the past two years there has been a work accident at JICT Jakarta is related to loading and unloading containers such as damage to spreader tools and falling over on maintenance and container cars which have deteriorated during the appointment process.

Goods container loading and unloading activities at the port have a high risk. Based on accident data obtained from the Maritime Department of Hong Kong, the incidence of accidents related to cargo handling / loading and unloading in Hong Kong is quite high. In 2006 there were 302 work accident cases related to container loading and unloading. In 2007 there were 240 work accident cases related to container loading and unloading. In the following year, from 2008 to 2010 each recorded 220 cases, 176 cases and 157 cases each year. The incidence of these accidents is seen to decline every year, but the decline is not accompanied by a decrease in the risk of death which reached its peak in 2010 as many as 6 deaths due to workplace accidents related to container loading and unloading.

The 24-hour bongkarmuat service that involved humans and machines definitely caused the danger of accidents such as dropping slings at the time of appointment, spreaders falling on head truck operators, falling containers on TKBM or head truck operators, TKBM falling into the river until collisions between QCC. Risk assessment is deemed necessary to minimize the incidence of accidents.

### Material and Method

This study uses a qualitative research design, using Job Safety Analysis (JSA) for the risk identification process, the US / NZ 4360: 1999 semi-quantitative risk assessment table for risk analysis and semi-quantitative risk level Cross (1988) for risk evaluation.

The population in this study were procedures / jobs in container loading and unloading activities carried out at PT. Pelabuhan Indonesia II (Persero) Palembang Branch.

Primary data in this study is in the form of data from field observations, as well as data from interviews with key informants and informants. Observation data is used to identify risks and get a description of the dangers in loading and unloading work at PT. Pelabuhan Indonesia II (Persero) Palembang Branch.

Secondary data in this study were in the form of library research, company profile, work instructions for planning container loading and unloading activities, work instructions for controlling loading and unloading activities, container service procedures for loading and unloading of PT. Pelabuhan Indonesia II (Persero) Palembang Branch and review of documents related to research.

Data obtained from the results of observations and interviews were analyzed using semi-quantitative risk analysis techniques to determine the level of risk and evaluated at each step of the work and involved workers.
in carrying out the assessment. In addition, data analysis based on observations is also done by confirming the observations in the form of photos of work procedures, known as photovoice. Furthermore, the data will be validated using triangulation of sources, methods, and data to test the credibility of the research results.

Discussion

The results of the research conducted during the container loading and unloading work at PT. Pelabuhan Indonesia II (Persero) Palembang Branch shows that there are 12 risks with very high risk levels. These risks are grouped into 4 types of risks, namely being crushed by the container, collision between the head of the truck, falling from a height, and the elevator falling.

The risk of overwritten containers is in several work steps. Work steps that have the risk of being hit by containers include, among others, lasing or unlasing containers, opening a twist lock on containers, head truck operators waiting for cargo, giving signals to TKBM and recording container numbers done by tally. In a day this work is usually done once so that the exposure value is given 6 (Frequently).

Another risk that has a very high level is the risk of being hit by a truck head when the head truck operator waits for the load of goods, the operator should not be allowed to get off the vehicle, but the operator comes down from the head truck and runs on the truck track. This can lead to the risk of an accident being hit by a vehicle that will exit or go to the QCC in front of it to load containers, therefore a 6 probability value. Consequences of 25 (very serious) because if the head truck operator is hit then it can cause injury and even permanent disability and exposure 3 (occasionally). The risk of getting hit by a truck head is not only for the operator. The risk of being hit by a truck head can also occur at the stage of signal loading and unloading by the TKBM to the head truck operator and at the stage of recording the container number by tally. The probability value 6 (Likely) is because the TKBM and tally are right next to the head of the truck and stand in the truck path when giving sinya and recording containers, this can cause TKBM and tally to be hit by trucks that will pass, moreover the activities are carried out at night. What consequences if TKBM or tally gets hit is the value is 25 (very serious) because it can cause injury to permanent disability. The expiration value is 3 (Occasionally) because if the sprider is lifting the container on the TKBM ship and tally will move to the safe lane provided.

Collisions between head trucks can occur when the activity of the head truck operator takes the truck to the truck or carries a load to the stacking field, the reason is that the head truck operator is not vigilant when driving a vehicle so that it strikes a vehicle in front of it and this is likely to occur because every cargo the container earns 2000 rupiah so the head truck operator ignores safety, the probability value is 6 (likely). The consequence is 15 (serious) because if there is a risk accident the occurrence can occur is a serious injury such as a broken bone, this activity takes place several times because after the head truck brings the container from the dock to the stacking field it will return to the dock so that the exposure value is 6 (frequently).

The next risk is included in the very high category, which is falling from a height. Falling from a height can cause mild to severe injuries such as fractures and even death of workers. This risk can occur at TKBM which opens a twist lock on a stack of containers that reaches 12 M. The twist lock is a prism-shaped locking iron located in four container corners, so that the container stack does not sway or move position. To open a twist lock on a container that is in the topmost stack TKBM must go up above the container and be on the edge of the container. Based on the results of interviews with workers, there has been a work accident because the TKBM is in an unhealthy condition and loses balance which causes the TKBM to fall from a height so that the possible value is 10 (continuous) severity that can occur if the TKBM falls permanently so the consequence value is 25 (Very serious). The exposures value is 6 (frequently) because this activity is done repeatedly. The same results were obtained from the study of Makomulamin and Safitri (2017), which stated that the danger of falling from a height occupies a high risk level with a score of 15, the possibility of occasional occurrence and severity is severe injury, broken bones, disability and death which means necessary carried out promptly by the company.

Conclusion

The results of risk identification in container loading and unloading work at PT. Pelabuhan Indonesia II (Persero) Palembang Branch has 36 risks. Preparation stage: hit by a head truck, crushed repair equipment, hand pinched, fell into a river, tripped, hit a twist lock throw, slipped lubricant, hit the head, crushed the container, fell from a height and collided between the head truck.
QCC operation: tripping, the elevator falls, hands pinched on the elevator door, tripping, head banging, hands pinched swift limit, head hit, collision between QCC and electric shock. The stage of moving containers: getting hit by a head truck, being hit by containers, tripping, slipping and traffic accidents.

The results of the risk analysis obtained illustrate that in container loading and unloading jobs there are 12 risks with very high risk levels which are grouped into the risk of being hit by containers, falling from a height, collisions between head trucks and lifts falling. 1 risk with the risk level of priority 1, namely the supervisor is exposed to a twist lock throw, 2 risks with a substantial level of risk, 5 risks with a level of risk of priority 3 are risk of hit head, collision between QCC, pinched hands and electric shock, and 16 risks with acceptable risk levels that is overwritten by repair equipment, tripping, slipping lubricant head hit and pinched hands.

The results of the risk level obtained are divided into 5, namely very high, priority 1, substantial, priority 3 and acceptable.

The results of the risk evaluation indicate that there are still dangers included in the category of risk level (existing level) non-acceptable or still need improvement in the implementation of work and improvement in the implementation of risk control. Besides that, it is also found that hazards including acceptable level levels or risk control efforts that have been carried out are considered to have reduced the level of risk to acceptable limits, although the intensity of activities that pose a fixed risk should be reduced to a minimum. These hazards include pinched hands, slippery areas of the ship due to oil spills or lubricants, Laying a twist lock that is careless on the road, Laying mechanical equipment carelessly so that it falls from above the head.

Correlation of Smoking and National Institutes of Health Stroke Scale (NIHSS) in Acute Ischemic Stroke Patients

Yunike Tourisiana¹, Mohammad Saiful Islam¹, Joseph Ekowahono Rahardjo¹

¹Department of Neurology, Faculty of Medicine, Universitas Airlangga-Dr. Soetomo General Hospital, Surabaya 60131, Indonesia

Abstract

Background: Ischemic stroke is the most common type of stroke with 87.00% prevalence of atherosclerosis as one of the causes of cerebral vascular lumen occlusion. Smoking is known as a modifiable risk factor for stroke. The process of atherosclerosis leads to a neurological deficit resulting in impairment of the patient. One of the scales used to assess impairment is the National Institutes of Health Stroke Scale (NIHSS).

Objectives: To know the correlation between smoking status and functional degree of acute ischemic stroke patients as measured by NIHSS.

Method: The subjects were 48 patients. The study design was cross-sectional and clinical sampling consecutive admissions and an acute ischemic stroke image imaging. Smoking status data was obtained through anamnesis at the time the patient was hospitalized supported by the testimony of the immediate family. NIHSS values were obtained on the first day of hospitalization. Data analysis used chi-square test and logistic regression.

Result: Sex (p = 0.001) and smoking (p = 0.013) were variables that had significant correlations with NIHSS. There was no association between smoking and the functional degree of acute ischemic stroke patients measured by NIHSS, (p = 0.57) with Adjusted Odds Ratio 1.5 (CI 95% 0.35 - 6.9).

Conclusion: There was no significant association between smoking with functional degree of acute ischemic stroke patients as measured by NIHSS.

Keywords: NIHSS, Acute ischemic stroke, Smoking status

Introduction

A stroke is a focal or global neurologic deficit that suddenly occurs over 24 hours unless it dies before 24 hours or surgery is performed, in the absence of other causes other than cerebral vascular disorders ¹. The prevalence of stroke in Indonesia has increased from 8.3 each mile in 2007 to 12.1 per mil in 2013. Ischemic stroke is the most common type of stroke with the prevalence of 87.00% ². Ischemic stroke is classified based on the mechanism of etiopathogenesis: Large Artery Atherosclerotic Stroke (LAA), cardioembolic stroke (CE), small artery occlusion or lacunar stroke (LAC), the stroke of other determined etiology and stroke of undetermined etiology ³.

One of the risk factors that increase the incidence of stroke is smoking behavior ⁴. Indonesia is ranked one in the world for the number of male smokers over the age of 15 (66.00%) ⁵. Exposure to secondhand smoke triggers many pathological effects in the endothelium, such as oxidative stress, platelet activation, trigger coagulation cascades and interfere with fibrinolysis ⁶,⁷. Smoking causes poorer functional outcomes at 3 months after the onset of ischemic stroke compared to non-smokers ⁸,⁹.

The scale to measure the functional deficit of acute ischemic stroke is NIHSS (National Institutes of Health Stroke Scale) ¹. Smoking is said to be associated with...
higher NIHSS scales in small vessel occlusion\textsuperscript{10}, while other studies produce different assumptions by using the same measurement tool\textsuperscript{11}. NIHSS has a specificity of 0.90 (CI 95%, 0.86-0.94), sensitivity of 0.71 (CI 95%, 0.64-0.79) and good accuracy of 0.83 (CI 95%, 0.79-0.87) in predicting post-stroke clinical outcomes\textsuperscript{12}.

How to know someone’s smoking status is with interviews that have sensitivity and specificity by 79.00\%\textsuperscript{13}. This method is known not invasive and does not require special techniques also cheap. The current studies on the relationship between smoking and functional degrees in acute ischemic stroke patients in Indonesia are not present. This study is expected to help clinicians to be more aggressive in controlling risk factors for stroke associated with the process of atherosclerosis, especially smoking, so as to reduce the degree of disability stroke patients.

\textbf{Method}

The subjects of the study were acute ischemic stroke patients in Dr. Soetomo General Hospital and treated in Seruni A and B rooms, from February to July 2017. The inclusion criteria of having the first attack of ischemic stroke and willing to participate the research. The exclusion criteria were having a history of brain tumors, brain infection, and head trauma as well as unclear or unreliable smoking status. The design used was cross-sectional study with a sample size of 24 patients using the technique of sampling consecutive admission. Patients were interviewed about smoking status and NIHSS scale measured on the first day of treatment.

Prior to the identification of the subject, the researcher conducted the ethical test (191/Panke.KKE/III/2017) in Dr. Soetomo General Hospital Surabaya, Indonesia. Primary data collection can be basic patient characteristics (age, sex, education level, smoking history, duration of smoking and number of cigarettes consumption each day) and clinical characteristics (history of brain infection, head tumor, head trauma, hypertension and diabetes mellitus). History of brain infection, brain tumor, and head trauma is evidenced by interviews, physical examinations, and radiology. Hypertension has a systolic standard of ≥ 140 mmHg and/or diastolic ≥ 90 mmHg according to the JNC 7 criterion and is measured by a sphygmomanometer. DM has a standard ≥ 200 mg/dL for laboratory examination. Measurement of functional deficits of acute ischemic stroke with NIHSS scale. Acute ischemic stroke patients were divided into 2 groups, i.e., NIHSS <5 were included in mild criteria and NIHSS ≥ 5 were included in moderate-severe criteria. The correlation between smoking status and functional grade of acute ischemic stroke patients was calculated and analyzed by chi-square statistic test and logistic regression with SPSS (SPSS, Inc., Chicago, IL).

\textbf{Results}

\textit{Clinical Characteristics and Basic Subject Research}

The mean age of the study subjects was 58.9 ± 12.3 years, with the youngest age of 27 years and the oldest 86 years old. The minimum random blood sugar level-maximum was 85 and 915. The systolic maximum values were 90 and 240. The diastolic maximum values are 60 and 140 (Table 1).

**Independent Variable Correlation and NIHSS Score**

Subjects of the study were male who had moderate-weight NIHSS 90.50%, it was greater than those with mild NIHSS (44.40%). The difference was statistically significant (p = 0.001), with Crude Odds Ratio of 11.875 (CI 95%, 2.297-61.396). In the age category, the majority of subjects aged ≤60 years, who had moderate-severe NIHSS were 57.10%, and it was smaller than those with mild NIHSS (77.8%) also were not statistically significant (p = 0.112).

Subjects with primary education (Elementary school - Junior high school) with moderate-severe NIHSS were 57.10% that greater than those with mild NIHSS (40.70%). In DM variables, those with moderate NIHSS were 28.60%, it was greater than those with mild NIHSS (22.20%). These two variables were also not statistically significant (p = 0.201) and (p = 0.431).

In hypertension variables, the study subjects who had moderate-severe NIHSS were 81.00%, smaller than those with mild NIHSS (88.90%) and were not statistically significant (p = 0.68). In smoking variables, NIHSS with moderate-weight was 62.00% greater than those with mild NIHSS (26.00%). The difference was statistically significant (p = 0.013), with Crude Odds Ratio of 4.64 (CI 95% 1.35-15.9) (table 3).

**Multivariate Analysis**

In bivariate analysis, there was a significant correlation between functional degree measured by NIHSS and sex variable also smoking status. Therefore, the analysis was continued with logistic regression. After multivariate analysis logistic regression was obtained p = 0.57 with Adjusted Odds Ratio 1.5 (CI 95% 0.35 - 6.9) meaning that there was no correlation between smoking status and NIHSS score.

**Discussion**

The average age was elderly (> 60 years) with the majority being male. This is consistent with studies suggesting that males have a higher risk of stroke than female and sex is one of the unmodifiable risk factors for stroke. The well-documented modifiable stroke risk factors include hypertension, smoking, diabetes, dyslipidemia, atrial fibrillation, asymptomatic carotid stenosis, hormone replacement therapy, nutrition and physical inactivity. Smoking was believed to cause the development of atherosclerosis by initiating endothelial lesions through the production of oxygen radicals or by direct toxic effects of the element of cigarette smoke.

Smoking was associated with higher NIHSS scores in small vessel occlusion. But other studies stated that smoking was not associated with good functional outcomes after acute ischemic stroke. Both studies used NIHSS as an indicator of clinical outcome.

NIHSS was a tool used to measure the functional degree of stroke. In this research, the maximum values of NIHSS were 2 and 19. The mean of NIHSS was 5.56 ± 3.8. The subjects were divided into 2 groups, those with
mild neurologic deficit were 56.30% and the group with the severe neurological deficit was 43.80%. This study compared to NIHSS scales in the smokers, diabetes, and hypertension groups. There was no association between diabetes and poor NIHSS on the first day of treatment. This was similar to other studies that there was no significant difference in the severity of stroke at baseline treated as assessed by NIHSS between patients suffering from DM and non-DM 15. While hypertension was also not associated with NIHSS that consistent with other studies which suggest that elevated blood pressure during the onset of ischemic stroke was indicated the mild stroke 16.

There were two statistically significant variables (p <0.05) that were sex and smoking. However, in the logistic regression analysis for both variables, there was no association between smoking and NIHSS. Differences in the results of the multivariate analysis with bivariate analysis results can be overcome by the addition of the number of research subjects.

Oxidative stress could cause disorders of cerebral blood vessel metabolism that resulting in vascular lesions with forms of lacunar stroke, white matter hyperintensity, and microbleeds. Oxidative stress possibly triggered by hypertension, diabetes, aging, and smoking 17. The neurologic deficits in ischemic stroke patients who smoked in this study were mostly mild, as they may be caused by small vessel disease with clinical forms of lacunar stroke.

Although there was no significant association between smoking and the functional degree of acute ischemic stroke was assessed with NIHSS, the majority of the subjects were smoking. Although the functional degree of stroke in this study was mostly mild, smoking has been recognized as a risk factor for stroke so anti-smoking campaigns must still be aggressive for the primary prevention of ischemic stroke.

**Conclusion**

Based on the sex and smoking variables, it had a significant relationship with the functional degree measured by the NIHSS scale. In a multivariate analysis, there was no significant association between smoking status and functional degree of acute ischemic stroke patients as measured by NIHSS. Further research with more objective measures such as CO levels in expiratory air and blood levels of cotinine was also worth considering.

Risk Assessment, Risk Management, and Risk Communication in the Carpet Industry: PT. ‘X’ Pandaan. East Jawa

Zikri Fathur Rahman¹, Nur lailatul masruroh², Abdul Rohim Tualeka¹
¹Department of Occupational Health and Safety, Faculty of Public Health, Airlangga University, Surabaya, East Java, Indonesia; ²Department of Nursing, Faculty of Health, Muhamdiyah University Malang, 65144 Malang, East Java, Indonesia

Abstract

There are many work-related accidents and diseases caused by weak risk management efforts. Risk management can be done by starting with a risk assessment. Risk assessment is an important aspect of occupational health and safety. The garment textile manufacturing industry has a high risk of occupational health and safety. This study aims to identify the level of occupational health and safety risks and provide control recommendations. This research was descriptive using the Job Safety Analysis (JSA) method. The results of the identification show that out of the 4 work stages and 19 job descriptions, 10 descriptions or 52.6% are at high risk for Occupational Safety and Health. Identified hazards include chemical, physical, ergonomic and fire hazards. High risks include hazards from chemicals as raw materials for the process of making carpets. Several control measures have been taken, but to ensure the health and safety of workers, additional efforts must be made such as personal protective equipment, special masks for use in chemical hazards and work accident emergency response procedures. Risk communication in drug companies is running well.

Introduction

Today’s industrial development in Indonesia is very rapid, which is characterized by free trade, increasing information, communication and transportation technology. Globalization has encouraged the growth of industries in various sectors by implementing various machinery technologies and production equipment and the use of various materials. This has an impact, especially on labor in the form of work accident risks. OHS problems have become a serious problem in our country and still lack attention. As a result, work accident cases in Indonesia are increasing every year. Workplace accidents are an unexpected event because in the event of a work accident can cause injury, injury and even death to workers.

Based on BPJS Employment data, there are 157,313 work accident cases throughout 2018, the number comes from several categories, including in the category of work accidents are traffic accidents on workers’ trips to the workplace, and trips back from work to residence, work accidents are not it only causes death, material loss, morale and environmental pollution, but can also affect productivity and people’s welfare. Workplace accidents also affect the human development index and national competitiveness. The East Java (East Java) Manpower and Transmigration Office (Disnakertrans) claims that there were 21,631 cases of work accidents throughout 2017. That number rose by around 200 cases compared to the previous year.

Occupational accidents and work-related diseases not only cause material losses and fatalities and health...
problems for workers but can disrupt the production process as a whole and even damage the environment which ultimately affects the wider community. Whereas in the case of Occupational Diseases (PAK) from 2011-2014 the trend has declined even though in 2012 and 2013 it has increased. In 2011 the number of PAKs in Indonesia reached 57,929 cases, in 2012 60,322 cases and in 2013 increased again to 97,144 cases, then in 2014 began to decline to 40,696 cases. The provinces with the most prevalence of PAK in 2011 were Central Java Province, in 2012 North Sumatra, South Sumatra and West Java, 2013 Banten Province, and in 2014 were the Provinces of Bali, East Java and South Sulawesi. Data shows that efforts to prevent accidents and occupational diseases are still not optimal.

Efforts to prevent work-related accidents and diseases can be carried out with a number of approaches, namely, approaches to weaknesses in human elements, such as selecting employees properly and developing knowledge or training. Approach to weaknesses in hardware or production equipment through design, production equipment maintenance, and work environment planning. Approach to all levels of management by conducting a fair distribution of tasks, and determining the implementation of risk assessments.

Risk assessment is the process of evaluating risks caused by hazards, taking into account the adequacy of the controls owned, and determining whether the risk is acceptable or not. One component of risk management is risk assessment. The stages of risk assessment are identification of hazards, risk assessment, risk control and residual risk assessment.

One method that can be used to identify risks is the Job Safety Analysis (JSA) method. JSA is the identification of risk methods by reviewing and assessing the risk of each stage of work performed. JSA itself is a method that studies a job to identify hazards and potential incidents related to each step, and is used to develop solutions that can eliminate and control hazards. The implementation of JSA has benefits and benefits as follows:

1. Can be used to provide training or training on work procedures more safely and efficiently
2. Providing training to new workers / employees.
3. Provide Pre-job instruction on jobs that are not permanent.
4. Review the job procedures after an accident.
5. Conduct a study of work to enable improvement in work methods.
6. Identify what safeguards need to be used while working.
7. Increase work productivity and positive behavior regarding safety.

The implementation of the JSA must be carried out proactively where the focus of the JSA implementation refers to the inspection of work and not the workers who carry out the work. JSA can be used as a response to an increase in injury or illness, but the process of identifying hazards and determining the necessary precautions must be carried out through the process of planning and organizing the stages of work.

PT. ‘X’ Pandaan is a company engaged in and producing textiles and garments. For the garment consists of departments, from some of them: patter / marker, cutting, sewing / knitting, finishing, pressing, quality control, packing, and deliveries. Workers at PT. ‘X’ Pandaan, work a day for 8 hours starting at 07.30 s / d 16.30 and resting at 12.00 - 13.00. Within a week they work for 6 days and 1 day off. There are several divisions within the company, including cutting, sewing cloth, sewing, mats, foam or sponges, making mattresses, laminates, packaging, and drivers. Workers at PT ‘X’ Pandaan, the majority have tenure over 5 years and above.

Based on visits made to PT ‘X’ Pandaan, there are several potential hazards that can cause accidents and occupational diseases. During the production process, workers make physical contact either through inhalation or dermal with chemicals as raw material for making production. Chemicals for lamination, namely ethyl alcohol, xylen benzene and toluene which are contained in glue that have the potential to cause health problems such as irritation, respiratory problems, and nervous system disorders.

The purpose of this study is to conduct occupational health and safety risk assessments in the Production Section I of PT. ‘X’ Pandaan, uses the Job Safety Analysis (JSA) method.

Material and Method

This study used a descriptive observational research
design. The danger is potential danger, the risk refers to the actual danger. Risks can be identified through direct observation at the production site. The research was conducted at PT. ‘X ‘Pandaan. East Java. The risk assessment method uses the JSA with the following risk assessment steps:

Select the place to be analyzed

1. Explain the stages of work
2. Identify various hazards and risks at each step of the work, and identify the various possibilities that have the potential to become accidents;
3. Risk assessment (likelihood and severity)
4. Categorize risk (risk assessment matrix)
5. Provide control recommendations

Risk Management is done by selecting control options that are in accordance with the characteristics of the risk. Evaluation of available controls, so as to provide additional control recommendations. Risk communication data is obtained by direct observation at PT. ‘X ‘Pandaan. East Java. Risk communication can generally be observed through the media, company management meetings with workers and local stakeholders.

Assessment of potential hazards identified by risk hazards through analysis and evaluation of risk hazards intended to determine the amount of risk taking into account the possibility of occurrence and the magnitude of the consequences. From the results of the analysis it can be determined the ranking of risk values so that risk assessment can be carried out which has a significant impact on the company and the risk is not important.

The results of the risk assessment will be the basis for risk control. Control (control) of hazards in the work environment is an action taken to minimize or eliminate the risk of workplace accidents through elimination, substitution engineering control warning system administrative control and personal protective
Findings

A. Risk Assessment

There are several stages in the production step in this company, including the measurement of the desired pattern cutting babahan, sewing materials, then filling the required filling material, as well as the lamination stage. The risks identified are, material workers result from cutting powder, which can cause shortness of breath. Workers who sit too long can cause Lob Back Pain (LBP), manual lifting can cause LBP and Thoracic Outlet Syndrome (TOS). All job descriptions at this stage are included in the high risk.

The next step is a series of results from cutting patterns, where the results of the pattern cuts were carried out by using a sewing machine. The risk identified at this stage is that workers experience eye fatigue when supervising the desired stitch pattern, and sitting too long can also cause low back pain. All job descriptions at this stage are included in the high risk.

The next step is filling the material in the form of a dacron to produce the shape according to the desired pattern. The risk identified at this stage is that workers experience inhalation of the remainder of the dacron which is not used because it is in the vicinity of the stack, after which the droron is flying as a result of lifting or transferring the results of filling. Risks identified include, workers can experience injuries, dizziness, shortness of breath and eye irritation. Two job descriptions are included in the high risk level and the other 2 are moderate risk levels.

The next stage is sewing all the patterns that have been filled by the dacron. All results are filled in sewing in such a way as to get the results obtained. The risk identified at this stage is that workers experience eye fatigue when supervising the desired stitch pattern, and sitting too long can also cause low back pain. All job descriptions at this stage are included in the high risk.

The last stage is packaging the products using lamination, where all the processed products are put into a specially provided plastic. The risk identified at this stage is that workers experience inhalation of the material contained in the plastic, workers can experience injury, dizziness, shortness of breath and eye irritation. All job descriptions at this stage are included in the Medium risk.

B. Risk Management

Based on the risk assessment above, it shows that of the 4 work stages and 19 job descriptions, 10 descriptions or 52.6% are at high risk for Occupational Safety and Health. The weighing and printing stage is the part where all the job descriptions are high risk. 8 descriptions of the rest or 42.1% are moderate risks and 1 description or risk is 5.3% lower than Safety and Occupational Safety.

Referring to the results of the risk assessment that there are several descriptions of tasks that have a high risk, these activities may not be carried out until the risk has been reduced or controlled. The purpose of risk control is to avoid workers from the worst consequences that can lead to loss of work time and worker productivity.

Some stages of production run the risk of causing health problems. Ergonomic risks are identified such as errors in manual handling, excessive physical burden, and posture incompatibility with the work station, the risk of causing muscle disorders.

Research conducted by Wahyu, P.D and Tualeka, A.R., 2013 in one of the welding industries in East Java, Indonesia explained that there were still residual risks despite risk control. So that residual risk assessment needs to be done so that it can further determine additional risk control recommendations.

PT. ‘X ‘Pandaan. East Java has made several efforts to control the risks identified. This effort is a combination of technical control, administration and the use of personal protective equipment. control that has been carried out between, providing masks, making Standard Operating Procedures, providing chairs for workers, work rooms equipped with refrigeration equipment, providing lightweight fire extinguishers, efforts to maintain workers’ fitness with gymnastics every morning, and providing a dining room to avoid contamination the ingredients in the production room enter the workers’ food.

Such control is still not enough to reduce some of the risks identified. Some controls must also be made, such as conducting safety talks, safety inspections, extending work intervals, giving awards and reprimands, providing fire and emergency response procedures, exchanging with tired and weak colleagues and providing personal protective equipment for work locations such as that is.
C. Risk Communication

PT. ‘X ‘Pandaan has not implemented OHSAS 18001: 2007, but Komitmet Top Management of work safety is very high as evidenced by the presence of occupational safety health officials in the company where it is a work safety and health management system. One form of system implementation is communication, participation and consultation12.

Risk communication is the exchange of information about the magnitude of health risks in the work environment 6. The forms of the application of risk communication carried out in the company include, meetings between all company structures including workers in communicating occupational health and safety policies. Risk communication media are installed such as posters and banners. Besides this effort, PT. ‘X ‘Pandaan East Java regularly holds meetings with workers on the National Occupational Health and Safety warning. This meeting is held so that there is an exchange of information between workers and company managers. And always do safety talk before work.

Conclusion

Based on the risk assessment above, it shows that of the 4 work stages and 19 job descriptions, 10 descriptions or 52.6% are at high risk for Occupational Safety and Health. The weighing and printing stage is the part where all the job descriptions are high risk. 8 descriptions of the rest or 42.1% are moderate risks and 1 description or risk is 5.3% lower than Safety and Occupational Safety. Risk management has been carried out, but additional control is needed so that the risk of illness and workplace accidents can be reduced. The risk communication process works well, risk communication involves management and workers. Media communication has been installed, and information exchanges with routine workers are carried out.

Abstract

Occupational illness is a disease caused by a person’s work or work environment. This disease is caused by the actions of someone who is unsafe (unsafe act) and unsafe condition (unsafe condition) in carrying out his work activities. The unsafe act is an act of someone who deviates from the rules of security standards that have been set in doing work. While unsafe conditions are conditions that can endanger workers. Acute respiratory infection is an acute inflammation of the upper and lower respiratory tract caused by infection with microorganisms, bacteria, viruses, and rickets, without or accompanied by pulmonary parenchyma. Factors that affect a person affected by ARI are environmental factors, individual characteristics, and worker behavior. Environmental factors include air pollution (air pollution due to industrial output and smoke from burning fuel). Dust particles that can cause acute respiratory problems from industrial products that pollute the air such as coal dust, cement, cotton, asbestos, chemicals, toxic gases, dust in rice mills (organic dust).

Keywords: dust, ARI, work-related diseases

Introduction

Occupational Diseases are diseases caused by work and the work environment. PAK risk factors include Physical, chemical, biological or psychosocial groups in the workplace. These factors in the work environment are the main causes and determine the occurrence of occupational diseases. Other factors such as individual vulnerability also play a role in disease progression among exposed workers¹.

Disease suffered by employees in relation to work both risk factors because of the conditions of the workplace, work equipment, materials used, production processes, work methods, company waste, and production results².

The risk factors that can cause PAK are as follows³:

1. Physical group
   a. Noise can cause interference with hearing through Non-induced hearing loss
   b. Radiation (radioactive rays) can cause blood and skin abnormalities
   c. High air temperatures can result in heat strokes, heat cramps, or hyperpyrexia. While low temperatures can result in frostbite, trench foot or hypothermia.
   d. High air pressure can cause caisson disease
   e. Lighting that is not enough can cause eye fatigue. High lighting can lead to accidents

2. Chemical groups
   a. Dust can result in pneumoconiosis
   b. Steam can cause metal fume fever, dermatitis and poisoning

Campus C, Jalan Mulyorejo, Surabaya, 60115, Indonesia, Tel: +62 81 333 519 732
Email: inzut.tualeka@gmail.com
c. gas can lead to CO and H2S poisoning
d. Solutions can cause dermatitis
e. Insecticides can cause poisoning

3. Group injection
a. Anthrax
b. Brucella
c. HIV / AIDS

4. Mental group

It can be caused by bad working relationships or monotonous work conditions that cause boredom.

The international body of the International Labor Organization (ILO) suggests 34% of the causes of deaths caused by occupation are cancer, 25% are accidents, 21% are respiratory diseases, 15% are cardiovascular diseases, and 5% are caused by other factors. Acute respiratory infection (ARI) is a major health problem as evidenced by the prevalence of ARI in Indonesia as much as 25.5% (range: 17.5% - 41.4%) with 16 provinces including prevalence above the rate national and pneumonia as much as 2.1% (range: 0.8% - 5.6%)\(^4\).

ARI is the main cause of infectious morbidity and mortality in the world. Nearly four million people die from ARI every year, 98% of which are caused by lower respiratory tract infections. Very high mortality rates in infants, children and the elderly, especially in countries with low and middle income per capita\(^5\).

Acute respiratory infection (ARI) is an acute inflammation of the upper and lower respiratory tract caused by infection with microorganisms or bacteria, viruses, and rickets, without or accompanied by inflammation of the lung parenchyma. The factors that influence a person’s risk of developing ARI are factors environment, individual characteristics, and worker behavior. Environmental factors include air pollution (cigarette smoke, air pollution due to industrial results and smoke from burning fuel for cooking with high concentrations). Individual factors such as age, sex, and education level can also influence the risk of susceptibility to ARI. Worker behavior includes smoking and the use of masks\(^6\).

Indonesia is one of the countries that are rich in minerals, including gold, silver, copper, coal, oil, and gas. The coal mining industry can increase the country’s foreign exchange but massive exploitation and use of natural resources by ignoring the environment results in short-term and long-term health impacts. The issue of energy sources is also becoming the government’s main focus in relation to rising oil prices. Indonesia’s coal reserves are larger than oil and natural gas reserves so the government began to see coal as an alternative energy source\(^7\).

Coal dust is a complex mixture of various minerals, trace metals and organic materials with different degrees of coal particulates. Research by Nullolli et al. Revealed an increase in the number of people with asthma in children who live near or far from open coal mining locations. This indicates that the disease due to coal dust is related to the nature of dust that is easily carried away by the wind. Air pollution due to processing or the results of the coal mining industry will have a negative impact on the lungs of workers and communities around the mining area. Respiratory diseases that generally arise due to exposure to coal dust particles namely decreased air quality to a level that endangers the health and ultimately leads to an increase in respiratory disease disorders such as ARI\(^7\).

Hasnur Group’s coal mining business is currently handled by two subsidiaries, namely PT Energi Batubara Lestari which has reserves of 80 million Metric Ton, and PT Bhumi Rantau Energi has reserves of 200 million Metric Ton, located in Rantau, Tapin Regency, South Kalimantan. In addition, there are several coal projects currently under exploration (IUP Exploration). Hasnur also has special coal terminals located on the Putting River and Sungai Salai, South Kalimantan and a special port in Pendang, Central Kalimantan\(^8\).

Material and Method

This study uses the Analytical Survey method with the Case Control approach which is an observational study that assesses the relationship of exposure to dust levels with people exposed to dust and those not exposed to dust, then compares the frequency of exposure to both groups.

This research was conducted in boiler units (cases) and filling units (control) in June 2017. The samples used were 40 people, namely 20 people from the boiler unit (control) and 20 people from the filling unit using a total sampling technique.
Data analysis used in univariate and bivariate analysis. Univariate analysis using frequency distribution and bivariate analysis using the Chi-Square test with a significance level of 0.05. If the value of \( p \leq 0.05 \) then Ho is accepted and if the value of \( p > 0.05 \) then Ho is rejected.

**Findings**

The measurement results of coal dust levels in the boiler unit are 2.2 mg / m³ and the unit filling is 0.9 mg / m³, so the results of these measurements on the boiler unit the dust content still exceeds the NAB and in the filling unit the dust is below the NAB, based on NIOSH (2011), that the NAB standard for coal dust in the permitted work environment is 2 mg / m³.

Based on the filling in questionnaires conducted on the boiler unit workforce, the results of 20 respondents who experienced ARI were 13 people (65%) and those who did not experience ARI as many as 7 people (35%) and in the unit filling workforce obtained results from 20 respondents who experiencing ISPA as many as 5 people (25%) and those who did not experience IspA as many as 15 people (75%).

From the results of measuring the levels of coal dust in the workplace environment and distributing questionnaires regarding ISPA on the workforce of PT. ‘X’ boiler units and filling units in South Kalimantan. Then performed a statistical test with the Chi-Square test using the SPSS version 21 computer program. For windows, the results were obtained regarding the levels of coal dust against ISPA in the workforce in the boiler unit of PT. ‘X South Kalimantan, with a value of 0.011 so the value is \( p <0.05 \), which means that the result is significant. Thus it can be stated that there is an effect of the level of coal dust on ARI on workers in the boiler unit of PT. ‘X’ South Kalimantan.

**Conclusion**

Occupational illness is a disease caused by a person’s work. The cause of this disease can be caused by unsafe acts and unsafe conditions. The unsafe act is an act of someone who deviates from the rules that have been set and can cause harm to themselves and others, one of which is ISPA⁹.

Risk factors for ARI are due to pollution, poor environmental conditions, for example, air pollutants, family member density, humidity, cleanliness, season and temperature. Some other factors are age, gender, smoking behavior, working period, length of exposure and use of masks that function as protective devices from dust¹⁰.

Dust exposure can cause acute respiratory problems, one of which is an industrial product that can pollute the air such as coal dust, cement, cotton, asbestos, chemicals, toxic gases, dust in rice mills (organic dust) and others. Various factors influence the emergence of diseases or disorders of the airways due to dust¹¹.

There is a relationship of dust to the incidence of acute respiratory infections in coal mining workers.

Enhancement the Antimicrobial Activity of Disinfectants by the Purified Lipase from *Coronobacter Dublinensis*

Alaa Naseer Mohammed Ali¹, Sahira Nsayef Muslim²

¹Department of Biology, College of Science, Mustansiryiah University, Baghdad, Iraq

Abstract

There are many different commercial disinfectants purchased, choosing of effective product is a prime target to ensure its decontamination efficiency. Thus we screened *Coronobacter dublinensis* isolates to produce lipase enzyme with using of vegetable oil like olive oil as inducer of lipase production in the medium. The lipase was purified by using two-step purification procedure consisting of ethanol precipitation and ion exchange chromatography with a yield of 48.3%. The lipase has an important role in enhancement of disinfectant activity. Since the combination between this disinfectant and lipase led to increase the activity of disinfectant to higher levels and the width of inhibition area enlarged to 28 mm against *Acinetobacter* sp. followed by *P. aeruginosa* and *S. aureus* with 25mm, respectively. So that we can conclude that lipase has excellent activity for enhancement of the commercial disinfectants purchased in decontamination activities in the laboratory and hospital environments.

Keywords: Lipase, *Coronobacter dublinensis*, disinfectants

Introduction

*Cronobacter* genus composes of a different groups of Gram negative and facultative anaerobic rods that belongs to Enterobacteriaceae family and closely related to *Enterobacter* and *Citrobacter* (1,2). It is includes seven opportunistic pathogenic species: *Cronobacter sakazakii, Cronobacter malonaticus, Cronobacter muytjensii, Cronobacter turicensis, Cronobacter dublinensis, Cronobacter universalis* and *Cronobacter condimenti* (1,3).

The organism has association with severe blood infections (sepsis), neonatal infections; necrotizing enterocolitis, septicaemia and meningitis which may be lead to fatal effect. However, these infections with *Cronobacter* are rare and occur in all age groups (2,3).

Lipases (triacylglycerol acylhydrolases, EC 3.1.1.3) catalyze the hydrolysis of ester bonds in water insoluble lipid substrates, acting at the interface between the aqueous and the organic phases (4). They are produced by animals, plants and microorganisms. Microbes have an ability to produce of lipases with high yields in comparison with the animal and plants, this return to that they are more common than animal and plant sources, easier in extraction and more commercialization in their involvement in enzymatic reaction (5,6). Lipases from microorganisms (bacterial and fungal) are the most used as biocatalysts in biotechnological applications and organic chemistry (7,8).

Disinfectants are antimicrobial agents that are applied to the surface of non-living objects to destroy microorganisms that are living on the objects. They are an essential part of infection control practices and aid in the prevention of laboratory and nosocomial infections (9). Many gram negative bacteria, gram positive bacteria and yeasts leads to nosocomial infections (10). As there are many different commercial disinfectants purchased, choosing of effective product is a prime target to ensure its decontamination efficiency.

The aim of this research was to detect the lipolytic activity in *Coronobacter dublinensis* and purification of lipase from *Coronobacter dublinensis* isolated from hospital environment clinical samples and using of lipase for enhancement of the commercial disinfectants purchased in decontamination activities in the laboratory and hospital environments.

DOI Number: 10.37506/v14/i1/2020/ijfmt/192940
Materials and Method

Bacterial isolates and Identification

In this study, we obtained 3 Coronobacter dublinensis isolates from blood samples of patients. All the laboratory procedures were performed at central public health laboratories of Teaching Laboratories / Medical city, Baghdad during July/2015. The phenotypic identification was confirmed by using of the morphological testes and by Vitek-2 system (Bio-Merieux, France).

Lipolytic activity on media

Lipase indicator plates were prepared in 1 liter by addition of 10 g peptone, 5g NaCl, 0.1g CaCl₂, 1ml olive oil, 10g agar-agar and 0.5g Congo red. The lipase activity was indicated by the formation of clear halos around the colonies (11).

Purification of lipase

Coronobacter dublinensis extracellular lipase was purified by a modification of the method (12). The cells were grown in the mineral growth medium (MGM) contained (in g/L): NaH₂PO₄ 12, KH₂PO₄ 2, MgSO₄·7H₂O 0.3 and CaCl₂ 0.25. Ammonium sulphate at 1% (w/v) and castor oil at 2% (v/v) were used as nitrogen and carbon sources, respectively (11) and incubated at 30°C in shaking incubator for 18-24h. The supernatant was carefully removed after centrifugation at 10000xg for 30min at 4°C and filtered through 0.22µm Millipore filters then lipase activity in supernatant was assayed. The supernatant was treated with ethanol at ratio of saturation 60% then the mixture was centrifuged and the lipase activity was assayed for the precipitate after dissolving in 20mM Tris buffer, pH=8. The supernatant was dialyzed against the same buffer.

The supernatant was loaded on diethyl aminoethyl (DEAE)- sephadex A-25 column (2.5 by 25cm) that has been equilibrated with 20mM Tris buffer, pH=8. The column was washed with 5 to 10 volumes of the above buffer. The lipase was eluted with a gradient elution from 0.1-0.5M NaCl solutions. The fractions (5ml) were collected and assayed for lipase activity.

Lipase assay

Lipase assay was conducted by a modified method based on (13). About 30mg of p-nitrophenyl palmitate (pNPP) was dissolved in 10ml of 2-propanol at 60°C and added to 90ml of 100mM potassium phosphate buffer (pH= 7.0) containing 10mM MgSO₄ to yield a final concentration of 1mM pNPP.50µl of sample was added to the substrate solution to give a final volume of 2.5ml, the solution was incubated for 15min at 37°C and the absorbance was measured at 410nm. One unit of lipase activity was defined as the amount of enzyme that produced an absorbance at 410 nm equivalent to 1µmol of p-nitrophenol in one min under the assay conditions.

Results

Bacterial isolates and identification

In this study, three Coronobacter dublinensis isolates were collected from blood samples of patients. These isolates were diagnosed by using many morphological and biochemical tests.

Lipolytic activity on media

The aims of this study was to screen the capability of Coronobacter dublinensis isolates to produce lipase enzyme. Therefore, we used olive oil as vegetable oil for determination of Coronobacter dublinensis harboring...
lipase activity. so the first step of the screening process, we analyzed for the hydrolytic action of *Coronobacter dublinensis* isolates. It is an easy, fast and economy test to act on solid media created on the optical examination of plates having one of the vegetable oils and presence of a clearing zone around the colony edges. The results revealed that all 3 *Coronobacter dublinensis* isolates have the ability to hydrolyze the olive oil but in different levels as shown in (figure-1). Therefore, Thus we can conclude that *Coronobacter dublinensis* had an ability to produce lipase in the medium by using olive oil as inducer.

**Figure 1: Lipolytic activity for *Coronobacter dublinensis* isolates**

---

**Purification of lipase**

Mineral growth medium (MGM) with 2%castor oil was chose as the best medium for lipase production because it composed of only inorganic nitrogen sources and some minerals. In *Coronobacter dublinensis* 2, the castor oil was used as a sole carbon source for lipase production. A two-step purification program consisting of the precipitation by ethanol and ion exchange chromatography by DEAE-sephadex A-25 column were used to obtain a highly purified lipase from *Coronobacter dublinensis*2. Table (1) showed the details for each purification step. 60% saturation for cooled ethanol solution was added to the crude extract and led to rise of the specific activity to 4.8 U/mg and revealed 2.5 fold of purification with 55.7% lipase recovery before the dialysis. Ion exchange chromatography by DEAE-sephadex A-25 column was the second purification step. When lipase solution was passed through DEAE-sephadex A-25 column and eluted with NaCl solutions(0.1 - 0.5M), two peaks of protein appeared in the eluted fractions with one peak of lipase activity located in the second protein peak (figure-2). Fold of purification was 11.2 in this step with 48.3% recovery.

Effect of lipase on the efficiency of disinfectants

The results showed that any one of each type of disinfectant had antimicrobial activity against all the tested microorganisms. The type one of disinfectant revealed higher effectiveness toward Acinetobacter sp. with diameter 23mm followed by 22mm for P. aeruginosa while lower effectiveness against Candida albicans. But in the combination with the purified lipase the effect increased and showed higher level toward Acinetobacter sp. followed by P. aeruginosa and S. aureus since the diameter of inhibition zone was 26mm for Acinetobacter sp. and 25mm for P. aeruginosa and S. aureus (table 2).

In the case of using the second disinfectant, this disinfectant had stronger effect against gram positive and negative bacteria and lower effect toward Candida albicans. On the other hand, the combination between this disinfectant and lipase led to increase the activity of disinfectant to higher levels and the diameter of inhibition zone became 28 mm against Acinetobacter sp. (figure 3) followed by P. aeruginosa and S. aureus with 25, respectively, and lower diameter was 22 mm against Candida albicans. According to these results we can conclude that the lipase has an important role in enhancement of disinfectant activity.

Discussion

Most Cronobacter spp. have been associated with human infections in newborn and infant infections, causing meningitis, necrotizing enterocolitis (NEC) and bacteremia or sepsis (16,17).

There is distribution of Lipolytic germs in flora and about 20% of them are lipase creators (16). Lipase production from Microbacterium sp. showed that the bacterial growing and lipase creation got to upper level after 48 hours at the start of stationary phase (17) and lipase activity in a late stationary phase was decreased and this can be owed to the presence of proteases in media of the culture. In contrast, Staphylococcus warneri produced higher level of lipase after 24 hours and at the beginning of the stationary phase (18), the parameters of growth such as optimum temperature, pH and enzyme specificity affected on lipase production (19).

Ethanolic precipitation with alginate led to rapid and almost completely harvest of lipase from the cell-free culture medium by (about 95% of the original exolipase activity was coprecipitated) (20). An ammonium sulphate precipitation trailed with Sephadex G-100 column chromatography led to clean of an extracellular lipase from Microbacterium sp. with a complete harvest of 20.8% and fold purification equal to 2.1 (21).

The isolation source, the type of culture medium that was used for growth of bacteria and the procedure that was used for purification of enzyme have effect on the enzyme activity, fold of purification and the recovery of purified enzyme (22). Lipases are used generally in house, dishwashers and modern laundry. They generally working as additives to cleaners, as they are added to the cleaners mostly in mixture with proteases and cellulases (9), besides to other enzymes such as amylases, peroxidases and oxidases. The hydrolysis of fatty stains by lipase to 15 hydrophilic parts that make these stains easily removed in comparison with non-hydrolyzed stains (21). Lipases should be both thermophilic (30-60°C) and alkalophilic (pH 10-11) add to a wide substrate specify to be able to hydrolyze fats of numerous compositions and a suitable chemical addition in cleaners and keeping their action in the presence of the numerous workings of clothes wash powder formulations like surfactants and proteases. In addition, they should have (10). The combination of genetic and protein engineering enhanced these properties of lipases in addition to their application in laundry, dish washing, contact lenses cleaning, degradation of organic wastes on the surface of exhaust pipes and toilet bowls, etc (23).

Conclusion

Disinfectants have limited levels in decontamination. The lipase has an important role in enhancement of commercial disinfectants purchased activity to achieve acceptable level of decontamination.

Abstract

Background: The Preterm Labor: is the mean reason of the (80%) from the neonatal intrapartem, postpartum morbidity and mortality. Recently, vaginal infections have been related to high risks of PPROM and PROM. However, preterm labor and subsequent neonatal bad outcome can be avoid through several protective actions. Methods: This study was prepared through the period from January to December 2018 at Babylon Province, were for estimate the effect of vaginal infections in patients pregnant women with premature rupture membrane, the samples were 100 pregnant women, 50 were vaginal infected (as patients) and 50 were no (as controls). Results. Shows significant increasing of the fetal weight, while significant decreasing of the Maternal age and duration time in the patients, also elevation in the percentages of C/S and PROM in patients when comparing all these with controls. The pathogenic microorganisms; were CONS (coagulase negative staphylococcus aures) are major insulated organism followed by Candida, and Bacteriod spp., and to less extent were Staph., Proteus and Bacteriod. The Cifixum, Ampicillin, Clotrimazol and Metronid were appropriate antibiotics used for treatment of the vaginal infections.

Keywords: Premature Rupture Membranes (PROM), Preterm Premature Rupture Membranes (PPROM), F. Outcome, Antibiotics and Pathogenic Microorganisms.

Introduction

Preterm delivery is the reason of (80%) from illness and death of the neonates, this occur earlier to 37 weeks of gestation, the premature rupture membrane is the natural rupture membrane and happen after 37 weeks from gestation before active labor, the preterm prelabour rupture membrane is the sobontanous split of the membrane and take place between (28 to 37) weeks from gestation without active labor (¹). Time from premature rupture membrane to usual active labor proposes occur within (24) hours of membranes rupture and (65%) of pregnant women go into usual active labor, in addition, the rise of the pathogenic microorganisms along the vagina will eventually infect the amniotic sac and fluid and this leads to the rupture of the sac and premature labor (²).

The genital infections and inflammations among the pregnant ladies lead to membranes rupture, the maximum serious consequence of the preterm, membranes rupture, preterm premature and rupture of membranes is frequently related with the infections of the maternal and the results that assessed showed the (12%) from perinatal deaths are directly or indirectly related to PROM, however, the all reasons of PPROM and PROM are not recognized, but a variety of conditions have been joined to vaginal infections, and the vaginal infections within ladies in age of reproduction were connected with amplified dangers to premature rupture of membranes (²⁻⁶).

The microbial toxins are produced after connection of pathogenic microorganism to specific receptors on the membrane and this lead to change in tensile power for amniotic membranes and it result inflammations then PPROM formation (⁷). These lead to increase metalloproteinase production, which responsible for collagen degradation and causes rupture of the membrane (⁷⁻⁸). The fact that collagen is the main component membrane which maintain the tensile power for amniotic membranes. Though, infection formed by going up pathogenic microorganisms may happen
owing to PPROM [9-10]. The microorganisms which were generally existing in the flora of vaginal, comprising group E. coli, Staph. aurous and B streptococci organisms and others which lead to bacterial vaginosis, secrete proteases & damage collagen then the amniotic membranes resulting in PROM [11-12]. Intrauterine infection had proved for up to (65%) from patients [9-10].

Additional modern information advocate several attack amniotic sac from the bloodstream after dissemination from distant places, e.g. from the gastrointestinal tract [13]. The single greatest threat to infant with preterm delivery, PPROM and PROM is respiratory distress syndrome (RDS). Prematurity is concomitant with approximately 60% of perinatal mortality [14]. There is increased incidence of perinatal mortality which may be owing to RDS, sepsis and asphyxia. Other reasons of death were cord accidents, intracranial hemorrhage and necrotizing enterocolitis. Incompetent blood brain barrier creates them more predisposed to brain damage. Since preventive methods can prevent the above phenomena, taking these facts into our attention.

However, several species of bacteria colonize both reproductive and gastrointestinal tracts, and have ability to colonize of the vagina and cause infections [15]. There are several types of antibiotics which include Ciprofloxacin, Norfloxacin, Gentamycin, Ampicillin, Cotrimoxazole, Amoxyccillin, Tetracyclin, Erythromycin and Clindamycin, these antibiotics have different mode of activity against vaginal infected bacteria and these bacteria include E. coli, S. aureus, Pseudomonas, Enterobacter, Klebsiella, Proteus and Group B streptococci [16]. Many antimicrobials have been used against pathogenic bacterial vaginosis, such as Metronidazole types and/or Clindamycin [17].

**Materials and Method**

A. The Patients:

The 100 pregnant women have been collected through the period from Jan/2018 to Sep/2018 at Public Teaching Babylon Hospital of Maternity and Children Babylon Province. Were 50 with vaginal infection (as patients) and 50 were no (as controls).

B. Identification of the pathogenic Microorganisms:

The swabs of vagina have been taken from control and patients groups, then send to the microbial unit for identification of the pathogenic microorganism. This were involved growing of swabs microorganisms on several type of the selective and differential media, as well as through use of several biochemical tests.

C. Detection of the antibiotics susceptibility:

Detection antibiotics activity against pathogenic microorganisms which were isolated from vaginal swabs were carry out on the Moller Hinton Agar medium through the use of several type of the antibiotics. This method involved incubated of the pathogenic microorganisms which were isolated from vaginal swabs with antibiotics discs on this medium and then measure the inhibition zone after 24 h.

D. Statistical analysis:

The results of this study were analyzed through the use of the SPSS version 20 program. This used for calculated the Mean, Standard Error, Standard Deviation and determine the least significant difference (LSD) between the study groups.

**Results**

Table (1) shows a significant elevation of the fetal weight in the patients women when comparing with the control ladies, whereas significant decreasing of the Maternal age and duration time in the patients ladies when comparing with the control women. Table (2) shows an increasing in the numbers of F. outcome (normal) at all three time categories in the control women. also shows an elevation in the numbers of F. outcome (RDS) at time category (0-8) hour as well as F. outcome (Sepsis) at time categories (9-17) and (18-26) hour in the patients women. Table (3) shows a number of the pathogenic microorganism isolates were identified in the infected vagina of the patients group, as well as appeared the used antibiotics types have activity with different modes against these the pathogenic microorganism.

Figure (1) shows an elevation in the percentages of C/S and PROM in patients when which comparing with control. Figure (2) shows a percent of the pathogenic microorganism isolates were identified in the infected vagina of the patients group, the largest number and percent were equal to (85) and (34%) respectively, while the smallest number and percent were equal to (3) and (2%) respectively, of Staph., Proteus and Bacteriod, in summation of the all disease
cases. And figure (3) shows the used antibiotics types have activity with different modes of action against pathogenic microorganism.

Discussion

In this study we performed vaginal swabs of the pregnant ladies with PPROM and PROM then send to the microbiological unit lab for detection of the vaginal pathogenic microorganisms and their antibiotic sensitivity were assessed. Found the more prevalence pathogenic microorganisms were associated with virginal infection are CONS then candida and more less prevalence pathogenic microorganisms are Staph., Proteus and Bacteriod. In addition, the neonatal outcome were identified. There is good connection between micro flora of the lower genital tract and organism developed in liquor or blood of neonates with early onset sepsis. In reviews study of the McDonald et al (18) and Das et al (19), who showed that the infection was three times more common in pregnant women patients with rupture of membranes before 37 weeks of gestation than when fetal
membranes ruptured at term. In our study early rupture membrane before labor higher in patient term group (72%) while lesser in patient preterm group (58%). The (60%) of the study group had high vaginal infection in preterm pregnant while (72%) of the study group had high vaginal infection in term pregnant that may explain the higher percentage in PROM group. The study was done by Sharma who demonstrated the E. coli bacteria were the most commonest pathogenic microorganism isolated (20). And the studies of the Das et al (19) (44%), Raunt et al (21). Whereas the study of the Hussein who found the Proteus spp. and Enterobacter spp. were more causes of the UTI Infection (22). In our study the CONS which the most commonest bacteria were isolated with the number and percent of the isolates were 17 (34%) respectively, and second most common microorganism isolated was Candida albicans with the number and percent of the isolates were 11 (22%) respectively. In a study done by Lanier et al, the incidence of chorioamnionitis after PROM is 20% (23).

In the present study there was no case of clinical chorioamnionitis because we gave short trial for labor for pregnant with rupture membrane to prevent such complication so take rapid decision of interventions i.e all the patients in the study were given prophylactic antibiotics and decision for termination of pregnancy whether by C/S or vaginal deliveries was taken rapidly before such complication developed were i.e. within 24 hrs from the onset of PROM, PPROM). A report done by Swati, who observed that neonatal sepsis was present in 25% of the cases (24).

Conclusions

The fetal weight, maternal age and duration time were more in non vaginal infected pregnant women than vaginal infected pregnant women. C/S and PROM were more in vaginal infected pregnant women than non vaginal infected pregnant women, whereas the NVD and PPROM were more in non vaginal infected pregnant women than vaginal infected pregnant women. The NCOS and Candida were more pathogenic microorganisms associated with the vaginal infections in pregnant women. The Cifixum, Ampicillin, Clotrimazol and Metronid were appropriate antibiotics used for treatment of the vaginal infections, in addition to the ciprofloxacin, gentamicin, chloramphenicol group, taxim and gentamicin but we don’t depend on these antibiotics because them causes of the teratogenicity through pregnancy period.

Criminal Responsibility among Murderer Presented to Forensic Committee in Al-Rashad Training Hospital/Forensic Department, 2016-2017

Basheer F. Hummadi1 Firas A. Al-Kadhimi1, Ghazi A. Al-mashhadani1
1Forensic Department, AL-Rashad Training Hospital, Baghdad, Iraq

Abstract

Background: The insanity defense, also known as the mental disorder defense, is a defense by excuse in a criminal case, arguing that the defendant is not responsible for his or her actions due to an episodic or persistent psychiatric disease at the time of the criminal act. This is contrasted with an excuse of provocation, in which defendant is responsible, but the responsibility is lessened due to a temporary mental state. The aim of current study was to find out the results of criminal responsibility assessment for the murderers and related mental illness as well as to study a sociodemographic and personal criterion for murderers. Methods: The study was conducted in AL-Rashad Hospital, forensic department in Baghdad. It was a descriptive retrospective study. Case files of (70) murderers, examined by the forensic committee during the period from 1st January 2016 till 31st December 2017, were studied. Comprehensive data were collected and analyzed by the SPSS version 23. Results: The study showed that murderers were mainly young adults within age group (20-40) years that were married, illiterate/low educational level and had no job or unstable type of jobs. About 30% of victims were 1st degree relative and 30% of them were family in law. The main weapon was used in the murder was gun (45.7%) and knife (40%). According to murderers who presented to the committee, about 38.6% had no mental illness, 17.1% had personality disorder, 32.9% had psychotic disorders and 8.6% had neurotic disorders. The majority of murderers (52.9%) presented to committee were considered responsible, 8.6% had partial responsibility and 28.6% considered irresponsible. Conclusions: This study showed that about more than half of murderers presented had full criminal responsibility and insanity defenses were succeeded only in one third of the cases. The studied murders appeared to be obvious among young adult age groups, with no job or unstable financial resources, and illiterate or had low educational level. The victims were more likely to be from 1st degree relatives or family in-law. The available weapon (gun and knife) was mostly used.

Keywords: murderer, criminal responsibility, mental illness, forensic psychiatric committee.

Introduction

The concept of defense by insanity has existed since ancient Greece and Rome. The first known recognition of insanity as a defense to criminal charges was recorded in a 1581 English legal treatise stating that “If a madman or a natural fool, or a lunatic in the time of his lunacy” kills someone, they cannot be held accountable. The British courts came up with the “wild beast” test in the 18th Century in which defendants were not to be convicted if they understood the crime no better than “an infant, a brute, or a wild beast (1). The M’Naghten test was the product of an English judicial commission created in response to another controversial insanity verdict. It required the defendant to prove that he or she was “laboring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing; or, if he did know it, that he did not know he was doing what was wrong.” Notwithstanding criticism of the rule’s exclusive reliance on cognitive incapacity, it was quickly adopted in most American jurisdictions. At least before the latter part of the 20th Century, reform efforts were largely directed at softening the rigid cognitive test, with alternatives such as the Durham product test when
the “unlawful act was the product of mental disease or defect (Durham v.U.S., 1954) and the American Law Institute’s proposal to exculpate a defendant who “lacks substantial capacity to either appreciate the criminality of his conduct or to conform his conduct to requirements of law (2).

The aim of current study was to find out the results of criminal responsibility assessment for the murderers and related mental illness as well as to study a sociodemographic and personal criterion for murderers.

Materials and Method

A descriptive retrospective study was conducted in the forensic psychiatry department at AL-Rashad Hospital in Baghdad, which is the only hospital in Iraq for psychiatric diseases. Clinical data was collected from records of forensic psychiatric committee (which usually joins twice weekly) for the period from 1st January 2016 to 31st December 2017 for all murder cases which were 70 cases.

Comprehensive data was collected about the murderers’ sociodemographic criteria (as age, sex, marital status, education and occupation) and data about crimes (as weapons used and degree of relationship with victim). The murderers were divided into 4 age groups (<20yr, 20-40yr, 40-60yr and >60yr). The victims were divided according to the degree of relationship with murderers into (1st degree, 2nd degree or 3rd degree relatives, or family in-law and foreign) (14).

Clinical data and psychiatric diagnosis by the committee were considered in this study. The courts asked forensic psychiatrists to evaluate the psychiatric disorder, criminal responsibility and if there was a need for mandatory treatment of the murderers. Criminal responsibility decision falls into four categories; ● full responsibility, ● partial responsibility, ● irresponsibility and ● no decision (due to long period between the murder and time of presentation and no clear information of mental state at time of murder).

The assessments by the committee are a duty of a team of three board certified psychiatrists who perform psychiatric diagnostic interviews, mental and physical examinations, psychological assessments, routine laboratory workups and, sometimes, brain-imaging studies. The diagnosis was made according to DSM-5 criteria.

Results

Sociodemographic data

Seventy murderers presented to forensic committee, their age ranged from 14 to 76 years (mean age = 36.39 years, STD=14.095).

Table 6 showed that murderers who had lower level of education and unstable type of job (self-employed) were more likely to be responsible for their crimes.
Discussion

In reviewing the results of this study, we found that murderers had mean age of about 36 years and the young adults were in their 3rd to 4th decade of life (20-40 years old) mostly had committed a murder (55.7%), while adolescents and elderly people were less likely to involve in murders. This result was compatible with the study of (3) who found that the mean age of murderers was 34 years.

Gender had a significant relation with committing murder because most of murderers (90%) were men this is probably related to physical ability difference and weapons accessibility with making attention to the basic difference between males and females in dealing with quarrel due to social and biological aspects. This result was compatible with study done by (4) who found that about 87.7% of murder defendants were males.

Regarding marital status, most of murderers were married (64.3%), this result was not compatible with many national studies and literature which showed that most of murderers had not been involved in long-term relationships or were not married (9,12). This may be related to our society differences when marriage and its continuation do not guarantee stable relationship or stable type of life because our society forces people to get married and continue their relation regardless of how the situation is bad. So, this factor may be misleading when we put in our mind that data collected reported the official type of relation instead of its quality (5).

We noticed that those who were unemployed (24.3%) or had unstable type of jobs (self-employed; 42.9%) were the main part of the sample. That may be related to financial difficulties which lead to unstable type of life with multiple problems and crises which lead to involvement in such criminal acts. This result was compatible with other national studies and literature which showed that most of the murderers were unemployed at time of arrest (1,8).

Regarding educational level, those who were illiterate or had low educational level (34.3% were illiterate and 37.1% had just attended primary school) are more likely to commit murder, that may be related to type of life which make those who have low educational level more difficult to have stable type of job and good financial income so that make them more prone to fall in difficulties and problems. Also, we must put in mind those who can’t precede in education more likely to due to their lower IQ level so that makes them more impulsive and less aware about legal consequences when they drive to do such act. This result was also compatible with study done by (4) who found that most of murder defendants had low educational level. Also, this result was compatible with study from USA (6) who found that schooling significantly reduces the probability of incarceration. In addition, they found that arrest and crime reduction are associated with high school graduation (6).

According to the victims, the majority of them were 1st degree relatives (30%) (the brothers were about half of cases in this group) or family in-law (30%) (The wives were more than half of cases in this group). These findings could be due to high likelihood for murderers to be involved in quarrel with those who have close relationship with them and it is easier for murderers to commit such crime to the persons who live with them in the same house. These results were compatible with literatures and studies which showed that people are more likely to commit crimes against those they know, and the spouses are the principal victims (7).

The main weapons used in murders were guns (45.7%) and knives (40%). That may be due to accessibility of guns and knives especially in Iraqi society. Also, such weapons have more success rate in committing complete murder. This result was compatible with most common methods used to murder in USA which put the firearm as the 1st method followed by cutting/piercing as a 2nd method (8).

Moreover, we found that 38.6% of murderers had no mental illness, 17.1% were diagnosed as having personality disorders, 32.9% were diagnosed as having psychotic disorders and 8.6% were diagnosed with neurotic disorders. This finding was also compatible with (4) who reported that 30% of murder defendant files noted a DSM-IV Axis I disorder and 28% of defendants were reported to have an Axis II disorder, whereas 38% had no psychiatric diagnosis (9-11).

Regarding the sociodemographic state and its relation to criminal responsibility, we found that females are more likely to be considered responsible about their murders, but we put in our mind that female sample is not enough to consider this result ($P$ value = 0.063).

Also, we found that those who had younger age more likely to be considered as responsible for their crimes even this result was not significant statistically ($P$
value = 0.395), but that can be explained by that those who became older in age are less likely to commit such crimes or act in impulsive way without complaint of specific illness.

There was no significant relation between marital status and criminal responsibility ($P$ value = 0.727)

Also, there was no statistically significant relation between educational level and criminal responsibility ($P$ value = 0.478) even results showed that those who were illtreat, or had low educational level, were more likely to be considered responsible.

Conclusions

This study showed that about more than half of murderers presented had full criminal responsibility and insanity defenses were succeeded only in one third of the cases. The studied murders appeared to be obvious among young adult age groups, with no job or unstable financial resources, and illiterate or had low educational level. The victims were more likely to be from 1st degree relatives or family in-law. The available weapon (gun and knife) was mostly used.

The Effect of Doubled Concentration of Nanoparticles with Gamma-Rays Energy as Simulation Radiotherapy in Lung Cancer

Shihab Ahmed Jasim¹, Nihad A. Saleh²

¹Department of Physics, College of Science/ Kufa University, Iraq

Abstract

Background: Nanoparticles are considered main mediators to improve the efficacy of radiotherapy. By their nano size, they can penetrate the cellular environment and concentrate inside it. Nanoparticles own high cross-section and energy mass attenuation coefficient which means that they have high energy absorption. This study focused on decreasing the irradiation dose required to kill malignant cells by direct injection of NPs inside tumor cells in order to increase the amount of absorbed dose by adding a doubled increased concentration of (zinc and tellurium) NPs in tumor cells with minimum injury to the surrounding healthy tissue and increasing the number of destroyed cancer cells. Method: The theoretical basis for conducting current study was that to increase organ tolerance for radiation dose absorption, the injected particles inside the tumor should have high radiation dose absorption inside tumor. Results: There was increasing apoptosis of cancer cells and decreasing malignant cells survivor in low dose in comparison with high dose without NPs. The number of dead cancerous cells was increasing with doubling increase of NPs which depends on cross-section that is usually depending on high mass energy absorption coefficient and type and amount of energy. Conclusion: Zinc and tellurium nanoparticles can potentiate the effect of radiotherapy on lung tumor cells through increasing number of destroyed malignant cells which depended on atomic number and cross-section.

Keywords: lung cancer, high energy gamma ray, absorbed dose, Zn NPs, Te NPs.

Introduction

According to World Health Organization, the International Agency for Research on Cancer, the number of cancer death is 6.7 million and there are 24.6 million people are still successful with cancer. The highest public cancers are lung (1.35 million) [1].

The radiobiology and radiation injury to the lungs has been described by several authors. The lung is the most radiosensitive organ in the thorax, because lung tissue has a lower density than other soft tissue. A nominal 8Gy corresponds to doses 8-15% higher to lung tissue using cobalt-60 gamma rays. Hence, 8Gy becomes 8.6-9.2 GY (cobalt-60). The earliest signs of radiation injury in the lungs are oedema and changes in blood circulation followed by pneumonitis and pronounced respiratory insufficiency, which appears after a latent period of 1-3 months after doses greater than about 8Gy [2].

The effect of radiation therapy on cancer occurs when applying high energy rays using the technology of nanoparticles [3]. The radiotherapy does not always give the required efficiency to treat tumor cells, because radiation sensitivity of tumor cells is limited, therefore; it appears necessary to increase the concentration of radiation within the ionizing zone and increase the Sensitivity Enhancement Ratio (SER), because of difficult treatment in the area and the limited tolerance dose of the organ [4].

The effective dose of radiation involves use of high energy rays and the concentration of ionizing radiation in the tumor within the dose. Sometimes, this method has limited effect on the treatment process [5].

The Direct injection technique of nanoparticles (NPs), such as ZnNPs and TeNPs in the tumor has some practical advantages such as to focuses the radiation within the desired area and increase the absorbed dose in
the tumor and to avoid surrounding healthy tissue from exposure to unnecessary radiation [6].

Radiotherapy involves the use high Gamma-energy (ionizing radiations) that lead to death or shrinkage of cancer cells, but this interaction causes injury to the enveloping healthy soft tissue. To create greater damage for malignant cells with fewer damage to healthy cells nearby the malignant tumor, we need to increase the organ tolerance for radiation dose absorption inside the tumor by injecting particles that have high radiation dose absorption inside tumor [7]. The choice of such material is for several reasons; it is easy manufactured as nano materials, possesses thermal stability, do not interact with organ tissue and do not have toxic effects [8].

The interaction of electrons and photons within malignant cells creates free radicals that lead to the damage of malignant cells [9,10].

Thus, the greater quantity of absorption of ionizing radiation has better formation of toxic molecules and so increased malignant cells damage. The injection inside cancer cells works on directing specific cellular components within the tumor tissue leading to severe damage at the injection site without affecting nearby health soft tissue [11,12].

The interaction between ionizing radiation with water inside the cell results in formation of free radicals. The accumulation of free radicals leads to formation of toxic molecules. These toxic molecules work cause destruction of cancer cells. Since the production of free radicals within the tumor is larger than in healthy tissue surrounds the tumor, the destruction inside tumor is larger [13].

The biological effect of ionizing radiation depends on absorbed dose, the energy of gamma rays radiation and organs irradiated. When photons enters to the body they lose energy and are finally absorbed, but also they give rise to new photons by multiple scattering. The magnitude of this new effective photon can be estimated by buildup factor which depends on atomic number of absorbing medium, energy of gamma rays and the penetration depth in addition to the shape of the radiation source and the medium [14].

The tables of mass attenuation coefficients and the mass energy absorption coefficients for 40 elements and 45 mixtures and compounds over energy range from 1keV to 20MeV. These tables, although widely used, should now be replaced by the Hubbell and Seltzer tabulation for all elements (Z=1-92) and 48 additional substances for diametric interest. The mass attenuation coefficient, a number of related parameters can be derived, such as mass energy absorption coefficient, total interaction cross-section, molar extinction coefficient, effective atomic number and the effective electron density [15].

The vascularity of malignant tissue is higher than surrounding healthy tissue so that when NPs are injected, they diffuse to the malignant tissue more than healthy tissue so that the absorption of ionizing radiation dose inside tumor become greater due to the presence of NPs.

This study focused on decreasing the irradiation dose required to kill malignant cells by direct injection of NPs inside tumor cells in order to increase the amount of absorbed dose by adding a doubled increased concentration of (zinc and tellurium) NPs in tumor cells with minimum injury to the surrounding healthy tissue and increasing the number of destroyed cancer cells.

**Methodology**

The theoretical basis for conducting current study was that to increase organ tolerance for radiation dose absorption, the injected particles inside the tumor should have high radiation dose absorption inside tumor [16,17].

The ionizing either causes destruction or shrinkage of cancer cells, but it may cause damage to surrounding health tissue, therefore; radiologist needs to find a way to produce maximum destruction in malignant cells with minimum damage to healthy cells surrounding the tumor [18].

Nanoparticles with high energy radiation interaction lead to ensure the production of electron and positron inside tumor which increase the ionization process inside tumor then lead to increase production of free radicals and toxic molecules. As a consequence, accumulation of reaction products leads to cancer cells death [19,20].

The total cross-section for lung with presence of nanoparticles as contrast agent inside lung equals sum of two cross-sections [21]:

\[
\text{Number of survival cells after irradiation} = \text{Number of initial cells before irradiation} \times \text{relative effectiveness}
\]

Where: Number of survival cells after irradiation. : Number of initial cells before irradiation and ( ) relative effectiveness [26].
The total cross-section for lung with presence of nanoparticles as contrast agent inside lung equals sum of two cross-sections $^{[21]}$:

$$\sigma_{total} = \sigma_{lung} + \sigma_{NPs} \quad \text{.................. (1)}$$

Where $\sigma_{total}$, $\sigma_{lung}$ and $\sigma_{NPs}$ equals to lung and nanoparticles cross-sections.

The correlation between cross-section ($\sigma$) and mass energy absorption coefficient ($\mu_{en}/\rho$) can be explained in the following equation $^{[22]}$:

$$\mu_{en}/\rho = \sum_i w_i \left( \frac{N_A \sigma_i}{A} \right) \quad \text{.................. (2)}$$

Where $N_A$: Avogadro's number, $A$: Mass number and $w$: The fraction by weight of the organ with added nanomaterial per volume (μg/ml).

We can modify the equations as follows:

$$\left( \frac{\mu_{en}}{\rho} \right)_{total} = \left( \frac{\mu_{en}}{\rho} \right)_{lung} + \left( \frac{\mu_{en}}{\rho} \right)_{NPs} \quad \text{.................. (3)}$$

Where $\left( \frac{\mu_{en}}{\rho} \right)_{total}$, $\left( \frac{\mu_{en}}{\rho} \right)_{lung}$ and $\left( \frac{\mu_{en}}{\rho} \right)_{NPs}$: Total Lung and Nanoparticles mass energy absorption coefficient.

The exposure rate constant($\Gamma$) relates activity of a point isotropic radiation source to the exposure rate in air at a given distance $^{[23]}$:

$$X = \Gamma \frac{A}{d^2} \quad \text{.................. (4)}$$

Where $A$ is the source activity, $(d)$ is distance from the source.

The equation (7) modification for a lung without and with nanoparticles that adding by direct injection technique with double increase concentrations. Each NP material interacts with extent of radiation falling energy ranging from 1 to 20Mev adding nanoparticles (zinc and tellurium) get from the National Institute of Standards and Technology (NIST2004) $^{[27]}$.

**Results and Discussion**

The irradiation equations applied on lung malignant tumor with usage of Zinc and Tellurium nanoparticles were shown in Figures (1), there was increasing apoptosis of cancer cells and decreasing malignant cells survivor in low dose in comparison with high dose without NPs. The number of dead cancerous cells was increasing with doubling increase of NPs which depends on cross-section that is usually depending on high mass energy absorption coefficient and type and amount of energy.

We noticed that at dose of 5Gy there was an increase in number of living cancer cells because of lowering the cross-section and decrease mass energy absorption coefficient in comparison with the non-injectable cells by NPs. The increasing concentration of NPs gives a possible decrease of irradiation dose with same number of killed malignant cells.

Figures (2) and (3) showed that the number of living cells was less with the use of Tellurium ($Z=52$) which has high cross-section with high atomic number in comparison to Zinc ($Z=30$) at dose of 4Gy. Thus, led to an increase in the number of destroyed cells and decreasing in the number of surviving cancer cells.
Conclusions

Zinc and tellurium nanoparticles can potentiate the effect of radiotherapy on lung tumor cells through increasing number of destroyed malignant cells which depended on atomic number and cross-section.

Therefore, the interaction of Gamma-rays will be concentrated into the tumor without affecting healthy tissue that surrounds the tumor. This means that the absorption of radiation dose will be concentrated into the tumor without the surrounding healthy tissue. High energy Gamma-ray helps increase free radicals that produce interaction with water molecules inside cells.

Evaluation the Levels of Thyroid Hormones among Iraqi Pregnant Women

Zahraa Safaa Al-deen Musa
Higher Health Institute, Al-Muthana Health Office, IRAQ

Abstract

The present study was carried out to evaluate the levels of thyroid hormones among pregnant Iraqi women according to the age. The study group comprised of (140) of full term pregnant women scheduled follow up the alterations of thyroid hormones, the control group included (50) of healthy women volunteers. Serum concentrations levels of T3, T4 and (TSH) were estimated using (ELFA) technique. In the study groups, blood samples were obtained from various ages pregnant women. Range age of the study groups was (20-40) years. In the control group: serum T3 and T4 levels were decreased slightly with increasing age respectively, while TSH levels were increased slightly with increasing age without significant difference P>0.05 and the values were within the normal range. In the hyperthyroidism which included (45) patients women, there were continuously higher in concentration levels of T3, and T4 than that in the control group, but TSH concentration decreased with highly a significant difference P<0.01. While, in hypothyroidism which included (45) patient women, the concentrations of T3 and T4 were lower than that in the control group, but TSH increased with a highly significant difference P<0.05.

Keywords: Thyroid Hormones; Pregnant Women; Enzyme Linked Fluorescent Assay; IRAQ.

Introduction

Female reproduction system is negatively manipulated by both hyper and hypothyroidism, also female infertility is adversely affected thyrotoxicosis. The thyroid gland makes two thyroid hormones thyroxine (T4) and triiodothyronine (T3) which is the active hormone and is made from T4, (1). Thyroid hormones production is regulated by thyroid stimulating hormone (TSH) which is made by pituitary gland in the brain, (1,2). When the thyroid hormones concentrations levels are low in the blood the pituitary releases more TSH and when the levels in the blood are high the pituitary respond by decreases TSH production. The thyroid functions normally, if (TSH) (T3) (T4) are all normal through pregnancy (1,3). The most common causes of maternal hyperthyroidism during pregnancy (80-85 %) is graves’ disease (4). The diagnosis of hyperthyroidism is based on history, physical exam and laboratory testing.

The most common cause of hypothyroidism during pregnancy is the autoimmune disorder known as Hashimoto’s thyroiditis. Untreated or in adequately treated hypothyroidism has been associated with maternal anemia (low red blood cell, count) myopathy (muscle pain, weakness), placental abnormalities, low birth weight infants and bleeding. Because of the important effects of thyroid hormones on the pregnant women and her baby, this project was done (3,5).

This study aimed to determine serum concentrations of thyroxine (T4), triiodothyronine (T3) and thyroid stimulating hormone (TSH), because of their critical role during pregnancy for the health of mother and baby (hypo or hyperthyroidism), so the condition can be recognized and treated immediately before or after birth.

Materials and Method

This study was carried out during the period from June 2013 to October 2013. A group of (ninety) pregnant women with disturbances of thyroid gland hormones (forty five) for each of hypo and hyperthyroidism. (Fifty) pregnant women as a healthy control were included in this study, with age range 20-40 years. They were attending the Specialized center for Endocrinology Hospital women and children in the province of Muthana. The patients and control were grouped depending on their age to four groups (20-24).
Venous blood samples (5 ml) were collected from patients and centrifuged after clotting at 3000 rpm for 10 min for hormone determination. Patients' sera were taken by micropipettes and stored at 2-8°C in disposable tubes for up to 48 hours until assay to obtain more accurate results.

Quantitative Determination of T3 (VIDAS) Test:

The assay principle combines an enzyme immunoassay competition method with a final fluorescent detection (ELFA) was used to determine total triiodothyronine (T3) in human plasma (lithium heparin). The Solid Phase Receptacle (SPR) serves as the solid phase as well as the pipetting device for the assay. Reagents for the assay are ready-to-use and predisposed in the sealed reagent strips. All of the assay steps are performed automatically by the instrument. The reaction medium is cycled in and out of the SPR several times. The sample is taken and transferred into the well containing the T3 antigen labeled with alkaline phosphate (conjugate). Competition occurs between the antigen present in the sample and the labeled antigen for the specific anti-T3 antibodies (sheep) coated on the interior of the SPR. Unbound components are eliminated during washing steps. During the final detection steps, the substrate (4-Methyl-umbelliferyl phosphate) is cycled in and out of the SPR. The conjugate enzyme catalyzes the hydrolysis of this substrate into a fluorescent product (4-Methyl-umbellifereone) the fluorescence of which is measured at 450 nm. The intensity of the fluorescence is inversely proportional to the concentration of antigen present in the sample. At the end of the assay, results are automatically calculated.

Results are calculated automatically by the instrument in relation to the calibration curve stored in memory (4-parameter logistic model) and are expressed in nmol/l. Samples with a concentration greater than 320 nmol/l, retested after diluted by 1/2 in T4 free human serum (1 volume of sample and 1 volume of T4 free human serum) and retested in the VIDAS T4 assay. If the dilution factor has not been entered when the work list was created, multiply the result by the dilution factor to obtain the sample concentration. Interpretation of test result should be made taking into consideration the patient's history, and in association with thyroid function assessment, including at least a TSH assay.

Quantitative Determination of T4 (VIDAS) Test:

The assay principle combines an enzyme immunoassay competition method with a final fluorescent detection (ELFA) was used to determine total thyroxine (T4) in human plasma (lithium heparin). The Solid Phase Receptacle (SPR) serves as the solid phase as well as the pipetting device for the assay. Reagents for the assay are ready-to-use and predisposed in the sealed reagent strips. All of the assay steps are performed automatically by
the instrument. The reaction medium is cycled in and out of the SPR several times. The sample is taken and transferred into the well containing the AntiTSH antibody labeled with alkaline phosphate (conjugate). The sample/conjugate mixture is cycled in and out of the SPR. The antigen binds to antibodies coated on the SPR and to the conjugate forming a “sandwich”. Unbound components are eliminated during washing steps. During the final detection steps, the substrate (4-Methyl-umbelliferyl phosphate) is cycled in and out of the SPR. The conjugate enzyme catalyzes the hydrolysis of this substrate into a fluorescent product (4-Methyl-umbelliferone) the fluorescence of which is measured at 450 nm. The intensity of the fluorescence is inversely proportional to the concentration of antigen present in the sample. At the end of the assay, results are automatically.

The TSH Results are calculated automatically by the instrument Using calibration curve which are stored by the instrument (4-parameter logistic model), the concentrations are expressed in mLU/ml (2nd IRP 80/558). Samples with TSH a concentration greater than 60 mLU/ml, must be realized after dilution in TSH diluted (R1). If the dilution factor has not been entered when the work list was created, multiply the result by the dilution factor to obtain the sample concentration. Interpretation of test result should be made taking into consideration the patient’s history, and the result of any other tests performed.

**Statistical analysis:** Data were summarized, analysed and presented using two software programs; these were the statistical package of social sciences (SPSS version 23) and Microsoft Office Excel 2010. The level of significance was considered significant at \( P < 0.05 \) and highly significant at \( P < 0.01 \).

**Results and Discussion**

Table (1) Shows that the values of T3, T4 decreased slightly with age and TSH decreased slightly with age without significant difference \( P>0.05 \) and the values were within the normal range. The above results agreed with the observation of other studies \((6,7)\). A healthy pregnant woman can adopt herself with this scenario and thyroid in pregnancy produce an extra amount of thyroid hormones on condition of a healthy thyroid gland in combination of enough iodine an essential element in the thyroid hormone structure \((8,9)\).

* Normal value:T3=0.4-9nmol/l
In addition, the pregnancy is a physiological period which can be associated with various thyroid malfunctions. The serum concentration of TSH, T3, T4 are the least thyroid parameter which should be evaluated during pregnancy to have a clear picture of a healthy fetus and maternal life. The normal range for thyroid hormone during pregnancy are altered and when thyroid hormone are assessed those specific values should be taken into consideration. Pregnancy itself might have an adverse effect on thyroid function, leaving the pregnant woman with subclinical, overt hypo and hyperthyroidism. It seems that autoimmunity to the thyroid during pregnancy is the major cause for hypothyroidism in particular (10, 11).

Table (2) shows the values of T3, T4 increased with age and TSH decreased with age without significant difference P>0.05 between the first and second group, while there was significant difference P<0.05 between the first and second group with the third group and highly significant difference P<0.01 between the first and second group and the fourth group and significant difference P<0.05 between the third and the fourth group. The protein responsible for the transportation of female sex hormones, defined as Sex Hormone Binding Globulin (SHBG). The protein responsible for the transportation for female sex hormones, defined as and also the serum estrogen level concentration are elevated during hyperthyroidism. Therefore, correlation between SHBG and female sex hormones during periodical cycles and pregnancy should be taken into close consideration. The correlation between SHBG and female sex hormones is a matter under scrutiny (12, 13).

Tables (1) and (2) showed that there was a highly significant difference P<0.01 between the values of T3, T4 and TSH in patients compared with the control group. The above results agreed with the observation of other studies, (14, 15). The most common cause (80%-85%) of maternal hyperthyroidism during pregnancy is Grave’s disease and occurs in one of 1500 pregnant, in addition to other usual causes of hyperthyroidism, very high levels of HCG, seen in severe forms of morning sickness my cause transient hyperthyroidism (16, 17). Many changes occur in thyroid function during the transition phase from the non-pregnant to the pregnant state, changes which stabilize by the end of second trimester or the onset of the third trimester. There is biochemical evidence of functional stimulation of the thyroid, such as in serum thyroglobulin levels, preferential T3 secretion increased T3/T4 ratio and slight increases in basal TSH at delivery (18, 19).

Table (3) showed that the values of T3, T4 decreased with age and TSH decreased with age. There was a highly significant difference P< 0.01 between the
first group and other groups and significant difference \( P < 0.05 \) between the second and third group with highly significant difference \( P < 0.01 \) between the second and fourth group, while there was a significant difference between the third and fourth group \( P < 0.05 \).

Table (1),(3) showed there was a highly significant difference \( P < 0.01 \) between the values of T3, T4 and TSH in patients compared with the control. The above results agreed with the observation of other studies, \(^{20-22}\). The most common cause of hypothyroidism is the autoimmune disorder known as hashimoto’s thyroiditis. Hypothyroidism can occur during pregnancy due to the initial presentation of hashimoto’s thyroiditis, in adequate treatment of a woman already known to have hypothyroidism a variety of causes, or over-treatment of a hyperthyroid woman with antithyroid medications. Approximately, 2.5% of women will have a slightly elevated TSH of greater than 6 and 0.4% will have a TSH greater than 10 during pregnancy, \(^{23-25}\). The incidence of hypothyroidism as normal cause among female is indirectly correlated with age and the prevalence of hypothyroidism in elderly female is about ten times higher compared to younger age in their twenties,\(^{26,27}\).

Distribution of Abnormal Number of Teeth and Gender Differences: A Sample of Al-Muthanna University Students Aged 18-24 Years Old

Hayder Saad Hanfoosh¹, Osamah Mohammed Aldaghir¹, Arkan Muslim Alazzawi²
¹College of Dentistry. University of Almuthanna, Iraq, ²College of dentistry. University of Babylon, Iraq

Abstract

Congenital or developmental missing teeth (Hypodontia) is one of important numerical anomalies of teeth. So that many subject field have been carry out in different element of the humans, to find the prevalence of hypodontia. Hyperdontic dentition are teeth that appear in plus to the regular number of teeth.

This review was planned to assess the distribution of abnormal number of teeth decreased (hypodontia), increased (hyperdontia) and gender differences.

This review was applied from 23 /10/ 2016 to 12 /4/ 2019 on 1971 (1065 males, 906 females) students in four colleges in Al-Muthanna University were College of medicine (294), College of dentistry (299), College of pharmacy (185) and college of economics (1193) were clinically examined, only (202) of them had abnormal number of teeth and subjected to orthopanto-mograms to detect the missing teeth and extra teeth. Their age was ranging from 18 to 24 years.

The abnormal number of teeth in (10.2%) students. Hypodontia in (9.18%) students. The hypodontia of maxillary lateral incisor in (34.8%) students followed by hypodontia in mandibular second premolar (30.9%) students. The hyperdontia in maxillary and mandibular teeth (1.06%) students. Mesiodens in (0.7%).

The study displays that about (10.2%) students had abnormal of teeth number. Hypodontia happens more often than hyperdonti. The foremost repeatedly absent tooth was maxillary lateral incisor and the second one was the mandibular second bicuspid. About hyperdontia, the most frequently hyperdontic tooth was Mesiodens. All of them, difference between gender was non-significant.

Keywords: Abnormal number of teeth, Gender differences, AL-Muthanna University.

Introduction

Teeth are classified into kinds according to their specific positions in the dental arch. In mammals, the difference between tooth types depend on the typical contour class, as incisors, canine, bicuspid, and grinder in human race. While difference in shape between tooth types are typical to the teeth in the same family similar each other (¹).

Supernumerary teeth are dentition formed as result of duplicating in the normal full complement as a consequence to excessiveness dental lamina in the dental arch (²).

Congenital missing of all dentition without any associated anomalies is extremely very rare; some studies found that anodontia have suggested to be autosomal recessive hereditary pattern.

Anodontia occurs as an extreme teeth phenotype in ectodermal dysplasia syndrome. In odontology, anodontia, also called anodontia vera, is a rare genetic disorder characterized by the congenital missing of all teeth (permanent or primary dentition. It is associated with other type of dermal and neural syndromes called the ectodermal dysplasia. Anodontia is usually part of a syndrome and rarely to occur as a separated syndrome (³).
Materials and Method

The Sample

Sample distribution was selected from university of Al_Muthanna students. lies south of Capital of Iraq. Age was selected depending on the last birthday giving an age from 18 years 0 months to 24 years 11 months (4).

Number of students presented in Al-Muthanna university were (13366) (Ministry of Higher education and Scientific research, Al-Muthanna University 2016). while the number of population were (842000). The minimum number should be represented of the sample was taken depending on the following equation (5):

\[
\text{The number of sample} = \frac{\text{Total number of students}}{\text{Total number of population}} \times 100000
\]

\[
= \frac{13366}{842000} \times 100000 = 1587
\]

No sort of systemic abnormality, particularly Down’s syndrome and cleft lip & palate because of delayed teeth development in such conditions (6).

Permission for this study was obtained from the Al-Muthanna University.

Methods of Examination

All students were examined clinically under day light using dental mirrors, for all the students that were not surely diagnosed as hypodontic, or hyperdontic, were subjected to orthopanto-mograms (O.P.G). A tooth was detected as congenitally absent when cannot be seen in the dental arch in the radiograph of the region and there was no history or evidence that it was accidentally missed or lost by extraction.

Their radio-graphs are obtained from orthodontic department clinics and radiographic department clinics at the College of Dentistry of Al-Muthanna University.

Statistical Analysis

The processing and analyzing of data done by using (SPSS Inc., version 25 for windows 10 and excel 2018). The most statistical methods were used in order to obtain the results include: inferential statistics, descriptive statistics, Z-test to compare between significant difference of two proportions. The following levels of significance are used:

\[ P > 0.05 \text{ NS Non-significant.} \]
\[ 0.05 \geq P > 0.01 \text{ * Significant.} \]
\[ 0.01 \geq P > 0.001 \text{ ** highly significant.} \]

Results

Distribution of abnormal number of teeth and difference between both gender as shown in (Table,1). The abnormal number of teeth presented in 202 (10.2%) students (104 (9.7%) males and 98 (10.8%) females). Hypodontia in 181 (9.18%) students (96 (9%) males and 85 (9.3%) females). Hyperdontia in 21 (1.06%) students (8 (0.75%) males and 13 (1.4%) females), difference between both gender was non-significant.

Discussion

Prevalence of hypodontia were presented in (9.18%) students, similar with researchers like Sanchez in Argentina (7), Ravn and Nielson in Danmark (8), Mangnusson in Iceland (9), Chung et al in Korea (10) and Dastjerdi et al in Iran (11).

More than other studies including Dolder in Switzerland (12), Werther and Rothenberg in U.S.A (13), Malik in Pakistan (14), Al-Mulla et al in Iraq (15), Silverman and Ackerman in U.S.A (16), Kinan in Iraq (17) and Al-Hamdany et al in Iraq/Mosul (18). This may reflect a persistent problem in different communities with variation in intensity that result due to racial, size of the sample, type of the study, gender and age variations.

Difference between both gender was non-significant (P>0.05), it agreed with many other studies like Dolder in Switzerland (12) and Werther and Rothenberg in U.S.A (13) and in Iran Dastjerdi et al (11).

Maxillary lateral incisors (34.8%) were foremost repeatedly missing which is followed by mandibular second bicuspids (30.9%) and maxillary second bicuspids (12.7%), then mandibular central incisor (7.1%), similar to Kinan (17), Augard and Gayard (19), Al-Hamdany et al in Iraq/Mosul (18), Dastjerdi et al (11), while others as Al Mulla et al (15), Al Judo (20) and Al-Jourany TS in Baghdad/Iraq (21) showed the mandibular second bicuspids were foremost repeatedly missing which is followed by maxillary lateral incisors. This can be due to racial difference and ethnic factor in the populations who were studied.

Difference between both gender was non-significant (P>0.05), it agreed with other studies Werther and Rothenberg in U.S.A (13), in Iran Dastjerdi et al (11) and Pérez et al (22).

Prevalence of hyperdontia presented in (1.06%) students while Gábris. in a research found that the prevalence of hyperdontic teeth were 1.53% (23). Vahid-Dastjerdi et al. examined radiographs of 1751 Iranian population and detected that 0.74% had hyperdontic teeth (24), while Udom et al. detected that the prevalence of 1.8% for hyperdontic teeth. The prevalence might be different in prevalence due to the differences in ethnic factor of population and in the sample size.

Most common hyperdontic tooth was mesiodens which followed by mandibular second bicuspids, maxillary lateral incisor, mandibular lateral incisor and maxillary first bicuspids (23). While Sogra et al, in a research found that most frequently hyperdontic tooth were mandibular bicuspids followed by mesiodens.

Difference between both gender was non-significant (P>0.05), it agreed with Pérez et al (22).

Conclusion

The study displays that about (10.2%) students had abnormal of teeth number. Hypodontia happens more often than hyperdonti. The foremost repeatedly absent tooth was maxillary lateral incisor and the second one was the mandibular second bicuspid. About hyperdontia, the most frequently hyperdontic tooth was Mesiodens. All of them, difference between gender was non-significant.

Impact of Residency Area on Dental Caries and Nutritional Status among 10 Years Old Children in Al-Hillah City, Iraq

Sarah Y. Al. Khafaji¹, Nadia Aftan Al Rawi¹

¹Department of Pedodontics and Preventive Dentistry, College of Dentistry, University of Baghdad, Iraq

Abstract

The dental caries are still the most common oral disease affecting children through the world especially in developing countries as in Iraq; however, these are not life threatening human disease.

This study was conducted to assess dental caries experience and the nutritional status among 10 years old primary school children in urban and rural area in Al-Hillah city.

Eight hundred ninety one (891) students, 10 years old, selected randomly from different primary school, in urban and rural area in Al-Hillah city. Oral examination of dental caries was done according to the criteria described by WHO in 1987. Nutritional status was assessed according to body mass index (BMI), then followed the criteria of Centers for Disease Control and Prevention growth chart (CDC).

A high percentage of total samples were affected with dental caries and significantly higher in urban areas than rural areas. The majority of children had normal weight and the lowest percentage had underweight.

This study revealed that a higher prevalence of dental caries experience was recorded, in children of urban than children of rural areas. Therefore, there is need for an improving public and school preventive programs, and encouraged to orient health knowledge in a positive direction.

Keywords: dental caries experience, urban and rural area

Introduction

Dental caries can be defined as a demineralization of the inorganic part of the tooth with the dissolution of the organic substance based on interaction of several factors: diet (fermentable carbohydrate) oral micro flora (acidogenic bacteria), time and host (¹, ²).

A variation in caries prevalence among different countries may be related to several factors, which include: water fluoridation, and dental education, as well as different dietary habit and socioeconomic status, age, gender, race, oral hygiene, and geographical location, all these factors if not available, may lead to higher caries prevalence among developing countries, and the reverse for developed one (³).

Iraq is one of the developing countries that showed as distressing increase in caries prevalence and severity (⁴, ⁵).

There are three mechanisms explained that malnutrition during tooth development can make teeth more susceptible to dental caries. The first is that malnutrition causes defectively formed tooth, the second one is that the eruption of teeth is delayed among malnourished children; the last mechanism is that malnutrition can lead to increased dental caries by affecting salivary gland development and function (⁶, ⁷).

It was thought that provide good nutrition during teeth development was the principle way to prevent dental caries. It was known that the topical effect of diet in the mouth after the teeth have erupted plays a much more important role (⁸).

So, the aim of this study is assessing dental caries and nutritional status in children aged ten years in primary schools in Al-Hillah city.
Materials and Method

Subjects:

Eight hundred ninety one (891) children aged 10 years old selected randomly from different rural and urban primary schools in Al-Hillah city. The cross sectional random sample was calculated for prevalence studies by the formula as $n = \frac{Z^2 P (1-P)}{d^2}$ (9).

$N= \text{Sample size.}$

$Z= \text{Z Statistics for the level of the confidence (at 95% confidence level, } Z=1.96).$

$P= \text{Prevalence of the proportion.}$

$D= \text{Precision (if the precision is 5%, } d=0.05).$

This study was done during the period from December 2018 to February 2019. A pre-study ethical approval was assigned, approval was taken from the General Directorate of Education of Al-Hillah city in order to achieve subject without obligation, also the children’s parent consent form which taken before start the study.

Inclusion criteria: Students with

- No history of medication, (anti- inflammatory or antimicrobial therapy) within previous 3 months.
- No history of orthodontic treatment.
- No history of any systemic disease.

Oral examinations were performed on chairs in a special room, under good illumination by using dental mirror, probe and dental tweezers.

Diagnosis and recording of dental caries were carried out by the criteria of WHO in 1987 (10). Nutritional status was assessed according to body mass index (BMI) indicator by using anthropometric measurement (weight and height) then followed the criteria of Centers for Disease Control and Prevention growth chart (CDC) (11). Children were weight by bathroom scale (12). From the child’s weight and height, BMI index determined according to this formula (12): \[ \text{Body weight / (height)}^2 = \text{BMI Kg/m}^2 \]

The result of that formula was compared with international reference values using CDC growth charts (11).

Results

This study included a total of (891) school children aged (10) years, children living in urban areas constituted (57.6%) of the sample, while the remaining (42.4%) children lived in rural areas, as illustrated in Table (1) illustrated distribution of total sample between the residences of children according to gender.

Table (2) illustrated distribution of the children by nutritional status between urban and rural residence. Urban residents have shown slightly higher percentage of underweight nutritional status than rural residents (5.26% vs. 4.76%). It had also shown a highly significant relationship, chi-square = 36.06, d.f. = 3, P-value < 0.001.

Table (4) illustrates the mean value and standard deviation of caries experience by fractions in primary dentition among children in regarding to nutritional status. It was found that primary teeth (dmft, dmfs, and ds) had a statistically significant relationship with nutritional status. Underweight children had significantly higher dmft, dmfs, and ds than other.

Table 4: Caries experience with fractions in primary dentition by nutritional status

Table (5) demonstrates the mean value and standard deviation of caries experience by fractions in permanent dentition among children in regarding to place of residence. Caries experience was found to be higher in urban area than rural area. DMFT, DMFS, Ds and Fs of permanent teeth were significantly higher in urban areas compared to rural areas while mean value missing surface was higher in rural area than urban.

Discussion

The result was shown dmft for primary dentition lower than that seen by Al-Galebi in 2011 matching with age (5). However, this results higher than other previous Iraqi studies by Al-Azawi in 2000 and Radhi in 2009 (13,14). The mean dmfs value of this study was lower than that seen by Diab in 2003 in the central region of Iraq (4), Droosh in 2007 in Sulalmania city (15), and Al-Galebi in 2011 in Al-Nassiyyia city (5).

The mean DMFT value of the present study was lower than that seen by Al-Azawi in 2000 (13), Al-Galebi in 2011 (5), Laith and Al-Rawi in 2016 (16). The result of DMFS was lower than reported by Ali in 2001 (17), Diab in 2003 (4), Al-Galebi in 2011 (5), and Laith and Al-Rawi in 2016 (16).

In present study, the result was shown the dmft/dmfs higher than DMFT/DMFS this result due to the selected age of schoolchildren in this study had been recently transitioned from primary to permanent dentition stage this mean most of permanent teeth were sound that are newly erupted there was no enough time to develop of dental caries (18).

Both dmft/dmfs; DMFT/DMFS were higher in urban area than rural area this result agrees with Al-Sayyab in 1989(19), Al-Azawi in 2000 (13), and finding from this study indicate that, dental caries considered as
a disease of civilization, in addition, rural area was well and natural nutritional status than urban area. This may affect mineralization of teeth and salivary composition, thus decreasing the susceptibility of teeth to dental caries \(^{(20)}\).

This study was shown that the decayed (ds/Ds) was the major component of dmfs /DMFs then ms/Ms and fs/Fs. This may reveal the poor demand for dental treatment for both primary and permanent dentition and even treatment was present it was directed for extraction rather than preserving permanent teeth. These results were in agreement with Baram in 2007\(^{(21)}\) and Al-Galebi in 201 \(^{(5)}\).

There were significantly higher ms in rural area than urban area while fs/Fs were in opposite picture. This indicates poor educational level in rural area towards dental health, this agree with Ali in 2001 \(^{(22)}\) and Al-Sadam in 2013 \(^{(23)}\).

In present study, the result was shown the percentage of dental caries was lower in obese children this agree with Al-Saadi in 2009 \(^{(24)}\). This result could be partially explained that a high amount of fat in the diet binds to various sugars in the diet thus decrease their solubility lead to drop in pH value and weaker acid attacks, and a fatty protective layer over plaque would prevent fermentable sugar substrate from being reduced to acid\(^{(25)}\).

### Conclusion

This study revealed that a higher prevalence of dental caries experience was recorded, in children of urban than children of rural areas. Therefore, there is need for an improving public and school preventive programs, and encouraged to orient health knowledge in a positive direction.

Molecular Investigation of Plasmid–Mediated Quinolone Resistant Genes among aminoglycoside-resistant uropathogenic *Escherichia coli* Isolates from Babylon Hospitals, Iraq

Khadeeja Obaid Alm’amoori¹, Zainab Jaber Hadi², Ali Muhsin Almohana³

¹Faculty of Medicine / Kufa University/Iraq

**Abstract**

**Background:** Uropathogenic *E. coli* is the most frequently causes of UTIs in humans, accountable 75-95% of UTIs. PMQR have been identified in family *Enterobacteriaceae* worldwide. The purpose of this study to examine the dissemination of *aac(6')-Ib-cr* and PMQR genes in isolates of UPEC.

**Method:** A cross sectional study of mid-stream urine of the participate patients their approval for direction usage their specimen. The susceptibility test by disk diffusion for UPEC were isolated from urine and screening of quinolone resistant by multiplex PCR for *qnrA*, *qnrB* and *qnrS* genes and monoplex PCR for *qunD*, *qepA* and *aac(6')-Ib-cr* genes.

**Results:** A total of 1072 mid-stream urine were collected randomly, overall 132 were identified *E. coli*, among these 60 aminoglycoside resistant UPEC isolates were screened to the five quinolone antibiotics. The resistance proportion to nalidixic acid and ciprofloxacin were 75.0%, as well as to lomefloxacin, norfloxacin and levofloxacin were 76.7%, 73.3% and 71.7%, respectively. The susceptibility test for antibiotics showed a high incidence of the resistance to the majority of antibiotics class. It was found that 73.3%, 38.3%, and 20.0% of the isolates harbored *aac(6')-Ib-cr*, *qnrS* and *qnrB* genes, respectively either alone or in combination, while the *qnrA*, *qunD*, *qepA* genes were not detected.

**Conclusion:** All isolates were identified as multiple antibiotic resistances, only one isolate can be considered as possible PDR and high prevalence of *aac(6')-Ib-cr*, *qnrS* and *qnrB* genes among isolates.

**Keywords:** UPEC, *aac(6')-Ib-cr*, *qnrB* and *qnrS*, plasmid mediated quinolone PMQR, multidrug resistance, extended drug resistant, pan drug resistance.

**Introduction**

UTI is the second most common clinical in primary and secondary care suggestion for experiential antimicrobial treatment(1). *E. coli* can cause both complicated and uncomplicated UTIs(2). Fluoroquinolones has represented an alternative therapeutic select for the treatment. But, newly the incidence of fluoroquinolones-resistance between uropathogenic isolates has also been described in different areas(3). Quinolone resistance mechanisms include mutation in target gene, elevated expression of efflux pumps and yielding of modifying enzyme and target protection protein(4). They involve the chromosome encoded and PMQR, three PMQR mechanisms have been identified: target protection by Qnr proteins, drug inactivation by AAC(6)-Ib-cr, and drug efflux by QepA and OqxAB(5). The rapid dissemination of MDR bacteria has become a concern worldwide and complicated the treatment of infections. This phenomenon is a consequence of the ability of bacteria to acquire exogenous genes by mobile elements (e.g. conjugative plasmids, transposons and integrons)(6).

Increased use of ciprofloxacin and other fluoroquinolones antibiotics in Iraq may be cause selection of isolates resistant to aminoglycosides by selecting the isolates that possess AAC(6')-Ib-cr.
The aim of this study to examine the dissemination of \(\text{aac}(6\text{'})\)-\(\text{Ib-cr}\) and PMQR genes in aminoglycosides resistance in UPEC isolates from Babylon hospitals.

**Method**

**Collection of specimens**

This cross section study of the participate patients their approval for direction usage their specimen was conducted in in two main hospitals in Babylon hospitals during the period of six months from March to September 2018 in patients clinically suspected to have UTI. The inclusion criteria for the volunteer patients were attended or admitted in the two hospitals.

**Isolation and Identification of \(E.\ coli\) isolates**

Identification of bacterial pathogens was made based on Gram reactions, culture characters, and routine standard biochemical tests. All \(E.\ coli\) strains were purified on EMB agar plates to confirm that there is no mixed culture. Additionally, \(E.\ coli\) isolates were also confirmatory identified by using commercially available API 20 E kit.

**Antibiotic Susceptibility Test**

Antibiotic susceptibility test was performed by Kirby –Bauer method based to the guideline suggested by the Clinical and Laboratory Standards Institute\(^{(7)}\).

**Examining for Quinolone Resistance and other Antibiotics**

The disk diffusion method was made to identify quinolone resistance in all aminoglycosides resistance UPEC by using Nalidixic acid (30\(\mu\)g), Ciprofloxacin (5\(\mu\)g) Levofloxacin (5\(\mu\)g) Lomefloxacin (10\(\mu\)g), Norfloxacin (10 \(\mu\)g). In addition, all aminoglycosides resistance UPEC were screen for other antibiotics.

**Examining for PMQR Genes**

Multiplex PCR were used to determine the presence \(qnrA, qnrB\) and \(qnrS\) genes and monoplex PCR for \(qunD, qepA\) and \(\text{aac}(6\text{'})\)-\(\text{Ib-cr}\) genes in quinolone resistance UPEC by using T300 (thermo cycle) and Go Taq Green Master Mix (Promega USA). The primer target for each PMQR genes were available elsewhere\(^{(8,9,10,11)}\).

**Results**

Out of 298 isolates of uropathogen, 132 (44.3\%) isolates were recognized as \(E.\ coli\) followed by \(Klebsiella\) spp (22.5\%), \(Proteus\) spp (10.0\%), \(S.\ aureus\) (9.4\%), \(S.\ saprophyticus\) (3.4\%), \(P.\ aeruginosa\) (3.4\%), \(S.\ faecalis\) (2.7\%), \(Enterococcus\) spp (1.7\%) \(Acinetobacter\) spp (1.3\%) and \(Citrobacter\) spp (1.3\%).

**Examining for Quinolone Resistance**

Overall, 78.3\% (47/60) of the aminoglycoside resistant UPEC isolates were non susceptible to at least one of the five quinolone antibiotics by disk diffusion methods. The resistance proportion to nalidixic acid and ciprofloxacin were 75.0\%, as well as to lomefloxacin, norfloxacin and levofloxacin were 76.7\%, 73.3\% and 71.7\%, respectively.

**Co-resistance of \(E.\ coli\) to other Antibiotic**

Antibiotic susceptibility test of all 60 uropathogenic \(E.\ coli\) against 28 antibiotics (belong to twelve classes) displayed high occurrence of resistance to the majority agents of antibiotics. According to the definitions proposed\(^{(12)}\), all of the 60 aminoglycoside resistant UPEC isolates (100\%) were multiple resistance to antibiotics. Based on their MDR, 49 (81.6\%) of the isolates were included, 2 (3.3\%), 1 (1.7\%), 4 (6.7\%), 5 (8.3\%), 18 (30\%) and 19 (31.6\%) were resistant to 3, 5, 6, 7, 8 and 9 antibiotic classes, respectively. While, 10 (16.7\%) isolates was considered as XDR organisms, of which 6 (10\%) were resistant to 10 antibiotic classes and 4 (6.7\%) were resistant to 11 antibiotic classes. PDR could be detected in only one isolate (1.7\%) in this study (Table 1).

Examining for PMQR Genes

PMQR genes were identified in 78.3% (47/60) of E. coli, harbor at least only one PMQR gene, and three types of PMQR (qnrS, qnrB and aac(6')-Ib-cr variant) were recognized alone or in combination (Table 2). The aac(6')-Ib-cr variant was present in 73.3% of the isolates, followed by qnrS (38.3%) and qnrB 20.0% of the isolates. Interestingly, qnrA, qnrD, and qepA were not found in any isolates.

Discussion

Frequency and Resistance of UPEC to Quinolone antibiotic

This study revealed that the UPEC isolates (44.3%) were the major causative agent of significant bacteriuria compared to other uropathogen due to enteric flora, the way of transmission is by fecal contamination and anatomical nearness to the genito–urinary tract in females and the poor hygiene. This result is agreement with other authors have the same findings, which E. coli was the predominant uropathogen.

The resistance rates to nalidixic acid and ciprofloxacin were 75.0%, as well as to lomefloxacin, norfloxacin and levofloxacin were 76.7%, 73.3% and 71.7%, respectively. This may be due to rampant use of quinolones as first line empirical therapy in UTI cases. The data reported in this study is close related with the previous study described that ciprofloxacin resistance rate 79.66% to E coli in Saudi Arabia. In the previous report of the ECDC, the presence of UPEC isolates resistant to fluoroquinolones were existent in low numbers in Sweden (7.9%) and Norway (9.0%), but they were dominant in Italy (40.5%) and Slovakia (41.9%).
Co-resistance of aminoglycosides and quinolones was observed in the UPEC isolates of the present study. The study report in Iraq the identification of a variant of the aminoglycoside modifying enzyme AAC(6′)-Ib, as a common incidence in *Enterobacteriaceae* isolates\(^{(18)}\).

**Antibiotic Resistance**

All UPEC isolates were identified as multiple antibiotic resistances. This result was considered a high level when compared to other report. Frequency of MDR 81.6%, which was relatively high prevalence when compared to rates reported, in Saudi Arabia it was 67.0\(^{\circ}\)%\(^{(19)}\), and in Iran it was 63.0\(^{\circ}\)%\(^{(20)}\). The reason of high MDR may be due to the most cases of UTIs are treated empirically in Iraq, where patients frequently cannot afford to consult a clinicians or have a laboratory tests. Therefore, there may be over cases of bacteria that are not responded to treatment.

XDR, 16.7% this finding are alarming since infections with these XDR UPEC isolates leave physicians with only one or two antibiotic treatment options, leading to increased mortality and morbidity\(^{(20)}\). In present study remarked PDR (1.6\%) of UPEC. No study investigation PDR-producers among UPEC. However, the prevalence of PDR in *Enterobacteriaceae* is rare in Europe and other countries\(^{(21,22)}\). Although infections by PDR *Enterobacteriaceae*, still rare, but have been associated with a high mortality.

**Occurrence of PMQR Genes**

PMQR determinants have been identified in family *Enterobacteriaceae* worldwide, with varying frequency rates\(^{(23)}\). 78.3\% of the isolates harbored at least one PMQR gene (Table 2). In Saudi Arabia, reported that 26.0\% of isolates carried PMQR genes\(^{(24)}\). Previous investigations conducted in Europe described fewer PMQR determinants in ESBL-*E. coli* isolates than found in the current study, 19.0\% in Spain, and 10.0\% in Sweden and Norway\(^{(25,26)}\).

The AAC(6′)-Ib-cr variant, an enzyme encoded by a plasmid-borne *aac(6′)-Ib-cr* gene, that inactivate selected fluoroquinolones (ciprofloxacin and norfloxacin) by acetylation in addition to aminoglycosides\(^{(27)}\). *aac(6′)-Ib* PCR positive products were further digested with BstCI to identify *aac(6′)-Ib-cr* variants. Present study demonstrated that the most prevalent PMQR gene was *aac(6′)-Ib-cr* as 73.3\%. This is also identified in other studies (84.0\%)\(^{(27)}\), (94.0\%)\(^{(28)}\) of the *aac(6′)-Ib* were of the *aac(6′)-Ib-cr* variant. Presence of this variant also increased the incidence of selection of chromosomal mutants (quinolone resistance determine region, QRDR) upon exposure to ciprofloxacin\(^{(29)}\). However, Spread of this variant is undesirable because these fluoroquinolones are used as first choice for treatment of UTIs in Iraq.

*qnrS* was the most prevalent 38.3\%, followed by *qnrB* (20.0\%). Present findings concurred with a previous European survey that *qnrS* was more frequently detected than other *qnr* genes in clinical *Enterobacteriaceae* isolates\(^{(30)}\). In the USA, among ceftazidime-resistant *Enterobacteriaceae* isolates, 23\% were positive for either *qnrA* or *qnrB*, while *qnrS* was absent\(^{(31)}\). In China among ciprofloxacin resistant *E. coli* is 7.5\%. *qnrA*, *qnrB* and *qnrS* were detected in 3.8\%, 4.7\% and 3.8\% of these isolates, respectively\(^{(32)}\). However, variations in distribution of *qnr* genes have been suggested to be attributing to differences in selection criteria or geographic area\(^{(33)}\). None of the *qnrA*, *qnrD* and quinolone specific efflux pumps (*qepA*) were found in present collection. This is not surprising since *qnrD* and *qepA* determinants are rarely found worldwide.

This study was revealed high combination of *aac(6′)-Ib-cr*, *qnrS*, followed by *aac(6′)-Ib-cr*, *qnrB* and *aac(6′)-Ib-cr*, *qnrS*, *qnrB* isolates as shown in Table (2). This could be explained by the coexistence of the *aac(6′)-Ib-cr* and *qnr* genes on the same plasmid\(^{(34)}\). The combination is also observed where 35.1\% and 1.3\% of the *E. coli* isolates carried two and three different PMQR genes, respectively.

Study of the Effectiveness of Some Raw Plants and Materials in the Treatment of Pediculosis in Najaf province Iraq

Sundus Wafi Al-Zayyadi
Collage of Education for Girls , Kufa university, Iraq

Abstract

Head lice are a public health problem and resistance to over-the-counter medications is a source of concern for many. The current study was conducted to evaluate the activity of three plants as a natural alternative to medical pesticides to treat pediculosis in Najaf province, Iraq. It was noted that the *Lawsonia Inermis* plant (Henna paste) mixed with mercury has scored the highest effectiveness for killing lice in two hours from the first use by 100% followed by the *Allium cepa* juice mixed with *Curcuma longa* plant, where the rate of killing 80% of the second use and finally vinegar mixed with sodium chloride (food salt) by 46.66%. Our suggestion that these blended Materials give better results than if they were alone and are excellent alternatives to medical pesticides.

Key words: pediculosis, raw plant, sodium chloride, mercury, vinegar.

Introduction

Head lice infection was associated with limited morbidity, but it caused anxiety among parents toward school-age. Multiple and excessive treatments to pediculosis have also promoted serious health concerns due to the lack of effective treatment to increase the resistance of lice to synthetic compound, so researchers have begun to looking for new synthetic components of treatment such as compounds obtained from plant source. Although most of the active synthetic pesticides were available in the market and efficient against *pediculus humanus capitis*, but these products were expensive and toxic effect on the human nerves. Hence non-toxic alternative options are needed to treat pediculosis. Natural sources remained less toxic and less expensive; therefore, natural extracts from medicinal plants were main rich source of treatment for various diseases and disorders of the human system.

More than 1000 species of plants had been described in many areas containing chemical components in seeds, stems, roots, leaves and flowers against insect pests but only a few plants had been used to control insects practically on a commercial scale in the past few decades. The efficient treatment of the pesticide to kill head lice and eggs, followed by manual removal of eggs is the most effective procedure for eliminating head lice.

*Lawsonia* is a shrub and dicot plant belong to the Lythraceae family, has only one species (*L. Inermis*) but it has several names such as Henna, Mendi, Shudi, Madurang, Manghati, Madayantika and Goranti. It is widely cultivated throughout Tropical regions as an ornamental plant and although the plant was used in the dye and small number of studies had been recorded in treatment of many diseases like anti-diabetes, immunomodulatory and liver activity.

Mercury is a chemical element previously known as a heavy silver mercury element, liquid in standard conditions of temperature and pressure. It was used in cosmetic recipes such as whiten the skin, treat pimples and freckles in the face, treat sores, warts and skin infections.

For long time, the onion plant (*Allium cepa*) was highly valued for its therapeutic properties, a medicinal plant used, but lately used for its effectiveness of heart vessels, anti-hypertensive and anti-diabetic by a few researchers.

*Curcuma long* belongs to the Zingiberaceae family and is considered to be very cheap, available, effective and acceptable in developing countries, without toxic or harmful reactions. The active ingredients known as curcumin have been shown to be highly therapeutic when used in recommended quantities.
In our study, 6 substances were studied, some of which were extracted from the plants, in addition to other substances, where each extract was mixed with another for the purpose of studying its adverse efficacy of extracts and their use as a human hair pesticide. In the absence of a similar study, the idea of the study came as follows:

1- Study the effectiveness of *Lawsonia* plant mixed with mercury as a lice pesticide

2 – Study the effectiveness of *Allium cepa* juice mixed with *Curcuma longa* plant (Al-Korkom or Curcumin)

3 - Study the effectiveness of vinegar mixture with sodium chloride

**MATERIALS AND METHODS**

A total of 45 randomized samples infected with pediculosis were collected with different ages ranging from 8 - 30 years, Ones were excluded before the examination weren’t eligible for inclusion in our study who used any form of head lice treatment for at least four weeks or any local medicine for 48 hours prior.

The experiment was conducted at room temperature 25°C and a relative humidity of 45%. The blended materials was placed on the hair of the affected women using the brush starting from the scalp with continuous combing the end of the hair and then wrapped in a plastic bag for two hours and then rinsed the hair with empty water with combing to get rid of dead lice And eggs.

Then hair was examined and the experiment was repeated on the second and third day if the lice hadn’t completely eliminated. People were also examined for the side effects of treatment on the skin and eyes, and recorded their impressions regarding smell, itching, etc., during and after treatment. The second test was performed 10 days after the first treatment to determine whether all lice were eliminated in the hair or not. preparation of experimental materials

1- *Lawsonia* paste and mercury

*Lawsonia* leaves and mercury were bought from herbal stores and taken 110 g of ground *Lawsonia* leaves mixed well with 200 ml of water. Then add 5g of mercury to get the henna paste.

2- A mixture of onion juice with ground turmeric:

Red onion (150g) sometimes called purple (*Allium cepa*) peel then squeeze to get onion juice, with a concentration of 100%. Then add 10 g of turmeric (after grinding the turmeric stalks) to the onion juice and mix well.

3- mixture of vinegar and sodium chloride

Concentrated vinegar (250 ml) was taken from the Al-Badawi factory (Iraq) and mixed with salt (25 g). The mixture was added to the vinegar and the salt was well dissolved.

**Result**

45 patients were successfully treated with natural treatments divided into 3 groups and each group contained 15 persons for each combination of experiment materials. The adults and nymphs head lice mortality rate was evaluated after two hours of treatment with Therapeutic materials. Table results show that henna blended with mercury had a high toxic effect in killing lice and eggs by 100% of the first usage, followed by mixture of onion and turmeric plant by 80% of the second usage, while the mixture of vinegar and food salt recorded 46.66% of the third day. The number of lice in the hair has decreased on the first day and the second for the last mixture.

Discussion

The Henna leaf paste is used as a coloring agent for hair. At the same time, the phytochemicals present in the leaves have a toxic effect of head lice. Our results are consistent with a study conducted by (2), that the phytochemical constituents of \textit{L. inermis} by GC-MS) \textit{Gas Chromatography-Mass Spectrometry}, where it revealed the presence of 72 compounds with different molecular weights. In another study, they found to contain naphthoquinone, xanthones, coumarin derivatives, fatty acids, amino acids and other components. It had been shown that the Naphthoquinone which obtained from \textit{L. inermis} leaves had a large immune effect. Quinonic compounds extracted from Henna have also been studied in vitro and have been shown to possess antimicrobial properties. Lawson isolated from \textit{L. inermis} leaves showed a significant antifungal effect (11).

(12) confirmed that it had anti-oxidant, antiviral and parasite effect and reduce larvae activity of some insects, anti-inflammatory, inhibition of enzymes activity, anti-coagulant effect, wounds healing and the activity of inhibition of protein.

Since ancient times, Henna paste has been placed on hands and feet to protect against fungal and to control lice and crust. In a study conducted by (13), 70 phenol compounds were isolated from different parts of the plant, Naphthaconon has been associated with many pharmacological activities, while terpenes and β ionone are responsible for the odor of essential oils isolated from flowers. In addition to other volatile terpenes, some types of non-volatile tryboinoid and two alkaloids and dioxin derivatives have been isolated from the plant. Henna is an important medicinal plant with important biological activities in vitro and in vivo. Although a myriad of pharmacological activities have been documented, the antioxidant and antimicrobial activities are most carefully researched.

(14) found that Henna was used in the treatment of lice mixed with several plant extracts such as wormwood(100%), helba 75% or karkada (50%), Head lice completely disappeared within a week between these patients.

As for mercury, it is known to be a poisonous substance, especially on insects. Thus, mixing it with henna paste gave an excellent result. It is one of the toxins that affects topically by its contact with the body, and affects after absorption on the various organs of the body and some of them called poisonous irritants and is considered a toxin of the nervous system and toxins reproductive system, affecting the activity of the reproductive system in both male and female causing infertility.

In a study conducted on a mummy of Ferdinand II, where samples were taken from the head and pubic hair on the mummy, and then tested for The presence of lice in the hair and mercury concentration, where it tended to accumulate in head hair as well as the presence of mercury in the liquid used for hair washing. This confirms the possibility of applying minerals externally.

Further toxicity tests were conducted to verify the presence of mercury on the skin, body cavities and pubic hair, where the results showed very low values. Therefore, the presence of these elements in the king’s hair could prove exposure to the metal for the purpose of killing the lice and through microscopical and radiographic examination No traces of mercury were shown in cavities of the skull or body in the Ferdinand mummy. Results revealed that parts of the abdomen of adult and seven unfinished had attached to the hair, parts of the lice eggs. The presence of massive mercury in Ferdinand II hair was explained by the use of quicksilver for artificial mummification For the corpse, Considering that there is no trace of the metal in the mummy except in poetry.

While the effects of mercury have been found in all hairs and it seems reasonable to attribute the high value of mercury to the use of solutions and ointments against lice, And the decrease in the percentage of mercury in pubic hair indicates that he has lice as well as the head, and to prove that this region has not received any treatment to control lice (9).

Furthermore, indicators of mercury therapy from other diseases such as ringworm and scabies are described as localized use of mercury on the skin lesion alone (15).

The absence of redness of the skin cells (the crust layer) in human treated with a mixture of henna with mercury is a sign of non-sensitization of this region and is evidence of the lack of absorption of cells of this material and thus non-penetration of the skin, indicating that the effect of this material on the parasite and the possibility of use for external use.
Comparing the results of the current study with a study conducted by(6), where they studied the effectiveness of onion extract in the killing of nymphs and lice in the laboratory and found that the mortality of head lice 10% and 20% after 30 and 60 minutes respectively.

Onion plant has many biological activities including antimicrobials, antioxidants, anti-cancer and anti-inflammatory(16).

(17) conducted that the onion plant as antimicrobial with different concentration of essential oil extracts of three types of green, yellow and red onion tested against two bacteria (staphylococcus aureus and Salmonella enteritidis) and three types of fungus where he was found that the essential oil of green onion led to a decrease in inhibition of bacterial activity when fungal activity was stopped significantly, especially in low concentration.

The onion plant contains two groups of compounds, which form the majority of active substances, sulfur compounds such as Allicin, Allyl propyl disulfide, Flavonoids such as Quercetin. Allicin shows its antimicrobial activity mainly through immediate and total inhibition of DNA and RNA and protein synthesis(18).

Oil products, especially those containing essential oils, may also prevent lice respiration or slow movement, making it easier to remove them from the hair with the soft comb, this is consistent with(19).

It has been suggested that essential oils as an alternative source of insecticide because they are rich sources of biologically active chemicals are commonly used as flavor and flavoring substances for food and beverages(20), because of this emphasis has been placed on plant essential oils or chemicals as potential sources for control of head lice(21). The activity of pesticides from aromatic oils has been well described by(20).

The Turmeric plant was used as a paste for treatment of scabies at the rate of 97% during 3-15 days of treatment and curcumin is the product obtained by dissolving the turmeric extract i.e., the ground rhizomes of Curcuma longa L. (Curcuma domestica Valeton) and purification of the extract by crystallization, it also possesses antioxidant properties(22).

Curcumin was soluble dye in oil and alkalis, stable at high temperatures and in acid, more effective than other spices in its ability to prevent fat peroxidation and its antioxidant effect was eight times stronger than vitamin E(23).

The mixture of vinegar and food salt may be attributed to killing of lice and eggs in the hair of the injured that the acid may work to soften the protective sheath of lice covers and attaches the egg on the hair and this is consistent with(24). The mechanism of action of sodium chloride on lice in laboratory studies is not fully known, but it has been noted that the tear in the digestive system of the lice with the application of food salt and this explains the drought when exposed lice for two hours of sodium chloride and this is consistent with(25).

Conclusions

Use plant raw materials and mix them with more than one substance to get better results in the treatment of pediculosis

Molecular and genotyping for *Cryptosporidium parvum* isolated from children with diarrhea in pediatric hospital of Karbala

Ahmed Hussain Mibder¹, Ghada B. Al-Omashi¹

¹University of Al-Qadisiyah/College of Medicine-Department of Microbiology/Iraq

Abstract

The study involved surveilling sampling of children suffered cryptosporidiosis like symptoms. The present study was conducted on 90 children who suffer from abdominal pain and diarrhea. Samples were collected from patients suspected infection by cryptosporidium who attended in pediatric hospital of Karbala Governorate from January-2019 to May 2019. They were (1 month-5 years old age). Each sample was divided into two parts. The first part was used to prepare a moderate thick smears stained with modified zehil nelson stain(m ZN stain) and the second part was preserved at -20 c for molecular detection by nested PCR to identify the positive samples and genotyping by RFLP-PCR that showed the PCR product analysis of HSP70 gene in *Cryptosporidium parvum* from Human stool samples, at (587bp) PCR product. Some positive samples by RFLP-PCR making nucleic acid sequencing. The main purpose of the current study was to explore the prevalence rate of cryptosporidiosis in the mentioned province targeting children at different age categories of both genders. For the gender and infection by *C. parvum*, the current work findings revealed the presence of *C. parvum* in the sampled children distributed under gender categories of male and female and the species was parvum. The results of the AFS showed that 12 (13.33%) out of 90 samples were positive to the presence of cryptosporidiosis. This technique is a good method for detecting *C. parvum* in stool samples of children in both genders, and 27 out of 90 samples was positive by nested PCR and RFLP-PCR respectively. For the age and infection by *C. parvum*, the current work findings revealed the presence of *C. parvum* in the sampled children distributed under three age categories of 1-6 months, 7-12 months, and 13-60 months. Positive results of the age categories were 5 (29.41%) out of 17 samples, 12 (32.43%) out of 37 samples, and 10 (27.78%) out of 36 samples, respectively. The total infection was 27 (30%) out of 90 samples. No significant (*p* > 0.05) differences were recognized for infection rates occurred for the age categories.

**Keywords:** pediatric hospital; *Cryptosporidium parvum*; diarrhea

Introduction

*Cryptosporidium* spp. is a coccidian protozoan parasite that causes waterborne outbreaks worldwide using the fecal-oral route for the transmission of infection. *Cryptosporidium* is one of the leading pathogens which are responsible of the majority of the diarrheal infections (1).

*Cryptosporidium* is considered as a major diarrheal cause of diarrhea in children and immune-compromised people with high death rates for those under 5 years of age (2).

Diagnosis is made by concentration of stools followed by acid-fast staining (AF), a nested PCR assay was developed to detect *C. parvum* DNA directly from stool specimens, after extraction of DNA from formalinized stool (3).

A polymerase chain reaction (PCR) restriction fragment length polymorphism analysis of a 587-bp region of the *Cryptosporidium parvum* 70-kDa heat shock protein (HSP70) gene was developed for the detection and discrimination of the two major genotypes of *C. parvum* (4).

Studies have recognized using modern molecular technologies some subtype families that can induce wide-spread diarrheal conditions (5).

Infection caused by *Cryptosporidium* spp. is a highly
common parasitic diarrhea known in humans and cattle. However, cases that show no symptoms, asymptomatic, are not well recognized for identification as that in the symptomatic case (6).

**Materials and Method**

**study design**

The study was conducted on 90 random samples of faecal smears of children from the laboratories of hospital Paediatric in Karbala City. The age of children ranged from 1 months to 5 years. The study started from January 2019 may 2019. The modified Ziehl-Neelseen stain (acid fast), used for examination of faecal smears to detect oocysts of Cryptosporidium follows. Smears were fixed with methanol alcohol for 5 minutes and allowed to dry at room temperature. Driedsmears were stained for an hour in carbolfucshin prepared by dissolving 15% carbolfucshin in methanol (stock solution). Ten ml of ZiehlFucshin were added to 90 ml of 5% phenol. Smears were rinsed in tap water and differentiated in 2 % H2SO4 solution for 20 seconds while agitating the slide and rinsed in tap water. Smears were counter stained with 5 % malachite green solution for 5 minutes, washed in tap water and left until dried. Stained smears were examined by using 40 X and 100 X oil immersion objectives. Oocysts were obtained from naturally infected children with acute diarrhoea and proved to be infected with Cryptosporidium as confirmed by M.ZN-ST.(acid fast).

**Molecular detection**

The specimens were stored at 4°C for DNA extraction. Faecal specimens from children with diarrhea whose suspected contained Cryptosporidium

Nexted Polymerase chain reaction (nPCR)

The nPCR technique was performed for detection Cryptosporidium parvum based 18S ribosomal rRNA gene from children samples (1 month to 5 years).

Genomic DNA Extraction (stool protocol)

Genomic DNA from feces samples were extracted by using AccuPrep® stool DNA Extraction Kit, Bioneer, Korea, and done according to company instructions.

Primer

The Nested PCR primers for detection Cryptosporidium spp. based 18S rRNA gene and another Nested PCR primers for genotyping Cryptosporidium parvum based hsp70 protein gene were designed according to (4). These primers was provided from Macrogen company, Korea as following table 1.

1. Direct Isolation of DNA from Patient Stools for Polymerase Chain Reaction Detection of Cryptosporidium parvum.

2. Sensitive genotyping of Cryptosporidium parvum by PCR-RFLP analysis of the 70-kilodalton heat shock protein (HSP70) gene.

**RFLP**

RFLP-PCR technique was performed for genotyping Cryptosporidium parvum based on HSP70 gene. This method was carried out according to described by (4).

RFLP-PCR Technique

RFLP-PCR technique was performed for genotyping
Cryptosporidium parvum based on HSP70 gene. This method was carried out according to described by(4) as following steps:

**PCR master mix preparation**

PCR master mix was prepared by using (AccuPower PCR PreMix Kit) and this master mix done according to company instructions as following table for each gene:

After that, these PCR master mix component that mentioned in table above placed in standard AccuPower PCR PreMix Kit that contains all other components which needed to PCR reaction such as (Taq DNA polymerase, dNTPs, Tris-HCl pH: 9.0, KCl, MgCl$_2$, stabilizer, and loading dye). Then, all the PCR tubes transferred into Exispin vortex centrifuge at 3000rpm for 3 minutes. Then placed in PCR Thermocycler (Mygene. Korea).

**DNA sequencing method**

DNA sequencing method was performed for species typing of positive Cryptosporidium sp isolates as following step:

1- The PCR product of 18S ribosomal RNA genes were sent to Macrogen Company in Korea in ice bag by DHL for performed the DNA sequencing by AB DNA sequencing system.

2- The DNA sequencing analysis (Phylogenetic tree analysis) was conducted by using Molecular Evolutionary Genetics Analysis version 6.0. (Mega 6.0) and Multiple sequence alignment analysis based ClustalW alignment analysis and The evolutionary distances were computed using the Maximum Composite Likelihood method by phylogenetic tree UPGMA method.

3- The Cryptosporidium species typing analysis was done by phylogenetic tree analysis between local Cryptosporidium sp isolates and NCBI-Blast known Cryptosporidium species.

Finally identified Cryptosporidium species isolates were submitted into of NCBI-GenBank to get Genbank accession number.

**Results and Discussion**

Acid-fast stain age based results microscopic

For the age and infection by *C. parvum*, the current work findings revealed. the. presence of *C. parvum*. in the. sampled children distributed under three age categories of <= 1 years, 1 – 3 years, and > 3yeaes, Positive results of the age categories were 7 (13.0%) out of 54 samples, 3 (10.3%) out of 29 samples, and 2 (28.6%) out of 7 samples, respectively. The total infection was 12 (13.3%) out of 90 samples. No significant (p>0.441) differences were recognized for infection rates occurred for the age categories by microscopic.

Indian Journal of Forensic Medicine & Toxicology, January-March 2020, Vol. 14, No. 1

Figure 1: Agarose gel electrophoresis image that showed the Nested PCR product analysis of small subunit ribosomal RNA gene in Cryptosporidium parvum from Human stool samples. Where M: marker (3000-100bp) Lanes (1-10) some positive patients samples at (540bp) PCR product.

Figure 2: Agarose gel electrophoresis image that showed the PCR product analysis of HSP70 gene in Cryptosporidium parvum from Human stool samples. Where M: marker (3000-100bp) Lanes (1-10) some positive patients samples at (587bp) PCR product.

For the infection rates and the age of sampled children, it has been shown identified, using RFLP PCR, that 4.8% of infection was detected in children under the age of 5 years old (the only sampled age category); however, and after performing genotypic characterizations, infection was higher due to C. hominis at 75% than that for the case of infection caused by C. parvum at 25.0%. The current work findings revealed the presence of C. parvum in the sampled children under the three age categories under 5 years old (5)(7) Nigeria. METHODS Stool samples were collected from 165 children aged 0-5 years with diarrhea. Cryptosporidium oocysts were examined by wet mount preparation, using formalin ether and a modified acid fast staining method. DNA was extracted from positive samples using QIAamp DNA stool mini kit and PCR-RFLP assay was carried out after quantification. Genotyping and phylogenetic analysis were done to determine the subtype families and their relatedness. RESULTS From the 165 children studied, 8 (4.8%). Our results agree with (8) who revealed that C. parvum infection rates were higher in children under 5 years of old, 3.15%, than those in older age categories especially students of middle schools, 0.82%. These results can be explained as there might have been an immunodeficiency problem facing the sampled children decreasing immune reaction directed toward C. parvum by the immune cells such as CD3+, CD4+ and CD4+/CD8+ and then resulting in immune response reduction (8).

Conclusion

1. Most of examined to the children from 1 month to 5 years whose suffer from abdominal pain and diarrhea was positive in most cases.

2. The detection of the stool-modified-acid-fast stained oocytes is performed using light microscopy; however, this technique is limited to the identification of the genus level only with no vital information regarding epidemiological properties. Currently, Cryptosporidium can be identified by molecular and genotyped using developed molecular techniques such as nested PCR, RFLP-PCR and nucleic acid sequencing in modern laboratories.

3. Nested polymerase chain reaction technique is the best method than others technique used in diagnosis of cryptosporidium by using specific primer for this parasite.

Hyperlipidemia that Induced in Male Rats and Role of Flavonoids Extract of *Quercus infectoria* in Treatment

Marwa Amer Shakir¹, Iman Nozad Mahmood¹

¹Medical Laboratory Department/University of Al-Qalam College, IRAQ

Abstract

The aim of the study demonstrates flavonoids of *Quercus infectoria* as anti-hyperlipidemia. 20 adult male rats used and divided to four equal groups (each group consist 5 rats); rats received ad libidium, rats were given normal water containing 0.5% of hydrogen peroxide and 1% of cholesterol in the feed for 60 days for induction of hyperlipidemia. Hyperlipidemia rats treated with (50mg/kg/daily) flavonoids, fourth Hyperlipidemia rats treated with (100mg/kg/daily) flavonoids. The results show non-significant changes (P < 0.05) in levels of HMG-reductase compare with control group. in hyperlipidemia rats, levels of malonedialdehyied (MDA) show significant increase (P < 0.05) in and significant decrease (P < 0.05) in levels of glutathione (GSH) and catalase compare with control group. While, after using flavonoids extract in treatment, the results showed non-significant changes (P < 0.05) in HMG-reductase, MDA, GSH and catalase compare with control group. It was concluded that flavonoids extract of *Q. infectoria* extract has been a protective effect in rats with hyperlipidemia.

**Keywords:** Quercus infectoria; hyperlipidemia; HMG-reductase.

Introduction

The plant *Quercus infectoria* Olivier (Family-Fagaceae) grows as a shrub or small tree, diclinous and monoecious. It is about 2.5 m in height with many spreading branches(1). The various Quercus species originated in Iran, Iraq and Turkey, but are now widespread and particularly common in Asia Minor, Europe and North Africa. Galls are irregular plant growth, which is stimulated by the reaction between plant hormones and powerful growth regulating chemicals produced by insects or mites(2). The Gall of Q. infectoria is described in detail in ethnobotanical and literature to possess various pharmacological actions such as analgesic, antidote, anti-inflammatory, antipyretic, antiseptic, antistomatitis, deodorant, derivative, desiccant, expectorant, germicidal, hypnotic, hypoglycaemic, powerful astringent, sedative, styptic, tonic, tonic to teeth and gum, and wound healing(3,4). Flavonoids and the other phenolic compounds are commonly known as plant secondary metabolites that hold an aromatic ring bearing at least one hydroxyl groups. More than 8000 phenolic compounds as naturally occurring substances from plants have been reported(5,6). Its broad spectrum, its biological properties and multiple applications have given rise to interest in investigating their characteristic according their origin. A lot of studies indicate that flavonoids and phenols in propolis can be able to scavenge free radicals in the human body(7-9). So the aim of study is detection of flavonoids role that extracted from *Q. infectoria* against hyperlipidemia in male rats.

Materials and Method

Flavonoid extraction methods

Flavonoid extract was prepared by immersing 100 gm of dried material of *Q. infectoria* in 500 ml ethyl alcohol (100%) for 24 hrs at room temperature using magnetic stirrer(10-12). The mixture was then filtered using Whatman No. 1 filter papers and the process was repeated using the remaining residue with 300 ml ethanol to ensure the complete extraction in each time. The two filtrates were added and treated with 100 ml lead acetate (1%) for 4 hrs for precipitation. The mixture was filtered, then a mixture of 250 ml acetone and 30 ml of concentrated HCl was added to the precipitate, and filtered. The resulting pellet was finally lyophilized (Freeze- dried) at -50o C under vacuum for 12 hrs. The extract was dissolved in ethyl alcohol, the extraction process was repeated for 1 hr, filtered to produce red
filtrate. Finely, the filtrate was placed in a clean and dry Petri dish away from light at room temperature until deep redbrown powdered was obtained.

**Animal model**

Twenty adult male albino rats used in this study, (wt 150-200 gm with age 3-65 month) and obtained from Science college/ Baghdad University, and ensure its normal and there isn’t any infection.

**Experimental design**

Twenty male rats were used and divided as follow (each group consist of five albino male rats):

I. Rats (negative group) were received standard pellet diet only for seven days and then killed to comparison with other groups.

II. Rats (positive group) were given normal water containing 0.5% of hydrogen peroxide (Saudi Hydrogen Peroxide Company (SHPC)) and 1% of cholesterol in the feed for 60 days.

III. Rats with hyperlipidemia and treated with (50mg/kg/daily) flavonoids, and then killed.

IV. Rats with hyperlipidemia and treated with (100mg/kg/daily) flavonoids, and then killed.

**Prepare of blood solution**

The blood collects from rats by cardiac puncher, under anesthesia, and put in test tubes. After clotting, the tubes were centrifugation for 10 min to obtain sera. The serum was taken and stored by deep freezing until used.

**Measurements**

**Determination of HMG - CoA Reductase Concentration**

The concentration of the HMG-CoA Reductase enzyme estimated using My Biosource analysis kit. using Elisa technology.

**Plasma Peroxidation levels (MDA), Glutathione (GSH) and Catalase**

MDA (malonodialdehyied), was measured based on the colorimetric reaction with thiobarbituric acid (TBA) using spectrophotometer\(^{(13)}\). GSH level estimated by mixed 2.3 ml buffer with 0.2ml of the sample and then added 0.5ml of 5,5-dithio-bis-(2-nitrobenzoic acid) (DTNB). The mixture was analyzed by spectrophotometer\(^{(14)}\). Catalase was measured by using the procedure of Biovision-USA kits. All parameters were done on liver extract.

**Statistical analysis**

The Data were analyzed using a statistical Minitab program. A statistical difference between the means of the experimental groups was analyzed using one-way analysis of variance (ANOVA).

**Results & Discussion**

**HMG reductase**

The levels of HMG reductase in positive group show non-significant increase (P < 0.05) compared with control group. The levels of HMG reductase in third and fourth groups show non-significant decrease (P < 0.05) compare with control group as shown in figure (1).

In terms of the enzyme HMG-CoA reductase, the results showed that the concentrations of the enzyme in the group given high cholesterol diet decreased but no significant differences found with the control group. The slight decrease in enzyme concentrations that were not significant with the group could be explained by the fact that the concentration of cholesterol inside the cells is regulated by Internal construction and taking from outside (via diet). Internal construction is done by hepatic HMG-CoA reductase feedback, while the external source is controlled by LDL receptors\(^{(15)}\). About the role of flavonoids to slightly decrees of HMG-reductase may back to its affect lipid metabolism through inhibition of acyl coenzyme A: cholesterol O-acyltransferase and 3-hydroxy- 3-methylglutaryl-coenzyme A (HMG CoA) reductase in rats\(^{(16-17)}\).

**MDA, GSH and catalase**

The levels of MDA (increase), GSH (decrease)
and catalase (decrease) in positive group show high significant changes (P < 0.05) compared with control group. The levels of MDA, GSH and catalase in third and fourth groups show non-significant changes (P < 0.05) compare with control group as shown in figures (2-4).

About the role of hyperlipidemia to increased MDA levels and decreased the levels of GSH and catalase. Anwer et al, referred that the elevated level of LPO is attributed to the enhanced production of ROS\(^{(18)}\). After treatment with flavonoids extract the MDA levels decreased and GSH and catalase levels increased that may back to they protect against oxidative damage by directly neutralizing reactive oxidants\(^{(19)}\). Al-Jumaily et al, referred that the flavonoids pure of Iraqi propolis has led to a reduction of the inhibitory effect as well as for damage to the work of the liver and there by protect members from free radicals and inhibit the liberation of these ROS\(^{(20)}\).

Abstract

**Background:** AMI (acute myocardial infarction) is one of the most common cause of death. In this study, the prognostic value of WBC count in patient with AMI was assessed in 24 hrs after admission. STEMI (ST segment elevation myocardial infarction) is frequently associated with leukocytosis, it is that the peripheral leukocyte count have important prognostic implication in AMI.

**Aim of The Study:** This study conducted to evaluate and measure level of WBC count in patient with STEMI and their effect on cardiovascular outcome.

**Patients and Method:** We have 100 patients (male and female) with mean age (40-80) years admitted to the AL-diwaniyha teaching hospital CCU (coronary care unit) department and peripheral blood sampling taken after 24 hrs of admission and another sample after 1 week and we record the main early and delay squally occurred. Patient that admitted to CCU were confirmed with AMI by clinical features, examination and investigations (ECG with ST segment elevation, positive cardiac troponin).

**Results:** The mean WBC count in all patients was 11.260 ± 3.600 X10³/CC. There is no significant difference in mean WBC count among patients with inferior, lateral and posterior wall MI (P > 0.05); however, mean WBC count was significantly highest in patients with extensive anterolateral MI (P<0.001); followed by patients with anterior MI. Early complications were observed in 52 patients (52.0 %), these complications were in the form of arrhythmias such as VF, VT, AF, heart block and bradycardia and acute heart failure. The most common early complication was VF (32.0 %).

Late complications were observed in 28 patients (28.0 %), these complications were in the form of chronic heart failure or unfortunately death of patients. We noted that patient with high WBC after admission have close relation to more damage and necrotic myocyte an liable for early complications like arrhythmia (VT, VF) and acute HF.

**Conclusion:** WBC count remained a significant predictor of complication after admission for patients with STEMI.

**Keywords:** late complications, patient, Leukocytosis, and myocardial infarction

**Introduction**

AMI the most common form where patient presented acutely in previously asymptomatic patient. STEMI occurs when coronary blood flow decrease abruptly, often thrombotic occlusion of coronary arteries previously affected by atherosclerosis, this injury produces or stimulate by risk factors (age, hypertension, DM, smoking, obesity, sedentary life style, alcohol and hypercholesterolemia). The pathogenesis of atherosclerosis is multifactorial. Broadly, endothelial injury and dysfunction result in the adhesion and transmigration of leukocytes from the circulation into the arterial intima as well as the migration of smooth muscle cells from the media into the intima, thus initiating the formation of atheroma or atherosclerosis.
All myocardium that supplied by the offender artery become ischemic. Resulting in chest pain and ECG evidence of transmural (full thickness) ischemia (ST segment elevation) in the leads reflective of that region of the heart.

Subsequently necrosis begins within minutes and progress during several hours in a wave front fashion from the endocardial surface to the epicardia surface. If ischemia persists for several hours, transmural infarction result. In contrast if blood flow is restored during the period of progressive necrosis, the ischemic myocardium is salvaged and size of infarction is reduced.

More than half of patient with AMI died before reaching the hospital.

To confirm the diagnosis of AMI in addition to ECG changes, positive cardiac biomarkers (troponin I, E — CK, MB myoglobin) may be needed.

This study focusing on leukocytosis as dependent predictor for mortality or adverse cardiovascular outcome in patients with STEMI.

In this setting elevated WBC count play a central role in the reparative process that takes place to replace the necrotic tissues.

Traditionally an elevated WBC count is an indicator of systemic inflammation has been acceptable as part of healing response following AMI.

It has frequently been shown to be a predictor of adverse cardiovascular events in addition to part of systemic inflammatory response that mention.

Elevated WBC count to be a proxy for the intensity of the peri-infarction inflammatory response.

The corner stone of this study shown an elevated WBC count measured during acute phase of MI (24 hrs. after admission) associated with adverse out come.

This relation ship strongly associated with extension of infarcted area. Leukocytosis in STEMI affect on seuality through multiple pathogenic mechanisms that mediate inflammation cause proteolytic and oxidative damage to the endothelial cells ,plug the microvasculature ,induce hypercoagulability and promote infarct expansion ,so leukocytosis is a risk factor for early and future cardiovascular events.

There is significant correlations between the ischemic severity and consequence of acute phase response (leukocytosis).

**Aim of the Study:** this study conducted to evaluate level of WBC count in patients with STEMI and record their effect on outcome that occur in patients with leukocytosis.

**Patients and Methods:** This study was done in CCU at Al-diwaniyah teaching hospital from (January 2018 –December 2018) including patients with STEMI, patients with acute coronary syndrome and ST-segment elevation in the ECG more than (1) mm in limbs leads and 2mm in the chest leads or new onset LBBB.

with elevated cardiac biomarkers especially cardiac troponin I, (patient with ACS without ST- segment elevation was excluded). which confirm the diagnosis by supervisor.

A (100) patients with STEMI were included.

**exclusion criteria:**

Patient with any recent infection ,those with hematological disorders , any chronic disease ,drugs, that causes leukocytosis. Those with non STEMI &females during menses were excluded.

Complete history & physical examination was done for every patient. venous blood sample into the plain tube for CBC was taken immediately after admission.

Another sample was taken after 7-8 days .Early complications that occur during the hospitalization time or late complications that occurs any time after discharge: VT, VF, HF, ventricular aneurism, dead , was closely recorded.

**Results**

In this study there is significant increase in WBC count in patient with STEMI The WBC count mean in all patients was 11.260 ± 3.600 X103/ CC, as shown in table 1. There was no significant difference in mean WBC count among patients with inferior, lateral and posterior wall MI (P > 0.05); however, mean WBC count was significantly highest in patients with extensive anterolateral MI (P<0.001); followed by patients with anterior MI, as shown in table 1.

**Discussion**

In 1974, Friedman et al. (13) first who described the association between WBC count and ACS. They found that an increased WBC count associated with increased risk of developing first AMI. Other studies later on confirmed this observation. Schlant et al. were the first to document an elevation in WBC count as a predictor of morbidity and mortality in patients who survived AMI (14).

Furman et al. (15) examined the association between WBC count and mortality.

Consistent with the findings from the present study.

More recently, Barron et al. (16) examined the association between WBC count and angiographic findings in the thrombolysis state in high TIMI score AMI. They found that patients with a closed infarct-related artery at 60 and 90 minute had a higher WBC count than patients with patent artery. (17)

Many epidemiological studies state that the baseline WBC is associated with increased incidence of AMI and mortality and there is current scientific interest in the prognostic value of the WBC determined during the acute phase of AMI to predict mortality. (18)

These findings are in agreement not only with this study, but also with other studies of other inflammatory markers as CRP and IL-6 elevations of which appear to primarily predict death rather than recurrent ischemic events (19). The basis for this till now unknown, but the early divergence of the cumulative mortality curves suggests that patients with an elevated WBC count have a higher risk of death from the index event (20).

Many explanations have been proposed to state this association: resistance to thrombolytic therapy due to alterations in the microcirculation, hypercoagulable state, a no-reflow phenomenon caused by leukocytes, indirect cardiotoxicity mediated by proinflammatory cytokines, promoters of ischemia-reperfusion injury, and lastly expansion of the AMI. Regarding this final point, it is important to bear in our mind that the leukocyte response that occurs following AMI is a central part of the inflammatory cascade which initiated to replace the necrotic tissue with fibrosis and scarring. This fact may suggest that the greater the amount of necrosis, the larger the leukocyte response, an assertion based on experimental studies that show a direct relationship between the extent of necrosis and the level of both the local and the systemic leukocyte response. (21)

In clinical settings, the extent of AMI is usually estimated using indirect parameters. Thus, various studies have related the WBC to various association with the size of the AMI: the development of heart failure, significant correlations with the peak level of isoenzyme MB of creatine kinase (CK-MB), or with left ventricular ejection fraction. (22)
In this study, WBC acted as an independent predictor of early and late complications. This finding provides indirect evidence in favor of an independent role for WBC in the pathogenesis of post-AMI complications.

Suggest that WBC is a useful and valid biochemical tool for risk prediction of patients with AMI. The neutrophils rule in animal models of ischemia-reperfusion(23)

the findings of this study and finding of Barron et al are consistent with the fact that WBCs may in some way be linked to the cause of the increased. In animal models of ischemia-reperfusion, neutrophils appear to lead to infarct expansion. In a canine model of AMI, neutrophil depletions was associated with a marked reduction in infarct size. The mechanism by which neutrophils cause this damage is unclear. Engler et al. and others state that reperfusion after prolonged ischemia leads to progressive leukocyte capillary plugging and the —no refow phenomenon. This plugging seem to be results in part from neutrophils binding to the ischemic endothelium via the leukocyte integrin CD11b/CD18 (Mac-1) receptor .Three animal studies have demonstrated that treatment with an antibody to the CD18 receptor on neutrophils reduces infarct size (24)

Conclusions

The finding of the current study showed that leukocytosis in patient with STEMI was significantly associated with high rates of mortality in short term follow up also more over the risk of in-hospital death .

Abstract

Toxoplasma gondii is a very common obligate intracellular parasite with highest infection rate among world populations. The Rheumatoid arthritis (RA) considered as an autoimmune disease characterized by loss immunological tolerance to self-antigens. Present study Aims to detection the seroprevalence of toxoplasmosis among RA patients and healthy control and evaluate concentrations of IL-33 to understand their role during infection. Seropositive cases of IgG was 36.7% percentage in RA patients with highest value of IgG 0.395 IU/ml while control group was 100% seronegative. Three cases only were seropositive to IgM with 1.17% and their mean 0.54 IU/ml.

IL-33 levels in RA patients with toxoplasmosis was highest 187.74± 33.24 pg/ml when compared with RA patients 107.88±18.41 pg/ml and control group 55.59±25.75 pg/ml ,there was a significant differences in comparison between studied groups.

Key words:- Toxoplasmosis, Rheumatoid arthritis, IgG, IgM, IL-33.

Introduction

Toxoplasmosis is a common obligate intracellular protozoan parasite zoonotic disease infectious by Toxoplasma gondii, classified as a Coccidia and phylum Apicomplexa (1). All or most marsupials and mammals can serve as intermediate hosts, while several Felidae, enrolled domesticated cats, are the final hosts for T. gondii (2). Human infection generally happened by uptake raw uncooked meat which have cysts (or possibly tachyzoites). animals, including herbivores can be infected by eating vegetables and plants contaminated with oocysts. However, infections can be transmitted through placenta from mother who suffered from infection during pregnancy (3). Infection leading to encephalitis in the fetus, cerebral calcification and mental retardation or psychomotor, T. gondii may be transmitted by transplanted organs or transfused blood (4).

The primary or secondary infections with Toxoplasma gondii can mimicry immune response and make change in the immune response to generate autoimmune disease including autoimmune thyroid diseases, inflammatory bowel disease, systemic sclerosis and rheumatoid arthritis (5,6). Rheumatoid arthritis is an autoimmune disease described by inflammatory polyarthritis of small and big joints, can cause major disability and uneasiness (7). That affects approximately 0.5% to 1% among adults a worldwide (8-9). The pathogenesis of this infection is multifactorial including genetic and ecological factors (10). It is identified by peripheral joints progressive inflammatory synovitis, cartilage damage, corrosions of bone and production of autoantibodies like rheumatoid factor and antibodies of the anti-citrullinated protein (10).

The present study was aimed to evaluate levels of interleukine 33 (IL-33) in patients with rheumatoid arthritis and infected toxoplasmosis infected which diagnoses by anti-Toxoplasma antibodies including IgG and IgM seroprevalence

Material and method

Study subjects

Study was implemented as A case-control study to identify the IL-33 role in the prevalence of T. gondii seropositivity in rheumatoid arthritis patients. samples were collected from patients attending to the department
of Rheumatology in Baghdad and Al-Kindi Teaching Hospitals in Baghdad province, in addition to outpatients clinics according to ethical approval of environmental and health ministry of Iraq. During March to July 2018, samples included 256 of rheumatoid arthritis patients that treated with methotrexate (207 females and 49 males) their age ranged from (15 – 65) years with a mean (40.77± 1.5), and healthy individual consisting of 50 person of healthy people (16 females and 34 males) did not suffer from any pain in the joints and didn’t have a satisfactory history of any autoimmune diseases.

serological testing

About five ml of venous blood were collected from patients and control groups in gel tube, its left at room temperature for 15 minutes then its centrifuged for 5 min at 3000×g . serum were collected in eppendorf tubes and stored at - 20.

The clinical diagnosis of rheumatoid arthritis implemented specialist physician in addition of clinical examination and several laboratory tests including Rheumatoid Factor (RF) (Biosysmeme, Spain) and C- Reactive Protein test (CRP) (Spinract, Spain). The T. gondii antibodies including IgG and IgM were analyzed using ELISA kits (Bioactiva, Germany).

Interleukin level was determined by a commercially available human ELISA kits for IL-33 (Peprotech, USA).

The Statistical Analysis System- SAS (2012) program was used to data analysis. The data was shown as percentage (%) and mean ± standard deviation (SD) and standard error (S.E.). Differences between means were assessed by Least significant difference –LSD test, at the probability level of 0.01 and 0.05 to assess the differences between the study groups.

Results and Discussion

The results of present study were shown that 36.71% were seropositive cases of IgG in 94 patients with RA compared to 162 seronegative cases at 63.2%, while the control group was 100% seronegative. High significant differences recorded between studied groups (p≤0.001) (table 1). The infections of Parasitic may encourage immunomodulatory variable impacts and control of autoimmune disease.

The most interesting association of T. gondii with other diseases is with rheumatoid arthritis. In humans, T. gondii infection may cause a symmetrical polyarthritis of the minor joints of hands, fingers, wrists and knees, as well as T. gondii may be implicated in autoimmune disease through acting as a ligand for toll-like receptors (TLRs).

In the current study, the relation between toxoplasmosis and RA in Iraqi patients was been recognized by the detection of antibodies IgG and IgM in sera of the studied groups by ELISA test. ELISA is an precise serological tool for the diagnosis of toxoplasmosis dependent on Ag - Ab interaction. The reaction can be evaluated objectively by quantization of the color that advanced by an ELISA reader. This technique is economical and also suited for analyzing large number of samples at the same time. The present study is agree with Kuba et al. which found that the seroprevalence of T. gondii IgG and IgM antibody were 33.33% and 20.40% respectively in RA patients treating with methotrexate, and 36.00% and 8.00% in RA patients without treatment, while it was 12.00% and 24.00% in healthy control. Salman and Mohammed found in Kirkuk city that the percentage seroprevalence of toxoplasmosis of IgG and IgM were (47.54% - 6.55%) respectively in RA patients. El-Henawy et al. showed that Anti-Toxoplasma IgG antibodies were positive in (76.7%) of patients with RA versus controls (48.3%), they suggested that higher seroprevalence of anti-Toxoplasma IgG antibodies in RA group refer to correlation between latent Toxoplasma infection and RA. Conversely, other study, show no significant difference of IgG levels which found between RA group and controls and T. gondii infection might be an incidental result.

The elevated seroprevalence of anti-Toxoplasma IgG antibodies in RA group may be expected as a result of diverse cooking methods and oocysts ability to live in different weathers in addition of a close association with cats. An increased risk of T. gondii infection in patients suffered from rheumatic diseases can be share in to changes in innate and adaptive immune responses. The Patients of RA were located to be highly vulnerable to T. gondii infection - particularly throughout periods of immunosuppression that followed treatment with TNF-α inhibitors. The Patients of RA were located to be highly vulnerable to T. gondii infection - particularly throughout periods of immunosuppression that followed treatment with TNF-α inhibitors.

</table>
of the elevation of rheumatoid factor (RF) titers in serum and synovial fluid is a characteristic feature of RA and perhaps implicated in pathogenesis of this disease (21). Rheumatoid factors are autoantibodies with specificity for the Fc portion of IgG and may be formed in multiple iso-types (22). The results of the test rheumatoid factor were similar with El-Henawy et al. (16) who found the mean of patients of rheumatoid arthritis with toxoplasmosis of 46 patients to be 74.01±8.62 (IU/mL), while the mean of patients without toxoplasmosis was 64.56±3.09 (IU/mL) represented 14 patients.

There is another possible marker for increasing the danger of rheumatoid arthritis, is a C-reactive protein (CRP), which one of the acute phase reactants that increase in inflammation response (23). The results of the current study were agree with Salih (24) which recorded in a study that women in the Kurdistan region suffering from rheumatoid arthritis and all samples were positive for the RF and CRP tests. These autoantibodies are linked with T. gondii especially when they are of high rates (25).

Table (4) shows that the level of IL-33 in the group of RA cases infected with toxoplasmosis was high levels with highly significant differences than other groups.

The Interleukin-33 (IL-33) is reported as one of cytokine of IL-1 family, which can be induced cytokine syntheses and inflammatory responses mediated through its receptor ST2. It is expressed in several tissues and cells like liver, lung, central nervous system also epithelial, endothelial, smooth muscle, macrophages and fibroblasts cells (26). The pathway of IL-33/ST2 have major role in defense of host and in immune organization in inflammatory and infectious diseases (27). IL-33 have capability to elevated the Th2 immune response and lowering the production of Th1 cytokines (28) also it plays major role in innate and adaptive immunity (29). The gene of IL-33 is located in chromosome 9 (30). Mature IL-33 mediate its biologic effects via T1/ST2 binding by activating NF-xB and MAP kinase (31). The present study is agree with AL-Shamma (32) which showed a highly significant increase IL-33 in concentrations in sera of toxoplasmosis female
of Iraqi patients compared with the healthy control. This finding may indicate that toxoplasmosis might influence cytokine production in these patients (33).

Treatment of Induced Lead Toxicity by using DMSA in Puppies

Omar-Althani Shareef Saed¹, S. M. A. AL-Kubaisi², Jassim Mohamed Suleiman¹, Mustafa Salah Hasan²
¹Department of Internal and Preventive Veterinary Medicine, College of Veterinary Medicine, University of Tikrit, Iraq, ²Department of Internal and Preventive Veterinary Medicine, College of Veterinary Medicine, University of Fallujah, Iraq

Abstract

To determine efficacy of DMSA in treatment of sub-chronic lead exposure in dogs, fifteen puppies aged 2-4 months from both sexes were used for experimental induction of lead toxicity. These puppies were adapted for two weeks and divided randomly to three groups, each group contain five puppies; Group 1 which was regarded as negative control; Group 2, this group was drenched 15mg/kg of lead acetate daily for sixty days; Group 3, this group was drenched 15mg/kg of lead acetate daily for sixty days then were treated with DMSA 10 mg/Kg twice daily orally for one week. These animals were clinically examined daily till the end of experiment, then whole blood, bone, liver and brain were collected for estimation the lead concentrations. The results showed presence of several signs after 15 days of exposure which included depression, diarrhea, tremor then these signs subsides after 7 days of treatment with DMSA. Also, the results presented a significant increasing in the concentrations of lead in liver, blood, bone and brain in group 2 as compared with control group, after treatment with DMSA, group 3 showed a significant decrease in lead concentrations in liver, blood, bone, and brain as compared with group 2. In conclusion, DMSA is an effective therapy for clinical cases of lead toxicity.

Key words: DMSA, Puppies, Lead, Toxicity.

Introduction

Lead is a toxic type of heavy metal causes an adverse effects on the GIT, nervous system, also, cardiovascular, urinary and hematological systems, the main mode of action is interrelation of lead affinity with proteins (¹).

Lead poisoning affects thousands to millions of children in many countries which may lead to many biochemical and some neurological dysfunctions (²), and it is commonly occurs via oral route by consumption a contaminated water, leaded paint and ingestion of leaded particles mainly the young dogs that have strange eating habits (³).

The dose of lead that can do the adversarial effects in dogs fluctuates, but 1 mg/kg bw/day of lead acetate can be regarded as a LOEL causing increase in blood pressure after ten days from exposure (⁴).

Rosenman et al. (⁵) stated that colic may combine with other signs such as constipation, vomiting, abdominal pain, cramping, nausea, anorexia, sometime diarrhea and weight loss.

Succimer (DMSA) is one of the most antidotes that used in cases of poisoning by heavy metals especially lead. The main advantage of DMSA is its high effectively when used orally because it is solvable in water (⁶).

Due to importance of lead toxicity in dogs, this study was aimed to induction of lead toxicity in dogs and evaluate the efficacy of DMSA in treating the lead toxicity.

Materials and Method

A Fifteen healthy puppies with same age (2-4 months) and both sexes were adapted for 2 weeks before initiation the experiment. These fifteen dogs were divided into 3 groups, each group have 5 animals:

a. Group 1 (Control): this group regarded as control negative.
b. Group 2 (Pb): this group was drenched orally with lead acetate at 15 mg/ kg per day for sixty days according to Faustman et al. (7).

c. Group 3 (DMSA+ Lead): this group was drenched orally with lead acetate at 15 mg/ kg/ day according to Faustman et al. (7) for 60 days then was treated orally with 10 mg/ Kg DMSA twice daily for one week.

**Clinical examination**

Clinical examination was carried out along the period of experiment for all dogs every day for any changes in appetite, presence of diarrhea or any other symptoms and every 2 weeks the pulse rate, rectal temperature and respiratory rate were examined.

**Lead level measurement:**

Specimens were taken for lead level measurement including whole blood, bone, liver and brain of all animals at the end of experiment (day 68), the tissues preserved by freezing immediately after collection, Lead analysis done by adding 20 ml of nitric acid and one ml of concentrated H$_2$SO$_4$ to digest 1g of tissues then heated at hotplate until foams appeared then 3 ml of nitric acid and 1ml of HClO$_4$ were added without roasting the sample then the volume was completed to 100 ml by using deionized water then the concentration was estimated by Atomic Absorption Spectrophotometer according to (8).

**Statistical Analysis**

All data were examined according to (9).

**Results**

Puppies were monitored daily for development of some clinical signs such as depression, diarrhea, dehydration and other signs. All lead treated puppies showed different degrees of depression appeared after day fifteen till to the end of experiment. Lead treated puppies showed slight decrease in appetite and many lead treated animals showed mild diarrhea and some showed tremor and aggressive behavior after 30 days of lead exposure. After treatment with DMSA, all puppies improved after 7 days of treatment and showed a normal signs. All puppies showed a normal temperature, pulse and respiratory rates before and after lead exposure till the end of experiment.

The results of estimation lead concentrations in different tissues showed that the concentrations of lead in liver, blood, brain and bone were increased significantly in group 2 as compared with control group (G1) , after treatment with DMSA, the group 3 showing a significant decreasing in the concentration of lead in bone, blood, brain and liver as comparing with group 2 (Table 1; Fig. 1,2,3,4).

![Figure 1: Lead concentration (ppm) in blood of all groups at the end of experiment](image1.png)

![Figure 2: concentration of Lead (ppm) in bone of all groups at the end of experiment](image2.png)
Due to presence of lead sources like leaded gasoline, leaded paint, improper dispose of battery and other sources and lead poisoning have accumulative nature, the risk of lead poisoning of human and animal in Iraq considered high level and its effects ranged from hypertension to death, depends on the dose, rout and body status.

The presented study showed that all lead treated animals exhibit different degrees of depression which appeared after day fifteen and extended to the end of experiment. The presented results were in compatible with results of Fewtrell et al. \(^{(10)}\) who showed that lead interfering with neurological functions in all stages of the life at low levels, and may cause many signs ranged from blindness to encephalopathy that causing dullness, muscular tremor and headache. Puppies showed slight decrease in appetite and eight out of twenty lead - treated animal showed mild diarrhea after 30 days of lead exposure. The current results were similar with results of Rosenman \(et\ al.\) \(^{(5)}\) which showed that colic may combine with other symptoms such as pain of abdomen, constipation, vomiting, cramps, anorexia, nausea, sometime diarrhea and loss of weight. GIT signs happen at blood lead concentration of 100-200 µg/dL, but sometimes associated with level between 40-60 µg/dL.

During lead exposure period, all puppies showed no shafting change in body temperature, pulse rate and respiration. Due to continues low dose of sub chronic exposure of lead there is no shafting change in temperature , pulse rate and respiration and these results are in agreement with those of \(^{(11)}\) which showed that signs occur in association with higher doses or increasing the exposures length. The lead toxicity doesn’t related to the route of exposure and it is depending on blood lead levels.

DMSA is non-toxic, water-soluble, when orally-administered may act as metal chelator, so that it can be used as antidote for heavy metal toxicity \(^{(12)}\).

Ramsey \(et\ al.\) \(^{(13)}\) showed that in dogs that treated with succimer (10 mg/kg B.W., PO, q 8 h) for 10 days, mean blood lead concentrations decreased 53.6, 76.2, and 60.9% from pretreatment value on days 3, 7, and 20, respectively, while, mean urine lead concentrations on days 0, 3, 7, and 20 were 70.0, 485.4, 254.3, and 28.3 micrograms/dl, respectively, they concluded that dogs with lead poisoning, when treated orally with DMSA for ten days it effectively reduced the lead concentrations in blood and absence of lead poisoning signs.

Studies in human with lead poisoning showed that DMSA rapidly increase the urinary excretion of lead, also in persons with low exposure to lead it give a significant improving \(^{(14)}\). An increasing the excretion of lead in urine is due to chelation therapy of DMSA. In a study of Graziano \(et\ al.\) \(^{(15)}\) which done to establish the DMSA therapeutic dose, it showed a 28-fold increase was seen in excretion of urinary lead after the first five doses.

In a study done to estimate blood and brain lead after DMSA treatment, they concluded using of DMSA to reduction of lead concentrations in brain \(^{(16)}\).

In conclusion, DMSA is a good therapeutic agent for treatment lead toxicity in human and animals.

Study the Effect of Humidity Variable on the Patient with Jaundice Stay Period inside the Incubator

Auns Q. Al-Neami¹, Yasser Ibrahim², Husam Yahya Naser³

¹Biomedical Engineering Department, College of Engineering, Al Nahrin University, Baghdad, Iraq,
²Iraqi Ministry of Health, Directorate of Medicine City/Iraq, ³Biomedical Engineering Department, College of Engineering, Al Nahrin University, Baghdad, Iraq

Abstract

In this study, a DHT22 sensor was used based on the Arduino platform for the purpose of measuring and monitoring the humidity in the incubator during the period of treatment of new-borns suffering from jaundice. This system was adopted because it has a range of advantages that make it accessible to researchers as it does not need a highly experienced or specialist operator because it is easy to use as well as low-cost. The use of this system provides continuous and real monitoring of the humidity in the incubator to help determine the effect of humidity on the treatment period of the child with jaundice in the hospital. In addition, checking the level in the humidity error and the difference between the required moisture and the actual moisture recorded.

Keywords (Jaundice, Humidity, and sensor)

Introduction

Jaundice which is a disease during which excess bilirubin accumulates in the blood, so the newborns are at raised risk of jaundice. When the newborn with jaundice let without treatment, which will result in neurological impairment and death. Jaundice ensuing from unconjugated bilirubin is well treated with exposure to blue light (1).

Immediately after birth, the newborn moves to a completely new environment that is radically different from the mother’s womb environment, an environment that is not sufficiently protected compared to the womb and is initially unsuitable for a child’s life due to the changing factors surrounding the newborn, especially the moisture factor.

If the relative humidity inside the incubator was increasing, so that will be reduced the loss of water for the skin of the premature new-borns and act as a contributed factor to the maintenance of his corporal temperature (2).

The early days of new-born life are a watershed in his life, because the daily evaporation loss of preterm infants can reach 20% of the body mass, and by increasing air humidity within the incubator, this loss can be reduced. The skin evaporative exchanges between the neonate and the environment are directly proportional to the water vapour partial pressure difference between the new-born’s skin and the air (3).

Thus it should give a healthful hydrothermal environment to decrease the risk of body hypothermia or hyperthermia for newborn infant (4).

The process of measurement the humidity of the therapeutic environment and so understand the perfect conditions for the treatment process is one among the most necessary things that should be of high interest, because it’s an excellent link between the conditions and factors related to the treatment method, and therefore facilitate the study of the impact of humidity alone or combined with different factors in effecting on diagnosing and treatment method.

The Arduino system is considered one among the simplest and most versatile electronic solutions in terms of easy use and speed of learning still as low price of producing components as well as simple to connect and programming by computers, additionally the availability of those electronic components in the local markets, permitting the research worker to work in a very wide
space of ideas to dynamical developing and therefore let to get output a lot of comprehensive solutions and optimality.

The main goal of this study is to manufacture an easy system which will provides a precise perception of measurement the humidity within the incubator and therefore facilitate to calibrate and determine the appropriate degree of treatment.

Theory

Neonatal jaundice is one among the foremost common conditions needing medical attention in newborn babies. About 60% of term and 80% of preterm babies develop jaundice within the 1st week of life, and concerning 10% of breastfed babies are still jaundiced at age one month. Neonatal jaundice is usually harmless, however high concentrations of unconjugated bilirubin could occasionally cause kernicterus (permanent brain damage) (5).

Neonatal jaundice is common, as a result of physiological jaundice or breastfeeding. In some neonates, unconjugated bilirubin concentration, in addition to different risk factors, is sufficient to permit free bilirubin to cross the blood-brain barrier and cause kernicterus. Another subgroup of infants is jaundiced as a result of elevated conjugated bilirubin; a marker for several pathological conditions. Bilirubin measuring should determine those infants in danger (6).

Materials and Method

The hardware and software are the main components of this technique, the hardware consists of two elements that are the AM2301 thermal sensing element and also the Arduino Uno platform.

The incubator was in the hospital which has its heat supply, through this sensing circuit the temperature of incubator is measured during treated the newborn with jaundice.

DHT21

The AM2301 thermal sensing element, that sensing digital humidity which contains the compound that has been calibrated the digital signal output of the humidity sensor. Application of a dedicated digital modules collection technology and also the humidity sensing technology, to make sure that the merchandise has high reliability and wonderful long-term stability. The sensing element includes a capacitive sensing element wet components and a high-precision humidity measuring devices and connected with a high-performance 8-bit microcontroller. The merchandise has wonderful quality, quick response, sturdy anti-jamming capability, and low price. The shape of procedures, the standardization coefficients hold on within the microcontroller, the sensor among the process of the heartbeat to call these calibration coefficients. Standard single-bus interface, system integration fast and simple. Small size, low power consumption, signal transmission distance up to twenty meters, creating it the most effective selection of all types of applications and even the most demanding applications. Product for the 3-lead (single-bus interface) connection convenience. Special packages in keeping with user wants (7). Fig. (1) Illustrates the DHT21 sensor.

Fig. (1) The configuration of DHT21 sensor.

Arduino Uno

The Arduino Uno has shown in fig. (3) utilized in this study, that is a microcontroller board grounded on the ATmega328 (datasheet) was chosen as the microcontroller for this study. This was a perfect choice, as the processor is extraordinarily strong and cost-effective. It contains of 14 digital input/output pins (out of that 6 is utilized as PWM outputs), six analog inputs, a 16 MHz ceramic resonator, facilitation for USB connectivity, a power jack, an ICSP header, and a button. Its styles comprise of help that supports the microcontroller in each possible way. To induce to figure with it one has to merely connect it to a computer with a USB cable or power it with an AC-to-DC adapter or battery (8).
Discussion

The incubator is considered an artificial womb and will have the most vital effect of protecting newborn. One of the most important duties of the incubator is to control the humidity of the newborn to achieve thermal neutrality, which is achieved by control humidity stability in the incubator. However, this study shows that there is a large swing in the humidity from one to another, although the fixed value is the same, and that is due to the difference in efficiency of each incubator parts because of its operational life and its ability to work such as heat source and heat radiator and efficiency of thermal insulation of the incubator walls, In addition to the external effect of room humidity on the humidity of the incubator.

This work opens the way for comprehensive study on the conditions affecting the humidity in the incubator to design an ideal incubator that provides ideal conditions that will help to actually reduce the treatment period for patients with jaundice.

Conclusions

The concluding observations of this study explain the effect of the humidity which is the most popular variable affected on the patient stay period in hospital.

It was clearly found that the performances of the fixed environment factors including temperature, humidity and other factors in the mother’s womb will disappear immediately after birth. This situation places the newborn in a state of sudden environmental change which requires a necessary and quick adaptation. The child who cannot cope with the new environment and if the mother is different in the blood group and RH factor in addition to children who born before 37 weeks (pre-term) the baby will suffer from jaundice disease.

It is clear that the patient stay period of the children with jaundice inside the incubator was closely related to the incubator’s high humidity percentage, for example the humidity of the incubator of the children who had
been cured in a short period varied between 1 and 3 days were at its lowest rates of 43.16% and at its highest rates of 50.6%

It was found that the speed of recovery for children with jaundice which the humidity percentage in its incubator environment is higher than those no closer to the humidity of the mother’s womb. This is due to the thermal regulation of the newborn inside the incubator is closer to the degree of the mother womb.

Prevalence and Classification of Maxillary Canine Impaction among Iraqi patients at An-Najaf City

Sarmad M. Hamozi 1, Kareem M. Alghanim1, Yahya Abdali2
1Lecturer, College of Dentistry, Alkafeel University, Iraq, 2Assist. Prof, College of Dentistry, Misan University, Iraq.

Abstract

Canines play an important role in functional occlusion, occlusion protection and in aesthetic smile. So the proper knowledge of permanent canine impaction incidence and its position is essential before orthosurgical procedures. The aim of this study is to highlight the prevalence and difficulty of the treatment of maxillary impaction canine. A 1995 panoramic radiographs were taken, total number of males were 737 (37%) and 1258 (63%) were females, a 79 (3.9%) patients were diagnosed with canine impaction where females were 3.6 times more than males, also most patients diagnosed with unilateral, right-sided and type II impactions.

Keywords: Maxillary canine, impacted canine, classification

Introduction

An impacted tooth is any tooth that fails to erupt into the oral cavity and occupies its proper anatomical position after completion of its root formation. Maxillary canine represents the second most common form of impaction after wisdom teeth(1,2,3). The prevalence of canine impaction ranging from 0.27% in Japanese population(4) to as much as 7.5% among Saudi people(5). females seem to be affected by 2.3-3 times more than males(4,6,7,8). Panoramic radiographs assist in localization of impacted canines in antero-posterior position in relation to adjacent teeth, classification of maxillary canine impaction described according to the long axis angles of canine with occlusal plane(9). So understanding the location and angulation of maxillary impacted canine is important in the treatment plan for both oral surgeons and orthodontics for proper flap design and approach and orthodontic appliances and techniques. The aim of this study was to determine the prevalence of maxillary impacted canine and its classification among sample of Iraqi people.

Materials and Method

This retrospective study collected data from 1995 panoramic radiographs for patients aged 16-37 years old who had attend oral and maxillofacial radiology center in An-Najaf city. All the panoramic radiographs were examined for the presence of impacted maxillary canines that fails to erupt into oral cavity in the future. All the impacted maxillary canines were matched to the seven subtypes of Yamamoto et al (9) classification system according to the long axis angles and occlusal plane [figure 1]. The collected data were analyzed in relation to gender, side either unilateral or bilateral, right or left and classification.

Results

Among 1995 panoramic radiographs there were 737 (37%) males and 1258 (63%) were females, the patients diagnosed with impacted maxillary canines were 79 (3.95%) patients. Females represented the highest proportion of impaction 62 (4.9%) patients compared to males 17 (2.3%) [table 1]. Table 2 described the unilateral impaction (72%) was higher than bilateral impaction (28%) in both males and females. The highest impaction matched type II (53.46%) followed by type IV (27.22%), type I (17.82%), type III (0.99%) and there were no cases for type V,VI and VII in this sample. Also this study reported that the right side of maxilla was highly affected by impaction than the left side [table 3].
Figure 1. A diagram represents the classification system of maxillary canine impaction. Teeth 2, 3 and 4 represent lateral incisor, canine and first premolar, respectively.

**Discussion**

The current study had shown the prevalence of impacted maxillary canine of 3.9% that lied within the range of other studies that had shown as 0.27% among Japanese (4), 2.1% among Chinese (10), 2.4% among Italian (6), 5.1% among Turkish (11), 5.4% among Hungarian (12) and 7.5% among Saudi population (5). This variation in proportions indicated that the incidence of maxillary canine impaction varied among different ethnic populations. There are many factors contributing to the impaction of maxillary canine as late maxillary canine tooth germ development and its long path of eruption also the delay in its eruption accompanied by increasing bone density and pressure from surrounding bony cavities such as nasal and orbital cavities and maxillary sinus (13). Although the first premolar tooth germ developed later than canine tooth germ, its eruption earlier than canine due to its short path of eruption in comparison to the long path of eruption of canine, so the space between lateral incisor that erupted earlier to them and first premolar must be maintained to facilitate eruption of canine (14). This study reported unilateral impaction (72.15%) was more common than bilateral impaction (27.85%), this result was in agreement with other studies (5,16,17). The current study reported a higher right side impaction than the left side impaction and this finding was confirmed by Altaee ZH study (18). This study reported that type II canine impaction was more predominant followed by type IV, type I and type III respectively and it was in agreement with Hassan AL-Zoubi et al (16) study. Canines play an important role in both occlusal stability and aesthetics so giving a complete picture - for oral surgeons and orthodontics according to population - about their prevalence and type of impaction is essential for proper treatment plan.

**Conclusions**

The prevalence of impacted maxillary canine is 3.9% among sample of Iraqi population. Females are more affected by impaction than males by 3.6 times. Unilateral impaction is more common than bilateral impaction, and the right side is more affected by impaction than the left side. Type II maxillary canine impaction represents the majority of impactions followed by type IV, I and III respectively.

The Efficacy of Chlorhexidine Gel as an Adjunctive Treatment for Patient with Chronic Periodontitis

Ban Zuhair Ahmad
Department of Periodontics, College of Dentistry, AL-Essra University College, Iraq

Abstract

Background: chronic Periodontitis is considered to be an inflammatory disease and is characterized by the damaging the connective tissue and supporting bone due to secondary infection by periodontal bacteria. Chlorhexidine has been used in the dental practice as an excellent antiplaque agent. Chlorhexidine not only exhibits special property of substantivity, it also possesses a broad antimicrobial spectrum which makes its use in wide variety of oral disorders. Virtually all disciplines of dentistry make use of this material in different formulations like mouth wash, gel, spray, varnish, and restorative material.

Aims of study: The aim of this study was to evaluate the clinical effectiveness of locally delivered Chlorhexidine gel as an adjunctive therapy to scaling and root planing in treatment of chronic periodontitis.

Material and methods: five patients with chronic periodontitis were selected. Pocket depth between 4 and 6 mm was selected and the patient had two sites on his mouth (splitting mouth). A total of 17 control sites were scaled and root planed and 17 test sites were scaled and root planed and Chlorhexidine gel was added. The clinical parameters, probing depth (PD), clinical attachment level (CAL), plaque index (PI) and bleeding on probing (BOP), gingival index were recorded at baseline, 1 week, 2 weeks and 4 weeks.

Results: From baseline to a period of 4 weeks, significant difference was found between test and control group for PD, CAL, PI and BOP.

Conclusions: Subgingival injection of Chlorhexidine gel adjunct with scaling and root planing appeared to cause significant improvement compared with scaling and root planing alone in persons with chronic periodontitis.

Keywords: Chlorhexidine gel, chronic periodontitis.

Introduction

Periodontal disease is an inflammatory condition initiated by a bacterial infection which affects the supporting structures of the teeth. The first stage of the disease is plaque-associated gingivitis (inflammation of the gingivae), which is a reversible inflammatory condition characterized by redness and swelling of the gingivae and a tendency for the gingivae to bleed easily. It is caused by the accumulation and persistence of microbial biofilms (dental plaque) on the teeth. In susceptible individuals, gingivitis may lead to the second stage of periodontal disease which is periodontitis. Periodontitis is an irreversible condition where inflammation of the gingivae is accompanied by connective tissue destruction and loss of the periodontal ligament and alveolar bone supporting the tooth. If untreated, periodontitis may ultimately lead to tooth loss. Chronic periodontitis, formerly known as adult periodontitis or chronic adult periodontitis, is the most prevalent form of periodontitis. It is generally considered to be a slowly progressing disease. However, in the presence of systemic or environmental factors that may modify the host response to plaque accumulation, such as diabetes, smoking, or stress, disease progression may become more aggressive. The use of adjuvant chemical antibacterial agents is considered an important complement to mechanical oral hygiene techniques, both those performed at home, as well as those performed in a professional setting, especially in cases where the patient is unable to maintain an acceptable standard of...
oral hygiene, or when surgical procedures represent a contraindication. (4)

**Chlorhexidine**

It is a bisbiguanide base, is a cationic antiseptic with broad-spectrum antibacterial activity (against Gram-positive and Gram-negative bacteria and certain mycetes). Consequently, it has been extensively studied in medical settings as an antiseptic compound. (5) The bactericidal action is more effective against Gram-positive cocci and weaker in case of Gram-negative ones. There is also a moderate activity against some mycetes, but not against viruses and alcohol-resistant bacilli. (6) The efficacy of CHX is not limited to its antiplaque effect, but extends also to its substantivity, which allows the molecule to remain attached to tissues and have an antibacterial action lasting for 8-12 hours making it possible to reach the minimum effective dose required to inhibit plaque formation, even with very few daily administrations (7). This property comes from CHX’s ability to bind mucins, proteins forming the salivary film covering teeth and oral mucosa surfaces: the CHX cationic portions can bind to the mucin carboxylic segment, which is negatively charged. (7) CHX inhibits bacterial colonization and is slowly released as it is displaced by the calcium ions secreted by the salivary glands. (8)

The antibacterial action of CHX is, therefore, most likely the result of an immediate bactericidal action, followed by a prolonged bacteriostatic action, due to its ability to attach itself to the enamel surfaces. (7)

**Materials and Method**

A total of 34 sites diagnosed as suffering from chronic generalized periodontitis attending the clinic at the Department of periodontics in College of Dentistry/AL-Issra University. All five patients were informed about the purpose of the study and their consents were provided prior to their enrollment into the study. The Exclusion criteria included: any chronic systemic disease, pregnancy, and smoking, use of antibiotics and/or anti-inflammatory drugs within the last 3 months, the Presence of periodontal pocket depth (PPD) sites located on the same side PD between 4 to 6 mm.

**Clinical procedure**

A special preform (stent) was designed for the present study so as to have a systemic and methodical recording of all the observation and information. The sites were divided into two half, one half of the mouth is control sites and the other half is test sites Fig. (1).

![Figure 1: examination kit.](image)

Control sites: 17 sites were treated by scaling and root planing alone.

Test sites: 17 sites were treated with scaling and root planing followed by the placement of the 30ml CHX gel (PRIOKIN) in the periodontal pocket.

The following parameters were recorded at baseline (day 0), 1 week, 2 weeks and 4 weeks using a Michigan “o” probe with marking of 1,2,3,5 by a single examiner:

- Gingival index (GI)
- Sulcus bleeding index
- Plaque index (PI)

The following parameters were recorded at baseline (day 0), and 4 weeks using a Michigan “o” probe with marking of 1,2,3,5 by a single examiner:

- Probing pocket depth - measurement to the nearest millimeter of the distance from the gingival margin to the depth of the pocket
- Relative clinical attachment level (CAL).

After recording all the parameters at the baseline, full mouth scaling and root planing was performed using ultrasonic instruments followed by hand instruments until all supra and subgingival root surfaces felt hard and smooth.

Following debridement, target sites were irrigated gently with cold saline to achieve hemostasis prior to placement of CHX gel (PRIOKIN) and it was applied into the deepest portion of periodontal pocket by means of a thin rounded tip needle.
Results

Probing pocket depth (P.I)

In control sits (table 1), the P.I mean showed a gradual decrease from 1.047± 0.212 at baseline to 0.993±0.595 at 1 week, 0.899±0.899 at 2 weeks and 0.793±0.489 at 4 weeks but however, there was no significant difference (p˃0.05) between the baseline and the 1, 2 weeks but significant difference between the baseline and the 4 weeks. The overall mean total of P.I in control sits was 0.933±0.112.

In CHX sits, the P.I mean showed a gradual decrease from 1.262± 0.439 at baseline to 0.918±0.552 at 1 week, 0.393± 0.552 at 2 weeks and 0.311±0.463 at 4 weeks and there was significant difference between the baseline and 1 week, 2 weeks and 4 weeks. Moreover, there were significant difference between the 1 week with 2 and 4 weeks but not between the 2 and 4 weeks. The overall mean total of P.I in CHX sits was 0.721±0.450. The mean of P.I in CHX treated sits was significant difference (P ≤0.05) when compared to the mean of P.I in control sits fig (1).

Table 1: Clinical parameters assessments (PI, GI and BOP%; Means ±SD) of patient control / treated with Chlorhexidine gel (CHX) examined on 1, 2 and 4 weeks.

Figure 2: Overall PI values (mean ±SD) of patient control and treated sits with Chlorhexidine gel (CHX) during the study
Gingival index (G.I)

The G.I mean (table 1) of the control sits decreased from 1.158±0.365 at the baseline to 1.109±0.772 at the 1 week and to 0.523±0.499 at the 2 weeks and to 0.095±0.293 at the 4 weeks, however there was no significant difference between baseline and the 1 week but a significant difference between baseline and 2,4 weeks. The results also showed that there were significant difference between the 1 week with 2 and 4 weeks and between the 2 weeks with 4 weeks. The overall mean total of G.I in control sits was 0.821±0.507.

The G.I mean (table 1) of the CHX treated sits decreased from 1.081±0.274 at the baseline to 0.868±0.664 at 1 week and to 0.180±0.384 at 2 weeks and 0.098±0.297 at 4 weeks. This decrease was significant difference when the baseline compared to 1 week, 2 and 4 weeks. However there was no significant difference between 2 and 4 weeks. The overall mean total of G.I in CHX sits was 0.557±0.491.

The mean of G.I in CHX treated sits was significant difference (P ≤0.05) when compared to the mean of P.I in control sits.

Bleeding index (B.O.P)

The results of the control sits (table 1) in this study showed that B.O.P was 10% and decreased to 8% at 1 week while at 2 and 4 weeks the values were 0%, no significant difference was observed between baseline and 1 week but a significant difference between the baseline and 2,4 weeks.

In the CHX treated sits the data at the baseline was 25% and decreased to 16% at 1 week and to 0% at 2,4 weeks no significant difference was observed between baseline and 1 week but a significant difference between the baseline and 2,4 weeks. On the other hand, both the control and treated sits showed no significant difference was observed between baseline and 1 week but a significant difference (0.05) when the baseline and 1 week compared to 2 and 4 weeks.

Clinical attachment lose CAL

The results (table 2) for the control sits showed a significant decrease from 5.240±1.068 at the baseline to 2.520±0.805 at 4 weeks, while the CHX treated sits also showed a significant decrease from 4.833±0.897 at the baseline to 2.222±0.415 at 4 weeks (table 2).
Table 2: Clinical parameters assessments (CAL and PD; Means± SD) of patient control / treated with Chlorhexidine gel (CHX) examined on baseline and 4weeks

Probing pocket depth (P.D)

Table 2 showed the results of P.D values in control and treated sits, in control sits the value was significant decrease from 5.125±0.619 at the baseline to 2.823±0.856 at 4 weeks. While the P.D values in CHX treated sits showed a significant decrease from 4.529±0.499 at the baseline to 2.176±1.464 at 4 weeks. Table 2 also showed that there were no significant difference between the values of control and CHX treated sits at 4 weeks of the study in both C.A.L and P.D.

Discussion

Chlorhexidine mouth rinsing is ineffective in eliminating a microbiota located beneath the gingival margin. Subgingival irrigation using chlorhexidine solution or even gels turn out to be effective in the treatment of periodontitis presumably due to its ability to retain biologically significant concentration of chlorhexidine for sufficient length of time within the confines of periodontal pocket (9,10). The studies have reported the treatment of periodontal pocket with chlorhexidine irrigation as an adjunct to scaling and root planning, provides a significant improvement in probing depth and reduces the microbial load. (11) The local delivery of CHX gel in periodontal pockets enhances the effect of scaling and root planning, thus CHX gel application shows long lasting (up to 90 days) favorable effects. (12)

In this study the CHX gel is supplied with a special needle having a blunt tip to facilitate the application of the gel without traumatizing or damaging the periodontal tissues. Periodontal probing is one of the most widely used diagnostic tools for the clinical assessment of connective tissue destruction in periodontal disease. Increased PD and loss of clinical attachment are pathognomonic for periodontitis and hence, serve as primary parameters in diagnosis of periodontal disease and evaluation the success of periodontal therapy. The significant reductions observed in plaque and gingival scores from baseline the results of this study are consistent with the results observed by Vinholis (13), when they evaluated the effect of subgingival irritation with a 0.2% CHX collagen gel in periodontal pockets as an adjunct to scaling and root planing. Mizrak observed similar reduction of probing pocket depth with both the group that were treated either by scaling and root planing alone or scaling and root planing with controlled release CHX chip. (14)

Mechanical debridement with subgingival chlorhexidine gel application provide significantly greater improvements in periodontal parameter compared to those obtained by scaling and root planing alone in the treatment of chronic periodontitis. (15) The bleeding upon probing (B.O.P) is a periodontal parameter evaluating the probability of periodontal disease progression. The result of the study are consistent with the findings of Heasman (16) who observed mean reduction of bleeding index score from baseline to the 4 weeks in the site (scaling and root planing with CHX gel) as well as control site (scaling and root planing alone). The result is similar to the results observed in the present study.

This study is considered a non-surgical treatment of chronic periodontitis and the results are similar to those obtained in the study done by Vadiati in 2017 (17) who observed that injection with CHX gel with scaling and leveling of the root surface resulted in a greater improvement in periodontal clinical indices than SRP alone.
A study done by Manthena, et al to compare the effectiveness of CHX varnish and gel and conclude that Subgingival application of highly concentrated CHX varnish and gel following SRP is beneficial in reducing microbial count in moderate to deep periodontal pockets.

**Conclusion**

1. Chlorhexidine gel when applied topically, significantly reduces the clinical parameters (plaque, gingival and bleeding index)

2. Can be highly recommended as an adjunctive treatment for chronic periodontitis.

Iron Overload Estimation by Oral Exfoliative Cytology in Beta Thalassemia Major Patients Undergoing Repeated Blood Transfusion

Anaam Mahdi Hadi 1  Layla Sabri Yas 1
1Department of Oral Diagnosis, College of Dentistry, University of Baghdad/Iraq

Abstract

β-Thalassemia major patients require regular blood transfusion therapy lifelong this lead to iron overload in the body tissues, which is a major cause of morbidity and mortality in these patients. Exfoliative cytology, a non-invasive and inexpensive technique based on microscopic evaluation of epithelial cells after a procedure of their fixation and staining. The aims and objectives of this study were: 1. To estimate iron overload by oral exfoliative cytology using Perl’s Prussian blue stain in β-thalassemia major patients. 2. To correlate Perl’s Prussian blue staining positivity with their serum ferritin levels. Smears were obtained from buccal mucosa of 60 β-thalassemia major patients (who had taken ≥10 transfusions) and 30 healthy subjects of the same age group (5-26) year. Smears were stained with Perl’s Prussian blue stain kit. Blood samples were taken from the study and control group at the same time for estimation of serum ferritin levels. Grading criteria were defined for assessing the Prussian blue positivity. Perl’s positivity was observed in 48 out of 60 of thalassemic patients (80%), with a positive correlation to serum ferritin levels. Perl’s Prussian blue staining of exfoliated cells from buccal mucosa can be used to assess iron overload in β-thalassemia major patients, as a screening tool.

Key words: β-thalassemia major, iron overload, exfoliative cytology, perl’s Prussian blue

Introduction

Beta-thalassemia syndromes are a group of hereditary blood disorders characterized by reduced or absent beta globin chain synthesis (1). β-Thalassemia major also known as Cooley’s anaemia. The recommended treatment for thalassaemia major involves lifelong regular blood transfusions, usually given every two to five weeks, to maintain the hemoglobin level above 9–10.5 g/dl. Long term transfusion has multiple complications (2). Iron stores in the body exist primarily in the form of ferritin (3). Ferritin is a positive acute phase response protein whereby concentrations increase during inflammation and thereby no longer reflect the size of the iron store (4). Transfusional iron overload develops in patients with chronic anaemia who need to have regular blood transfusions. About 250 mg of iron is the unit of transfused blood, while only about 1 mg of iron that the body excreted per day (3) (5). Hemosiderin deposits in the liver, heart, endocrine glands and lungs of the affected patients (2). Iron deposits have also been found in the gingivae (6) (7). Serum ferritin, Serum iron, iron-binding capacity, Serum non-transferrin bound iron, Bone marrow biopsy (Perl’s stain) for iron within reticuloendothelial stores, Liver biopsy (parenchymal and reticuloendothelial (RE) stores), Liver CT scan or MRI and Cardiac MRI (T2 * or Ferriscan technique) are methods used to monitor iron overload status and effect of iron chelation therapy in these patients (8).

Exfoliative cytology is painless, bloodless, noninvasive, quick and simple procedure (9). it based on microscopic evaluation of epithelial cells after a procedure of their fixation and staining. There are 2 methods in use: the indirect cell collecting method, such as aspiration subjects with Self exfoliated cells, and the direct method, rub cells of mucosal surface (10). This study is an attempt to measure iron overload in those patients by means of exfoliative cytology, an inexpensive technique (11).

Aims and Objectives

1. Assessment of iron overload in beta thalassemia major patients by oral exfoliative cytology using perl’s
Prussian blue stain.

2. Correlation of Perl’s Prussian blue staining with serum ferritin levels.

**Materials and Method**

This cross sectional study was conducted in Ibin Albaladi hospital for gynaecology, obstetric and pediatrics -thassemia center, in Baghdad during the period from January to April 2019. Sampling sessions were limited to the hours between 9:00 and 11:00 AM, data about diagnosis and number of transfusions were taken from patients’ files.

The present study comprised of 90 subjects, with an age range of (5-26) years of both gender, broadly classified into two groups:

1. study group comprised of 60 beta thalassemia major patients
2. Control group: comprised of 30 clinically and hematologically healthy individuals

**Inclusion criteria:**

1. Patients aged (5-26) year, receiving regular blood transfusion ≥10 transfusion.
2. Patient was included based on confirmation by hemoglobin electrophoresis.
3. Control group: clinically and hematologically healthy individuals, in the age range (5-26) years. Subjects selected on the basis of history, clinical examination and blood investigations within normal range.

**Exclusion criteria:** subject with history of any other major illness and newly diagnosed cases yet to receive blood transfusion. Control subjects should have no confirmed acute and chronic liver damage, malignancy, megaloblastic anemia, iron deficiency anemia, and hepatitis.

**Sample collection.**

Patients from the study group and the control group were asked to rinse their mouth with distilled water to remove any debris. Buccal mucosa of the patients was cleaned by guaze and then cells from buccal mucosa were collected by using interdental brush. Scraping were placed on the middle of clean and dry frosted glass slide and spread over a large area to avoid clumping of cells. Slides then placed in coplin jar containing 70% ethanol alcohol for fixation and transferring to laboratory for staining by iron staining kit (abcam 150674).

The smear was first examined at x10 lens followed by examination at x40 lens to study the presence or absence of intra cytoplasmic blue-colored iron granules.

Ten high power fields (objective lens x40) fulfilling the following criteria were chosen for grading purpose:

1. Evenly dispersed cells with minimal overlapping.
2. Minimum 20 epithelial cells and maximum 30 cells per high power field(x40).

The images were captured with a camera attached to the microscope. All the images of the cells were captured with x40 achromatic objective. Captured Images were stored on the computer and analysis was done using the software image J software version 1.52 a. An average of findings in 10 high power fields (x40) were taken and accordingly, appropriate grade assigned.

- Grade 0 - No granules
- Grade I – less than 5 granules/high power field
- Grade II—5–10 granules/high power field
- Grade III—10–20 granules/high power field
- Grade IV—Clumps seen in less than 3 high power field
- Grade V—Coarse granules or clumps seen in 3 or more than 3 high power field.

Venous blood was collected at the same time of taking exfoliative cytology from study and control groups, the sample were centrifuged at 4000 rpm for 20 min to get clear supernatant. then serum ferritin were estimated in the hospital by VIDAS® Ferritin which is an automated quantitative test for the determination of ferritin in human serum or plasma using the Enzyme Linked Fluorescent Assay technique using ferritin kit (bioMérieux).
Figure 1: Perl’s Prussian blue staining of squamous epithelial cells from buccal mucosa showing blue intracytoplasmic iron granules, counter stain used is nuclear fast red stain, positive control tissue used is bone marrow.

Statistical analysis

Data analysis was performed using statistical package (SPSS) ver. (22.0), Chi square test was applied to compare the control and study groups, Analysis of variance (ANOVA) was used and F-test calculated to correlate the buccal smear positivity with serum ferritin levels.

Results

In this study 48 (80%) patients out of 60 in the study group showed positivity for the Perl’s Prussian blue staining in the exfoliated cells of the buccal mucosa. Maximum number of patients, 22 (36.6%) out of 60 had Grade IV positivity, followed by 13 (21.6%) patients having Grade III while 8 (13.3%) patients was Grade II, 3 (5%) patients having grade V, 2 (3.3%) patients having grade I and 12 (20%) patients have grade 0 (negative for perl’s Prussian blue staining). All 30 subjects in the control group (100%) were negative for Perl’s Prussian blue stain. Chi square test was applied to compare the Perl’s staining of the control and study groups. It was found to be statistically highly significant at 1% level of significance (p value > 0.001).

In order to correlate the buccal smear positivity with serum ferritin levels, ANOVA was used and F-test calculated. The comparison of buccal smear grades of the study group was made with their respective mean serum ferritin levels. This was again found to be significant at 5% level of significance implying that buccal smear grades correlated with the mean serum ferritin levels, as shown in table(2):

Discussion

Blood transfusion therapy being the major cause of iron overload in thalassaemia major. When thalassaemia major patients receive regular blood transfusion, iron overload is inevitable because the human body lacks a mechanism to excrete excess iron \(^{10}\).

In this study, exfoliated cells from the buccal mucosa of 48 of the 60 thalassemic patients (80%) group revealed positivity for Perl’s Prussian blue reaction. Further, it was observed that none of the control subjects showed Perl’s Prussian blue positivity. These results of Perl’s Prussian blue staining positivity were similar to Gururaj and Sundharam et al study (2004) who reported 100% Perl’s positivity in the 10 patients that they examined \(^{14}\), Nandprasad et al study (2010) who observed 65% Perl’s positivity (65 out of 100 patients), Bhat et al study (2013) who reported 71.7% positivity (43 patients positive out of 60), Chittamsetty et al study (2013) who observed 72.5% (29 out of 40 b-thalassemia major patients) and Gupta et al study (2014) who observed 61.6% Perl’s positivity (37 out of 60 cases) \(^{15-18}\). Leekha et al study (2016) who found Values to be positive in 35 (87.5%) out of 40 patients \(^{19}\), And Gajaria et al. study (2017) who observed 98% perl’s positivity (49 out of 50 cases). In the present study, result is higher than of Nandprasad et al. study (2010), Bhat et al. study (2013), Chittamsetty et al. study (2013 and Gupta et al. study (2014), but lower than Gururaj and Sundharam et al. study (2004) and Gajaria et al. study (2017). This variation in positive results can be attributed to the difference in the total sample size of various studies as well as the varying mean serum ferritin levels of the respective patients in the studies \(^{11}\). Also comparison between the study and control group Perl’s Prussian blue staining implied that positivity in the study group was not by chance. Thus, there was a strong association between the thalassaemia patients who were undergoing repeated blood transfusions and suffering from hemosiderosis with their buccal smear iron stain positivity. This proved that iron does accumulate in squamous epithelial cells of buccal mucosa in hemosiderosis and these cells can be scraped to assess iron overload. The controls were healthy and did not suffer from iron overload explaining their negative results. The negative reaction in study group even in spite of high serum ferritin levels in those patients can be explained by either fault in the technique of staining or already shedding of the affected squamous epithelial cells. The excess amount of iron that gets accumulated in various tissues is dependent upon various factors including the formation of iron storage pool. Moreover, amount of ferritin formed in exfoliated buccal cells, may vary, which may invariably affect the Perl’s positivity \(^{11}\). When hemosiderosis occurs, iron accumulates in reticuloendothelial macrophages first and only later spills over into parenchymal cells \(^{20}\). It was observed that the grade of buccal smear positivity correlated well with the serum ferritin levels of these patients and therefore this simple, non-invasive test can be used to monitor iron overload in patients taking regular transfusions.

Nandprasad et al study. And Chittamsetty et al study. Had included the patients with 15 or more number of blood transfusions in their study \(^{15-17}\). In Gajaria et al study (2017), Perl’s Prussian blue positivity was observed even with the number of transfusions being (12), in this study positivity observed with (10) transfusions implying that this test can be used as a screening modality also, besides regular monitoring. Most of these patients were on chelation therapy, yet Perl’s Prussian blue positivity was detected in their buccal smears further validating the usefulness of this test.

The various factors affecting the iron overload in this subset of patients are number of transfusions, age of initiation of iron chelation therapy, whether taking the chelation therapy regularly, socioeconomic status, nutritional deficiencies and other associated comorbidities.

Studies to compare the Exfoliative cytology Perl’s Prussian blue positivity with liver biopsy, T2* MRI of liver/heart, MUGA scan (Multigated acquisition), liver dry weight iron need to be conducted. Also a co-relation of this test with clinical manifestation of iron overload in various organs needs to be done.

Conclusion

Perl’s Prussian blue reaction can be utilized as an objective indicator of iron overload in β-thalassemic patients with high levels of iron overload.

Perl’s Prussian blue staining of exfoliated cells from buccal mucosa can be used to assess iron overload in β-thalassemia major patients, and as a screening modality to detect iron overload in patients yet to start chelation therapy. With the grading system we can even give a
semi quantitative assessment of the same. Since these grades correlated positively with the respective serum ferritin levels, it can be used to monitor iron overload in those Patients.

The Incidence of Contrast Induced Nephropathy-Acute Kidney Injury after cardiac catheterization in Basra Cardiac Catheterization Center. A Prospective Cohort Study

Alhasan Mujtaba¹, Mohammed Abbas Taher¹, Hayder Kadhum AlRubay², Mazin Abed Hazza³, Hasan Mohammed AlRubaye⁴, Hamid AbdulWahab⁴, AbdulAmeer AbdulBari³

Abstract

Introduction: Patients who opt for coronary interventions to help them with their IHD problems face several adverse reactions; the most frequently faced is acute kidney injury from contrast media exposure or contrast induced nephropathy. Those patients have higher mortality and morbidity both in the short and longterm period. The incidence of this adverse reaction in Al-Basra Cardia Center is poorly studied so far. We measured the incidence of AKI in this center and tried to correlate the risk with some important covariates identified by previous researches. Method: this was an observational prospective study. It was a part of the double blind single center study (the effect of spironolactone on the incidence of AKI in patients with Stable IHD admitted for coronary intervention, trial registration: ClinicalTrials.gov NCT03329443). Results: The overall incidence of CIN was 20.2% in this cohort sample. Priori defined high risk variables were tested in univariate logistic regression, and if found to be significant they were to be added to a Multi-Logistic regression model analysis. In Regression analysis only GFR (Log Odds ratio) [0.984 (0.971-0.998)] and Mehran Risk score [Mehran >6 (2.456(1.335-4.519), Mehran >11 (3.931) Mehran >16 (12.366) compared to Mehran <5) were positive in the model analysis. Conclusion: there seems to be a high incidence of AKI in this cohort. Important significant factors include low GFR and a good correlation with Mehran risk score.

Key words: AKI, Acute Kidney Injury, CIN, Contrast Induced Nephropathy, Angiography, PCI, Percutaneous Coronary Intervention, IHD, Ischemic Heart Disease, CI-AKI, Mehran risk score

Introduction

Contrast induced nephropathy-Acute Kidney Injury (CIN-AKI) is a well-established complication of coronary angiography or any procedure involving the administration of Intravenous Contrast Agents regardless of the type (1–5)

Affected patients have higher cardiac and non-cardiac adverse events post procedure including and not limited to mortality even in patients without practical clinical manifestations or a need for dialysis or follow up (6–11)

Our Basra Cardiac center is relatively new opened since 2012 and the incidence of CIN-AKI in our center is not rigorously identified as far as we know.

Method

This study was a prospective cohort study at Al-Basra Cardiac Catheterization (Iraq-Basra) between September 2017 and June 2018. The study protocol was reviewed and approved by the institutional review board in the hospital and Baghdad University. All patients gave an informed consent to be included in the study.

Four hundred ninety patients were prospectively followed up that composed the total study group of our study population (the effect of spironolactone on the incidence of AKI in patients admitted for coronary angiography). Patients’ inclusion and exclusion criteria along with detailed trial design and rationale is reported previously (12).

Briefly, Patients’ demographic data were prospectively collected at admission date by researchers
using a prespecified datasheet and is called upon on day 2-3 for further interview and data collection. Coronary angiography/plasty were done by a senior cardiologist according to an established local and global (American College of Cardiology/American Heart Association) standard practice via the femoral approach (13).

The use of CIN prophylaxis was left to the treating physician but whoever received a pre-angio protocol and/or an isotonic fluid after were carefully collected by the research team.

A suitable amount of blood was taken from each patient immediately prior to the procedure and 2-3 days later. Measured parameters included serum creatinine at admission and after 2-3 days, serum Potassium at admission and after 6 hours later. CIN was defined according to K-DIGO guidelines as an increase of 0.3mg/dL or more than 0.25% elevation of Serum creatinine from baseline within 2-3 days of the procedure.

Statistical analysis

All statistical analysis was done using IBM SPSS Statistics 23. Continuous variables were recorded as Mean ± Standard Deviation (SD); categorical variables were recorded as a percentage (%). Normally distributed data were compared using suitable parametric tests. For any deviation from normality, a variable will be subject to a suitable transformation or switch to non-parametric tests. Logistic regression and model analysis was done for analysis of the effect of specifically predefined covariates on the incidence of CIN in the selected group. A p-value of 0.05 was set to be significant.

Result

The overall incidence of CIN was 20.2% in this cohort sample as shown in figure 1. Patients with AKI had a higher Serum Creatinine after 2-3 days Figure 2. They also tend to have a lower GFR [96.54(19.57) vs. 77.24 (21.31)], received more massive amount of Dye [248 (142.32) vs 208 (133.99)], especially more than 150 ml per procedure [71.28% vs. 63.07%], more probably having DM, congestive heart failure, a higher Mehran risk score and an initial Serum Creatinine at presentation, Table 1.

</table>
Interesting to note that the incidence of AKI did not depend on the type of procedure (PCI vs. Angiography), and type of artery involved in the intervention.

Drugs during the periangio period include ACE inhibitors and hydration that were not associated with either an increase or a decrease in AKI incidence, while there was a negative influence in patients taking Metformin on the incidence of AKI in this cohort.

All previously mentioned risk factors in our analysis were added to a Logistic regression model analysis as shown in figure 2. In Multivariate Logistic Regression analysis only GFR (Log Odds ratio) [0.984 (0.971-0.998)] and Mehran Risk score [Mehran >6 (2.456(1.335-4.519), Mehran >11 (3.931) Mehran >16 (12.366) compared to Mehran <5) remained positive in the model analysis.

### Table 1. Baseline characteristics of patients with and without CIN

| Hypertension | 332 (89.49 %) | 84 (89.36 %) | N.S. |
| DM | 122 (32.88 %) | 48 (51.06 %) | S |

Discussion

The main finding in our study is that there is an alarmingly high rate of CIN in this trial cohort. Several reports have calculated the risk of CIN in various populations including the higher risk sample (patients admitted for coronary intervention). The risk is usually low and correlate well with Mehran risk score (≈ 3% in low risk groups and up to 60% and more in high risk groups) (4,14,15).

The overall risk in our trial was around 20%, and this is higher than most of the reported incidence in the global centers (2-14%) (14,15). On further analysis patients from Iraqi population might have a similarly high incidence as a similar study in Babil Center has demonstrated a higher risk (40% in a small cohort sample, Mehran score was not reported for an appropriate comparison). Another study was done in Erbil center and reported an incidence of 13% which is also high but come within the high range of some reported incidences in global centers (16,17). Similar high rates (23%-31%) were also have been reported in nearby Iraqi centers (18–20).

Many possibilities could be the basis of this reported outlier. First, this trial cohort has a relatively higher Mehran risk score than the populations usually tested in similar studies reported in the literature. A study by Taher et al. in Egypt has reported an overall incidence of 13%, but the majority of its cohort (84.5%) were in the low risk category. Compared to our cohort which has only 44% in the same risk category. Interesting to note that the incidence of AKI in our low risk group was 12% which is an excellent approximation to the Taher et al. trial (4).

Such high percentages might be due to the lack of using preventive measures at the time of PCI (21–25). The use of hydration before and after the procedure is a well-known prophylactic procedure given liberally to almost all patients at the periPCI time (22–28). Our sample of patients came fasting for at least 8 hours before the procedure. Such fasting may aggravate dehydration and compromise the already defective renal parenchyma during a period of toxicity or ischemia and augment the toxic effects of contrast agents on the nephrons (7,8,28,29). Some of our patients received post procedure I.V. fluid, and they are also given oral fluid after the procedure. Those who received I.V. fluid (mostly because of PCI related issues) had a decreased incidence of AKI but unfortunately not significant because of the low sample size (no. of patients who received post contrast hydration was only 31 patients with an estimated CIN of 13%) incorporated in our analysis.

Mehran risk score was widely accepted as a standard risk score to calculate and manage the risk of AKI in order to apply a suitable preventive measure in selected high risk patients (15,30). This trial tried a similar analysis given the considerable reduction in power (this sample were around 500 patients, and Mehran et al. used more than 5000 patients to develop the model). We analyzed each factor in Mehran score individually and then the complete final score at last (1).

Individual risk factors that were associated with AKI include (DM, HF, S.Cr>1.4 and contrast media over 150 ml/procedure) this cohort did not receive Intraaortic balloon pump counterpulsation (IAPB), nor they had significant hypotension at the procedure. These risk factors were previously described by Mehran et al. as an independent risk factors for the development of CIN (15).

All individually significant risk factors along with Mehran risk score were added to a multivariate logistic regression analysis to define the independent power of each factor alone given the interaction with other factors. In this analysis, only Mehran risk score and GFR remained significant after correction for other covariates in the analysis. This results contrast with a similar study by Shams-Eddin et al who reported that contrast type, volume of contrast above 400 and Age above 65years were the only predictors of CIN. Shams-Eddin et al. did not show any significant effect of Mehran score with CIN, but again the majority of the studies population were in the low range (Mehran <6) score. This study population had a higher sample size (490 compare 200 for Shams-Eddin et al.) and a significant proportion of this cohort were in the mid-High risk range as well (4).

Conclusion

There seems to be a high incidence of CIN-AKI in this trial cohort and the risk correlate well with Mehran risk score.

Evaluation of the Correlation Between Vitamin D3 Serum Level, Age, gender and BMI in Rheumatoid arthritis Patients in Al- Kut City/Iraq

Ameerah M. Zarzoor1, Wafaa Sahib Hamza2, Zaidon T. Al-aqbi3
1Middle Technical University/Technical Institute/ Kut/Iraq, 2Al-diwaninya Health Department / Ministry of Health/ Iraq, 3Plant Protection Department- College of Agriculture- University of Misan/Iraq

Abstract

Rheumatoid arthritis (RA) is an auto-immune disease a chronic characterized leading to joint loss (RA) disease affects nearly 1% of the world. This study is aimed to determine the effect of age, gender and vitamin D level on the efficacy of RA. One hundred and twenty patients (twenty male and one hundred female) with RA in this study were divided, into groups according to their age. Vitamin D levels were measured in the serum using the enzyme-linked immunosorbent assay (ELISA) blood test. Assessment of the relationship between disease severity and average level of vitamin D was examined by the scale of scores in different groups with rheumatoid arthritis. At p<0.05, significant levels of the above tests have been detected. The current study indicates there is a significant relationship between overweight high underweight below (18.5) BMI and age rate (26-36) patients with RA with deficiency of vitamin D level in serum. The results showed a highly significant difference between patients’ gender groups in as compared disease severity, female more than male with RA disease.

Keywords: Rheumatoid Arthritis, Vitamin D3, Age, gender, Body Mass Index (BMI)

Introduction

Rheumatoid arthritis (RA) is an immunomodulatory disease that results in erosion, synovial soreness, and damage to the bone, leading to a direct effect on the joints [1]. Premature diagnosis and therapy are pivotal in reducing the damage of this disease, but the cause of this disease and causing rheumatoid arthritis are still unclear. Both genetic and non-genetic elements (like ecological, infectious, and hormonal components) may be the main cause of disease outbreaks [2]. It is one of the most severe diseases affecting about 1% of the world population. This disease is characterized by chronic pathway, unpredictable flares with severe pain that causes disability [3]. Vitamin D is one of the most important ecological risk agents associated with rheumatoid [4]. It is considered as a one of the most significant vitamins in cartilage and bone metabolism. The low concentration of vitamin D in the body has a negative effect on calcium metabolism, bone density, matrix staining, osteoporosis and articular cartilage [5,6]. In all patients with RA, the deficiency of vitamin D is common. Studies have confirmed that the deficiency of vitamin D increases the risk of RA [6]. However, the effect of vitamin D deficiency on pathogenesis of various illness is provocative. Vitamin D that was first recognized in the 1920, a lipid-soluble vitamin [7] is vital for neurodevelopment and neuropsychiatric disorders [8]. It is one of the four vitamins dissolve in fat (A, D, E, and K) stored in body tissues, also called calciferol. Vitamin D is generally used to describe two specific terms (vitamin D2), ergocalciferol (vitamin D3), and cholecalciferol. Vitamin D3 is made in the body when exposed to ultraviolet rays (from the sunlight), is a hormone with steroidal structure, regulates the calcium homeostasis, and bone formation with reabsorption through kidneys, parathyroid glands and bowel while vitamin D2 is a naturally occurring vitamin that is found in plants [9-10]. Vitamin D is the only vitamin that can be manufactured by the human body. About 90% of (vitamin D3) of human requirement reliance on endogenous productions (stimulation by exposure to U.V sunlight) and exogenous sources (principally reinforced foods, diet,) to biological necessities of vitamin D [11].
proliferation the vital role played widely known by vitamin D in them. Another indicator shows that the receptors of vitamin D affect important parts of the brain, such as immune and nerve integrity, and maintain control of proliferation, which acts as a regulator of the proliferation and differentiation of brain cells, which enters the growth of the brain. Vitamin D has various substantial roles in many vital processes such as cellular growth and differentiation, metabolism of calcium, bones, cardiovascular and immunity functions. The main potential risk influences for vitamin D deficiency may comprise age more than 65, in many studies the association among vitamin D deficiency and different diseases both observational and randomized trials have been reported.

**Materials and Method**

One hundred and twenty random cases from patients with RA (Twenty men and one hundred women) ranging in age from 15 to >70 years at Al-Kut Government/Iraq, were divided to many groups according to their age, gender, BMI and Vitamin D concentration. They have been classified into three groups shown below accordant (IOM) as:

1. (> 30 ng/mL) sufficient
2. (20–30 ng/mL) insufficient
3. (< 20 ng/mL) deficient.

They were diagnosed by a rheumatologist. The weight and height were measured in an examination room. Body mass index (BMI) was calculated as (weight (kg)/height (m2)). The level of vitamin D in the serum was measured through by ELIZA after taking a blood sample of 5 cc.

**Statistical Method**

Percentages and Frequencies were equated through the use of three groups of vitamin D with Chi-square analysis. Associations between vitamin D concentrations and disease severity, and BMI in various groups with RA. The considerable level of the mentioned examinations was fixed at p<0.05. The results were studied by using the Statistical Package for Social Sciences (SPSS) version 17.5.

**Results and Discussion**

In this study, we have enrolled 120 patients including (100 women), women comprised 83.3% of the study participants while (20 men) patients comprised 16.7, and a healthy volunteer as controls mean of age (31.1±6.2) years in the RA patients, the mean duration of the disease was of 5 years. There was no significant difference between age and sex groups (p> 0.05). Mean of the 25-OH Vitamin D conc. was 47.65±21.80 nmol/l in RA patients, 93.60±61.82 nmol/l in the healthy volunteer controls (n = 20). We found that the average of the 25-OH D vitamin conc. of the patients (RA) was meaningfully less high than that of controls (p < 0.01). Concerning the (BMI) for patients with RA, in this study, we have recorded a high overweight percentage and the largest proportion in sample was (71.7 %) while underweight percentage was recorded as below (18.5) BMI in patients’ low percentage were composed (5%) as an out total number of the study sample as summarized in Table 1.

Considering the frequencies and percentage, Table 2 presents the sample characteristics as age, gender, body mass index, and their vitamin D3. Findings depicts that the (28.3%) of study sample are within second age groups (26-36) years old. Regarding gender, most of the study participants were female, it constituted (83.3%) out total number. In regarding with Vitamin D3, most of the study sample (47.5%) were deficiency as (< 20 ng/ml) as well as (26.7% and 25.8%) were sufficient and insufficient respectively.

Chi-square observer,  Chi-square critical, D_f = Degree of freedom,  P-value= Probability value, S= significant, N.S= non significant
The study showed that age rating (26-58) statistically has a significant relationship with vitamin D levels deficiency in patients with RA while the mean age (57-70) was the lowest in vitamin D shortage. The results of the evaluation also showed that women are more predisposed to vitamin deficiency than men.

The study also recorded a significant decrease in the levels of vitamin D for patients with a body mass index BMI (Overweight 25.0-29.9), the mean decreases of vitamin D3 levels in the patients with RA according to their BMI, gender, and age was significant (p<0.05). In addition, the examination of a lack of vitamin D levels and deficiencies in previous studies identified as the level of 25 (OH) -D <20 ng / mL and < less than 30 ng / ml and sufficient (> 30 ng / ml) with Table 2. Vitamin D has a lively role in most physiological roles as well as an important role in bone balance [17]. The main function of vitamin D is to supply besides preserve calcium in addition phosphorus caffeine in the body to ease optimal metabolism. Depressed levels of vitamin D have an important association with extent of diseases and disturbance. It is well known that the incidence of vitamin D and bone diseases such as rickets and osteomalacia are well identified [18]. Findings depicts that the (28.3%) of study sample are within second age groups (26-36) years old, and it is also mean age were (2.63) with standard deviation (1.39). Regarding gender, most of the study participants were female, it constituted (83.3%) out total number. RA is a chronic inflammatory disease of its prominent epithelium (inflammation of the articular membrane) which can usually include wrists, tarsus and each joint. This disease is affected by gender and age, increasing the incidence of this disease with increasing age and hormonal changes in women [19-20].

Concerning body mass index, the overweight were the largest proportion (71.7%). Only small percent were composed (5%) underweight as an out total number of the study sample. Fatness is a medical disorder which means having excess body fat amassed to the range that it may have a negative influence on the health [21]. Healthy life is typically related with adequate concentrations of vitamin D in the serum, which may be described by the external action of men, that is, an increase in duration of revealation to the sun further than women may be due to the nature of life and customs of communities, including Iraq [22]. In regarding with Vitamin D3, most of the study sample (47.5%) were deficiency as (<20 ng/ml) as well as (26.7% and 25.8%) were sufficient and insufficient respectively.

Serum 25OHD below (20 ng/ml), (50 nmol/ liter) defined as insufficiency in vitamin D according of The World Health Organization. However, others have begun in the definition of deficiency of vitamin D serum level 25OHD below (20 ng / ml) and the inadequacy of vitamin D is less (30 ng / ml) (75 nmol / L) [32]. The different lifestyles and physical activity might be the reason behind those results [23, 24]. Exposure to the sunlight is often limited by lifestyle and other options, resulting in insufficient vitamin D intake and insufficient access to the diet; therefore, Patients with a deficiency may need long-term supplements. Moreover, there was a significant correlation between patients in terms of gender, BMI, age, and their vitamin D3 levels (p<0.05). The results of Rajai et al., In 2017, suggested a significant inverse connection between vitamin D serum and rheumatoid arthritis acuteness based on DAS [28] increasing the severity of the disease with low vitamin D serum levels [25].

Conclusions

There were a significant relationship, between levels of vitamin D in the serum and RA severity based on Patients body mass index, age, and , gender have been active affected their deficiency of vitamin D3.

Effect of Antimicrobial Agents Extracted from American Cockroach Insect *Periplaneta Americana* L. on Some Species of Microbes

Alaa Ali Hussein Al-Hindera¹, Osama nadhom Nijris², Husham Nagy Hamoudi¹
¹College of Education, University of Samarra/Iraq, ²College of Applied Sciences, University of Samarra/Iraq

Abstract

The current study was conducted for the period of October 2017 until November 2018 to investigate the effect of antimicrobial material of American cockroach *Periplaneta americana* hemolymph against strains of pathogenic bacteria and yeast. The samples of adults American cockroach was collected and divided into three major groups, the first collected their haemolymph without injecting the cockroaches with bacteria (non-immunizator) the second collected their haemolymph after 12 hours of being injected with *E. coli* (immunizator 12h), and the third group after 24 hours of being injected with the same bacteria (immunizator 24h), then divide each totals above to two subgroups one by cooling centrifuge on 4°C and the other by table centrifuge at room temperature (non-cooling). Protein concentration had measured of all transactions and was the highest value is immunizator 12-hour by cooling centrifuges.

Keywords: species of microbes; *Periplaneta americana* L.; Antimicrobial Agents

Introduction

Excessive and non-organizer use of antibiotics contributed increased resistance of microbes to antibiotics and emergence of new strains more resistant than their predecessors, it becomes a great challenge for human health [1], that make various medical institutions looking for new sources instead of antibiotic, one of it the antimicrobial peptides symbolized AMPs for short, scientists and researchers have focused in the past on plants only to find antimicrobial articles, but as the plants produce those articles most insects produce these complex chemicals for various purposes including defense against microbes, mating, communication, and other operations that help bugs survive [2], it has been found that a wide variety of living organisms and especially insects produce AMPs as part of their defensive line, scientists have identified hundreds of these peptides and explained their significance in the innate immune system [3]. This AMPs are self-produces without induction or either after induction by some infectious or inflammatory stimuli like bacteria or bacterial molecules, a hypothesis developed that animals which live in unsanitary and contaminated conditions they evolution of ways to protect themselves from disease causing by microorganisms [4]. Toke [5] stressed that AMPs have a key role in the fight against invading pathogens in insects. The cockroaches are common household insects that live in human environments and feeding at random on a litter therefore various pathogens carried on their body [6], the ability of roaches flourish under such threats and prevent diseases causing because them body are a good source of antimicrobials [7]. So the aim of this study is to investigate f antimicrobial substances in the haemolymph of American cockroaches *Periplaneta americana* on some microbes.

Materials and Method

Types of microbes: In this study used microbes obtained from the microbiology laboratory at the University of Samarra College of Applied Sciences three gram negative bacteria were *Escherichia coli*, *Klebsiella pneumonia*, *Proteus mirabilis*. and two gram positive bacteria which were: *Staphylococcus aureus* and *Staphylococcus epidermidis*, and one type of yeasts *C. albicans*.

Collection of cockroach samples

90 adult cockroaches were collected from different part of Samarra city from the gardens, houses, and...
sewers manually included male and female, cockroaches diagnosis based on phenotypic characteristics in the natural history museum and research center at the University of Baghdad according to 601 system rankings and Q.S standards, The insects have putted in perforated plastic container to ensure ventilation feeding in laboratory conditions, haemolymph directly extracted [8].

**immunization of Periplaneta americana and extraction**

Immunization is injection a specific type of bacteria to stimulate insect immune system to production antimicrobial materials [9]. E. coli chosen to inject cockroaches as in [10] with dose 100 microliter contain almost CFU/ml had compared with McFarland standard 0.5 [11], insects refrigerated for anesthetized putted on a sterile petri dish on dorsal part, with needle size 1 ml injection 100µ of bacterial suspended solution in phosphate buffer solution between the 4th and 5th abdominal ring slowly to prevent bleeding [12].

**Collection of cockroaches Hemolymph**

All samples were divided to three main groups first was non immunizator did not injected with bacteria their haemolymph had extracted immediately after anesthetized and injected 0.1 ml ringer solution for every insect then hind pair legs were cut with a sterile scissors in coxa membrane [13] the second their haemolymph had extracted after 12 hours of immunization and a third after 24 hours of immunization [14], after the completion of the time required, each major group was split into two subgroups, first extracted with table centrifuge at 1800 rpm and CFU 6000 g for 15 minutes [12] second extracted with cooling centrifuge (Sigma Germany) at temperature 4 ºC with 14000 rpm and accelerate17968 g for 15 min [15], Finally insects had threw extract stored in clean and chilled tubes with information at -20 ºC until used [13], sterilized all of previous extracts using Millipore filters 0.22mµ [7], this crude extract was used in all tests In this study.

**The protein concentration assay**

Determined concentration of proteins for all transactions by Biuret test [16], according to [17]. The total protein concentration was calculated for each sample by equation:

\[
\text{total protein concentration} = \frac{\text{sample absorbency}}{\text{standard absorbency}} \times \text{standard concentration}
\]

**Antimicrobial assay**

Antimicrobial assay was done by Wells Agar diffusion method in Muller Hinton Agar, 20 µl of crud extract putted in every well after spreading 0.1 ml of microbial suspended, incubated plates at 37ºC for 24 hours, measuring Inhibition Zone as in [18].

The toxicity assay on human Polymorphonuclear cell PMNs

PMNs human cells were isolated as in [19] followed method in [20] to measure the viability of PMNs, cells accounted by Haemocytometer under microscope as dyed cells, dead cells that didn’t take the dye are living cells, calculating the percentage by: percentage of cells viability= number of living cells / total x100

**Static analysis**

All the results of the current study were analyzed by analysis of variance test ANOVA of factorial treatments, at implemented P< 0.05 by SPSS software.

**Results**

**The protein concentration of samples**

All value of protein content of haemolymph in table 1, statistical analysis showed high moral differences of protein content of haemolymph immunizator 12-hour cooling centrifuge at P > 0.05 symbol a followed by of non- immunizator cooling centrifuge symbol b followed by the haemolymph immunizator 24-hour cooling centrifuge symbol c, the remaining transactions that symbol typefaces d didn’t show any moral differences at P > 0.05.

Figure 1 Antimicrobial activity of crude haemolymph extracted from *Periplaneta americana*.

Effect of extracted haemolymph on Polymorphonuclear leukocytes cell viability

The extracts Immunizator 12 hour and Immunizator 24 hour both with cooling centrifuge were selected to test their effect on availability of human Polymorphonuclear cell PMNs because their top antimicrobial activity in this study compared to other extract, PMNs cells-viability in table 2. Statistical analysis has shown that control symbol a the highest moral differences that haven’t treated followed by treatment with Immunizator 24-hour cooling centrifuge symbol b decreased PMNs cells-viability because of extract’s toxicity, The latest treatment with Immunizator 12 hours cooling centrifuge moral difference with the first and second transactions moral level P > 0.05 symbol c this means PMNs cells-viability decreases due to the increased of extract toxicity.

Discussion

Cooling centrifugation at temperature 4 °C gave higher levels of protein content compared to the non-cooling for all transactions may reason is the difference in speed between the two devices, the more Speed and power increased the efficiency of the device unplug macromolecules including peptides [21], with terms of immunization, the Immunizator 12-hour extract was the highest protein content due to stimulate their immune system to synthesis peptides after being injected with bacteria, protein content decrease until less than the normal rate after 24 hours of Immunization with bacteria which shows weakness period of insects from bleeding gets, either bugs that didn’t immunized has protein content too because exposure to pathogens, In addition to the natural proteins in their body.

The study found that cockroaches injected with bacteria effective against microbes higher than others did not injected especially on microbe used in immunization *E. Coli*, duration left after injection until extraction was affected too, which was 12 and 24 hours, as well as the centrifuge device used had impact on antimicrobial activity. the haemolymph non-immunizator by cooling centrifuge was affecting on *E. coli*, *C. albicans* and *S. Epidermidis* might because live in environments filled with these microbes [22], cockroaches use similar immune response in vertebrates to face a life-threatening [23]. Seraj et.al. (2003) has an explanation for the effectiveness of the haemolymph non-immunizator by non-cooling centrifuge called him non induced might revert to having a basic AMPs effectively against *E. coli* [14], but the on *S. aureus*, and other types of microbes have been weak because their high resist than the activity of extract. Study did not agree with [24] about
non immunizator haemolymph stating that no affected against both *E. coli* and *S. aureus* may because he used a pathogenic bacteria of nosocomial hospital, there an activity of extract although its protein content indicating that mean presence anther antimicrobial compounds which may fats or proteins associated with lipids or with carbohydrates, like AMP lectins a carbohydrate-binding proteins as in [13]. Some research findings supported the idea of a peptide natively in cockroaches by intestinal and exoskeleton extracts against *S. aureus* and *E. coli* he [2]. The activity of Immunizator 12-hours non-cooling centrifuge decreased for all microbes by changing the centrifuge device to non-cooling despite the stability of the duration of immunization, but had effect on *C. albicans* may target on yeast different from on bacteria. One reason to changes antimicrobial activity is fragmentation haemolymph contents and became useful for bacteria as food or lose activity due to braking of the disulfide bond and Hydrogen bond by heat of centrifuge device which led to change alpha helix or beta sheet shape which help penetrate microbe’s membrane [25], all of the positive charge and hydrophobicity and the length of peptide’s chain were important to activity [26], so may heat of centrifugation had change this properties lowering activity. Our results have agreed with respect to immunization period with [14] that highest effective between 9 to 12 hours after injection then declined after 24 hours. inhibition diameters decreased in the non-cooling centrifuge for most microbial species, Either the immunizator 24 hours cooling centrifuge had decreased antimicrobial ability on most microbes but still highly effective on *E. coli* and was higher effect on *C. albicans* that showed the persistence of antimicrobial activity against microbes even after 24 hours of exposure to microbes. While the antimicrobial activity of immunizator 24-hours non-cooling centrifuge decreased significantly in our study results came in line with [14]. effectiveness of AMPs depend on microbial plasma membrane but some AMPs show broad spectrum activity [27]. differences between study and others due to differences in feeding cockroaches, environmental qualities and humidity factors morph type of species used, and dangerous of bacteria injection [24].

**Conclusion**

Results show that antimicrobial activity of haemolymph extract on microbes with Well diffusion agar was higher inhibiting to immunizator 12 hours by cooling centrifuges on *E. coli* with 24 mm. Also Determined effect of the extract on a viability of polymorphonuclear leukocytes of human.

Is there Any Correlation between Periodontal Diseases and Sleeping

Nadia Mohammed Kadim¹, Wasan LaftaAbdulla², Suha Talal Abd³

¹Department of Periodontology, College of Dentistry, University of Baghdad, Iraq.
²Department of Basic Science, College of Dentistry, University of Baghdad, Iraq.

Abstract

Background: Sleep deficiency has develop a worldwide occurrence, and epidemiologic facts show that little sleep period unfavorably influences human physical health. Essential methods include variation of immune-inflammatory mechanisms. These modifications possibly will donate to potentiation of critical periodontal disease.

Aim of the study: The aim of this study was to assess if there was a relationship between periodontal diseases and sleeping in a sample of patients from the College of Dentistry.

Materials and Method: Forty-Five subjects were sorted into 3 groups (n = 15 each) viz. clinically healthy, gingivitis and periodontitis. Periodontal status of subjects was evaluated by plaque index, gingival index and probing pocket depth. All the study subjects were managed Pittsburgh Sleep Quality Index (PSQI) questionnaire for the judgment of sleep deficiency.

Results: Current study shown that the mean of PSQI was statistically non-significant for all all groups in this study which are: Healthy, Gingivitis and Periodontitis.

Conclusion: This study with initial results is indicative of independent association of sleep deficiency with severity of periodontal disease, but certainly calls on for another studies in the future with larger samples number.

Key words: Periodontal Diseases, Pittsburgh Sleep Quality Index, Sleeping.

Introduction

The gingiva, alveolar mucosa, alveolar bone, cementum and periodontal ligament is the main compositions of periodontium. The periodontium is comprised of these constituents help to reinforce the teeth in their site in the alveolar bone. The color of gingiva is characteristically coral pink in color, but possibly will change because of physiologic pigment with certain races. The age is affected on the texture of gingiva which appear smooth in the period of youth and became stippled at the period of adulthood and then retain to smooth at the period of advancing age. The stippled tissue of gingiva has a consistency like to the peel of an orange and its occurrence does not essentially indicate health(1). The most common oral diseases is gingivitis that concerns humans, it is expressed as an inflammation of the soft tissues around the teeth. As a global health concern, it influences the majority of adolescents and even children (2,3,4 and 5). The term sleep denotes rest or relaxation, it is merely an easy term, but it is a complicated and vital biological activity that is mandatory for all humans on a daily basis irrespective to age, ethnic origin or even sex(6). The role of sleep in systemic physiology and brain function is critical, comprising appetite control, metabolism, and the managing of immune, hormonal, and cardiovascular systems(7). Sleep with two types long and short intervals were related with deprived self-related health. Equally long and short durations of sleep were reported to be predictors, or markers, of type 2 diabetes mellitus, cardiovascular outcomes. Sleep disturbances, including insomnia, independently contribute to the risk of inflammatory disorders and major depressive disorder. Sleep loss induces a functional alteration of the monocyte pro inflammatory cytokine response, resulting in changes of immune cell physiologic characteristics
and several hormones become upregulated \(^{(8,9,10,11,12)}\). The aim of this study was to evaluate if there was an association between periodontal diseases and sleeping in a sample of patients from the College of Dentistry/University of Baghdad.

**Materials and Method**

**Human sample**

The subjects included in this study were drawn from patients attending the periodontics department in the college of dentistry/University of Baghdad from the beginning of February 2018 to the end of April 2018.

The entire study samples composed of 45 patients (17 males and 28 females), classified into three groups, each group composed of 15 patients with age range from 20 to 65 years.

The patients were divided into 3 groups:

- **Group I:** 15 subjects with age range from (20-30) considered as Healthy.
- **Group II:** 15 patients with age range from (20-35) gingivitis patients.
- **Group III:** 15 patients with age range from (30-65). considered as chronic periodontitis patients.

A questionnaire which is self-reported was prepared to be full for each individual who included the PSQI questionnaire.

**Exclusion Criteria**

2. History of Periodontal treatment at the last 3 months.
3. Patients who were smokers.
4. Pregnant females.

**Materials and Instruments**

The following materials and instruments have been used during this study.

1. Disposable mirror.
2. Periodontal probe (Marquis color-coded probe).
3. Mask and gloves.
4. Disposable towel tray.
5. Cotton and Alcohol.

**Clinical Periodontal Parameters**

The clinical examination of periodontal parameters which done by using Marquis color-coded probe include:

**Plaque Index Parameter (PLI)**

The four surfaces of all teeth except 3rd molar were scored and examined according to system of plaque index \(^{(13)}\).

**Gingival Index (GI)**

According to the principles of the gingival index explained in the publication by \(^{(14)}\) each of the four gingival areas of all teeth except 3rd molar (facial, mesial, distal, palatal and lingual) is evaluated for inflammation and given a score from (0-3). Bleeding is assessed by running a periodontal probe along the entire soft tissue wall of the gingival crevice or periodontal pocket.

**Probing pocket depth (PPD)**

Probing pocket depth is determined from the gingival margin to the point at which the probe tip was stopped. It’s generally used to express the effect of inflammation and the causing tissue loss in periodontal disease. The tip of the periodontal probe at all times penetrates into tissue that is below the sulcus or pocket fundus, yet when the advocated probing force of 0.20–0.25 N is applied. \(^{(15)}\). It is imperative to preserve the periodontal probe parallel to the contours of the root of the tooth and to insert the probe down to the base of the pocket. This results in obscuring a section of the periodontal probe’s tip. The first marking visible above the pocket indicates the measurement of the pocket depth. It has been found that the average, healthy pocket depth is around 3 mm. Depths greater than 3 mm can be accompanying with attachment loss of the tooth to the surrounding alveolar bone, which is a distinguishing found in periodontitis \(^{(16)}\).

**Statistical analysis**

Data were analyzed and computed using SPSS (statistical package of social science) software version 24.
Results

The presents of data which was systemically analyzed in tables and the score respond with the aim of the study as follows:

Results of the clinical periodontal parameters analysis

Table (1): Descriptive statistics and groups’ differences for plaque index.

**Discussion**

This might impair an individual’s capacity to perform adequate oral hygiene practices, thus increasing the risk of periodontal disease\(^{(17)}\). Grover, Malhotra and Kaur made a research in (2015) for Exploring association between sleep deprivation and chronic periodontitis using the Pittsburgh Sleep Quality Index. The results indicated a positive correlation of PSQI with GI and PPD in gingivitis and periodontitis groups. Another study was made by Wiener in 2016\(^{(18)}\) to conclude if there is an relationship of routine insufficient sleep and periodontitis. The data sources for the present study were National Health and Nutrition Examination Surveys of contributors who were of ages 30 years and above who had complete periodontal and sleep data in the NHANES 2009 to 2012 data sets. Contributors were also asked during an interview to report age, sex, race, education level, and smoking status among other questions. The variables were grouped as follows: age (45 years to less than 55 years, 55 years to 69 years); sex (male, female); race/ethnicity (non-Hispanic White, non-Hispanic Black, Mexican-American, etc.); education level (high school graduate or less, some college/technical school or above that), and smoking status (current smokers, former smokers, and never smokers). Body mass index was categorized as less than 25, 25 to less than 30, and 30 and above which matched to normal weight, overweight, and obesity. In un corrected analysis, usually sleeping less than 7 hours at night on weekdays or workdays was associated with periodontitis. The association was attenuated and failed to reach significance in adjusted analysis. Han K, Park YM, Park JB made a study in (2018)\(^{(19)}\) to estimate the association between long sleep duration and periodontal disease among men and women using nationally representative data. They found that the propensity of periodontitis increased with longer sleep duration in women. Compared with women who slept 5 hours or less, women with a sleep duration of 6 to 8 hours and 9 hours or more had higher odds of periodontitis. A significant relationship between sleep duration and periodontitis was not found in men. So the connection between long sleep duration and periodontitis was proven by multiple logistic regression analyses after adjusting for confusing factors among Korean women, especially in premenopausal women. Long sleep duration may be considered an independent risk indicator of periodontal disease among Korean women. The Pittsburgh Sleep Quality Index (PSQI) is a self-report questionnaire that assesses sleep quality over a 1-month time interval. The measure consists of 19 separable items, creating 7 components that produce one global score, and takes 5–10 minutes to complete. It was developed by researchers at the University of Pittsburgh (University of Pittsburgh Sleep Medicine Institute, 2016). The questionnaire of PSQI has been used in many settings, including research and clinical activities, and has been used in the diagnosis of sleep disorders.

The PSQI is an useful instrument used to measure the quality and patterns of sleep in the older adult. It is brief, reliable, valid, and standardized self-reported measure of sleep quality. It differentiates “poor” from “good” sleep by measuring seven domains: Subjective sleep quality, sleep latency, sleep duration, habitual sleep efficiency, and sleep disturbances, use of sleep medication, and daytime dysfunction over the last month\(^{(20)}\).
The (PSQI) suffers from the same problems as other self-report inventories in that scores can be easily overstated or diminished by the person completing them. Like all questionnaires, the way the instrument is administered can have an effect on the final score. The PSQI is a quite new measure and as a result has not received enough investigation to determine the totality of the psychometric measures (21).

Conclusion

Non-significant differences in PSQI were discovered between the (healthy, gingivitis and periodontitis group) (i.e. the sleeping quality and quantity didn’t show an obvious effect on the periodontal status). Non-significant relation was found between PSQI and PLI, GI and PPD in all groups. Gingivitis group shows the lowliest sleeping states among the 3 three groups. The sample size which may be the cause for these results.

Establishing the Ordinary Narration of Men with Originally Negative Prostate Biopsies

Ahmed Turki Obaid

1College of Medicine / University of Babylon / Consultant Urologist / Urology Department / Hilla Teaching Hospital/ Babylon province / Iraq

Abstract

The prostate is an organ of reproduction in the man, resembling chestnut or walnut in shape and size, located directly under the bladder and in front of the anus surrounding the first part of the urethra. The aim of study is determine the health results of Basra Governorate, Iraqi males with history of a single negative transrectal prostate biopsy TRUS-Bx, from January 1, 2010 to December 31, 2018. The researcher used billing claims from Basra Educational Hospital database (BEH) to determine the patients whom have understand about TRUS – BX with using billing claim of PNB (Prostate Needle Biopsy) and was separated for concurrent ultrasound pelvic. The 94% from database was practicing in Basra as billing claim which meaning that who doesn’t accept billing will compensate accordingly. The drugs tests were implantation for all patients as Basra Educational Hospital ethical. Compassion, specialty, high quality predictive rate and negative prophetic value had been used to decide the analytical rate of PCa diagnosis of TRUS-Bx. The records were then analyzed by the use of SPSS version 14. The ethical was asked patients to own an eleven minutes rest before measure of their pressure level of blood and whole experiment. Young people (under the age of 45) are considered low levels (the risk of prostate cancer is few), when they are less than 2.5 Nano g/ml. For older men (older than 45 years), the value is low if it is less than 4 Nano grams/ml. In spite of the foregoing, it is known that about half of the cases of Prostate-Specific Antigen PSA in proportions that do not exceed these limits. For this reason, it is important to monitor the PSA values every year. Large-scale prostate biopsy identifies large prostate cancer in many men and of whom the previous sextant was a benign biopsy. This procedure should be considered when the suspicious results are for the morrow, despite the previous negative TRUS-BX.

Keywords: Prostate Biopsy, Radical Prostatectomy, Prostate Cancer

Introduction

The prostate is an organ of reproduction in the man, resembling chestnut or walnut in shape and size, located directly under the bladder and in front of the anus surrounding the first part of the urethra (1). The constant growth of the prostate leads to its enlargement, or the so-called Benign Prostatic Hyperplasia (BPH), which means the increase of its cells, which increases the amount of PSA protein secreted, a portion of it appears in the blood is measured by the type of prostate disease, whether benign hypertrophy, bacterial infection, Chronic inflammation or cancer.

Only men have a prostate, a small gland located below the bladder near the rectum. The prostate gland surrounds the urethra, which is the corridor inside the penis through which urine and men pass (2). The prostate is often described as the size of a walnut and naturally grows as men grow older. This may sometimes pose problems, such as difficulty urinating. These problems are common in older men and are not always symptoms or signs of cancer (3).

Corresponding author:
Ahmed Turki Obaid
E-mail: ahmed.carm5@yahoo.com
In the early stages there may not be any symptoms. In later stages, however, some prostate cancer symptoms may include:

- Frequent or sudden feeling of need to urinate
- Having difficulty urinating (e.g. difficulty in starting urination or being unable to urinate despite feeling the need for it or slow flow of urine)
- Some pain when you pee.
- The presence of blood in the urine or semen
- Pain in the lower back or upper thighs or hips

The factors most relevant to the development of prostate cancer are:

- **Age:** Prostate cancer is an age-dependent disease, which means that the likelihood of infection increases as age progresses. The risk of prostate cancer by the age of seventy five is 1 in 7 men. This risk is increased by the age of 83 to 1 in 5 men.

- **Family history:** If you have a first-class relative with prostate cancer, you are more likely to be infected than men who don’t have family histories like this.

- **Heredity:** Genes are present in each cell of the body. They control the way cells grow in the body and behave.

- **Diet:** There is some evidence that eating too much processed meat or fat-rich foods may increase the risk of developing prostate cancer.

- **Lifestyle:** There is evidence to show that the environment and lifestyle may affect the risk of prostate cancer.

**Prostate-Specific Antigen Test**

PSA is a diabetic protein (Glycoprotein-protein with leftover sugars) produced by prostate cells. It is actually a protease, a protein that is capable of dismantling other proteins. It is present at a high rate in the tissues of the prostate and semen.

The significant increase in the PSA level, which exceeds 0.75 Nano-g/ml within a year, increases the likelihood of prostate cancer and is a reason for taking a prostate sample. However, despite the limited nature of PSA screening, it remains the best predictor of prostate cancer or to follow patients who have received treatment for prostate cancer. Prostate cancer rarely returns, after treatment, without a high level of PSA.

Also, you should tell your doctor if you have a urine catheter (catheter) or a prostate biopsy or if your prostate inflammation is diagnosed because these cases may increase the PSA rate.

**Radical Prostatectomy (RP)**

The traditional surgical procedure for the resection of the prostate is to open a wound of approximately 15 – 20 cm in the abdomen beneath the navel. As the complications of this process are manifold, the surgeons thought of an alternative, where the patient’s suffering is less and the duration of recovery is shorter, the process known as Minimal Invasive Surgery (MIS), which can be translated by the smallest surgery aggression or an incursion into the body of the patient which was
introduced almost two decades ago\(^{(11)}\).

The laparoscopic Radical prostatectomy or (LRP) device or telescope flattens the natural depth of the position on which the operation is conducted but faces various obstacles, including hardening or non-movement of the wrist/wrist in this device\(^{(12)}\).

In Canada, Dr. Stephen Butler - from the St. Joseph’s Health Centre in London - is successfully using it between 10 – 12 times with the robot – so we can be more precise than normal open surgery. Also, the robot avoids the important nerves and muscles of the nerve and urinary incontinence\(^{(13)}\).

**Aim**

The aim of study is determine the health results of Basra Governorate, Iraqi males with history of a single negative transrectal prostate biopsy TRUS-Bx, from January 1, 2010 to December 31, 2018.

**Methodology**

The experiment was described as cohort study using related data from Basra Educational Hospital in Iraq which consist from males only who have history of single negative transrectal prostate biopsy between periods January 1, 2010 to December 31, 2018.

**Sample**

The researcher used billing claims from Basra Educational Hospital database (BEH) to determine the patients whom have understand about TRUS – BX with using billing claim of PNB (Prostate Needle Biopsy) and was separated for concurrent ultrasound pelvic. The 94% from database was practicing in Basra as billing claim which meaning that who doesn’t accept billing will compensate accordingly. The drugs tests were implantation for all patients as Basra Educational Hospital ethical.

**Inclusion criteria**

1. Age older than legal consent > 35 years.
2. Prostate needle biopsy.
3. Ultrasound Pelvic with 3 days of (PNB) prostate needle biopsy

**Exclusion criteria**

1. Woman gender
2. Males age less than 35 years.
3. Death prior biopsy.
4. Before January 1, 2010
5. After December 31, 2018
6. Implantation of hormone pellets.
7. Censored in the first 60 days from index biopsy.
8. Any evidence of infection.
9. Patient’s refusal to participate in the study.

**Statistical Process**

The average, mean and standard deviation were present in variables established; whilst frequency and ratio have been decided on to represent qualitative variables. Compassion, specialty, high quality predictive rate and negative prophetic value had been used to decide the analytical rate of PCa diagnosis of TRUS-Bx. The arrangement stage among single negative transrectal prostate biopsy was determined using RP rates. The records were then analyzed by the use of SPSS version 14.

The researcher used sensitivity analysis for comparing the results of patients that have negative TRUS – BX and patients have any type of prostate biopsy. Additional, the researcher was used following tests for all patients beside drugs test:

1. PCa diagnosis rates
2. Frequency distribution of repeat biopsies
3. RP rates

**Ethics**

The ethical was asked patients to own an eleven minutes rest before measure of their pressure level of blood and whole experiment. Ethics Committee of Basra Educational Hospital in Basra government (Iraq) and AHAPs permitted the analysis method, and printed consent were attained from all of the members before beginning of the study.

**Results**

**Demographic**

As mention in methodology section, we haven’t
sample size, we used database of Basra Educational Hospital database as principle objectives.

The databases of Basra Educational Hospital have 395650 males’ patients, amount of 293908 patients (74.3 %) were excluded because of many reasons such as have not first prostate biopsies, prior in PCa diagnosis that called prostate cancer. The amounts of 101742 patients have negative prostate biopsy with ratio of (25.7 %). The 101742 was total sample of our study, 65412 patients have TRUS-Bx with ratio (64.3 %) and 36330 patients haven’t TRUS-Bx with ratio (35.7 %).

The final sample was 65412 male patients have TRUS-Bx, as shown in Table 1.

(NS= No statistical significance)

The numbers of males with age between (35 – 44 years) were 14,758 patients (22.56 %), age between (45 – 54 years) were 16241 (24.83 %) patents, age between (55 – 64 years) were 15421 (23.58 %) patients, age between (65 – 74 years) were 10214 (15.61 %) patients, and greater than 75 years old were 8778 (13.42 %) patients. P value for all above results was more than (0.05), which was statistically not significant.

**Prostate diagnosis**

The sample size was 65412 male patients between periods from January 1, 2010 to December 31, 2018 to determine the single negative transrectal prostate biopsy TRUS-Bx.

We found that the patients have prostate cancer diagnosis for 5 years with age 35 – 44 was (7.50 %), 45 -54 (11.85 %), 55 – 64 (12.02 %), 65 – 74 (15.81 %) and greater than 75 was (16.10 %). The PCa diagnosis for 10 years with age 35 – 44 was (11.15 %), 45 -54 (17.70 %), 55 – 64 (20.87 %), 65 – 74 (20.98 %) and greater than 75 was (20.27 %). The PCa diagnosis for 15 years with age 35 – 44 was (14.60 %), 45 -54 (21.07 %), 55 – 64 (24.21 %), 65 – 74 (23.19 %) and greater than 75 was (20.78 %).

Figure 3 PCa diagnosis as taken single negative TRUS-BX

Young people (under the age of 45) are considered low levels (the risk of prostate cancer is few), when they are less than 2.5 Nano g/ml. For older men (older than 45 years), the value is low if it is less than 4 Nano grams/ml. In spite of the foregoing, it is known that about half of the cases of Prostate-Specific Antigen PSA in proportions that do not exceed these limits. For this reason, it is important to monitor the PSA values every year.

When diagnosing prostate cancer that has not spread out of the prostate, it is usual to have a radical resection of prostaglandins or prostate biopsies. After the surgical procedure, the level of PSA in the blood should be reduced to 0. If the PSA level is higher than 0, the order indicates (in this case) the presence of residue from the prostate tissue, or the spread of the tumor elsewhere. The same applies if the prostate is frozen (Cryotherapy).

Sometimes a decision is taken to conduct radiotherapy. If the PSA level continues to rise three times in a row, it is considered a failure of treatment.

Additional, we made frequency distribution of repeat prostate biopsies in sample size for negative prostate biopsies in Iraq men in Basra, all results shown in frequency distribution of repeat prostate biopsies was identified in 19624 of 65412 men (30 %). The biopsy revealed a Gleeson degree of 6-8 (Median 6.4). In 26709 out of 65412 patients (41 %) and of whom prostate cancer was identified was only 100 positive core biopsy. Although the PSA biopsies was higher and had a total of free PSA less in those with cancer, it was only a statistical indicator of positive PSA speed biopsy (P < 0.001). Prostate cancer was observed in 64% of men with PSA. The 19079 patients of total sample (65412 patients) undergoing prostate resection patients were identified as having a great disease in all. Extensive biopsy complications included urinary retention in 15320 patients and rectal bleeding.

The results show that 45% of the radical prostate (RP) was not suffering from the single negative transrectal prostate biopsy TRUS-Bx, while 30% of patients were died due to the radical prostatectomy and suffered from prostate cancer.

The sensitivity analyses incontestable that once this restriction wasn’t applied, and every one man with a negative prostate diagnostic test were enclosed, the PCa diagnosing rates weren’t clinically considerably completely different. The patients UN agency underwent biopsies at completely different time points within the study amount had variations within the accumulative incidences of the assorted study outcomes, which may well be a mirrored image of the impact of changes in variety of cores sampled on malady outcomes. Similarly, temporal changes within the relative frequencies of finger-guided versus TRUS-BX over the study amount may are assessed to additional demonstrate changes in diagnostic testing technique over the years and to judge the temporal changes in patient exclusion thanks to having undergone a finger-guided biopsy.

Conclusion

The aim of study is determine the health results of Basra Governorate, Iraqi males with history of a single negative transrectal prostate biopsy TRUS-Bx, from
Young people (under the age of 45) are considered low levels of prostate cancer risks. Large-scale prostate biopsy identifies large prostate cancer in many men and of whom the previous sextant was a benign biopsy. This procedure should be considered when the suspicious results are for the morrow, despite the previous negative TRUS-BX. The method of radical prostatectomy (RP) is not treated as a panacea for prostate cancer in several cases, and depends on the degree of cancer prevalence in this area.

For future work, we will suggest that knowledge transfer occurs by sharing the results of this study with the rest of the medical community. We will present our findings at various international conferences such as the annual American Urological Association Meeting. We also plan on publishing our results in a peer-reviewed journal, ensuring that our results become available to as wide an audience as possible.

Mutans Streptococci and Removable Orthodontics

Kasem Ahmed Abeas¹, Zainab Al-Mahdi², Issam Merza³, Lamis Khudir⁴
¹University of Babylon, Faculty of Dentistry, Department of Orthodontics/ Iraq

Abstract

Numerous studies have investigated the influence of orthodontic therapy and appliances on the oral microbial flora. Little is known about the effect of removable orthodontic appliances on oral colonisation by mutans streptococci. The original aim of the present investigation was to assess the mean and the statistical mean difference of colony values of S. Mutans in a removable orthodontic appliance fabricated from two types of acrylic resin for an Iraqi sample. According to certain predetermined sample criteria; the present study consist of eleven consecutive young patients scheduled for orthodontic treatment with removable orthodontic appliances at the department of orthodontics at the college of dentistry/ University of Babylon as well as dental student seeking orthodontic treatment. Each subject included in the present study had to wear an upper (hot cured) and lower (cold cured) well adaptive removable orthodontic appliance. A swab was taken from the lingual/palatal gingival and inoculated within the brain heart agar then cultured within Mitis- Salivarius Bacitracin (MSB) agar. The colonies were calculated for each plate, afterwards the colony forming unit (CFU) will be calculated. of the present study showing that all bacterial colony values were higher in the lower than upper arch. However, a statistical non significant difference was registered between the colony mean values of both arches. The present study signify both types of acrylic resins (heat/ cold) can be used as an orthodontic acrylic base in removable appliances within the orthodontic practice with a careful monitoring of patients treated orthodontically for risk of caries development.

Keywords: mutans streptococci, heat cure acrylic, cold cure acrylic.

Introduction

Acrylic resins are mostly used as denture and orthodontic base material in dental practice. These are available in different forms according to the polymerization reaction as heat cure acrylic resin, rapid cure auto polymerizing acrylic resin, light cure resin and specialized form resins used for microwave. Usually, heat-cured (polymethyl methacrylate) PMMA is used as the so-called “gum-work” for removable full dentures or removable partial dentures;¹⁰ the cold-cured PMMA is used for denture repair, reline and orthodontic removable appliances involved in thumb deterrent, tipping teeth, block movements, overbite reduction, space maintenance and retention.²,³

Nowadays orthodontic treatment is adopted by wide section of society not only for the correction of malocclusion but also improves mastication, speech and appearance, as well as overall health, comfort, and self-esteem.⁴ Although the orthodontic appliances has many known benefits, these appliances are also associated with a number of damages and disorders of oral cavity.⁵

Oral cavity is a complex environment supporting a many distinct bacterial species or phylotypes, of which over 50% are yet to be cultivated, residing specifically in diverse niches in the oral cavity and executing different roles.⁶,⁷ Presence of ortho-dontic appliances in oral cavity alters the balanced ecosystem of oral microbiome; as it provides an additional retentive site for food, different physio-chemical environment and surfaces for adhesion and attachments of normal oral microflora.⁸ Regarding the long term existence of baseplates of orthodontic appliances (BOA) in mouth and their surface porosities may have a negative impact on oral microbiota, promote the biofilm formation and may contribute to dental caries, gingival inflammation and periodontal disease.⁹,¹⁰ Streptococcus mutans (SM) is considered one of the main organisms in plaque that contributes to the initiation of caries. Despite being ubiquitous in the oral cavity, SM prevalence often indicates caries susceptibility and poor oral hygiene.¹¹
Numerous studies have investigated the influence of orthodontic therapy and appliances on the oral microbial flora. [12,13] Little is known about the effect of removable orthodontic appliances on oral colonisation by mutans streptococci. [14] The original aim of the present investigation was to assess the mean and the statistical mean difference of colony values of S. Mutans in a removable orthodontic appliance fabricated from two types of acrylic resin for an Iraqi young sample.

**Materials and Method**

**Sample enrollment:**

According to certain predetermined sample criteria; the present cross sectional study consist of eleven out of seventeen (7 males and 4 females) consecutive young patients scheduled for orthodontic treatment with removable orthodontic appliances at the department of orthodontics with age ranging from 18 to 25 years were enrolled to be included in this study during the period from December 2018 to July 2019. The study sample were requited from patients attending the teaching hospital at the college of dentistry/ babylon University as well as dental student seeking orthodontic treatment. As each patient was receiving upper and lower orthodontic appliance; so the study sample were further subdivided into eleven upper as well as lower arch that receiving appliances.

**Inclusion sample Criteria:**

1) Good oral hygiene  2) Cooperative compliant patient  3) Clinically healthy gingiva 4) Well fabricated upper and lower removable orthodontic appliance  5) Patients’ malocclusion is within the scope of removable appliance.

**Exclusion sample criteria:**

1) History of systemic diseases 2) medicament such as antibiotics, steroids, or nonsteroidal anti-inflammatory drugs at least 3 months prior to appliance insertion 3) Presence of fixed bridges/crowns or partial dentures 4) Smoking habit.

**Materials**

1) Transport media 2) Petri dish, test tube, flask, rick 3) Loop and glass Spreader. 4) Micro and electro-pipette. 5) sterile saline and distilled water. 6) Mitis salivarius agar, brain heart agar, agar agar. 7) Bacitracin. 8) Cold and Hot Cure Acrylic. 9) Incubator, Dry oven, Autoclave. 10) Refrigerator. 11) Millipore filter(0.4μm) 12) Gram stain.

**Methodology (bacterial isolation):**

Each subject included in the present study had to wear an upper and lower well adaptive removable orthodontic appliance. The upper and lower appliances were fabricated from heat and cold cure acrylic resin, respectively following the manufacturer’s instructions ( Surrey, U.K., England). At the time of 1st appliance activation after 2 weeks of their insertion; a swab was taken from the lingual/palatal gingival area were the acrylic base plates were extended using a selective transport media (fig. 1) . After 24 hour of their initial anaerobic incubation at 37º C; the swab was inoculated within the brain heart agar as a broth media that facilitating over growth of bacteria and incubated again for 24 hour. Afterwards and before cultivation, serial dilution was done to be ready for cultivation (0.1 ml of sample is plated) within Mitis- Salivarius Bacitracin (MSB) agar using a sterile spreading glass. After 24 hour of incubated bacterial cultured plates at 37º C, a growth of bacterial colonies (a cluster of clones in bluish distinctive colour) were seen clearly and distributed on the surface of MSB agar (fig. 2 left ).

The colonies were calculated for each plate using colony counter device, afterwards the colony forming unit (CFU) will be calculated and the data were submitted and stored in an excel program within a computer for satistics.

**S. Mutans identification:**

The identification of S.mutans is based on (according to the information in Bergeys Manual of Determinative Bacteriology 9th ed.,1994) [15] distinctive colonial morphology on selective and nonselective agar, Gram staining, distinctive cell shape on light microscopy. Morphologically, a gram-stained isolated Mutans Streptococci were viewed under a light microscope at an objective magnification of 40x. The size of the observed colonies ranged from 0.5 to 1 μm. The mutants bacterial cells resembled chains of cocci long as beads in their spatial arrangement. (Fig.2 right).
Figure 1: A transport media with plates

Figure 2: The pictures shows the macro- and micromorphology of Streptococcus Mutans isolate from study sample. (left) S. mutans colonies with a characteristic rounded bluish color grown on the MSB selective agar; (right) The isolated colony of S. mutans is gram stained and viewed under light microscope, the coccus cells arranged in chains.

Colony forming unit

A colony-forming unit (CFU) is a unit used to estimate the number of viable bacteria or fungal cells in a sample. Not all bacterial cells produce colonies; For this reason results are reported as colony forming units (CFU)/ml of bacterial culture. Ideally only plates with 25-250 colonies are used. In order to make the calculation of the number of cells/ml in the original samples less formidable, dilutions are designed to be easy to handle mathematically. The number of colonies present in a particular test sample was determined using the formula

\[ CFU/ml = \frac{\text{Number of colony} \times 1}{\text{dilution} \times \text{volume of sample plated}}. \]

\[ CFU/ml = (X) \times 10^6 \times 10. \]

\[ CFU/ml = 0.0X \times 10^9. \] In present study for a given no. of colonies; a 0.1 ml from a $10^{-6}$ dilution of the original sample was plated.

**Mitis- Salivarius Bacitracin agar (MSB agar):**

Following the method of Geigy [18]; Al-Mudallal et al [19]; Naji [20] in this agar media preparation:

MSB agar is a selective media were used for cultivation of S. mutans. It was prepared by addition of selective agents: bacitracin antibiotic and sucrose, at the optimal levels determined to the Mitis –Salivarius Agar (MSA).

**Mitis- Salivarius Agar (MSA)**

Is the main components of the prepared media that suppress the growth of most microorganisms but allows the growth of Streptococcus Spp. This media prepared according to the manufacturer’s instruction by dissolving 90 g of MSA in 1000 ml distilled water. Afterwards sterilized by autoclave at 121°C 1.5 bars per square inch for 15 minutes, and left to cool until 45 °C. To inhibit bacteria other than Mutans Streptococci; bacitracin and sucrose were added to the Mitis agar medium; since a relative resistance of S. mutans to high concentration of both bacitracin and sucrose had been reported.

**Bacitracin antibiotic**

Under aseptic condition, bacitracin antibiotic solution was added to the agar media. A bacitracin stock solution was prepared by dissolving 0.2661g of bacitracin powder in 100 ml of de-ionized water. This will supply concentration of 200 IU /L (1 unit of bacitracin =0. 0133 mg). [18] Millipore filter (0.4μm) was used to sterilize bacitracin solution. A new fresh solution was prepared every 2-3 weeks and stored in a refrigerator.

**Sucrose**

After the sterilization of the Mitis agar medium till cooling, sucrose was added to provide concentration of 200 g/L. Sucrose solution was sterilized by Millipore filter(0.4μm). 200 g/L of sucrose can inhibit the growth of S. sobrinus and S.cricetus and enhance the growth of S.mutans.[19] Moreover, The inclusion of sucrose leads to the formation of glucans and the appearance of colony formation to aid identification.

After the addition of these two components to the Mitis agar, a Mitis -Salivarius Bacitracin (MSB) agar will be form. The latter formed media then poured into
plates while solidify and stored in a refrigerator (after overnight incubation at 37 °C) till use thereafter.

**Results**

The results of the present study showing that all bacterial colony values were higher in the lower than upper arch. However, a statistical non significant difference was registered between the colony mean values of both arches.

**Table (1): Reveals the mean, maximum, minimum, standard deviation, error values for the upper and lower Streptococcus Mutans colonies.**

**Discussion**

Plaque accumulation followed by enamel demineralization and gingivitis is a well-known complication in orthodontic therapy when fixed or removable appliances are used. When use the orthodontic appliances, the acrylic plates are placed in contact with teeth, and thus the resulting plaque accumulation commonly is due to food retentive configuration of the acrylic materials. Regarding the long term existence of base plate of orthodontic appliances in mouth and their surface porosities may have a negative impact on oral microbiota, promote the biofilm formation and may contribute to dental caries, gingival inflammation and periodontal disease.

Streptococcus mutans (SM) is considered one of the main organisms in plaque that contributes to the initiation of caries. For this reason it is necessary to investigate the degree of adhesion as well as virulence of S. Mutans using the two types of orthodontic acrylic resins in isolated study by CFU calculation.

Regarding the present study result; the colony forming unit for the lower S.colonies are higher than the upper colonies in all values (mean, minimum, maximum) as the mean lower S. colonies is (148 × 10^7 cfu/ml) while (127 × 10^7 cfu/ml). Such higher lower colony units of S. mutans in spite of smaller mandibular surface area suggesting that cold cured acrylic resins of removable orthodontic appliance is more favourable environment for mutans S. colonization than hot cured resins. However, a non statistical mean difference was found between the S. colony units for both acrylic resins ( P. value = 0.9) which can be attributed to sample size methodological factors. It was found that the use of removable appliances may lead to the creation of new retentive areas and surfaces, which favour the local adherence and growth of Mutans Streptococci.

In cold-cured acrylic resins the problem is even more prominent, because they display more surface porosities than the heat-cured ones. These porosities hamper the complete removal of dental plaques, such that mechanical cleaning often turns out to be inadequate. Surface roughness may contribute to the positively correlated rate of microbial colonization and plaque maturation on
surfaces. Lewis also showed that heat cured PMMA, often the kind used for making a Hawley retainer, showed the most bacterial adherence, specifically by S. mutans. Importantly, S. mutans adhered more, or to the same extent to acrylic, as it did to enamel. A study demonstrated that the subgingival flora did not change, implying that the periodontal condition of the patient was not affected. Moreover; although bacterial levels may increase with orthodontics, patients with removable retainers are similar to healthy nonappliance wearers demonstrating no increased gingivitis or periodontitis.

The Impact of Prenatal Nutritional Status on Occlusion of Primary Teeth among Kindergarten Children in Al-Kut City/Wassit

Wathba Mohammed Jabber¹, Ban Sahib Diah²

¹AL Kut University College-Ministry of higher Education and scientific Research/Iraq,
²College of Dentistry, University of Baghdad/Iraq

Abstract

Background: When malnutrition begins early in life it affects adversely various aspects of growth including dental arch and increase the severity of oral problems in later life. The aim of present study was to assess the effect of prenatal malnutrition on the occlusion of primary teeth.

Material and method: This survey was conducted among urban kindergarten children in Al-Kut city of Wasit governorate. The sample 959 children aged 4 and 5 years were randomly selected from different areas of Al-kut city. The assessment of nutritional status was performed using prenatal anthropometric measurements, and primary dentition terminus was used for assessing dental arch relation.

Result: According to prenatal anthropometric indices preterm children constitute 23.46%, whereas low birth weight children constitute 13.66%. Flush terminus plane was the more prevalent type of occlusion for the total sample 47.86% while among preterm and low birth weighted children the mesial step terminus was more prevalent type of occlusion.

Conclusion: The prenatal malnutrition had some effect on the arch relation among kindergarten children.

Keywords: Wassit; primary teeth; prenatal Nutritional Status

Introduction

Nutritional status is a state that is resulting from the balance between the nutrients intake and the nutrients expenditure 1. Nutritional anthropometry remains the most practical and useful means for assessment of the nutritional status of population, particularly among infants and young children. Nutritional anthropometry is able to detect an imbalance of energy and nutrients in relation to need. Anthropometric indices are indices of post natal malnutrition 2 and prenatal malnutrition which include gestational age and birth weight 3.

Gestational age defined as the number of weeks from the first day of the last normal menstrual period to the date of delivery. It is one of the varieties of anthropometric indices of prenatal malnutrition 4. Full term infants are those that born between 37 to 42 weeks of gestation, post term infants are those born after 42 weeks of gestation and preterm infants are those of less than 37 weeks gestation 5. Birth weight is another anthropometric index of prenatal malnutrition 3. WHO (1972) and Mayes et al (1997) define any infant weighting less than 2500 gram at birth should be called low birth weight child, this definition is useful to identify a group of newborn at high risk of postnatal health complication and death 6. Weight at birth is a good indicator not only for the mother’s health and nutritional status, but also the newborn’s chances for survival, growth, long term health and psychosocial development; low birth weight increased risk of dying during their early months and years 7.

The science of occlusion is described by Foster (1982) that the occlusion of the teeth is any position in which the upper and lower teeth come together and the articulation of teeth is the functional movement of the lower dentition in contact with upper dentition 8. The term normal occlusion encompasses minor deviations from the ideal, which do not constitute the esthetic
or functional problems. It is not possible to specify precisely the limits of normal occlusion and so there can be disagreement even between experienced clinicians about categorization of border line cases. On the other hand Jones et al (2000) defined the normal occlusion as that occlusion which classifies the requirements of function and aesthetic but in which there are minor irregularities of individual teeth. Malocclusion is defined by Jones et al (2000) as an occlusion in which there is a mal relation between the arches in any of the planes of space or in which there are anomalies in tooth position beyond the limit of normal. Malocclusion refers to any degree of irregular contact of the teeth of the upper jaw with the teeth of the lower jaw. This would include overbites, under bites and crossbites. There is no specific system of deciding how much misalignment is too much. WHO (1997) including malocclusion under the heading of handicapping dentofacial anomaly, because it can cause problems with the child’s bite, gum tissue, speech development and appearance. As far there is no previous Iraqi study concerning the effect of prenatal nutritional status on the dental arch relation this study was conducted in order to assess the effect of gestational age and birth weight on the occlusion of primary teeth.

**Materials and Method**

After taking permission from Ministry of education, eight kindergartens had been selected randomly from 23 governmental one in AL-Kut city. A cluster sampling is done by carrying out a complete enumeration of each of selected kindergarten. Any children with systemic disease and uncooperative children were excluded. The age of the child in this study was calculated according to the criteria mentioned by World Health Organization (1987) that was according to the last birthday. Prenatal nutritional status was assessed by using anthropometric measurements including Birth weight according to the criteria of Roberton in 1993 that include When child’s birth weight is ≥ 2500 gm is consider as normal birth weight while when child’s birth weight is < 2500 gm is consider as low birth weight; other anthropometric measurement include gestational age that assessed according to Steer (1995) that include description of full term infants are those born between 37-42 weeks of gestation, while post term infants are those born after 42 weeks of gestation however the preterm infants are those of less than 37 weeks gestation. Concerning occlusion of primary teeth primary terminal plane was used in this study; this terminal plane can be classified into one of the three categories:

1) Flush terminal plane (flush terminus): means that the anterior- posterior positions of the distal surfaces of opposing primary second molars are in same vertical plane.

2) Mesial step terminus: is defined as a lower second primary molar terminal plane that is mesial to the maxillary primary terminus.

3) Distal step terminus: is descriptive to the situation in which the mandibular second primary molar terminus is distal to the upper second primary molar terminus.

Statistical analysis: data description, analysis presentation were performed by using Statistical package for social sciences (SPSS). Descriptive analysis: frequency, percentage used for nominal variables. Level of significance: not significant at P>0.05, significant at P≤0.05, and highly significant at P≤0.01.

**Result**

In the present study the total sample involved was 959, whereby 398 children aged 4 years (41.50%) and 561 (58.50%) children aged 5 years. The distribution of the sample according to gender illustrates that the male constitute 49.74% while female constitute 50.26% of the total sample. However in the present study the prevalence of preterm children was 23.46% while the prevalence of low birth weight in the present study was 13.66%.

The distribution of children according to relationship of primary terminal plane by age and gender is shown in Table 1. Data analysis of primary terminal status in this study showed that for the total sample the percentage of children with flush terminus (47.86%) was higher than percentage of mesial step terminus (46.72%) and distal step terminus (5.42%). This figure is true among children aged 5 years as well as among total male. While the opposite picture was found among total female as well as 4 year old children that the highest percentage was mesial step terminus and the lowest percentage was distal step terminus.

Table 2 demonstrates the distribution of children according to relationship of primary terminal plane by gestational age and birth weight. Data analysis shows that among full term children teeth with flush terminus
was the more prevalent, while among preterm the prevalent type was mesial step terminus. Concerning birth weight; children with normal birth weight had the higher percentage of flush terminus, on the other hand teeth with mesial step terminus was the more prevalent among low birth weight children.

**Discussion**

There are no previous available Iraqi studies dealing with prenatal nutritional measurement (gestational age, birth weight) in relation to oral health conditions that can be used to compare the results of this study with. However in the present study the prevalence of preterm children was 23.46%, this percentage was higher than that found by Offenbacher (1999) in Turkey 17 and Blanc (2005) in United States 18. On the other hand the prevalence of low birth weight in the present study was 13.66% that was lower than that found by Allen.
These differences may attributed to the difference in the whole environments of the pregnant women that include nutritional status of the pregnant women, their general health, their social class, ethnic group, and their oral health 20, 21, 22, 23.

There was no available Iraqi study concerning occlusion of primary teeth in preschool children to compare our result with. However the percentage of flush terminus plane was the more prevalent type for the total sample, the flush terminus plane indicate or predict the normal occlusion later on in permanent teeth 16, in addition the most prevalent type of primary terminal plane among preterm and low birth weight was mesial step in the present study, while among full term and normal birth weight was the flush terminus. This may attributed to the fact that poor nutrition in pre and post natal period highly affect the development of mandible and position of teeth 24.

**Conclusion**

Flush terminus was the most prevalent type of occlusion (47.86%). Among preterm and low birth weight children the mesial step terminus was the most prevalent type of occlusion.

The Association between Mn-SOD Gene Polymorphism and Peripheral Neuropathy in Type2 Diabetic Patients of Babylon Province-Iraq

Asma’a H. Mohamed1, Haider K. Zaidan2, Ali H. Al-Saadi3
1Department of Radiology Techniques- Al-Mustaqbal University College/Iraq, 2Departement of Scholarships and Cultural Relations, Ministry of Higher Education and Scientific Research, Baghdad-Iraq, 3Department of Biology- College of Science-University of Babylon/Iraq

Abstract

Background: Oxidative stress has been known to be implicated in the onset and development of impaired insulin secretion and insulin resistance and both are involved in diabetes. The mechanisms involved in oxidative stress-induced diabetic peripheral neuropathy include the generation of reactive oxygen species ROS, excesses reactive nitrogen species RNS, lipid peroxidation, DNA damage, and reduction in cellular antioxidants. Polymorphisms in genes responsible for encoding these antioxidant enzymes causes the development of diabetic peripheral neuropathy (DPN). Aim: this study was aimed to indicated the role of genes encoding manganese (Mn-SOD) superoxide dismutase in the pathogenesis of DPN in a type2 diabetic patients of Babylon province. Ala(-9)Val polymorphism of Mn-SOD gene polymorphism were studied in type2 diabetic patients with (n=30) and without DPN (n=30).

Results: Polymerase chain reaction (PCR) technique were used for detection Mn-SOD polymorphisms. This technique included the use of PCR primers (Forward and Reverse) to produce a restriction site in the amplified Mn-SOD gene product just with the polymorphic base. Then, the product of (PCR) was digested with Bsh T1 restriction enzyme to detect Ala(-9) polymorphic position. The results of Ala(-9)Val polymorphism showed that the frequency of Ala/Ala, Ala/Val, and Val/Val were 63.3%, 20%, and 13.3% in healthy control subject and 36.6%, 33.3%, and 30% in diabetic without neuropathy countered by 23.3%, 20%, and 56.6% in diabetic with neuropathy. This proposed that the Ala(-9)Val polymorphism in the Mn-SOD gene is significantly associated with a risk for progression of diabetic peripheral neuropathy.

Conclusions: Homozygote pattern Ala/Ala were more frequent in control groups compared with homozygote pattern Val/Val were significantly more frequent in diabetic peripheral neuropathy patients.

Keywords: Oxidative stress, diabetic neuropathy, SOD, Mn-SOD polymorphism.

Introduction

The exposure to high levels of circulating glucose and fatty acids especially in non-insulin sensitive tissues like eye, kidney, and nervous system results in oxidative and nitrosative stress(1) leading to imbalance between oxidants and antioxidants in favour of the oxidants and consequently diabetic complications(2).

Oxidative stress has been known to be implicated in the onset and development of impaired insulin secretion and insulin resistance and both are involved in diabetes(3). The mechanisms involved in oxidative stress-induced diabetic peripheral neuropathy include the generation of reactive oxygen species ROS, excesses reactive nitrogen species RNS, lipid peroxidation(4), DNA damage, and reduction in cellular antioxidants triggering the disruption of lipids of the myelinated structure of nerves leading to loss of axons and damaging the microvasculature of peripheral nervous system(5) causes hyperexcitability in the afferent nociceptors and central neurons resulting in generation of spontaneous impulses within the axons and dorsal root ganglions of the nerves forming the pain that are associated with diabetic peripheral neuropathy(6).

DOI Number: 10.37506/v14/i1/2020/ijfmt/192966
SOD catalyze the diversion of superoxide anion into hydrogen peroxide and oxygen:

\[
O_2^- + O_2^- + 2H^+ \rightarrow H_2O_2 + O_2
\]

SOD activity was primarily reported by McCord and Fridovich in 1969\(^7\) they consequently demonstrated that SOD is the key antioxidant enzyme implicated in the detoxication of superoxide radicals and it plays an essential protective roles against cellular and histological disruption that are causes by ROS\(^8\) and also has an important role in inhibiting inflammatory response which is closely correlated with minimizing hyperalgesia, several forms of SOD have been found in all mammalian tissues with different locations within the cell, these are metalloproteins each containing a distinct metal ion in its center: intracellular Cu-Zn-SOD or SOD 1, Mn-SOD or SOD 2, and extracellular EC-SOD or SOD 3, and each of which is produced by a special gene\(^9\).

Mitochondrial SOD (Mn-SOD) is present in the mitochondrial matrix in two separating forms, dimeric Mn-SOD and tetrameric Mn-SOD and each has a subunit contains one Mn (III) ion\(^1\). Mn-SOD is generated in a constitutive manner, but can also be triggered by cytokines such as IL-1 and TNF, endotoxin, and by numerous oxygen metabolites in particular cell types having important role in occurrence of tissue damage in the case of oxidative stress also has been believed that transcriptional regulation of Mn-SOD is mediated by the activation of nuclear transcription factor \(\text{NF-kB}\) propped by oxidants\(^1\) ).

Mn-SOD or SOD2 gene is the only known antioxidant enzyme present in matrix of mitochondria suggesting that is the first line of defense against free radicals production, and it located on chromosome 6q25.3 consisting of five exons interrupted by four introns and the promoter which control the gene expression, structural and/or functional SNP of the Mn-SOD encoding gene, and have an important role in maintenance of cellular ROS levels\(^1\)

In human there are at least 190 SNPs have been reported, the best known functional SNP that is associated with diabetic peripheral neuropathy is Ala-9Val SNP is a Restriction Fragment length Polymorphism (RFLP) with chromosomal position in the codon 56 (2 exon at position 9) of Mn-SOD gene, the substitution of C to T (GCT to GTT) that is alanine to Valine results in structural changes of the mitochondrial targeting sequence of the enzyme leading to less efficient transport of Mn-SOD into the mitochondrial matrix and can compromise the capacity to neutralize superoxide radicals in the cell\(^1\)

Materials and Method

Study subjects

The study samples were collected in Marjan teaching hospital in AL-Hilla City/Babylon province-Iraq. Subjects in this study comprised from (30) patients suffer from type 2 diabetes with peripheral neuropathy, (30) patients without peripheral neuropathy as a positive control group with duration of disease (1-5, >5-10, >10 years) and with average age between (35-65 year). In contrast, the study included (30) apparently healthy people aged between (35-65) as control matched with disease group. The presence of type 2 diabetic peripheral neuropathy or not were diagnosed for all patients by a specialized doctor.

Venous blood samples were collected from fasting patients and control subjects after a period of fasting 8-10 hours by vein puncture using 5ml disposable syringes, 2 ml was placed into EDTA tubes mixed gently for 3 minutes and then being divided into two parts: the first part used in hematological tests and especially for HbA\(_1c\) assay and the second part was stored in – 20 ºC for using later for genetic analysis.

DNA extraction and genotyping of Mn-SOD

The manufacturer protocol (Geneaid/Korea) was followed for extraction the DNA from frozen blood samples by using some components of the extraction kit. The purity of extracted DNA were determined by using Nano-droop apparatus. Sequences of primers used for PCR amplification of Mn-SOD include the:

Forward strands F: ‘5-CCAGCAGGCGAGCTGGCCG-3’ and

Revers strands R’5-TCCAGGGCGCCGTAGCGT-3’, the band size of about (91 bp).

Polymorphic sites were amplified by using polymerase chain reaction technique (PCR). The PCR reaction mixture considered of < 250ng/μl template DNA, 400μM of each dNTP, 12.5 μl buffer of 1U Go Taq DNA polymerase (Promega), 10 μM of each primer and 3 mM MgCl$_2$ in 25 μl of total reaction volume.

Amplification reactions were carried out by using GTC Series thermocycler (Cleaver Scientific/UK) apparatus. The following program was set in the thermocycler after determination of the optimum annealing temperature to amplify Mn-SOD gene (55°C for 30 seconds + 37 cycle). PCR-RFLP technique included the addition of restriction enzyme BshTI of about (0.5 μl to 10 μl PCR product), incubated at 37°C overnight.

Statistical analysis

SPSS version 23 was used for analysis the clinical variables whereas, Chi-square test used for comparison genetic frequencies of Mn-SOD between patients and control group. Odds ratios (ORs) with confidence intervals (95% CL) and their associated P-Values were used to calculate the results. A P-Value of ≤ 0.05 considered statistically significance.

Results

Mn-SOD genotyping

The results of Mn-SOD gene genotyping show that the PCR product had one band about (91bp) for both type2 diabetic patients and control group as shown in figure (1).

![Figure 1: The electrophoresis pattern of PCR product for Mn-SOD gene, 1% agarose, 75V, 20mA for 1h.](image)

RFLP-PCR for Mn-SOD gene

The results of PCR-RFLP of Mn-SOD for type2 patients with and without DPN and control group by using Bsh TI restriction enzyme show that the homozygous AA pattern has one band about (91bp), the homozygous VV pattern has two bands about (17 and 74 bp) and the heterozygous AV patterns has three bands (17, 74, and 91 bp) as shown in figure (2).

*P≤0.05,   DPN: Diabetic Peripheral Neuropathy

Discussion

Antioxidant enzymes represents one of the crucial cellular protective mechanisms against oxidative stress in the human body so that the polymorphism of the antioxidant genes can lead to change the enzyme activity\(^{(14)}\). Mn-SOD is a mitochondrial enzyme which is responsible for the formation of \(\text{H}_2\text{O}_2\) from...
superoxide radicals, the variant allele of Mn-SOD has been associated with increased oxidative stress which is induced by diabetes mellitus leading to the development of diabetic neuropathy(15). Oxidative stress can trigger the damage of neurons by nerve lipid peroxidation, the impairment of mitochondrial DNA, the respiratory chain inhibition, and the cross-linking of the neurofilament protein(16). The oxidative disorders also cause rapid changes in glia cells, suffering, severe pain, disability, cardiac death and silent myocardial ischemia, all these disorders are some of the most important consequences of diabetic peripheral neuropathy(17).

Shimoda-Matsubayashi et al.(18) indicated that the (Ala) allele has an alpha-helical structure which represents a common conformation for mitochondrial leader signals, while the (Val) allele may alter its conformation from alpha-helix to beta-sheet starting from the position (16) because of amino acid substitution, this meaning that the (Val) allele is lesser transported into the mitochondria than the (Ala) allele of the enzyme. In the inner mitochondrial membrane, the poor recognition of signal sequence by membrane receptor may results in mistargeting and impairment splitting of a particular sequences leading to reduction of enzyme activity of an imported protein like Mn-SOD within the mitochondrial compartment. Processing studies have been suggested that the basal level of the Mn-SOD activity may be most increased for (AA), followed by (AV), and then (VV)(19). The (AV) dimorphic site is located in Mn-SOD gene within exon 2(20), found that Knock-out mice lacking exon (1) and (2) display a progressive motor disorders because of neuronal degeneration.

In mitochondria, the (V) allele of the Mn-SOD may be present in a lower concentration so that the homozygous (VV) should have lower resistance to oxidative stress than patients with other Mn-SOD alleles which is a common feature of diabetes mellitus with different aging and neurological impairment, the ineffective targeting of Mn-SOD may drop out the mitochondria with low defended against superoxide radicals results in protein oxidation, mutations of mitochondrial DNA and damage which are common in the development and progression of diabetic neuropathy, and neurodegenerative disorders like Alzheimer and parkinson’s disease(21).

Lemon Crude Extract Modulates Ito Cells Activation in High Cholesterol Diet-Induced Liver Steatosis in Male Mice

Liqaa Oday Ali¹, Ahmed G. AL-Helal¹
¹Faculty of Dentistry/ University of Babylon, Iraq

Abstract

Background: Different types of polyphenols exist in many sources such as fruits, vegetables and herbs. For example, lemon has mainly flavonoids (such as Hesperidine, Eryoketrine, Narignine, Hesperidine, routine and chlorogenic acid). Research conducted in vivo and in vitro showed that lemons have different health benefits, such as anti-cancer effect, antimicrobial, antihyperlidemia and protective effect against liver disease. In addition, lemons are used to treat liver disorders. Therefore, current research was aimed to investigate the protective effect of the prolonged use of Lemon Crude Extract.

Methods: Sixty male albino mice (4 weeks old, weighing between 20-25g) were used. They were divided into 3 groups (n= 20) for each group during the period from January 2018 to May 2018. Group I was used as control, Group II induction group was fed with (HCD), Group III was fed a (HCD) and treated with 1:1m/v of 100% (LCE) for 12 weeks.

Results: Histological variations were identified in Group II by disturbed hepatic architecture, congestion in blood sinusoids and portal veins and infiltration of lymphocytes. Also, there was peri portal steatosis that was observed in HCD-fed mice. In addition, there was significant increase in Ito cells that was identified by desmin antibody. Moreover, these variations were less noticeable in Group III.

Conclusion: Lemon has a protective effect against activation of Ito cells in fatty liver.

Key words: Steatosis, LCE, Ito cells, HFD, fatty liver.

Introduction

Modern lifestyle has had an impact on most food habits in humans leading to eating high-calorie food filled with high carbohydrate and fat, which are known as (fast food). This leads to increased risk of increasing weight, obesity and chronic non-transmissible diseases, such as liver disease (1). Several studies dealt with the importance of active compounds that constitute foods which have maintaining and prevention of various diseases. For example, polyphenols have an effective role in the healing and treatment of many diseases (2). They contain an enzyme capable of modifying the immune function (3). Different types of polyphenols exist in many sources such as fruits, vegetables and herbs. For example, lemon has mainly flavonoids (such as Hesperidine, Eryoketrine, Narignine, Hesperidine, routine, and chlorogenic acid) (4). Research conducted in vivo and in vitro showed that lemons have different health benefits, such as anti-cancer effect, antimicrobial, antihyperlidemia and protective effect against liver disease (5). In addition, lemons are used to treat liver disorders (6).

Ito cells, also called hepatic stellate cells, fat-storing cells, lipocytes, peri-sinusoidal cells, vitamin A-storing cells, are located in the space of Disse between hepatocytes and sinusoidal endothelial cells (7). These cells constitute about 5% of the total number of liver cells, they help in reducing the turnover of parenchymal cells and normalize liver regeneration (8). Ito cells are transformed to myofibroblasts which cause fibrosis then cirrhosis. Myofibroblasts secrete a large amount of extracellular matrix proteins like collagens type I and III, proteoglycan, glycoproteins cytokines and chemokines (9). They stimulate hepatic fibrogenesis, together with fibroblasts and parenchymal cells, into mesenchymal cells (10).

Materials and Method

Lemon Crude extract

Fresh mature (lemon citrus) fruits are used. The taxonomic identity of the plant was made by the Biology Department, Faculty of Science/ University of Babylon. Extract preparation was modified from (11). The fruits
with their peel about (500g washed well with deionized water then cut to small pieces, after that their seeds were removed then blended and squeezing using a commercial blender and was filtered to remove the residues by filter with Whitman filter paper (2l).

**Preparation of high fatty diet**

Fatty diet was prepared by adding 1% cholesterol to the standard diet. Cholesterol was purchased from Sigma Company. The high-fat diet was prepared every 2 days, kept at 4°C until used and left at the room temperature for 1h before use (12).

**Histological and Immunohistochemistry**

**Light microscopic observations**

The livers were collected then as soon as fixed with 10% buffered formalin and embedded in paraffin. Sections (5μm) were prepared and then stained with hematoxylin-eosin dye for photo microscopic observations.

**Immunohistochemical Technique**

The following markers were used in this study (Dako Cytomation Denmark):

- Monoclonal Mouse Anti-Human Desmin, Clone: D33, Code Number: M 0760. After DE waxing, dehydration, washing (with distilled water) and then pre-treatment of tissues with heat-induced epitope retrieval in Micro Wave Oven was done prior to staining (using Labeled Streptavidin Biotin LSAB™+/HRP kit, code number K0697 detection system). The staining procedure followed dakocytomation technique (13).

**Results**

**Histological findings**

The liver sections obtained from Group I showed hepatocytes with one cell thickness arranged in cords and can identify the central vein at its center and Ito cells lined the space of Disse (Figure 1). The liver sections obtained from Group II showed many variations in the form of narrowing and congestion in sinusoids, most hepatocytes showed cytoplasmic vacuolation appeared with ballooned hepatocytes and cellular infiltration in addition to multiple small microvesicular steatosis (Figure 2). The liver sections obtained from Group III showed that most of the hepatocytes showed renewal of their cytoplasm (Figure 3).

**Immunohistochemical findings**

Immunohistochemistry was used to demonstrate the presence of Ito cells. Examination of anti-desmin immunohistochemical-stained sections of both Group I and group III revealed anti-desmin positive cells in between hepatocytes (Figures 1 and 3). Examination of anti-desmin immunohistochemical-stained sections obtained from group II revealed an apparent increase in number of anti-desmin-positive cells (Figure 2).

**Discussion**

Lemon is one of the main citrus, it is extensively cultivated in the middle area. It has antimicrobial, anti-parasitic, antiviral and anticancer effects. It was proved that it lowers blood sugar, inhibits low-density lipoprotein oxidation (14,15). The current study dealt with the protective role of Lemon Crude Extract (LCE) against fatty liver induced in male albino mice. In this study, Livers obtained from group II showed disturbed hepatic architecture which was explained as increased oxidative damage in hepatocellular proteins or necrotic changes in hepatocytes that lead to abnormality in the orientation of the hepatocyte plates and disturbing hepatic architecture, dilatation of central veins, blood sinusoids and portal veins were attributed to inflammatory changes or ischemia and hypoxia following high-fat diet (15). In addition, cellular infiltration was observed, this result is considered diagnostic of steatohepatitis. The adipocytes in steatosis secrete many immune modulator elements in the form of pro-inflammatory cytokines (IL-6, TNF-α and ROS). All these factors contribute to chronic inflammatory condition and to hepatocytes injury (16,17).

Microvesicular steatosis is an abnormality in metabolism, synthesis and export of lipids which is associated with defective beta-oxidation of fatty acids (18). Furthermore, cytoplasmic vacuolation was attributed to lipid peroxidation because of oxidative stress that damages cell membrane as well as membranes of cell organelles leading to an increase in their permeability and disturbance of the ions concentrations in the cytoplasm and cellular organelles (19).

The present study showed an increase in the numbers of Ito cells. These findings may be attributed to fibrosis and altered phenotype called capillarization that lose the ability to prevent Ito cells activation and inactivate activated hepatic stellate cells (20). In the present work, we observed that daily administration of LCE with HCD diet ameliorates previous changes. A previous
study revealed that daily administration of lemon juice has hepato-protective role against steatosis in alcohol-induced liver injury in Mice\(^{(21)}\). Lemon contains many compositions including phenolic compounds, vitamins, carotenoids, essential oils, minerals and dietary fiber\(^{(22)}\). The hepato-protective effect of lemon may be attributable to preventing oxidative damage including lipid peroxidation\(^{(23)}\). Some studies concluded that vitamin C alone could reduce oxidative stress induced by ethanol and the hepato-protective effect of vitamin C treatment was more effective than silymarin, quercetin and thiamine\(^{(24, 25)}\). Flavonoids interact with hydroxyl radicals, and then inhibit oxidases\(^{(26)}\). In a previous study\(^{(27)}\), lemon Flavonoids were shown to possess hepato-protective effects on liver damage induced by carbon tetrachloride, the mechanism of the protective effect was related to the antioxidant activity\(^{(27)}\).

Figure 1 Liver sections for control group showed central vein (C.V), hepatocytes (H) and Ito cells (I) (H&E A 200X).

Figure 2 Liver sections for GII showing cellular infiltration (CI), Ito cells (I) ballooning degeneration (B) with microvesicular steatosis (MI) (H&E 200X).

Figure 3 Liver sections for GIII showing normal structure of liver (H&E 200X).
**Conclusion**

Lemon has a protective effect against activation of Ito cells in fatty liver.

Assessment of Serum Advanced Glycation End-Product Level and Its Effect on Periodontal Health Status in Type 2 Diabetic Patients with Chronic Periodontitis

Lara Kusrat Hussein¹, A.N. Mohammed²
¹College of Dentistry/ University of Anbar, Iraq. ²College of Dentistry/ University of Baghdad, Iraq

Abstract

Background: The bidirectional relationship between diabetes mellitus and periodontitis was obvious as both of them are considered chronic diseases. The risk of developing periodontitis was reported to be higher in diabetic patients specially with poorly control diabetes mellitus, which in turn can negatively impact glycemic control. Advanced glycation end-products have intertwined relationship with oxidative product; increased in advanced glycation end-products could lead to oxidative stress and vice versa. The aim of current study was to investigate the possibility of using serum levels of (AGEs) for identification of the periodontal pathological condition in periodontitis patients with and without diabetes. Method: Twenty healthy individuals (control group), 30 patients with severe chronic periodontitis and 30 poorly controlled diabetic patients with severe chronic periodontitis were included. Full mouth (plaque index PlI, gingival index GI, bleeding on probing BOP, probing pocket depth PPD, clinical attachment loss CAL) were recorded by periodontal probing and serum advanced glycation end-products concentration were assayed using enzyme linked immunosorbent assays. Results: A non-significant difference was reported in plaque index PlI, gingival index GI, bleeding on probing between diabetic and non-diabetic patients with chronic periodontitis, while probing pocket depth, clinical attachment loss revealed a significant difference between diabetic and non-diabetic patients. Advanced glycation end-products presented with highest level in diabetic group (26.92) followed by chronic periodontitis group (15.91) then the control group (6.60), however, the correlation was non-significant with periodontal parameters. Conclusions: It is possible to use serum advanced glycation end-products level in the early diagnosis of chronic periodontitis in patients with and without diabetes.

Keywords: chronic periodontitis, advanced glycation end-products, plaque index, gingival index, bleeding on probing.

Introduction

Diabetes mellitus has a series of metabolic disorders recognized by disorders in insulin action, secretion or both causing hyperglycemic state (¹), diabetes complications occurs with long periods of poor glycemic control (²).

Periodontal diseases are inflammatory diseases caused by infection of the supporting tissues with bacteria (³). In spite of the essential role of bacteria in dental plaque, alone it’s not enough for the initiation or advancement of periodontium breakdown. So, host response activation causes irreversible tissue destruction, then inflammation and disease resulted from interaction of these microbiota with immune defenses (⁴).

The gingivitis and periodontitis considered as the most popular forms of periodontal diseases. Gingivitis, a stable form, it is considered a reversible inflammation of the gingiva with no involvement of the attachment apparatus, while periodontitis includes the deeper structure of periodontium leading to loss of attachment with the destruction of periodontal structure (⁵).

Chronic periodontitis (CP) is considered as the most popular type of periodontitis it mostly affects adults between 40 - 50 years old and it is reported as the essential cause of tooth loss. It progresses slowly, but may be subjected to periods of exacerbation (⁶).

The relationship between diabetes mellitus and periodontitis was reported as a bidirectional cyclical relationship (⁷). Moreover, in several studies the presence
of diabetes was associated with higher incidence, prevalence and severity of chronic periodontitis (4,8). Thus, CP was counted as the sixth complication of diabetes (7), and diabetes considered as a risk factor for boosting periodontal disease (9). The risk of developing periodontitis was reported to be three-fold higher in people with poorly-controlled diabetes, which in turn can negatively impact glycemic control (10).

Advanced glycation end products (AGEs) are proteins or lipids that turn into glycated following exposure to sugars. AGEs represent a heterogeneous complex that is produced continuously under physiologic conditions and their production is greatly increased in case of atherosclerosis, hyperglycemia as well as inflammation and oxidative stress (11). A study conducted in 2018 confirmed the results of previous studies about the intertwined relationship between AGEs and oxidative product (OP) (12). Furthermore, recent studies confirmed the past evident on the involvement of AGEs in periodontal disease (13) and diabetes complications (14). All of that motivated us to perform current work in order to study the possibility of using serum levels of (AGEs) for identification of the periodontal pathological condition in periodontitis patients with and without diabetes.

Materials and Method

Study participants

Human samples consisted of eighty males; age range was (35-55) years. Information taken from each participant about the name, age, full dental and medical history, if he was taken any medications, smoking or drinking alcohol, level of HbA1c for diabetic patients and the diabetic period.

The study was approved by the ethical committee of college of dentistry/ university of Baghdad. Each subject was informed about the aims of the investigation according to the informed consent written in simple English and Arabic words, and they were free to choose whether to participate in this study or not. Participants were categorized into three groups: A. Poorly-controlled type 2 diabetes mellitus with sever Chronic periodontitis (CP+pT2DM); composed of 30 males with mean clinical attachment loss ≥ 5mm, HbA1c >9% and on oral hypoglycemic medication. B. Sever chronic periodontitis (CP) without any systemic disease; composed of 30 males with mean clinical attachment loss ≥ 5mm. C. Systemically healthy with clinically healthy periodontium (control group); composed of 20 males seemingly healthy without any systemic diseases with apparently healthy periodontium.

Inclusion and exclusion criteria

The inclusion criteria were 1. patients with generalized severe chronic periodontitis CP must have CAL ≥3mm at >30 % of the sites with mean of CAL ≥5mm (15), 2. At least 16 teeth present, 3. Patients with T2DM for ≥5 years and on oral treatment only, 4. All participants within normal range of body mass index (18.5-24.9kg/m²). The exclusion criteria were: 1. Females were excluded from the study, 2. Presence of systemic disorders other than T2DM, 3. Patients who were receiving periodontal treatment within three months before the study, 4. Patients with T1DM and T2DM receiving insulin as a treatment, 5. Having a course of antibiotic in three months prior to the study, 6. Medications that may affect periodontal tissue and 7. Drinking alcohol or smoking.

Clinical periodontal parameters

All participants were subjected to full mouth periodontal examination excluding 3rd molar by Michigan O periodontal probe for (plaque index PlI, gingival index GI, bleeding on probing BOP, probing pocket depth PPD, clinical attachment loss CAL) on four surfaces (mesial, buccal/ labial, distal and lingual/ palatal).

HbA1c measurement

A volume of 5ml venous blood was gathered from each individual, for diabetic group 1ml placed into Ethylene diamine tetra acetic acid (EDTA) tube in order to measuring HbA1c and 4ml gathered into a serum separating tube (gel tube) and then centrifuged at 3000rpm for 15 minutes. Serum was divided into Eppendorf tubes then labelled and stored at -50°C till used for analysis.

The measurement of HbA1c for patients with T2DM was done by using Standard A1c Care Test kit analyzer. The procedure was executed according to manufacturer’s instructions.

Biochemical analysis of advanced glycation end products (AGEs)

Assessment of AGEs level was performed using ELISA kit (96 wells) for quantitative measurements
of AGEs in serum (CUSABIO AGEs ELISA kit Catalog Number.CSB-E09412h, china) according to manufacturer’s instructions.

**Statistical Analysis**

Data were processed and analyzed using the Statistics Package for Social Sciences (SPSS; version 22) with both descriptive and inferential statistics. Means were used to express all values. LSD test and t-test were used in data analysis to compare mean values among the groups. Correlation between AGEs and clinical periodontal parameters was tested by Person’s Correlation Coefficients (r) test. Moreover, in the statistical evaluation, differences were considered significant when probability value \( P<0.05 \) and \( P>0.01 \).

**Results**

Thirty (CP+pT2DM) patients, thirty CP patients and twenty healthy control individuals were studied. PLI and GI of control group revealed significant differences from (CP+pT2M) and CP groups (Table 1). Moreover, BOP presented non-significant difference, while CAL and PPD showed significant difference from (CP+pT2M) and CP groups (Table2).

Discussion

A significant difference in PI and GI between control group and both of diabetic and non-diabetic groups with CP, while a non-significant difference was reported between (CP+pT2M) and CP groups. This could be attributed to the effect of microbial dental plaque since it is considered as the essential factor in the pathogenesis of periodontal disorders (5,16), and its causes gingival inflammation due to its accumulation on teeth with sign and symptom of inflammation (erythema, edema, bleeding, tenderness and enlargement) (17). Since both groups had been chosen with strict criteria with same degree of severity, this may explain the non-significant difference between study groups, (CP+pT2M) and CP. Moreover, BOP reported a non-significant difference between study groups. This could be attributed to similarity in subgingival microbiota between diabetic and non-diabetic patients (18).

On the other hand, the CAL and PPD revealed significant differences between study groups. This could be attributed to the effect of DM on the production of proinflammatory cytokines, like IL-6, by human gingival fibroblasts which cause an increase in their production when compared to non-diabetic (19). Also, patients with hyperglycemia and periodontal disease reported an increase in the expression of TLRs in periodontal tissues which cause higher inflammatory response in those patients (20). Thus, the incidence, prevalence and severity of periodontitis will be higher in diabetic than non-diabetic individuals (21).

The biochemical analysis of serum AGEs demonstrated the highest level in diabetic group followed by CP group and then control group with significant differences between them. This could be explained by the significant association of AGEs with oxidative stress and inflammation (22). Levels of ROS were reported to be higher in periodontitis patients than healthy controls (23).

On the other hand, poor glycemic control leads to an increase in AGEs accumulation (24,25) and their formation rate was highly increased in case of hyperglycemia and oxidative stress (26). So, in case of diabetes together with condition of chronic high oxidative stress will lead to further acceleration in the process of formation of AGEs (22).

Regarding the correlation between AGEs and clinical periodontal parameters, although the correlation was non-significant, there was an elevated level of this marker in chronic periodontitis groups compared to healthy control group suggesting its association with periodontitis and this could be explained by the association of AGEs with progression of periodontal disease (26).

Accumulation of advanced glycation end-products (AGEs) in oral tissues including periodontal fibroblasts and gingival tissues and its interactions with their receptors (RAGE) reported to be associated with impaired fibroblastic growth in periodontal tissues (25) and causes an increase in formation and release of ROS from cells of periodontal ligament with subsequent induction of metalloproteinase (MMP) and proinflammatory cytokines. All that will lead to degradation of connective tissue, osteoclast activation and bone loss (27).

Conclusions

The increased level of serum AGEs in CP groups suggested their potential role in initiation or progression of periodontitis in patients with and without diabetes. Also, the higher level of AGEs in CP group compared with control group may raise the potential involvement of AGEs in the etiology and progression of periodontal diseases. Furthermore, it is possible to use serum AGEs level in the early diagnosis of CP in patients with and without diabetes.

Serum Fatty Acid Synthase Level in Patients with Prostate Cancer and Benign Prostatic Hyperplasia

Farooq Yaseen Khuhair1, Hassan H. AL-Saeed1, Laith Amer Abd-Al-Hussain2
1Department of Chemistry and Biochemistry, Collage of Medicine/Al-Nahrain University, Iraq, 2Department of Surgery Collage of medicine/Al-Nahrain University, Iraq

Abstract

Background: Human Fatty Acid Synthase is highly expressed in many human cancers. Previous studies have shown that this enzyme is expressed at very high levels in prostate cancer and that the growth of prostate cancer cell line can be inhibited by pharmacological inhibitors that target this enzyme. Additionally, some studies have reported that this enzyme is overexpressed not only in tissue, but also in serum of patients with various cancers. The aim of this study was to evaluate serum levels of this enzyme in patients with prostate cancer and in patients with benign prostatic hyperplasia as well as to investigate whether it can be used as a biomarker for detection of prostate cancer and benign prostatic hyperplasia. Methods: By using an FASN ELISA kit, we measured serum levels of Human Fatty Acid Synthase in 35 patients with prostate cancer and 35 patients with benign prostatic hyperplasia. We also measured serum FASN levels of 35 healthy volunteers enlisted as normal controls. Results: Serum FASN levels in prostate cancer patients were significantly higher than in healthy control subjects, but FASN levels in patients with benign prostatic hyperplasia were not significantly higher than in healthy control subjects. Conclusions: Serum FASN levels are expressed at significantly high levels in human prostate cancer. Serum FASN levels were not expressed at significantly high levels in human benign prostatic hyperplasia. FASN serum levels may be additional biomarker for prostate cancer detection.

Keywords: Fatty acid synthase, prostate cancer, benign prostatic hyperplasia, ELISA.

Introduction

Prostate cancer (PC) and benign prostatic hyperplasia (BPH) are common prostate tumors. Prostate cancer is the most widely recognized non-cutaneous malignancy tumor in men [1]. Benign prostatic hyperplasia is a non-cancerous increase in size of prostate gland. It is the most common benign tumor found in men [2].

Although transrectal ultrasound-guided prostate biopsy is gold standard in the diagnosis of prostate cancer, it can be hurtful with possible side effects of biopsies including pain, serious infections and bleeding [3].

Additionally, serum prostate-specific antigen (PSA) levels do not have a direct correlation with increasing grade and stage of prostate cancer [4]. Thus, a novel biomarkers that have a stronger association with prostate cancer and have direct correlation with increasing grade of prostate cancer and have less side effects are needed.

A marker that is considered in this study is human fatty acid synthase (FASN), a metabolic enzyme that catalyzes the biosynthesis of longchain fatty acids [5]. FASN was first identified as oncogenic antigen 519 in patients with a poor prognosis for breast cancer [6]. In normal human tissue de novo fatty acid synthesis is suppressed and the low levels of lipogenic enzymes expression are maintained. Normal cells preferentially depend on dietary lipids to satisfy their metabolic needs. In contrast, increased lipogenesis is a major hallmark for tumor progression with cancer cells change to dependence on de novo fatty acid synthesis to support rapid cell growth [7]. The main enzyme responsible for the synthesis of fatty acids in the cell is fatty acid synthase (FASN) [8]. FASN has been found to be common sense overexpressed in about every type of cancer and is associated with their progression and development [9]. This enzyme is overexpressed not only in tissues, but also increased enzyme concentration in serum of patients with various cancers such as colorectal...
cancer, gastric carcinoma and esophageal neoplasia [10-12]. Serum FASN levels are elevating in patients with prostate cancer compared with healthy controls [13]. In addition, the levels of serum fatty acid synthase are associated with stage of disease in patients with colorectal cancer [14].

The aim of this study was to evaluate serum levels of this enzyme in patients with prostate cancer and in patients with benign prostatic hyperplasia as well as to investigate whether it can be used as a biomarker for detection of prostate cancer and benign prostatic hyperplasia.

Materials and Method

Study subjects

The present study included 35 patients with prostate cancer (15 patients underwent trans urethral resection or prostate biopsy surgery and 20 patients from oncology hospital. In addition, 35 patients with benign prostatic hyperplasia who were diagnosed and had blood samples collected between September 2018 and April 2019. Patients were divided into three groups; control, BPH and PC. Fasting serum samples were collected from patients preoperative or prior to treatment in addition to serum samples from 35 healthy individuals (controls).

FASN ELISA

A total of 100μl serum was analyzed using a commercially available ELISA kit, FASN ELISA (cusabio biotech), according to manufacturer’s recommendations. Using a pipette, a volume of 100μl of standard and sample was added per well. Then covered with the adhesive strip provided, incubated for 2 hours at 37°C, then the liquid of each well was removed by inverting plate and rapidly flicking the liquid away from the plate. Using a pipette, a volume of 100μl of Biotin-antibody (1x) was added to each well and covered with a new adhesive strip. Incubated for 1 hour at 37°C, then each well was aspirated and washed, and the process was repeated two times for a total of three washes. It was washed by filling each well with wash buffer (200μl) using an auto-washer and it was left to stand for 2 minutes. After the last wash, any remaining wash Buffer was removed by decanting. The plate was inverted and blot it against clean paper towels. Then by pipette (100μl) of HRP-avidin (1x) was added to each well. The micro titer plate was covered with a new adhesive strip and incubated for 1 hour at 37°C. The aspiration/wash process was repeated for five times as in step 6, then (90μl) of TMB substrate was added to each well and incubated for 15-30 minutes at 37°C in the dark. The a volume of 50μl of stop solution was added to each well using a pipette, the plate was gently tapped to ensure thorough mixing. The optical density was determined of each well within 5 minutes, using a micro plate reader set to 450nm.

Statistical Analysis

Statistical analysis was carried out using Microsoft excel 2013 and SPSS version 20. The numerical data expressed as mean ±SD. Furthermore, comparisons between mean serum concentrations of FASN in control and study (PC and BPH) groups were performed. All P values were two sided and statistical significance was set at P≤0.05. Receiver Operating Characteristics (ROC) curve was calculated to estimate the sensitivity and specificity of the used FASN as biomarker and discriminatory ability.

Results

In this study, ELIZA method was used for estimation of the concentration of FASN in sera of patients with prostate cancer, benign prostatic hyperplasia and healthy controls (Figure 1). FASN concentration in sera of patients with prostate cancer ranged from (0.87ng/ml) to (24.19ng/ml) with a mean±SD of 5.8±4.9ng/ml, and showed a significant elevation in comparison with control group (P=0.001; Table 1). On the other hand, the mean±SD FASN concentration in sera of benign prostatic hyperplasia patients was (3.3±1.8) and showed no significant elevation in comparison with control group (P= 0.17; Table 2).

Discussion

A novel biomarker that has stronger association with prostate cancer and has direct correlation with increasing grade of prostate cancer is needed. Identification of serum protein markers of prostate cancer and benign prostatic hyperplasia together with other markers already known could help provide such a non-invasive diagnostic and prognostic screening tool. FASN is a major component of the de novo fatty acid synthesis pathway that catalyzes the oxidation NADPH-dependent formation of large free fatty acids from two carbon donors. A strong association was found between increased FASN levels in malignant tissue and the presence of other unfavorable prognostic indicators in primary prostate cancer, as determined by immunohistochemistry methods [15]. Patients with prostate cancer rich in FASN display significantly poorer clinical prognosis than those with prostate tumors containing lesser amounts of FASN enzyme.

In this study, FASN concentrations were determined in sera of patients. The findings indicated that the concentrations of FASN in sera of patients with prostate cancer were higher than in sera of healthy subjects. We have detected high FASN concentration in 71% of participant patients with prostate cancers depending on FASN cut-off value and the mean±SD was (5.8±4.9ng/ml).

This finding was in agreement with study of [13], however, the mean and standard deviation of serum FASN in that study was (0.79±0.76 units/I) which was different from the mean and standard deviation in our study, because the (ng/ml) unit was used in our study to measure sera FASN concentration.

This was the first study that serum concentration of FASN in patients with benign prostatic hyperplasia was determined. The results shown that no significant different between BPH and healthy subjects groups (P=0.17; Table 2). This approved that FASN has a role in development of prostate cancer and indicating that serum FASN concentration could aid as a diagnostic marker for prostate cancer, because most men with an elevated PSA level turns out not to have prostate cancer; just about 25% of men who have a prostate biopsy due to an elevated PSA level actually are found to have prostate cancer when a biopsy is done [16] and novel biomarkers that have stronger association with prostate cancer are needed.
A receiver operatory characteristic (ROC) curve is a graphical plot used to show the diagnostic ability of binary classifiers. It was first used in signal detection theory, but now it is used in many other areas as medicine. ROC curve is instituted by plotting the sensitivity against the (1-Specificity).

Sensitivity is the ratio of observations that were correctly predicted to be positive out of all positive observation. It equals:

\[
\text{Sensitivity} = \frac{\text{True positive}}{\text{True positive} + \text{False negative}}.
\]

In contrast, specificity is the ratio of observations that are correctly predicted to be negative out of all negative observations. (1 – Specificity) equals:

\[
\text{Specificity} = \frac{\text{False positive}}{\text{True negative} + \text{False positive}}.
\]

In this study discriminatory ability of increased serum FASN levels for PC was tested by ROC curve (Figure 2). The area under curve was 77% and this indicated how well serum FASN can distinguish between patients with prostate cancer and healthy subjects.

The sensitivity was 71%. This meant that the positive detection rate was 71%. This is higher than positive detection rate in study of [13] which was 53%. The latter study had only 29 samples with prostate cancer and may be this the cause that made their results vulnerable to bias, additionally the incubation time and temperature of the first incubation ELISA method in that study were overnight at 4°C and this is different from current study where the incubation time was 2 hour at 37°C.

**Conclusion**

This study suggested that serum FASN levels were expressed at significantly high levels in human prostate cancer. Thus, FASN serum level may be an additional biomarker for prostate cancer detection with a sensitivity and specificity of 71% and 23%, respectively. The study concluded that there was no significant different between serum FASN of patients with BPH and healthy subjects. In addition, serum FASN concentration is not useful biomarker for diagnosis of PBH. This approved that FASN has a role in development of prostate cancer. Subsequent studies should investigate how serum FASN levels relate to clinical responses to prostate cancer therapies. Subsequent studies to investigate relationship between transcription factors of FASN and Gleason score. Determine the cut-off value of serum FASN concentration for each class of Gleason score in patients with prostate cancer. Also, studying correlation between serum concentration of FASN with stage of prostate cancer is highly recommended.

Antibacterial Activity of Crude Extracts of *Spirulina Platensis* Against Some Pathogenic Bacteria and Fungi Isolated from Different Sites on Human Body

Intesar Kareem Abdul Hassan¹, Ammar Adnan Tuama¹, Khamael Ali Kareem¹

¹Faculty of Basic Education, University of Diyala, Iraq

Abstract

*Spirulina platensis* are filamentous, undifferentiated, non-toxigenic cyanobacteria that have been used as food since ancient times. There have been numerous studies on its antioxidant and antimicrobial actions. *Spirulina* as many other cyanobacteria species have the potential to produce a large number of antimicrobial substances, so they are considered as suitable organisms for exploitation as biocontrol agents of plant pathogenic bacteria and fungi. In the present study, antimicrobial activity of *Spirulina platensis* solvent extracts in serial dilution was investigated against pathogenic bacteria and fungi. The antimicrobial activity of *Spirulina platensis* was determined against pathogenic bacterial and fungal isolates. The methanol extract of *Spirulina platensis* showed maximum zone of inhibition against all the bacterial and fungal isolates.

Keywords: *Spirulina platensis*, Inhibition zone

Introduction

Early interest in *Spirulina* was focused mainly on its potential as a source of protein, vitamins, especially vitamin B12 and provitamin A (β-carotene), and essential fatty acids like γ-linolenic acid (GLA). Recently more attention has been given to study its therapeutic effects, which include reduction of cholesterol and nephrotoxicity by heavy metals, anticancer properties, protection against radiation, and enhancement of the immune system⁽¹⁾. *Spirulina* also possesses other biological functions such as antiviral, antibacterial, antifungal, and antiparasite activities⁽²⁾.

Microalgae, such as *Ochromonas* sp., *Prymnesium parvum*, a number of blue green algae produce toxins that may have potential pharmaceutical application. Nature has been a source of medicinal agents for thousands of years and an impressive number of modern drugs have been isolated from natural sources, of which many are based on their uses in traditional medicine⁽³⁾. *S. platensis* produce a diverse range of bioactive molecules, making them a rich source of different types of medicines. Pathogen resistance to synthetic drugs and antibiotics that are already in use makes search for plants with antimicrobial activity more important, as they can substitute for synthetic antibiotics and drugs⁽⁴⁾.

Characteristics of plants that inhibit microorganisms have been investigated in laboratories since 1926. The past decade has witnessed a significant increase in the prevalence of resistance to antibacterial and antifungal agents. Resistance to antimicrobial agents has important implications for morbidity, mortality and health care costs in U.S. hospitals, as well as in the community. These developments and the associated increase in bacterial infections intensified the search for new, safer, and more efficacious agents to combat serious bacterial infections⁽⁵⁾.

Materials and Method

Preparation of biomass and harvesting

A prepared flask containing 100 ml of Bg-11 culture media and transfer 25 ml of isolated algae then incubated for 14 days; transfer this culture growth to 500 ml of culture media and incubate again for 14 days, then transfer this culture growth to 1000 ml of Finally, the culture of growth is transferred to glass basins of 4L dimensions (50 cm long, 40 cm wide and 30 cm high) for biomass culture⁽⁶⁾. These pools were covered with a piece of gauze and the air was supplied with rubber. With bubble stone⁽⁷⁾.
The 20-day biomass culture was harvested by centrifugation at 4000 rpm for 10 minutes. The samples were washed with sterile water and dried in the oven with 38-40 °C. These samples were then weighed and stored in the refrigerator.

Preparation of organic extract of the spirulina platensis

According to with some modifications, were followed to prepare the crude extracts of algae as follows: One gram of spirulina platensis powder was extracted with 250 ml of 97% ethanol using a Soxhlet extraction device at 76 C for 3-4 hours until the solvent becomes insoluble the color. The raw extract was dried by rotary evaporator at 40 °C.

C. The residues (raw extracts) were collected and stored at -20 °C until use again. The extract was weighed and the percentage of the extraction yield was calculated in terms of the primary algae material used in extraction.

The method of posting agar well:

Antimicrobial and fungal activities from the crude extracts of Spirulina platensis were tested using the Agar method for good propagation. Four different concentrations were prepared (10-20, 30, 40 µg/mL). Nutrient agar plates were fortified with 100 ml in a 24-hour broth culture of tested bacteria or 100 ml of Dextrose Sabouraud’s culture soup 5 days of tested fungus. Four wells (6 mm) were manufactured and filled with 100 ml extract. The dishes were incubated for 24 hours at 37 °C for bacteria or for 3 days at 30 °C for fungus. The diameter of the region was measured to discourage recorded results. In addition, antimicrobial activity was compared with the standard.

Analysis by Gas Chromatography – Mass Spectrometry (GC-MS)

For GC-MS analysis, a high-temperature column (Inert cap 1MS; 30 m × 0.25 mm id × 0.25 µm film thickness) was purchased from Agilent Technologies (SHIMADZU—Japan), by employing a high-temperature column. Derivatization of each sample was eliminated. The injector and detector temperatures were set at 280 °C while the initial column temperature was set at 100 °C. A 5 µL sample volume was injected into the column and ran using split (1:10) mode After 1 min, and the oven temperature was raised to 225 °C at a ramp rate of 12.5 °C/min (hold time 4 min). The oven temperature was then raised to 300 °C at a ramp rate of 7.5 °C/min (hold time 5 min). The helium carrier gas was programmed to maintain a constant flow rate of 17.5 mL/min and the mass spectra were acquired and processed using both Agilent GC-Mass. Solution (SHIMADZU—Japan) and postrun software. The compounds were identified by comparison of their mass with NIST library search and authentic standards.

Statistical Analysis

The Statistical Analysis System- SAS (2012) program was used to effect of difference factors in Inhibition Zone Diameter. Least Significant Difference-LSD test was used to significant compare between means in this study.

Result

The present study included bioactivity of crude extracts of Spirulina platensis on some pathogenic organisms isolated from different site as presented in the table (1).

The result showed the different sensitivity to the series of extraction on inhibition zone to an microorganism under study, table (2).

The zone of inhibition of Spirulina platensis extracts against bacteria was ranged between (0-13 mm at 10 mg/l and 8mm - 15mm, 8- 13mm and 7mm-15mm at 20mg/l, 40mg/l and 50mg/l respectively.

The zone of inhibition of Spirulina platensis extracts against fungi was ranged between (0-9 mm at 10 mg/l and 7mm - 8mm, 0-7mm and 9mm-13mm at 20mg/l, 40mg/l and 50mg/l respectively.

The St aureus bacteria show more sensitivity and inhibition zone which reach a significant level (P<0.05) in all dilution were compare with other microorganisms, while Asperniger was less sensitive in compare with other organisms as shown figure (1) as well as the result show a significant differences in any dilution between all pathogenic organisms inhibition zones, furthermore there are found a significant difference between serial dilution against the same pathogen under probability levels (P<0.05).

Discussion

The antibacterial activity of algal compounds extracted from algae depends upon the type of solvent used for extraction.

Spirulina has been studied because of its therapeutic properties and the presence of bioactive compounds\(^{(13)}\). The occurrence of antimicrobial compounds in plants was well documented and these compounds are known to possess antimicrobial activity in biological systems. But, the antioxidant characteristics of algae and cyanobacteria are less well documented, although decreased cholesterol levels have been reported in hypercholesteremic patients fed Spirulina and the antimicrobial activity of phycobiliproteins extracted from Spirulina platensis has also been demonstrated.

Many investigations mentioned that the methanol extracts of Nostoc muscorum revealed antibacterial activity on Sclerotinia sclerotiorum by\(^{(14)}\). Also the methanolic extract of a blue green alga has been investigated by\(^{(15)}\) for in vitro antimicrobial activity against Proteus vulgaris, Bacillus cereus, Escherichia coli, Pseudomonas aeruginosa, Aspergillus niger, Aspergillus flavus and Rhizopus nigricans using agar cup diffusion method. The antimicrobial activity of methanolic extract of S. platensis was also explained.
by\textsuperscript{(16)} due to the presence of \textit{γ}-Linolenic acid and compound was also present in the methanol extract in the present study as observed by GC-MS analysis. Previous publications reported that the compounds such as 1-Octadecene, 1-Heptadecane were found in both algae and plants show anticancer, antioxidant and antimicrobial activity\textsuperscript{(17,18)}. Antimicrobially active lipids and active fatty acids are present in a high concentration in this alga. It was hypothesized by \textsuperscript{(19)} that lipids kill microorganisms by leading to disruption of the cellular membrane as well as bacteria, fungi and yeasts because they can penetrate the extensive meshwork of peptidoglycan in the cell wall without visible changes and reach the bacterial membrane leading to its disintegration. Present investigations is contradictory with the results of other studies\textsuperscript{(20,21)} may be due to the production of bioactive compounds related to the seasons, method, organic solvents used for extraction of bioactive compounds.

### Conclusion

It is concluded from the study that extracts of algal strain used in the present investigation showed better antibacterial activity against the pathogens used, but further researches should be made to identify and purify natural product against antibacterial and antifungal. The enhanced antibacterial activity expressed in sequential extraction might be due to the fact that both hydrophobic and hydrophilic bioactive compounds were extracted. An improved knowledge of the composition, analysis, and properties of \textit{S. platensis} with respect to antimicrobial compounds would assist in efforts for the pharmaceutical application of this cyanobacteria.

The Problem of Multidrug Resistance Bacterial Strains in Daily Clinical Practice in Dealing with Typhoid Fever in Mid-Euphrates Region of Iraq: A Cross Sectional Study

Huda Jabbar Dibby¹, Radhi Farhod Shlash²

¹Assistant Professor of Physiology/Department of Physiology/ College of Medicine/ University of Al-Qadisiyah/ Al-Diwaniyah Province (58001) / Iraq, ²Professor And Physician / Department of Internal Medicine / College of Medicine/ University of Al-Qadisiyah/ Iraq

Abstract

Background: in our community, typhoid fever is common infectious disease based on daily clinical practice and the emergence of multidrug resistant strains a evidenced by worldwide reports and our daily clinical observation necessitate optimizing antibiotic approach to treat such common infectious disease.

Aim of the study: we aimed in this study to highlight the problem of multi-drug resistance in daily clinical practice when treating typhoid fever.

Patients and methods: The present cross sectional study included 95 cases with clinical and laboratory evidences of typhoid fever. Venous blood sample was obtained from each patient and sent to the lab for purpose of culture and sensitivity. The study was carried out at the department of Medicine / Al-Diwaniyah teaching hospital, Al-Diwaniyah province, Mid-Euphrates region of Iraq. The study started on January 2018 and extended through October 2018.

Results: Regarding amoxicillin, azithromycin and cefotaxime, isolates obtained from 60 patients (63.2 %) were resistant whereas isolates from 35 patients were sensitive. Ciprofloxacin and ceftriaxone were totally ineffective since resistance was recorded in all enrolled isolates (100.0 %). On the other hand, chloramphenicol, trimethoprim-sulphamethoxazole and imipenem produced the best results since all isolates were sensitive to these antibiotics. The resistant strains of Salmonella enterica serotype typhi were more associated with urban areas than with rural regions, 75 % versus 58.2 %; however, the difference did not reach statistical significance (P > 0.05).

Conclusion: antibiotic approach to typhoid fever is a dynamic rather than a static phenomenon that needs revision regularly and that drug individualization according to culture and sensitivity rule should be adopted by all health workers and institutes when dealing with outbreaks of Salmonella enterica serotype typhi.

Key words: multidrug resistance, typhoid fever, Iraq

Introduction

Typhoid fever, a term first used by Pierre Louis in 1829 to describe an infectious disease which was proved later to be caused by Salmonella enterica serotype typhi (¹). This gram negative rod shaped baceterium has only one reservoir which is the human being (²). The disease is mainly encountered in geographic regions with low socioeconomic status in which poor sanitation is common and it is mainly seen in young adults and children (³). The incidence of typhoid fever in 2000 was estimated to reach 21.7 million cases worldwide with 216,000 cases died of the disease. In 2010 the disease was estimated to affect 11.9 million patients and to kill 129,000 individuals in low to intermediate income regions of the world (⁴, ⁵). Indeed, these figures may not represent the gloomier picture and be an underestimate to the truth as a large number of cases are treated on outpatient basis. The biggest proportion of the 200 to 300 cases diagnosed annually in the United States is attributed to travelling to
endemic areas (6). In Iraq, the reported annual incidence of the disease in Sulaimania was estimated to be 21 cases per 10000 per year (7). Unfortunately, despite thorough search in the available published articles in the internet, we did not get an article dealing with the true incidence of the disease in the Mid-Euphrates region of Iraq during the last 10 years; however, in clinical practice the disease is fairly common. The introduction of antibiotics has dramatically reduced the rate of mortality caused by typhoid fever from approximately 15 % in the pre-antibiotic era to less than 1% following antibiotics administration (8).

Chloramphenicol was the first antibiotic to be indicated to treat Salmonella enterica serotype typhi infections (9). Resistant forms of the bacterium were identified in the population with just 2 years of administrating the drug (8). Nowadays, ofloxacin or ciprofloxacin have been considered as the mainstay of treating Salmonella enterica serotype typhi infections (10). In spite of the risks accompanying quinolone treatment in children, they are justified for severe infection or when other modes of therapy are lacking (11). A wide spectrum cephalosporin (e.g. ceftriaxone) or azithromycin may be indicated. When resistance to a quinolone is discovered. Combination therapy of the macrolides, cephalosporins and fluoroquinolones have been justified in patients when above measures fail to control the disease (5, 8).

The detection of enteric fever becomes difficult in a lot of countries around the world due the development of multidrug resistance (MDR) by Salmonella enterica serotype typhi as well the alteration in the presentation mode of the disease (11). The term MDR was used to describe a condition in which all three first line medications; chloramphenicol, ampicillin, and trimethoprim-sulfamethoxazole fail to control the disease (13). Dated back to 1972, the first report of cases resistant to chloramphenicol was registered, following which reports around the world have been recorded about the emergence of Salmonella enterica serotype typhi that are resistance to alternative forms of monotherapy until we reached the era of multi-drug resistance (12, 15). The isolation of the first MDR strain was done in Southeast Asia about 30 years ago following which the bulk of data about MDR has been grown (15). Therefore the use of quinolone or 3rd generation cephalosporins has been justified in the treatment of typhoid fever instead of the traditional approach of chloramphenicol, ampicillin and trimethoprim-sulfamethoxazole (16). The prevalence rate of MDR in five Asian countries was estimated to range from 7 up to 65 % (17).

Because of the relatively high incidence rate of typhoid fever in Iraq and the difficult control of the disease following the published guideline, we aimed in this study to highlight the problem of multi-drug resistance in daily clinical practice when treating typhoid fever.

Patients and methods

The present cross sectional study included 95 cases with clinical and laboratory evidences of typhoid fever. The mean age of enrolled patients was 43.14 ±5.21 years with an age range of 11-58 years. Venous blood sample was obtained from each patient and sent to the central laboratory of Al-Diwaniyah teaching hospital for purpose of culture and sensitivity. The study was carried out at the department of Medicine / Al-Diwaniyah teaching hospital, Al-Diwaniyah province, Mid-Euphrates region of Iraq. The study started on January 2018 and extended through October 2018.

The study was approved by the Ethical Approval Committee of College of Medicine / University of Al-Qadisiyah. Statistical analysis was done using statistical package for social sciences (SPSS, version 23) and Microsoft Office Excel 2010. Data were expressed as mean standard deviation, number and percentage. Chi-square test was used to study association between categorical variables. The level of significance was considered at P ≤ 0.05.

Results

In the present study, 95 patients with clinical features suggestive of typhoid fever were enrolled and the diagnosis was confirmed based on blood culture results. The study included 45 male and 50 female patients with an age range of 11 to 58 years and a mean age of 43.14 ±5.21 years, as shown in table 1. According to residency, patients were classified into 67 patients from urban regions and 28 patients from rural areas accounting for 70.5 % and 29.5 %, respectively, table 1. The antibiotic sensitivity results are demonstrated in table 2. Regarding amoxicillin, azithromycin and cefotaxime, isolates obtained from 60 patients (63.2 %) were resistant whereas isolates from 35 patients were sensitive. Ciprofloxacin and ceftriaxone were totally ineffective since resistance was recorded in all enrolled isolates (100.0 %). On the other hand, chloramphenicol,
trimethoprim-sulphamethoxazole and imipenem produced the best results since all isolates were sensitive to these antibiotics, as shown in table 2. The resistant strains of *Salmonella enterica* serotype typhi were more associated with urban areas than with rural regions, 75% versus 58.2%; however, the difference did not reach statistical significance (P > 0.05), table 3. The distribution of patients according to 10 years age intervals is shown in figure 1 together with corresponding proportions of sensitive and resistant strains. It is obvious that resistant strains are more frequent among patients younger than 40 years of age; nonetheless, we were not able to assess the significance level because chi-square was not valid.

**Figure 1: The distribution of patients according to age showing the proportion of multi-drug resistance**

**Discussion**

In this study it was obvious that the oldest drug chloramphenicol was the best drug to treat nowadays strains of *Salmonella enterica* serotype typhi that are common in our community in addition to Trimethoprim-Sulphamethoxazole. Of the newly introduced antibiotics, imipenem was also 100% effective in fighting these *Salmonella enterica* serotype typhi strains. The striking finding in this study, was that the first line drug ciprofloxacin was totally ineffective despite being recommended by the well known medical textbooks to control typhoid fever. Ceftriaxone also showed failure to eradicate these resistant strains. Multi-drug resistance was encountered in 63.2% of isolates enrolled in the current study, which is indeed a horrible figure that require prompt awareness to adopt new strategies in fighting *Salmonella enterica* serotype typhi that are common in our community.

In the near past, ciprofloxacin was recommended as the first-line drug to treat *S. typhi* infections as
majority of the conventional antibiotics became of no benefit leading to excessive use of this drug, namely ciprofloxacin, for the control of typhoid fever. Nevertheless, resistance to ciprofloxacin was recorded in the late 80s and early 90’s of the past century, and the number of reports of treatment failure following this antibiotic became increasingly higher toward the beginning of this century. In our study we found supporting evidence that ciprofloxacin is no more effective in controlling the disease and recommendation should be shifted to other effective drugs such as the “old fashion” chloramphenicol or other effective antibiotics and that sensitivity results must direct the proper choice of antibiotic therapy in an individual manner. Mutation on genetic level of the S. typhi strains may explain the emergence of such resistance as shown by some authors. When resistance to ciprofloxacin was observed other drugs such as ceftriaxone and azithromycin gained wide acceptance as effective regiments in controlling the disease, however, several later reports documented the failure of these antibiotics in treating significant proportion of patients suffering from typhoid fever around the world in addition to our finding in the current study that ceftriaxone showed total failure and that significant proportion of patients included in our study were infected with bacterial strains that are resistant to azithromycin. We believe that the irrational use of antibiotics in our community is one of the major reasons for the emergence of resistant bacterial strains and that the ministry of health should take measures in cooperation with other governmental institutes that insure rational and well controlled prescription of antibiotics.

**Conclusion**

it is obvious that antibiotic approach to typhoid fever is a dynamic rather than a static phenomenon that needs revision regularly and that drug individualization according to culture and sensitivity rule should be adopted by all health workers and institutes when dealing with outbreaks of *Salmonella enterica* serotype typhi.

Analysis of CTLA-4 (+49A/G) Gene Polymorphism and the Risk of Pulmonary Tuberculosis in Babylon province of Iraq

Raafat M. Al-Enzi¹, Jawad Kadhim Tarrad¹, Moshtak A. Wtwt¹
¹College of Medicine, University of Babylon, Hilla, Iraq

Abstract

Background: Pulmonary tuberculosis (pTB) is an infectious disease caused by the bacillus Mycobacterium tuberculosis (M. tuberculosis). It typically affects the lungs, but can also affect other sites (extra-pulmonary TB). The disease is spread when sick individuals expel bacteria into the air, for example by coughing.

Aim of Study: To highlight the effect of CTLA-4 (+49A/G) gene polymorphism on the risk of pulmonary Tuberculosis (pTB).

Patients and Methods: This case-controlled study used single specific primer-polymerase chain reaction (SSP-PCR) to analyze the CTLA-4 (+49A/G) gene polymorphism in 60 patients with pTB who were referred to consultant clinic for respiratory diseases in Hilla – Babylon province/ Iraq during the period from December 2017 to July 2018, and 60 healthy persons’ control. Blood samples were collected from both groups according to the standard methods.

Results: Data analysis revealed that the frequencies of AA, AG and GG genotypes in patients were 73.33%, 23.33%, and 3.34% respectively. In controls, this frequency was 51.67%, 35%, and 13.33% respectively. Logistic regression test detected a significant difference in the frequency of the (GG genotype) mutant homozygous of this polymorphism between patients and controls (3.34% versus 13.33%), The GG genotype of CTLA-4(+49A/G) showed a significantly decreased risk of pulmonary tuberculosis disease (OR= 0.18, 95% CI= 0.04 – 0.88, P value = 0.035).

Conclusion: The GG genotype of CTLA-4 may decrease the risk of pTB.

Keywords: Pulmonary Tuberculosis; Mycobacterium; CTLA-4.

Introduction

Tuberculosis (TB) has existed for millennia and remains a major global health problem. It causes ill-health for approximately 10 million people each year and is one of the top ten causes of death worldwide. It has been the leading cause of death from a single infectious agent(1). The major risk factors that increase early death of TB patients are being positive for human immunodeficiency virus (HIV), being of old age, being underweight or undergoing retreatment(2). About one-third of the world’s population are estimated to be infected with M. tuberculosis, albeit mostly without clinical symptoms. These silent carriers bear a life time risk of developing active disease, with more than 95% of cases and deaths occurring in the developing world(3). Population genetic studies have made significant contributions to reveal the role of human genetic variation in susceptibility to TB infection(4). Macrophages and neutrophils play a decisive role in host responses to intracellular bacteria including the agent of tuberculosis, the role of both reactive nitrogen intermediate (RNI) and reactive oxygen intermediate (ROI) as central mediators of innate immune defense in human M. tuberculosis infection is well established(5).

The entry of M. tuberculosis into the body induces activation of cellular immune mechanisms which play important roles in the mechanism of T cells. TH1 cells induce macrophage activation and phagocytosis reactions. Eradication of these pathogens requires secondary administrative cellular immune mechanisms such as cytotoxic T lymphocytes (CTL)(6).
CTL-associated antigen 4 (CTLA-4) is a CD28 receptor that inhibits T cell proliferation through combination with B7 molecules. The human CTLA-4 gene is located on chromosome 2q33. The CTLA-4 (rs231775) polymorphism is located in the first exon of CTLA-4 +49A/G base substitution can cause a change from threonine to alanine amino acid in the coding region of CTLA-4 (7), (8), revealed a significant relationship between the GG genotype of CTLA-4 and the increased risk of TB.

The present study aimed to investigate a possible correlation between CTLA-4+49A/G gene polymorphism and the risk of pTB in a sample of the Iraqi population.

Materials and Method

Study Groups:

This study designed into two groups. The first group involved 60 pTB patients. Those patients were referred to consultant clinic for respiratory diseases in Hilla – Iraq during the period from December 2017 to July 2018. All patients were subjected to full clinical and radiological examinations prior to laboratory examination. The subjects with pTB were selected from those who had a confirmed diagnosis by a healthcare professional and who presented clinical symptoms, radiological evidence and positive sputum acid-fast bacillus (AFB) smears. The second group involved 60 apparently healthy individuals were considered as control group. This control subjects had no previous history of pTB, autoimmune disease, diabetes, and chronic disease.

Collection of Blood Samples

The blood was collected by venous procedure. The site of venipuncture is sterilized by 2% iodine. Five milliliters of venous blood were collected from each participant and kept in EDTA tube. A total of 120 blood samples were collected (60 subjects with pTB patients and 60 healthy controls). DNA extraction was accomplished using (Favorgen/ Taiwan) kit according to the manufacturer’s instructions. After estimation of the quality of DNA by Nanodrop, the Specific Sequence Primer (SSP-PCR) method was used to analyze the genotyping of CTLA4 (+49A/G) with the primers given in (Table -2). The PCR conditions for the amplification of CTLA-4 were as follows: initial denaturation phase comprised 5 minutes at 94°C; next 30 cycles (1 minutes at 94°C, 1 minutes at 57°C, and 1 minutes at 72°C); then, seven minutes at 72°C. The samples were stored at 4°C until electrophoresis as in (figure -1).

Statistical Analysis

The Statistical Package for the Social sciences (SPSS, version 20) was used for statistical analysis. Risk association between the genotype and TB susceptibility was estimated by the calculation of adjusted odd ratio and 95% confidence intervals using multivariate logistic regression. For this analysis, subjects who were homozygous for the wild type genotype were considered as reference, and polymorphisms as dependent variables. Chi- square was used for testing the deviation from Hardy- Weinberg equilibrium, and to compare between patients and control. A $P$-value < 0.05 was considered statistically significant.

Results

The demographic characteristics of study population for pTB patients and controls groups were involved the following factors as in (Table -1).

**Discussion**

T-cell activation is a complex process that requires >1 stimulatory signal. TCR binding to MHC provides specificity to T-cell activation, but further costimulatory signals are required. Binding of B7-1 (CD80) or B7-2 (CD86) molecules on the APC with CD28 molecules on the T cell leads to signaling within the T cell. Sufficient levels of CD28:B7-1/2 binding lead to proliferation of T cells, increased T-cell survival, and differentiation through the production of growth cytokines such as interleukin-2 (IL-2), increased energy metabolism, and upregulation of cell survival genes.

\textit{CTLA-4} +49 A/G binding to B7 may actually produce inhibitory signals that counteract the stimulatory signals from CD28:B7 and TCR: MHC binding\textsuperscript{(10)}. Proposed mechanisms for such inhibitory signals include direct inhibition at the TCR immune synapse, inhibition of CD28 or its signaling pathway, or increased mobility of T cells leading to decreased ability to interact with APCs\textsuperscript{(11)}. The polymorphism in \textit{CTLA-4} +49 A/G gene may reduce the risk of being infected with pTB, and can down-regulate the inhibition of cellular immune response\textsuperscript{(12)+6230G>A (rs3087243}. The \textit{CTLA-4} +49 A/G (G) GG genotype are more frequent in healthy subjects than patients and may associate with a protection role against intracellular infection\textsuperscript{(13)}.

Screening Motives among Attendants of Breast Cancer-Early Detection Clinics, in Iraq

Marwah Imad Al Ameen¹, Khalid Kareem Rajab², Besmah Mohammed Ali³, Jawad Kadhim Al Diwan⁴
¹FABHS.CM, Al Karamah Teaching Hospital-Baghdad/Iraq, ²Prof. (Consultant Surgeon. FICMS), College of Medicine, Mustansiryah University/Iraq, ³FICMS.CM, Gazi Al Hariri hospital- Baghdad/Iraq, ⁴Prof. (MSc, DCN, FIBMS, FFPH), Dept. Family and Community Med. College of Medicine, University of Baghdad/Iraq

Abstract

Background and Objectives: The early detection model for breast cancer in Iraq is a combined program of an early diagnosis for symptomatic attendants and an opportunistic unsystematic breast clinical examination screening that mainly depend on attendants’ request. With an aim to initiate breast cancer screening program, the current study’s objective is to illustrate the prevalence and motives of screening behavior among attendants.

Method: A cross sectional study was conducted for a period of three months, interviewing 500 randomly selected attendants of two breast cancer early detection clinics in Baghdad city. Data presented in frequency and percentages and analyzed by binary logistic regression, P ≤ 0.05 reflected a significant association.

Results: The results showed that only 42 (8.4%) attended the breast clinics with screening intention. Being employed (OR= 3.198; 95% C.I.= 1.284 – 7.964; P=0.013) or a student (OR=6.605; 95% C.I.= 1.125 – 38.759; P=0.037), of high socioeconomic status (OR=2.695; 95% C.I.= 1.036 –7.012; P =0.042) and having a positive family history of breast cancer (OR= 5.17; 95% C.I.= 2.466 –10.855; P <0.001) were significant reasons for breast cancer screening.

Conclusions: Reforming the health system and tackling access barriers to screening should be endorsed through applying multiple components interventions to increase women participation in the service with a special focus on the less empowered under-served ones.

Keywords: Breast cancer; early detection; Screening; Screening intention; Screening motives.

Introduction

Breast cancer; the most frequent cancer among women, impacting 2.1 million new cases each year, contributing about 11.6% of the total cancer incidence burden worldwide. In 2018, it is estimated that 627,000 women died from breast cancer—that is approximately 15% of all cancer deaths among women. ¹ In Iraq, it stands as the second cause of cancer mortality (12.01%) and the commonest cancer among Iraqi women (34.27%) with 4922 newly diagnosed cases in 2016, of them 828 (16.8%) women were below 40 years of age. In Baghdad, the capital city of Iraq, breast cancer incidence reaches to 41.65 per 100,000 women. ²

Early detection practices are the most important ways to catch breast cancer early and increase survival rates, hence it is the second pillar of the national cancer control program (NCCP) with the principles of providing national educational campaigns about early warning signs of breast cancer via mass media involvement and school curricula, in addition to strengthening the efficacy of breast early detection program and encouraging researches in the area. ³

The early detection model of breast cancer in Iraq is a combined program of an early diagnosis for symptomatic attendants presenting with breast pain, mass and nipple discharge etc. and an opportunistic unsystematic breast clinical examination screening. ⁴,⁵ That might be followed by mammograms (for 40 years and older women) or ultrasound (for women younger than 40 years of age), these are provided on a woman’s request or by her physician’s recommendation.
Therefore, screening is not regulated, there are no centrally prearranged invitations nor a follow-up system for screening. \[6\]

According to the triple assessment protocol trailed in the breast early detection clinics, patients with positive radiological evaluation (mammography and/or ultrasound) are sent for tissue sampling through fine needle aspiration or excisional biopsy. \[5\] Due to lack of awareness and screening opportunities, breast cancer is usually detected at a later stage. According to the national Iraqi cancer registry in 2016, more than 80% of cases presented with infiltrative ductal carcinoma as their main morphology. \[2,7\]

**Justification of the issue:**

It had been reported that making the decision to implement screening as part of breast cancer control strategy should be preceded by promoting education not only to public but also to health care professionals. \[5\] Yet resource limitations dictate the national priorities. Regularly monitoring cancer control activities to ensure they are effective and remain effective is essential. \[8\]

As a result, providing information on the prevalence of screening among breast clinics attendants would reproduce the public willingness to screen plus it will provide a feedback results on the awareness campaigns that had been ongoing since establishment of the NCCP program from one hand, and identifying the demography of screeners would serve as a contrast to find out those who need to be targeted by the awareness campaigns from the other hand.

**Research questions:**

1. Do people visit the early detection clinics for screening?
2. What is the prevalence of screen-attendants?
3. What motivate attendants to screen for breast cancer?

**Aim**

Initiating breast cancer screening program.

**Objectives:**

2. Demographic characteristics of the screeners.

**Patients & Methods**

A cross sectional study was conducted from the first of November 2018 to the end of January 2019, in two major hospitals in Baghdad- Iraq (Al Yarmook Teaching Hospital and Al Eliwiya Maternity Hospital). Each hospital had an active, functioning and fully equipped breast cancer early detection clinic (i.e. with an ultrasound, mammography and fine needle aspiration units attached to the breast clinic). These clinics are installed in the outpatient wards of the hospitals. Using the sample size equation \[9\]: 

\[ n = \frac{z^2 \cdot p(1-p)}{E^2} \]

where \( n \) is the sample size, \( Z \) is the critical value in a two-tailed test and equals to 1.96, \( E \) is the sampling error equals to 5%, \( P \) is the estimated prevalence, here it is considered 0.50.

Through systematic random sampling, 500 randomly selected attendants were approached, verbal consents were obtained after explaining the aim and objectives of the study. Interviews were completed within facility premises using a structured questionnaire that was developed based on literature review, meeting with focus group and supervisors’ experiences. The requested information was age of respondent, educational achievement, employment, husbands’ education, area of residency, reasons for attending the clinic, source of referral to the breast clinic, family history of breast cancer and a set of questions regarding socioeconomic status (SES) which was determined using a newly proposed Iraqi scale. \[10\]

The questionnaire was tested and piloted on twenty-five clinic-attendants and changes were made accordingly. The questionnaires which were distributed during the pilot phase were not used in the final analysis. Data were coded and analyzed using **statistical package for the social sciences** version 18. Binary logistic regression was used to identify the demographic predictors for screening among attendants. P value equal or less than 0.05 was considered significant.

**Results**

 Majority of women who attended the breast early detection clinics were symptomatic. Figure (1) illustrates the reasons for attending the breast clinics among the studied sample. The mean age for symptomatic attendants (complaining) was 42±11.8 years ranging from 16 up to 66 years. While the average age for the
asymptomatic group (screening) was 44.5 ±10.4 years, within a range of 22 to 63 years.

Figure (1): Distribution of the sample according to reasons of attendance the breast clinics (n=500)

The main complaint was having breast pain (245; 49%), followed by feeling a lump (150; 30%), nipple discharges (45; 10.8%) and other symptoms (9; 1.8%). Only 42 (8.4%) attended the breast clinics with screening intention. Eleven (26.2%) women were employed and three participants were university students at the time of the interview. As for the source of referral to the breast clinic, 18 (42.9%) women were self-referred, 13 (31%) had a friend or a family member registered in the same breast clinic and 11 (26.2%) were recommended to screen their breasts regularly by their private physicians. Table (1) demonstrates the distribution of the studied sample by the sociodemographic characteristics according to reason for visiting the breast clinic.

Logistic regression analysis was employed to predict the probability that a participant would attend breast clinic for screening. The predictor variables were age, residency, employment status, family history of breast cancer, socioeconomic status, participants’ and their husbands’ education levels. A test of the full model versus a model with intercept only was statistically significant, \(X^2(15, N = 500) = 58.035\), \(p < 0.001\). Table 2 shows the logistic regression coefficient, Wald test, and odds ratio for each of the predictors.

Having a positive family history of breast cancer is 5.173 times more likely to attend breast clinic for screening than those with no such history. High socioeconomic status women were 2.695 times more likely to screen for breast cancer. Being employed or student were 3.198 and 6.605 times more likely to request breast cancer screening respectively.

Discussion

Nearly one out of twelve clinic-attendants, was there for screening purposes, this low (8.4%) percent is consistent with another Iraqi study where only 9.5% of women visited the breast center for routine screening. [11] While in Jordan the percent rises to 25.4% (16.8% had clinical breast examination and 8.6% had periodic mammography screening). [12] This might be explained by the neglect of screening education and promotion, which is probably related to Iraq’s unique situation of conflicts (wars and civil wars) that in turn modified priorities. Breast cancer screening and even clinical services on breast cancer have been neglected particularly due to lack of available equipment, funds, organizational structure and quality criteria. [7] Having breast pain was the main complaint for visiting the breast clinic followed by feeling a lump, which goes in line with a previous study. [11] Lack of women knowledge about breast cancer screening would result in missed screening opportunity. [13] When public screening-demands are low, doctors’ words remain a proven influence for pursuing screening particularly when clients don’t fully realize the idea of visiting the health facility without having symptoms. [6, 14-16] It had been reported that the most frequent reasons for not going to breast cancer screening exams regularly were absence of breast problems. [17] Henceforth increasing population demand for screening together with healthcare providers’ delivery interventions [18] through engaging community and family physicians in screening services might be useful to increase service beneficiaries; since these physicians are the health
promoters, educators and the preventive force for the health system. [19, 20]

Similar to reported findings in literature, employed ladies are more empowered, financially capable of seeking screening and most likely will self-refer to the breast clinic. Being a student means more exposure to educational campaigns whether via media or school curriculum that in turn influence a positive attitude toward screening. Having a relative diagnosed with breast cancer might rise the perceived risk of breast cancer and eventually motivates screening behavior. [12,14, 21,22]

Therefore; in the absence of a breast cancer screening program, it appears clearly that the most empowered women are the ones who are motivated for requesting screening whether it might be due to their knowledge or ability to pay for services, or due to perceived risks of breast cancer. This sequentially indicates a need to reform awareness campaigns and extend its audience further to the less privileged. Initiating a breast cancer screening though is still a goal, yet increasing women participation in the early detection service and mainly among the screening group might be the first step to attain that goal.

Conclusion and Recommendations

There is an urgent need to increase both public and healthcare providers’ awareness about screening, reforming the health system and tackling access barriers to screening should be endorsed through applying multiple components interventions to increase women participation in the service with a special focus on the less empowered under-served ones.

Study the Toxicity and Anticancer activity of Some New Amic Acid and Their Derivatives of Mefenamic acid

Ali A. Sabah¹, Muna S. Al-Rawi¹, Jumbad H. Tomma¹

¹Department of Chemistry, College of Education for Pure Science Ibn Al-Haitham, University of Baghdad, Baghdad, Iraq

Abstract

A series of amic acid derivatives of mefenamic acid were synthesized with the aim of inhibiting topical gastrointestinal toxicity of mefenamic acid. The key intermediate amic acid (III) was prepared from the reaction of acid hydrazid of mefenamic acid(II) with phthalic anhydrides in dry actone. The new type of imide compound (IV) was dehydrated the amic acid(III) with acetic anhydrous and sodium acetate. The esterification of hydroxyl groups of amic acid (III) produce corresponding ester(V), which was condensed with hydrazine hydrate to give acid hydrazide (VI), then the later compound reacted with syringaldehyde in dry benzene to yield new schiff base (VII). The new derivatives containing heterocyclic unit (VIII)-(X), four and five, member ring were successfully formed such as azetidin-2-one, thiazolidin-4-one, and,imidazolidin-4-one. The structures of the synthesized compounds were confirmed using FTIR, ¹HNMRI, Mass and CHN-S. The antibacterial activities of some synthesized compounds were screened and showed a highest or low inhibition against Staph.aureus (G+), Bacillus subtilisa (G+), Klebsiella pneumoniae (G-), and E.coli (G-). Also, The cytotoxic effect of different concentrations of some the synthesized compounds was tested against MCF-7 cell line (human breast carcinoma cells) and positive results were obtained for some of them, which encouraged us to study the toxicity using living organisms (mice) to evaluate its acute toxicity and proved the resules of non-toxicity of the derivatives.

Keywords: Mefenamic acid, imidazolidin-4-one, antibacterial activities, MCF-7 cell line, acute toxicity study.

Introduction

Mefenamic acid is one of the anthranilic acid derivatives class of non-steroidal anti-inflammatory drugs (NSAID)) is thought to be due to their interference with prostaglandin biosynthesis, and is used to treat strong analgesic and antiinflammatory agents in the treatment of degeneration of joint cartilage, rheumatoid arthritis and musculoskeletal disease [¹].

The general view in the literature shows that mefenamic acid undergoes a number of reactions, this has been used in the preparation of many compounds containing heterocyclic moiety of therapeutic molecules for different applications, including the presence of effective anti-cancer drugs, antimicrobial, inflammatory and cytotoxic activities[²].

Amic acid and its derivatives have been extremely used in drug industry, advanced materials and biologically active heterocycles. In fact, amic acid carrying suitable position of carboxylic group are prime precursors for synthesis of heterocyclic derivatives[³].

A large number of heterocyclic compounds have been explored for developing pharmaceutically molecules. Among this the derivatives: azetidin-2-one (β-lactam), thiazolidin-4-one, and imidazolidin-4-one, have been playing an important function in the pharmaceutical chemistry [⁴]. This study is aimed at synthesis new active molecules with fewer side effects that can be successfully used as drugs, the cytotoxic effect and non-toxicity proved the resules of this derivatives.

Experimental

Materials and instruments:

All solvents and chemicals were purchased from Sigma- Aldrich, and GCC Chemicals company. Melting points were recorded using electrothermal melting point apparatus and are uncorrected. The FTIR spectrums were registered using KBr discs on Shimadzo (Ir prestige-21) Fourier Transform Infrared Spectrometer. $^1$HNMR spectra were recorded on Bruker, Ultra Shield (300)MHz, Switzerland and using DMSO-$d_6$, and CDCl$_3$ with reference to TMS as internal reference. Elemental micro-analyses were carried out using an EuroEA Analyzer. Mass spectra of compounds were measured by Electron Impact (EI) 70eVmass using a MS Model: 5973 spectrometer.

\(\text{Ar} = 4-\text{OH,3,5-OC}_3\text{CH}_{12}\)
Preparation of methyl 2-(2,3-dimethylanilino) benzoate (I)

This compound (I) was prepared following the procedure described by Lit. [5] yield 80%; m.p(96-98)°C.

Preparation of 2-(2,3-dimethylphenylamino) benzohydrazide (II)

This compound (II) was prepared following the procedure described by Lit. [5], yield 78%; m.p (118-120)°C.

Synthesis of 2-(2-(2-(2,3-dimethylphenylamino) benzoyl)hydrazine-1-carbonyl) benzoic acid (III)

In a flask with magnetic stirrer, a solution of (2.55g, 0.01 mol) of acid hydrazide (II) in 20 mL of acetic anhydride was dripped into a solution of (1.48g, 0.01 mol) phthalic anhydride in 20 mL of acetic anhydride for 30 min at room temperature. Stirring was continued for 5 hrs. The brown solid precipitate was filtered, washed, dried and recrystallized from ethanol to give a new amic acid (III), yield 74%, m.p (167-169)°C; FTIR (ν ,cm⁻¹): 3392-2571(OH), 3340-3309 (NH), 3012 (C-H arom.), 2939-2922(C-H aliph.), 1712, 1653 (C=O), and 1255 (C-O); ¹H NMR (δ ppm): 6.66-8.09 (m,11H,Ar-H), 9.45, 7.91, and 7.58 for (s,1H,NH); mass spectra (relative intensity%): m/z=403(5), 223 (75), 178(70), 123 (70), 69(100), 104(68), 51(25):Elemental analysis: Calcd. for C₂₉H₂₉NO₄: C, 71.68; H, 4.93; N, 10.90; Found: C, 71.98; H, 5.11; N, 11.03.

Synthesis of methyl 12-(2-(2-(2,3-dimethylphenyl) amino) benzoyl) hydrazine-1-carbonyl) benzoate (V):

A mixture of compound (III) (4.03 g, 0.01mol), absolute methanol 30mL and H₂SO₄ 5.4 mL was refluxed 6 hrs. After cooling washed the mixture with NaHCO₃ solution, the resulting of a white crystals solid was filtered off, washed with water, dried and recrystallized by ethanol to give compound (V), yield 71%; mp (137-139) °C; FTIR (ν ,cm⁻¹): 3330-3309 (NH), 2987 (C-H arom.), 2939-2922(C-H aliph.), 1732, 1685, 1657 (C=O), and 1255 (C-O); ¹H NMR (δ ppm): 2.08 (s, 3H, CH₃), 2.27 (s, 3H, CH₃), 3.86(s,3H,OCH₃), 6.66-8.09 (m,11H,Ar-H), 9.66,and 9.18 for (s,1H,NH); Elemental analysis for this compound : Calcd. for C₂₉H₂₃N₃O₄; C, 69.06; H, 5.51; N, 10.07; Found: C, 69.45; H, 5.80; N, 10.30.

Synthesis of N′-(2-(2,3-dimethylphenyl) amino) benzoyl) phthalohydrazide (VI):

A mixture of ester compound (V) (4.17gm,0.01mol), was dissolved in absolute ethanol 3mL. Hydrazine hydrate(0.5gm,0.01 mol) was added slowly and the mixture was refluxed for 6hrs. The mixture was cooled and the pale yellow solid was filtered, then used ethanol to recrystallized, yield 70%, m.p (158-160)°C, FTIR (ν ,cm⁻¹): 3305-3145(NH₂,NH), 3001(C-H arom.), 2941-2822(C-H aliph.), 1660,1639(C=O amide); ¹H NMR (δ ppm): 2.11 (s, 3H, CH₃), 2.28 (s, 3H, CH₃), 6.56-8.05 (m,11H,Ar-H), 9.13, and 8.18 for (s,1H,NH); Elemental analysis: Calcd. for C₂₉H₂₃N₃O₅; C, 66.18; H, 5.51; N, 16.78; Found: C, 66.70; H, 5.78; N, 17.01.

Synthesis of (Z)-N′1-(2-((2,3-dimethylphenyl) amino) benzoyl) -N′2-(4-hydroxy -3,5-dimethoxybenzylidene) phthalohydrazide (VII):

A mixture of new compound (VI)(4.17g, 0.01 mol) , Syringaldehyde (1.82g,0.01mol) with EtOH 15 mL and 6hrs, cooled after that filtered the product and crystallized from ethanol,dark yellow powder, yield 70% , m.p (150-152) °C, FTIR (ν ,cm⁻¹): 3548(OH), 3469-3344(NH), 3016 (C-H arom.), 2968-2935(C-H aliph.), 1651(C=O amide), 1626(C=N); ¹H NMR(δ,ppm,CDCl₃): 2.10 (s, 3H, CH₃), 2.29 (s, 3H, CH₃), 2.51(s, 1H,OH ), 3.84 (s,6H, OCH₃),6.68-8.58 (m,13H,Ar-H),7.32(s,1H(CH-N)
A number of new mefenamic acid derivatives were synthesized by the reaction between the carboxylic acid group in mefenamic acid and methanol in acidic medium (I), which was converted to acid hydrazide (II), then the later reacted with phthalic anhydride with heating in dry acetone to give compound (III) in good yield. FT-IR spectrum for (III) show the new absorption stretching bands due to O-H of COOH moiety in the region (3392-2571)cm⁻¹, a stretching band to C=O for COOH appeared at 1712 cm⁻¹, a stretching band asymmetry and symmetry of N-H group appeared at 3340-3309 cm⁻¹. Imide compound (IV) was synthesized by cyclization of amic acid (III) using acetic anhydride and anhydrous sodium acetate. Results and Discussion

A number of new mefenamic acid derivatives were synthesized by the reaction between the carboxylic acid group in mefenamic acid and methanol in acidic medium (I), which was converted to acid hydrazide (II), then the later reacted with phthalic anhydride with heating in dry acetone to give compound (III) in good yield. FT-IR spectrum for (III) show the new absorption stretching bands due to O-H of COOH moiety in the region (3392-2571)cm⁻¹, a stretching band to C=O for COOH appeared at 1712 cm⁻¹, a stretching band asymmetry and symmetry of N-H group appeared at3340-3309 cm⁻¹. Imide compound (IV) was synthesized by cyclization of amic acid (III) using acetic anhydride and anhydrous sodium acetate. FT-IR spectrum for (IV) show characteristic absorption bands at 3344 cm⁻¹ due to N-H imide, and absorption bands at (1747, 1645) to carbonyl imide groups[6].

The esterification of hydroxyl groups of amic acid (III) produce corresponding ester(V), the FTIR spectrum for (V) a display absence absorption stretching bands O-H and C=O groups together presents of new bands at 1732 cm⁻¹and 1255 cm⁻¹assigned to carbonyl and C-O groups of ester moiety, respectively. Ester(V) was condensed with NaOH to give acid hydrazide (VI), the FTIR spectrum display stretching vibration asymmetry and symmetry of NH and NH groups in the region(3305-3145)cm⁻¹ as well as stretching absorption at 1651cm⁻¹for C=O amide. When the reacted compound(VI) reacted with thionyl chloride, new Schiff base (VII) was formation. FTIR spectrum for
compound(VII) display absence of bands of NH$_2$, NH groups with a new stretching band C=N group at 1626 cm$^{-1}$. Finally, three derivatives containing heterocyclic unit (VIII-X) four, and five member ring synthesized from reacted the shiff base(VII) with chloroacetylchloride, thioglycolic acid, and glycine in triethylamine, respectively. All compounds are identified by physical properties, and by spectral methods FT-IR, $^1$HNMR and elemental analysis.

**Biological Activity**

Mefenamic acid has analgesic action three times more than that of aspirin. However, like all classical NSAIDs are associated with an increased risk of gastrointestinal ulcers. This study involves synthesis, evaluate antibacterial activity , cytotoxic effect, and toxicity in vivo of new amic acid and their derivatives of mefenamic acid, which are expected to have fewer side effects than the original compound.

**Antibacterial activity**

The antibacterial activity of the compounds were examined (in vitro) against *Staph. aureus* (G+), *Bacillus subtilisa* (G+), *Klebsiella pneumoniae* (G-), and *E.coli* (G-) using the agar diffusion method[7]. Most of the derivatives display high or low biological activity versus bacteria, the data are listed in table(1) . Compound (VIII) showed good inhibition against *Staphyllococcus aureus*, this could be related to the presence of azetidin-2-one(β-lactam), while compound (X) showed slightly active against *Klebsiella pneumonia* and *E.coli*.

**Anticancer screening**

The cytotoxicity of new amic acid and their derivatives of mefenamic acid (III, IV, VII, VIII, IX) against a human breast cancer cell line[8] for 48h. MCF-7 cells were seeded in (96-well)culture plates at 200 µl/ of cell suspension was filled to each well and the plates covered by plate and sealed at Para film and put in an incubator, then incubated for 24 h in humidified chamber at 37°C with 5% Carbon dioxide gas and medium fill up with 10% bovine serum and 1% of penicillin / streptomycin mixture until the cells reached confluence. The plate was checked out for contamination, and cultured at different concentrations 10 - 500 µg/ML, while 200µl of maintenance medium were added to each well of monitoring group, then plates were tight with Parra film and regressed to the incubator. Evaluation of cytotoxicity was carried out after 48 , the supernatant was removed, 150 µL of DMSO was added to the solution then shaking, and absorbance values reeds at $\lambda = 450$ nm to calculated the rate of inhibition of cell growth. Cytotoxicity assay for derivatives (III, VII, and VIII) caused good inhibitory effect on the growth of cell line except compounds (IV, and IX), table (2). compound (III)showed more than 50% inhibition for MCF-7and compound (VII and IX) less than 50% inhibition for MCF-7cell line.

**Acute Toxicity Test**

In this research, three groups of 45 albino mice (each consisting of 15 mice) were used to evaluate the acute toxicity of some synthesized compounds (III, IV, VII, VIII, IX), using the Lorke-written method[9]. Mice were fasted for 18 h with free arrival to water before experiment. The compounds were dissolved in distilled water and treated via the oral route (5 and 10 g/kg). The mice are fed, weighed and observation of general signs of toxicity symptoms, behavior, and mortality for 14 days. The study exhibited : no mortality with doses 5 and 10 g/kg body weight, no contrast in the weight of the mice (weighted every day) between the group control and the treated groups, no change in mice behaviors was in the weight of the mice daily measured between the group control and the treated groups, no modification in mice behaviors was recorded, and no toxicity symptoms were announced next 14 days. Moreover, some mice were sacrificed by cervical dislocation and kidneys, liver, and heart were weighed. Finally, visual estimate of organs of mice showed normal cases.

**Conclusion**

Amic acid represent a major class of organic compounds and used some of these derivatives in therapeutic purposes, therefore modification structure of the amic acid derived from mefenamic acid have allowed using multistep processes to the synthesized of new derivatives may be having a broad spectrum of biological activity. Some amic acid and their derivatives of mefenamic acid were screened for their antibacterial, anticancer activity and acute toxicity test . We need to further examination to know mechanism by which the heterocyclic compounds act to give a potent cytotoxic effect that might get the mefenamic derivatives being blight anticancer product.

Investigating Effects of *Salvia Officinalis* (Sage) on Development of Mice Embryos Kidney and Some Hormonal Effect of Treated Mothers

Ban Thabit Al- Ani1, Rana R Al Saadi2, Raad Ghazi Reshan3

1High Institute of Infertility Diagnosis and ART’s, Al Nahrain University, Baghdad, Iraq

**Abstract**

**Background** *Salvia officinalis* (sage) is commonly employed in both medicinal and culinary preparations, *Salvia* plants are antioxidant and can improve ‘head and brain’ function.

**Aim of study**: To examine effects of aqueous plant extract of sage on development of mouse embryos kidney and hormonal effect of treated mothers.

**Material and Method**: Thirty adult albino Swiss female mice were used in this experiments study, their weight was 23-27 gm, three groups with 10 mice per group were categorized as:

G(A) orally treated with sage aqueous extract (167.8) mg/kg, G(B) administration orally with sage aqueous extract (83.9) mg/kg, G(C) orally treated with distilled water (control group) for 6 weeks. For histological study, the pregnant female mice have been sacrificed at day 17 of gestation of each group and 30 mice embryos were fixed in Bouin’s fixative, paraffin infiltration. Specimen stains with H&E. After 24 hours from last orally dose of treatment period, 3 animals from each groups were sacrificed under ether anesthesia, 3 ml blood sample was collected from each animals, serum reproductive hormonal assay of FSH, LH, E2 and P4 were performed depends on kit assay procedure of ELISA kit.

**Result**: Histological examination of embryonic kidney after maternally oral administrated of *sage* reveals, different histopathological changes of embryonic renal tissue, also results revealed an increase that is highly significant (*P*< 0.01) in the numbers of fetuses belongs to G(A) and G(B) mothers at day 17 in comparison with G(C). Statistical analysis revealed in contrast with G(C) a highly significant (*P*< 0.01) rise in weights of fetuses (males and females) belonged to mothers of G(A) and G(B), while, serum hormones level show highly significant (*p*≤0.01) rise in E2 and P4 level in G(B) when compared with G(A), while significant decrease (*P*<0.05) in FSH level in G(A) and G(B), and there was a significant rise (*P*<0.05) in LH hormone level in G(A) and G(B).

**Keywords**: *Salvia officinalis* (sage), aqueous extract, mice embryo.

**Introduction**

In the past years, *Salvia officinalis* (sage) Medicinal plants were regarded as the only form of healthcare accessible to the mainstream of human population (1). Likewise, numerous plants was empolyed as sex stimulants in classical medicine (2). It contains steroid and flavonoid such as genistein, daidzein and coumestrol (3) that are recognized as phytoestrogens. The metabolites of phytoestrogens act an estrogenic effect on central nervous system which stimulates cell division and growth of the genital tract of female animals (4). *Sage* is similarly employed internally in the treatment of night sweats, excessive lactation, profuse perspiration (as in tuberculosis), excessive salivation (as in Parkinson’s disease), depression, anxiety, menopausal problems and female sterility (5) (Fig.1), *Sage* likes being a panacea; it was employed as sexual debility; to treat mental and nervous conditions for menstrual and menopausal problems (6). There are numerous bioactive compounds existing in this plant, like terpenes and phenolic compounds (7)and (8), that are believed to be the key for...
various therapeutic properties accredited to sage\(^{(9)}\). 

\textit{Sage} have antioxidant activities may be therapeutically helpful and it was revealed that the antioxidant potential of plants due to their phenolic components \(^{(10)}\). Nevertheless, their impact on preimplantation embryos does not have reasonable amount of studies to examine such impact \(^{(11)}\). The estrogenic activity of \textit{sage} was demonstrated experimentally, the herb has strong effects in cases of oligomenorrhea and amenorrhea \(^{(12)}\). Therefore, it can be used as premenstrual tension, cysts, pelvic congestion fibroids, irregular (or heavy menses), and endometriosis for hormone imbalances, and it is not permitted to use in pregnancy \(^{(13)}\).

\textbf{Figure (1): Sage (\textit{S. officinalis})} \(^{(5)}\)

\section*{Materials and Method}

\subsection*{Preparation of Plant Extracts}

Plant extracts were done according to \(^{(11)}\). Leaves were air-dried and powdered using coffee grinder. Using soxhlet apparatus and water bath, 50 gm. of the leaf powder were removed for 3 H in 250 ml of the solvent (distilled water) at 45°C. Via a rotary evaporator, the leaf extract solution was evaporated at 45°C and the resulting crude cutting was held at -20°C.

\subsection*{Sage Doses and Concentrations:}

Aqueous plant extract was assessed in a mammalian model (albino mouse). Two doses of sage extract were used (83.9 or 167.8 mg/kg). These doses were correspondent to 10 and 20%, respectively of the dose in mice.

\subsection*{Laboratory Animals:}

Albino Swiss female mice were used in the experiments. Their age and weight at the beginning of experiments was 6-8 weeks, and 23-27 gm, respectively. Mice were grouped, each of which was kept in a distinct plastic cage. The mice were preserved at a temperature of 23 – 25°C, and had free access to food (standard pellets) and water.

\subsection*{Animals Groups:}

Effects of two doses (83.9 and 167.8) mg/kg of sage extract (aqueous) with control were investigated. Therefore, animals were grouped into three groups according to treatment procedure:

\textbf{GA}: Orally with the aqueous extract of sage (83.9) mg/kg (10 animals) for 6 weeks.

\textbf{GB}: Orally with the aqueous extract of sage (167.8) mg/kg (10 animals) for 6 weeks.

\textbf{GC}: With distilled water (control = 10 animals) for 6 weeks.

\subsection*{Blood sample collection and hormonal assay:}

After 24 hours from last orally dose of treatment period, 3 animal from each group G (A), G (B), G (C) sacrificed under ether anesthesia, blood was collected from the animals in each group by cardiac puncture used disposable syringe of 5ml, blood samples were collected in a centrifuge tubes for maximum coagulation and separation of serum, after centrifuged at 3000 rpm/10minutes, serum was isolated, frozen at (-20°C) and then processed for hormonal assays. The serum reproductive hormonal assay of E2 and p4 were performed depends on kit assay procedure of ELISA kit (Germany).

In the metestrus phase, females remained with mature healthful males for mating (1 male/ 2 female). Vaginal plug incidence regarded as the initial day of pregnancy \(^{(14)}\) the following days were consecutively counted. The pregnant female (PF) was extracted into separate cages.

When PF in G(A), G(B) and G(C) reach day 17 of gestation, animals undergo abdominal incision, plenty of died and alive fetuses in each horn were reported. Each fetus was washed and weighted for all groups. The embryos were stable in Bouin fixative and paraffin and implanted sections were stained with eosin and hematoxylin, two pathologists unaware of the plant and the dose individually read and reviewed the specimens.
Results

Daily administration of either 83.9 mg/kg b wt. as G(A) and 167.8 mg/kg B wt. as G(B) of Salvia officinalis (sage) to female mice for 6 week until day 17 of gestation cause some changes including:

A- Weights changes: significant rise \( (P < 0.01) \) in fetuses weights (males and females at day 17 of gestation) in G(A) and G(B) in comparison with G(C) as showed in (Table 1). Differences recorded between body weight of males and females fetuses at right and left uterine horns in G(A) and G(B) administered mothers. These results showed that female’s weights were higher than the males. These differences lacked significance (Table 1).

B - Numbers of fetuses: important rise \( (P < 0.01) \) in the numbers s of fetuses belongs to G(A) and G(B) mothers at day 17 in comparison with G(C) (Table 2).

C- Level of serum hormones: The result of hormonal level show a highly significant \( (p \leq 0.01) \) increase in E2 level in G(B) in contrast with G(A) as show in (Fig.2), Similar results seen in P4 level in G(B) in contrast with G(A) (Fig.3).

D - Histological Observations including:

1- Control group (fetal kidney)

The embryonic kidney of the control group displays the histological features of the normal renal tissue (Fig.4).

2- Treated group (Histopathological Changes of kidney fetus)

Fetus kidney shows that, glomeruli appeared shrunken, swollen with wide, narrow capsular spaces (CS) respectively (Fig.5). The convoluted tubules showed some abnormal changes in its histological organization; Nuclei of its epithelial cells were pyknotic (P) with condensation in chromatin material. Also, an evidence of degeneration in glomeruli (G) of Bowman’s capsule (BC) was recorded (Fig.5).

Table (1): Changes in fetal body weight at day 17 of gestation belongs to G(A) and G(B) treated with Salvia officinalis (sage) as compared with GC (Mean± S.E.).

(H&E, A400X, B1000X, C200X).

Discussion

The daily administration of aqueous extract of *salvia officinalis* as 83.9 mg/kg b wt. as G(A) and 167.8 mg/kg B wt. as G(B) orally to pregnant female mice showed a significant reduction in fetal weight, these result agreed with that found by Evans *et al* (15) who proved that infants born to mothers with prenatal exposure to steroids had an increased risk of low birth weight. This reduction because *Salvia officinalis* contain steroid, isoflavones, and isoflavonoids (13) The mechanism of decreased fetal growth because progesterone possess both membrane and cytoplasmic receptors in a numerous reproductive and non-reproductive tissues including the brain and is a powerful inhibitor of GnRH for that exogenous progesterone may disturb the normal hormone work and interfere with normal genital development in fetal reproductive tract as demonstrated by Mari S (16).

In experimental groups G(A) and G(B), there were a highly significant decrease in fetuses number at day 17 of gestation and at birth time, this result explained on bases that progesterone make it harder for fertilized ova to be linked to the walls of the uterus, resulting in a lower probability of pregnancy as shown by Nagel (17).
Moreover, there are some differences in numbers of female fetuses which was higher in comparison with the numbers of male fetuses in G(A) and G(B), these results are due to that sex hormones powerfully impact the functional and anatomical organization of the sex organs, muscular and skeletal structure, and central nervous system (CNS), therefore is a major contributor to sexual discrepancy (18).

After 6 weeks of administration of *silva officinalis*, preovulatory secretion of P4, even though restricted, can apply positive feedback on the estrogen-primed pituitary to enlarge LH release (19). This phytoestrogen that is operating at high or low concentration disturbs diverse target tissues and performs as agonist or antagonist to E2. Phytoestrogens have ability to affect rudimentary cell biology to their impact on cellular enzymes, in addition to their aptitude to impact growth factors, instance, cytokines, and to control genes apply antioxidant actions even at a low level as shown by (20). The Corpus Luteum secretes E2, P4, and inhibin, as documented by Knobil (21). The estrogens use negative feedback at both low and high concentrations. On the other hand, progestins are operational just at high concentration (22).

Kidneys at second and third trimesters typically have the same configuration as in postnatal life, their appearance depend on the gestational age at normal configuration help in early diagnosis and optimize fetal safety then reduce the high prenatal morbidity and mortality (23).

Association among Vitamin D Deficiency with some Inflammatory Marker in Iraqi Patients with Autoimmune Thyroiditis

Noor Alhuda Kh. Ibrahim1, Zaid Nsaif Abbas2, Wasnaa J. mohammad1
1College of Nursing University of Baghdad/ Baghdad, Iraq, 2College of biotechnology/Al-Nahrain University / Baghdad, Iraq, 3College of Nursing /University of Baghdad/ Baghdad, Iraq

Abstract

Background: Hashimoto thyroiditis (HT) is a common chronic autoimmune disease of the thyroid gland, characterized by painless goiter and elevated thyroid antibodies. Hypovitaminosis D (vitamin D insufficiency and deficiency) is common among patients with HT.

Method: The study include (60) subjects compared with 30 apparently healthy control group were visiting nursing home hospital in Baghdad medical city, Levels of serum thyroid-stimulating hormone (TSH), free-triiodothyronine (FT3), free thyroxine (FT4), TgAbs, and TPOAbs were determined with automated immuno chemiluminescent assay (ICMA) kits (Abbott Laboratories, IL, USA). Levels of serum 25-hydroxyvitamin D 25(OH) D) were determined using a competitive protein-binding assay (Roche Diagnostics, Mannheim, Germany). The inter-assay variation coefficient for 25(OH)D measurement was 8.5%.

Results: The level of the study parameters in autoimmune thyroiditis which show significant correlation in age ,BMI, vitamin D, anti TPO antibody,IL-17, TNF-α and thyroid function (p<0.05) (p<0.01) test but calcium show non significant correlation between patients and control group.

Conclusion: The present work shows a significant association between circulating 25(OH)D and HT, also IL-17.

Keywords: Vitamin D; autoimmune thyroiditis; Iraqi patients

Introduction

Autoimmune thyroid disease (ATD) is the most prevalent endocrinopathy (1). The prevalence of ATD was as high as 60% of patients, 40% of whom additionally suffered from thyroid disorders including overt hypothyroidism (24%), subclinical hypothyroidism (8%), and hyperthyroidism (8%) (2). According to Krzewska et al. the ATDs Hashimoto’s thyroiditis and Graves’ disease, are the most prevalent autoimmune diseases in children and adolescents. The autoimmune pathology in clinical practice seems a difficult task for endocrinologists, with many unknowns. Modern laboratory diagnosis with high sensitivity allows the detection of autoantibodies in autoimmune thyroiditis (AIT) and the monitoring of a wide spectrum of markers of the immune status of patients for diagnostic research and treatment (3).

Hashimoto thyroiditis (HT) is the most common chronic autoimmune thyroid disease characterized by painless goiter and elevated serum thyroid antibodies. HT may emerge with stimulation of environmental factors in genetically susceptible individuals. Predisposing genes are human leukocyte antigen (HLA), cytotoxic T lymphocyte antigen-4 (CTLA-4), protein thyrosin phosphatase non-receptor type 22 (PTPN22) and thyroglobulin (Tg) genes (4). In recent years, vitamin D deficiency is reported to cause autoimmune diseases. Vitamin D receptors (VDR) were shown to be present in intestinal epithelium cells, osteoblasts, renal cells and most importantly immune system cells (T lymphocytes, monocytes, dendritic cells and also B lymphocytes). Vitamin D inhibits T lymphocyte proliferation, particularly T helper 1 (Th1) lymphocytes. It may increase T helper 2 (Th2) lymphocyte formations. Role of vitamin D in pathogenesis of HT is reduction...
of anti-inflammatory Th lymphocytes and elevation of inflammatory Th1 cells. T helper 17 (Th17) cells were also found to be associated with HT pathogenesis (5).

25-hydroxyvitamin D [25(OH)D] is involved in the regulation of many physiological processes in the body and beneficial effects related to treatment with cholecalciferol were noted in immunodeficiency, cardiovascular disorders, anemia, diabetes, various pathologies of the liver, and gastrointestinal tract disorders, as well as for tuberculosis and malignant tumors of the breast and intestine (6,7). Both genetic predisposition and environmental factors may contribute to the development of autoimmune diseases. Increased levels of immune inflammation markers may affect the course of immuno-endocrine pathology. A gradual development of the autoimmune inflammatory process, when combined with hypothyroidism and DM, may significantly contribute to the development of endothelial dysfunction and the consequent development of vascular complications (8).

Recently, Th17 cells and their hallmark cytokine (interleukin, IL)-17 have been recognized as crucial contributors to the pathogenesis of thyroid autoimmunity (9). Production of IL-17A and IL-17F is characteristically attributed to Th17 cells. These ILs can act on a broad range of cells, including epithelial cells, fibroblasts, and macrophages inducing the release of proinflammatory tissue mediators such as interleukins IL-1β, IL-6, and IL-8, growth and hematopoiesis stimulating factors – tumor necrosis factor-α (TNF-α), granulocyte-macrophage colony-stimulating factor, and granulocyte colony-stimulating factor (G-CSF), and tissue components degrading enzymes metalloproteinases (10). Early studies demonstrated that IL-17 stimulates production of other cytokines such as IL-6, IL-8, and G-CSF in nonimmune cells such as connective tissue fibroblasts and epithelial cells via activation of the nuclear factor-κB (NF-κB) transcription factor (10).

In addition, IL-17 demonstrates strong synergic action being combined with other cytokines, such as IL-1β and TNFα. Previous studies have shown that patients suffering from AITD have enhanced levels of IL-17A and Th17 lymphocytes revealed in blood and colonizing thyroid tissue as well as a marked in vitro differentiation of Th17 cells (10).

Methods and material:

The study included (60) subjects compared with 30 apparently healthy control group were visiting nursing home hospital in Baghdad medical city between October to April 2019. The diagnosis of Hashimoto thyroiditis was made on the basis on clinical examination, and Anti TPO antibody in all of patients.

The Demographic and clinical variables were obtained from participant report and electronic medical records. Demographic include age, sex, and body mass index (BMI). BMI was calculated as weight (kg)/squared height (m²). A fasting morning venous blood sample was obtained from each participant. Levels of serum thyrodstimulating hormone (TSH), free-triiodothyronine (FT3), free thyroxine (FT4), TgAbs, and TPOAbs were determined with automated immuno chemiluminescent assay (ICMA) kits (Abbott Laboratories, IL, USA). Levels of serum 25-hydroxyvitamin D (25(OH)D) were determined using a competitive protein-binding assay (Roche Diagnostics, Mannheim, Germany). The inter-assay variation coefficient for 25(OH)D measurement was 8.5%.

Inclusion Criteria

The age range samples were taken between 18–45 years for two groups and without any chronic condition other than thyroid are included in this study.

Exclusion Criteria

The criteria were excluded from this study including: bone and muscle cardiac disease, pancreatic, hepatobili, diabetes, hypertension, malignancy, oral contraceptive pills (OCP), and pregnancy.

Statistical analysis

The Statistical Analysis System- SAS (2012) program was used to effect of difference factors in study parameters. The standard deviation was used to significant compare between means. The correlation coefficient between difference parameters in this study was estimated.

Results

Table(1) show the level of the study parameters in autoimmune thyroiditis which show significant correlation in age, BMI, vitamin D, anti TPO antibody, IL-17, TNF-α and thyroid function (p<0.05) (p<0.01) test but calcium show non-significant correlation between patients and control group.

Discussion

Hashimoto’s thyroiditis (HT) is the most prevalent autoimmune disorder characterized by the destruction of thyroid cells caused by leukocytes and antibody-mediated immune processes accompanied by hypothyroidism. In recent years, evidence has emerged pointing to various roles for vitamin D, including, proliferation and differentiation of normal and cancer cells, cardiovascular function, and immunomodulation. Vitamin D deficiency has been especially demonstrated in HT patients (11).

Our results show the level of the study parameters in autoimmune thyroiditis which show significant correlation in age, BMI, vitamin D, anti TPO antibody, IL-17, TNF-α and thyroid function (p<0.05) (p<0.01) test but calcium show non-significant correlation between patients and control group.

In recent study The results of this study showed a significant reduction of anti-Tg Ab (anti-thyroglobulin antibodies and) TSH hormone in the Vitamin D group compared to the start of the study; however, there was a no significant reduction of anti-TPO Ab in the Vitamin D group compared to the placebo group (p=0.08). No significant changes were observed in the serum levels of T3 and T4 hormones. Therefore, vitamin D supplementation can be helpful for alleviation of the disease activity in HT patients (12).

Recently, the receptors of 1,25-dihydroxyvitamin D have been found on many cells, including immune cells(13).The expression of 1α hydroxylase (cy27B1) activity in many of these cells supports(14-16) the idea that the Vitamin D has immunomodulating effects. Several genetic studies have shown an association between gene polymorphism of Vitamin D receptor and of 1α hydroxylase (cy27B1) (17-20) with autoimmune thyroid diseases (AITDs).

However, the relationship between Vitamin D and AITDs is still a controversial issue (21). Many studies have already pointed out a relation between low concentration of Vitamin D and AITDs; (22-25) however, the cause and effect relationship is not known. The findings of one prospective case-control study were performed in Amsterdam(26) and did not support the association between low Vitamin D level and early stages of thyroid autoimmunity.

Kivity et al. in a cross-sectional study compared the level of Vitamin D in patients with AITDs, non-AITDs, and healthy people. They showed that the prevalence of Vitamin D deficiency was significantly higher in patients with AITDs than healthy persons. The rate of Vitamin D deficiency was also higher in patients with non-AITDs than healthy population.(27)

Shin et al. in Korea studied the association between Vitamin D and TPO-Ab in patients with and without AITDs. They demonstrated that there was a significant negative correlation between Vitamin D level and TPO-Ab in patients with AITDs. (23)

In a study in Turkey, Bozkurt et al. studied the relation between Vitamin D deficiency and Hashimoto’s thyroiditis. They compared the level of Vitamin D and severity of Vitamin D deficiency between euthyroid patients with Hashimoto’s thyroiditis and a healthy control group. Their results pointed out that there was correlation between severity of Vitamin D deficiency and thyroid volume, level of thyroid autoantibodies as well as duration of Hashimoto’s thyroiditis. They concluded that Vitamin D may have potential role both in development and progression of Hashimoto’s thyroiditis to hypothyroidism. (24)

In a study in Tehran, Iran, Mansournia et al. reached to the similar conclusions. Furthermore, they showed that by 5 ng/mL increases in the level of Vitamin D, the risk of occurrence of Hashimoto’s thyroiditis would be decreased by 19%.(28).

On the other hand, some studies did not support the association between Vitamin D and thyroid autoimmunity (29-32). Effraimidis et al. have conducted two case–control researches in the framework of Amsterdam AITD cohort study to determine the association between Vitamin D and early stages of thyroid autoimmunity. In one cross-sectional study, they compared the concentration of serum Vitamin D between euthyroid participants with genetic susceptibility for AITDs and negative thyroid antibodies and controls who were healthy women without family history of AITDs.

Although Th1-driven autoimmune response has long been considered as dominant for HT development, recent studies are suggesting an evident participation of Th17 cells in AITD, particularly HT pathogenesis.

A Statistical Study on Microorganisms that Cause Tooth Decay and Prevention and Treatment Methods

Widad Sameer Jaaz¹, Ohood Salman Jawad², Hassanain Jwad Abid Al Hussein¹

¹Collage of Dentistry, Kerbela University, Iraq, ²College of Applied Medical Sciences, Kerbela university, Iraq

Abstract

The current research includes knowledge of the effect of microbes on dental caries, by providing the environment suitable for the growth of bacteria and fungi that cause this decomposition, fermentation and decay and thus erode the texture of the tooth and then full tooth decay. These are the macrophages that lead to tooth decay (streptococcus species, Staphylococcus aureus, Candida, Lactobacillus, Actinomycosis, Micrococcus, Antibacterials, Bacillus, Actinobacillus) in different percentages: 33.3%, 21.3%, 14.7%, 12.1%, 8.2%, 4.5%, 3.4%, 1.3%, 1.2%), respectively. There are many other factors that help tooth decay occur: the host (tooth and saliva), microorganisms in the form of tooth plaque, substrate (diet).

Keyword: microbes , tooth decay, Prevention and Treatment.

Introduction

Dental caries is an infectious microbiological disease of the teeth that results in localized dissolution and destruction of the calcified tissues. It is the second most common cause of tooth loss and is found universally, irrespective of age, sex, caste, creed or geographic location. Saliva has a cleansing effect on the teeth. Normally, 700–800 ml of saliva is secreted per day. Caries activity increases as the viscosity of the saliva increases. Eating fibrous food and chewing vigorously increases salivation, which helps in digestion as well as improves cleansing of the teeth. The quantity as well as composition, pH, viscosity and buffering capacity of the saliva plays a role in dental caries (¹, ²). Dental caries is one of the most common preventable diseases which is recognized as the primary cause of oral pain and tooth loss. It is a major public health oral disease which hinders the achievement and maintenance of oral health in all age groups (³).

Dental caries refers to the localised destruction of susceptible dental hard tissues by acidic by-products from the bacterial fermentation of dietary carbohydrates.

It is a chronic disease that progresses slowly in most of the people (⁴), which results from an ecological imbalance in the equilibrium between tooth minerals and oral biofilms (plaque) (⁵). Caries is an etiologically complex disease process. It is likely that numerous microbial, genetic, immunological, behavioral, and environmental contributors to risk are at play in determining the occurrence and severity of clinical disease. Assessment tools based on a single risk indicator are therefore unlikely to accurately discriminate between those at high and low risk. Multiple indicators, combined on an appropriate scale and accounting for possible interactions, will certainly be required.

Caries may be characterized by the experience of pain, problem with eating, chewing, smiling and communication due to missing, discolored or damaged teeth. The microbial community of caries is diverse and contains many facultatively and obligately-anaerobic bacteria belonging to the genera Actinomyces, Bifidobacterium, Eubacterium, Lactobacillus, Parvimonas and Rothia (⁶). It can also be caused by other bacteria, including members of the mitis, anginosus and salivarius groups of streptococci, Propionibacterium, Enterococcus faecalis, Scardovi, Prevotella, Selenomonas, Dialister, Fusobacterium, Pseudorambacter, Veillonella, Atopobium, Granulicatella, Leptotrichia and Thiomonas (⁷-¹⁰).

E-mail: hasanin.jawad@yahoo.com
Indian Journal of Forensic Medicine & Toxicology, January-March 2020, Vol. 14, No. 1

Bacteroides, Prevotella, and Porphyromonas species are prevalent on mucosal surfaces and reach very high concentrations in dental plaque, gingival crevices and tonsillar crypts (7).

Traditional approaches to the treatment of dental caries have focused on repairing the consequences of the disease (cavities) rather than the disease itself. From our perspective, person-centered approaches, such as individual risk assessment, active surveillance, oral health literacy, and preventive interventions/therapies, supplemented, when necessary, by surgical care (drilling, filling, extraction) are the essential evidence-based approaches for the effective management of this disease. We see that factors such as fear, total and reimbursed costs, provider availability, transportation, and even parent or caregiver characteristics, including financial distress, depressive symptoms, and limited social networks, can be barriers to care (11). Recently, nanotechnology has emerged in the treatment and protection of teeth, such as nanopowder technology and nanotechnology for metals, which has become a major concern for scientists and researchers.

Materials and methods of work

First\ Materials:-

All diagnostic and general plant media, used reagents and solutions are manufactured by a company (Mast and Oxoid).

Second\ methods of work:-

1. Collection of samples

A total of 40 mouth and teeth swabs were collected for patients that have dental caries in the Dental Unit at Manpuole Hospital in Andrapradesh city, Hyderabad State, India, during (April and May of 2014).

2. Isolation and diagnosis

Samples were growth directly on pre-prepared culture media and laboratory tests were performed to diagnose the bacteria based on the methods of (smith, 2002) and (colle and et al, 1969)(12), according to the following diagnostics:-

A) Cellular diagnosis:

This was done by examining the pigmented dye of gram to determine the shape and assembly of bacterial cells and the nature of their interaction with the dye.

B) culture diagnosis:

It ensures the diagnosis of the shape and size of bacterial colonies and their effect on the general and specific agro-culture and diagnostic communities.

C) Biochemical tests:

Diagnosis of bacteria is based on their ability to produce enzymes and their biochemical effectiveness.

3. Statistical analysis:

The results of isolation and diagnosis were analyzed statistically using the Kay square test (Daniel, 1978)(13).

Results and Discussion

The percentages of germs isolated from oral infections showed that streptococcus species represented (33.3%) , followed by Staphylococcus aureus species (21.3%) , while the Bacillus and Actinobacillus species represented (1.4% ,and 1.5%) respectively. While the rest of the isolates recorded different ratios of germs as shown in the table (1)

In general, the results of this study were consistent with previous , (Saini, 1999) , (Socransky, 1970) such as (Gibbons ,et al. 1946) (Carlsson, 1967) (14-16). The prevalence and spread of germs of various kinds in the oral cavity, which leads to tooth decay, especially in the
case of negligence and non-cleaning of the teeth and lack of care, which provides a catalyst that leads to loss of age and seek compensation instead of because the presence causes the mouth to disease including tissue damage and even cancer, which finds the right environment to occur easily. Tooth decay is so widespread that many people do not treat it with the proper seriousness. It is common, for example, lack of interest in the injury of children tooth decay in milk teeth. However, dental caries can lead to complications and complications of serious and far-reaching, even in children whose teeth have not yet developed. Among these complications. Abscesses, Abscess in the teeth, tooth loss, broken teeth, chewing problems, Acute infections. In addition, when dental caries reaches a stage where the aches are very severe, this may interfere with normal daily life, to the extent that it prevents the student from going to school or to work. If the aches are severe and hinder the process of eating or chewing, they may lead to malnutrition and weight loss. If decay leads to tooth decay, this may negatively affect self-confidence. In some very rare cases, abscess caused by dental caries may lead to severe contamination that may endanger the patient’s life if not properly treated. The percentage of pathogens that cause oral diseases varies depending on the type of the isolation and method of infection.(17).

Dental plaque is a thin, tenacious microbial film that forms on the tooth surfaces. Microorganisms in the dental plaque ferment carbohydrate foodstuffs, especially the disaccharide sucrose, to produce acids that cause demineralization of inorganic substances and furnish various proteolytic enzymes to cause disintegration of the organic substances of the teeth, the processes involved in the initiation and progression of dental caries. The dental plaque holds the acids produced in close contact with the tooth surfaces and prevents them from contact with the cleansing effect of saliva.(18, 19).

A Biological Factors of dental caries:-

There is interaction and cooperation between a group of factors that are active and help to prevent tooth caries, and these factors are the conditions that provide suitable and controlled in the incidence of this disease, We can epitomize it up with the following:-

1-Host (teeth and saliva):(20, 21)

A\ Tooth:

Composition:- Deficiency in fluorine, zinc, lead and iron content of the enamel is associated with increased risk caries. Morphological characteristics:- Deep, narrow occlusal fissures, and lingual and buccal pits tend to trap food rubbish and bacteria, which can cause caries. As teeth get worn (attrition), caries declines.

   Position:- The interdental areas are more oversensitive to dental caries. Malalignment of the teeth such as crowding, abnormal spacing, etc., can increase the susceptibility to caries.

B\ Saliva: (22, 23)

Saliva has a cleansing effect on the teeth. Generally, 700– 800 ml of saliva is secreted daily. Caries activity increases as the viscosity of the saliva increases. Eating fibrous food and chewing vigorously all them increases salivation, which helps in digestion as well as lead to cleansing of the teeth. The quantity as well as composition, pH, viscosity and buffering capacity of the saliva plays an important role in dental caries.

   • Quantity: Reduction of salivary secretion as found in xerostomia and salivary gland aplasia gives rise to increased caries activity.

   • Composition: Inorganic fluoride, chloride, sodium, magnesium, potassium, iron, calcium and phosphorus are inversely related to caries. Organic ammonia retards plaque make up and neutralizes the acid.

   • pH: A neutral or alkaline pH can neutralize acids created by the action of microorganisms on carbohydrate food substances.

   • Antibacterial factors: Saliva keep enzymes such as lactoperoxidase, lysozyme, lactoferrin and immunoglobulin (Ig)A, which can inhibit plaque bacteria.

2-Microorganisms in the form of dental plaque: (24, 25)

Dental plaque is a thin, tenacious microbial film that forms on the enamel layer. Microorganisms in the dental plaque ferment carbohydrate foodstuffs, especially the disaccharide sucrose, to produce acids that cause demineralization of inorganic substances and furnish various proteolytic enzymes to cause disintegration of the organic substances of the teeth, the processes implicated in the initiation and progression of dental
caries. The dental plaque conclude the acids produced in close contact with the tooth surfaces and prevents them from contact with the cleansing action of saliva.

3-Substrate (diet): (26, 27)

The role of reiterated carbohydrates, especially the disaccharide sucrose, in the aetiology of dental caries is well established. The total amount consumed as well as the physical form, its oral clearance rate and frequency of consumption are important factors in the aetiology. Vitamins A, D, K, B complex (B6), calcium, phosphorus, fluorine, amino acids such as lysine and fats have an inhibitory effect on dental caries. So, caries requires a susceptible host, cariogenic oral flora and a suitable substrate, which must be present for a sufficient length of time.

Prevention and control of dental caries:

Increase the resistance of the teeth.(20, 21)

Systemic use of fluoride:
1- Fluoridation of water, milk and salt.
2- fluoride supplementation in the form of tablets and lozenges.
3- consuming a fluoride-rich diet such as tea, fish, etc.

Topical:
1-Use of fluoridated toothpaste and mouth wash.
2-use of fluoride varnishes (in-office application, longer duration of action, high fluoride content).
3-use of casein phosphopeptide–amorphous calcium phosphate (CPP–ACP), which is available as tooth mousse, helps to remineralize the soft initial carious, demineralized areas of the teeth.

Treatment of dental caries

Treatment comprises removal of decay by operative procedures and restoration with appropriate materials such as silver fillings, gold inlays, composite resin, glass ionomer cement, full metal or porcelain crowns, etc. In advanced cases, where the pulp of the tooth is involved, endodontic treatment may be required. Where there is extensive destruction of the tooth structure or when endodontic treatment is not feasible, extraction of the tooth and replacement by an artificial prosthesis may be required.

In vitro Antifungal efficacy of *Saccharomyces Cerevisiae* Mediated Nanoparticle Against Resistant *Candida Albicans* Isolates

Hussein A. R. Abbood¹, Bari L. Mohammed², Hawazin A. Aboid²

¹Medical Analysis Department, University of Al-Qalam College, IRAQ,
²Department of Biology, College of Science, Kirkuk University, Iraq

Abstract

Dry yeast *Saccharomyces. cerevisiae* was obtained from markets in Kirkuk and used to study their ability to prepare silver nanoparticles and shows that the silver nitrate solution at 1Mm changes its color to brown and is an initial indication of the formation of nanoparticle particles and X-ray diffraction peaks were measured at (111), (202) and (220) respectively. Particles also appeared in clear minutes in the scanning electron microscopy images at a size of 44 nanometers. A total of 103 vaginal swabs were taken from women who suffered from vaginitis from the Kirkuk General Hospital. The results revealed that Candida types were responsible for 67% of the cases. *Candida albicans, C.glabrata, C.tropicalis, C.krusei* and *C.parapsilosis* were isolated. 30.8%, 22.8%, 20%, 15.8% and 11.5%, respectively. In addition, the sensitivity of the drug in the drilling method against the isolates of Candida albicans showed high resistance to fluconazole and gresiofulvin antagonists, with 100% of gresiofulvin (85%) of fluconazole. For nystatin, Resistance ratios (14%) The solution of the nano-silver particles recorded from *Saccharomyces Cerevisiae* yeast was also shown. had a significant inhibitory effect on Candida albicans, a multi-resistance yeast antimicrobial resistance (21,21,22mm) at 100% and (10,13,10mm)at 50% and inhibition(5, 4, 5 mm) has a 35% dilution and a 25% concentration did not receive any inhibition.

**Keyword:** *Saccharomyces cerevisiae*, silver nanoparticles, *Candida albicans*

Introduction

Nano science is the science that is interested in studying and characterizing materials ranging from 100 to 100 nanometers apart, as well as assigning their chemical, physical and mechanical properties to study related phenomena arising from their small size. Nano science is also known as nanoscale science because it studies materials in the atomic or molecular ladder, which differ significantly from the properties of the same materials in a larger scale. Biological and chemical nanoparticles can be obtained from bacteria and fungi that have the ability to produce nanoparticles with antimicrobial properties. Yeast microbes are the oldest beneficial microorganisms used by humans for the purpose of fermentation and bread making since ancient times. Archaeologists in Egypt, during their excavation in archaeological areas, found grinding stones, bread fermentation chambers, as well as drawings of bakeries and ferrets dating back 4000 years. The first to be observed through the microscope was the scientist Anthony van Levenhoek (1680), but at that time he did not describe it as a living organism, but rather the first German form of Fleishman, the first to isolate yeast (*Saccharomyces. cerevisiae*). Are widely used industrially in fermentation production of alcohol and calcioir. Saccharomyces means saccharine. This type of yeast has two types: *S.cerevisiae* and *S.boulardii*, which are used in the manufacture of bioreactors. These two types of non-pathogenic species were thought to be the first type of species, but it was later identified as a new species.

Vaginitis is one of the most common problems in women of fertile age. There are more than one cause of this type of inflammation such as bacteria, viruses, parasites, chemical and other chemical factors, but the most common causes are yeast *Candida genus*. The other normal microflora in the mucous membranes play a role in limiting their growth and formation, such as the
Lactobacilli in the vagina that inhibits the adhesion of candida to the vaginal epithelial cells(7).

Material and Method

Collect sample

103 samples were collected from Kirkuk General Hospital (vaginal swabs) By a sterile speculum as it was inserted into the vagina and the sample was taken from the cervix by a sterile swab and sent directly to the laboratory.

Direct test

The samples were examined directly by making two slices, the first one was Smear, as it was sprayed on the glass slide and gram-stain to observe the positive yeast cells of this dye The second slice was placed with a drop of the swab of the swab solution and tested under the force (x40) after placing the lid of the slide to observe the white blood cells WBC and epithelial cells .

Laboratory culture

After the vaginal swabs were transferred to a laboratory directly planted on the center of the malt extract agar, three replicates of the sample were incubated under 37 ° C for 24 hours. Yeast growth was examined and secondary cultivar of the dishes showed positive result. The dishes which showed no growth Considered negative (6).

Diagnosis of candida spp

To examine the growth of the yeast cell well by preparing a slice of the colony and pigment chromium with the observation of the virtual shape of the colony and then conducted the following tests(8).

- Potassium nitrate reductase test
- Urea by drolysis test
- Germ tube production test
- Test the production of Chalmyspores
- Carbohydrate fermentation test
- sensitivity of fungal antibiotics test

A sensitivity test was occurred by spread method in the solid medium and according to (9) the use of 6 types of antifungal processed by Oxide.

Preparing a yeast culture and producing nanoparticles

Saccharomyces cerevisiae yeast was obtained dry from the market and then prepared a pure culture by preparing a culturing medium consisting of (1% Yeast extract, 2% Peptone and 2% of Dextrose) YPD broth in flask 100 ml and heated at 35° in 48 hours and then centrifuge at 10,000 cycles in one minut For 10 minutes, Then use supernatant solution in silver nanoparticles synthesis. .

We take the supernatant and put it in a 1000-ml flask and then add g17 silver nitrate to 100 ml of supernatant yeast And then i was put in completely dark conditions and after the discoloration the nanoparticles formation were examined by X-RD , ( Shimatzu) in physics department collage of science Baghdad university and SEM (TESCAN.VEGA) in university of technology . Iraq (Nanotechnology and Advanced Materials Research Center)to detect the size and the shape of the particles.

Preparing for soluation of nanoparticles

Use the solution of silver particles after filtering from the yeast using the sterile filter (filter paper No 1) and sterilize by the exact filtration unit 0.22mm and attended the following stacks:

First concentration: Contains 1mM of AgNPs solution and is 100% concentrated

The second concentration was attended by adding 5 ml of the initial solution in 5 ml of sterile distilled water to become the concentration to 50%.

The third concentration was attended by the addition of 3.5ml of the initial solution and diluted in 6.5ml of distilled water to a concentration of 35%.

The fourth concentration was attended by 2.5 ml of the initial solution and diluted in 7.5ml of distilled water to a concentration of 25%

Results and Discussion

Isolation and Diagnosis

The current study has shown that 70 isolates to candida spp yeasts by studying some of the apperance and microscopic characteristics and biochemical tests as follows:
Characteristics of fungal colony

The colonies appeared smooth, convex, creamy white, and characteristic yeast, and the cells were spherical or oval and the presence of spores and pseudohyphae\(^{(10)}\).

Potassium nitrate reduction test and analysis of urea

The result of these negative tests of *Candida albicans* as shown in table (2) testing the fermenting and the representation of carbohydrates (sugars)

The test results showed a fermentation gas in a tube for positive and also change color from violet to yellow centered. Table (2) representation of carbohydrates the show of growth around the hole topic by sugar and change color from violet to yellow is a positive result.

Growth properties test on liquid medium

Use this test to diagnose types of *candida spp* through surface growth characteristic table 2

Test production Germ tube

This test is a rapid diagnosis of *Candida albicans* yeast which showed a combination filament arose from yeast cell.

Chlamydospores Production test

This test was used to disperse the yeast *Candida albicans* from other types of *candida*, which showed spherical cells with a thick wall.

According to the tests mentioned above, *Candida albicans* yeast was 21%, followed by *C.glabrata* with 16 isolates, 22.85%, and *C.krusei*, 14 isolates, 20%, *C.parapsilosis*, 11 isolates, 15.71% and *C. tropicis*, 8 isolates. Or 11.42%.

Formation of silver nanoparticles AgNPs

The formation of nanoparticles was observed through indicators as follows:-

Visual observation

The results of this study showed a silver nano particles are AgNPs using yeast *S.cerevisiae* (image 1) through show color change resulting from the reduction of silver nitrate AgNO3 this color shift caused by raising surface of alblasmon (Foundation of this vibration is electron delivery group) Silver nano particles\(^{(11)}\).

X-Ray Diffraction

(Fig. 1) shows the X-ray diffraction spectra of the nanoparticles (AgNPs) prepared using the yeast of *S.cerevisiae*. We show the peaks of diffraction (111), (202) and (220) at angles (38.20, 48.34 and 63.43) The angles are adjacent to the angles mentioned with the card of the International Center for Diffraction Data (JCPDS) and are consistent with\(^{(12,13)}\).
Scanning electron microscopy

Figure 2 shows the scanning electron microscope images of the nanoparticle particles formed by the S. cerevisiae yeast, which appear in clusters that confirm the formation of nano-silver particles.

Antifungal susceptibility test

The antifungal sensitivity of Candida albicans isolates was studied using 5 types of fungal antifungal solutions, and the results were determined by measuring Zone of Inhibition as shown in Table (3) based on. The results showed that there was a difference resistance of isolates under study to antifungal used isolates showed high resistance to fluconazole and gresiofulvin with 100% resistance and 85% to fluconazole. Clotrimazole resistance was 71%, Ketoconazole (23%). In contrast, nystatin was the best treatment option with 14% resistance.

The results indicated relative resistance to most of the yeast isolates under study for most of the antibiotics used. Nystatin was one of the most potent antifungal with the highest inhibitory due to the fact that nystatin inhibits the important Ergosterol synthesis in the cell membrane of the yeast. Inhibition between (25-17) mm This result is consistent with the outcome of the which found that nystatin was one of the best inhibitor in the growth of candida. Ketoconazole antifungle ranged from 22 to 16 mm in diameter with a clear effect, with 77% of isolates yeast. Clotrimazole was the third in terms of the ability to inhibit the growth of candidiasis, and explained that this antibody is effective in inhibiting the growth of Candida.

Fluconazole was the fourth most important inhibitor of the growth of the types of Candida under study. The rate of inhibition was 18-11%. This result may be due to the large number of antibiotic use, as well as the type of resistance these isolates possess against most of the antibiotics used.

Grisofulvin was the last to inhibit the growth of the types of candida under study. Inhibition of 100% was observed. Grisofulvin had no effect on Candida yeast. There was no inhibiting growth in the concentrations used.

Table (2) represents the resistance and sensitivity of Candida albicans to the antibiotics used

Table (2) represents the resistance and sensitivity of Candida albicans to the antibiotics used
Effect of AgNPs on Candida albicans Resistance:

Antimicrobial activity of AgNPs has been verified against antimicrobial resistance by diffusion method. The diameter of the inhibition zone in millimeters around each hole was determined at the level of different concentrations of NPs. The study showed that the silver nanoparticles produced from S. cerevisiae yeast had high efficacy on both isolates (3), (11) and candida albicans respectively resistant to antifungal agents as shown in Table (3).

In the 100% concentration, the inhibition diameter (22, 21.21 mm) against the three isolates with multiple resistance to antifungal resistance and 50% dilution (10,10,13 mm) While he has 35% loss reached diameter inhibition (5, 4, 5). The concentration of 25% did not get any discouragement and that the small size of the nanoparticles and the large surface area where the smaller size collected in larger numbers on the surface of the cells leading to increased toxicity of microorganisms through its effect on the permeability of the plasma membrane and thus cell death (19, 20).

The mechanism in which nanoparticles interact with yeast cells is that microorganisms carry negative charges while nanosynthetic oxides carry a positive charge, creating an electromagnetic attraction between the yeast and the surface of the minutes. The nanoparticles release the ions that interact with the thiol- Which increases the permeability of the membrane and thus cell death.

Application of Chemical Techniques in the Manufacture of Some Industrial Dental Materials

Hamed Ibrahim Mohammed¹, Aara Ali Hadi¹, Hassanain jwad abid al Hussein¹
¹Collage of Dentistry, Kerbela university. Iraq

Abstract

This method of manufacturing Separating Medium was used in the field of chemical polymerization, in which a semi-gelatinous liquid was placed on the dental kits to prevent the adhesion of the gypsum material to the dermis made of hot processed polymer. After the experiments on the plant seeds, specifically the flax plant, the final extraction of the substance has been reached. It has given all the desired good specifications that are used in the field of dentistry. It is known that this material is a polar compound was diluted with distilled water after preparation. It is worth mentioning that 10% of the industrial pigments have been added to give them the red or pink color as these colors are desirable and common in the commercial markets as well as It is recommended for the dental products manufacturers, as well as 10% of the original alcohol and 1% of formalin to prevent the growth of bacteria and other types of microorganisms that cause rotting and decomposition of the manufactured material.

Keyword: Superating Medium, Chemical Techniques, Extractions.

Introduction

It is important to know the importance of polymers in our daily lives and the extent of their applications in all areas in the individual, as well as their importance in many fields of industrial and medical. Doctors are not familiar with a variety of polymer materials. The use of polymers in the field of dentistry in many of the scientific experiments conducted by the researchers, by selecting the choice of dental adhesive and other materials of the other teeth, including the manufacture and production of the insulating material between the layers of plaster and acrylic work stage dental mold synthesis. It is possible to make this choice, more specifically, if we can clarify the mechanical, characteristics of various dental adhesives. The main objective is to establish strong bonds for remaining age and for composite white fillings, which are usually some other polymers. They resemble self-etch adhesives in composition as they contain acidic monomers(¹), and are characterized by chemical interaction with dentin hydroxyapatite(²,³).

Linum usitatissimum belongs to the Linaceae family, an important flowering plant grown all over the world. Although this species consists of more than 100 species, L. usitatissimum has long been considered a valuable agricultural plant due to the production of oils And other synthetic and medical products . Traditionally, flax products and compounds have been prescribed to treat many chronic human diseases such as diabetes, high cholesterol, cardiovascular disease and other related conditions .There are two types of flax (flax fiber and flax seed) which are widely used nowadays. A significant trend has been observed in reducing the area of flaxseed in favor of flaxseed in some countries in recent years and because of the ever-increasing importance of flax as a plant used in many chemical, pharmaceutical, food and animal feed industries. Oilseed crops (⁴). Flaxseeds are used as a diet and a preventive enhancer, and have been used for a long time in both gastrointestinal diseases (constipation, inflammation of the bowel, colon, gastritis) and respiratory diseases (cough and dyspnea). This type of plant has also been used in the industry, because its seeds contain a high percentage of organic fibers which made it used in the manufacture of paper, ink, cloth and fishing nets, as well as in the manufacture of soap and oils that Working on hair (⁵). A separate medium is defined as representing

Corresponding author:
Hassanain Jwad abid al Hussein
E-mail: hasanin.jawad@yahoo.com
a coating layer formed on a surface that prevents the second surface from sticking to the first surface (6). This layer is a medium that rises above the surface of the material such as the plaster, metal or wax to prevent adhesion between the denture And other materials that are in contact with him during preparation (7). And also used to seal all the pores in the stone model without adding any additional materials (8). Separating media are materials that used for filling any porous surface in order to effect easy separation of other materials which are later poured against them. Therefore the acrylic resin must be carefully protected during processing from the gypsum surface in the mould spaces for two reasons: 1-Any water incorporate in to the resin from the gypsum during processing will defined affect the polymerization rate and the cold of the resin: the denture procedure will craze readily of water after the processing: particularly if the resin is not cross-linked. 2-Disolved polymer and free monomer must be prevented from soaking in to the investing medium, portions of gypsum material will be joined to the denture after polymerization: with result that it will be virtually impossible to separate the investing material from the resin (9).

Application

Materials and Method

The amount of 100 grams of flax seed is taken and the quantity is boiled in 5 liters of distilled water and 100 degrees Celsius. The boiling process lasts from half an hour to an hour. The longer the boiling period, the more the solution becomes somewhat thick or semi-gelatin. The mixture is heated through sieves for a liquid that is seed free and free from impurities, and then leaves the solution to cool down. After that, the amount of formalin and 1% of the solution is added to the solution and 10% of the ethyl alcohol is added to prevent the growth of microorganisms from bacteria, fungus and others. Then we put (0.001) of the red industrial pigments and mix the solution well in order to homogenize to obtain a liquid substance that is similar in specifications, shape and work to the insulating material. And add varying proportions of polymer solution suitable for use as a mixture to give a liquid or gelatin to meet the required specifications that lead to the purpose we are looking for. After the manufacture of the material, a sample of hot acrylic was prepared. Using the usual plastic technique, 3ml of the insulating material, using a small brush, was placed on the plaster containing the gypsum material (prepared by the dental kit). Then the acrylic sample was placed and pressed with 30 pascal. (15-60 °C). After the cooling process, the mold was opened and it was observed that the acrylic material was not attached to the stone material. Their success and efficiency It is known that flaxseeds are available in the market, cheap and easy to prepare, and the possibility of storage for a long time without decomposition, used in this research is a natural plant material gives good results in the separation of gypsum material from the kit. The teeth are made of acrylic, and have no negative effects on the mechanism of the work of dental molds. Through the preparation of the mold, and the traditional technique follows its steps, the bottom of the tooth flask is filled with a dental stone according to the manufacturer’s instructions: W / P is 25ml / 100g; a layer of stone mixture is placed on the metal mass to avoid air retention. Insert the metal block into the stone mixture after coating with separate media. It is known that after the stone was laid, both stone and metal patterns were coated with separate media. The top half of the flask is placed at the top of the bottom part and the stone is packed, and with continuous stirring, to get rid of the trapped air. The stone was allowed to harden for 60 minutes before opening the flask. Then the bottle and the metal are opened. The patterns are removed from the mold carefully and carefully. The material is then wiped with a soft brush.

Results and Discussion

Polymers are materials made from long, repetitive chains of molecules. These materials have unique properties, depending on the type and how they interconnect. The purpose of the extraction phase is to obtain the desired component and leave the unwanted components aside, which are the residues of the seeds from which the material was extracted. This extraction should be done well and sufficient to obtain a material of desirable specifications and highly efficient in the formation of the crust necessary to prevent the adhesion of gypsum material to the dentures. This extraction process is done by heating the seeds used (flax seed) with distilled water to 100 degrees Celsius. The boil is then extracted from the seeds and the boiling continues from half an hour to an hour. This response to the extraction was obtained by the presence of water as a polar compound and the fact that flaxseed is a plant component, which is considered a complex carbohydrate, so it decomposes with water and by the temperature as a catalyst for the period mentioned above because these seeds are surrounded by a protective layer cannot access water easily. The normal situation. (10%, 15%,
The optimum concentration of the polymer mixed with the extract was 20%, giving the desired result in the separation between the acrylic and stone. If the polymer was used alone in this separation process, it did not give the result to be obtained, as well as the extract if we used it alone. The result is not the same as after mixing. Therefore, the extract and the polymer used should be mixed with this ratio because it gives the physical and The chemical that qualifies it to be usable as a buffer separating the gypsum and acrylic layers. The measurements taken are as shown in Table (1). It is not surprising that we get liquid synthetic material such as the insulation of plant seeds such as flaxseeds. Purifying the desired component of the “desired material” after its removal from the unwanted component (seed) is very important because it ultimately gives us a transparent liquid slightly tilted to a homogeneous, semi-gelatinous, polarized color that can be diluted by ordinary water. Gives the red or pink color desired when the dental laboratory owners any color of the dental kit. Pigment additives, dyes or colored materials are the basic material where the product acquires attractive colors or may act as light or oxidative protective materials and other physical and chemical properties (9). After obtaining the required liquid “flaxseed extract” mixed with the polymer, the molded gypsum material is coated with a soft brush and left for at least five minutes, then the acrylic material prepared to form the tooth kit is then applied to special equipment and subjected to temperature ranging from (60 - 80) for half an hour and harden in the end. Here, after the opening of the molds, we saw that the gypsum material was not attached to the mold. This is the secret to success in the experience of manufacturing this material, which is of great benefit. However, if the insulating material is not applied, this gypsum material will stick to the denture, making it difficult to remove it, distorting the kit and not properly and accurately imprinting it in the patient’s mouth, as well as transferring water molecules from the gypsum material in the mold to the dental kit during the process of sclerosis. Poor specifications and not good research The water molecules in the kit appear in clear bubbles and this is evidence of its lack of validity. The selection of these flaxseed seeds in our current research is not random, but is done through scientific research and laboratory experiments. This is why chemical industries start with simple raw materials obtained from natural sources such as mines, forests, agricultural fields, , In addition to the most abundant material in nature which is the water that cannot be established or the duration of any vital effectiveness without it and it is agreed that one of the most important goals of science, scientists, scientific researchers and industry workers is to harness their science creatively to develop new technology A new material “utilized in the industrial and medical fields, and the use of raw materials improved and in most cases in developed countries find new technology protection it by registered Kpraouat invention and discoveries as the discoverers true for these materials and save their rights periods specified time by a special (10). In this research, a comparison was also made between the insulating material extracted from the flaxseed and other good insulation materials available in the market. The Indian “ISOLIATE” model was selected in comparison. The two models were used to show that the proportion of gypsum materials adhering to the dental prosthesis is very small compared to The original article. Some characteristics of both materials were measured for comparison purposes and as shown in Table (1):

The table (1): shows the comparison of the chemical properties of the insulating material (manufactured by extraction and polymers) and the Indian product (ISOLATE).

<table>
<thead>
<tr>

</tr>
<tr>
<td>PH</td>
<td>8</td>
<td>6.55</td>
</tr>
</tbody>
</table>

However, when the table is observed, soluble salts are found to be non-existent in both substances. However, the conductivity and pH function of the Isolate insulation material is slightly higher than that of flaxseed. This little difference is not affected by the work of the insulating material in the formation of the cortex that separates the two electrodes when used. This discrepancy is shown in Figure (1):
Figure (1): Shows the comparison between the Indian and the extract in terms of turbidity, conductivity and acid function, respectively.

It is known that the manufacture of separating medium, which is used in the manufacture of teeth from flax seeds, works to produce a polar compound diluted with normal and distilled water. This material creates a layer of thin crust that prevents the adhesion of gypsum material to the dentures made of hot acrylic treated. It is possible to have a separating medium with a transparent yellowish color if a distinctive dye is added to it from an industrial, not a pharmaceutical, substance.

**Conclusion**

The main objective of this study is to obtain local products that enrich the markets with manufactured materials inside the country and not to import foreign materials as much as possible, in order to promote the economy of the country. Therefore, the country is satisfied with this material which is reached in scientific and industrial ways and applied practically in all Laboratories and dental clinics. It is a realistic study in which plants invest, specifically flax plants, which are mixed in calculated proportions with polymer solutions. Therefore, a high quality industrial material is produced with high efficiency.

Isolation and Identification of *Pantoea agglomerans* from Open Heart Operations Unit of Marjan Hospital in Hilla City

Enas R . Al-Kidsawey¹, Kawther H. Mhdi¹, Mohammed A. Al kaif³

¹Hilla university college/Ministry of higher Education and Scientific research/Iraq

Abstract

The nosocomial infection of *Pantoea agglomerans* has become an important cause of many systemic infections in humans, and considered of present study was to isolate and identify this pathogen from open heart operation unit of Marjan hospitals in Hilla city during a period from April to September 2018, (19) isolates of *Pantoea agglomerans*. Was isolated from (150) swaps which were collected from the environmental of open heart operation unit. 8/30 isolates from system, 3/35 from bed, 3/25 from earth, 3/35 from door and 2/25 from nurse hands isolated identification of microbes were done according on the morphological, cultural, microscopically characterization and list of biochemical test. To emphasize the identification of *Pantoea agglomerans*. We used the API20 technique biochemical strips (biomerieux SA/marc y-1 Etoile France).

The antimicrobial susceptibility pattern of the isolates was studied using different types of antibiotics. The microbes showed resistance to the routinely used antibiotics.

**Key Words:** *Pantoea agglomerans*, characteristic, Isolation, nosocomial, hospital.

Introduction

*Pantoea agglomerans* is a Facultative anaerobic gram negative bacteria, previously named *Erwinia herbicola* (¹) or *Enterobacter agglomerans*, motile with peritrichous Flagella non spore forming, commonly found in environment such as water, soil, dust, air, sewage, seeds of vegetables and food. As well as reported as both commercial and opportunistic pathogens of animal and humans (²). *Pantoea agglomerans* is an opportunistic microbes can be isolated from different sites of hospitals such as wall, door, bed, floor, clothes of nurse, and also could be isolated from clinical specimens including blood, wounds, urine, throat, and stool(³). *Pantoea agglomerans* is worldwide bacterium commonly isolated from plant surfaces, and many research has shown that *Pantoea agglomerans* can serve as a plant pathogen (⁴). It was identified as a nosocomial pathogen to human in mid-1960s. It could be a cause of opportunistic human infections, mostly by wound infection with plant material or by hospital-acquired infection especially in human with immune compromised (⁵). The survey for infective agent is very important to reduce the occurrence of infection with different types of microbes, therefore to prevent spreading opportunistic microbes and spreading drug resistant bacteria between the patients the CDC recommends use of contact isolation, precaution, enhanced environmental cleaning, dedicated patient care equipment and reduce using of antibiotics. This study mainly aims to isolation and identification and determination the prevalence of *Pantoea agglomerans* from the hospital environment of open heart operation in Marjan hospital and to recognize the antimicrobial susceptibility.

Materials and Method

One hundred fifty (150) swaps were collected from April to September 2018 from environmental locations of open heart operation of Marjan hospital Hilla city. The Swaps which was taken from system, bed, doors, earth and nurse hand, was moistened by normal saline (2 ml) of sample was placed in sterile tubes containing brain heart infusion broth (BHT), transporting by ice box to...
the laboratory (6), each sample was cultured in Luria Bertani (LB) agar by spreading methods, the plate were incubated at (37°C) for 3 days, the colonies which appeared after that were transferred to slants of the same medium, then the colonies were collected according to the morphological, characteristics appearance, agar surface and purified by culturing on nutrient agar plates, and identified with gram stain, and the main characters of colonies on solid medium such as shape, texture, and pigmentation for characterization the biochemical and physiological test, were used the isolates were maintained at (4°C) and cultured in LB medium. The biochemical tests used for identification depending on macroscopic motility tests: oxidase, catalase, indol, H₂S production, vogas proskanter (7; 8), for further identification various carbon sources used such as: glucose, xylose, mannose, Rhamnose, salicin, sucrose, Trehalose, maltose (9). The identification was emphasized by using API20E (Biomerieux SA/ marcy_1 Etoile France). The test done according to the manufactures direction, the systems were incubated at (35 °C) and the results were read after (20-24) hrs. Stored for long time by the identified isolates were culturing in tryptic soy broth (TSB) with 20% glycerol at -20°C (Merk co.).

Antibiotic Susceptibility

The antibiotic susceptibility test was done according Kirby-Baner (10) disc diffusion method by using Muller Hinton agar plate. the antibiotic used: ampicillin (10 Mg), carbenicillin (100 Mg), ceftazidiume (30 Mg), cefotaxime (30 Mg), imipenem (10Mg), streptomycine (10Mg), amikacin (30 Mg), gentamycine (10 Mg), tobramycine (10 Mg), pipracillin (100Mg), colistin (25 Mg), tetracycline (30Mg).

Results

The results in Table (1) are summarized the total of (150) environmental sample, the highest number of of Pantoea agglomerans was isolated from system 8/30 (26.6%) followed by earth 3/25 (12%), then bed samples 3/35 (8.57%), door 3/35 (8.57%) and 2/25 (8%) for nurse hand sample. p

Table (1): The number and percentage of Pantoea agglomerans isolated from different locations of open heart operation unit of Marjan hospital.

</table>

The results showed that (19) isolates was isolated from different environmental locations of open heart operation unit of Marjan hospital were positive for catalase, simmon citrate, motile, negative indol, H₂S production and the other test.

The API20E test strips was used which emphasized that identification of (19) isolates have the same profile with systems indicate that the isolates are aerobic, ferment, galactose, lactose, glucose, arabinose, mannitol, inositol, rhamnose, maltose, melibiose and vogas proskauer was positive, indol negative, citrate positive.

The results of antimicrobial susceptibility was summarized in Table (2).

All 19 isolates of of Pantoea agglomerans showed high resistance toward most antibiotics which mean that the isolates have multidrug resistance (MDR) and they can adapted to antimicrobial agents, this process enable these pathogens to oppose the action of certain antibiotics remanding the antibiotics ineffective.

**Discussion**

The results of our study showed that, the isolation of (19) isolates of *Pantoea agglomerans* on pure culture, All the isolated colonies of yellow pigmented with slightly concave centers (5mm) in diameter, The isolates are a Gram negative rod and partially hemolytic sheep red blood cells.

The phenotypic characteristic of the isolates agree with the characteristic of *Pantoea agglomerans* Which described in the bergeys mannal of determinative bacteriology (9,11).

The identification of isolated pathogen was done by using several biochemical tests which summarized in Table (2) which showed that the characteristic of *Pantoea agglomerans* (12).

The results of identification ensured by API 20 system technique.

Recently the microbes of *Pantoea agglomerans* Regarded as opportunist pathogen which cause severe infection when introduced in to system of humans or animals (13).

The infection caused by this pathogen often involve patient that are already by other origin disease (14).

There are a little information about *Pantoea* spp. Especially in Iraqi hospitals. The result of this study showed that the occurrence of *Pantoea agglomerans*. In the open heart operation in Marjan hospital in Hilla city. This results are very important to clarify the possible role of *Pantoea agglomerans*. As a nosocomial pathogen in common parts of hospital infection and regarded as a first report of this pathogen in such part of hospital, survey for infective agent is very important to reduce the infection with different type of pathogen. In recent years there is an increased in nosocomial infection especially in neonate intensive care unit (NICN) also in oncology department, these unusual microorganisms including *Pantoea agglomerans*. So the aim of present study was tried to isolate and determine the occurrence of *Pantoea agglomerans*. From hospital environmental of open heart operation in marjan hospital *Pantoea agglomerans*. Which isolated in this study showed multi resistant to many antibiotics used (15).

The antimicrobial resistance of *Pantoea agglomerans* are of great concern both in human and veterinary medicine wide world. Antibiotic resistance is a serious problem in the treatment of human and animal with microbial diseases (13). The antibacterial susceptibility test of *Pantoea agglomerans* Is done by disc diffusion method using the Kirby and Bauer technique (10) Table (2)

*Pantoea agglomerans* is an opportunistic pathogen and when in to human and animals organs caused severe diseases especially in fatal infection, the most serious are individuals with underlying diseases such as young Persons (16). Infection caused by *Pantoea agglomerans* is difficult to diagnosis. To our knowledge there is no previous report on the isolation and identification of *Pantoea agglomerans* from environmental of open heart operations of Marjan hospital. The results of our study showed that contamination of the environment unit with *Pantoea agglomerans*. These results is very important especially the isolated pathogens showed multdrug resistance to many antibiotics used in this study and have inherent capability to remain viable.
and grow well at room temperature because of this the contamination occurred in these parts of hospital.

Immunological and Molecular Study of Human Cytomegalovirus contribution to Anemia in patients with Chronic Kidney Disease

Zahraa Abdulridha Baqer AL-Fayyadh1, Musa Nima Mezher1

1University of Kufa/ Faculty of Sciences, Department of Biology/Iraq

Abstract

Background: Renal failure is a condition in which the kidneys fail to remove metabolic end-products from the blood and regulate fluid, electrolytes and pH balance of extracellular fluids. The aim of current study was to investigate the role of human cytomegalovirus in renal failure and its contribution to anemia among patients with renal failure. Methods: This study was carried out at AL-Sadder Medical City Hospital during the period from December 2018 to February 2019. The study involved a total of 50 patients (32 males and 18 females) with kidney disease with age range between (20-70) years and 20 healthy individuals considered as controls. The human cytomegalovirus antibody were detected by cassette (rapid test) and compared the results of cytomegalovirus diagnosis (by rapid test) with molecular technique (Real time-Polymerase chain reaction ) results. Erythropoietin hormone concentration was detected by ELISA technique. Results: Data obtained from rapid test showed that positive patients for human cytomegalovirus were 32(64%) for all cases, while patients negative for human cytomegalovirus were 18(36%) compared with those of controls. Real time-Polymerase chain reaction amplification for presence of human cytomegalovirus DNA in serum samples revealed that human cytomegalovirus genome was detected in 10(20%) of the 50 serum samples. Erythropoietin hormone showed lower concentration in patients than controls. Erythropoietin showed significant decrease (P<0.05) in all groups of patients compared to those of control group. Conclusion: Human cytomegalovirus seemed to have relationship with chronic and acute renal failure and can affect patient’s immune status. Also, the decrease of erythropoietin hormone is the mean cause of anemia in renal failure patients.

Keywords: renal failure, Human Cytomegalovirus virus, Erythropoietin hormone, Real time-Polymerase chain reaction technique.

Introduction

Renal failure is a systemic disease and usually turns into a route cause for several kidney and urinary tract diseases. Renal failure induces a slow and progressive decline of kidney function enhanced by various factors including infections, diabetes, auto immune diseases, endocrine disorders, cancer and toxic chemicals [1]. The immunity of patients with hemodialysis becomes weak and this causes viral infections such as Human Cytomegalovirus (HCMV) [2]. It is commonly a result of complications arising from other serious medical conditions. Unlike acute renal failure, which happens speedily and suddenly, chronic renal failure occurs gradually (over a period of weeks, months or years) as the kidneys slowly stops working leading to an end-stage renal disease (ESRD) [3,4].

Anemia is a frequent complication during the later stages of chronic kidney disease. When present, it may cause symptoms such as fatigue and shortness of breath. The pathogenesis of anemia in chronic kidney disease is complex, but a central feature is a relative deficit of erythropoietin (EPO) [5]. The latter is a glycoprotein produced in the kidney under hypoxic conditions. It functions as the principal regulator of red blood cell production by controlling the proliferation, survival

Email: Zahraaalhossainy578@gmail.com
and differentiation of immature erythroid progenitors into mature red cells [6].

On the other hand, HCMV is one of the causes of inflammation in the kidney in the developed world; 40–60% of individuals are infected by time they reach adulthood, with seroprevalence approaching 100% in some populations [7]. Although initial HCMV infection is often asymptomatic in healthy individuals, it can cause severe and sometimes fatal disease in immune compromised individuals and neonates [8].

HCMV is one of the most common causes of birth defects resulting from an infectious agent, with 20% of congenitally infected infants exhibiting permanent neurological squeals including blindness, deafness and/or mental disability [9]. HCMV can also cause severe diseases in organ transplant recipients and AIDS patients after either primary infection or reactivation of a latent infection [10]. HCMV establishes a persistent infection, remaining silent in the host and undergoing productive reactivation cycles that contribute to its efficient transmission. HCMV infects and replicates in a wide variety of cells including epithelial cells of gland and mucosal tissues, smooth muscle cells, fibroblasts, macrophages, dendritic cells, hepatocytes and vascular endothelial cells [11,12]. The aim of current study was to investigate the role of human cytomegalovirus in renal failure and its contribution to anemia among patients with renal failure.

**Patients and Method**

This study was carried out at AL-Sadder Medical City Hospital during the period from December 2018 to February 2019. A total of 50 patients (32 males and 18 females) with kidney disease, with age range between (20-70) years, and 20 healthy individuals considered as controls were included. A 5-ml blood sample was collected from each participant. The blood samples were obtained by vein puncture from all patient after cleaning the skin with 70% alcohol, then blood left for about 30 minutes at room temperature, then they were centrifuged for 5 minutes at 3000rpm to separate serum and then transferred into other tubes. Serum samples were kept in capped plastic tubes and frozen at -20°C until being used. Each sample was labeled and given a serial number together with patients’ name.

**Immunological tests**

**CMV cassette rapid test:** The sample and test components were prepared to room temperature if they were refrigerated or frozen. The sample was mixed thoroughly before the test was performed, after which the cassette was placed on a clean surface. The test strip was numbered with the patient’s sample number. The pipette was filled with sample and the droplet retained. One drop (about 10µl) of the test sample was placed in each sample hole. The 2 drops (80µl) from the sample diluents were added directly to each specimen well. The results were read within 15 minutes.

**Molecular tests:** Sample extraction: (G- spin DNA extraction kit).

A 150-µl sample was added into microcentrifuge tube and a 570-µl volume of VNE Buffer was added into the sample and mixed well by vortexing and then incubated for 10 minutes at room temperature. A 570-µl volume of ethanol was added to the sample mixture and mixed well by plus-votexing. VNA Column was combined with collection tube and transferred up to 700ml of sample mixture to the VNE Column and then centrifuged at 8,000×g for 1min then discarded the flow-through and then combined with the VNA Column with used collection tube. The rest of sample mixture was transferred to the VNA Column and centrifuged at 8,000×g for 1min. A 500-µl volume of wash Buffer1 was added to the VNA Column and centrifuged at 8,000×g for 1min. A 750-µl volume of wash Buffer2 was added to the VNA Column and then centrifuged at 8,000×g for 1min. A 750-µl volume of wash Buffer2 was added to the VNA Column and then centrifuged at 8,000×g for 1min. Then centrifuge at full speed (18,000×g) for an additional 3min to dry the VNA Column and then discarded the flow-through and the Collection tube. The VNA Column was combined with elution tube and added 50µl of preheated RNase-free water to the membrane center of the VNE Column and then the VNE Column left to stand for 2min, centrifuged for 2min to elude the nucleic acid. Nucleic acids were stored at -70°C.

**Erythropoietin hormone assay procedure**

A 100-µL volume of dilutions of standard, blank and samples were added into the appropriate wells. Wells were covered with the sealing plate and incubated for 1 hour at 37°C. The time was started after the last sample addition. The liquid of each well was removed without wash. A 100-µL volume of detection reagent A was added to each well and they were covered with plate sealer and incubated for 1 hour at 37°C.
solution was aspirated and washed with 350μL of 1× wash solution to each well using a squirt bottle, and let it sit for 1~2 minutes. Then the remaining liquid was removed from all wells completely by snapping the plate onto absorbent paper. Totally washed 3 times and after the last wash, any remaining wash Buffer was removed by aspiration. The plate was inverted and blotted against absorbent paper. A 100-μL volume of detection reagent B was added to each well and the wells were covered with plate sealer and incubated for 30 minutes at 37°C. The aspiration/wash process was repeated for 5 times as conducted. A 90-μL volume of substrate solution was added to each well. Wells were covered with a new plate sealer, incubated for 10-20 minutes at 37°C and protected from light. The liquid will turn blue by the addition of substrate solution. Fifty-μL volume of stop solution was added to each well. The liquid will turn yellow by the addition of stop solution. The liquid was mixed by tapping the side of the plate. Any drop of water and fingerprint on the bottom of the plate were removed and confirmed there was no bubble on the surface of the liquid. Then, the microplate reader was run and conducted measurements at 450nm immediately.

**Statistical analysis**

All values were expressed as means ± SE. The data were analyzed using of SPSS (T test) version 23 and Microsoft Excel computerized programs. P value less than 0.05 was taken as the lowest limit of significance.

**Results**

Fifty patients with kidney failure, who referred to Central laboratory at Al-Sadder Teaching Hospital in AL-Najaf Governorate with age range of (20 to 70) years, were distributed according to gender 32(64%) males and 18(36%) females (Table 1).

**Age groups and percentages of the study groups**

In the current study, renal failure patients’ age ranged between (20-70) years. The current study showed that patients within the age group (20-30) years represented 18% of the study sample, while the age group (>50) years represented the highest percentage of 32%; (Table 2). In addition, result showed that 20% and 30% were within age groups (31-40) and (41-50) years, respectively, while the age of control group ranged between (20-60) years (Table 2).

Erythropoietin hormone detection with participants' gender

In the present study, there was a decrease in the level of erythropoietin (EPO) hormone concentration for patients with renal failure compared with control groups. The concentration of erythropoietin hormone in males (positive and negative for HCMV) decreased to (3.8905 pg/ml and 9.0727 pg/ml), respectively, compared with male controls (14.71 pg/ml), while the concentration of EPO in females (positive and negative for HCMV) decreased to (3.6909 pg/ml and 8.7286 pg/ml), respectively, compared with female controls (14.62 pg/ml) with significant difference ($P<0.05$; Figure 3).

Figure (3) Erythropoietin hormone concentrations according to participants' gender.

Discussion

The present study showed that the percentage of males (64%) with kidney failure was more than females (36%). There was no reason to give a response to another category in terms of infection, but the weakness of immune system may be the main cause of the disease. This result was agreed with the results of [13, 14, 15] who shown that males with renal diseases are more susceptible to infections than females, due to daily efforts of males as compared to females in addition to the increase in muscle mass in males than females leading to high proportion of creatinine in males and kidney damage. In this study, one of the common immunological techniques, cassette technique, was used. After the examination of samples of patients with renal failure and control samples, current results showed that out of 50 patients, only 32 (64%) were positive for HCMV, whereas 18(36%) showed negative results for HCMV by rapid test. The results were consistent with the results obtained by [16] who found the presence HCMV antibody in patients with kidney failure (83%) compared to control group. The proportion of positive serological test differed for this virus in patients with hemodialysis and that the cause of this variation was linked to the number of patients screened, the geographical distribution and sensitivity of the immunological techniques used to determine the Anti-CMV antibodies [17].

The results of current study were positive for human cytomegalovirus among the group of patients with renal dysfunction for males and females using one of the sensitive molecular techniques, RT-PCR. The results in this study reported that there was about 10(20%), out of 50, samples gave positive viral DNA existence and these results were in agreement with [18] who found that about 32(32.7%) of the samples tested gave positive results for viral genome and the difference in such subject areas may be ascribable to the sample type or in some case
disease type and stage\textsuperscript{[19]}. RT-PCR has been developed to detect HCMV because of its time-saving feature and high sensitivity and specificity\textsuperscript{[20]}. Current study showed a significant decrease in erythropoietin hormone, for both genders (negative for HCMV), responsible for the production and development of red blood cells and these lead to cause anemia in these patients, this result was in agreement with \textsuperscript{[21]}. The results showed that the level of EPO in renal failure patients (positive for HCMV) decreased more than in patients negative for HCMV, and this study was in agreement with \textsuperscript{[22]}. HCMV targets renal glomerular, vascular, epithelial, interstitial and tubular cells, including fibroblast-type cells in the renal cortex that activate EPO production in the setting of local tissue hypoxia and these lead to decrease EPO production and cause anemia.

**Conclusion**

Human cytomegalovirus seemed to have relationship with chronic and acute renal failure and can affect patient’s immune status. Also, the decrease of erythropoietin hormone is the mean cause of anemia in renal failure patients.

Comparison between HSP70 Levels in Acute and Chronic Coronary Artery Diseases

Wurood A.Kadhim1, Noora M.Kareem2, Samar A. Al-Shami3
1Assistant lecturer, Medical Microbiology Department, Al-Nahrain College of Medicine, /Iraq, 2Lecturer, Pathology Department, Al-Nahrain College of Medicine, Iraq, 3Assistant Lecturer, Pathology Department, Al-Nahrain College of Medicine, Iraq

Abstract

Background: Heat shock proteins are a family of endogenous proteins that act as molecular chaperon and increase in different stress situations like heart disease and atherosclerosis. Therefore, the aim of this study was to investigate whether there is a difference between Hsp70 level in the blood of myocardial infarction patients and apparently normal population; and between recent myocardial infarction patients and previous myocardial patients using immunocytochemistry technique. Method: Peripheral blood sample was taken from 50 patients with history of myocardial infarction divided into two groups (11 with acute or recent myocardial infarction and 39 with old or chronic myocardial infarction. Another 50 apparently healthy individuals were taken as a control group. Heat shock protein 70 level was measured by immunocytochemistry technique. Results: There was significant rise of heat shock protein 70 in myocardial infarction patients as compared with control group. Also, a significant decrease in heat shock protein 70 level in the chronic myocardial infarction patients group as compared with the acute myocardial infarction patients group. Conclusion: this study showed that heat shock protein 70 increases in acute myocardial infarction patients' but its level decreases in chronic myocardial infarction. So heat shock protein 70 can be used as a biomarker to differentiate acute, from chronic, myocardial infarction and may be helpful as an indicator of acute myocardial infarction.

Keywords: acute myocardial infarction, heat shock protein 70, chronic myocardial infarction, immunocytochemistry.

Introduction

Cardiovascular disease is one of the global public health problems contributing to 10% of the global disease burden and 30% of global mortality (1). Myocardial infarction (MI) is one of the five main presentations of coronary heart disease, which include unstable angina pectoris, stable angina pectoris, MI, heart failure and sudden death, and is defined as myocardial cell necrosis due to remarkable and sustained ischemia. It is usually an acute manifestation of atherosclerosis-related coronary heart disease (2).

Atherosclerosis is a widely accepted risk factor for coronary heart disease and a well-known inflammatory disease (3). In addition to inflammation in the coronary plaque, there may be myocardial inflammatory response after acute myocardial infarction (AMI) as part of the healing and scar formation processes (4).

Heat shock proteins (HSPs) are a family of endogenous proteins responsible for different types of stresses. They are classified according to their molecular weight into families, e.g. HSP27, HSP70, etc (5). They have the capability to act as ‘molecular chaperones, since they guide protein folding, stabilize macromolecules, carry out refolding and get rid of irreversibly denatured proteins in the cell (6). In addition, HSPs can be overexpressed in various stressful conditions such as hyperthermia (7), hemodynamic stress caused by heart diseases (6), physical exercise (8) and atherosclerosis (9). After cell death or stress, HSP peptide complexes may be presented on the cell surface or released to the

Noora M.Kareem
Email: dr.nooramk@gamil.com
circulation leading to activation of the adaptive immune system cells in addition to activating innate immune system, thus; signaling cell stress or damage to the immune system (10). Among HSPs, HSP70 is a powerful endogenous activator of the innate immune system working as a putative Toll-like receptor (TLR) ligand and is capable of stimulating the production of cytokines by macrophages (Figure 1) (11).

Multiple previous studies indicated and confirmed the protective role of HSP especially in myocardial ischemia (9, 12). Hsp70 may suggest important mechanisms of ischemic injury including misfolding, unfolding or pathological changes of critical proteins (13). Therefore, the aim of this study was to investigate whether there is a difference between Hsp70 level in the blood of myocardial infarction patients and apparently normal population; and between recent myocardial infarction patients and previous myocardial patients using immunocytochemistry technique.

Figure 1 Schematic representation of potential role of HSP in atherogenesis. Various stressors induce HSP production in the arterial wall, soluble HSPs bind to TLR complex resulting in proinflammatory responses and autoimmune reactions which contribute to atherosclerosis. TLR: Toll-like receptor). MQ: macrophages (9).

**Materials and Method**

This cross-sectional study was approved by Al-Nahrain College of Medicine Ethical committee. All participants gave their informed consents prior to their inclusion in the study. The study was carried out from September 2018 till 31st, December 2018. There were three groups of participants, their age ranged from 42-80 years, first group (group A) included 11 patients (7 males and 4 females) with acute myocardial infarction who were admitted to the Cardiac Care Unit (CCU) at Al-Imamain Al-kadhymain Teaching Hospital in Baghdad. The second group (group B) included 39 patients (33 males and 6 females) who were attending the outpatient clinic of Ibn –Albitar Hospital in Baghdad with chronic MI (more than 4 weeks from diagnosis of MI) (14). Third group (group C) of 50 apparently healthy individuals, who were age-, and sex-, matched to patients participants, were included as control group.

The diagnosis of patients was done by a specialist in cardiology based on clinical presentation and history of ischemic heart disease, which was confirmed by ECG, cardiac enzymes and coronary artery catheterization.

**Blood samples collection:** A 3-ml venous blood sample was drawn from each participant, for group A, within less than 24 hours from the myocardial infarction, for group B, after 4 weeks from MI diagnosis. The blood sample was immediately transferred to sterile heparinized
vacutainer tubes for lymphocytes separation.

After rehydration of smears, peroxidase block and protein block were added respectively. Primary antibody (US biological company) was added on smears (20ml of diluted mouse monoclonal Ab specific human CD marker) and incubated for 1 hour at 37°C, washed then incubated with secondary antibody and peroxidase conjugate and substrate-DAB chromogen complex were added respectively with buffer washing between each addition. Finally, the slides were counter-stained with hematoxylin, and then slides were covered with cover slide using mounting media. The slides were examined under 400x magnification power of light microscope (Olympus). The dark brown cytoplasmic or membranous staining of cells were considered positive (Figure 2), the percentage of positive cells was calculated as follows:

Percentage of positive cells = (No. of positive cells / total No. of cells)*100%.

Statistical analysis was performed with Statistical Package for Social Sciences (SPSS, version 15.01). Data analysis was done using independent sample $t$-test for tables with means and standard deviations. $P$ value of ≤0.001 was used as the level of highly significance. Descriptive statistics for the clinical and laboratory results were formulated as mean and standard deviation.

### Results

HSP70 expression on PBLs was detected by immunocytochemistry technique. A comparison between patients (groups A and B) and control groups and between group A and B were summarized in Table 1 and Table 2, respectively. Independent sample $t$-test revealed a high statistically significant difference between patients and control groups ($P=0.001$). In addition, there was a high statistically significant difference between acute and chronic MI patients group ($P=0.000$) in expression of HSP70 on PBLs.

### Discussion

HSP70 proteins are central components of the cellular chaperone system associated with folding, assembly, disassembly and degradation of proteins (16). During the last decades, a number of studies had suggested that stress-induced overexpression of HSP70 may confer protection against ischemia and reperfusion injury of the heart (17).

Previous studies had evaluated the role of Hsp70 in heart failure (18,19), but few of them had investigated its...
role in myocardial infarction and none had compared between recent and old MI.

Our study revealed that Hsp70 was significantly increased in peripheral blood of myocardial infarction patients in comparison with healthy control group, these findings were similar to (20) who had measured serum level of Hsp70 in 24 patients with acute MI at the arrival, 6 hours later and in the next morning using ELISA method and found that serum HSP70 in patients with acute MI were significantly higher than in the control group at all-time points and concluded that there was a relation between HSP70 and the extent of myocardial necrosis measured by the increase in cTnT and CK-MB (known markers of myocardial necrosis), as well as by typical echocardiographic findings. Our study agreed with (21) who had investigated synthesis of HSP70 in the human heart (in vivo) after CABG and found that the increase in HSP70 occurred after at least 2 hours of stress induction by CABG. Similarly (22) had examined the immunohistochemical expression and distribution of HSP72 after various periods of ischemia (from 30 minutes to 7 days) and reperfusion in the non-stress-pretreated rat heart. Moreover, (23) also studied the protective role of HSP70 by direct HSP70 gene delivery in rabbits hearts (in vivo) and inducing ischemic condition. They concluded that HSP70 reduced the size of infarcts and thus reducing the severity of ischemic injury. HSP70 was studied by (24) in atherosclerotic plaques in aorta of humans and rabbits through immunohistochemistry and they found that HSP70 staining was most pronounced in the central portions of advanced atherosclerotic plaques.

Our method of HSP70 detection in blood by immunocytochemistry was never been reported in previous studies. Also, no previous similar studies had compared the difference between recent or acute MI from old previous MI in humans.

**Conclusion**

HSP70 may be used as a biomarker for myocardial infarction and as a confirmatory test to differentiate between acute and chronic MI.

¹Almamoon University College, Iraq, ²Department of Biology, College of Education For Pure Science/ Diyala University, Iraq, ³College of Dentist Medicine/ University of Al-Iraqia, Iraq, ⁴Environmental Engineering Department, College of Engineering/ AL-, Mustansiriyah University, Iraq

Abstract

Background: Exposure to sun in the sunny days for 10 to 15 minutes a day and two to three times a week is enough to get vitamin D requirements in the majority, but people with darker skin need to be exposed to sun for longer periods to get their vitamin requirements. The purpose of this research was to achieve a statistical study to know and determine the factors behind deficiency of vitamin D among men in Baghdad city in addition to knowing the most important diseases associated with its deficiency in order to inform and educate the community as well as to raise awareness of the society about the role of this vital vitamin, prevention of its deficiency and to propose appropriate treatment for it. Methods: The research was conducted in several private clinics in Baghdad throughout 2017. The investigation was including study of 500 cases of men who were randomly selected. The cases were divided according to age groups into two groups: the first group was (20-40) years, while the other group was (more than 40 years). Also, the cases were classified according to vitamin D level to sufficient, insufficient and deficient. Results: The results obtained from the study showed that the percentage of vitamin D insufficient and deficient were 69.6% and 18.8%, respectively, while the sufficiency percentage was the lowest and scored 11.6%. Common chronic diseases, such as high blood pressure and diabetes as well as sleep disorders and muscle fatigue, were also followed in the cases. The results illustrated that 47.6% of men cases had diabetes and 39% had high blood pressure, while 28.2% and 17.2% of them had muscular fatigue and sleep disorders, respectively. These chronic diseases and symptoms were related in one way or another with Vitamin D deficiency. Conclusion: Vitamin D can be given for preventive and therapeutic purposes.

Keywords: vitamin D, diabetes mellitus, sun exposure, calcitriol.

Introduction

The mention of Vitamin D is directly related to sunlight, which is called the vitamin of sun rays, because this vitamin is made in sufficient quantities inside the body when exposed to the moderate sunlight with the association of cholesterol (¹). So, taking this vitamin is not considered a necessary food in the event of adequate exposure to sunlight. Exposure to sun in the sunny days for 10 to 15 minutes a day and two to three times a week is enough to get vitamin D requirements in the majority, but people with darker skin need to be exposed to sun for longer periods to get their vitamin requirements (²). Despite the easy access to the body’s needs of vitamin D through the sun, many people avoid sun exposure, or use sunscreen - which hinders the production of vitamin D in the skin - to protect the skin from damage caused by sun such as wrinkles and skin cancer (³). For the benefit of exposure to sunlight and avoid damage at the same time, the best thing to do is to use the sunscreen after exposure for a long time enough to get requirements of vitamin D. the latter, although called vitamin, is actually not a vitamin but a hormone produced in the body as a result of exposure to sunlight (⁴). The active form of this hormone

DOI Number: 10.37506/v14/i1/2020/ijfmt/192983
is represented by 1, 25-dihydroxycholecalciferol, or 1alpha, 1, 25-dihydroxyvitamin D3 also called (Calcitriol). The manufacture of this hormone begins in the skin and then activated by two steps; the first in the liver and the second in the kidneys (5). People living in the Arctic cannot get their vitamin D needs through exposure to sun, especially in the winter, as well as people who do not leave the home or whose live confined to indoor areas and buildings and people living in crowded places where air pollution is high, which prevents the arrival of ultraviolet light adequately (6). Also dark-skinned people, as dense skin pigments can prevent up to 95% of ultraviolet rays from reaching deep layers of skin, the manufacture of vitamin D3. The use of sunscreen with a protective factor of 15 or more reduces skin’s ability to manufacture vitamin D for up to 99% (3). When talking about the importance of vitamin D and its functions in the body, the first thing that comes to mind is its importance in the absorption of calcium and phosphorus as well as bone health, but science is still discovering functions and other important roles of vitamin D (7). Vitamin D functions include maintaining balance of calcium and phosphorus in the body by stimulating the absorption of calcium and phosphorus as well as reabsorption in kidneys (1,2). It works with the hormone of parathyroid gland to promote release of calcium from bones. Also, it remove phosphorus through urine when the level of calcium in the blood is decreased, which thus maintains the concentration of calcium and phosphorus in the blood to allow the bones to precipitate them (1), guaranteed getting adequate amounts of vitamin D and calcium to preserve the level of calcium in the blood, thus preserving bone health (3). Moreover, it maintains normal growth, differentiation and proliferation rates of cells of many body tissues such as muscles, skin, immune system, parathyroid gland (1) as well as nervous system, brain, genital organs, cartilage pancreas, breast and colon (2). Furthermore, it contributes to prevention of abnormal reproduction of cells in the prevention of cancer (3). It contributes to the metabolism of muscles and affects their strength and constriction. In contrast, people who do not have sufficient vitamin D are at increased risk of muscle weakness, this includes weakness of the heart muscle (3). Some studies had found that the level of vitamin D (calcitriol) in the blood is inversely proportional to insulin resistance and reduces the risk of type 2 diabetes mellitus (4). Vitamin D contributes to the control of immune system responses that cause certain autoimmune disorders, such as type 1 diabetes mellitus, scleroderma, inflammatory bowel disease (3) and rheumatism caused by autoimmune defects (5). One of the major diseases caused by vitamin D deficiency is rickets in children, osteoporosis and osteomalacia in adults, because its paucity leads to a decrease in the intake of calcium from food, and as a result, calcium is released from bones in order to maintain a constant rate of calcium in the blood. Vitamin D deficiency affects not only bones of children and adults but also affects teenagers, preventing them from reaching the largest bone mass they can reach (6). In addition to the above, vitamin D deficiency has other effects such as increased chance of asthma as it was found to be associated with severe asthma in children (7,8). Vitamin D deficiency causes increasing risk of bacterial and viral respiratory infections (8), the chance of depression (9), the chance of weight gain and obesity (10) as well as the chance of hypertension (11). In addition, vitamin D deficiency increases the incidence of cognitive retardation in older persons (12) and increases the chance of death from any reason (11). Vitamin D deficiency is considered as a major cause for increasing the risk of death from heart and vascular diseases. One of the major reasons for increasing cholesterol level in the body is deficiency of vitamin D (11) and its deficiency is related with cancer (13). As well as all previously mentioned, deficiency of vitamin D leads to autoimmune diseases such as type 1 and 2 diabetes mellitus, multiple sclerosis and others.

The purpose of this research was to achieve a statistical study to know and determine the factors behind deficiency of vitamin D among men in Baghdad city in addition to knowing the most important diseases associated with its deficiency in order to inform and educate the community as well as to raise awareness of the society about the role of this vital vitamin, prevention of its deficiency and to propose appropriate treatment for it.

**Methodology**

Vitamin D, which is taken or synthesized in the skin, turns into a compound known as calcidiol, 25-hydroxycholecalciferol, or 25-hydroxyvitamin D (abbreviated 25(OH)D) (14). Thus, the best test of body content of vitamin D is analysis of total level of 25-hydroxyvitamin D. There is a variance in the definition of vitamin D deficiency or inadequacy. In general, a person is severely deficient vitamin D (Deficient) if the result of 25-hydroxyvitamin D test
is less than 10ng/ml, while it is deficient (Insufficient) in the case of result between 10-29ng/ml. If the result is between 30-100ng/ml, it is normal and good (Sufficient), however, levels higher than 100ng/ml may cause toxicity (Potential toxicity) \(^{(15)}\). The present study was carried out in five private clinics in different regions of Baghdad in 2017 (from 1/1/2017 to 31/21/2017), which covered 500 cases of men and was laboratory monitored by a special questionnaire including checking date, the clinical condition and laboratory tests. The investigations of study comprised two parts; the first part was laboratory analysis and testing of vitamin D (which is 25-OH Vitamin D Total) and tests for chronic diseases (diabetes and high blood pressure), while the second part included followed up of accompanying symptoms of sleep disorders and muscle fatigue periodically for all men cases.

**Statistical analysis**

Statistical analysis of study results of was carried out by dividing data into the two groups; the first group was analyzed according to laboratory tests and the second group was according to age groups of participated men.

**Results obtained according to laboratory tests**

The study cases were divided according to results of laboratory tests of vitamin D-25 total deficiency into the following three groups; Group 1: Normal level of vitamin D (Sufficient) ranged between 30-100ng/ml, Group 2: Low level of Vitamin D (Insufficient) ranged between 10-30ng/ml and Group 3: Very low level of vitamin D (Deficient) with a value >10ng/ml. The number of cases who studied in these five private clinics was 500 persons who were monitored periodically via a special questionnaire for one year.

**Table (1) Distribution of participants according to level of 25-OH Vitamin D Total**

<table>
<thead>
<tr>
<th>Vitamin D status</th>
<th>Reference Range</th>
<th>Number of Cases</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sufficient</td>
<td>30-100</td>
<td>94</td>
<td>18.8</td>
</tr>
<tr>
<td>Insufficient</td>
<td>10-29</td>
<td>348</td>
<td>69.6</td>
</tr>
<tr>
<td>Deficient</td>
<td>&gt; 10</td>
<td>58</td>
<td>11.6</td>
</tr>
</tbody>
</table>

From Table (1) was clear that the proportion of men with normal (Sufficient) level of vitamin D was the lowest, while the percentage of men with vitamin D deficiency was high and the highest proportion of participated men was with insufficient vitamin D.

**Table (2) Distribution of vitamin D levels according to age groups of participating men**

<table>
<thead>
<tr>
<th>Age group/yr</th>
<th>Number of cases</th>
<th>Percentage</th>
<th>Vitamin D Level</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>

<td>136</td>
</tr>
<tr>
<td>Total</td>
<td>500</td>
<td>100</td>
<td>94</td>
<td>348</td>
</tr>
</tbody>
</table>

Table (2) showed that the percentage of men who were deficient of vitamin D was the lowest one in both age groups followed by the percentage of men with sufficient vitamin D level with a clear increase in number of men with low level of vitamin D (Insufficient).

Two types of chronic diseases (diabetes mellitus and hypertension) are associated with vitamin D deficiency and were studied in current study. Also, follow-up of some of the accompanying symptoms, such as sleep disturbance and muscle fatigue, were studied, noting that it was probable that patients were suffering from more than one disease at the same time (Table 3).
Table (3) Relation of Vitamin D Deficiency with Other pathological conditions

<table>
<thead>
<tr>
<th>Pathological condition</th>
<th>Number of Cases</th>
<th>Percentage</th>
<th>Vitamin D Level</th>
<th>Sufficient</th>
<th>Insufficient</th>
<th>Deficient</th>
</tr>
</thead>

</tr>
<tr>
<td>Muscle Fatigue</td>
<td>86</td>
<td>17.2</td>
<td></td>
<td>19</td>
<td>57</td>
<td>10</td>
</tr>
</tbody>
</table>

Table (3) showed that the number of men with diabetes mellitus and insufficient level of vitamin D was the highest among all associated diseases followed by those with hypertension, sleep disturbances and muscle fatigue, respectively. On the other hand, a high number of men with diabetes, high blood pressure and sleep disorders had vitamin D deficiency, both insufficient and deficient, indicating a close correlation between these diseases and vitamin D deficiency.

Vitamin D deficiency by months of the year

As previously illustrated, this research was conducted over a period of one year and follow-up of the cases during that period. All laboratory tests for vitamin D deficiency were performed for all the cases throughout the year (Table 4).

Table (4) Distribution of Vitamin D levels during months of the year

<table>
<thead>
<tr>
<th>Vitamin D Level</th>
<th>Months of the year</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>Sufficient</td>
<td>12</td>
<td>9</td>
</tr>
<tr>
<td>Insufficient</td>
<td>43</td>
<td>32</td>
</tr>
<tr>
<td>Deficient</td>
<td>5</td>
<td>7</td>
</tr>
<tr>
<td>Total number of cases</td>
<td>60</td>
<td>48</td>
</tr>
<tr>
<td>Percentage of (Insufficient + Deficient) Vitamin D</td>
<td>80</td>
<td>81.25</td>
</tr>
</tbody>
</table>

Table (4) showed that the percentage deficiency (both Insufficient and Deficient levels) of vitamin D was very high in comparison with the normal cases along the year. In winter and spring months (i.e. from October to March) there was significant increase in vitamin D deficiency, both Insufficient and Deficient levels, while in the summer months, these level was lower. This is certainly due to the fact that the sun light in the summer months is stronger and available more than in the winter months, so the body can get its requirement from Vitamin D easily.

Conclusions

Deficiency of vitamin D is considered as an important factor in the development of a large number of diseases and possibly all diseases, which can be called “the disease of all diseases”. The following conclusions can be drawn from current study:

- A high percentage of patients are suffering from vitamin D deficiency making it a pandemic and is considered to be related to quality and quality of life.
• It is needed for wide and comprehensive surveys of vitamin D deficiency in children, women and men and all ages.

• It has become clear that vitamin D deficiency is indicated in front of any clinical exhibitor or a satisfactory condition.

• Vitamin D can be given for preventive and therapeutic purposes.

• Increase awareness of the benefits of exposure to sunlight, which represents a large energy away from all diseases.

• This study is considered as a first step in a series of steps to be taken in order to identify more comprehensively vitamin D deficiency among different population groups.

Recommendations

• Provision of free vitamin D in health centers for all who suffer from a shortage.

• Focusing on the scientific side by giving awareness lectures and seminars for medical staff and patients in health centers and hospitals similar to lectures and seminars on vaccines.

• All practitioners should consider vitamin D deficiency as one of the causes of chronic diseases and other clinical symptoms and perform a vitamin D deficiency analysis for patients in parallel to any other type of analysis.

• Exposure to sunlight directly for a period of 10-20 minutes 3 times a week and when sun is vertical (10-12 am), this is easy and available to sunny countries most of the year, like Iraq.

• Focus on eating foods rich in vitamin D such as fish (rosacea and tuna), egg yolks, liver, orange juice, legumes and mushrooms.

Mutation Evaluation in $P_{53}$ exon 5 in Iraqi AML Patients with 4 Growth Levels

Ishtar Imad$^1$, Abdulameer N. Ghaloub$^1$, Mehemt Ozaslan$^2$, Alaa F. Alwan$^3$

$^1$Department of Biology/ Mustansiriyah University, Baghdad, Iraq, $^2$Department of Biology/ University of Gaziantep, Gaziantep, Turkey, $^3$Clinical Hematology/ The National Center of Hematology/ Mustansiriyah University, Iraq

Abstract

**Background:** The role of TP$_{53}$ is not limited to repairing damaged DNA and regulating its proliferation, it also activates other repairing genes and prevents mutated DNA from multiplying which prevents malignancy formation that’s why it’s called “DNA’s gatekeeper”. The aim of current study was to evaluate the role of Exon 5 of $P_{53}$ gene in the development of AML in Iraqi patients. **Method:** Sixty newly diagnosed AML patients at Baghdad (haematology national centre) were involved in current study. Peripheral blood samples were collected in EDTA tubes then they followed a month after receiving 3 and 7 AML treatment regimens to compare mutational status pre and post treatment. The patient divided into 4 age groups based on growth level (0-15 years, 16-40 years, 41-65 years and 66 years and above) in a 15 sample for each.

**Results:** We uncovered transcriptional downregulation of significant p53 acetyltransferases in both CN-AML and APL, joined by expanded Mdmx protein articulation and deficient Chk2 protein enactment. Mutation study on exon 5 of $P_{53}$ gene showed no differences in gene sequence from the standard sequence of NCBI geneBank sequence.

**Conclusion:** Exon 5 of $P_{53}$ gene not included in the AML causes since the patients of this study showed no alteration in sequence from the reference sequence.

**Keywords:** AML, $P_{53}$, exon 5, growth level, PCR.

Introduction

TP53 and correlations with AML

According to the last review paper published by (1) who explained the role of TP$_{53}$ as a producer for the protein called tumor protein suppressor that regulates cell division to keep it in order and do not allow fast or uncontrolled proliferation. This protein binds directly to DNA to evaluate if DNA is repairable after toxins, chemicals or UV exposure damage or the cell should apoptosised. The role of TP$_{53}$ is not limited to repairing damaged DNA and regulating its proliferation, it also activates other repairing genes and prevents mutated DNA from multiplying which prevents malignancy formation that’s why it’s called “DNA’s gatekeeper”(3).

Choosing the type of causative mutation of AML, helps decide treatment type. A previous study (3) investigated genes and DNA errors associated with TP$_{53}$ mutations and found that (hub genes) are responsible for it which are: $LEP, BMP_2, ITGA_2B, MNX_1, TRH, NMU, CDH_1, KDR, CASR$ and $APOE$. These genes may change the type of treatment received by patient and may increase his healing opportunity.

A pioneer researcher (4) found that MDM2 inhibitors are under investigation for therapy of acute AML patients in M3 clinical trials. To study resistance formation to MDM2 inhibitors in AML cells, we here established 45 sub-lines of the AML TP$_{53}$ wild-type cell lines MV4-11 (15 sub-lines), OCI-AML-2 (10 sub-lines), OCI-AML-3 (12 sub-lines) and SIG-M5 (8 sub-lines) with resistance to MDM2 inhibitor nutlin-3. The outcomes showed that all MV4-11 sub-lines harbored the same R248W mutation and all OCI-AML-2 sub-lines harbored the same Y220C mutation, indicating the selection of pre-existing TP$_{53}$-mutant subpopulations. In concordance, rare alleles harboring the respective

Corresponding author:
Ishtar Imad
email: ishtar.imad@yahoo.com
mutations are detectable in the parental cell lines. The third and fourth sub-lines were characterized by varying TP$_{53}$ mutations or wild type TP$_{53}$, indicating the induction of de novo TP$_{53}$ mutations. For the most part, loss of p53 capacity was not associated with diminished affectability to cytotoxic medications. They suggested that loss of p53 capacity is associated with chemo obstruction in AML, nutlin-3-adapted sub-lines displayed, in the majority of experiments, similar or increased drug sensitivity compared to the respective parental cells. Hence, chemotherapy may remain an option for AML patients after MDM2 inhibitor therapy failure.

Nonsexual chromosomal mutation may give alarm to AML to be, even years before its diagnosis. Under this subject, (5) published their study to show the example of substantial changes seen at analysis of AML. Moreover, 2012 healthy women who eventually develop AML within average of 9.6 years, when compared their DNA sequence with healthy age-matched women gene mutations found in P$_{53}$, IDH$_1$ and 2, splecosome, TET$_2$ and DNMT$_3A$, all mutated subjects develop AML. That study proved that there is genetic predisposition for AML and it could be diagnosed early before AML becomes evident, which may be called latent AML.

In addition, (6) found that TP$_{53}$ changes were recognized in 18% of patients with AML that have mutated TP$_{53}$ with missense mutation (histidine to arginine) on different codons. These mutations correspond with unfavorable karyotyping (ch5, 7 and 17) which come with poor prognosis. Patients with mutated TP$_{53}$ showed mutations also in FLT$_{3}$, RAS and NPM$_{1}$ when compared to wild TP$_{53}$ and these mutations were the same for patients above and less than 60 years. On the other hand, remission differed between wild and mutated types of TP$_{53}$ with rates of 57% vs 41%, respectively, and overall survival rates of 24% vs 9%, respectively, for wild and mutated types.

Bioinformatics analysis by (7) uncovered that p53 is not practical in CN-AML and APL influences at initiating its most significant utilitarian results: cell cycle capture, apoptosis, DNA fix and oxidative pressure barrier. They uncovered transcriptional down guideline of significant p53 acetyltransferases in both CN-AML and APL, joined by expanded Mdmx protein articulation and deficient Chk2 protein enactment. It revealed that p53 pathway was differentially inactivated in various AML subtypes. Centered quality and protein examination of p53 pathway in CN-AML and APL patients suggested that useful inactivation of p53 protein can be credited to its disabled acetylation. Their investigations showed the need in further precise assessment of p53 pathway working and guideline in unmistakable subtypes of AML.

The aim of current study was to evaluate the role of Exon 5 of P$_{53}$ gene in the development of AML in Iraqi patients.

**Methodology**

**Samples collection**

One hundred and twenty peripheral blood samples were collected between 1$^{st}$, May to 20$^{th}$, September from AML patients attending Baghdad Special Nursing Center (which is the drainage of all Iraq to diagnose the tumor type) and AL-Yarmouk Hematology Center using EDTA tubes. Blood was centrifuged then plasma was gathered. In addition, 60 non-AML blood samples of healthy patients, within same age groups of the patients, were collected in EDTA to compare the results with the pre and post treatment groups.

**DNA extraction**

A volume of 200µl of whole blood placed into a sterile 1.5ml micro centrifugtube. Also, 400µl of whole blood lysis buffer was prepared (Qiagen® SV Lysis Buffer + 1% Triton® X-100 for every 200µl of whole blood. Then, Proteinase K solution prepared (20mg/ml) by re-suspending 100mg Proteinase K in 5ml nuclease-free water. Moreover, 40µl Proteinase K (20mg/ml) were added to the 200µl of whole blood in the micro-centrifuge tube, incubated at room temperature for 10 minutes. Invert the tube occasionally to mix. After that, 400µl of prepared whole blood lysis buffer was added to the Proteinase K-treated whole blood sample. Vortexed briefly to mix, incubated at room temperature for 10 minutes, vortexing occasionally to mix.

**DNA purification from Whole Blood Lysate**

The genomic DNA eluted 75–250µl nuclease-free water. The optimal elution volume depends on volume of original whole blood sample and the desired concentration of genomic DNA for downstream applications. Elution in smaller volumes will concentrate DNA but may lower total yield. Larger elution volumes will give optimal yields but a more dilute final DNA preparation. We recommend eluting in 100µl of nuclease-free water and
adjusting from there based on need.\(^{(8)}\)

**NanoDrop**

Logged into the computer next to the NanoDrop machine, on the desktop the ND1000 program was opened, in the pop-up window click “Nucleic Acid” for DNA samples, the NanoDrop pedestal cleaned (the little platform where the sample placed) with wipes and water. Then, 2μl of H\(_2\)O loaded and click “Okay”, clicked “Blank” to calibrate it where it says “Sample Type” click DNA-50 for DNA samples. After that, 2μl of sample loaded onto the pedestal, then click “Measure”. After the machine analyzes it, data saved. If it is a good reading, the graph will show a smooth curve. The absorbance readings at 230nm and 280nm should be about half the reading at 260nm, which means it is a pure DNA sample.

* Pedestal should cleaned between each reading\(^{(9)}\).

The final products were analyzed by 2.0% agarose gel electrophoresis and stained with safe stain (Novel Juice). The gel was run at 100 volts for 45 minutes. The DNA fragments were illuminated by UV-light.

**Nucleotide Sequencing**

**PCR sequencing procedure**

Sixty DNA fragments of the P53 gene were excised.
from the agarose gel and used as source of DNA templates for PCR amplification. The ratios of other substrates were the same (Table 1). The total volume of PCR reaction mixture for each sample will be 25µL; and then run it on a thermo-cycler machine (Eppendorf, German) with the same conditions of PCR reaction (Table 2).

C- Pre-Sequencing Preparation procedure

Protocol of PCR production cleanup with ExoSAP

The ExoSAP mixture consists of sterile water, exonuclease I (10U/µl), shrimp alkaline phosphatase (1U/µl)). The Exonuclease I functions for degradation of primers and Shrimp Alkaline Phosphatase was for degradation of unincorporated nucleotides to prepare template for sequencing. The ExoSap mixture was prepared as follows:

5µl of PCR product+3µl of Exo/Sap.

The purification of DNA template was performed in the thermocycler (Eppendorf, German) according to the conditions indicated in Table (3).

The solution was put on vortex for 45 minutes to mix it. The empty receiver column was placed in 1.5ml collecting tubes and 850µl of sephadex solution was added into each receiver column tube. The tubes were centrifuged at 3,800rpm for 2 minutes, then the receiver column was replaced in a new clean collecting tube. After that, 10µl of the PCR sample was added to a prepared column. Then the PCR samples were transferred and placed in the center of the receiver column matrix without touching it. Then, the tubes were placed in the centrifuge at 3,800rpm for 2 minutes.

Results and Discussion

This test was done at Turkey/Gaziantep University/Biology Department. We had ordered the primers for P53 gene from Qiagene.

DNA sequence of exon 5 of P53 gene was screened to find different genotypes. Both exons sequences of P53
gene were screened by genetics analyzer (nucleotide sequencing) (Figure 1).

The DNA sequences of \( P53 \) gene of \(^{(10)}\), to look at the subsequent DNA groupings of AML (Query Sequence) with the reference groupings.

![DNA sequence of \( P53 \) gene (exon 5 sequences were indicated in blue color).](image1)

No variety was found in the succession of PCR format for the objective areas in the wake of contrasting and the reference grouping (GenBank sequence). Figure (2) indicated and revealed the partial sequence results without any variation (Mutation).

![The partial sequence result of exon 5 of \( P53 \) gene.](image2)

According to the results of \(^{(11)}\) study, there was an overall reduction in the level of p53 expression in patients with AML, meanwhile p53 showed differential expression in AML subtypes and M3 subtype showed higher expression in comparison with other AML subtypes. It was suggested that p53 expression has a possible relation with granulocyte maturation and prognosis. Further investigations needed to clarify the exact role of p53 expression fluctuations in AML patients as basic molecular events in malignant cells.

In addition, \(^{(12)}\) uncovered noteworthy and differential changes of p53 pathway-related quality articulation in the greater part of AML subtypes. They found that p53 pathway-related quality articulation was not associated with acknowledged gathering of AML subtypes, for example, by cytogenetically-based guess, morphological stage or by sort of sub-atomic transformation. Their bioinformatics investigation uncovered that p53 was not practical in CN-AML and APL influences at prompting its most significant utilitarian results: cell cycle capture,
apoptosis, DNA fix and oxidative pressure guard. We uncovered transcriptional downregulation of significant p53 acetyltransferases in both CN-AML and APL, joined by expanded Mdmx protein articulation and deficient Chk2 protein enactment.

Also, (13) found that $TP_53$ transformations are free indicators of short survival and chemo-refractoriness, and that CLL giving $TP_53$ changes without del17p13 passage as inadequately as CLL conveying del17p13. Since CLL harboring $TP_53$ changes without del17p13 as of now not perceived by ordinary analytic methodologies, these outcomes might be pertinent for an exhaustive prognostic portrayal of CLL.

**Conclusion**

Exon 5 of $P_53$ gene not included in the AML causes since the patients of this study showed no alteration in sequence from the reference sequence

**Ethical Clearance:** The research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq.

Assessment of Antagonistic Effect of Alcoholic Extract from Cyanophyta (Spirulina Platensis) Against Several Human and Plant Derived Pathogenic Fungi

Raghad J. Fayyad1, Rasha Saad Nuaman2, Noor T. Hamdan3, Rasha Saatam Hameed4, Sara A. J. Maliki5

1Biology Department- Collage of Science/ Mustansiriyah University, Iraq

Abstract

Background: Blue-green algae have been proved to producing different bioactive compounds. For this reason Spirulina platensis isolates have been used in the present study as a biocontrol agent against several human and plant pathogenic fungi. Current study was aimed to investigate the use of crude extract of Spirulina platensis as antifungal agent by determining the antagonistic activity of methanolic extract of Spirulina platensis against several human and plant pathogenic fungi. Also, to determine the antifungal phytochemicals within algal alcoholic extract through GC-mass analysis.

Method: Four different concentrations of alcoholic extract were prepared (100, 75, 50 and 25mg/ml) from algal isolates and their antagonistic activity was investigated against molds isolated from spoiled fruits (two isolates of Aspergillus niger, Aspergillus flavus, Mucor sp. and Botrytis sp.) and against several Candiada spp. (Candida albicans, Candida glurbrate, Candida fameta, Candida lustrans) which were isolated from different clinical sources.

Results: The results showed that algal extract displayed wide range of antagonistic activity against tested fungi depending on applied algal extract concentration and tested fungal species. Also, GC-Mass data analysis had been performed for algal extract and 36 different bioactive chemicals have been identified including eight compounds authenticated as having antifungal activity.

Conclusion: Spirulina could be used as alternative drug to treat Candida sp. infections as well as added to food industries to enhance their nutritional value and simultaneously decreasing the possibility of food spoilage by molds.

Keywords: algal extract, bioactivity, onychomycosis, fungi, candida spp.

Introduction

Nature has been a source of therapeutic agents for thousands of years and a remarkable number of recent drugs have been isolated from environmental sources. In addition, biologically active constituents have recently received notable attention. Algae are rich sources of constituents that are novel in their structure and authenticated as biologically active metabolites, primary or secondary metabolic products produced by these organisms may exhibit potential bioactivity in pharmaceutical industry (1). Blue-green algae have been proved to produce different bioactive compounds. These comprise antibiotics which inhibited microorganisms responsible for human and plants diseases(2).

Spirulina is blue green algal genus belongs to Oscillatoriaeae which is characterized as free floating, spiral, multicellular and filamentous in appearance. The filaments are approximately 50-300μ long and 10μ in diameter and nitrogen-non fixing (3). Fungi cause a broad range of superficial mycoses diseases in both humans and animals, involving the outer layers of the skin and frequently leadings to chronic infections. The major etiological agents of mycoses infections are Candida spp. and dermatophytes (4). Also, fungal pathogens are important problem in agriculture, since most of the fungicides engaged exhibit lower effectiveness under field conditions and may cause chemical environmental pollution as well as poisoning of crops. In addition, some species, e.g. Aspergillus flavus can contaminate food and produce severe mycotoxins (5).

Spirulina as many other blue-green algae are producing varieties of antimicrobial agents, so they are
considered as suitable natural agents for manipulation as biocontrol mediators of plant pathogenic fungi and bacteria (1).

Therefore, current study was aimed to investigate the use of crude extract of *Spirulina platensis* as antifungal agent by determining the antagonistic activity of methanolic extract of *Spirulina platensis* against several human and plant pathogenic fungi. Also, to determine the antifungal phytochemicals within algal alcoholic extract through GC-mass analysis.

**Materials and Method**

**Source of algae**

Pre-isolated and characterized *Spirulina platensis* used in the present study was obtained from the laboratory of higher graduate at Biology Department in AL-Mustansiriyah University, Baghdad. The obtained isolate was cultured and maintained on BG-11 Medium and grown in an illuminated incubator.

![Figure 1](https://example.com/figure1.jpg)

**Figure (1) Microscopic view of Spirulina platensis (40X)**

**Preparation of algal Extract**

Algal extract was prepared according to (6). The *Spirulina platensis* materials were grounded to a fine powder and a weight of 40 gram from algal powder was extracted successively with 200ml of solvent (methanol) in Soxhlet extractor until the extract was clear. The extract was evaporated to dryness by reduced pressure using rotary vacuum evaporator and the resulting pasty form extracts were stored in a refrigerator at 4°C for future experiments.

**Collection of human pathogenic tested Yeast**

Four different species of *Candida* were obtained from the laboratory of higher graduate of Biology Department in AL-Mustansiriyah University, Baghdad. These species were (*Candida albicans, Candida glubrarete, Candida fameta* and *Candida lustrans*). These yeasts were isolated from different clinical sources and maintained using Sabouraud dextrose agar (SDA) medium according to (7).

Isolation and identification of tested plant pathogenic Molds

The examined plant-pathogenic molds used in this investigation were isolated from different local spoiled fruits according to (8) and were identified using cultural and morphological features such as conidial morphology, pigmentation and colony growth pattern, according to the technique of (9).

**Bioactivity test of hot alcoholic extract of Spirulina platensis against molds**

According to (10) technique that has been used for this test, different concentrations of hot alcoholic algal extract (100, 75, 50 and 25mg/ml) were incorporated into PDA medium (potato dextrose agar) before pouring in Petri dishes. Also, clotrimazole (10μg/ml) was tested against tested molds to compare between the antifungal activity of natural agent (*Spirulina extract*) and industrial antifungal (clotrimazole). PDA medium Petri dishes without additions have been used as negative controls. All experiments ran in three replicates. Moreover, 3mm discs of fungal plugs were inoculated in the center of Petri dishes and incubated at 28±2°C for (8 – 10) days. The radial growth of the colony was measured. Percentage of inhibition of mycelial growth was calculated as follows:

$$\% \text{Radial growth Inhibition} = \frac{(R1- R2)}{R1} \times 100$$

Where: R1 is the average of radial growth in control plates; R2 is the average of radial growth in plates treated with algal extract or clotrimazole.

The spore suspension was collected from above culture. Through suspensions of spores in sterile DW then centrifuged. A hemocytometer was used to calculate the percentage of sporulation inhibition using the formula given by (11):

$$\text{Sporulation inhibition ratio} = \frac{(X-x)}{X} \times 100$$

Where: X is the average number of spores in control plates; x is the average of spores’ number in plates treated with nanoparticles.
Bioactivity test of alcoholic extract of *Spirulina platensis* against *Candida* spp

Antagonistic activity of algal extract was estimated in vitro by using well diffusion method according to (12). Four concentrations of algal extracts had been tested (100, 75, 50 and 25 mg/ml) and 100 μL of each concentration was added to each well after spreading of each *Candida* sp. isolate by sterile loop and incubated at 37°C for 24 hrs. Also, 10 μg/ml clotrimazole was tested as positive control. All tests were performed in triplicate. Antifungal activity was determined by measuring the clear zone around the wells in millimeters.

Gas Chromatography-Mass Spectrometry

GC-Mass analysis was performed according to (13) using (SHIMADZU—Japan) and post run software. The phytochemical compounds have been identified by comparison of their mass with NIST library search and authentic standards.

Results and Discussion

Identification of isolated fungi

Five molds isolates were isolated from spoiled food and identified these molds were *Aspergillus niger* (two isolates), *Aspergillus flavus*, *Mucor* sp., *Botrytis* sp. These molds were used to estimate antifungal activity of *Spirulina platensis* crude extract. Some food-born fungi are implicated in human diseases. These fungal infections are categorized into systemic, subcutaneous, superficial and opportunistic (14). Spores propagules from *Aspergillus* and *Mucor* pose dangerous public health problems. For instance, *A. niger* causes aspergillosis which is common amongst employees who inhale soil dust particles (14,15). Inhalation of spores of *Mucor* spp. and *Aspergillus* spp. produces allergic reactions in human. These diseases are difficult to treat. Furthermore, *A. flavus* have been reported as dangerous to humans through causing aspergillosis that’s associated high human mortality rates and producing serious toxins (16).

So that, there is a serious needs to improve naturally antagonistic products to eliminate food spoilage by these molds.

Bioactivity test of hot alcoholic extract of *Spirulina platensis* against molds

In current study, results of antagonistic activity of *Spirulina* methanolic extract revealed that algal extract displayed potential inhibition percentage against tested molds as compared to controls. Data from current study revealed that algal extract gave 89%, 78% and 95% inhibition in 100mg/ml against *Botrytis*, *Aspergillus flavus* and *Aspergillus niger* 2, respectively. In case of *Aspergillus niger* 1, there was 94% inhibition caused by algal extract in (75mg/ml), while 85% inhibition caused by fungicide (Figure 2). However, no growth inhibition was noticed against *Mucor* for both algal extract and clotrimazole.

![Figure 2](image_url) Growth inhibition percentages of different concentrations of *Spirulina platensis* methanolic extracts and clotrimazole against isolated plant-pathogenic molds.

As shown in Figure (3), spore germination was inhibited by *Spirulina* extracts. Spore germination of *Aspergillus flavus* was the most inhibited by algal extract (55%) at (100mg/ml), while *Botrytis* spore germination was less inhibited by algal extract (17.5%) at concentration (25mg/ml). Also, for *Botrytis* data, Figure (3) revealed that *Spirulina* extract (100mg/ml) inhibited spore germination for this mold by (44%). This percentage was higher than that caused by clotrimazole (28%).

![Figure 3](image_url) Spore germination inhibition percentages BY different concentrations of *Spirulina platensis* methanolic extracts and clotrimazole against isolated plant-pathogenic molds.
These findings agreed with other authors. The previous authors tested *Spirulina* methanolic extracts against several fungi as *Candida* spp., *Aspergillus niger*, *Aspergillus flavus* and *Fusarium* spp. Their results showed that extract exhibited strong antifungal activity against these fungi. In addition, reported that since the algal extracts are considered natural products which may have efficacy for fungal diseases management, a directed search is needed to understand culture conditions enhancing production of biologically active chemicals. During the present study, *Spirulina* have cultivated using BG-11 medium. The results of indicated that *Spirulina* exhibited the highest antimicrobial effects when being cultured in BG-11 medium against tested microbes. For *Mucor* spp., algal extracts did not exhibit antagonistic activity against it. On the other hand, reported that *Spirulina* extract exhibited stimulation of *Geotrichum* and *Cladosporium* growth. The author suggested that this growth stimulation probably due to *Spirulina* nutritional value properties.

**Bioactivity test of alcoholic extract of *Spirulina platensis* against *Candida* spp**

Algal extract displayed variable zones of inhibition against tested candida species compared to clotrimazole. In terms to *Candida fameta Spirulina*, extracts exhibited higher inhibition zone (18mm) against it than clotrimazole (15mm). Also, *Spirulina* methanolic extract gave (19 and 20mm) inhibition zones against *Candida lustrans* as compared with (18mm) caused by clotrimazole. No inhibition zone was detected by DMSO-containing well against all tested *Candida* spp. (Figures 4 and 5).

These tested species of *Candida* may cause serious infections such as progressively common nail infection (Onychomycosis) which is mainly caused by dermatophytes fungi. The disease is extremely difficult to treat. Since that Onychomycosis is not threatening human life, this type of nail infection is an essential public health concern due to its high incidence, low response to therapy as well as suggestive clinical, social and economic impacts.

**Gas Chromatography-Mass Spectrometry**

As a result of GC-Mass analysis, a total of 36 phytochemical constituents were detected for *Spirulina* alcoholic extract. These compounds possess various biological activities. Eight chemical compounds are authenticated to exhibits antifungal effect. These constituents were listed in Table (1).
Several screening studies have been achieved over the past years to record new antibiotic metabolites from microalgae particularly green and blue-green algae \(^{(28)}\). *Spirulina platensis* is known to produce a wide range of bioactive molecules, making them a rich natural source of various types of medications \(^{(1)}\). This alga showed many therapeutic properties, i.e. the ability to prevent cancer, decreasing blood cholesterol levels, decrease toxicity of kidneys and protection against the harmful effects of radiation \(^{(29)}\).

### Conclusions

The data obtained from this study indicated that *Spirulina platensis* alcoholic extracts act as a potential source of antifungal constituents against plant and human diseases caused by fungi. This activity depends on fungal species. GC-Mass data analysis clearly revealed the presence of many documented antifungal chemical constituents. So that, authors suggested that *Spirulina* could be used as an alternative drug to treat *Candida* spp. infections as well as added to food industries to enhance their nutritional value and simultaneously decrease the possibility of food spoilage by molds.

The Differentiation between Premenstrual Tension Syndrome and Dysmenorrhea in Young Age Group in Kerballa City: Cross-Sectional Study

Manal Nasih Ahmed Hamdan¹ Maysaloon Adnan Abdul Razzak²
¹Obstetric and Gynecology Department, College of Medicine, Kerbela University, Iraq

Abstract

Background: The repeated psychological and physical symptoms that occur during the luteal phase of menstrual cycle and relief with menstruation called Premenstrual syndrome.

The aim of study is to identify the symptoms of dysmenorrhea and premenstrual tension syndrome in young age group female and how can differentiate between these two symptoms.
