Material & Method: The study was across sectional which was conducted with 259 students randomly selected from Karbala secondary nursery school of girls, Their ages ranged from (range 15-29 years) with mean age 17.85±1.920 years. A questionnaire was used to collect the data, and was distributed randomly to all students in 3 classes in period from October 2017 to May 2018.

Results: 259 girl shared in this study with mean age 17.85±1.920 years (range between 15-29 years). Out of 259, 205 had PMS (79.15%) with different symptoms. Most patients with PMS, developed dysmenorrhea (77.5%) There was significant difference between them p value (<0.001).

Conclusion: high rate of young girl had premenstrual syndrome. The diagnosis of PMS is generally undervalued due to different features for PMS are used in different research. Though dysmenorrhea would distort the physicians about the actual giving symptoms from these women.

Keywords: rate of young; diagnosis; dysmenorrhea.

Introduction

The repeated psychological and physical symptoms that occur during the luteal phase of menstrual cycle and relief with menstruation called Premenstrual syndrome. (1) PMS is a public health problem among young girls. (2)

The main symptoms of PMS includes the symptoms connected to mood and physical conditions. (3) The symptoms are severe and very disabling in some women and affect with their career, social function and family relations. (4)

Dysmenorrhoea a painful cramps that start before the onset of menstruation and may continue for hours to days. Dysmenorrhea may be primary, with no recognizable cause, or secondary due to pelvic diseases. (5)

The PMS begins before the MC and stops shortly after menstruation. (6)

The prevalence rates of PMS between 16% to 93% In the Middle East. (7) PMS was the collaboration between hormonal, neural, environmental and psychosocial factors. (8,9) the underlying pathophysiology of PMS remains uncertain. (10)

The diagnosis of PMS mostly depends on the patients complains and symptoms, which over Two MC using a symptom record.

Corresponding author:
Manal Nasih Ahmed Hamdan

To achieve that diagnosis 3 key element must be present: (1) symptoms should happen during the luteal phase and resolution occur within 1 to 2 days after the start of menstruation; (2) symptoms should be recognized for several MC; (3) no medical or psychological disorders behind these symptoms. According to ACOG diagnostic criteria the diagnosis of PMS was done when at least one somatic symptom and one emotional symptom had been occurred.

Estrogen and progesterone effect on Serotonin receptors, and selective serotonin reuptake inhibitors (SSRIs) are proven to reduce PMS symptoms. The relationship between Prolactin levels, hypoglycemia or vitamin deficiencies and PMS had not been established.

Materials and Method

The study was across sectional which was conducted with 259 students randomly selected from Karbala secondary nursery school of girls. Their ages ranged from (range 15-29 years) with mean age 17.85±1.920 years. A questionnaire was used to collect the data, and was distributed randomly to all students in 3 classes in period from October 2017 to May 2018.

The study was approved by the Ethics Committee of the University of Karbala and informed consent was obtained from all participants.

The students were instructed to fill out the questionnaire over 2 menstrual cycle.

All of the questionnaire related to symptoms asking to them before include week before, week after and others. Also include the severity of symptoms which include mild, moderate, severe.

For severity of dysmenorrhea we select MMS criteria (Multi dimensional Scoring system criteria).

The MSS grading of pain is as follows:

Grade 0: not painful Menstruation and un affected daily activities.

Grade 1 (mild): not painful Menstruation and rarely affected daily activities.

Grade 2 (moderate): moderate painful Menstruation and affected daily activities. Grade 3 (severe): extreme painful Menstruation and inhibited daily activities.

Result

259 girls participate in this study with mean age 17.85±1.920 years (range between 15-29 years).

The mean BMI 22.40±5.285 kg/m² (range 17.1-29.3 kg/m²), Most of them 65.3% had normal BMI as shown in table (1).

Discussion

Out of 259, 205 had PMS (79.15%) with different symptoms, while the Royal College of Obstetrics and Gynecology published in her Green-top Guideline No. 48 (15) that the prevalence of PMS is 40% depending on Pearlstein et al study (16) this percentage is not the same in all the world and according to Sanctis, et al (17) study which is held in 2016 he found that the prevalence of dysmenorrhea varied greatly from different countries it was 94% (Oman), 59.8% (Bangladesh), 34% (Egypt) to 0.9% (Korea). This prevalence varied according to many factors which influence the disease occurrence and severity of the disease like the type of food, degree of knowledge.

Only 11.6% (30 patients) of these girls ask for doctor advice to control their symptoms and only 17% (44 patients) took drugs to relieve symptoms. This finding is compatible to that reported by Chan et al. (18).
Pain is the most frequent symptom experienced by those girls and from the total 259 participants, 191 (73.7%) describe pain and dysmenorrhea in the first 2 days of period.

During the period, Out of 259, 191 (73.7%) developed symptoms in first 2 days of period as shown in table (3), cramps and backache are the main symptoms developed during the 1st two days of the cycle.

We found in our study that females weight and BMI did not affect the symptoms of pain and dysmenorrhea. There was insignificant difference between groups (p value =0.2), this result differ from that obtained from Madhubala and Jyoti Kala in 2012 in Rajasthan – India which reveal a significant relationship between dysmenorrhea and BMI (19) . he advice to reduce weight because decrease adipose aromatase activity and increase estrogen metabolism and excretion which may modulate the pain during the cycle(20).

According to age, Most patients with dysmenorrhea with age group 16-20 years as shown in table(6). There was significant difference between them (p value <0.001). In comparison with Dawood (21) recognized dysmenorrhea in half of young women.

58% of studied group between the age group of 11 years to 22 years had dysmenorrhea and 22% and 17% had severe and moderate constituted respectively. This indicates that dysmenorrhea had negative effect on social environment, work and psychological status (22).

Most patients with PMS, developed dysmenorrhea (77.5%). There was significant difference between them p value (<0.001) as shown in (table 7). Orhan Derman et al., which propose that the diagnosis of PMS is usually underestimated and he advice primary care physicians to be alert of this health insult in order not to underestimate the disease and its consequences on patients life(23). Backache which usually perceived by the patient as pain correlated to menstrual cycle found to be mild in 17.4%, moderate in 24.3% and sever in 32.4% in the week before the cycle this figure changed to mild 30.1, moderate 26.3, sever 26.6, the severity of backache slightly decrease after menstruation which may be due to the relief of menstrual tension while mild pain increased which may be correlated to dysmenorrhea.

Conclusion

high rate of young girl had premenstrual syndrome. The diagnosis of PMS is generally undervalued due to different features for PMS are used in different research. Though dysmenorrhea would distort the physicians about the actual giving symptoms from these women.

Bacteriological and Pathological Study on Kidneys of Slaughtered Sheep in Fallujah City

Ahmed Sami Jarad¹, SMA AL-Kubaisi¹, Roua Jamal Abdulkhaliq², Mustafa Salah Hasan¹

¹University of Fallujah, College of Veterinary Medicine, Department of Pathology and Poultry diseases/Iraq, ²University of Fallujah, College of Veterinary Medicine, Department of Parasitology/Iraq.

Abstract

This study was carried out to determine the prevalence and type of renal lesions in sheep that were slaughtered at Fallujah abattoir. A total number of 100 clinically normal sheep of different sex and age randomly selected, renal samples were taken for , bacteriological, macro and micro study. One hundred swabs were taken from cortex and medulla were cultured on blood, nutrient, and MacConkey agars, then biochemical tests were done for identification of these bacteria. Bacteriological examination of kidney revealed that (65%) of samples show positive results in bacterial isolation including (15%) Bacillus, (10%) Escherichia coli, (11%) Klebsiella, (18%) Staphylococcus, (8%) streptococcus, (3%) Corynebacterium spp., (3%) pseudomonas aeruginosa, (1%) Salmonella and (1%) Proteus. Pathological study showed that 24 (24%) and 38 (38%) gave positive results in macroscopic and microscopic lesions respectively, the results of gross pathology were renal hemorrhage 8%, pale kidneys 4%, enlarged kidneys 4% white spotted kidneys 3%, renal fibrosis 2%, pigmented kidney 2% and renal cyst 1%. Meanwhile the microscopic lesion were nephritis 24%, nephrosis 5%, kidney fibrosis 3%, infarcted kidneys (2%), amyloidosis 2% hemosiderosis 2%. From the presented study, it was concluded that most kidneys are infected with many gram negative and gram positive bacteria and many kidney problems such as renal hemorrhage and interstitial nephritis are the most common renal lesions in sheep.

Keywords: Kidney, sheep, bacteria, pathological.

Introduction

Slaughter houses and butchery shops afford an excellent opportunity to detect animals health problems so it is a potential source of information for both economic and public health (1). Sheep as food animals act as worthy strength to the economy of the nation (2), besides economic losses, diseases of sheep might constitute an epidemiologic and zoonotic threat (3).

Kidneys are paired organs structures and with their physiological functions such as excretion of waste materials, regulation of acid-base balance, body fluid balance and hormonal effects, it plays a vital role in the life of animals for close inspection, the information resulting from abattoir data are a good source for evaluation and monitoring of renal disease in livestock (4, 5, 6).

Renal diseases are common and they are significant important problems and causes illness and death in many species of animals (3).

Renal diseases are not detected until they become generalized, leading to renal failure and death so collected evidence from abattoir studies remain a good source for evaluation and control of renal diseases in animals (7).

Many researches were done for bacterial isolation from the offal especially the kidneys in abattoir, from these a study of Abdul-Hadi (2010), who showed that the prevalence of microorganisms identified in kidneys...
and other offal were Staphylococci, Corynebacterium, Streptococci, Micrococcus, Salmonella, *Escherichia coli* and Yeast (8).

The goal of this study was a bacterial isolation and pathological examination of kidneys of sheep slaughtered in Fallujah City/ Iraq.

**Materials and Method**

The study was conducted on 100 kidney samples of sheep collected from local abattoir during 5 months (November 2018 to March 2019). Swabs were taken from every sample (cortex and medulla) and inoculated in a nutrient broth, then incubated aerobically at 37°C for 24-48h. The primary growth were sub-cultured on nutrient, blood agar, EMB and MacConkey agars. The pure cultures obtained were subjected to gram stain and biochemical tests including catalase, oxidase, TSI, indole, Citrate and carbohydrate fermentation for characterization and identification, these were done according to 9. Markey et al. (2013) (9).

For pathological study, gross pathological lesion of each sample was established and recorded as described by Gracey (1985) (10). The Sectioning and staining were done according to Luna (1968) (11).

**Results and Discussion**

Out of 100 samples swab taken from cortex and medulla of sheep kidneys, total bacterial isolated (65%), while negative samples were (35%). Table (1) shows the distribution of percentage of finding bacteria according to isolates culturing media.

The bacteriological examination of kidney were the following microorganisms isolated from kidney sheep include *Bacillus spp.* was (15%), *Klebsiella spp.* was (11%), *Escherichia coli* was (10%), *Staphylococcus aureus* was (9%), *Staphylococcus spp.* was (9%), *Streptococcus spp.* was (8%), *Corynebacterium spp.* was (3%), *pseudomonas aeruginosa* was (3%), *Salmonella spp.* was (2%), *Proteus spp.* was (1%) (Table 1).

It has been reported that the most common causative organisms in kidney disorders were *Klebsiella* and *Escherichia coli*, bacteria that is responsible of ascending infection causing kidney disease (12). Also other bacteria are involved such as *Proteus*, *Staphylococcus* and *Streptococcus*. The kidney infection can also occur through blood in the case of *Salmonella* and *Pseudomonas*. Kidney infection via the hematogenous route (suppurative embolic nephritis) is much less common but may result from bacteremia with such agents as *Salmonella* species (13, 14). These results were in compatible with our results.
The current study were also in agreement with results of Mohammed (2009) who found that *Escherichia coli, Staphylococcus aureas, streptococcus spp., Proteus spp. and Klebsilla spp.* were the most bacteria isolated (15). Also, Hirsbrunner *et al.* (1996) reported that Corynebacterium species is an obligate pathogen of the urinary mucosa and isolated this bacteria from cow suffered from unilateral pyelonephritis (16).

Out of one hundred animal’s kidneys randomly collected from clinically healthy sheep, thirty four kidneys showed affection with different pathological conditions include 24 macroscopic and microscopic lesions table (2) and also 12 kidneys with microscopic lesions, table (3).

The results of this study indicated that the highest incidence of occurrence of gross pathology were renal hemorrhage 8% , pale kidneys 4%, enlarged kidneys 4% white spotted kidneys 3%, renal fibrosis 2% , pigmented kidney 2% and renal cyst 1%.

The most common gross lesions were the hemorrhages in sheep kidneys with incidence of (8%) and it varied from pin point petechia to ecchymosis, renal hemorrhages may occur due to acute nephritis or with septicemia and bacterial intoxication (17,18).
The paleness of kidney also recorded, with prevalence (4%) paleness may be due to, amyloidosis, infarction and obstruction of blood vessel at the base towards the periphery, nephrosis (17, 19). While renal enlargement showed prevalence of (4%), it was occur as a result to accumulation of blood, edema, fluid, fat and urine in pelvis or tubules, moreover enlarged kidneys with pale grey color may be due to Interstitial nephritis, glomerulonephritis and tubular nephritis (20). This results agreed with the result stated by Ali and Aljeboori, (2017) (21).

White spotted kidney prevalence were (3%), It is possible that these results are due to several pathogens especially bacteria e.g. Leptospirosis spp., Escherichia coli septicemia, also other pathogens cause this lesion (20, 22, 23).

kidneys with severe fibrous tissue formation (renal fibrosis) prevalence were (2%), fibrous tissue formation appear grossly as enlarged, fibrosed, hard and cut with difficulty, similar changes were observed in sheep kidney by several investigators (2).

Otherwise the presence of cyst in the kidney was (1%), this might be due to congenital malformation or obstructive lesion or as fundamental change of unknown origin may occur in the tubular basement membrane and result in formation of sacculation or fusiform dilatation of tubules (hydronephrosis), (17, 19, 24). These results are in agreement with those obtained by Ali & Aljeboori, (2017)(21).

All these histopathological changes were also recorded by other researchers, Jibat et al. (2008) and Woube (2008) reported nephritis as the major pathological observation and it is the principal cause for kidney condemnation in sheep(25, 26). Also Ali and Aljeboori, (2017) who reported renal infarction was 28.57% followed by nephritis 26.53%, renal haemorrhages 20.40%, renal amyloidosis 14.28% and hydronephrosis 10.20%(21).

Our histopathological examination revealed that nephritis were the highest incidence.

The most common observed histological nephritis was Interstitial nephritis 9% which were characterized by lymphocyte and plasma cell infiltration in the interstitium with degenerative changes in the Proximal convoluted tubules (Fig.1). Interstitial nephritis occurred from bacterial and viral septicemias or following ingestion of certain irritants, poisons or toxins (4, 20, 27), also it were occurred due to side effects reactions to drugs, there were more than 100 different medications may trigger Interstitial nephritis like Antibiotics and NSAIDs (28).

Our Histopathological study showed prevalence of glomerulonephritis (6%) This finding corroborated with the findings of Sastry and Rao (2006) and Jones et al. (2006) (29, 30). Also Mahouz et al. (2015) recorded the incidence of glomerulonephritis were (6.2%)(3).

Histologically, glomerulonephritis characterized by increase cellularity of glomerular tuft in size and number of endothelial and mesangial cells. Glomerulonephritis mainly occur due to antigen- antibody reactions to the foreign proteins and as a sequel to bacterial and viral diseases (29, 31, 32). Caseous lymphadenitis may cause glomerulonephritis (33).

Tubular nephritis in microscopic examination coms with prevalence of (5%), kidney showed degeneration and necrosis of renal tubular epithelium with pyknotic nuclei (Fig.2). Sastry and Rao (2006) and Jones et al. (2006) also described degenerative and necrotic changes renal tubular epithelium(29, 30). All these changes accrued due to various irritant toxic substances which act directly to produce degenerative changes and necrosis of delicate epithelial cells lining the tubules (19).

Acute Tubular Necrosis (hydronephrosis) also recorded with prevalence of 5%, This finding is in agreement with the findings of Sastry and Rao (2006) and Jones et al. (2006) (29, 30), hydronephrosis in microscopic view showed scattered atrophic glomeruli remain in the thin and fibrous mass with presence of polymorphs and monomorphic cell infiltration (Fig. 3). The obstruction produced by the stasis of urine causing its back pressure leading to atrophy of renal parenchyma was the primary cause (20, 24).

On histopathological examination of infarcted kidneys with prevalence (2%), showed glomeruli and the tubules were discerned through the whole area taking a homogenous pink stain showing coagulative necrosis. Such lesions in kidney were also described by Sastry and Rao (2006) and Jones et al. (2006) (29, 30). All these histological alteration occurred due to the occlusion of main or branches of renal artery (20, 24, 27).

Our results showed prevalence of amyloidosis was (2%). Histologically, kidney showed presence of pinkish amyloid material in Bowann’s space of hypercellular
glomeruli. Similarly, Mensua et al. (2003) also described the renal amyloidosis in sheep and goats (34).

The histomorphologic results showed the presence of hemosiderin pigment with prevalence of (2%). The pigment deposited in the epithelial cells of renal tubules and glomeruli, resulted from degradation of resorbed hemoglobin (17, 24).

**Conclusion**

It was concluded that most kidneys are infected with many gram negative and gram positive bacteria and the pathological examination revealed that the most common observed lesions were renal hemorrhage at macroscopic exam and interstitial nephritis at microscopic exam.

Prevalence of Dental Anomalies (Mesiodens and Enamel Hypoplasia) Among Primary School Children in Badra/Iraq

Sanaa Rasheed Abd Al-Aaloosi¹, Maitha Sameer Kadhim², Basma Fathi Alanbari³
¹Department of Prosthodontics, Al-Rafidain University College, Iraq, ²Department of Preventive Dentistry, Al-Rafidain University College, Iraq, ³Department of Periodontology, Al-Rafidain University College, Iraq

Abstract

Background: Dental anomalies considered as one of the developmental defects during teeth formation caused by both genetic and environmental factors which responsible for notable deviation from normal size, color, number, contour and developmental degree. The aim of this study was to determine prevalence of defect in number (hyperdontia or mesiodens teeth) and structural defect (enamel hypoplasia, localized and generalized,) among primary school children.

Material and methods: A cross sectional study that comprises data from 403 boys and 411 girls; a primary school students aged from 5-12 years with a total of 814 student; was conducted in Badra/ Iraq.

Results: The study shows a prevalence rate of a mesiodens from 814 students was 0.49% and it represented more frequently in males more than females with a ratio of 3:1. While, the prevalence of enamel hypoplasia was estimated to be 0.86 % among the observed population, it observed more in girls than in boys, with the proportion being around 1: 1.333 male: female ratio.

Conclusion: the prevalence of dental anomalies was found to be more in males than in females and most of the cases found in age group between 8-10 years old. Routine checkup for these anomalies during primary and mixed dentation which can help for early diagnosis and detection of these disorders that will help minimizing future complications and give well prognosis.

Key words: prevalence, Dental anomalies, mesiodens, enamel hypoplasia.

Introduction

Dental anomalies are brought about by both hereditary and environmental factors; the deformities in specific genes are the most compelling etiological factors in the prenatal and postnatal periods which responsible for abnormality in tooth measurement, morphology, position, number and structure ¹, ², ³.

Supernumerary teeth (Fig.1) are extra teeth in comparison to normal condition, is one of the developmental problems in children ⁴. Mesiodens are one the most common type of these defects, it mostly present in the midline between the two central incisors. ⁵. It may occur as single, multiple, unilateral or bilateral. It happens in 82% of cases in the maxilla, specifically in the premaxillary district only a few numbers of studies have revealed the occurrence of mesiodens in the mandible ⁵, ⁶, ⁷. The incidence of mesiodens in primary dentition is uncommon in contrast to permanent dentition ⁸, with a two-time risk of appearance in the male when compared to the female ⁹. Morphologically; mesiodens may have various structures cone-like or peg structure, tuberculate and supplemental (tooth like) have been recorded, of which the cone form is the most popular ⁶, ¹⁰. Mesiodens may erupt into oral cavity spontaneously or they stay impacted and not erupted, which intervene with permanent teeth eruption and may be give rise to malocclusion. In general, mesiodens may cause different types of oral problems such as malocclusion, impaction of food, aesthetics problems and formation of cyst ¹¹, ¹².

Enamel defects are divided into four forms which include: pit, plane, linear, and enamel hypoplasia (Fig. 2). Enamel hypoplasia is one of structural abnormalities, caused by defect in formation of enamel matrix. Both primary and permanent teeth susceptible for this deformity. It is two types, either hypo-mineralization, which is a diminution in mineral substance of tooth enamel or hypo-calcification, which is a distortion of tooth enamel in which normal amount of enamel are formed but hypo-calcified, in both types, the enamel is weak than normal.

Studies have recommended that enamel hypoplasia, especially in anterior teeth, is related with poor esthetics; tooth sensitivity; malocclusion and susceptibility to dental caries.

Early identification and treatment of this anomalies is important to prevent malocclusion, delay eruption, function, esthetic and psychological problems.

The aim of this study was to determine the prevalence of defect in number, hyperdontia (mesiodens teeth) and structure defect enamel hypoplasia among primary school children in Badra- Wasit/Iraq. Data will be useful to evaluate the effectiveness of dental services and preventive programs among population in this small city.

Materials and Method

A cross sectional study that comprises data from 403 boys and 411 girls; a primary school students aged from (5-12) years with a total of 814 student; was conducted from (8) primary schools found in Badra city /Wasit governorate/Iraq. The total number of people population of that city was about 10000 people during time of examination. The examination was done by a well-trained dentist inspector and as a part of the governmental preventive program named “oral and dental care program” to control dental caries and enhance oral health among primary school children in whole of Iraqi cities after obtaining approval from the school administrations and the students’ families for the examination.

The presence of mesiodens and enamel defect were recognized by direct visual assessment using a torch to enhance visualization and disposable dental mirror and probe for each child, radiograph not taken at this study because the field of survey was a classroom of school. All obtained data were statistically analyzed using Microsoft excel sheet to determine the mean and percentage of occurrence.

Results

According to this study, only four patients were recorded with a mesiodens from 814 students as shown in table 1 and 2 with a prevalence to be 0.49% of Badra’s primary school children population (Fig. 3). It occurs more frequently in males more than females with a ratio of 3:1. All mesiodens seen was conical shape, single and concerning to position all mesiodens was palatal placed causing space between the central incisors.

The same tables show that the prevalence of enamel hypoplasia was estimated to be 0.86 % among the observed population (Fig. 3). It happened more much of the time in young female than in young male with approximately proportion being around 1: 1.333 male: female. Most of the anomalies found in age group (8-10) years as shown in table 1.

Fig. 3 Pie chart showing prevalence of mesiodens and Enamel Hypoplasia in Badra’s primary school children population

Discussion

The present study was conducted for searching dental anomalies “mesiodens and enamel hypoplasia” from 814 primary school students in Badra which is small oil city in the middle and far East of Iraq.

The type of mesiodens found in this study was a single conical tooth found in the midline of the maxilla, with prevalence 0.49% of total sample, this finding is agreed with other studies like: Najm and Younis 19 in Missan governorate\Iraq 0.36%, Al-Nori & Talabani 20 in Baghdad city\Iraq which was 0.4% and Abdullah 21 in Anbar governorate (Fallujah city)\Iraq 0.3%, and less than the prevalence of other studies that reported by Sirkis 22 in AlRadwaniya village in Baghdad which was 0.93% , Bashir 23 in 2006 in Khartoum 7.4% and Peedikayil et al 6 in India 0.71%.

According to this study the male to female ratio was 3:1 which is agreed with Peedikayil et al 6, Rajab and Hamdan 10 and Najim and Younis 19. The findings of the present study are disagreed with Abdullah 21 which found male to female ratio of about 1:1.67 and Najim et al 24 where they found a ratio of 1:3 male to female.

The differences in prevalence of mesiodens teeth in this population as compared to other studies may be due to variation in age of study group, sample size, location of study and nutritional status in addition to that in this study no radiograph was taken so impacted mesiodens were excluded.
The main causes of mesiodens still unclear; but it was suggested to have a genetic origin, higher rate of hyperdontia have been noticed between related families 25.  

Treatment choice includes normal extraction of extra tooth at early of mixed dentition so as to encourage spontaneous eruption and alignment of the incisors, which may be reduce the need for orthodontic treatment 5. Authors suggested that “postponed remove of mesiodens tooth about the ten of age when the central incisor apex almost forms may complicate the treatment plan in which intricate surgical and orthodontic treating may be needful “. Therefore early detection permit the most suitable treatment. 26.

For enamel hypoplasia, the result of the present study found a prevalence of (0.86 %) among the surveyed population which considered less than prevalence of enamel hypoplasia in studies done in different areas in Iraq as they found a percentage of (9.04%) in Fallujah 21; (6.61%) in Mosul 27; (5.8%) in Al-Radwaniya 22; (2.07%) in Sulimania 28 and 2.04% in Missan 19. The findings of this study were also less than other several studies done in different countries which was found (21%) according Enwonwu 29, (6%) of children examined had enamel hypoplasia as stated by Slayton et al 30 in Iowa, USA.

In this study enamel hypoplasia found more recurrent in girls than in boys, with male: female ratio 1: 1.333. There is a controversy in the enamel defect prevalence in relation to the gender, many studies show that there is no significant difference in the prevalence of enamel defect between males and females (Slayton et al 30, and Soviero Soviero et al 31). Other studies recorded greater prevalence among males than females (Malliville 32, Steinberg & Luckas 38), while another studies show the opposite as a higher prevalence of enamel defect found among females as compared to males (Al-Nori &Al-Talabani 20).

The presence of enamel defects may be attributed to local factor such as trauma or infection to the primary tooth which leads to development of defect in permanent successor 34, in addition to general factors such as systemic diseases, like “chickenpox, measles, hypocalcemia, congenital syphilis, and may be due to birth injury or premature birth” 35. On other hand the prevalence of enamel defects may be increases with increasing levels of fluoride ingested 36. Rugg-Gunn recorded that “boys of 14 years classed as malnourished, by height for age percentage had a higher prevalence of enamel defects than those classed as well-nourished” 37. Hover, the deficiency of vitamin D has been reported as a cause of enamel hypoplasia 38. Psychological stress during tooth development may be associated with defect of enamel and enamel hypoplasia 39.

Evaluation of the PCR Method for the Diagnosis of Cutaneous Leishmaniasis in AL Hawija District, Kirkuk, Iraq

Husain F. Hassan¹, Moath M. Salman¹, Burhan M. Mohammed¹
¹Department of Biology, College of Science, University of Kirkuk, Iraq

Abstract

Males (191) and females (229) with skin lesions were enrolled in this investigation with the highest incidence of the disease in both sexes being in the age group (0-5) years. The clinical features of the lesions were covered by firmly adherent crust and some were edematous. By using classical microscopic examinations, the amastigotes were detectable in 143 cases out of 200 lesion samples. On the other hand, the use of specific PCR system and DNA sequences provided evidence that Leishmania tropica is the only etiologic agent of cutaneous leishmaniasis in AL Hawija district, Kirkuk province, Iraq.

Key words: Cutaneous leishmaniasis; Polymerase chain reaction (PCR); Diagnosis, AL Hawija

Introduction

Cutaneous leishmaniasis (CL) is the most widespread form of anthropozoonotic disease caused by hemoflagellate of the genus Leishmania, which infect the vertebrate host after a bite by infected sandfly of the genus Lutzomyia in the New World and phlebotomus in the Old World (¹). Human cutaneous infections display a clinical spectrum ranging from primary lesions (oriental sore) that often selfheal to severe mutilating mucocutaneous lesions (Chilcero ulcer, espundia) to diffuse cutaneous leishmaniasis (²). In Iraq CL (Baghdad boil) is widely distributed in the central parts of the country with most cases being caused by L. tropica (urban, dry CL) or L. major (rural, wet CL) (³). During the past decade polymerase chain reaction (PCR) approaches have been developed as sensitive alternatives (⁴) to augment existing an early diagnostic methods based largely upon microscopic examination of Giemsa stained smears, culture of lesion biopsies, histopathology and immunological tests (⁵). The kinetoplast DNA (kDNA) in members of the genus Leishmania represent an ideal PCR target since contains 10000 small minicircular DNAs and have conserved and variable regions that allow differentiation between Leishmania species (⁶). In the present study our validation of kDNA amplification for the diagnosis of CL as part of an epidemiological surveys confirmed the high current rate of infection in an area of endemicity in AL Hawija district, Kirkuk province, Iraq.

Method

Dermal scraping specimens were collected by slitting the border of a skin lesion from 420 patients with clinically suspected CL, who had admitted to AL Hawija hospital from August 2018 to July 2019. The specimens were divided into three samples. The first sample was used for microscopic smear examination. The tissue aspirate was smeared on to glass slide, fixed with methanol and stained with Giemsa. The second sample was used for in vitro culture which was performed by inoculation of tissue fragment in Nove-MacNeal – Nicole (NNN medium) and incubated at 26 C. After 5 days, the samples were transferred to fresh medium and observed for at least 6 weeks before they were diagnosed as negative culture. The third sample was processed for PCR.

Extraction of DNA. DNA as purified using the Genomic Prep Cells and Tissue DNA isolation kit (Bioneer, Korea) according to the protocol of the manufacturer. Frozen tissue sample (20 mg) were lysed by incubate 30 μl of lysis buffer (10 mM Tris –HCl, pH 8.0, 10 mM EDTA, 1 mg/ml of protease K) at 65 C for 2 hours with subsequent heating at 100 C for 30 minutes to denature the enzyme. Cell debris and proteins were removed by centrifugation (10000 Xg at 4 C for 10 minutes) and the supernatant fraction containing the DNA used for PCR. Five microliters of the DNA solution was added to the PCR mixture.
Polymerase chain reaction amplification. The PCR amplification was performed using the oligo primers forward T2b(5'-CGGCTTCGCACCATGCGGTG-3') and reverse B4 (5'-ACATCCCTGCCCACATACGC-3') which were previously reported to specifically amplify the entire 750-bp minicircle kDNA of Leishmania species. The PCR reaction mixture (25µl) containing 10 mM Tris – HCl, 50 mM KCl, 0.1 mg of gelatin per ml, 1.5 mM Mg CL2, 0.2 mM each deoxynucleoside triphosphate, 25 pmol of each appropriate primer and 2.5 U of Taq DNA Polymearse (Promega, USA) was amplified using Perkin-Elmer thermocycler following thermal profile which composed 32 cycles (preincubation at 94 C for 5 minutes, denaturation at 94 C for 1 minute, annealing at 60 C for 1 minute, extension at 72 C for 1 minute and extra incubation at 72 C for 10 minutes). Aliquots (10µl) of amplified PCR mixture were subjected to electrophoresis on 1% agarose gel using X TBE running buffer (0.045 M Tris borate, 1 mM EDTA) and PCR product bands visualized by staining with ethidium bromide (0.4 µg/ml). Positive control DNA was purified from promastigote of L.tropica and from human monocyte and amplified by PCR using the same protocol as described above.

Sequence analysis. PCR was purified using GFX PCR DNA product and Gel band purification Kit (Amersham, UK) following the manufactures instruction. The purified PCR product was sequenced by Macrogen Corporation Korea. Multiple sequence alignment was done using Clustal W method (Bioedit DNA analysis software).

Result

AL-Hawija district, approximately 70 km from the center of Kirkuk province, was chosen as a site for field studies because it is an area of alluvial plains with scattered irrigation channels moderately cultivated. People of this area mostly poor farmers living in mud houses in small scattered villages and are in close association with domestic animals. Four hundred twenty patients with skin lesions were enrolled in the study; 191 were males and 229 females. The age distribution of skin lesions (Table 1) showed the highest peak incidence of the disease in both sexes was in the age group (1-5) years. The median duration of the lesions was 6 months with the highest frequency being presented in September (19%) followed by October (15.4%), November (13%) and December (11.9%). Seventy nine patients (18.79%) presented with multiple lesions (4-7 lesions). It is interesting to note that one patient was with 19 lesions. The lesions were located primarily on the lower extremity (8.8%), face (10.7%) or upper extremity (11.9%). Of the 200 lesion samples 143 lesions were positive by Giemsa – stained smear (figure 1), Yielding a sensitivity of (7% 5%) and only 12 were culture positive with NNN medium. Total DNA was extracted from 24 lesion samples and assessed by electrophoresis on the agarose gel. The extracted DNA was used as templates in PCR reaction. Molecular characterisation of the isolates revealed amplification of the characteristic 600 bp minicircle band (figure 2). The PCR of human monocyte DNA samples from healthy control with no previous exposure to CL-endemic area showed amplification of a band of a size (340-bp) which confirm the fact that the amplicon of 600-bp of lesion isolate being not derived from host DNA (figure 3). The sequencing of the PCR product of 600-bp for each sample after correction and filling the missed nucleotide depending on reverse sequence using chromat Pro, the multiple sequence alignment was done by Clustal W method using Bioedit (DNA analysis program) and compared with previously reported references of Leishmania gentypes was due to L. major starins.

Discussions

Rural and urban forms of cutaneous leishmaniasis are known to be prevalent in Iraq probably since 3000 - 2000 BC (6). During the last ten years there have been an outbreak of CL in Alhawija district, Kirkuk province of Iraq. As a result of the second gulf war, the increased human mobility and long distance travel may contribute to the spread of CL in areas where the disease was not endemic. This could possibly make diagnosis and species critical for the importance of establishing control strategies. Prevalence of infected female phlebotomine sand flies in urban and suburban areas of Iraq where USA military personal have been stationed could possibly confirm emergence of new Leishmania foci and the coexistence of multiple Leishmania species in the same geographical local (7). In addition, accurate diagnosis of CL is often difficult because some of the dermal disease have some resemblance to those found in patients with CL. Direct microscopic smear examination of tissue sample for the presence of Leishmania is cheap and simple but rarely successful and require great expertise. Axenic culture of parasites from biopsy specimens or lesion aspirates is sensitive but it is time consuming and is subject to contamination. Therefore, there has been a great need for a more reliable laboratory test for diagnosis of CL in this area. The present study reports the application of PCR as a tool for the identification of Leishmania in lesion aspirates attained from patients suspected to have CL. In the present study we use PCR primers based on sequences present in World Health Organisation reference strain (8). Although, they also anneal to DNA from strains from ALQadessia district, Iraq (9), this had not formally demonstrated in isolate from regions of endemicity in Kirkuk. Thus typing of Leishmania isolated from patients with CL by PCR yielded results in agreement with thus obtained by typing cultured Leishmania tropica (10). The evidence available at present incriminates L. tropica as the only causative agent of CL in Alhawija, Kirkuk district of Iraq and this is in agreement with results reported from neighbouring Iran and Turkey. (11). Thus PCR is more sensitive than conventional methods of diagnosis and is likely to be valuable tools not only for species identification but also for investigation of relationships between causative agents and the clinical manifestation and epidemiology of the disease.

Conclusions

This study showed that PCR technique is the sensitive methods in the diagnosis of leishmaniasis. And from DNA sequencing have found that the main causes of cutaneous leishmaniasis in AL Hawija district is Leishmania tropica.

Evaluation of Some Blood Parameters in Anemic Patients in Relation to Periodontal Condition

Noor Sabah Irhayyim
Department of Periodontology, College of Dentistry, University of Tikrit, Iraq

Abstract

Background: Periodontal diseases are the inflammatory process result from microbial-host interaction in the tissues surrounding the teeth. Gingivitis and periodontitis are the most common type of periodontal diseases. Anemia of the chronic disease (ACD) is common health problem occur in patients with acute or chronic activation of immune system and production of inflammatory cytokines, so it is resemble to periodontal diseases from this aspect.

Aims of the study: To compare the clinical periodontal parameters (plaque index (PLI), gingival index (GI), bleeding on probing (BOP), probing pocket depth (PPD) and clinical attachment level (CAL)) and the levels of hemoglobin (Hb), mean cell volume (MCV), and Mean corpuscular hemoglobin (MCH) in blood, and correlate them in patients with gingivitis, chronic periodontitis (CP) and clinically healthy periodontium.

Materials and method: 90 subjects included in the study with age range from 30-50 years old. There were divided into three groups: 30 patients with chronic periodontitis, 30 patients with gingivitis, and 30 subjects with clinically healthy periodontium. Blood samples were collected from the subjects for automated blood analyzer to determine the levels of Hb, MCV, and MCH, after clinical periodontal examination was done for (PLI, GI, BOP, PPD, CAL).

Results: statistically highly significant differences among the groups (Gingivitis and chronic periodontitis) in PLI, GI and BOP score. The highest mean value of Hb shown in control group (15.33) while the highest mean value of MCV demonstrated in gingivitis group (87.44) and the highest mean value of MCH demonstrated in control group (32.09). The correlation of Hb, MCV, and MCH with clinical periodontal parameter shown almost weak negative correlation.

Conclusion: the periodontal diseases like other inflammatory diseases can lead to development of anemia type (anemia of chronic disease) and the severity of disease increase with increase the severity of periodontal diseases.

Key Words: periodontal diseases, Anemia of the chronic disease, Hb, MCV, MCH.

Introduction

Periodontal diseases (PD) are group of inflammatory diseases result from the interaction of periodontal pathogenic bacteria with host, which cause damaging in the tooth supporting tissues[1]. Dental plaque is the main etiological factor of the periodontal diseases, which is a diverse community of microorganisms found on the tooth surfaces as a biofilm[2]. Gingivitis is the reversible inflammatory and more stable type of periodontal disease, characterized by the inflammation of soft tissues surrounding the teeth without formation of pocket and loss of attachment[3]. Periodontitis is a chronic irreversible inflammation caused by specific periodontic pathogenic bacteria mainly anaerobic that accumulate subgingivally in the periodontal pocket. These bacteria and their product (protease, hyaluronidase collagenase, and other endotoxin) cause destruction of alveolar bone and periodontal ligament (PDL)[4,5], that result periodontal pocket or gingival recession or both and may be lead to loss of tooth[6]. Anemia of the chronic disease (ACD) is the second most prevalent type of anemia after iron deficiency anemia, as a result of neoplastic...
conditions, or inflammatory or chronic infection where the bone marrow do not affected and there is a sufficient amount of vitamins and iron that stored[7]. This type of anemia characterized by increase production of pro-inflammatory cytokines like: interferon, tumor necrosis factor(TNF-α) and interleukin 1(IL-1)[8]. The microorganisms or their toxin of the periodontal diseases penetrate the protective barrier of sulcular and junctional epithelium into blood stream cause direct systemic effect (dysfunction or injury of endothelial) or indirectly by their lipopolysaccharides(LPS) which provoke the immune response and produce inflammatory cytokines, so the periodontal diseases resemble other chronic infection can be lead to systemic disease like anemia. This elevation in the production of pro-inflammatory cytokines, lead to change in the iron homeostasis, erythroid progenitor proliferation, production of erythropoietin and the life span of erythrocytes, all of these can be lead to development of ACD[9].

The aim of the present study, evaluate and compare the relationship between the different types of periodontal diseases and anemia by estimation the levels of some blood parameters look like hemoglobin(HGB), mean cell volume(MCV),and mean corpuscular hemoglobin(MCH), to find if the periodontal diseases with different kind of severities can lead to ACD.

Materials and Method

This study is a case-control study, included 90 samples(males and females), age range from(30-50) years old. They were selected from the department of periodontology at Teaching Hospital of College of Dentistry, University of Tikrit and from laboratories of Salah Al-Din Hospital in Tikrit for 3 months from January to March. The inclusion criteria included in the study were: all teeth included in the measurement except third molar teeth, there were at least twenty teeth exist for each patients, should be systemically healthy subjects, the patients with chronic periodontitis must had a probing pocket depth at least ≥4mm for four sits and clinical attachment loss at least 1-2mm, while the patients with gingivitis should had signs and symptoms of gingival inflammation(redness, swelling, bleeding on the probing, other) without loss of the alveolar bone, all of these designed according to international classification of periodontal diseases[10,11]. The subjects that classified, as a healthy periodontium should had no signs and symptoms of gingival inflammation and no pocket formation or clinical attachment loss. The exclusion criteria of the study were: smokers, alcoholism, patients subjected to periodontal treatment and/or received course of antimicrobial, anti-inflammatory, or other medication for treatment of anemia in the three month prior to the study and had other systemic diseases. Subject’s agreement documented by signing on specially designed informed consent. Patients shared in the study had been divided into three groups: group of 30 patients had chronic periodontitis, group of 30 patients had gingivitis and control group consist of 30 subjects with clinically healthy periodontium. Full information for all participants were taken through specially designed case sheet. 5ml venous blood was collected by using 20-gauge needle with 5 ml syringe under aseptic field from ante - cubital fossa for each subject after the measurement of clinical periodontal parameters by using graduated Michigan O periodontal probe that included (plaque index (PLI)[12], Gingival index (GI)[12], bleeding on the probing (BOP)[3], probing pocket depth(PPD)[3], clinical attachment loss[13]), for four sits (mesial, distal, lingual/palatal, buccal/labial ). The collected blood put in the Ethylene diamine tetra acet acid tube then blood analysis were done for Hb, MCV, MCH. The statistical analysis used in the study were mean, mean percentage, standard deviation(SD), Kruskal-Walis H test, and Simple person’s correlation coefficients (r). In the statistical tests, the levels of significant(S) when 0.05≥P≥0.01, non-significant (NS) when P>0.05, while highly significant (HS) when P≤ 0.01. We certify that this study involving human subjects is in accordance with the Helsinki declaration of 1975 as revised in 2013 and that it has been approved by the relevant institutional Ethical Committee[14].

Results

The results in table(1) shows that the high mean value of age parameter appear in CP group(42) and the lowest mean value in control group(31).Table (2) revealed that there are statistically highly significant differences among the groups(Gingivitis and chronic periodontitis) in PLI, GI and BOP score1, also table(3) shown statistically highly significant differences among the groups in Hb, MCV, and MCH. The highest mean value of Hb shown in control group (15.33) and the lowest mean value shown in CP group(10.45). The highest mean value of MCV demonstrated in gingivitis group(87.44) and the lowest mean value demonstrated in CP group(81.43).The highest mean value of MCH shown in control group(32.09) and the lowest mean value demonstrated in control group(22.54) in table(3).
Table (4) revealed, almost non-significant weak correlation of Hb with PLI, GI, BOP, PPD as well as CAL, however the control group in GI show weak positive correlation with Hb. Almost non-significant weak correlation of MCV in all groups with PLI, GI, BOP, PPD and CAL, demonstrated in table (5). Weak positive correlation of MCH with PLI shown in chronic periodontitis group while the other index revealed weak negative correlation with MCH in table (6).

Discussion

The results showed that the lowest mean value of age parameter appear in the control group while the highest mean value demonstrate in chronic periodontitis group and this may be due to that the incidence of CP is usually associated with old age [15]. The highest mean value of PLI showed in CP group compared to that in other study group with highly significant differences among the study and control group. Dental plaque has important role in the pathogenesis of periodontal diseases, because it is considered the primary cause of gingivitis and with subsequent accumulation of biofilm in inadequate oral hygiene and absence of mechanical plaque control lead to progression of gingivitis to periodontitis [16].

The highest mean value of GI and BOP score1 revealed in CP group with highly significant difference among the study and control group, and this due to the accumulation of plaque result in alteration of gingival index and beginning of disease process with all signs and symptoms of gingivitis and subsequent development of CP [17]. The lowest mean value of HB, MCV and MCH showed in CP group with highly significant difference among the study group and control group, this due to that the periodontitis caused by specific types of microorganisms mainly gram negative, anaerobic bacteria with high percentage of spirochetes accumulate in gingival sulcus in the periodontal pocket [18], the actual active sits of connective tissue loss showing have a high percentage of P.gingivalis(P.gingivalis), Aggrigatibacter actinomctecomitance(A.a), Campylobacter rectus(C. rectus), and etc., when it is compared with non-active sits that do not have loss of attachment[19].

These Mo. liberate toxic substances such as lipopolysaccharides, protease, collagenase and other that motivate the innate and adaptive immune system of the host[20]. Antigen presenting cells such as dendritic cells, B cells, and macrophage begin to interact with T cells that lead to differentiation of plasma cells and produce of chronic lesion with beginning the signs and symptoms of inflammation [21]. All these process lead to release of inflammatory cytokines in blood such as TNF-α, IL-6, IL-8 and other from various cells like monocytes, macrophage, fibroblast. The liberation of these cytokines (interleukins’ and TNF-α) lead to bone and attachment loss and construes the pathogenesis of periodontal diseases [22,2].

Previously chronic inflammation or infection may be interpret the underlying cause of ACD, and increase some of inflammatory cytokines such as TNF-α, IL-1 are observed in ACD. These cytokines lead to decrease the life span of RBC and impair erythroids development and reduce erythropoietin response to anemia and abnormality of iron store, in addition the increase production of inflammatory cytokines inhibit the maturation and differentiation of erythrocytes[23,24].

Because of the same cytokines observed in ACD and periodontitis and the treatment of periodontal diseases show the improvement of anemia, can proposed the relation between these two diseases, and this agree with Yamamoto et al. [25], and Naik et al. [26], this determine the association between blood parameters and periodontitis which the aim of the study. While the almost weak non-significant correlation showing in the study may be due to the small human sample size of data.

So, we can concluded that the periodontal diseases like other inflammatory diseases can lead to development of anemia type(anemia of chronic disease) and the severity of disease increase with increase the severity of periodontal diseases because decrease erythroid proliferation in bone marrow and life cycle of red blood cells decrease because the cytokines prevent release the erythropoietin from kidney[27].

Effect of Algal Extracts on the Growth of Tow Bacterial Types Isolated from Pollutants Discharge

Thaer Mohammed Ibrahim¹, Raad Abdul Hadi Nayyef², Buthaina Abdul- Aziz Hassan Al-Magdamy¹

¹College of Education for Pure Sciences- Ibn- Al-haitham, University of Baghdad, Iraq,
²Ministry of Education, Open Educational College, Iraq

Abstract

Effect of Chlorococcum humicola alcoholic algae extract was studied on the growth of, Pseudomonas aeruginosa, and Klebsiella pneumonia, which were isolated from contaminated water. The extract of Ch. humicola showed a high efficiency in reducing the numbers of the two types of bacteria. The removal rate of K. pneumonia were 0.0, 48.4 and 57.0, The removal rate of P. aeruginosa were 63.1, 79.8 and 82.9% after 24, 48, 72 h respectively. The results improved that the K. pneumonia is more sensitive than P. aeruginosa for algae extract concentrations used in study, and the best effective time is 24h for the two bacterial species. The aim of the study was to eliminate microorganisms using the Alcoholic algae extract. Especially P. aeruginosa and K. pneumonia of bacterial isolates that cause many diseases for human and animals.

Keywords: Alcoholic algae extract, toxicity, polluted water

Introduction

Klebsilla pneumonia infections may occur at almost all body sites, but the highest incidence was found in the urinary and respiratory tracts. The main population at risk are neonates and patients predisposed by prior surgery, diabetes, malignancy, etc. [1]. Also it is found in mammalian mucosal surfaces and opportunistic pathogens and the principal pathogenic reservoirs of infection are the gastrointestinal tract of patients and the hands of hospital personnel organisms can spread rapidly. Often leading to nosocomial [2]. As well as K. pneumonia occurs in the lungs. Where they cause destructive changes inflammation, hemorrhage and sometimes producing a thick, bloody, mucoid sputum described as currant jelly sputum [3].

Pseudomonas aeurginosa causes disease in healthy persons. Most infection occurs in compromised hosts or only when they reach tissue outside the intestinal tract, particularly the urinary tract, biliary tract, lung, eye, kidney, ear intestine and damaged or burned skin and causing inflammations at these sites [4].

P.aeurginosa infection occurs in three stages the bacterial attachment and colonization followed by local invasion and dissemination and systemic disease, And two mechanisms contribute to the complex pathogenesis of these respiratory infections with P.aeurginosa: first the bacterial adhesion to the respiratory epithelial cells initiates infections. And secondly inhibition of phagocytosis by macrophages and poly morph leucocytes far ours progression. And during both mechanisms. Bacterial cells become mucoid by secreting an exopoly-saccharide containing alginate [5].

From another view the water environment has a great importance in the world through covering an area of about 75% of the world. Therefore, attention to water resources is necessary for the purpose of ensuring the requirements of human use in all fields.

Water Sources, especially surface water, is exposed to the dangers of pollution, which leads, directly or indirectly, to the ecosystem. Water pollution means any change in the physical, chemical and biological characteristics of water, as well as the pathogens resulting from the effects of microorganisms such as bacteria, fungi and viruses [6].

Corresponding Author:
Buthaina Abdul- Aziz Hassan Al-Magdamy

The rivers are the most water bodies susceptible to pollution because of the discharges resulting from the various human activities that make them unusable only after the adoption of additional treatment and liquidation units of high and cost technology.

In addition to the use of chemical sterilizers, the algae are microorganisms that are highly efficient in inhibiting the growth and effectiveness of various microorganisms [7].

It also contributes to the process of self-purification in the water bodies through the photosynthesis process, where they release the dissolved oxygen gas, which causes the gas balance between oxygen and carbon dioxide between the atmosphere and water, that have a biological, medical and economic importance and are necessary to sustain life [8].

As well as algae have recently received a lot of attention as a new biomass source for the production of a new energy [9]. Some of the main characteristics which set algae apart from other biomass sources are that algae can have a high oil or starch content do not require agricultural land. Fresh water is not essential and nutrients can be supplied by waste water and CO₂ by combustion gas [10]. The first distinction that needs to be made is between macroalgae or microalgae [11].

Therefore, the aim of the study was to eliminate some microorganisms, Pseudomonas aeruginosa, and Klebsiella pneumoniae using the Alcoholic algae extract.

**Material and Method**

1. Isolation and diagnosis of bacterial

The bacteria, P. aeruginosa, and K. pneumoniae bacteria were isolated from the drainage water of the Rustmiya Sewage Treatment Plant in Baghdad using Prescott method [12]. They were grown on the Nutrient agar medium, then 1ml were taken from pure isolation into glass vials containing broth nutrient medium and incubated at 37°C.

2. Preparation of dried algae

Chlorococcum humicola was isolated from small stream near the University of Baghdad - Jadriya, from different places where several samples were collected, according to [13].

Then the algae was laboratory diagnosed using a microscope based on the diagnosis method [14].

The algae was cultured and purified in 10ml test tube with Chu13 medium by using dilution method and streaking plating under constant laboratory conditions (temperature of 25±2 °C, 16:8h light:dark, 3000 LUX) [15]. The axenic algal culture was incubated in the incubation room for 18 days, the harvesting where by Centrifuge with of 3000 rpm/minute speed for 15 minute. Then the sediment dried in 45°C for 48h and saved in dark until used.

3. Extraction of active substances from algae

1.5 g of the dried algae was dissolved in 250 ml of Chloroform and then placed in shaking incubator at 25 °C with 70 rpm/minute for 15 min and then dried at 40 °C [16].

4. Preparation of concentrations of algae extract

(1) 1ml of bacterial suspension was taken for each isolation of bacterial isolates and placed in a sterile glass flask containing different concentrations of the extract: (0.07, 0.15, 0.31, 0.62, and 1.25) (mg / l) prepared from the primary concentration by the dilutions and then the volume was completed to 100 ml of sterile sewage water with (2) repeated of each bacterial isolation, In addition to the control treatment which was free of the algae extract and incubated at 37°C for 72 hours [17].

The number of bacterial cells was calculated in (1) ml of bacterial suspension using the method of Hemocytometer (Chamber counting) where the calculation was daily for 72 hours [18].

**Results and Discussion**

The results showed that the algae extract showed a clear effect on the microorganisms used, where the numbers of were decreased that treated with different concentrations of C. humicola extract (1.25, 0.62, 0.31, 0.15, and 0.07) mg / l within 72 hours.

The algae extract showed no effect on the number K. pneumoniae in 24 hours. On the 48 hours, the number of bacteria decreased from 470 cells/ml to 422, 400, 386, 330, and 290, cells/ml. On the 72 hours, the number of bacteria was 350, 300, 290, 276, and 200 cells/ml. As shown in Fig.(1).
The effect of algae extract on *P. aeruginosa* bacteria, using different concentrations (0.07, 0.15, 0.31, 0.62, 1.25) mg / l, was the decrease in the number of cells on the first day of the total 410 to (390, 280, 220, 176, 155) cell / ml. The decrease in the number of bacteria on the 48 hours was (350, 264, 230, 100, 85) Cell / ml. On the 72 hours, the numbers were as follows: (300, 210, 120, 83, and 72) cell / ml. As shown in, Fig.(2)

The study results showed the effect of algae extract towards bacteria *P. aeruginosa*, while the *K. pneumoniae* showed resistance to the effect of the extract was low.

As compared to other types of bacteria. This is because they contain complex layers in their walls, making them more difficult to penetrate into the cell walls [19].

The studies also indicated that the algae extract had a clear inhibitory effect on *P. aeruginosa* and, and the reason is due to their contain of the peptides rings and alkaloids, in addition to polysaccharides [20].

The study agrees with [2], who pointed to the ability of the algae extract to reduce the bacterial numbers, where these fatty acids interact with membrane proteins causing deformation in the structure and effectiveness of the membrane.

Also the study agrees with [21], which indicated the ability of *Cladophora phare* extract to reduce the number of *E. coli* bacteria, the reason is due to the secretion of many substances such as Ferpenoids, fatty acids. amino acids, which have inhibitory effect on bacteria [22]. And they produce a wide variety of chemically active metabolites in their surroundings, potentially as an aid to protect themselves against the other selling organisms [24]. These active metabolites also known as biogenic compounds, such as halogenated compounds, alcohols, aldehydes, terpenoids, are produced by several species of marine macro and macroalgae and have antibacterial, anti-algal, and anti-fungal properties which are effective in the prevention of bio fouling and have other uses in therapeutics [24].

The algae extract has an inhibitory effect against the positive and negative bacteria (Gram stain) by inhibiting the Enzyme of phosphatase protein, which plays an important role in the process of inserting substances into the body of the organism [25].

The active substances found in the algae extract have an effect on the positive bacteria of (Gram stain) rather than on the negative bacteria [26].

As indicated by [27]. The reason is that the negative bacteria are less sensitive than the active compounds found in positive bacteria of (Gram stain) due to their cell wall structure, which consists of many layers.

The results of the study showed that the concentration of 1.25 mg / l was the most concentrated effect on bacterial cell count, where *Klebsiella pneumoniae* was the most resistant to the effect of the extract, and the effect of the algae extract was more effective on *E. coli*. [28]

Prevalence of Aerobic Bacterial Vaginosis and Trichomonas Vaginalis Associated with Socioeconomic Factors among Women in Misan Governorate

Zahrah Adnan¹, Huda Dhaher², Mohammed F. Marjani³
¹Iraq/College of Sciences/Misan University, ²Iraq/College of Medicine/Al-Nahrain university, ³Iraq/College of Sciences/Mustansiriya University

Abstract

Vagina is an ecosystem balance, human vagina is dominated by lactobacillus spp which creates a vaginal acidity environment(3.8-4.5) to protect vagina from Vaginitis pathogen. Vaginitis is an inflammation of vagina caused by bacterial vaginosis and Trichomonas vaginalis. The aims of this study were investigated aerobic bacterial vaginosis, lactobacillus spp, and T.V in women with vaginitis. Study the clinical feature and demographic factors with vaginitis. 345 samples were collected from women with vaginitis. Study a demographic variables such as age, education level, socioeconomic state, residence, parity, in pregnant and non-pregnant women.

Keywords: Aerobic bacterial vaginosis, Vaginosis, Trichomonas vaginalis, Socio demographic, Lactobacillus spp

Introduction

Aerobic bacterial vaginosis is abnormal vaginal bacteria derived from bacterial vaginosis types. It is caused by replacement lactobacillus spp with Escherichia coli, Staphylococcus aureus, Streptococcus agalactiae. Aerobic bacterial vaginosis caused to increase in Vaginal pH>4.5 and inflammation with WBCs infiltration. Bacterial vaginosis causes abnormal vaginal secretions. Trichomonas vaginalis is an extracellular single cell flagellated parasite of different in shape, with active motility.

Materials and Method

Patients: Three hundred and forty five sample were obtain from females with different age (15-45) year attending to gynecology Out-patients department in Al-Sadder hospital( Missan city).

Measurement of ph: For ph measurement, vaginal secretion be occurred by placed on ph paper. The ph paper color after that compared to the pH value on a standard chart.

Whiff test: Examination a whiff test is positive when a (10% )KOH is added to discharge and release a bad odor as a positive indicator.

Microscopic examination : Which include a wet amount technique for vaginal discharge to detected Trichomonas vaginalis, bacteria, clue cells, and WBCs. Clue cells is a large epithelial vaginal cells adhesion coated with bacilli bacteria. Gram stain used for examining aerobic bacterial vaginosis.

Cultivation of vaginal specimens: All vaginal swabs were cultured immediately on Blood, MacConKey Chocolate agar for bacterial isolates and MRS agar as a selective media for lactobacillus spp. about three vaginal swabs from each infected woman, first swabs for cultivation laboratory media and second swabs for cultivation on MRS agar with or without (3-5)% CO₂ for lactobacillus spp grow. Third swabs for wet amount technique and gram stain.

Biochemical tests: Some biochemical test was used for diagnosing bacterial vaginosis such as Vitex-2, Catalase test and Oxidase test.

Identification of Trichomonas vaginalis: To identify of Trichomonas vaginalis in swabs by taking vaginal discharge from women with vaginosis. Then take one drop from PBS and put on glass slide and put a cover slide on it this technique called wet a mounting technique and giemsa stain to determinate a flagellated
parasite positive results was a motility of parasite \(^{(10)}\).

**Results**

**Socio Demographic characteristics of population:**

In table (1) high percentage was age groups F range from (40-45) year were 68(80%). The second variable was education level and related with vaginal infection is an important part due to education may help to decreased a diseases. The socio-economic level was taken the high percentage was in women with a middle social level of 114(76%), in this study rural was recorded a high percentage 157(79.3%). As for the parity of the study, the high ratio with multiparity 158 (77.1%). The pregnancy state effect on women with vaginosis but highest ratio was documented in non-pregnant women 277 (75.9%).

* (In present trichomonas vaginalis, aerobic bacterial and lactobacillus spp)

Effect of ph measurement with vaginosis pathogen:

Change in ph help to encourages the growth of pathogenic microorganisms which prefer alkaline ph. This study showed the effect of ph with lactobacillus spp when ph was acidity. In Trichomonas vaginalis, the highest percentage was observed 62(78.5%). The high percentage of aerobic bacterial when ph was 156(60%) as in table (3) and figure (1) show amoeboid shape of Trichomonas vaginalis and lactobacillus spp.

Discussion

Socio-Demographic characteristics of population

Women in age groups F (40-45)years as a higher rate 68(80%). These results was disagree with Bhalla and Chawla.,2007 were recorded a highest percentage among age groups (25-49) year was 57(32.5%) which had a high sexual activity and high hormones activity with bacterial vaginosis (11). In Sulaimania ( Kadir and Fattah .,2010) were documented a high percentage between age group (26-35)year was 5(2.48%) these disagree with this results (12). However, the age groups F (40-45)years more effect than young age . This age groups may be relation with low activity of hormones as estrogen hormone and low secretion of glycogen ,elevated ph to alkaline when advance in age which courage pathogens . Primary education was recorded a highest rate 100(76.9%)and this results in line with report in Nigeria (13). This results agree with Singh and Kanti .,2016 (14).In Iraq were documented that illiterates women were more effected (15).The most common causes related to neglect their health ,lack of education, bad body hygiene and lack of health are women’s awareness programs (16). In socio-economic level a highest percentage in middle state 114(76%). This study also agrees with Yasmeen and Mohamoud.,2011 (17).The main reasons for the role of socioeconomic stranded to infected by many women below the average in level of nutrition and health neglect (18).A current study reported a high percentage in rural residence157(79.3%).This results disagree with Mahmoud .,2017 due to lack of awareness of health neglect and low education and poor life style (19). In parity  observed that multipara had a higher rate of 158(77.1%).(Singh.,2015) study a parity as parameter with Trichomonas vaginalis was recorded a high percentage in multipara 31(26.7%) (20). These results related to abortion ,vaginal delivery , douching uses and having oral contraceptive ,intrauterine device use and sexual activity those similar to Victor.,2016) (21). This related to low education, poor feeding, bad .Current study showed vaginitis based on women  states with non-pregnant women state this agree with Yasmeen.,2011 (17).

Clinical Manifestations of vaginal infection :

Vaginal discharge recorded a high percentage 247(76%) . The percentage of vaginal discharge was 247(76%) with aerobic bacterial and Trichomonas vaginalis. Others studies had shown a percentage of

Cont...
discharge with bacterial vaginosis 11(34.4%) and Trichomonas vaginalis 13(13.1%) (22). An abundant itching was documented 239(75.4%) and this results different with Mateus.,2016 were documented a vaginal discharge 56(0.18%) (23). Also Ranjit.,2018 in her studies was reported ,itching as a vaginal signs 13(23.2%) and no vaginal itching 78(75%) (24). (Nzyomo.,2013) was reported a high rate abdominal pain (25), his study agree with this results . Bacterial vaginosis had a special bad odor. This study had another clinical manifestations as a malodor that was reported 226(75.8%) and agreement with Ranjit.,2018 was study a foul odor as one of a clinical manifestations was 31(29.9%) in non- present (24). A bad odor with Trichomonas vaginalis in this study similar to Al-Samarraie.,2002 was documented a bad odor (88.09%) and discharge (11.09%) this causes may be related to metabolic by products of aerobic bacterial (26). Fishy odor may related to volatilization of amine such as putrescine and cadaverine which produce by bacterial (27). Abdominal pain in this study was reported 131(75.7%) this agreement with Bhallo.,2012 (28). Ranjit .,2018 was study abdominal pain as symptoms of vaginosis was a 22(26.6%) agree with this results(24). Pelvic inflammatory, was recorded 38(77.6%), this study agrees with (Yasmeen.,2011) observed a pelvic inflammatory and reported 53(74.6%) and its similar with this data (17) this result may be related to douching use, that enhance to growth bacteria(29).

**Correlation of pH levels of Vagina with vaginosis pathogen:**

PH is complementary in diagnosis vaginitis as an evidence of inflammation. Lactobacillus spp was recorded a higher pH level at less than 4.5 was 187(62.3%). The study was observed and agreement with Tachedjian and others.,2017. Estrogen hormone also rise during puberty leading to increase glycogen deposition in vaginal epithelial cells as well as increased colonization of lactobacillus spp and pathogenic microorganisms. Lactobacillus spp breakdown glycogen into glucose and maltose , then convert to lactic acid and led to decrease pH (30). Trichomonas vaginalis and bacterial vaginosis, which were preferable to alkaline pH at expense of lactobacillus spp. Valadkhani ,2004 showed the role of pH in adhesion and colonization of trichomonas with lactobacillus spp at 47% and 35%. Trichomonas vaginalis, was recorded a highest proportion with alkaline pH 62(78.5%) (31). Also this study documented a high pH in alkaline pH 156(60%) with aerobic bacterial vaginitis and this identical with Liston had shown a suitable pH is an important with development of Trichomonas vaginalis. Some factors that help to elevate pH level like antibiotics treatment, seminal fluid and intercourse. The vaginal acidity related to increase estrogen hormone and lead to increase a thick of stratified epithelium during sexually maturity which help lactobacillus spp to colonize epithelium and increase of glycogen.

**Distribution of Aerobic bacterial vaginosis in vaginitis women:**

This study documented a high rate of aerobic bacterial vaginosis was E.coli 36(13.8%). Adane was studied some bacterial Vaginitis like Escherichia coli was a high rate 43(28.5%), therefore his data agree with our data which reported Escherichia coli a high rate (32). In McDonald work, on a vaginal discharge and associated with aerobic bacterial and recorded it ,he founded Streptococcus spp group, Staphylococcus aureus and Escherichia coli. were important aerobic bacterial vaginosis related with pregnancy. Escherichia coli is a causative agent of vaginosis because Escherichia coli is a normal flora in GI and may be transferred to genital tract and causes bacterial vaginosis. Also washing under wear with strong detergent poor body hygiene.

Synthesis, Characterization of New Tris Hydrazones based on Cyanuric Acid and Studies the Biological Activity as Antibacterial and Antifungal

Thaer Saleh Ghali
Directorate of Education Dhi Qar, Ministry of Education, Iraq

Abstract

In this study synthesis of new Tris Hydrazones derived from Cyanuric acid, these compounds synthesized by reaction of Cyanuric acid with Chloro ethyl acetate to product [I], then converted it to acid Hydrazide [II] by reacted with Hydrazine hydrate(80%) in absolute ethanol as a solvent. Compound [II] refluxed with different aromatic aldehyde in present of Glacial acetic acid (GAA) as a catalyst to formation new Tris Hydrazones [III]a-f. All new compounds were synthesized characterization by FT-IR and $^1$H,$^{13}$CNMR spectroscopy. The biological activity of new Tris Hydrazones studies against to positive and negative Gram bacteria also test it against to Candida albicans as a sample of Fungi.

**Keywords:** Cyanuric acid, Hydrazones, antibacterial, 1,3,5-Triazinane-2,4,6-trione, antifungal.

Introduction

The 1,3,5-triazines or s-triazines, as represented by Cyanuric acid are among the oldest recognized organic compounds. Cyanuric acid was known to Scheele as early as 1776, as “pyro-uric” acid (1). This compound is found in two tautomers are known the keto and hydroxy forms

Although the keto structure is generally more stable than the hydroxy structure. Only a few reaction of cyanuric acid occur by replacement of hydrogen of oxygen in alkaline solution the hydroxyl structure is formed over the keto structure (2).

While many derivatives of cyanuric acid synthesis by replacement of hydrogen of nitrogen atom such as N- chlorinated isocyanurates, which are employed most importantly in swimming pool disinfectants, household bleaches, industrial and institutional cleaners, dishwasher detergents (3) and the ether derivatives are uses as antioxidant (4), rust inhibitor (5), light stabilizer, cross-linking agent for vinyl polymers (6), insecticidal activity (7). The hydrazones are obtained from the condensation of hydrazides with aldehyde or ketones (8,9). These compounds have been used in the various chemical synthesis (10) and wide application in biology and medicine as antiviral (11), antimalarial (12), antibacterial (13), antifungal (14,15), antitumor (16), anticancer activity (17). In this work synthesis and characterization new tris hydrazones by condensation reaction of tris acid hydrazide derived from cyanuric acid with different aromatic aldehyde and study the biological activity as antibacterial and antifungal.

**Materials:** The chemical compounds were supplied from Merck, Himedia and CDH chemicals Co. and used as received.

**Instruments:** FT-IR spectra were recorded using KBr disc on a Shimadzu (Ir prestige-21) FTIR spectrophotometer. $^1$H-NMR spectra were obtained with Bruker spectrophotometer model ultra shield at 400 MHz using tetramethylsilane (TMS) as internal standard and DMSO-d$_6$ as solvent at 298 k. Uncorrected melting points were determined by using Hot-Stage Gallen Kamp melting point apparatus. Thin layer chromatography (TLC) was carried out on aluminum sheets. Experimental Synthesis of Tris (ethoxycarbonyl methyl) isocyanurate [I].
In the round bottom flask (500mL) put 250 mL of anhydrous dimethyl formamide (DMF) and dissolved a mixture of (10.002 g, 0.0775 mol) of cyanuric acid and anhydrous potassium carbonate (32.132 g, 0.2325 mol) then added ethyl-2-chloro acetate (28.492, 0.2325 mol) the reaction mixture was stirred and heated under reflux for 12hrs then allowed to cool at room temperature and poured onto cold water and cooled at 5 ºC overnight. The precipitated solid was filtered, washed and recrystallized from ethanol to product white needle, mp.: (74-75)ºC ; yield (59%) ; FT-IR(KBr, ν(cm⁻¹) : 2985-2877(C-H aliph.), 1697(C=O endocyclic), 1759(C=O ester), 1211(C-O), 1100(C-O) ; ¹H NMR (DMSO-d₆) δ(ppm): 4.59(s,6H,3N-CH₂), 4.14-4.18(quart,
6H,3O-CH₂), 1.20 -1.23(t,9H,3CH₃ ); ¹³C NMR (DMSO-d₆) δ(ppm):166.4(C=O ester),147.51(C=O amide), 60.87(OCH₃), 42.93(N-CH₃), 13.35(CH₃).

**Synthesis of Tris (Hydrazinecarbonyl methyl) isocyanurate[III]**

A solution of tris ester(3.8735 g, 0.01 mol) [I] dissolved in 12.5 mL of absolute ethanol and hydrazine hydrate (80%) 7.5 mL was heated under reflux condition after half hour the white precipitate was formed for 24hrs and the reaction mixture followed by thin layer chromatography (TLC)(4:6) ethylacetate:n-hexane. The mixture was then cooled at room temperature and the solid obtained was filtered and recrystallized from DMF/ethanol(¹⁹) to product white powder, mp. : >300ºC ; yield (81%); FT-IR(KBr , ν(C=O endocyclic)) : 3194(NH), 3062(C-H endocyclic), 2990-2885(C-H aliph.), 141.67(C=N), 123.39,127.53 , 129.01, 139.58 (C=C aliph.), 43.06 (CH₃) , 166.4(C=O amide endo),43.10(CH₂).

The general procedure from synthesis Tris hydrazones [III]a-f The compounds [III]a-f were synthesized by dissolving (0.03 mol) of an aromatic aldehyde in 10 mL of absolute ethanol and some drops of glacial acetic acid , then(3.4528 g , 0.01 mol) of tris hydrazide [II] was added and the reaction mixture was refluxed for 12 hrs. (²⁰). Afterword the mixture was cooled in ice bath. The resulting precipitate was filtered, dried and recrystallization from DMF/ethanol.

**Synthesis of 2,2',2''-(2,4,6-trioxo-1,3,5-triazinane-1,3,5-triyl)tris(N'-(E)-4-hydroxy-3-methoxybenzylidene)acetohydrazide) [III]a** White powder, mp. : >300ºC ; yield (88%); FT-IR(KBr , ν(cm⁻¹) : 3194(NH), 3062(C=H aromatic), 2962-2854(C=H aliph.), 1712(C=O endocyclic), 1681(C=O hydrazide), 1597(C=N), 825(C=Cl) . ¹H NMR (DMSO-d₆) δ(ppm):11.66(s, 3H,3NH), 8.63(s,3H,3CH=N), 6.45-7.98(m, 12H, aromatic), 4. 97 (s,6H,3N-CH₂), 3.39(s,9H,3OCH₃). ¹³C NMR (DMSO-d₆) δ(ppm): 166.25 (C=O amide exo), 148.38 (C=OH aromatic), 148.18(C=O amide endo), 144.27(C=N), 108.68 , 114.90 ,121.12 , 127.76(C=C aromatic), 55.02(OCH₃), 43.06(CH₂).

**Synthesis of 2,2',2''-(2,4,6-trioxo-1,3,5-triazinane-1,3,5-triyl)tris(N'-(E)-4-nitrobenzylidene)acetohydrazide) [III]c** Yellow powder, mp. : >300ºC ; yield (97%); FT-IR(KBr , ν(cm⁻¹) : 3186(NH), 3086(C=H aromatic), 2962-2800(C=H aliph.), 1705(C=O endocyclic), 1681(C=O hydrazide), 1589(C=N), 1458 and 1342(NO₂) . ¹H NMR (DMSO-d₆) δ(ppm):11.89(s, 3H,3NH), 8.63(s,3H,3CH=N), 6.45-7.98(m, 12H, aromatic), 4. 94 (s,6H,3N-CH₂), 3.82(s,9H,3OCH₃). ¹³C NMR (DMSO-d₆) δ(ppm): 166.25 (C=O amide exo), 160.39(C=OCH₃), 148.15 (C=O amide endo), 143.81(C=N), 113.84,127.77 , 129.44(C=C aromatic), 54.02(OCH₃), 43.07(CH₂).

**Synthesis of 2,2',2''-(2,4,6-trioxo-1,3,5-triazinane-1,3,5-triyl)tris(N'-(E)-4-nitrobenzylidene)acetohydrazide) [III]d** Beige Yellow powder, mp. : >300ºC ; yield (95%); FT-IR(KBr , ν(cm⁻¹) : 3186(NH), 3086(C=H aromatic), 2962-2800(C=H aliph.), 1705(C=O endocyclic), 1681(C=O hydrazide), 1589(C=N), 1458 and 1342(NO₂) . ¹H NMR (DMSO-d₆) δ(ppm):11.89(s, 3H,3NH), 8.63(s,3H,3CH=N), 6.45-7.98(m, 12H, aromatic), 4. 94 (s,6H,3N-CH₂), 3.82(s,9H,3OCH₃). ¹³C NMR (DMSO-d₆) δ(ppm): 166.25 (C=O amide exo), 160.39(C=OCH₃), 148.15 (C=O amide endo), 143.81(C=N), 113.84,127.77 , 129.44(C=C aromatic), 54.02(OCH₃), 43.07(CH₂).

**Synthesis of 2,2',2''-(2,4,6-trioxo-1,3,5-triazinane-1,3,5-triyl)tris(N'-(E)-4-nitrobenzylidene)acetohydrazide) [III]e** Yellow powder, mp. : >300ºC ; yield (97%); FT-IR(KBr , ν(cm⁻¹) : 3186(NH), 3086(C=H aromatic), 2962-2800(C=H aliph.), 1705(C=O endocyclic), 1681(C=O hydrazide), 1589(C=N), 1458 and 1342(NO₂) . ¹H NMR (DMSO-d₆) δ(ppm):11.89(s, 3H,3NH), 8.63(s,3H,3CH=N), 6.45-7.98(m, 12H, aromatic), 4. 94 (s,6H,3N-CH₂), 3.82(s,9H,3OCH₃). ¹³C NMR (DMSO-d₆) δ(ppm): 166.25 (C=O amide exo), 160.39(C=OCH₃), 148.15 (C=O amide endo), 143.81(C=N), 113.84,127.77 , 129.44(C=C aromatic), 54.02(OCH₃), 43.07(CH₂).
Synthesis of 2,2’,2”-(2,4,6-trioxo-1,3,5-triazinane-1,3,5-triyl)tris(N’-(E)-3,4-dimethoxyacetohydrazide) [III]<sub>a-f</sub>Yellow powder, mp.: >300°C; yield (94%); FT-IR(KBr, ν (cm<sup>-1</sup>): 3201(NH), 3062(C-H aromatic), 2962-2839(C-H aliph.), 1712(C=O endocyclic), 1681(C=O hydrazide), 1597 (C=N), 1265(C=O). <sup>1</sup>H NMR (DMSO-d<sub>2</sub>) δ(ppm): 11.68(s, 3H,3NH), 8.13(s,3H,3CH=N), 6.48-7.95(m, 9H, aromatic), 4.99(s,6H,3N-CH<sub>2</sub>), 3.80(s,18H,6OCH<sub>3</sub>). <sup>13</sup>C NMR (DMSO-d<sub>6</sub>) δ(ppm): 166.30(C=O amide), 159.77(C=N), 126.50(C-4), 148.18(C=O amide endo), 143.97(C=N), 107.84,110.93, 55.01(OCH<sub>3</sub>), 54.17(CH<sub>2</sub>). Biological activity

The antibacterial activity of new hydrazones [III]<sub>a-f</sub> were synthesized studies by agar disc diffusion method against four types of pathological bacteria, two (G<sup>+</sup>)(Staphylococcus aureus) and (Bacillus subtilis), So that two(G<sup>-</sup>)(Escherichia Coli) and (Klebsiella pneumonia) whereas the antifungal activity from new hydrazones [III]<sub>a-f</sub> screening against to strains fungal Candida albicans. DMSO was used as a solvent The test was preform at (100 mg/ ml) conc. and The bacteria and fungi were carried out in agar and potato dextrose agar medium and these plate were incubated for 24hrs. at 37°C.

Results and Discussions

The synthetic routes for synthesized hydrazone compounds [III]<sub>a-f</sub> are outlined in Scheme 1. The initial step including replacement of hydrogen on nitrogen from cyanuric acid by potassium carbonate anhydrous then Nucleophilic attack to chloro ethyl acetate to formation cyanuric acid by potassium carbonate anhydrous then endocyclic as well as elucidate the absence of signals carbon atoms from ethyl groups. The end step including reaction of hydrazide [II] with virus substituted aromatic aldehyde under Schiff base conditions to product the hydrazones [III]<sub>a-f</sub> correspond. These compounds characterization by FT-IR spectroscopy which show disappearance of stretching vibration bands of amino group so that exhibited the stretching vibration bands of C-H aromatic ring in the region at 3109-3062 cm<sup>-1</sup> also appearance the ν(C=N) in the region at 1604-1589 cm<sup>-1</sup>. On the ether hand the <sup>1</sup>HNMR spectra of these compounds show the singlet signal in the region at δ (11.59-11.89) ppm attributed to three protons of (3NH) in addition appear the singlet signal in the region at δ (8.09-8.80) ppm refer to proton azomethine (3HC=N) groups in addition appearance the multiplet signals in the region at δ (6.43-8.35) ppm attributed to aromatic protons. Moreover the <sup>13</sup>C NMR spectra from these compounds showed the signal of carbon azomethine group in the region at δ (141-67-144.27) ppm (22).

Antimicrobial activity:

In this study uses the Amoxicillin drug as a standard antibacterial and antifungal for compared with the new hydrazones [III]<sub>a-f</sub> activity. The results tests of these compounds are summarized in table (1). All the compounds show moderate activity against to Staphylococcus aureus except compounds III<sub>a</sub>, III<sub>b</sub> while exhibited high activity toward Escherichia Coli and Candida albicans except compound III<sub>f</sub> do not show any activity. On the ether hand compound [III]<sub>b-f</sub> showed any activity.
showed high inhibition zone against Klebsiella pneumoniae while only compounds III_d, III_f have been high activity to Bacillus subtilis.

### Conclusion

The tris hydrazones were synthesized in very good to excellent yields about 81-97% in our work characterized by FT-IR, ¹HNMR, ¹³CNMR Spectrometry and showed that their compositions matched their proposed structures. The study of biological activity of these compounds shown good activity toward Gram-negative bacteria comparative with Gram-positive bacteria of most compounds also good inhibition zone against to Fungi (Candida albicans) comparative with Amoxillin.

Assessment of Hyperuricemia in Patient with End Stage Chronic Kidney Disease

Sarah Salih Mahdi¹, Elaf Ayad Kadhem¹ and Nada Nazar Al-faris¹
¹Al Safwa University College, Karbala, Iraq

Abstract

Chronic kidney disease (CKD) has become a global public health problem because of its high prevalence and the accompanying increase in the risk of end-stage renal disease, cardiovascular disease, and premature death. Progression of CKD is associated with a number of serious complications including increased incidence of cardiovascular disease, hyperlipidemia, anemia and metabolic bone disease. Hyperuricemia may be a major contributor to the development of progression of chronic kidney disease (CKD). Although there is no clear cutoff uric acid (UA) value associated to the risk for kidney damage, it appears to be an increased risk as UA rises.

Key words: Chronic kidney disease (CKD), Uric acid (UA), Hyperuricemia.

Introduction

CKD is characterized by progressive deterioration of kidney function, which develops eventually into a terminal stage of chronic kidney failure (CKF). CKF has traditionally been categorized as mild, moderate, or severe [1].

During the last few years, an international consensus has emerged categorizing CKF into five stages according to the glomerular filtration rate (GFR) and presence of signs of kidney damage: stage 1: GFR > 90 ml/min and signs of kidney damage, stage 2: GFR = 60-89 ml/min and signs of kidney damage, stage 3: GFR = 30-59 ml/min, stage 4: GFR = 15-29 ml/min, and stage 5: GFR < 15 ml/min [2]. Stage 5 represents the total inability of kidneys to maintain homeostasis, and this metabolic state is incompatible with life. Thus, at this stage, it is necessary to use methods that substitute for kidney function to ensure patient survival; these methods include peritoneal dialysis & hemodialysis [3].

CKF is associated with many kinds of metabolic changes caused by the kidney disease and also attributable to dialysis treatment. Phenomena such as accumulation or deficit of various substances and dysregulation of metabolic pathways combine in the pathogenesis of these changes [4]. In the process of accumulation, decreased urinary excretion plays a crucial role and leads to retention of metabolites in the organism (e.g. creatinine, urea, uric acid, electrolytes, water). The increased formation of metabolites through catabolic processes and alternative metabolic pathways also exerts an influence. Regular dialysis treatment partly decreases this accumulation, but cannot avert the overall deficit [5].

Chronic kidney disease leading to chronic kidney failure is an urgent medical problem in the context of demographic trends. In addition to the basic kidney disease, many metabolic disorders develop in the course of CKF. Particularly, patients in the terminal stage of CKF are endangered [6]. Regular dialysis treatment decreases the accumulation of metabolites; however, it contributes to a deficit of some important metabolic regulators and to the development of a chronic inflammation state. These factors can lead to serious secondary complications in CKF, including atherosclerosis and related cardiovascular disease, malnutrition, anemia, renal bone disease, and other problems [7]. These complications markedly and negatively affect the prognosis and quality of life of patients with CKF and increase costs for their treatment. The prognosis of CKD patients can be improved if kidney disease is diagnosed early and...
properly cured, including secondary complications. Appropriate treatment encompasses consistent control of blood pressure, prevention of malnutrition, anemia, and hyperparathyroidism, and treatment of metabolic disorders [8].

Because humans lack uricase, they cannot convert the uric acid generated during purine metabolism into a soluble form. This can lead to an increased risk for hyperuricemia and monosodium uric acid crystallization in joints and tissues [9]. Because approximately 70% of uric acid is excreted from the kidney, hyperuricemia occurs when renal function deteriorates. Hyperuricemia is defined as a level of serum uric acid greater than or equal to 7.0 mg/dl (420 μmol/l) in man and 6.0 mg/dl (360 μmol/l) in women. CKD is associated with decreased excretion of uric acid and resultant hyperuricemia. Other mechanisms may be implicated in CKD since variations in serum uric acid do not account for most of the risk for developing gout [10]. Hyperuricemia can be caused by the overproduction of uric acid, but is more often the result of insufficient kidney uric acid excretion. Observational data also suggest that hyperuricemia, even in the absence of gout, may independently worsen CKD, possibly via a pathogenic role in hypertension (Figure 1), and diabetic nephropathy, the two leading causes of CKD [11,12].

Hyperuricemia may be a consequence of decreasing of glomerular filtration rate (GFR), reflecting tissue hypoxia or cell lysis associated with renal disease [13].

Materials and Method

Subjects: Between 1st October 2019 and 1st December 2019, 100 subjects were recruited to this study, 50 consecutive patients aged between 25-70 years old, diagnosed by expert physicians as having CKF from kidney dialysis unit (KDU) in Al-kafeel hospital in Karbala City, in addition to age and sex matched (50 subjects) without CKF with similar risk factors considered as control group. This study was matched for gender, the ratio of male: female was 2:1 for both sexes. This study was performed in the Biochemistry laboratory in Pharmacy Department in Alsafwa collage.

Ethical Issues: The objectives and methodology were explained to all participants in the current study and their verbal consent was gained.

Sample collection: Five ml of blood were obtained from each subject by vein puncture in sitting or lying position, and then pushed slowly into disposable tubes containing separating gel. Blood in the gel containing tubes was allowed to clot at room temperature for 2 hours and then centrifuged at 1000 ×g for approximately 15 minutes then the supernatant were obtained and stored at -20°C until analysis.

Materials: Uric acid biochemical kit (Biolab).

Methods: uric acid serum level assayed by Biolab biochemical kit.

Statistical analysis: The collected data were tabulated and analyzed by using the Statistical Package for Social Sciences (SPSS) for Windows version 20th version. Data were expressed as (mean ± SD). Independent sample t-test was used to compare means between two groups. P values less than (0.05) were considered significant.

Results

a. Differences of Patients with Chronic Kidney Failure and control by Socio-Demographic Characteristics:

The overall mean age of patients with ACS and control were (40.28±12.02) and (38.21±11.61) years old, respectively and the extremes were 25 to 70 years old. There was no significant mean difference between the mean age of patients and control. This age matching helps to eliminate differences in parameters’ results. This study was matched for gender, the ratio of male: female was 2:1 for both sexes.

b. Differences of patients and control by uric acid serum level

There were significant differences of UA serum level by patients and control subjects as shown in table (1).
Table (1): Mean differences of patients and control by UA serum level

Discussion

This study revealed that hyperuricemia is clinically significant in the setting of CKD, especially when drugs used for their management can further impair kidney function. The established role of CKD as an independent risk factor for hyperuricemia may therefore warrant screening for CKD when gout is first diagnosed, as presented by Juraschek SP et al. The role of hyperuricemia as an independent risk factor for CKD, however, is still being debated. Large randomized controlled trials can provide definitive answers about its relationship to CKD, and how its treatment might forestall CKD progression in populations such as those with hypertension and diabetic nephropathy. The finding of this study agreed with Tae Ryom Oh et al. who reported that in the case of CKD, renal excretion of uric acid is decreased, resulting in hyperuricemia. It is thought that the interstitial accumulation of sodium urate induces the deterioration of the disease. This suggests that patients with renal impairment are more likely to be exposed to higher uric acid concentrations, which means that the multisystem effect of uric acid can be further strengthened. A recent study by Verzola D et al. utilizing immortalized proximal tubular epithelial cells from normal adult human male kidney has demonstrated that increasing levels of uric acid cause NAPDH-dependent oxidative changes which promote apoptosis. This finding sheds light on the connection between hyperuricemia and tubule-interstitial renal damage. The association of hyperurecemia with CKD also was reported by Jalal DI et al. & Momeni A. Momeni (2012) who concluded that hyperuricemia is frequently found in patients who are found having chronic renal failure. Epidemiological studies have detected an association of hyperuricemia and heart and vascular disease in the general population and in chronic renal insufficiency patients.

Conclusion

- There is significant elevation of serum uric acid in CKD patients.
- The challenge remains that the significance of elevations in uric acid is difficult to assess in those with chronic kidney disease because, as clearance decreases, the levels of serum uric acid naturally increase.
- Hyperuricemia may be used as a disease marker for the potential to develop renal disease in the future as well as predict risk for a patient with renal disease to develop worsening renal function.

Reduced Glutathione, Lipid Peroxidation and Malondialdehyde Status in Women with Mild and Severe Preeclampsia for Babylon Governorate

Taha H. Farhood¹, Mufeed J. Ewadh¹, Suhailah F. Alshaik¹
¹University of Babylon, College of Medicine, Hilla, Iraq

Abstract

The presented study aims to evaluate the levels of serum reduced glutathione, lipid peroxidation and malondialdehyde status with Mild, severe preeclampsia and healthy pregnant control in the case – control study. Twenty five patients with severe preeclampsia, twenty five patients with mild preeclampsia and fifty healthy pregnant as control in Babylon province / Iraq were enrolled in this study. Results of this study were shown The median serum reduced GSH concentration in the preeclampsia group was significantly lower than that in the group with normal pregnancy, indicating that there is more extensive oxidative stress in preeclamptic pregnancy. Also In this result, there was increased in malondialdehyde level in preeclampsia pregnant women groups when compared with non-preeclampsia pregnant women group.

Keywords: Babylon Governorate ; Severe Preeclampsia ; Glutathione, Lipid

Introduction

Pregnancy complicated by gestational hypertension is managed based on its severity, presence of preeclampsia, and gestational age. Increases in systolic and diastolic blood pressure can be either normal physiological changes or signs of developing pathology. Heightened surveillance permits more prompt recognition of ominous changes in blood pressure, Critical laboratory findings, and clinical signs and symptoms (1).

Pre-eclampsia (PE) is defined when BP ≥140/90 mm Hg and proteinuria (≥300 mg per 24 hours) after 20 weeks of gestation with an incidence of 2-8%. Its complications lead to placental abruption, eclamptic fits. Moreover, PE has been strongly associated with increased risk of later-life death due to liver insults and cardiovascular disease (2). It is a major cause of preterm birth, accounting for 15% of all preterm Deliveries (3).

Oedema is no longer included as a diagnostic criterion for preeclampsia because its occurrence is expected in pregnancy and has not been shown to be discriminatory. If untreated, the symptoms get progressively worse (4). Although PE is associated with abnormal trophoblast invasion in the first half of pregnancy, it is not until later in the pregnancy that the clinical syndrome of PE is seen. The timing of onset and the clinical course are unpredictable. In some, hypertension and proteinuria are the only manifestation, while others may present with severe renal or liver impairment, and in yet others the most prominent feature might be intrauterine fetal growth restriction secondary to placental disease.

The term pregnancy-induced hypertension (PIH) suggests a disorder of blood pressure that arises because of the presence of pregnancy. Pregnancy induced hypertension and PE rarely develop before 20 weeks gestation unless associated with trophoblastic disease or fetal triploid (5).

Mild and Severe Pre-eclampsia:

Pre-eclampsia is divided into mild and severe forms, depending on the severity of the hypertension, the
amount of proteinuria, and the degree to which other organ system are affected (6).

**Mild Pre-eclampsia:**

Is defined as the presence of hypertension (BP ≥140/90 mm Hg) on 2 occasions, at least 6 hours apart, but without evidence of end-organ damage in the patient (7).

**Severe Pre-eclampsia:**

Is defined as the presence of the following:(2)

1. Severe hypertension (systolic blood pressure ≥160 mm Hg, or diastolic blood pressure ≥ 110 mm Hg) at rest, on two occasions at least 6 hr apart.

2. Heavy proteinuria (at least 5 g in a 24-hr collection or a qualitative value of 3+ in urine samples collected 4 hr apart.

3. Oliguria (<500 mL in 24 hr).

4. Cerebral or visual disturbances.

5. Pulmonary edema or cyanosis.

7. Impaired liver function (elevated liver enzymes).

8. Thrombocytopenia.

**Materials and Method**

**Ethical Issues**

a- Approval by scientific committee of the Clinical Biochemistry Department, College of Medicine/University of Babylon, Iraq.

b- Approval by Babylon Health Directorate, Ministry of Health and Information centre for Research and Development of Babylon Province.

c- The objectives and methodology were explained to all subjects and verbal consent had been taken.

**Date and Durations**

The period extended from October 2018 to April 2019. This work was done in the Department of Biochemistry, College of Medicine University of Babylon and in Hilla city. Iraq.

**Study Design**

This study design was a case – control study.

**Patients and control**

A total of 50 patients divided to 25 sever and 25 mild with preeclampsia were enrolled in this study. 50 subjects who were apparently healthy control group of pregnant.

**Exclusion Criteria:**

Age over 35 years.

Previous history of PE.

Conditions in which the placenta is enlarged like multiple pregnancy

Pre-existing hypertension or renal disease.

Pre-existing vascular disease (as diabetes or autoimmune vasculitis.

**Determination of Serum Reduced Glutathione**

Determination of serum reduced glutathione levels in patient and control group were depends on the action of sulfhydryl group (8).

**Determination of Lipid peroxidation**

Determination of lipid peroxidation was done by Elabscience (USA) kits and according to Colorimetric method.

**Determination of MDA**

Determination of MDA was done by Elabscience ELISA kits and according to Competitive-ELISA principle.

**Results**

According to the clinical and laboratory examination the patients participating in this study divided in to two main groups illustrated below in Table 1
Table 1: Number of the different stage among preeclampsia patients.

Discussions

The median serum reduced GSH concentration in the preeclampsia group was significantly lower than that in the group with normal pregnancy, indicating that there is more extensive oxidative stress in preeclamptic pregnancy. Reactive oxygen species cause decreases in antioxidants. In patients with preeclampsia placental angiogenic activity is significantly lower than in the placenta of normal pregnancy(9). Other studies are similar, as shown by the significant decreases in the mean value of endogenous antioxidants such as GSH, superoxide dismutase, and glutathione peroxidase in preeclampsia cases as compared with normotensive pregnant women.

In this study extremely low level of reduced glutathione in sever preeclampsia go with the idea that says increase production of ROS In conjunction to increase the severity of preeclampsia the matter that will extremely increase the consumption of glutathione to neutralize the ROS and other free radicals. Glutathione plays essential roles in T cell function and proliferation (10). Reported that Activation of T helper cell results in decreased levels of reduced glutathione (GSH) and production of ROS. In sever preeclampsia there is a demand to increase activation of T helper cell, that may contribute the consumption of reduced glutathione pool in the serum of preeclampsia.

Lipid peroxidation is oxidative degradation of lipid by which, free radicals steal electron from lipid in cell membrane and resulting in cell damage (11). Lipid peroxidation represent a crucial and causative role in the pathogenesis of atherosclerosis and it involve also, in the oxidative modification of LDL which lead to initiation of hypertensive and preeclampsia (12). Excessive lipid peroxidation occurring in preeclampsia can be attributed to hypercholesterolemia. Hypercholesterolemia promotes the formation of free radicals.

Increased oxygen demand to meet the bodily functions in pregnancy is also a contributory factor for the oxidative stress that results in the formation of free radicals. Thus, lipid alterations observed may promote oxidative stress, leading to endothelial dysfunction in preeclampsia(13).

In this result, there was increased in malondialdehyde level in preeclampsia pregnant women groups when compared with non-preeclampsia pregnant women group. Products of lipid peroxidation are the candidate factor that mediate disturbance of the maternal vascular endothelium and may inhibit prostacyclin synthesis and also stimulate smooth muscle contraction that lead to widespread vasospasm, a prominent feature of preeclampsia(14). The decrease of red cell deformability due to the increase of plasma malondialdehyde level may be the underlying mechanism of pregnancy induced hypertension(15).

Conclusion

Preeclampsia patients in Babylon province have low reduced glutathione level comparing to normal subjects and this level decrease more as the preeclampsia progress to advance severity. As regard to glutathione antioxidant and immune supporting properties, glutathione consumed during elimination of ROS that produced by lipid peroxidation processes. Also, preeclampsia patients in Babylon province have high Malondialdehyde and Lipid peroxidation level comparing to normal subjects and this level increase more as the the preeclampsia progress to advance.
severity. The oxidative stress underlying the occurrence of systemic inflammation in patients with preeclampsia indicates that there is an imbalance between free radicals and the antioxidant defense mechanism in the course of pregnancy.

Association of Autoimmune Thyroiditis and Type 1 Diabetes Mellitus With Severity of Children with Celiac Disease

Bashar S Khalaf

Pediatric Dept., Hammurabi faculty of Medicine, Babylon University, F.I.B.M.S, C.A.B.P General pediatrician.

Abstract

Purposes of study: analysis and measurement of incidence and association between autoimmune thyroiditis (AIT) and type 1 Diabetes mellitus (T1DM) with clinical and serological severity of patients with Celiac disease.

Design and Methods: This is prospective study, All children (107 children with 41 male and 66 female) with celiac disease are admitted and follow up in Hospital. Age groups (1-12 years) are arranged into two groups (1-6 and 7-12 years old). The celiac disease are divided into: Group1= 25-50 IU/ml, Group2 = 50-100 IU/ml, Group3 >100 IU/ml. All patients with celiac disease are follow up for AIT and type 1 T1DM.

Results: (107) patients with celiac disease, mean age is 6.78±2.85, median age is 8, and female :male ratio are 1.6:1. All celiac patients are divided into: group 1 (43 patients), group 2 (50 patients), and group 3 (14 patients). Incidence of T1DM in all patients is 8.4% while AIT 2.8%. T1DM incidence in group 2 is 3.7% and in group 3 is 12.3%. But AIT incidence in group 3 is 4.6%. All cases with AIT have hypothyroidism with TSH > 100 µU/ml. All diabetic patients have random blood sugar > 450 mg/dl. Age group are divided into two groups, 1-6 and 7-12 years old. Incidence of T1DM are 6.25% and 11.6% in these two age groups respectively, while AIT is 7% in age group 7-12 years. The association between celiac patients groups with T1DM and AIT is insignificant association (P value is 0.265 and 0.717 respectively). Also age groups have no significant association with T1DM and AIT (P value is 0.48 and 0.062 respectively).

Conclusion: follow up of celiac disease is important step for diagnosis AIT and T1DM. These two autoimmune diseases are increasing especially when there high concentration of IgA anti-tissue transglutaminase level (>100 IU/ml) and advanced children age group. AIT may presented initially with hypothyroidism.

Key words: Celiac disease, autoimmune thyroiditis, type 1 diabetes mellitus.

Introduction:

Celiac disease is an initially described as bowel disease in 1st century A.D. It is also called gluten sensitive enteropathy or celiac sprue (1). Sex distribution have also different rates of disease involvement, female is increased 1.5-2 folds in compare to male(3).

Celiac disease is intestinal autoimmune disease which is triggered by gluten ingestion in genetically liable persons. The main distinctive features of celiac disease are systemic symptoms, serologically autoimmune antibodies, and lastly, there is genetic association (2). Since, there is commonly unclear and wide variation clinical symptoms of celiac disease and so the real prevalence of this disease is not accurate(4-6). Consequently, patients with celiac disease is underdiagnosed in about 90%(7-9).

Gastrointestinal symptoms of celiac disease are malabsorption with diarrhea and subsequently, it is leading to weight loss. The intestinal biopsy shows mucosal inflammation of proximal small bowel with variable level of inflammatory extension to jejunum and...
ileum\(^{(10)}\).

The prevalence distribution of this disease is 1%-2% in North and South America, North Africa and Middle East with first suggestion in the same degree in Asian population\(^{(11)}\). Family history of 1st degree people is also rising the incidence of celiac disease to about 10%-15%\(^{(12)}\).

European society of pediatric gastroenterology, hepatology and nutrition (ESPGHAN) have diagnostic principles and recommendation for diagnosis of celiac disease.

Celiac diagnostic criteria is yet depending on intestinal biopsy that have typical findings with positive response to gluten free diet but further biopsies (2\(^{nd}\) and 3\(^{rd}\)) are done only when first biopsy findings is unclear and/or gluten free diet ingestion is not changing clinical outcome of patients. Most recent diagnostic criteria (ESPGHAN-2012) is depending on characteristic symptoms, titer level of transglutaminase antibodies (ten times greater than upper normal value), and presence of associated HLA-genotype\(^{(13)}\).

Regarding serology, patients is testing by serum IgA anti-tissue transglutaminase antibodies\(^{(14)}\). If they have IgA antibodies deficiency, both serum IgG anti-tissue transglutaminase and IgG anti-deaminated gliadin antibodies can use\(^{(15)}\).

Incidence of celiac disease is increasing in previous fifty years and the mechanism of these changes is not completely identified but it might be related mostly to environmental factors in addition to effect of genetic abnormalities\(^{(16)}\).

Type 1 diabetes mellitus (T1DM) is common endocrine disease that is appearing in children adolescence age group. T1DM is a result as outcome of defect in patient genes, immunity, and environmental stimulation factors, and these factors result in stimulation of T-cell autoimmunity against beta cells of pancreas\(^{(17)}\).

Thus, T1DM is resulting from decrease insulin secretion from pancreas, and it is associated frequent urination and thirst. Diagnostic standardization of world health organization standardization of T1DM are fasting blood glucose \(\geq 7\) mmol/L or blood glucose \(\geq 11.1\) mmol/L in addition to diabetes mellitus symptoms or when oral glucose tolerance test is resulting two hour blood glucose \(\geq 11.1\) mmol/L\(^{(18)}\).

The T1DM is rising in incidence and it is risk could be increase to double level in children by 2020\(^{(19)}\).

T1DM are associated other autoimmune diseases and so with firstly autoimmune thyroiditis and then celiac disease\(^{(20)}\).

Autoimmune thyroiditis (AIT) is a widespread autoimmune disorder, it is affecting 0.2% and 2% of men and women respectively\(^{(21)}\).

Autoimmune hypothyroidism is a common etiology for acquired hypothyroidism that presenting from children to adult age group, AIT prevalence is 1%-2% and female is four folds than male\(^{(22)}\). Autoimmune hypothyroidism is commonly associated with systemic lupus erythematous, celiac disease, and other diseases\(^{(23)}\).

Antithyroglobulin and antithyroid peroxidase autoantibodies is found in about 60% and 95% respectively in patients with both diffuse goiter and hypothyroidism or one of them\(^{(24)}\).

Aim of study is to evaluate incidence and association between autoimmune thyroiditis and type 1 Diabetes mellitus with clinical and serological severity of patients with Celiac disease.

**Materials and Method**

This is prospective study, All children (107 children with 41 male and 66 female) with celiac disease are admitted and follow up in Babylon teaching hospital for gynecology and pediatrics, in period between April/2017 to February/2019. Age group involved is 1-12 years old that arranged into two groups (1-6 and 7-12 years old). The diagnosis of celiac disease is depending on symptoms, serum anti-tissue transglutaminase IgA (TTGA) and intestinal biopsy. The celiac disease are divided into three groups according to concentration of IgA anti-tissue transglutaminase: (1) Group1 = 25-50 IU/ml; (2) Group2 = 50-100 IU/ml; (3) Group3 >100 IU/ml.

All patients with celiac disease are follow up for AIT and T1DM.

T1DM is diagnosis by random blood sugar with clinical symptoms and fasting blood sugar. Also, autoimmune thyroiditis is followed with antithyroglobulin and antithyroid peroxidase autoantibodies in addition to
presence of goiter with other thyroid disorder symptoms. Then, if the children has AIT, we do thyroid serology for thyroid stimulating hormone (TSH) and free thyroxine (FT4) hormones.

In Hospital laboratory, the serology of TSH and FT4 is measured with cobas e 411 analyzer. anti-tissue transglutaminase IgA, antithyroid peroxidase antibodies, and antithyroglubin antibodies measured by Chorus trio machine.

Laboratory normal reference for following data are: FT4: 10-35 pmol/L, TSH: 0.25-5 µU/ml, anti-tissue transglutaminase IgA titer < 12 IU/ml (negative) and 12-18 IU/ml (equivocal), antithyroid peroxidase antibodies titer < 35 IU/ml, antithyroglubin antibodies titer: 2.6-25 ng/ml.

SPSS version 22 program was using for Statistical evaluation. Mean ± SD and median are represented the continuous variable. Pearson’s chi square (X2) and Fisher’s Exact Test are assessed the association between categorical variables, and Significant P value is ≤ 0.05.

**Results**

107 patients are diagnosis with celiac disease, mean age is 6.78±2.85, median age is 8, and female :male ratio are 1.6 : 1.

All patients with celiac disease are divided according to level of TTGA into group 1 (43 patients), group 2 (50 patients), and group 3 (14 patients).

During period of follow up of those patients, the incidence of T1DM in all patients is 8.4% while AIT 2.8%. T1DM incidence in group 2 is 3.7% and in group 3 is 12.3%. But AIT incidence in group 3 is 4.6% as in table1 and Fig.1.

*Fisher exact test

The association between celiac groups with T1DM and AIT is insignificant association (P value is 0.265 and 0.717 respectively). Also age groups have no significant association with T1DM and AIT (P value is 0.48 and 0.062 respectively).

Discussion

In this study, we study association of AIT and T1DM in patients with originally diagnosis as celiac disease, all these diseases have an autoimmune origin, and many studies support their relationship.

Celiac disease is commonly associated with T1DM, AIT, and Sjogren’s syndrome.

Kahaly et al indicated in their research that type 1 diabetic patients are fifty percentage that may progress to autoimmune thyroiditis and forty percentage are presented with celiac disease.

This present study is accomplished in hospitalized children, mean age is 6.78 predominant female (female : male ratio is 1.6 : 1). Antonella et al. study was done in 324 children that had always celiac disease, mean age is 6.6 years old, and female to male ratio is 2:1.
Our study shows percentage of T1DM (8.4%) is more than autoimmune thyroiditis (2.8%). Antonella et al. \( (27) \) and Collin et al. \( (28) \) exhibited that autoimmune thyroiditis were found 10.5% and 3.5% respectively in patients with celiac disease.

Also, T1DM was diagnosis about 3.5%-10% in patients having celiac disease\(^{(29-31)}\).

Study of PEKKA et al. \( (32) \) was diagnosis of both autoimmune thyroid disease and T1DM with equal evidence (2%-5%) in celiac disease.

High IgA anti-tissue transglutaminase level (\( >100 \) IU/ml) in group 3 has more (in compared to other groups) association to develop T1DM and AIT, but their association is not reach to significant level (\( P \) value is 0.265 and 0.717 respectively).

Age factor in celiac disease responsible for prediction of developing autoimmune diseases, rather than the period of gluten ingestion as a registered by authors\(^{(33)}\)

Two age groups in present study are insignificant associated with AIT and T1DM in this present study, but age group 7-12 years are higher frequency with AIT(7%)in compare to age group 1-6 years (0%), similar study of Giuseppina et al.\(^{(34)}\) is 4.3% for age group < 6 years in compare to 27.7% age group > 6 years old.

Also, T1DM is occurring in both age groups (6.25% and 11.6% respectively) that have celiac disease, and as known that T1DM is common disease in both children and teenager\(^{(35)}\).

In conclusion, follow up of celiac disease is important step for diagnosis AIT and T1DM. These two autoimmune diseases are increasing especially when there high concentration of IgA anti-tissue transglutaminase level (\( >100 \) IU/ml) and advanced children age group. AIT may presented initially with hypothyroidism.

Role of PSA in Diagnosis of Chronic Prostatitis

Yasir Abdulateef
Head of Clinical Laboratory Science Department, Pharmacy College, University of Anbar

Abstract

Background: Prostatitis is the poor cousin of prostatic cancer and Benign hyperplasia. The prevalence of prostatitis in general population was estimated to be 0.5 to 14.2% in developed countries. Publishing in Iraq was concern mainly with treatment of prostatitis.

Objective: This work was carried out to comment on the concept of prostatitis in clinical practice.

Method: A total of 275 males was included in this study. They were complaining of urinary symptoms (frequency, urgency, hesitancy, straining, difficulty in initiation urinary stream). All cases were confirmed to have chronic prostatic after excluding prostatic carcinoma by abdominal ultrasound, free to total PSA and urinary Prostatic carcino-antigen-3. Their age was 45.6 ± 9.6 year. Urine samples were proceeded immediately after collection. Centrifuged and non-centrifuged specimen were examined.

Results: PSA was affected significantly by age (p = 0.002). A significant high level was observed among those complaining of pain during ejaculation (p = 0.0001). Those showed epithelial cells in urine had significant high level of PSA (p = 0.0001). Uric acid in urine was associated with significant high level of PSA (p = 0.03).

Conclusion: The diagnosis of CP / CPPS might be outside the traditional urologic practice and might consider PSA level too.

Key words: Prostatitis, PSA, urinary symptoms, chronic pelvic pain syndrome, Iraq.

Introduction

Prostatitis is a microscopic inflammation of the prostate gland that covers a wide range of clinical conditions in relation. Prostatitis is the “poor cousin” of prostate cancer and benign prostate hyperplasia (BPH) which is the most common urologic diagnosis in younger than 50 years, and the 3rd most common diagnosis in men older than 50 years. Factors identifiable with prostatitis are microorganism, urine reflux and high voiding pressure, immunological status and mental stress.

Prostatitis was classified by National Institute of Health (NIH) into four categories, I, II, III, and IV, representing acute prostatitis (CP), chronic prostatitis/chronic pelvic pain syndrome (inflammatory and non-inflammatory) (CPPS) and asymptomatic inflammatory prostatitis, respectively.

Acute prostatitis is mostly caused by several different types of bacterial infections and represented as a medical emergency. 5% of patients might end up with chronic bacterial prostatitis, which is mostly caused by E. coli and other gram negative Enterobacteriaceae.

Chronic nonbacterial prostatitis, also known as chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS), is long term pelvic pain and symptoms with urination without evidence of a bacterial infection.

Asymptomatic inflammatory prostatitis is a painless inflammation of the prostate gland where there is no evidence of infection.

PSA was first identified in human prostatic tissue extracts in 1970, purified and characterized by Wang and associates in 1979, and detected in human serum by Papsidero and associates in 1980.

PSA is a single chain, 240–amino acid glycoprotein
with a molecular weight of 33 kDa. The human PSA gene is located on chromosome 19 (544). The mRNA of PSA, like other cytoplasmic serine proteases, is translated as an inactive pro-PSA/pro-PSA precursor. Following passage through the intracellular secretory pathway, the signal peptide is cleaved, yielding the proform of the protein. Evidence suggests the conversion of pro-PSA to the mature enzymatically active PSA requires the action of human kallikrein 2 (hK2) 9.

PSA shares sequence homology with the human kallikreins and, in fact, a 78% homology with hK2. PSA possesses chymotrypsin-like activity and has a weak interaction with the plasma inhibitor, aprotinin. PSA also has modest overlapping homology with urokinase-like plasminogen activator and is capable of facilitating the degradation of the extracellular matrix. PSA is primarily produced by intraluminal or secretory cells of the prostate and the epithelial lining of the periurethral glands 10.

The basal cells of the prostate do not express this protein. It is androgen regulated and one of the most abundant serine proteases in the seminal plasma (1,000,000 ng/mL). Its major physiologic role is to promote the liquefaction of seminal clot. Seminal clotting is due to the presence of semenogelin 1 and semenogelin 2 and fibronectin. PSA targets the semenogelin component, thus liquefying the seminal clot, which in turn facilitates sperm motility. The half-life of PSA is 2.2 to 3.2 days 11.

Low levels of PSA and/or PSA-gene expression have been detected in various tissues, particularly those that have constitutive expression of the steroid receptor superfamily, including the uterine endometrium and amniotic fluid, normal lactating breast tissue and the milk of lactating women, breast cancer, perianal/periurethral glands, salivary glands, adrenal/renal neoplasms, and various other malignant tumors 10.

The prevalence of prostatitis in general population was estimated to be 5.0 to 14.2%. The figure was for developed countries (America and Europe). No publish figure on prevalence of prostatitis in Iraq which might be endemic like other endemic diseases in Iraq like hydatid cyst and brucellosis, and publishing were mainly concerned with treatment with antibiotics.

The aim of this study is to comment on the role of PSA in chronic prostatitis in clinical practice.

---

**Materials and Method**

During the study period July 2016 to April 2018, a total of 275 males referred to Lagash laboratory for general urinalysis because pain and urinary symptoms (frequency, urgency, hesitancy, straining, difficulty in initiation of urinary stream and incomplete bladder emptying). After excluding prostatic carcinoma by abdominal ultrasound, free to total PSA values, and estimating the level of Prostatic carcinoma-3 in urine by ELSA method (PCA-3), the diagnosis of CP / CPPS was according to NIH criteria. Their age was 45.6 ± 9.6 year.

Urine samples were processed immediately after collection. The centrifuged and the non-centrifuged specimen were examined under 10x and 40x of bright field microscope to find out the presence of pus cells, RBCs, casts, crystals and bacterial cells. Blood samples to obtain serum PSA levels and was processed by Snibe Maglumi 800 Immunoassay Analyzer chemiluminescence immunoassay system.

Data was dichotomized for age (≤ 50 and > 50 year), pain on ejaculation (yes and no), epithelial cell in urine (present and not present), pus cells in urine (present or not present), bacteria in the urine (high density or low density), uric acid (present or not), seminal fluid pus cells (present or not present), seminal fluid uric acid (present or not present) and history of smoking (positive or negative).

Student’s t test was carried out to examine the differences in means of PSA between the dichotomized variables. P value < 0.05 was considered significant.

**Results**

PSA among those aged ≤ 50 and > 50 year, were 1.6 ± 0.1 and 1.4 ± 0.1, respectively. A significant difference in PSA between the two groups (t = 3.1, d.f. = 273, p = 0.002). (Table 1). PSA was increasing with age (Fig.1).

Men complaining of pain on ejaculation had significantly higher PSA (6.6 ± 1.5) than those with no pain on ejaculation (5.1 ± 1.2) (t = 6.6, d.f. = 273, p = 0.0001).

Those men showed epithelial cells on urinalysis had a significant higher PSA (9.2 ± 1.7) than those showed no epithelial cells on urinalysis (6.2 ± 1.5) (t = 5.1, d.f. = 273, p = 0.0001).
Pus cells in urine was significantly associated with higher PSA (6.4 ± 1.5) than those without pus cells in urine (4.7 ± 1.1) \((t = 3.8, \text{ d.f.}= 273, p = 0.0001)\).

Men showed bacteria in urine with a significant higher PSA (6.7 ± 1.7) than those without bacteria in urine (6.2 ± 1.4). There was a significant difference in PSA between the two groups \((t = 2.6, \text{ d.f.} = 273, p = 0.006)\).

Men with uric acid in urine showed higher PSA (6.6 ± 1.8) than those without uric acid in urine (6.2 ± 1.4). A significant difference was observed between the two groups \((t = 2.1, \text{ d.f.} = 273, p = 0.03)\).

Smokers showed a level of PSA (6.4 ± 1.6) and non-smokers showed (6.3 ± 1.6). No significant difference in PSA due smoking was noticed \((t = 0.7, \text{ d.f.} = 273, p = 0.4)\).

Discussion

Prostatitis refers to a fascinating urologic diagnosis with spectrum of etiologies and varying natural histories. The term Chronic prostatitis (CP) / chronic pelvic pain syndrome (CPPS) were usually used as (CP/CPPS).

PSA was not mentioned in diagnosis of CP/CPPS in the recent published data. This report was done to comment on the role of PSA in diagnosis of the CP/CPPS.

This study revealed that PSA was significantly elevated in men with CD/CPPS. This finding is in agreement with that reported recently. This finding is intriguing in the light of general practice in Iraq. However, recently a postulation that genetic variations in the promoter of gene of PSA might contribute to the individual variations in the serum PSA levels in men without prostatic diseases.

The study revealed that PSA was significantly higher among those ≤ 50 years than among those > 50 years old (p=0.002). This finding is similar to that reported in Jordan.

In the line with that in literature, PSA was showing a positive significant association with age in the above normal levels. Recently, it was reported that ageing is usually characterized by a mild chronic pro-inflammatory state. This phenomenon is called inflammageing. Therefore, the finding that PSA level was associated with age might be attributed to inflammatory process.

The study showed that markers of inflammation (epithelial cells, pus cells and bacteria cells) in urinalysis were associated significantly with elevated PSA level than that showing no inflammatory markers (p = 0.0001 for each marker) which could indicate that PSA is part of the pathophysiological inflammatory reaction.

Presence of pus cells in seminal fluid was significantly associated with higher PSA level than that in patients with no pus cells in their seminal fluid (p =
0.0001). Literature documented that chronic bacterial infection of prostate has been identifiable with virulent microorganism in prostatic secretion. The finding shows the PSA as a reflection to the inflammatory state of prostate.

It was stated that painful ejaculation in men address prostatitis and. This study showed that painful ejaculation was associated with elevated level of PSA which is it non malignant than that not complaining of painful ejaculation (p = 0.0001). The finding might be suggesting that PSA reflects prostatitis again.

**Conclusion**

The diagnosis of CP / CPPS might be outside the traditional urologic practice and might consider PSA level too as an acute reactant protein. PSA increase in Chronic prostatitis indicates it’s an inflammatory marker not only a tumor marker.

**Limitation of detection:**

Free PSA was not included.

Treatment and Experimental Infection with *Klebsiella pneumoniae* in Rats

Aqeel A. Alsadawi1, Dhuah Hayder Abdul-Jawad1, Noor Hani AL-Naji1

1Medical Laboratory Techniques Department, Collage of Medical Technology, The Islamic University, Najaf, Iraq

Abstract

So many diseases are caused by *Klebsiella* species including urinary tract infections (UTIs), pneumonia, sepsis, diarrhea and bacteremia. Also *Klebsiella* is responsible for a significant number of community-acquired infectionssuch as pneumonia that results in severe injury in the lung and responsible for a high death ratein children. The intranasal and left lung route of *K. pneumoniae* infection causes pathological change in the lungs tissues due to acute and chronic injury. Conducted to detect the histological and immunological changes in experimental rat’s lung infected by different routes with *K. pneumoniae*.

Twenty-seven Albino Swiss male rats (Rattus rattus) were infected with 0.2ml of *K. pneumonia* suspension in different routes. After seven days from the last injection *K. pneumoniae*, the Lung and spleen are examined for histopathology changes. The blood vessels congestion with dispersed lymphocytic cells, infiltration throughout pulmonary parenchyma parts, edema formation along with hemorrhages Early neutrophils distribute into the Broncho-alveolar space, were detected. An acute splenitis was present in rat’s infection by left lung injection route after 10 days, were observed in the Spleen tissue with mild white pulp within pulp hyperplasia.

What makes *K. pneumoniae* infections more difficult to treat is that they gradually became more virulent and antibiotic resistant through time. The early *K. pneumoniae* infection -induced secretion of tumor necrosis factor alpha as pro-inflammatory cytokines. The level of cytokines has been related to severity of pulmonary inflammatory process. TNF-α is important for the acute phase response as proinflammatory responses.

**Keywords**: Acute lung injury, acute splenitis and TNF-α.

Introduction

*K. pneumoniae* is a gram-negative, non-motile, rod-shaped, lactose-fermenting, facultative anaerobic bacteria with a prominent polysaccharide capsule. Some strains of *K. pneumonia* have been implicated in bloody diarrhea, such cases became not easily treated as a result of the developing capability of *K. pneumonia* to resist the effects of various antibiotics (1).

*Klebsiella* known of their ability to produce enterotoxin that is heat stable and can be considered as a cause of their pathogenicity, the major virulence factors of *K. pneumonia* which play essential roles in pathogenesis include capsular polysaccharide, lipopolysaccharide, type 1 and type 3 fimbriae, and siderophores (2).

Recently, *K. pneumoniae* are emerging worldwide as a Leading cause of nosocomial infections, including pneumonia, bacteremia, urinary tract infections and wound infections (3). *K. pneumoniae* causes the pneumonia disease which is recognized by an excessive macrophage and neutrophil infiltration associated with exacerbated inflammatory response, severe lung injury and high production of pro-inflammatory cytokines (4).

Local inflammation gives an advantage in such infections by avoiding pathogen spreading, long lasting hyper-inflammation usually comes together with death and chronic inflammatory disorders (5).

Other researchers determined that *Klebsiella pneumoniae* taken from bloody diarrhea has the ability to bind to cytoskeletal proteins and Henrietta lacks
cells, such as the actin that gathers at the bacterium-host contact point (6).

Antibiotic resistance of G- bacteria is related to raising death, long periods of hospitalization and hospital expenses (7). *Klebsiella pneumoniae* and other species may inhabit the pharynx, intestinal tract and the skin of humanand it also colonizes in urine, sterile wounds and might presents as normal flora in many organs such as the intestine, biliary tract and colon (8).

TNF-α(cachectin) has significant functionality as an antitumor, inflammation, anorexia, immune modulation, viral multiplication, cachexia, septic shock and platelets agglutination. Many factors stimulating the secretion of cachetin by macrophages such as bacterial infection and it can be produced by many other types of cell such as NK cells, CD4<sup>+</sup> lymphocytes, mast cells, neutrophils, eosinophils, and neurons (9).

Biofilm of *K. pneumoniae* that is found on Contaminated medical devices such as catheters is the major cause of infections in catheterized patients (10). *K. pneumonia* is a major cause of bacteraemia, and abscesses. These infections may be nosocomial, healthcare-related or community-acquired (11).

**Materials and Method**

The specimens were collected carefully ways to avoid contamination. The specimens were transported by sterile transport swabs to the bacteriological laboratory, and each specimen was inoculated on blood agar, MacConkey agar, then inoculated at 37°C under aerobic condition for 18-24 hrs.

**Culture of Clinical specimens**

The bacterial sample was obtained by taking a colony from MacConkey and blood agar and repeating it’s growth to gain a pure culture and was diagnosed according to it’s cultural and morphological characteristics, microscopic characteristics after Gram’s stain, then further identified by biochemical tests (12). The final identification was performed with automated VITEK-2 compact system using G-ve ID cards.

**Animals Study:**

Twenty-seven Albino Swiss male rats (*Rattus rattus*) were used as the experimental animals. their ages ranged between eight to ten weeks and 230-270 g in weight. Rats were divided into three groups as following:

**Group A:** 3 rats treated with normal saline as control suspension.

**Group B:** 12 rats were infected with 0.2ml of *K. pneumonia* suspension in different routes. 3 rats infected orally, 3 rats infected intranasal, 3 rats intra-dermally and 3 rats infected inklung.

**Group C:** 12 rats infected with *K. pneumonia* and divided in to four sub-groups to treated with antibiotics (Tetracycline, Ciprofloxacin, Amoxicillin, amoxicillin and ciprofloxacin).

**Histopathological examination**

Lung and spleen were removed after seven days from the last injection and fixed in 10% formalin in PBS for 24 h, dehydrated in ethanol, cleared with xylene, infiltrated and embedded in paraffin. The histological section is cut with rotary microtome. Without knowing the origin of the tissue slides, hematoxylin and eosin stained slides were scored by a pathologist for inflammatory parameters. The sections are conveyed into water bath (52°C) to plain the tissues then fixed on slides containing Glycerin-Albumin mixture, as a thin film and placed for drying in the oven at 40°C for 24 hrs. Harris hematoxylin and Eosin are used in the tissue section staining while Southgate’s Mucicarmine and Periodic Acid Schiff-(PAS) stains are used to stain the polysaccharide capsule according to (13). Then Paraffin-embedded sections from each specimen are cut into 3-5 μm thick, sections are placed on positively charged slides, and left over night to dry at room temperature, or put slides in oven 60°C for 60min for Dewaxing. according to (14). The Slides are deparaffinized by heating in an incubator at 37°C Cover night.

**Immunological Assay:**

TNF-α was measured in serum, plasma and other biological fluids of rats by Sandwich enzyme-linked immunosorbent assay. the ELISA kit are prepared according to the manufacturer’s instructions.

**Statistical Analysis**

All statistical analysis was performed by using SPSS v.24 software program. Also, it was drawing histograms by Microsoft Excel 2013.

**Results**

**Samples collection and examination:**
140 clinical specimens were collected from stool, urine, burns, wounds and bone inflammation. 115 specimens are positively bacterial growth (18 specimens are *k. pneumonia*, 97 specimens are other types of bacteria) and 25 specimens were not growth. Only 10 *k. pneumonia* isolates were obtained from urine and 8 *k. pneumonia* isolates were obtained from stool. The initial identification of bacteria depended on some characteristics such as morphological colonies, Grams stain, and biochemical diagnosis.

**Histopathological examination after induce infection by *k. pneumonia* from different infection routes:**

In present study, there was significantly (p < 0.05) between different infection routes (Intranasal, Left lung, Orally, and Intra-dermal), *K. pneumonia* causes acute inflammation in the rats lungs through the intranasal and left lung routes. See figures (1, and 2).

The microscopic examination of lungs showed normal histological features (normal alveoli and interstitial parenchyma portion’s) in control group, whereas infected group by *K. pneumonia*, the lung sections showed pathological changes in the rats lung, which is characterized by blood vessels congestion with dispersed lymphocytic cells, infiltration throughout pulmonary parenchyma part’s, lymphocytes are distribute in the pulmonary tissue, and lymphoid aggregates, edema formation along with hemorrhages, congestion.
and severe lymphocyte and macrophage infiltration were detected. Histological examination exposed that at 10 days after injection of *K. pneumonia*, the rats had moderate to severe multifocal bronchopneumonia characterized by a cellular infiltrate composed almost exclusively of neutrophils and a few macrophages. These cells filled alveolar and bronchiolar spaces of affected areas. Alveolar spaces at the margin of a lesion were filled with eosinophilic proteinaceous edema fluid.

**The comparison between types of cytokines with different infection routes**

The comparison between different cytokines types with route infections showing TNF-α, IL6 and IL10 levels was different increases in *K. pneumonia* dose $10^5$ CFU/ml in comparison to infection routes and slightly significant increased other level compared to control group, selection left lung injection and intranasal routs continuously research and experiments working as showed in Table (1).

**Histopathological observations after infection by *K. pneumonia* from different infection routes and treatment by different antibiotics:**

A histological study showed that the intranasal and intraperitoneal routes of infection with *K. pneumonia* have caused pathological changes in the lung tissues, which is characterized by congestion of blood vessels with dispersed lymphocytic cells, infiltration throughout pulmonary parenchymal components, lymphocytes are distribute in the pulmonary tissue with blood vessels blocking, and lymphoid masses(Figures 3 – 4).

Discussion

One of four scores was the lung pathology which was assigned according to their severity of inflammation as follows: 1- mild focal inflammation, 2-normal histology, 3- moderate to severe focal inflammation with areas of normal tissue, 4- severe inflammation to necrosis (15).

K. pneumoniae is a vital cause of community-acquired and nosocomial infections, so gaining attention due to the high morbidity and mortality rates and the rising number of resistant strains to the antibiotic effects (16)(23).

Lungs considered as important organ of respiratory system, is susceptible to many agents smoking, genetics, and microbial infection that are responsible for numerous pathological conditions (17).

Pulmonary infection can cause a number of histological changes in the architecture of lung, as well as in the extrapulmonary organs as in the case of bacterial dissemination via blood stream, and these changes can impact the result of disease (18).

Pulmonary infection can cause a number of pathological changes in the lung, as well as in the extra-pulmonary organs as in the case of bacterial dissemination, and these changes can impact the outcome of disease. One of the greatest limitations to the study of microbial virulence factors is the availability of relevant animal models (19).

The present study, states that TNF-α has considerable differences in levels between control and study groups and significant differences between these groups that are shown in table (1) In comparison with (20) who found significantly increased levels of TNF-α in groups of animals under acute stress and chronic mild stress due to bacterial LPS compared to non-stressed control groups.

TNF-α is a major pro-inflammatory cytokine mediate the development of many inflammatory lung diseases and its concentrations significantly higher 4 to 6 fold after 6 and 24 hours respectively from infection (16). Moreover, TNF-α mediate lung inflammatory diseases by enhances macrophage inflammatory protein, KC secretion, play an important role in the up-regulation of cellular adhesion molecules, vasodilatation and increasing the vascular permeability (21).

TNF-α, IL-1β and IL-6 main functions are to attract neutrophils to the site of inflammation, induce the acute phase response, i.e. starting inflammatory processes such as production of APPs in the liver. Stimulated macrophages by (lipopolysaccharide LPS) secret wide array of proinflammatory cytokines such as TNF-α, IL-1β, IL-6, and IL-8 (22).
Conclusions

*Klebsiella pneumoniae* infection and lung diseases are important topics regarding public health interest. Neutrophils are one type of the first innate immune cells recruited to the site of infection to prevent bacterial colonization and clear bacteria.

Abstract

Objectives: The purpose of this in vitro study was to evaluate post-cementation vertical marginal seating of full contour zirconia crown restorations using different finish line designs (deep chamfer and shoulder) with different occlusal reduction schemes (planar and flat).

Materials and Method: Thirty-two sound maxillary first premolar teeth freshly extracted for orthodontic purposes were collected to be used in this study. Teeth were divided into two main groups according to the design of finishing line used (n=16): Group A: Deep chamfer; Group B: Shoulder. Each group was then subdivided into two subgroups according to the scheme of occlusal reduction used (n=8): (A₁, B₁) Planar; (A₂, B₂) Flat. Standardized preparation for full contour zirconia crown restorations was carried out with finishing lines depth 1.0 mm, total convergence angle of 6 degrees and axial height 4 mm (buccally and palatally).

Results: The results of this study showed that there were statistically highly significant differences among different groups (p < 0.01) using one-way ANOVA analysis and Student’s t-test. Additionally, comparison of significance between each pair of subgroups at pre and post-cementation intervals using Paired-Samples t-test showed a statistically highly significant differences.

Conclusions: Deep chamfer with planar occlusal reduction scheme provided better marginal fit compared to that obtained with shoulder. On the other hand, shoulder with flat occlusal reduction scheme provided better marginal fit compared to that obtained with deep chamfer. Concerning the effect of the cementation procedure, the marginal gap was increased post-cementation as compared with the pre-cementation gap for all subgroups, but still within the clinically acceptable limit.

Key words: Chamfer and shoulder finishing line, Digital impression, Full contour zirconia, Marginal fit, Planar and flat occlusal reduction scheme.

Introduction

The success of all ceramic restorations strongly depends upon marginal adaptation. A well fitted margin is expected to reduce plaque accumulation, recurrent caries which result in damage to the tooth with its supporting periodontium, and potentially decreases the longevity of the restoration (¹). The clinically acceptable limit of the marginal discrepancies is reported to be less than 120 μm (²).

One of the CAD/CAM technology is a digital impression which provides speed, accuracy, high quality of restoration as its designing is based on materials characteristics, ability of storing captured information indefinitely and transferring digital images between the dental office and the laboratory (³).

The designs of tooth preparation can affect the success of the crown restoration (⁴). Cementation of an indirect dental restoration is the final step after finishing all the clinical and laboratory stages and it is considered
to be an equally important stage that can affect the longevity of the restoration (5).

**Materials and Method**

Thirty-two sound human maxillary first premolar teeth of comparable size and shape extracted for orthodontic purposes were selected and collected to be used in this study.

The teeth samples were divided into two main groups according to the design of finishing line used (n=16):

- **Group A**: Deep chamfer design.
- **Group B**: Shoulder design.

Each main group was, then, subdivided into two subgroups according to the scheme of the occlusal surface reduction (n=8):

- **Subgroup A₁ & B₁**: Anatomical occlusal reduction.
- **Subgroup A₂ & B₂**: Non anatomical occlusal reduction.

All the teeth were prepared for full ceramic crown restorations with the following preparation features: A total convergence angle of 6 degrees, the depth for both deep chamfer and shoulder finishing line of 1.0 mm and a standardized axial height of 4 mm (buccally and palatally), these dimensions were checked using a modified digital caliper (Fig. 1).

After an axial reduction of each tooth according to its respective group, occlusal surface of all teeth was prepared with diamond wheel to produce flat occlusal reduction scheme. According to the scheme of occlusal surface reduction, all teeth samples in subgroups A₁ and B₁ received further occlusal reduction to change the design into planar using rugby ball bur. All sharp angles or internal line angles were rounded to prevent stress concentration on the crown restoration.

A three dimensional digital image for each tooth sample was taken by AC Omnicam intra-oral scanner (Sirona Dental Systems, Bensheim, Germany) (powder free). Full contour zirconia crown restorations were then fabricated using In-Lab MC X5 milling device used (Sirona InCoris TZI C blank).

A custom made holding device was especially fabricated in this study to be used during seating of the zirconia crown, it serve as a screw that secured the zirconia crowns to the natural tooth sample. Furthermore, it hold the specimens on the horizontal table of the microscope to allow for viewing the references points during measurement of vertical marginal gaps (Fig. 2).

The measurements were made at two intervals (before and after cementation) at four points determined...
on each surface of the tooth (two at the edges of the line, two points drawn in the mid of the surface by permanent marker, while the other two points were at a distance of (1mm) from the previous one, on both (left and right sides). Sixteen measurements were obtained from each tooth sample; highest one was selected to represent the maximum marginal gap of that sample \(^6\) (Fig. 4).

Figure 4: Four points of measurement at a magnification of 50X.

The measurement of the marginal gap of four different points at four areas (mid-buccal, mid-mesial, mid-distal and mid-palatal) was used by Khdaier and Ibraheem (2015) \(^7\) and Abdulkareem and Ibraheem (2016) \(^8\).

Statistical methods were used in order to analyze and assess the results included:

- Descriptive statistic.
- Inferential statistics.

1. One-way ANOVA (analysis of variance).
2. Paired-Samples t-test.

### Results

Table (1) showed the descriptive statistics of vertical marginal gap for the four subgroups measured in \(\mu\)m at pre and post cementation intervals. At Pre-cementation interval, the table showed that the lowest mean of vertical marginal gap values was scored by subgroup \(A_1\) (38.837±9.30), while the highest mean of vertical marginal gap values was belonged to subgroup \(B_1\) (66.636±8.57), however on the other hand, at Post-cementation interval, the table showed that the lowest mean of vertical marginal gap values was scored by subgroup \(A_1\) (79.281±10.25), while the highest mean of vertical marginal gap values was belonged to subgroup \(B_1\) (110.082 ±9.63).

Paired-Samples t-test was applied in (Fig. 5), showed that there was highly significant differences between the subgroups, this mean that cement have significant negative effect on the amount of vertical marginal gap of the crown restorations.

Discussion

The results of this in vitro study showed statistically highly significance difference but still within the clinically acceptable limit (<120 µm) for all tested subgroups. It is worth to mention that when reviewing the available literature, no previous studies concerning the effect of both finishing line designs with different occlusal reduction schemes on the marginal fit of full contour CAD/CAM zirconia crown restoration was found.

Statistical analysis of the results of this study showed that the teeth prepared with deep chamfer finishing line and planar occlusal reduction showed less mean marginal gap values than teeth prepared with flat occlusal reduction. This might be due to that the occluso-axial line angle is a right angle in the case of flat occlusal reduction scheme that may impede proper seating of the crown restoration.

However, the phenomenon was the opposite when the finishing line changed to the shoulder design where the mean marginal gap values of the teeth prepared with flat occlusal reduction was less than of that teeth prepared with planar occlusal reduction. This might be due to that the flat occlusal surface might produce smaller surface area than that produced with planar occlusal surface which might lead to even distribution of the load that going to be applied on the crown restoration during seating.

Furthermore, teeth prepared with shoulder finishing line and flat occlusal reduction showed less mean marginal gap values than the teeth prepared with deep chamfer finishing line. This might be due to that the force applied on the axio-gingival angle of the shoulder design was perpendicular on the surface of the margin, while in the chamfer design the force applied at the line angle of that surface was smaller and the applied pressure was thus smaller, so the seating of the crown restoration was not as good as in the shoulder design.

In addition to that, the teeth prepared with deep chamfer finishing line and planar occlusal reduction showed less mean marginal gap values than the teeth prepared with shoulder finishing line. This might be due to that deep chamfer finishing line design has a more round angle between the axial and gingival seat which enables more accurate seat for the crown restoration. Furthermore, the stress concentrated at the area of the finishing line during the crown seating is more evenly distributed. This is in total agreement with what has been stated by Rosenstiel et al. (2016) (9) stated that “The occluso-axial line angle of the tooth preparation should be a replica of the gingival margin geometry”. In addition this is total agreement with: Wostmann et
al. (2005) (10) concluded that the lowest mean value of marginal gap was obtained for the chamfer preparation, while the 90° shoulder finishing line always produced the highest mean value. Comlekoglu et al. (2009) (11) reported that the cervical finish line type had an influence on the marginal adaptation of the tested zirconia crown restorations. This is also in agreement with Alzubaidy and Alshamaa (2015) (12) stated that the deep chamfer finishing line is more preferable than shoulder finishing line for full contour CAD/CAM zirconia crown restorations.

However, this disagrees Subasi et al. (2012) (13) revealed that the finish line design had no influence on the marginal adaptation of zirconia crown restorations.

On the other hand, the quality of the three dimensional image of a tooth preparation might be a factor that affect the marginal adaptation of the final crown restoration (14). The scanning accuracy have the limitation of finite resolution; which can result in edges that are slightly rounded and leads to interfering contacts at the incisal/occlusal edges (15). Furthermore, Reich et al. (2005) (16) reported the scanning system that depend on optical impression, experience problems with rounded edges and positive error (which simulates virtual peaks near the edges, so-called ‘over-shooters’). The ‘rounded edges’, “point clouds” and ‘over-shooters’ phenomena have been described for the CEREC intraoral camera. In addition, the scanning process based on the principle of “not at the same plane surface” that is obtained in the scanning area were the scanning process transformed into smooth continuous surface (17).

Kunii et al. (2007) (18) reported the anisotropic shrinkage of zirconia blanks during construction procedure might play a role in the vertical marginal gap of different subgroups in this study, as a result, sintering shrinkage in the vertical axis was smaller than that in the horizontal axis due to this shrinkage property.

Effect of cement

The result of this in vitro study showed that the luting cement and cementation procedure play an important role in the final accuracy of the marginal fit for all ceramic crown restorations and this clearly shown when compare the result of pre-cementation with that recorded of post-cementation for all tested subgroups. Furthermore the statistical analysis of the results has proven the presence of those significant differences between each two subgroups at these two intervals.

The closing angle between tooth preparation and restoration becomes smaller, the flow of the cement is inhibited and its escapement becomes more difficult. Resin cement increased viscosity too rapidly to flow toward the cervical area and extruded from the margins of the crown, this will create the problematic discharge of excess cement and hydraulic pressure that is going to push the cement upward, this will result in great amount of luting cement to be accumulated on the occlusal surface of the prepared tooth that might interfere with proper seating of crown restoration after cementation procedure (19).

The luting cement and cementation procedure play an important role in the final accuracy of the marginal fit for all ceramic crown restorations, so, the marginal gap values were increased significantly post-cementation but within the limits of clinical acceptability (<120 μm), this is in total agreement with other previous studies: Okutan et al. (2006) (20).

Effect of the Different Disinfectants on the Microbial Contamination of Alginate Impression Materials

Haider M. A. Ahmed¹, Rawof Rasheed Jawad², Mohammed Nahidh¹

¹Department of Orthodontics, College of Dentistry, University of Baghdad, Iraq. ²Department of Prosthodontics, College of Dentistry, University of Karbala, Iraq.

Abstract

Objectives: This study aimed to evaluate the efficacy of different solutions used to disinfect Alginate impression material.

Materials and Method: Twenty Alginate impressions for the maxillary arch of five patients recently completed their treatment (four impressions for each patient) were taken swabbed before and after disinfecting them with Chlorhexidine, Desident CaviCide and Alcohol and one just washed with tap water as a control. Swabs were cultured to detect bacteria and fungi and count them.

Results: Only Streptococcus bacteria were detected with no fungal contamination. Tap water reduced the bacterial count while other disinfectants killed the bacteria completely.

Conclusions: Chlorhexidine, Desident CaviCide and Alcohol can be used to disinfect the dental impression effectively.

Key words: Disinfection, infection control, dental impression.

Introduction

There is a great danger nowadays about transferring of infectious organisms to the workers in dental field’s treatment as orthodontists, prosthodontists, oral surgeons and their assistants whom dealing with dental impression for patients required prosthesis ¹, ².

Disinfection can be defined as the procedure that kills vegetative organisms, in the same context; sterilization is the procedure of terminating spores too³.

There are many researches that study the effect of different disinfectant on irreversible hydrocolloid dental impressions and they monitor that effect on the measurements of the dental cast produced from a disinfected impression ⁴, ⁵.

Alcohol is not highly recommended for sterilization since it lacks the sporicidal activity while it works well in the category of antimicrobial activity against bacteria, fungi and viruses (cell lysis and proteins denaturation) in the range of 60-90% but it demonstrates low activity below 50% ⁶.

Chlorhexidine had a wide range anti-microbial activity against many micro-organisms. Jani et al. ⁷ in 2010 used chlorhexidine from different manufacturers to disinfect alginate dental impressions and found that Corsodyl was the most potent one in killing Streptococcus Mutans and Lactobacilli.

Desident CaviCide is a disinfected solution with broad anti-microbial activity used in recent Iraqi study to disinfect the contaminated clamping tweezers. It showed potent antibacterial activity but poor antifungal effect ⁸.

This study aimed to test the effect of different solutions in disinfecting irreversible hydrocolloid alginate dental impressions.
Materials and Method

Sample

Five orthodontic patients (3 males and 2 females), whose had just finished their orthodontic treatment that lasting more than 12months, will be carefully selected with fair oral hygiene and full complement permanent teeth.

Method

The patients or patients’ parents were asked for permission to participate in this research and a written consent form was signed by the patient or the parent. A total of 20 alginate impressions were taken (four maxillary dental impressions taken successively for each patient) using Hydrogum soft mint scent alginate, Zhermack, Germany). Alginate was mixed according to manufacturer instructions (2 spoons 18 gm mixed with 2 levels 36 ml of water loaded into a disposable dental tray and left to set for two and half minutes). The impressions were grouped according to the disinfectant used as followed:

Group A: represented the first impression that will be taken, swabbed (A1) then washed with running tap water and swabbed again (A2).

Group B: represents the second impression that will be taken, swabbed (B1) then washed and immersed in Desident CaviCide (Spofa Dental Co., Czech Republic) for five minutes and swabbed again (B2).

Group C: represents the third impression that will be taken, swabbed (C1) then washed and immersed in Alcohol 96% (Teeba Co., Iraq) for five minutes and swabbed again (C2).

Group D: represents the fourth impression that will be taken, swabbed (D1) then washed and immersed ten minutes in Corsodyl (Chlorhexidine 0.2%, Omega Pharma Manufacturing GmbH & Co. KG, Germany) mouth wash and swabbed again (D2).

The surface of each impression was swabbed with sterile cotton swab and dipped in normal saline then sent to the laboratory for incubation and culturing on three agar media Blood agar, McConkey agar, and Sabouraud dextrose agar (Hi-Media Co., India) to detect the aerobic and facultative anaerobic bacteria of both types Gram positive and negative, in addition to candida species before and after disinfections using manual colony forming counting.

Statistical Analyses

Data were managed statistically using SPSS version 25 software. Means, standard deviations were obtained for each disinfection solutions in addition to the tap water.

Findings

Table 1 showed the means and standard deviations of the colony forming units of Streptococcus bacteria isolated from five successive dental impressions of the five patients.

Generally, the highest CFU was decreased after washing in tap water but still there is growth in contrary to other disinfectants that kill all bacteria. No fungal contamination was detected.

Discussion

One of the major infection control procedure in the dental practice is disinfecting the dental impressions as the microorganisms can be transmitted effortlessly by saliva and blood to the dental staff and technicians, so a high standard of hygiene and disinfection of dental equipment, including dental impressions is recommended.

Generally, chemicals are broadly used in dental practice because of their easy application although their actions is influenced by many factors like the numbers and types of the organisms, disinfectant concentration, presence of blood and mucus which act as a insulating layer preventing the disinfection from contact with surface, time of contact with the disinfectant and the nature of the surface weather it is porous or not.\(^9\)

In this study swabs from Alginate dental impression materials were obtained from five successive impressions for five patients completed their fixed orthodontic therapy that lasts more than one year. The main aim of this study was to evaluate the efficacy of different agents in disinfecting the dental impressions. Tap water was used as a negative control and had been tested previously in two studies\(^7,11\), while Desident CaviCide is tested for the first time in this study. It possessed wide range anti-microbial activity in short period of exposure reaching to 30 seconds.

Immersion not spraying technique of disinfection is used to ensure uniform contact between the disinfectant and dental impression. Disinfection with spraying method decreases the possibility of distortion, particularly in hydrocolloids impression materials, but will not reach the areas of undercuts and may releases air that leads to occupational exposure\(^10\).

Correia-Sousa et al.\(^12\) found a 48.5% reduction in the microbial load after washing alginate impression with tap water. The present study reported lesser percentage of reduction (Table 1). Jani et al.\(^7\) reported that tap water fail to kill the Streptococcus Mutans and Lactobacilli while Chlorhexidine kill Streptococcus Mutans completely. Chlorhexidine is a positively charged molecule that binds with the negatively charged sites of the bacterial cell wall so interferes with the osmosis. Moreover, it assaults the cytoplasmic membrane and leaks the components that lead to cell death. It has been shown that Chlorhexidine at high concentration of 2% demonstrated antimicrobial activity against S. aureus, E. coli, and B. subtilis, but not C. albicans\(^13\).

Desident CaviCide contains low concentration of Alcohol and enable to inactivate the bacterial growth in the impression by alkylating the amino and sulfhydral groups of bacterial proteins, the present findings come in agreement with that of other studies\(^8,14,15\).

Isopropyl alcohol has high bactericidal activity in concentration as high as 99% but is relatively inefficient in the presence of blood and saliva. It lacks sporcidal activity and also causes corrosion of metals. Ethyl alcohol has more bactericidal than bacteriostatic activity in addition to tuberculocidal, fungicidal, and virucidal activity against enveloped viruses but has no effect against bacterial spores and non-enveloped viruses. They work by denaturation the bacterial proteins and lipids and leads to cell membrane disintegration so, inactivating the microorganisms. The optimum bactericidal concentration in water is 60% to 90%, and the lethal activity falls when diluted below 50% concentration. Ethanol has shown clear bacterial growth inhibition, especially when used in high concentrations against S. mutans and S. aureus\(^16,17\). In this study, Alcohol was used in a concentration of 96% and it as able to kill all detected bacteria (Table 1).

In a previous study, Mohammed et al.\(^11\) tested the effect of sodium hypochlorite, Biosanitizer M and Zeta plus 7, used as disinfectant for Alginate impression materials, on the teeth and dental arch measurements and the results proved non-significant effect. Further studies are needed to check the efficacy of the tested disinfectants in this study on the viral and fungal contaminations and their effect on the dimensional stability of the resultant model.

Conclusions

Disinfecting dental impressions is far important procedure to control the transmission of microorganisms among the dental staff. Tap water was able to reduce the microorganism while Desident CaviCide, Alcohol and Chlorhexidine eradicated the bacteria completely.

Role of Respiratory Syncytial Virus and Some Bacteria Causes Tonsillitis among Children Under 5 Years Old in Duhok City

Najat Abdeal-Qadir Zaman¹, Asma Sumiea Karomi¹, Nora Esam Aldeen Mahmood¹
¹Department of Biology, College of Science, University of Kirkuk

Abstract

Background: Acute infection of the respiratory tract is a prevalent cause of death in children under the age of 5 years, particularly in developing nations. Infection with respiratory syncytial virus is a causative factor for bacterial co-infection with an increase in the incidence of respiratory disease.

Objective: This research was intended to clarify the connection between the Respiratory Syncytial Virus RSV and the tonsillitis-causing bacteria.

Method: In 120 patients with acute and chronic tonsillitis, swabs were obtained from the tonsils to detect pathogenic and commensal bacteria in the throat, and blood samples collected to identify RSV infection by identifying the antibody value in the serum.

The results: Culture results showed that 78.53% of the bacteria isolated belonged to the Gram-positive group and that only 21.47% belonged to the Gram-negative group, (51.98%) were positive for pathogenic bacteria while (48.02%) were positive for commensal bacteria and showed the highest rate of pathogenic bacteria isolated from tonsillitis patients was to Staph. aureus and Strep. pyogenes. Serological testing using ELISA showed that respiratory syncytial virus infection increases tonsillitis co-infection. Type of antibodies showed a change depending on the sex group and the stages of immune response maturity.

Key word: Respiratory syncytial virus RSV, Tonsillitis, Bacteria, ELISA, Co-infection, IgG, IgM.

Introduction

Recently, acute respiratory tract infections (ART) have been found to be among children’s most common disease. Recent research by the World Health Organization (WHO) has shown that acute respiratory infections are responsible for 22% of child deaths. Under the age of five, which represents more than 2 million children, 99% of these deaths happen in developing nations, the primary cause of which is RSV (1).

ARI can be categorized into two kinds depending on its anatomical place: upper respiratory infections and lower respiratory infections. The most prevalent infectious diseases such as rhinitis (common cold), sinusitis, ear infections, acute pharyngitis, and tonsillitis are acute upper respiratory infections. Infections of the ear and pharyngitis lead to more serious problems such as acute rheumatic fever and deafness (2).

A community of mucosal dwelling microorganisms (the microbiota) colonizes the healthy URT, which includes both commensals and prospective pathogens kept under host immune system control. There is growing evidence that viral respiratory infections can significantly increase bacterial load (3).

In children as well as adults, many viruses and bacteria can cause pharyngitis and acute tonsillitis. About 75% of pharyngitis is caused by viruses (4). Group Aβ hemolytic Streptococci and Staphylococcus aureus are one of the primary causes of tonsillitis, particularly in the event of acute and chronic tonsillitis (5,6).

Physiologically, the lower respiratory tract is usually sterile. However, there is a prevalent connection between bacterial infection and respiratory infection,
and bacterial co-infection development enhances the severity of infection \(^\text{7}\).

The RSV virus is one of the most frequently recognized variables in young children with ARI and is the main reasons for hospital admission. Where the elevated incidence of RSV infection is a severe result of increasing the risk of RSV-associated hepatitis infection among children \(^\text{8}\).

Studies have shown that some respiratory viruses alter the colonization of bacteria and increase the likelihood of secondary bacterial diseases. The immune response to respiratory viruses may rely on certain bacteria spreading \(^\text{9}\).

Antibodies have a major part of protective immunity and that cellular immunity is important for clearing the infection. The protective contribution of antibodies in human disease is probably best demonstrated by the interconnection between Superior levels of maternally acquired antibodies and less serious disease in infants and the ability of high tittered RSV intravenous immunoglobulin (Ig) to decrease the risk of serious disease when administered prophylactically \(^\text{10}\). Therefore, the objective of this study was to detect the role of Respiratory Syncytial Virus and some bacteria in children causing tonsillitis and to identify the relationship between RSV infection and secondary bacterial colonization.

### Material and method

The groups in this study consisted of 120 throat swab and serum samples from acute and chronic tonsillitis patients and 30 people were collected as a control group at the Hivi Pediatric Teaching Hospital in Duhok city. For the period from the middle of December (15/12/2018) to the beginning of April (8/4/2019) and for children less than five years age for both sexes. Ethical approval for this study was obtained from Duhok Directorate General of Health, Department of planning, Scientific Research Division. (Approval reference number /27112018-9). The samples were taken with a swab from the tonsils. Were cultured on blood agar, MacConkey agar and chocolate agar and incubated at 37°C for 24-48 hours \(^\text{11}\). The growth diagnosed using biochemical tests and the Vitek 2 compact system 5ml venous blood was collected from all patients. Blood was placed in a test tube and Centrifuge and immediately stored in an Eppendorf tube and frozen at -20°C until assayed for serological diagnosis of RSV (Respiratory syncytial virus) was assayed by EIISA kits which performed according to the instruction of the manufacturing company (Vircell company Spin).

### Results

</table>
In this study, the rate of pathogenic bacteria was (51.98%) which represent 92 isolates, while commensal bacteria represent 85 isolates with rate 48.02%. The most common types of pathogenic bacteria which causes tonsillitis in children are *Staph. aureus* 25.99% and *GAβ hemolytic Streptococcus pyogenes* 20.33% which have been found to be Co-infection in cases of respiratory Syncytial Virus.

**Discussion**

The development of the immune response in children depends on the early exposure to respiratory viruses and bacteria, where acute viral respiratory infections lead to increase the readiness for bacterial infection (12).

This study included the collection of 120 throat swabs and serum samples from children with respiratory diseases and recorded bacterial co-infections with the RSV which was diagnosed by measuring IgG and IgM and there are different types of gram positive and gram negative microorganisms were detected by throat swab culture of which gram positive bacteria constituted (78.53%) and gram negative one were (21.47%); these findings of bacterial percentage goes with that of (4,5). These results agreement with (13) Which indicated how severe diseases like infant virus acute respiratory infections can help us better comprehend secondary bacterial infections and long-term respiratory results of predisposition. In a study conducted by (9) they postulate that local bacterial ecosystems modulated the immune response of the host to RSV infection severity.

The results of serological diagnosis of RSV infection indicate that the highest rate of RSV-IgG was found in male tonsillitis patients, while 38.23% was found in females. The highest rate of RSV-IgM was found in male. Also, the highest rate of both RSV-IgG and RSV-IgM together was found in male tonsillitis patients, our results agreed with the results of (14) in terms of numbers of infected males, That was greater than females. This is in line with some research on gender relationships which suggest that the reasonable to compare immune reactions among males and females because many early-stage infections predominate among males (15). In our study, the limitation includes the small cohort size. Because of this study’s restricted cohort size, substantially induced immunological factors following RSV infection Could have been undervalued. Following the outcomes of this research, in-depth research would elucidate real protein correlates against RSV diseases by following a bigger cohort, particularly examining the correlation of clinical seriousness and immunological variables. Thus, in this study gender-specific antibody response profiles against RSV infection are considered as a hypothesis, and should be confirmed by further clinical data in future study.

In the present study, 177 bacterial isolates were obtained (51.98%) of which were pathogenic bacteria and (48.02%) were commensal bacteria. These results were agreed with (16) who obtained (55%) pathogenic bacteria, while (34.2%) were found with similar study in KSA (17).

The microbial content of the infant’s pharynx is usually low (18). The isolate of *Staphylococcus aureus* was proved to be the major causative microorganism of tonsillitis which constituted (25.4%) of total isolates. While the rate of *strep. pyogenes* are 20.33%, which represents 36 isolates. These results agreed with (4,5) and other studies (6,19) have described *Staphylococcus* is one of the most predominant genera, while (20,21) reported that main tonsillitis factors were *Strep. pyogenes*, followed by *Staph. aureus*.

The structure of airway microbiota is extremely vibrant and various environmental factors have been shown to affect colonization patterns. Vaccinations and antimicrobial use, as well as exposure to tobacco smoke, may result in changes in the airway microbiota (22).

**Conclusion**

Our results suggest that 41% of respiratory tract viral infections, which caused by RSV are associated with different microbial profiles that causes tonsillitis.

Broad-Spectrum Cytotoxic Effect of *Calendula officinalis L* Against Breast Cancer Cells

Khulood M. Alsaraf¹, Maeda H. Mohamed¹, Ahmed Majeed Al-Shammari², Ibrahim S. Abbas³

¹Pharmacy department, Al-Esraa University College: Baghdad, Iraq, ²Experimental Therapy Department, Iraqi Center for Cancer and Cancer and Medical Genetic Research, Mustansiriyah University, Baghdad, Iraq, ³Department of Pharmacognosy and Medicinal Plants, College of pharmacy, Mustansiriyah University, Baghdad, Iraq

**Abstract**

**Background:** *Calendula officinalis L* used in Iraqi folklore medicine for several medical applications. This research evaluated the leaves extract as an anti-breast cancer agent in in-vitro cancer cell line systems and studies its active compounds. Crystal violet viability assay was used to determine the cytotoxicity of the leave methanolic extract of *Calendula officinalis L* against diverse breast cancer cell lines. Human breast cancer MCF7, AMJ13, MDAMB, and CAL51 cells were treated with different concentrations of extract for 72 hours. Morphological study for the exposed cell was done by examination under a phase-contrast inverted microscope. High-performance liquid chromatography (HPLC) analysis was performed to measure the concentrations of each component of phenols and flavonoids in the *Calendula officinalis L* extract.

**Results:** It was found that methanolic extract of *Calendula officinalis L* inhibits the proliferation of all breast cancer cells significantly at the meantime; it does not affect normal embryonic cells. Additionally, it induced the cytopathic morphological changes in cancer cells. Furthermore, HPLC study revealed that *Calendula officinalis L* extract contained an important component of flavonoids. **Conclusions:** *Calendula officinalis L* leaves extract inhibited the proliferation of breast cancer cells especially MDAMB cells with no effect on normal cells. This work showed that *Calendula officinalis L* is a possible natural source as broad-spectrum anti-breast cancer drug.

**Keywords:** Cytotoxicity; HPLC analysis; Flavonoids; Iraq; Clonogenic assay

**Introduction**

Cancer disease is a highly complex condition that hard to treat (1). Its incidence is increased globally and especially in Iraq due to several factors mainly related to environmental pollution for several years of war conflicts (2). Breast malignant tumours are ranking second causing of mortality in Iraqi females. Conventional cancer treatments such as chemotherapy, radiation, targeted therapy; immunotherapy, etc, have their unwanted side effects. Therefore, herbal medicine has shown as a useful alternative for the present therapies (3, 4). Herbal medicine widely used for the treatment for several types of diseases such as viral infections and cancer as it has fewer side effects that may be caused by conventional cancer therapeutics (5-7). Marigold (*Calendula officinalis L.*) belong to Asteraceae family and was considered among the most important medicinal and garden plants (8). Several species of this plant are widely distributed in different Mediterranean countries. Marigold is an aromatic annual, seldom biennial. It grows between 30 and 50 cm height and has about 20 cm long tap root and numerous thin secondary roots (9). The stem is erect, angular, down, and branched from the base up or higher. The alternate leaves are almost spatulate at the base, oblong to lanceolate above and are all tomentosae. Several phytochemical studies have been established to investigate the presence of numerous classes of chemical compounds. The main
compounds are terpenoids, flavonoids, coumarines, quinones, volatile oil, carotenoids, and amino acids (10, 11). Pharmacological studies have confirmed that C. officinalis shows a wide range of biological effects such as anti-inflammatory, antioxidant, hepatoprotective, and immunostimulant activities (12, 13). Cytotoxic effect of C. officinalis on tumour cell lines in vitro and its anticancer efficacy in an in vivo briefly outlined 20 years ago (14). According to the most active compounds that have high bioactivity this research was conducted to evaluate the leaves extract as an anti-tumor agent in in vitro cancer cell line systems.

Materials and Method

Collection of plant samples:

Flowers of the marigold plant were collected from medical plants garden at the college of pharmacy. The collected flowers were authenticated and did the formal identification of the plant material by the National Herbarium Centre in Abu – Graib countryside/Iraq and a specimen of this material has been deposited in its data base. Furthermore, the flowers were washed under running tap water to remove the surface pollutants, dried for two weeks at room temperature in the shade, then after, grinded to fine powder, weighed, and stored for future studies at room temperature.

Plant extraction:

100 grams of flower powder was extracted by using soxhlet apparatus in the presence of ethanol 90 (500 ml) till exhaustion. The extract was concentrated by using rotary evaporated, then mixed with 50 mL of distilled water and extracted with 30 mLX 3 of ethyl acetate. The upper layer which was ethyl acetate layer was separated by a reparatory funnel, then dried by using anhydrous sodium sulphate, and labelled as Ethyl acetate extract (15).

Method of Analysis

Phenols & Flavonoids in Calendula Extract:

Analysis of phenols & flavonoids in Calendula officinalis was performed by HPLC for the detection of flavonoid. A 3 micrometre particle size Column (50*4.6 mm 1.D ) Shimpack C-18 with a mobile phase of 0.1% phosphoric acid : acetonitrile (52:24, V/V), and a detection UV set at 285nm. The flow rate is 1.5 ml / mainland at a temperature of 25°C. The concentration for each compound were quantitatively determined by comparison the peak area of standard with that of the sample (16).

Maintenance of cell cultures

The human breast cancer cell lines AMJ13 (17), MCF7, MDAMB, CAL51 and the mouse embryo fibroblast (MEF). The AMJ13 cell line was cultured in an RPMI-1640 medium (USbiological, USA) with 10% fetal bovine serum (FBS) (Capricorn- Scientific, Germany), 100 units/mL penicillin, and 100 μg/mL streptomycin. A human breast cancer cell lines MCF7, MDAB, CAL51, were cultured in MEM medium (USbiological, USA) supplemented by 10% fetal bovine serum (FBS) (Capricorn- Scientific, Germany), and 100 μg/mL streptomycin, 100 units/mL penicillin. The cells were incubated at 37 °C in a humidified environment and 5% CO2 (17) for 72 hours.

Cytotoxicity Assays

Crystal violet cell viability assay was employed to measure the cytotoxic effect of plant extract. Human Breast cancer cell lines (MDAMB, AMJ13, MCF7, and CAL51), as well as normal mouse embryonic cells (MEF), were seeded at 7000 cells/well in 96-well plates (Santa Cruz Biotechnology, USA), after 24hr or until confluent monolayer is achieve. Cells were treated with (extract) at 2 fold dilutions from 4000, 2000, 1000, 500, 250, 125, 62.5, 31.25, 15 μg of culture media. The assay was done in triplicate and the cell viability was determined after 72h of exposure by staining with 50 μl of Crystal violet (Sigma Aldrich, USA) and incubated at 37°C for 2h. The stain was aspirated, and PBS used to wash the wells. The microplate reader (Biochrom, UK) was used to measure the absorbency at 492 nm; Results were shown percentage proliferation with respect to control cells (18, 19).

Morphology analysis

The treated and untreated cells were photographed at a magnification of 200x at four haphazardly selected cultured fields using an inverted light microscope (Leica-microsystems, Germany) and a digital colour camera (Leica-microsystems, Germany) (20).

Statistical Analysis

The data of the current study are presented as means ± standard error of the mean. One-way analysis of variance was used for data comparison between treatment groups. Data were considered statistically
significant at P < 0.05. A GraphPad Prism 6 software was used for the analysis (GraphPad Software, Inc. San Diego, California).

Cytotoxicity assay

The current study investigated the selective cytotoxic effect of the Calendula officinalis L. extract in breast cancer cells. In this study, four human breast cancer cell lines were used, CAL51, MCF7, AMJ13, and MDAMB, and the normal mice embryonic cells, MEF. All cell lines were exposed to Calendula officinalis L. extract at 2-fold concentrations started from 0.0 µg/mL to 4mg for 72 h, and cytotoxicity was determined using crystal violet assays. As shown in Figure-2a, the Calendula officinalis L. extract had no cytotoxic effect on the normal cells as the IC50 was very high dose (4440mg/ml) compared to the IC50 on cancer cells which were 2088µg, 1737µg, 3081µg and 4.732µg for the AMJ13, MCF7, CAL51, and MDAMB, respectively. These results indicate that Calendula officinalis L. extract is very effective against MDAMB cells as revealed by Figure-3.
Cytopathological observation showed that Calendula officinalis L extract-treated cells had lower cell count due to detachment in compare to the control (not treated cells). Furthermore, there were condensed nuclei which refer to early apoptosis in the treated cell compared to untreated cells and this photo is shown in the highest concentration used of exposure. Untreated cancer cells continue to proliferate to form monolayers. Early apoptotic cells that have condensed nuclei and stained darker along with normal lightly stained cells (Figure-4).

Figure-2, The Calendula officinalis L extract cytotoxicity assay. A) showed no cytotoxicity against normal mouse embryonic cells as the IC50 was very high dose 4440mg, while against breast cancer cell lines were very low IC50 values. B) AMJ13 the IC50 value is 2088 µg/ml. C) MCF7 IC50 is 1737 µg/ml. D) IC50 value in CAL51 cells was 3081 µg. E) IC50 in MDAMB cells was 4.732 mg/ml. F) the comparative study for IC50 values showed that cancer cells are very sensitive to the Calendula officinalis L extract in comparison to the normal embryonic cells.
Figure-3, Comparison between cancer cell lines according to their sensitivity to the Calendula officinalis L. extract. The figure indicates that Calendula officinalis L. extract is very effective against MDAMB cells, and this cell line is very sensitive to the extract more than other cells types.

Figure-4, Cytomorphology of treated and control cells. A) MCF-7, A1 control, A2 treated cells showing the extract induces cell death. B) CAL51, B1 control, B2 treated, showing the extract induce cell shrinkage. C) MDA MB-468, D1 control, D2 treated, the extract reduced cancer cells number due to detachment. E) MEF, E1 control, E2 treated, E3 image analysis showing a high dose of extract was cytotoxic on normal cells. 400xg (Crystal violet stain)

Discussion

HPLC analysis for Calendula officinalis L. extract revealed the presence of active compounds mainly flavonoids. Active compounds have been recognized and isolated to be used in cancer therapy (21). Flavonoid compounds were founds to be the major constituent of the extract as revealed by HPLC analysis. There is over 4000 type of flavonoids; several of them are accountable for the beautiful colors of fruits, flowers, and leaves (22). The scavenging of oxygen-derived free radicals is a significant effect of flavonoids that also showed anti-carcinogenic properties (23). The antioxidative effect is the top-defined feature of nearly every group of flavonoids. The flavones and chaechins are flavonoids that protect the body from reactive oxygen species (ROS). Cells organelles and components can be damaged by ROS, and free radicals, that are induced by exogenous damage or produced during the metabolism of oxygen (24, 25). Throughout injury, production elevation of reactive oxygen species results in consumption and exhaustion of the endogenous scavenging compounds. Flavonoids may have an additive effect on the endogenous scavenging compounds (26). Our experiments outcomes of cytotoxicity assay revealed that Calendula officinalis L. extract have antiproliferative and cytotoxicity against breast carcinoma cell lines, especially the MDAMB breast cancer cells. Other researchers found that Calendula officinalis extracts also had cytotoxicity on human melanoma and epidermoid carcinoma cells (27). The cytotoxic effect of Calendula officinalis L. extract was explained by the presence of the major flavonoids, which are flavone and luteolin-7-O-β-glucoside (28). Other research found that that luteolin-7-O-β-glucoside is promising anti-cancer molecule, that possesses anti-breast adenocarcinoma (29). C officinalis described as important agent for developing novel cancer therapeutics, moreover, it used to reduce the side effects of radiotherapy (8).

Conclusions

In Conclusion, we reported for the first time that Iraqi Calendula officinalis L. extract is selective broad spectrum anti-breast cancer agent different type breast
cancer cells such as estrogen progesterone positive or triple negative breast cancer and has no toxic effect on normal cells which make it very promising candidate as cancer therapy for clinical application.

The Role of c-ERBB2(Her-2) and P53 in Differentiating Low Grade from High Grade Urothelial Carcinoma of Urinary Bladder

Roaa Salih Mahdi
College of Medicine, University of Babylon /Iraq

Abstract

Background: Urothelial carcinoma of the urinary bladder, represents 90% of all primary tumors of this organ, and one of the most common ten malignancy in Iraq and world wide. These tumors can range from low grade papillary neoplasms to less frequent more aggressive and invasive solid tumors. More than 70% of superficial tumors recur, and about one-third of the patients have tumor progression, which can affect the quality of their life. HER-2/neu receptor as an important growth factor. This receptor possesses intrinsic tyrosine kinase activity and all members of this family are frequently overexpressed or their respective genes are amplified in human neoplastic tissue. Its overexpression has been associated with high grade and advanced stage of bladder carcinoma specially TCC. Altered expression of the p53 gene has also been associated with transitional cell carcinoma. Materials and Methods: 62 patients with TCC were included in this study and conducted in the Department of Pathology, Faculty of Medicine, Kufa University during the period from January 2012 through April 2013. EnVision method (polymer based immunohistochemistry) was used for the immunohistochemical detection of p53 and Her_2/neu. Results: HER-2/neu overexpression was found in 62.9% of bladder carcinoma, and no expression in benign bladder lesions (cystitis) was detected, (P value < 0.05). HER-2/neu overexpression and its intensity were well correlated to grade of tumor indicating that HER-2/neu positive bladder carcinoma are biologically aggressive and detected more frequent in grade III than grade I or grade II (P value < 0.05, R = 0.0181). P53 was expressed in (66.12%) of bladder carcinoma, and no expression in benign bladder lesions (cystitis) was detected, (P value < 0.05). P53 overexpression and its intensity were well correlated to grade of tumor indicating that P53 positive bladder carcinoma are biologically aggressive and detected more frequent in grade III than grade I or grade II (P value < 0.05, R = 0.0821). Conclusions: From the above results we concluded that p53 and Her_2/neu over-expression play an important role in pathogenesis of urothelial carcinoma evolution, as their positivity associated with higher tumor grade.

Introduction

Urothelial carcinoma, formerly known as transitional cell carcinoma is a common malignancy, representing approximately 90% of all primary tumors of this organ. In Iraq it is one of the ten most common cancers according to Iraqi cancer registry of 2005. Urothelial carcinomas range from papillary to flat, noninvasive to invasive and low grade to high grade. Low-grade carcinomas are always papillary and are rarely invasive, but they may recur after removal. Tumor progression with increasing degrees of cellular atypia and anaplasia are associated with an increase in the size of the lesion with increasing tendency of invasion into deeper structures of the bladder wall. Occasionally, these cancers show foci of squamous cell differentiation; only 5% of bladder cancers are true squamous cell carcinomas (SCC). Adenocarcinomas account for less than 2% of primary bladder tumors. The urinary bladder may also be affected rarely by neuroendocrine tumors (including small cell carcinoma), carcinosarcoma, malignant lymphoma, rhabdomyosarcomas (mainly in children), and leiomyosarcoma. The latter is the most common sarcoma of the bladder. Aims of the study: to assessment of P53 and Her/2neu expression in different grades of urothelial carcinoma, correlation between the expression of both markers and the use of P53 and Her/2 as prognostic markers.
Materials and Method

This study was carried out from January 2012 through April 2013. Sixty two patients with TCC of the urinary bladder were included in this study, fifteen specimens of benign bladder lesions taken from patients with cystitis were considered as control group. The specimens were formalin-fixed, paraffin embedded tissue blocks, from these blocks, 5 micrometer-thick tissue sections were obtained and stained with hematoxylin eosin staining method and immunohistochemical Envision staining method. Scoring according to Sophia KA et al at objective 40 as in P53 Scoring system and HER2/neu scoring system. Statistical analysis was done with SPSS software version 18 (SPSS Inc, Chicago IL). Significant differences between non-parametric variables were done by Chi squared test and between parametric variables by independent t-test. Pearson Correlation was calculated to evaluate the relations between parameters. P values ≤ 0.05 were considered statistically significant and P values ≤ 0.01 were considered statistically higher significant.

Results

Sixty two cases of bladder carcinoma were included in this study 50(80.65%) patients were males and 12 (19.35%) were females (Table 1), showing highly significant difference between male and female.

Assessment of age presentation of patients, there is a significant difference between age group (Table 2). The intensity of immunostaining of HER-2/neu protein was assessed in relation to the grade of tumor, and there is a significant difference between the intensity of HER-2/neu and the grade of tumor (R= 0.0181) (Table 2). The intensity of p53 was assessed in relation to the grade of tumor, and there is a significant difference between the intensity of HER_2/neu and the grade of the tumor (p <0.05) (R=0.691).

</table>
HER-2/neu in the presented benign and malignant bladder tissue. Regarding the assessment of the control group (cystitis), all cases were negative for HER-2/neu immunohistochemical staining this finding agrees with that reported by Sanna E., et al., (2004)\(^8\). Truls G., et al., (2005)\(^7\), showed high percentage of (80%) HER-2/neu overexpression in bladder carcinoma. Wester K., et al., (2002)\(^9\), found that HER-2/neu was overexpressed in 81% of the bladder carcinoma. While Rafael E., et al., (2001)\(^10\), found that the HER-2/neu overexpression were 28% of bladder carcinoma. Mohammed Reza N., et al., (2004)\(^11\). Regarding the intensity of HER-2/neu in correlation with TCC type of urinary bladder carcinoma the finding agreed with Vildan C., et al., (2008)\(^12\), the majority of HER-2/neu–positive patients (93%) were detected by IHC, and a minority (26%) were positive by FISH or serology (23%). This is very important in the new research, in studying the role of trastuzumab. This often requires eligible patients to have either +3 overexpression by IHC or +2 expression by IHC with positive FISH results\(^13\). The immunohistochemical analysis of the results revealed that HER-2/neu overexpression agreed with Regina E., et al., (2002)\(^15\) showed that the HER-2/neu expression was significantly higher in high grade muscle invasive bladder carcinoma. Coogan CL., et al., (2004)\(^16\), had found that overexpression of HER-2/neu was significantly increased in grade III and invasive tumors than grade I, II or superficial tumors, Gokhan Atis, et al., (2007)\(^17\) had found that overexpression of HER-2/neu increased as the grade increased, Mohammed Reza N., et al., (2004)\(^11\), found that the overexpression of HER-2/neu has a direct significant relationship with grade of TCC of urinary bladder. Mohammad R. Jalali, et al., (2007)\(^18\), found that HER2/neu was positive in 7.1% of grade I, 28.6% of grade II and 65.4% of grade III, \(P=0.002\). Our findings state that there was no relationship between age group and HER-2/neu overexpression in bladder carcinoma patients (\(P > 0.05\)). This is in agreement with Gokhan Ates, et al., (2007)\(^17\) and Mohammad R. Jalali, et al., (2007)\(^19\). Our results state that in TCC, there is male increasing significantly than female in relation to HER-2/neu protein overexpression (\(P < 0.05\)).

The immunohistochemical analysis of the results revealed that P53 overexpression was increasing as the grade increased, with significant difference among these grades (\(P = 0.014\)). However, it is significantly correlated to the grade of tumor (\(R = 0.821\)). Venyo A., et al., (2012)\(^24\) found that 28.88% of grade I, 66.66% of grade II and 80.7% of grade III were p53 positive, Salah A. Ali et al., (2012)\(^20\) show that the p53 expression was increasing with increasing grade of tumor. There was statistically a highly significant correlation between p53 expression and grading of cases of TCC (\(P < 0.001\)), Hong-Lin Cheng, et al., (2002)\(^25\) showing that p53 immunostaining was positive in 26% of grade I, 57% of grade II, and 42% of grade III. Findings of the current work also agreed by Nurcan Kilicli-Camur, et al., (2002)\(^25\), Ming-Lan Lu et al., (2002)\(^22\), and Sunanda J. et al., (2004)\(^23\). While Underwood MA et al., (1996)\(^26\) found no predictive prognostic value for p53 immunohistochemistry over grade value and this may be due to the usage of polyclonal antibody to p53 in their study. In the presented study there was no relation between p53 expression and age \(p>0.05\) in agreement with Salah A. Ali et al., (2012)\(^20\). In our study, positive immunostaining of Her2 was reported in 38.88% in grade I transitional cell carcinoma, while P53 was positive in 44.44% of the same grade. In grade II Her2 was positive in 50% of cases compared with 60% positive P53 in the same grade. Finally Grade III showed 91.66% positive Her2 while P53 showed 87.5%. Most of positive Herr bladder cancers were positive for P53. There was strong positive correlation between Her2/neu and P53 regarding all the three grades. Yuh-Shyan T. et al., (2005)\(^18\) show similar correlations between HER2/neu with P53 overexpression in transitional cell carcinoma although Gunia S., et al., (2011)\(^27\) found a positive correlation between the two markers while evaluating their role in separating CIS from benign flat lesions of urinary bladder.

### Discussion

From the above results we concluded that p53 and Her_2/neu over-expression play an important role in pathogenesis of urothelial carcinoma evolution, as their positivity associated with higher tumor grade.

Serum Secretagogin and Focal Adhesion Kinase as Markers for Type 2 Diabetes Mellitus and Beta Cells Function

Shahad Ali Al-Eqabi1, Zeena Abdul Ilah1, Mahmood Shakir Khudhair2

1Department of Chemistry and Biochemistry, College of Medicine, Al-Nahrain University, Iraq, 2Department of Medicine, College of Medicine, Al-Nahrain University Iraq

Abstract

Diabetes mellitus (DM) is one of the world’s major public health problems. The increasing incidence of DM worldwide makes it a leading cause of morbidity and mortality for the anticipated future. Secretagogin (SCGN) is a protein enriched and secreted from pancreatic islets, it demonstrates protective effects on β-cell function. Focal adhesion kinase (FAK) plays a critical role in β-cell survival and is a vital regulator of insulin secretion. In this research, serum SCGN, FAK, fasting blood glucose (FBG), HbA1c, C-peptide, lipid profile, blood urea nitrogen (BUN) and creatinine were measured in patients diagnosed with type 2 diabetes mellitus (T2DM) and in healthy volunteers. The results showed that there was a significant increase in the levels of serum SCGN in patients with T2DM compared to the control group. There was a significant decrease in levels of FAK and C-peptide in T2DM patients compared to the control group. In addition, a significant increase was seen in FBG and HbA1c levels in T2DM patients compared to the control group. The lipid profile of T2DM patients was altered compared to the control group. There was no significant difference in the levels of BUN and creatinine among the study subjects. The results of this study suggest that both SCGN and FAK may serve as potential biomarkers reflecting the state of islet cells dysfunction in T2DM patients which may present additional markers for the diagnosis of T2DM.

Keywords: Serum secretagogin, focal adhesion kinase, C-peptide, glucose, HbA1c, type 2 diabetes mellitus.

Introduction

Diabetes mellitus (DM) is a heterogeneous group of metabolic disorders commonly associated with hyperglycemia resulting from insulin secretion disorders, insulin action, or both[1]. DM is a common public health issue worldwide and continues to increase its prevalence[2, 3]. DM is of the top five major death causes in developed countries. The International Diabetes Federation (IDF) estimated that in 2015, the global population of people with diabetes was 415 million and is expected to increase to 642 million by 2040[4].

Secretagogin (SCGN) is a Ca2+ sensor protein that has six EF-hand helix-loop-helix motifs for binding calcium. Originally, SCGN was cloned with pancreatic β cells[5]. It has been revealed recently that SCGN also plays key roles in insulin secretion in pancreatic β-cells by interacting with vesicle fusion, protein trafficking[6] and actin cytoskeleton[7]. The human protein atlas shows by systematic comparison of expression in various human tissues that SCGN has its largest amount of protein expression in Langerhans islets relative to other tissues[8].

Focal adhesion kinase (FAK) is a largely conserved 125 kDa non-receptor tyrosine kinase that plays a critical role in motility, survival and proliferation of adhesion-dependent cells in responding to signals of receptors of integrin and growth factor[9]. FAK protein is overexpressed in cancers such as ovarian, cervical, kidney, pulmonary, pancreatic, brain, colon, breast, and skin cancer[10]. In addition, FAK plays a critical role in regulating F-actin remodeling and insulin secretion[11]. In pancreatic β-cells, integrin β1-mediated intracellular signaling activates and phosphorylates FAK and paxillin upon glucose stimulation. The present study aims to investigate the role of SCGN and FAK in the pathogenesis of T2DM and the possibility of using these proteins as markers that may reflect β-cells dysfunction and thus aid as additional and more accurate markers in the diagnosis of T2DM.
Materials & Method

Study subjects:

The study subjects were divided into two groups. The first group included 40 patients diagnosed with T2DM (21 males and 19 females) with an age range of (70 – 36 and 65 – 44 respectively) and the second group included 40 healthy individuals (23 males and 17 females) with an age range of (70 – 25 and 70 – 26 respectively) serving as the control group. The patients enrolled in the present study were attending the Al-Imameen Al-Kademen Medical City and Al-Kindi Hospital. This study was approved by the Department of Chemistry, College of medicine, Al-Nahrain University, Baghdad, Iraq.

Exclusion criteria:

Patients were excluded from the study if they had one or more of the followings; treatment with statins or any hyperlipidemia drugs, type 1 diabetes, liver or pancreatic inflammation and any type of cancers or tumors.

Samples collection:

Five milliliters of venous blood were taken from each patient and healthy control. (3 mL) of the blood was transferred into a gel tube to separate the serum. The remaining (2 mL) of the blood was transferred into an EDTA tube to prevent the blood from clotting. The obtained samples were stored at (-20 ºC) until assayed.

Biochemical Analyses:

Human serum secretagogin and FAK were measured by enzyme linked immunosorbent assay (ELISA) using Human secretagogin and Human FAK ELISA kits purchased from (Mybiosource/ USA) following the manufacturer’s instructions. C-peptide was measured by cobas e411 using C-peptide kit purchased from (Roche Diagnostics/ Switzerland) following the manufacturer’s directions. HbA1c, FBG, lipid profile, creatinine and blood urea nitrogen were measured by cobas c111 using HbA1c, FBG, lipid profile, creatinine and blood urea nitrogen kits purchased from (Roche Diagnostics/ Switzerland) following the manufacturer’s directions.

Statistical Analyses:

Biochemical data were analyzed using statistical package for social sciences (SPSS) version 25. T-Test was used to calculate mean ± standard deviation (SD) and the p value.

Results & Discussion

Tables (1) show that there was a significant increase in the levels of SCGN in the sera of patients diagnosed with T2DM )104.52 ± 1.8 pg/mL) compared to the control group (59.1 ± 2.73 pg/mL) (p > 0.000). A significant decrease of FAK serum levels was also observed T2DM patients )402.82 ± 76.1 pg/mL) compared to the control group (1312.35 ± 163.35 pg/mL) (p > 0.000), there was a significant decrease in the levels of C-peptide in the sera of patients diagnosed with T2DM )0.7 ± 0.12 ng/ml) compared to the control group (3.54 ± 0.95 ng/ml) (p > 0.000). There was a significant increase in the levels of FBG in the sera of patients diagnosed with T2DM )203.15 ± 82.88 mg/dl) compared to the control group (97.70 ± 4.82 mg/dl) (p > 0.000). There was also a significant increase in the levels of HbA1c in the sera of patients diagnosed with T2DM )8.82 ± 2.11 %) compared to the control group (5.37 ± 0.30%) (p > 0.000). There was a significant increase in the level of Triglyceride in the sera of patients diagnosed with T2DM )189.26 ± 80.39 mg/dl) compared to the control group (101.07 ± 31.58 mg/dl) (p > 0.000). The result showed a significant increase in the level of cholesterol in the sera of patients diagnosed with T2DM (185.74 ± 53.56 mg/dl) compared to the control group (156.42 ± 24.44 mg/dl) (p > 0.003). There was a significant decrease in the levels of HDL in the sera of patients diagnosed with T2DM (40.64 ± 14.26 mg/dl) compared to the control group (49.21 ± 13.53 mg/dl) (p > 0.007). There was a significant increase in the levels of LDL in the sera of patients diagnosed with T2DM (106.21 ± 45.56mg/dl) compared to the control group (86.84 ± 22.37 mg/dl) (p > 0.018). There was also a significant increase in the levels of VLDL in the sera of patients diagnosed with T2DM (37.79 ± 16.09 mg/dl) compared to the control group (20.20 ± 6.32 mg/dl) (p > 0.000). In this study, there was no significant difference in the levels of creatinine and BUN among the study subjects.
SCGN appears to have an extra role in cytoskeleton reorganization during insulin release, it affects the dynamics of F-actin to promote the transportation of the vesicle to the periphery and the remodeling of the focal adhesions\(^7\). In the present study, there was a significant increase in the levels of the SCGN in the sera of patients diagnosed with T2DM compared to the control group, and the results were in accordance with the results of a recent study that found increased levels of SCGN in T2DM patients\(^12\). The study showed that SCGN release was not fluctuating in relation to insulin release and that it could enable SCGN to reflect a certain disease condition that cannot be captured by insulin, C-peptide or proinsulin levels. These results support that SCGN release from the islets was sufficient to create quantifiable levels in the plasma as part of islet failure (i.e. increased islet stress)\(^12\). Another study supported that intracellular SCGN protected β-cells from apoptosis, in which apoptosis was inhibited by overexpression of SCGN\(^13\). In addition, a recent study suggested that intracellular SCGN promoted the survival of pancreatic β-cells and reduced Endoplasmic reticulum (ER) stress by stabilizing deubiquitinating proteins\(^14\).

FAK is an exercise-sensitive protein that plays a part in skeletal muscle morphology, metabolism and insulin sensitivity\(^15, 16\). FAK regulates insulin-mediated cytoskeletal rearrangement in skeletal muscle cells, which is essential to normal glucose transportation and glycogen synthesis\(^17\). FAK’s role in regulating glycogen synthesis was also revealed in HepG2 cells and hepatic insulin signaling in vitro\(^17, 18\). In the current study, there was a significant decrease in the levels of the FAK in the sera of patients diagnosed with T2DM compared to the control group. This study represents the first attempt to measure the levels of FAK in the blood of T2DM patients however, there are a number of previous studies describing the role of FAK in tissues. A previous study showed that activated FAK-paxillin complexes were integrated into nascent focal adhesions when main rat β-cells were stimulated by glucose. Focal adhesion remodeling in response to glucose is Ca\(^{2+}\) -dependent, fast, reversible and connected to short-term glucose-induced signaling pathway activation of ERK1/2. Finally, these glucose-mediated occurrences are crucial for controlled β-cell insulin secretion\(^19\). Another study showed that FAK is needed to maintain both pancreatic β-cell mass and in vivo function so that glucose homeostasis is disturbed in its absence. The study also showed that deletion of FAK in β-cells has been shown to result in impaired cell proliferation, survival and function. In the absence of FAK, deficiencies in actin dynamics related to impaired focal protein dynamics and insufficient trafficking of insulin granules resulted

*Significant at the levels of (p ≤ 0.05).
in decreased insulin exocytosis. The study concluded that FAK has a critical dual role in controlling both the viability of β-cells and cell functions and can be a prospective therapeutic target for T2DM(20).

C-peptide is a helpful and commonly used technique for evaluating the function of pancreatic β-cells(21). The concentration of C-peptides has been shown to decrease over decades with diabetes length(22). Lower concentrations of C-peptide and lower function of β-cells were associated with higher rates of glucose variability(23). In the current study, FBG and HbA1c levels were higher in the T2DM patients compared to the controls. Our findings were supported by a number of previous studies that showed increased levels of FBG and HbA1c in T2DM patients compared to controls(24).

In the present study, levels of serum triglycerides were higher in the patients diagnosed with T2DM compared to the control group. Previously reported studies had suggested that the levels of TG in serum were positively associated with DM. Moreover, it has also been shown that increased serum TG levels over time enhanced the risk of developing DM in various populations(25). In the current study, serum TC, VLDL and LDL in the patients diagnosed with T2DM were higher than the control.

**Conclusion**

The results of the present study suggest that both SCGN and FAK may serve as potential biomarkers reflecting islet cell dysfunction in T2DM patients and that they may aid as additional markers for the diagnosis of T2DM. SCGN and FAK may differentiate β-cells dysfunction T2DM from insulin resistant T2DM. The patients of the present study suffered from β-cells dysfunction. Alterations in the lipid profile of the patients was associated with T2DM. The kidney function reflected by BUN and creatinine levels was not affected by T2DM in patients of the present study.

Thyroid Nodules of Iraqi Patients with Acromegaly

Nihad Abdallah Selman¹, Abbas Mahdi Rahma², Atheer Yass Ali³, Hayder K. Abed⁴
¹F.I.B.M.S.(Endocrinology) College of Medicine ;University of Babylon; Babil; Iraq; ²Consultant Physician (Endocrinologist) Mustansiriyah University/ National Diabetes Center/Iraq; ³F.I.B.M.S.(Endocrinology) Mustansiriyah University/ National Diabetes Center/Iraq; ⁴M.D Radiology/Specialized Center For Endocrinology & Diabetes /Baghdad Al-Rusafa Health Directorate/Iraq

Abstract

Acromegaly is a chronic endocrine disorder caused by excessive secretion of growth hormone. The incidence of malignancy like colorectal carcinoma is well documented to increase in patients with acromegaly. While the real incidence of thyroid neoplasm in these patients are not well known.

**Aims:** Find out the rate of structural thyroid disorders in a sample of Iraqi patients with acromegaly; Identify the rate of thyroid malignant transformation in patients with acromegaly.

**Settings and Design:** A case control study

**Methods and Material:** seventy patients with acromegaly were enrolled compared with 70 controls from 2 endocrinology centers from Jan. - Dec. 2017. Their mean age 46 +/- 11 years; 41 (58.5%) males. Thyroid ultrasound was conducted for all participants while fine needle aspirate conducted for those with nodule diameter ≥1 cm.

**Results:** Goiter was founded more in patients with acromegaly versus control group (81.4% vs 18.5% respectively; P<0.0001). The overall nodular thyroid disease were found in (61.4%) acromegalic patients of those: (11.4%) had single thyroid nodule and (50%) had multiple thyroid nodules. The ultrasonic feature of thyroid nodule were suspicious in (13.9%) of acromegaly group and none in control; P<0.0001. The fine needle aspirate results were suspicious in (9.3%) acromegaly group versus none in control group, P<0.05). One patient (2.3%) with acromegaly had papillary thyroid carcinoma and none in control; P=0.31).

**Conclusions:** Nodular thyroid disease were more prevalent in Iraqi patients with acromegaly but the risk of malignancy is not significantly different from normal population.

**Keywords:** thyroid nodule, acromegaly, goiter, multinodular goiter, ultrasonography

Introduction

Acromegaly is a chronic endocrine disorder caused by excessive secretion of growth hormone (GH) [¹] and subsequently Insulin –like Growth Factor 1 (IGF-1) [²]. IGF1 is consider as a potent mitogen for different cells [³]. Some report appear that these patients are at a high risk of developing neoplastic disease [⁴]. The incidence of some types of malignancy like colorectal, breast & prostatic carcinoma are well documented in patients with acromegaly [⁵]. While The real incidence & prevalence of thyroid neoplasm in patients with acromegaly are not well known[⁶]. However this study designed to identify the prevalence of thyroid tumors in Iraqi patients with acromegaly.

Subjects and Method

This is a case control study in which 70 patients with acromegaly were enrolled from January - December 2017 from 2 endocrinology specialized centers compared with 70 (age and sex matched) healthy control.

This study have been accepted by research ethics committee of Iraqi Board of Medical specialization before starting a study. An informed consent have been obtained from all patients, signed and dated before participation in...
this study. The enrolled subjects were already diagnosed as acromegaly clinically, biochemically, and radiologically before their enrollment in the study. The diagnosis of acromegaly was based on unsuppressed GH level after OGTT (>1.2 mUI/L) and increased IGF-1 value for age and sex; fortified by detection of pituitary adenoma by MRI either macroadenoma (>10mm) or microadenoma (<10mm).

The collection of data in regard of age per years, sex, duration of acromegaly, size of tumor (micro- or macroadenoma), history of hypophysectomy, radiotherapy, medical therapy (total dose for each patient) GH level in 1st and last visits (by chemiluminescent immunoassay), IGF1 in 1st and last visits (according to sex and age matched limits measured by immunochemiluminometric assay), disease activity (assessed as described in the 2009 international consensus statement [7]), history of smoking, family history of thyroid disease, family history of malignant disease.

The thyroid ultrasonography conducted to all patients and control subjects by to assess the morphology of thyroid gland (size of thyroid gland and thyroid nodule(s) -if any- its/their characteristics. According to American thyroid association guidelines 2015 [8] suspicious thyroid nodule(s) sent for Fine Needle Aspirate (FNA). Furthermore, according to the cytology report patients with suspicious nodules sent to thyroid surgeon for thyroidectomy; followed by histopathological examination of the removed specimen.

Continuous variables were expressed by mean +/- SD while categorical variables as percentage. All these collected data & variables analyzed by using Chi square test or Student’s unpaired t-test. The value of <0.05 considered as statistically significant.

Results

Seventy cases of acromegaly were enrolled in this study with a mean age 46 +/-11 years. Forty one (58.5%) males and 29 (41.5%) females. Duration of disease ranged from 1 year -30 years (average 8 +/- 6). A growth hormone producing macroadenoma was the cause of acromegaly in 62 patients (88.5%) and in the remaining 8 (11.5%) had microadenoma. Thirty six (51.4%) underwent hypophysectomy. Six patients (8.5%) were exposed to gamma knife & another one to conventional radiotherapy. All of our patients received monthly Octreotide (Sandostatin (LAR)). Twelve (17.2%) had inactive disease while the remainder 58 (82.8%) had active disease.

Hypophysectomy, radiotherapy and/or medical therapy for acromegaly induced a significant reduction of mean GH and IGF-1 levels (27.83 +/- 25.69 vs. 4.73 +/- 6.72 ng/ml, p< 0.001 and 772.15 +/- 521.9 vs. 404.2 +/- 278.6 ng/ml, p < 0.001 respectively).

Thirteen patients (18.5%) were smoker.

Family history revealed thyroid disease or goiter in 17 (24.2%). While 12 (17.1%) had family history of malignancy (of those: 2 of them had family history of thyroid malignancy).

The control group was composed of 70 healthy subjects 47 (67%) female and 23 (33%) with the mean age 42.9 +/-14.3.

Ultrasound characteristics

Goiter discovered in 57 (81.4%); of these 14 (20%) had diffuse and 43 (61.4%) had nodular goiter (both single 8 (11.4%) and multinodular goiter (MNG) 35 (50%)).

Cytological & histopathological diagnosis

Out of 43 patients with nodular goiter; FNA performed in 23 (53.4%) patients while none of nodules in control group required FNA because all of their ultrasound characteristics were either benign looking or purely cystic.

The FNA results were benign follicular cells without any metaplasia or dysplasia in 19 patients with acromegaly (44.2% out of all nodular disease and 82.6% out of all cytological examined sample); P value < 0.05. While 4 of patients with acromegaly (9.3% out of all nodular disease and 17.4% out of all cytological examined sample) had suspicious for dysplasia, metaplasia or malignancy, (P value < 0.05).

Seven patients sent to thyroid surgeon for thyroidectomy (all 4 patients of suspicious FNA cytology & 3 had large multinodular goiter with obstructive symptoms). One patient had malignant histopathology in form of papillary thyroid carcinoma (2.3% out of patients with thyroid nodules and 1.4% out of the entire group of patients with acromegaly) that was statistically non-significant compared with control group (P value = 0.3). While the others had benign histopathological results.
**Correlation study**

In table (1) the patients subdivided according to thyroid ultrasound findings.

There is a significant differences in gender with male predominance in diffuse goiter group and female predominance in MNG group (13(97%) male vs 1(3%)female, (19(54%) female versus 16(46%) male ; respectively \( P <0.05 \) in both). There is significant predominance of MNG among patients with macroadenoma versus microadenoma (34(97%) vs 1(3%); \( P <0.05 \) ). There is also a significant development of MNG in patient who had active disease versus inactive disease (32(91.4%) vs 3(8.6%); \( P <0.05 \) ). While there is a significant difference in development of both diffuse goiter and MNG in non-smoker patient versus smokers(8(57%) vs 6 (43%), and 10 (91.5%) versus 3(8.5%)respectively; \( P <0.05. \))

We could not found statistically significant differences disease duration, mean last GH , mean last IGF1, history of hypophysectomy or family history of thyroid disease between patient with diffuse goiter ,single thyroid nodule or MNG( table 2).

In table (3) the patients who had thyroid nodule (whether single or multiple) are subdivided according to ultrasonic feature and cytological examination .There is a significant female predominance in patients with benign ultrasonic feature group (20(54%) female versus 17(46%) male, \(<0.05\)).

The mean last IGF1 has significant relationship with development of both suspicious ultrasonic feature group and suspicious FNA cytology group(\( P \) value <0.05 respectively).

In patients with suspicious FNA group there is a significant occurrences in patients with past history of hypophysectomy versus those without surgery (\( P \) value=0.05).

While there is no significant relationship between any nodular thyroid characteristics from one side and duration of disease of acromegaly ,size of pituitary adenoma, activity of the disease and mean last GH level on the other side.

**Discussion**

In our study of 70 patients with acromegaly we searched for structural thyroid abnormalities, we found an increase prevalence of goiter(81.4%) both diffuse and nodular types ,thyroid nodules were(61.4%), MNG were(50%). These result of nodular disease are similar to newer studies that shows prevalence 62% in Gullu et al \[9\], 63% in Baldys-Waligórska et al \[10\], 57.6% in Tita et al \[11\] and 74.1% in Anagnostis et al. \[12\].

In our study we found that diffuse goiter was in 20% which was slightly higher than what is founded in Turkish study; Dugan S. et al \[13\] which shows approximate results of 14.1%& in Brasil study \[14\] were 10.4% however the differences can be accepted because of individual and environmental factors. While in comparison with these studies we found that MNG were 50 % in our patients ;which is similar to Turkish study \[13\] that shows 48.6% ,while on the other side our results was lower than other study in Brasil \[14\] that shows (32.5%) this could be explained by similarity of geographical ,environmental factors that had an effect on our patients &Turkish patients

The suspicious FNA cytology was detected in 9% of the FNAs specimens in our study which were lower than the finding in other studies that was 13% \[14\]. However the differences between our study and the other study can be accepted.

We found a significant relationship between MNG and activity of acromegaly which is similar to what is found in other study like Uchoa et al. \[14\] We also found a significant relationship between MNG and the size of pituitary macroadenoma.

We fail to found a relationship between goiter development ,thyroid nodule and the last GH,IGF1 ,and disease duration that are similar to other studies\[13,15\]. The prevalence of thyroid cancer was (2.3%)in our study which is like other studies 0.8% \[16\] and 2.9% \[10\], but these results are much less than other studies which found thyroid cancer in 11.8 % \[17\] and 7.2% \[11\].

* US: ultrasound † FNA: Fine Needle Aspirate ‡ done by Chi square test § Done by Student’s unpaired t-test

Conclusion

The prevalence of structural thyroid disease are increased in Iraqi patients with acromegaly compared to the general population in form of goiter [both diffuse & nodular types] mainly MNG, increased thyroid nodules of suspicious ultrasound & cytological characteristics. While the rate of thyroid cancer is not significantly different from that in general population.

Study on the Role of Interleukin-2 and Human Cytomegalovirus in Cases of Recurrent Spontaneous Abortion of Women in Wasit Province

Kadhum J. Gatti¹, Suhad F. Hasson¹, Asawer K. Alsadoon¹

¹Wasit University / College of Science / Department of Biology/Iraq

Abstract

Recurrent spontaneous abortions (RSA) is the loss of pregnancy for two consecutive times at least before the arrival of the fetus for 24 weeks gestation. This study was conducted to investigate the role of IL-2 and human cytomegalovirus in recurrent spontaneous abortions women in Wasit province. to conduct immunological studies and viral by 90 women who suffer from abortion frequently (At least two abortions) and two sets of control (pregnant and healthy women), The average age of the groups ranged between (17-45) years, the results showed a high significant increase (≤0.001) at the level of IL-- 2 patients compared with pregnant women and healthy women, according to different age groups. And also it showed the results of a study of opposites immune IgM, IgG-virus human cytomegalovirus rise significantly (≤0.05) for patients when compared with pregnant women and healthy women in the cases of chronic and acute infection.

Key words : Recurrent spontaneous abortions (RSA) , Interlukin-2, CMV, IgM, IgG , Enzyme Linked Immunosorbenent Assay (ELISA).

Introduction

Recurrent spontaneous abortion (RSA) which known as repeated pregnancy loss ,it has no clear define at now Opinions differed about it, The American Reproductive Medicine Organization depend the tow pregnancy loss as (RSA) , While the European Organization of Embryology and Reproduction is considered three successive abortions and above as repeated spontaneous abortions¹. It is one of the most important and complications of pregnancy, especially in Iraq they have increased significantly in recent years, The causes are multiple, but most of the previous studies concentrate on parasitic and Viral causes². Studies have shown a number of factors causing spontaneous abortion But the most common causes are immune disorders, Hormonal and metabolic disorders, anatomical uterine anomalies and infectious causes The most common are toxoplasmosis and cytomegalovirus However, more than 50% of the cases are still unclear³.

The role of interleukin 2

In general, about 5% of couples are believed to have recurrent spontaneous abortions which are immunological reasons and increase this percentage may reach up to 40% after four losses of pregnancy⁴. The success of any pregnancy must be recognized and accepted by the mother’s immune system Otherwise, it is considered as foreign and be expelled, Here comes the role of cytokines, which are low molecular weight proteins they are used to allow connections between cells⁵ They are particularly important in both innate and adaptive immune responses. For its central role in the immune system, Cytokines are involved in a variety of immune, inflammatory and infectious diseases. Its functions are not limited to the immune system, but it has a major role in many developmental processes during the stage of embryonic development and during pregnancy⁶. Interleukin 2 is a monomer has 15.5 kD consisting of 133 amino acids, discovered more than 30 years ago in active T cells. It is mainly produced by cells (CD4-CD8-T) and a little produce it DCs and NK cell, IL-2 acts as a growth factor and promotes the proliferation and differentiation of natural killer cells to increase the normal functions of cells, It is also an effective stimulant for cell proliferation (T)If absent, T cells tend to go into hibernation or inactivity, It is therefore important to induce T cell proliferation and in maintaining both the regulatory and inflammatory role of T cells⁷.
The role of cytomegalovirus

The cytomegalovirus (CMV) came from the Greek word (cyto), meaning cell, and (megalo) large or overgrown. This is a viral genus from the group of human herpes viruses known as human herpes virus (HCMV)\(^8\). It’s one of the main causes of abortions and birth defects. Their clinical manifestations and symptoms in 90% of cases vary from severe fetal damage to death due to abortion\(^9\). The prevalence of herpes virus (CMV) infection among women of childbearing age ranges from 35% to 95% in different countries, and increases with age\(^{10}\). Cultural awareness as well as socio-economic status have a role in the spread of CMV infection and transmission\(^{11}\). A recent study in Baghdad\(^{12}\) indicates a high seroprevalence of cytomegalovirus in different age groups for men, women and children. The percentage was (68.78%) among the Iraqi patients and the rate of increase and rise compared to another study in Iraq as well was 57.2%\(^{13}\).

Materials and Method

This study was conducted in the College of Science / Department of biology / Wasit University, In cooperation with Laboratories of Al Karama Teaching Hospital, Al Zahra Teaching Hospital, Al-Kut Hospital for Pedantries and Gynae obstetrics and some private clinics during the period from of 2019. The study included 90 women with recurrent spontaneous abortion and two control groups (pregnant and healthy). There were (60) women, (30) pregnant women and (30) healthy women who are not pregnant. The average age of the two groups ranged between (17-45) years. All information included: age, weight, height, housing, number of previous births, number of abortions and body mass index (BMI) value was calculated for all samples.

Interleukin-2

The work was done according to a company Cusabio Biotech is of Chinese origin, since this test uses Sandwich Enzyme Immunoassay.

Measuring the level of cytomegalovirus infection

We have been working in accordance with\(^{14}\), detecting the presence of immunoglobulins (IgG / IgM) in the serum of both infected and two control groups, by using the ELISA method based on the principle of color change resulting from the binding of specific antibodies. Where (100 ml) from each diluted samples (Control Samples) and control solutions (Controls groups sample) of each (NC –CC –PC), The additives are double for control solutions to ensure accurate results and are single for samples. Then read in a short time not exceeding half an hour the results are recorded by the absorbance reading on along a wavelength (450 nm).

Statistical Analysis

Data were analyzed statistically using the program (Discovery Gen Stat) for statistical analysis of variance (ANOVA) was used. To find out the least significant difference (LSD). Comparisons were made between patients and control groups for the same age groups to find the significant differences between them was the least significant difference for the examinations studied below the probability level (P <0.05 )\(^{15}\).

Results and Discussion

rate of changes in the level (interleukin 2) by Age Groups

The significant differences (P <0.001) shown in Table (1) between the groups of aborted women and the control groups of pregnant and healthy. Interleukin 2 has been shown to play a major role in recurrent miscarriages and for all ages, it has also been shown to decrease its production during pregnancy as cytokines are originally regulatory immune proteins. It may affect some endocrine and placental activities and control the levels of secreted hormones. It also plays a major role in maintaining optimal conditions for fetal development and continuity of pregnancy or termination of pregnancy by abortion\(^{16}\). Because it is categorized based on its inflammatory reactions to inflammatory cytokines and anti-inflammatory cytokines since inflammatory cytokines include interleukin 2, interferon IFN-γ and tumor necrosis factor (TNF-α), And its action in the cell are reactions delays hypersensitivity reactions it may also attack the fetus and trophoblast\(^{17}\). So I found very high levels in our current study and for all age groups. The main act of increasing abortions is to increase the contractility of the uterine muscles by interleukin-2, as confirmed by a previous study\(^{18}\). Therefore, the value of interleukin-2 for pregnant and normal women is much lower than abortifacients. This is proven by our study as the normal state is the balance between TH1 / TH2 cytokines, Turns towards the production of TH2 cytokines for successful and continuing pregnancy or tends to increase the production of inflammatory cytokines TH1, including interleukin 2, therefore,
pregnancy fails and ends with miscarriage or death of the fetus and this is confirmed by\(^{(19,20)}\), the results of our current study are identical to a study in Iraq by\(^{(21)}\).

*** CMV IgG Chronic infections of cytomegalovirus

*** CMV IgM Acute infections of cytomegalovirus
Influence of Cytomegalovirus Infection by Age Groups

The significant increase found in our study Table (2) in the case of chronic CMV IgG infection among women with miscarriage and control groups of pregnant and healthy and for all age groups. As well as acute infection CMV IgM where the result was a significant increase for the third category with pregnant women, and a significant increase for the second and third categories with healthy. Clear evidence of the prevalence of CMV infection for women in the province of Wasit It is known according to recent statistics prevalence of CMV infections widely, especially among Iraqi women. The cytomegalovirus has a major role in repeated spontaneous abortions. Our study showed that the rate of chronic infection is higher than that of acute infection, these results corresponded to a study (22) in the province of Dhi Qar and also a study (23) in the province of Baghdad. In another study on abortifacients in Baghdad and the role of cytomegalovirus, seroprevalence of IgM from cytomegalovirus was the highest and most infections were in the first trimester of pregnancy, Given that pregnant women are the most affected category of viral infection, especially if the infection occurred during pregnancy, it either end the life of the fetus or be born deformed. So most studies have focused on the time of infection and infection in the first months of pregnancy is the most harmful. As the cytomegalovirus has the ability to alter the host’s immune response, it changes the cellular nature of the placenta and weakens the immune mechanism of the fetus and its mother. This leads to the life of the fetus (24). The results of the present study are consistent with (25,26).

Single Nucleotide Polymorphism of Follicle Stimulating Hormone Receptor Gene in Iraqi Infertile Men

Randa Rasool Ghmayes1, Abdul Kareem A.Alkazaz1, Ahmed Adnan A.Rasool2

1Biotechnology Dept. College of Science- University of Baghdad/Iraq, 2Kamal Al-Samarie IVF Hospital- Ministry of Health, Baghdad, Iraq

Abstract

The study was directed to determine Single Nucleotide Polymorphism (rs6166 A>G) of follicle stimulating hormone receptor gene and their association as a risk factor with male infertility in Iraqi sterile patient. In the present study after seminal and serum analysis 50 patient (25 Azoospermia and 25 oligozoospermia) and 50 healthy fertile control were joined. The samples were collected from the Biotechnology Department/college of science/Baghdad university and Kamal Al-Samarie IVF Hospital, Baghdad, Iraq, through the period of two months from November 2018 to January 2019. The SNP (rs 6166) determination was carried out by using real-time polymerase chain reaction (qPCR) of blood samples. The difference in the mean of genotype showed a significantly different (p<0.05) in infertile patients group likened to corresponding means infertile control group. Survey of follicle stimulating hormone receptor gene SNP genotypes and allele frequencies in Azoospermia and oligozoospermia patient groups with the control group, showed that there was a significant variation in the heterozygous (AG) and homozygous mutant (GG) genotype frequencies in (rs 6166). It concluded that this SNP may have a role in an Azoospermia and oligozoospermia Iraqi patients complaining from idiopathic infertility.

Keywords: Follicle stimulating hormone receptor gene, Single nucleotide polymorphisms (SNPs), Azoospermia, Oligozoospermia, Iraqi sterile patients.

Introduction

Infertility is a disabling issue that affects public health and typically defined as the inability to conceive after a year of regular, unprotected sex 1,2. It is experienced by 10–15% of couples and is on the rise. It has previously estimated that half of these cases are due to male infertility 3. In the other hand there only a significant improvement in the diagnostic workup of infertile men 4.

The causes behind infertility are unexplained in 50% of all cases, this is described as idiopathic male infertility and frequently characterized by sperm dysfunction and spermatogenic failure 5. It is widely accepted that many genetic and environmental factors interact and are involved in the deficiency of spermatogenesis and consequent infertility 6. Genetic factors including chromosomal aberrations and single gene mutations account for 10-15% of severe male infertility. However recent research has submitted that idiopathic infertility may be produced in part by mutations or alterations in genes involved in spermatogenesis 7.

Spermatogenesis is a finely controlled process, exquisitely regulated by two gonadotropins secreted in the pituitary, namely FSH and LH 8,9.

Understanding the mechanisms of how FSH and LH regulate spermatogenesis is a very important goal in the area of male reproductive endocrinology, infertility, and contraception. FSH stimulates testicular development and spermatogenesis in the testis and folliculogenesis and steroidogenesis in the ovary 10,11. The role of FSH and its receptor (FSHR) is extensively considered in the setting of infertility and it may be relevant for impacting on ethnicity-related human reproductive achievement 12.

The FSHR is a G protein-coupled receptor with 76 kDa, part of the rhodopsin-like receptor subfamily and made of 695 amino acids 13. Located on the chromosome 2.p21, lengths more than 190 Kbases with 10 exons and 9 introns. Exons 1 to 9 encodes for the extracellular domain
allotted to ligand binding, while the largest one exon 10 that encodes part which called “hinge region”, for the seven transmembrane-spanning domains and for the intracellular C-terminal tail. FSHR is expressed mainly in granulosa and Sertoli cells, in which it mediates steroid synthesis and gametogenesis. Upon ligand binding, the receptor undergoes a conformational change, leading to the simultaneous activation of multiple signaling pathways at the intracellular level. More than two thousand SNPs located within coding and non-coding regions of the FSHR gene were described. Two of them displaying strong relationship uncertainty were largely studied in the role of infertility: rs6165 replaces threonine by alanine, it results in a change from a polar (T) to a nonpolar, hydrophobic (A) amino acid and removes a potential O-linked glycosylation site; rs6166 exchanges asparagine for serine in the intracellular domain of the receptor, introducing a potential phosphorylation site both located in the exon 10 an amino acid alteration in the hinge region and in the intracellular domain of the protein receptor are due to these SNPs.

A large body of evidence available previously suggests that FSH signaling is essential for the induction and maintenance of normal spermatogenesis. The modulatory activity of the FSHR p.As680Ser SNP on fertility was recently proposed in men, in which a slight correlation between the Ser/Ser homozygous state and a lower testicular volume was found.

For its critical role in spermatogenesis and sperm function, polymorphisms in the FSHR gene might disturb normal spermatogenesis and affect male reproductive ability. However, little is known about the FSHR gene polymorphisms in Iraq.

In this study, we explored the possible effects SNP of the FSHR gene on male infertility and serum FSH levels in Iraq by the case-control study, which included well-defined idiopathic infertile males and fertile controls.

2. Patients, materials, and methods

2.1. Patients

This study was approved by the Ethics Committee of Department of Biotechnology, College of Science, University of Baghdad, Baghdad, Iraq. Study subject was fifty Iraqi infertile male included in this study and 50 healthy fertile men from the same ethnicity without any systemic diseases were served as control. The patients were recruited from Kamal Al-Samaraie Hospital, Baghdad, Iraq. The healthy fertile men were volunteers with at least one child. With average age between (17 – 47) years old. The patient’s group was divided according to the semen analysis into 25 infertile men with azoospermia (Z) and 25 infertile men with oligozoospermia (O). In addition to fifty fertile male as a control (C) to this study.

Excluded criteria included: patients with secondary infertility, abnormal karyotype, obstructive azoospermia, varicocele.

2.2. FSHR gene SNPs

Primers and probes for FSH receptor gene (rs6166 A>G) were designed by Li, (2011) they provided in a lyophilized state by Macrogen Company (Korea) stored at (-23°C). The sequences of each of the probes and primers used in the allelic discrimination experiments are shown in table 1.

ReliaPrep™ Blood gDNA Miniprep System is used in this study to extract whole genomic DNA from leukocytes pellets of the blood samples according to the manufacturer instructions. Genotypes were detected by TaqMan allelic discrimination Assay on (MIC-4 Real-time PCR System, Australia).

The amplification reaction components and their final concentrations are 5µl Go Taq qPCR Master Mix (Promega/USA), 0.5µl of each primer, 0.5µl of each probe, 1.5 µl DNA, and 1.5µL nuclease-free water. The mix was transferred to a real-time thermocycler (MIC-4 Real-time PCR System, Australia).

The Real-time PCR System was programmed for optimized cycles shown in Table 2.

**Statistical analysis**

Data analysis was done by utilizing SPSS for Windows, version 17 (SPSS Inc. Chicago, IL, United States). Data appeared as mean ± standard deviation. Shapiro–Wilk normality test was used to determine whether the studied parameters followed a Gaussian distribution.

Variables in which the distribution of data did not conform to normality were first log transformed for analysis and then converted back to standard units for presentation. Categorical variables were analyzed by the Chi-square test. Tukey’s, Dunnett, and Bonferroni Post Hoc test for multiple comparisons were applied after ANOVA tests.

Hardy-Weinberg equilibrium calculated using a web tool 18. The difference in frequencies of genotypes and alleles between the patient groups and the control group were analyzed using the Chi-square test. Odds ratios (ORs) with a 95% confidence interval (CI) were calculated for measuring the strength of the association between the studied gene SNP and male infertility. The association degrees between variables were analyzed by Pearson correlation analysis. A two-tailed p-value less than 0.05 (p<0.05) was considered significant 19.

**Results**

3.1. FSHR gene SNPs

The SNP of the FSHR gene (A > G; rs6166) was presented with three genotypes (AA, AG, GG) and two alleles (A and G).

Analysis of Hardy-Weinberg equilibrium (HWE) in (Z) group and (C) revealed that the genotypes were consistent with equilibrium. And significant differences (p <0.01) were detected between the observed and expected genotype frequencies in both control and patients groups (table 3A).

Inspecting FSHR gene genotypes and Allele Frequencies in (Z) group and (C) group revealed that there was significant variation between these frequencies. Although a decreased frequencies of G allele (84 vs. 65%) and an increased frequencies of A allele (16 vs. 35%) were observed in patients compared to control (Table 3 B).

In both GA and GG Polymorphisms, the odds ratio for the GA genotype was 0.09(0.01 -1.45) with p=0.025 and the odds ratio for the GG genotype was 4.12(1.26 -13.49) with p=0.021 indicating that heterozygous genotype GA and homozygous GG was a higher risk of (Z) group than the wild type AA.

 Discusses

4-1 - FSHR gene SNPs

Male infertility is common, especially in developing countries as a result of the complicated interaction between genetic and environmental factors. Due to the importance of FSH signaling for the pubertal initiation of spermatogenesis and maintenance of quantitatively normal sperm production in adults, genetic abnormality of the FSHR, as well as FSH, would be involved in some form of male infertility, such as azoospermia or oligozoospermia. However, to date little is known about mutations or polymorphisms of the FSHR gene in Iraqi infertile men. In the present study, we established the hypothesis that the polymorphism in the FSHR gene might be the reason behind idiopathic male infertility and related to the serum FSH levels of them. The result was observed significant differences in the distribution of FSHR genotypes between infertile men and fertile males in the control group. The proportions of Asn/Asn and Ser/Ser were 16% and 84% respectively in patients groups and 26% and 56% correspondingly infertile men, while Asn/Ser genotype was not observed in the patient group through its proportion, was 18% in the control group, and there was a significant difference between the two. This result disagrees with some studies that failed to prove the difference in the prevalence of FSHR genotype infertile or infertile men. Recent study among Iranian population found that FSHR gene polymorphism might increase the risk factor of azoospermia, which similar to our findings. Recent study among Iranian population found that FSHR gene polymorphism might increase the risk factor of azoospermia, which similar to our findings. The association between FSH levels within the sera and A919G and A2039G alleles and genotypes were also investigated. MATERIALS AND METHODS This case control study was performed on 212 men with azoospermia (126 non-obstructive and 86 obstructive.

Despite the fact that multi unidentified factors might increase susceptibility to male infertility, the outcomes of this study showed that single nucleotide polymorphisms in FSHR gene might account as one of the susceptible factors for the etiology of idiopathic male infertility. In conclusion, the present study findings demonstrated that the genetic polymorphisms in the FSHR gene might have a role in an Azoospermia and oligozoospermia Iraqi patients complaining from idiopathic infertility. However, additional investigations are recommended to be directed on other ethnic populations to approve the results of this study.

2Educational laboratories, City of Medicine, Baghdad/Iraq

Abstract

The study was carried to determine Single Nucleotide Polymorphism (rs6165) of Follicle Stimulating Hormone Receptor (FSHR) gene in blood samples of 62 Iraqi women with primary amenorrhea and 40 healthy control females. The research included chromosomal study and serum analysis of 62 patient samples. The samples were collected from Educational laboratories, City of Medicine, Baghdad and Biotechnology Dept. College of Science- Baghdad University through the period from October 2018 to March 2019. The determinations of SNP (rs6165) were carried out by real-time PCR. Results of rs6165 genotyping showed significant variations between PA patients and controls, inspecting FSHR gene genotypes and allele frequencies in PA patients groups with the control group, revealed that there was significant variation in the heterozygous (AG) and homozygous mutant type (AA) genotype frequencies in (rs6165). the SNP of target gene may have a role in PA patients complaining from idiopathic puberty problems.

Keywords: primary amenorrhea, Follicle Stimulating Hormone Receptor (FSHR) gene, SNP, Iraqi women patient.

Introduction

Primary amenorrhea (PA) could be defined as the absence of menses by 14 years of age in the absence of growth or development of secondary sexual characteristics or absence of menses by 16 years of age regardless of the presence of normal growth and development including secondary sexual characteristics and1. According to WHO, amenorrhea stands as a 6th largest major cause of female infertility and affects 25% of women in the reproductive age. During normal female menstruation cycle, Gonadotropin-releasing hormone (GnRH) is released from the hypothalamus, and it works on the pituitary to release FSH and LH and these 2 hormones from the pituitary act on ovaries that finally make estrogen and progesterone to work on the uterus to carry out the follicular and secretory phase of menstrual cycle. Any failure at any level of this normal physiology can cause amenorrhea2. The absence of menses in a female of reproductive age is related to the disturbance of normal hormonal, physiological mechanism or female anatomic abnormalities. The normal physiological mechanism works by balancing hormones and providing feedback between the hypothalamus, pituitary, ovaries, and uterus 3. According to the ministry of health of Iraq statistics for 2017 and 2018, 9.68% and 17.78% of women respectively suffering from primary amenorrhea and problems with menarche.

The FSHR is a 76 kDa G protein-coupled receptor, consisting of 695 amino acids and belonging to the rhodopsin-like receptor subfamily. The FSHR gene is located at chromosome 2.p21, spans more than 190K bases and embeds 10 exons and 9 introns. Exons 1-9 encode for the extracellular domain deputed to ligand binding, while the large exon 10 for part of the so-called “hinge region”, for the seven transmembrane-spanning domains and for the intracellular C-terminal tail. FSHR is expressed mainly in granulosa and Sertoli cells, in which it mediates steroid synthesis and gametogenesis. Upon ligand binding, the receptor undergoes a conformational change, leading to the simultaneous activation of multiple signaling pathways at the intracellular level and4. More than two thousand
SNPs falling within coding and non-coding regions of the FSHR gene were described so far. One of them displaying strong linkage disequilibrium were largely studied in the setting of infertility: p.Thr307Ala (c.919 G > A; rs6165). This SNP is located in the exon 10 of the FSHR gene and leads to an amino acid change in the hinge region protein receptor5. The biggest difference between SNPs and mutations is that SNPs are inherited. Some of these genetic differences have proven to be very important to human health. If those inherited SNPs are high-risk candidates, they deserve our attention, and their investigation will lead to further mechanistic research to develop new treatment programs6.

Patients, materials, and methods

This experimental work was carried out in the Educational laboratories, City of Medicine, Baghdad, from October 2018 till February 2019 and at the University of Baghdad, College of Sciences, Department of Biotechnology to investigate molecular parameters. The healthy control group included 40 apparently healthy females of different ages ranged from 12-35 years. Abnormalities were not found in selected blood samples taken from blood donors and therefore being used as controls for comparison with blood samples taken from primary amenorrhea patients. A total number of 62 patients, attended to the Educational laboratories, City of Medicine, Baghdad, were diagnosed with primary amenorrhea. Patient’s ages were ranged from 12-35 years. All patients were suffering from primary amenorrhea symptoms. Meanwhile, all blood samples were subjected to molecular studies. Venous blood samples (5ml each) were collected from affected individuals. Six patients were excluded from this study due to chromosomal abnormalities.

FSHR gene SNP

TaqMan fluorescent oligonucleotide probes and primers sequences for FSH receptor gene SNP (rs6165 G>A )designed by7 which mediates the effects of FSH, is essential for normal spermatogenesis and male reproduction. This study aimed to investigate the effects of the FSHR polymorphisms on idiopathic male infertility and serum FSH levels in Han-Chinese population. Methods: A case-control study was conducted with 364 idiopathic infertile patients (97 nonobstructive azoospermic, 79 oligozoospermic and 188 normozoospermic. And they provided in a lyophilized state by Macrogen Company (Korea), stored at (-23°C). The sequence of probes, forward and reverse primers are listed in the table (1):

The Genomic DNA was extracted from blood using the Wizard genomic DNA purification kit (Promega, USA) according to the manufacturer instructions, then the samples were subjected to a real-time polymerase chain reaction(qPCR). The reaction mix was adjusted to a final volume of 10 µl as suggested by the manufacturer and included: 5µl GoTaq Probe qPCR Master Mix (Promega/USA), 0.5µl of each primer (each lyophilized primer was dissolved in free nuclease water to prepare the stock solution in a concentration of 100 pmole/µl. Then the working solution is prepared by adding 10µl of the stock solution to 90µl of free nuclease water), 0.5µl of each prob, 1.5 µl DNA, and 1.5µL nuclease-free water. The mix was transferred to a real-time thermocycler (MIC-4 Real-time PCR System, Australia ), which was programmed for the following optimized cycles: initial denaturation for 5 min at 95°C (one cycle), 40 cycles of denaturation (20 sec at 95°C), annealing (30 sec at 60°C) and extension (30 sec at 72°C), and finally one cycle of melt curve at 65–90°C.

Statistical Analysis

Data analysis was done by utilizing SPSS for Windows, version 17 (SPSS Inc. Chicago, IL, United States). Data appeared as mean ± standard deviation. Shapiro–Wilk normality test was used to determine whether the studied parameters followed a Gaussian distribution. Variables in which the distribution of data did not conform to normality were first log transformed for analysis and then converted back to standard units for presentation. Categorical variables were analyzed by the Chi-square test. Tukey’s, Dunnett, and Bonferroni Post Hoc test for multiple comparisons were applied after T-tests.

Inspecting FSHR gene genotypes and Allele Frequencies in (PA) group and (C) group revealed that there was significant variation between these frequencies, Although an increased frequencies of G allele (60 vs. 61%) and a decreased frequencies of A allele (40vs. 38.7 %) were observed in patients compared to controls (Table 4).

Results

FSHR gene SNP

The SNP of FSHR gene (G>A rs6165; located on Chromosome2p21-16:242193529 bp) was presented with three genotypes (GG, AG, AA) and two alleles (G and A).

Analysis of Hardy-Weinberg equilibrium (HWE) in (control) group and (patients) group revealed that the genotypes was consistent with the equilibrium, and significant differences (p <0.01) were observed between the observed and expected genotype frequencies in control and significant (p>0.05) in patients group (Table 3).

In AG Polymorphism, the odds ratio for the AG genotype was 0.25 (0.10 - 0.58)with P value =0.002 indicating that heterozygous genotype AG was a protective factor to (PA) group and mutant type AA which considered as a risk factor for primary amenorrhea according to the odds ratio 4.21 (1.14 - 15.58) with p-value 0.03.

Discussion

FSHR gene SNP

FSH and its receptor play a major role in the development of follicles and regulation of steroidogenesis in the ovary. The interaction of this hormone with its cell surface receptor initiates a chain of intracellular reactions characteristic of G-protein-coupled receptors, if any Structural changes occurred in this region that could lead to changes in the amino acid configuration of the FSH receptor gene, resulting in functional changes in the gene in which Some of it leads to enhance functionality of the receptor, while some reduce it.10 Many studies investigated about the main cause of amenorrhea and the impact of polymorphisms on the disease, but there is a little knowledge about it in Iraq so this study could help to seek for the main genetic cause of amenorrhea. Our results illustrate that significant differences in the distribution of FSHR genotypes between PA patients and control group. The proportions of Thr/Thr, Thr/Ale and Ale/Ale were 54.54%, 29.1% and 25.45% respectively in patient group and 12%, 25% and 3% correspondingly in control group, and there was a significant difference between the two. According to11 results showed that there was a difference in distribution between non ovulatory patients and normal-ovulatory controls was significant for polymorphism 6165 (P<0.05 for position307), with a distribution of (AA) and (AG), genotypes higher in patients than controls, that agree with our findings, also there were some studies that disagree with these results and failed to prove the significance of the SNP and disease.12

Despite the fact that multiple causes might increase susceptibility to primary amenorrhea, the results of this study showed that single nucleotide polymorphisms in FSHR gene might consider as one of the susceptible factors that result in amenorrhea. However, additional investigations are recommended to be directed on other ethnic populations to approve the results of this study.

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq

Abstract

This research aimed to study effect of Clarithromycin drug on Cryptosporidium Parvum and efficiency of ELISA technique in diagnosis comparison with some traditional methods in vitro. Samples collected from four different sources water were 400 liters:100 liters tap water provider by Al-Kufa District River,100 liters house tank water,100 liters from sea of Al-Najaf and 100 liters stagnant water during period from October 2018 to April 2019.Examined samples by three laboratory methods: Modified Ziehl-Neelson stain, Flotation by saturated sugar solution method and ELISA to detecting from Cryptosporidium oocysts in the water as used Clarithromycin drug effective against C.parvum in vitro. Capability test was performed by impregnation of isolate on cell monolayers and determination the parasite counted after 48 h from the incubation at 37°C. Differ concentrations from Clarithromycin were 4, 8, 16 and 32 mg/L respectively compared with control group.

Results of the current study showed that oocysts were found in 182 from 400 liters 45.5% as showed that height oocysts in stagnant water then followed Sea of Al-Najaf were 55% and 45% respectively, height percentage of oocysts were in April and March were 69.09% and 66% while decrease percentage of infection in October was 25%. As showed study results presence significant differences in efficiency of ELISA technique was 83.33% at detection from oocysts compared with Flotation by saturated sugar solution and Modified Ziehl-Neelson stain methods were 66.66% and 61.11% respectively. Shown results this study that Clarithromycin drug in concentrations of 16 and 32 mg/L caused decrease in number oocysts was 17.3±3.5 and 15.4±3.9, sporozoites counts was 17.1±3.4 and 14.9±4.0 compared with control group was 20.5±2.8. As observed significance differences (P˂0.05) in the mean numbers of oocysts and sporozoites in three replicate plates after 48 h. These results proved that Clarithromycin have effectiveness in inhibition C.parvum in vitro.

Keywords: Cryptosporidiosis, Water, Oocysts, Sporozoites, Clarithromycin, in vitro.

Introduction

Cryptosporidiosis is protozoan disease occurred by Cryptosporidium spp from phylum Apicomplexa is unicellular organisms include number of pathogenic infect human and mammals by food and contaminated water (1). Oocysts transmitted in arduous environment where not killed by conventional disinfectants and chlorination which causes diarrhea, massive dehydration, malnutrition and weight loss lead to abomasal cryptosporidiosis (2). Oocysts resisted tough environmental condition for six months where can stay alive for twelve weeks at 10°C (3). Transmission riot by the fecal oral and involve drinking water, recreational water, person to person, animals to person and contribution of sexual pursuit may be locomotion through persons with human immunodeficiency HIV virus (4).

C.parvum infections diagnosed through knowledge number of infestation and non-invasive methods. The non-invasive methods, microscopic examination more common (5) or identification of these parasite is based on morphologic examination by using modified acid-fast...
staining method (6), important alternate the development of antigen parasite enzyme linked immune-sorbent assay (ELISA) these assay shown comparable sensitivity to experienced microscopic examinations, fairly simple to perform and do not require the observation of intact organisms (7).

Recently, observed there increase in number of infection with C.parvum correlating with increase in number of immune-compromised patients and resistance against drugs, this disease currently endemic in 88 countries world and showed diffusion increase in immunosuppressive conditions such as HIV/AIDS (8), Clarithromycin known as being semisynthetic antibiotic from macrolide derivative family (9). Also good distribution excellent activity against intracellular pathogens such as: Toxoplasma gondii (10), Leishmania donovani (11) and Cryptosporidium parvum (12) invitro as featuring effective, least side effects, low cost and easy administration. Clarithromycin, Azithromycin and Roxithromycin are effective in inhibition C.parvum growth at concentrations close to those achievable (13). The aim this research is study effect of Clarithromycin drug on oocysts and sporozoites in vitro and efficiency of ELISA technique in diagnosis comparison with some traditional methods.

Materials and Method

Water samples were collected during the period from October 2018 to April 2019 of Al-Najaf governorate. A total amount was 400 liters: 100 liters of tap water supplies by Al-Kufa District River, 100 liters of house tank water, 100 liters sea of Al-Najaf and 100 liters of stagnant water, put in sterile bottles which delivered to the laboratory of pharmacognosy and medicinal plants in pharmacy college/ kufa university.

Diagnosis parasite: 5 liters from water samples distributed in sterile test tubes placed in the centrifuged 1000g/10-15 min to get on sediment, taken 5 ml of sediment and added 15 ml of distilled water then aspirate during six layers of gauze for get rid of the suspended waste then centrifugation procedure was performed again 1000g/10 min. 10 ml add of saturated sugars solution to the sediment well mix (14). Taken drop from the upper layer of the tube by Pasteur pipette placed on glass clean slide left to dry in the air for 10 min, smear fixed by absolute methyl alcohol for 5 min and left to dry, added modified ziehl-neelson stain to the fixed smear and heating for 5 min by Bunsen burner until vapor appears and washed with tap water, the slide is immersed in 10% HCL for 10-15 sec and washed again with water then dye was stained with methylene blue for 2 min, wash the well slide with running water then air-dried, examined by microscope 40X and 100X magnification to investigate parasite oocysts by many criteria’s as size, shape, color stain and surface feature (15).

ELISA technique: Used in these technique particular oocysts antibodies where placed these antibodies in the pits for the plate ELISA method and these antibodies have ability to interact with oocysts find in samples then plate incubated for 1 h at 21°C, wash the plate by washing solution and add the conjugation solution containing antibodies to the parasite associated with the peroxidase enzyme then incubate and wash the plate again. Add chromogen tetramethylbenzidine is solution of the reactive substance which contained bottle inside size 25 ml with ELISA diagnostic components, if the water container on oocysts, conjugation solution remains linked with the pit and the enzyme converts chromogen from colorless to blue color composite where strength this color is proportional with number of oocysts in the examined sample, stopped the enzyme reaction after addition of phosphoric acid solution then measured optical density at the wavelength of 450 nm using optical spectrum (16).

Experiment study invitro: Oocysts isolated from the water by ELISA method was used throughout this study. Clarithromycin (Abbott, Italy) were dissolved in 50% methanol and 50% acetone to obtain 1 mg/ml of stock solution for perpetrated different concentrations where stored at –80°C in the dark. In these experiment indicated that concentrations of methanol, acetone were used in dilution of drugs did not inhibit the growth of C. parvum.

Oocysts Preparation: Occur by suspending portion of stock oocysts in bleach solution containing nine parts sterile deionized water and one part 0.55% sodium hypochlorite for 10 min, washed twice in sterile water, centrifuged and re-suspended in Dulbecco’s modified Eagles medium (DMEM) (Bio-Whittaker) then incubation in phosphate buffered saline PBS (Bio-Whittaker) containing penicillin G (2000 U/mL), streptomycin (2000 mg/L) and amphotericin-B (10 mg/L) for 4 h at 37°C. Excystation of sporozoites was achieved by incubating oocysts in PBS containing 0.25% trypsin (Sigma-Aldrich) and 0.75% sodium hypochlorite for 60 min at 37°C. Free sporozoites were pelleted by
centrifugation 500g/10 min, re-suspended in (DMEM), counted in haemocytometer for culture (17).

Cell Culture: Isolated 500 cells from human stomach carcinoma were maintained in 25cm2 tissue culture flasks. Medium consisted of (DMEM) with 10% fetal bovine serum (Bio-Whittaker), 4% L-glutamine (Bio-Whittaker), 1% non-essential amino acid, penicillin G (100 U / ml), streptomycin (100 mg/l) and amphotericin B 0.5 mg/l. Cells were lifted from the surface of flasks by using solution of 0.25% trypsin and 0.53 mM EDTA in phosphate buffered saline then quantitated using hemocytometer. 500 cells were plated onto 35 mm diameter tissue culture plates at concentration of 105 viable cells in total volume 5 ml, viability was assessed by trypan blue exclusion (18).

Infection of cells with C.parvum: Infection of the cell monolayer was started by adding 105 sporozoites in volume of 0.2 ml of medium. After incubation for 4 h at 37°C in 5% CO2 to allow attachment and penetration of sporozoites, monolayers washed with (DMEM) to remove noninvasive sporozoites, residual oocysts and no adherent epithelial cells. Infected cell cultures were keeping at 37°C in 5% CO2 throughout this study (19).

Antibiotics agents: Clarithromycin concentrations prepared were 4, 8, 16 and 32 mg/L respectively, Experiments were performed in triplicate the monolayers were incubated for 48 h at 37°C in 5% CO2. Following four washes in phosphate buffered saline to remove free oocysts and no adherent epithelial cells then fixed with 75% methanol and stained by Giemsa stain to estimate presence of sporozoites within cells to vision both intra and extracellular oocysts. The number of parasites was calculated by mean ± standard deviation of the mean of number of sporozoites and oocysts observed in three monolayers of each of ten isolates exposed to same concentration of drug by microscopic examination of 40 fields under 1000X magnification (20).

Statistical analysis: In these study association between presences of oocysts with various source of water depending to months this study and efficiency of the diagnostic methods used during the experiment by (P<0.05) (21).

Discussion

Cryptosporidiosis is one of the major diarrheal diseases caused by protozoan parasites and poses significant public health worldwide and poorly understood and many livestock farming industries as water consider of sources for zoonotic infections.

In the present study found oocysts 182 of 400 liters from water samples with total prevalence 45.5% this rate varies depending to water source with significant differences. Oocysts found about 40% in tap water provides by Al-Kufa river, as found 42% in tank houses water while oocysts appear 45%, 55% in sea of Al-Najaf and stagnant water samples respectively, this study agrees with (22) showed infection rate in the children at Al-Najaf city was 13.6% causes contamination drinking water contained on oocysts (23). As in Table1

As showed in the relation between oocysts presences and season appeared significant differences was recorded upper infection in April and March were 69.09% and 66% while decrease percentage of infection in October was 25%, this study agrees with (24) where recorded highest percentage in the spring and lowest winter, in Iraq which attributed to appropriate climatic conditions help on survival of oocysts in the environment and increased consumption of water contaminated. As in Table2

Results of the study current existence significant differences in efficiency of ELISA technique was 83.33% at detection from Cryptosporidium oocysts compared with Flotation by saturated sugar solution and Modified Ziehl-Neelson stain methods were 66.66% and 61.11% respectively, which may lead to examination of large number of samples, accuracy in reading results and shortening the duration of the diagnosis, this study agree with (25). As in Table3

Clarithromycin showed potent anthelmintic activity in vitro, crucial importance is whether the drug would penetrate into larger metacestode tissues in our in vitro experiments, by using metacestode material cut into small blocks; this possible barrier was not of concern (20). In current study showed that clarithromycin in concentrations of 16 and 32 mg/L caused decrease in number oocysts was 17.3±3.5 and 15.4±3.9, sporozoites counts was 17.1±3.4 and 14.9±4.0 compared with positive control group was 20.5±2.8 respectively, lead to significance differences in the mean numbers of oocysts and sporozoites in three replicate plates after 48 h. As in Table4
The mechanism by clarithromycin decreases the number of parasite attributed to ability inhibit protein synthesis by binding to the transpeptidation site of the larger ribosomal subunit thus is logical that these agents should also affect C.parvum by inhibiting protein synthesis (26).

There are research showed that this drug is effective against protozoa such as T. gondii, Cryptosporodium spp(27) and L. Major in vitro by action mechanism effects on microorganisms is carried out through reversibly connecting to 50S ribosomal subunits and inhibiting the protein synthesis (28).

Indirect Method for Determination of Paracetamol in Pure and Pharmaceutical Drugs using CFIA with Homemade Ayah 3S\textsubscript{BGR-X3-3D} Solar Cell Microphotometer Analyzer

Nagam S. Turkey Al-Awadie\textsuperscript{1}, Marwah A. Kadhim Al-banaa\textsuperscript{2}

\textsuperscript{1}Department of Chemistry, College of Science, University of Baghdad, Baghdad, Iraq, \textsuperscript{2}Department of Optical Techniques, Dijlah University College, Baghdad, Iraq.

Abstract

A method is described for the determination of paracetamol (based on the formation of an orange-reddish color species by reduction of Fe(III) to Fe(II) by paracetamol and then reacted with 1,10-phenanthroline) in the range 0.001-0.09mMol.L\textsuperscript{-1} (r = 0.9801, r\textsuperscript{2} = 0.9606 , and R\textsuperscript{2} = 96.06) with a detection limit (LOD) 21.77ng/160µL(3SB)(S/N=3) and with RSD\% for 0.01 and 0.07mMol.L\textsuperscript{-1} less than 1\% (n=6). The method was applied successfully for determination of paracetamol in pharmaceuticals formulation. Analysis of drugs used the standard additions method via the individual t-test. The results showed a significant difference between the quoted value of each company with calculated t-test at 95% confidence(\(\alpha\)=0.05) from new method.

Key words: spectrophotometer, flow injection analysis, paracetamol

Introduction

Paracetamol (Acetaminophen, 4-Acetamidophenol, N-(4-hydroxyphenyl) acetamide), Tylenol), is now probably the most commonly used drug worldwide, available over the counter, used as an analgesic and antipyretic drug\textsuperscript{(1,2)}. It is preferred alternative analgesic-antipyretic to aspirin, particular in patients that could not be treat with non-steroidal anti-inflammatory drugs, such as people with pregnant or breastfeeding women, children under 12 years of age, bronchial asthma, salicylate-sensitized people, peptic ulcer disease , hemophilia. It is available in uncontaminated type as various trade-name preparations for oral use and organize combined in over 200 preparations with further drugs\textsuperscript{(3)}.

Some side effect may occur of paracetamol observed after higher doses (4g/24h), specially in the liver, so United States Food and Drug Administration (USFDA) produced it on the recorded elaborations, which will endure definite checking on the basis of data from the system on adverse reactions. The preparations containing paracetamol will be assess in term of introducing adverse skin reactions \textsuperscript{(4)}.

Several methods for determination of paracetamol have been reported such as LC\textsuperscript{(5)}, RP-HPLC\textsuperscript{(6)}, spectrophotometry\textsuperscript{(7)}, Chemiluminescence\textsuperscript{(8)}, Electrochemical detection\textsuperscript{(9-13)} and Merging zone-continuous flow injection technique\textsuperscript{(14)}. In the present study, (Ayah 3S\textsubscript{BGR-X3-3D} solar cell microphotometer analyzer\textsuperscript{(15)} was used) as a sensitive and simple method, for the determination of paracetamol via the recorded of the signal from the measurement of absorbance at 525nm green light emitted diode (LED) as a source.

Experimental

Chemicals

The following stock solutions were prepared

- Paracetamol solution, 0.05 Mol.L\textsuperscript{-1}(151.16g.Mol\textsuperscript{-1}, BDH,UK). Dissolve 1.8895g of C\textsubscript{8}H\textsubscript{9}NO\textsubscript{2} in distilled water in a 250mL volumetric flask.

- 1,10-phenanthroline, 0.1 Mol.L\textsuperscript{-1}(180.2g.Mol\textsuperscript{-1}, BDH,UK ). Dissolve 9.01g of C\textsubscript{12}H\textsubscript{8}N\textsubscript{2} in distilled water in a 500mL volumetric flask.

- Iron(III),0.2Mol.L\textsuperscript{-1} (278.0146g.Mol\textsuperscript{-1})
Dissolve a weight of 13.9007g FeSO$_4$.7H$_2$O after that the addition of 2-3 drops of concentrated H$_2$SO$_4$ followed by the addition of 80mL of H$_2$O$_2$.0.1Mol.L$^{-1}$ which is prepared and purified through passing on a cation exchanger Amberlite 120) warming the solution with constant stirring for the completion of oxidation of Fe(II) into (III), continuation of doing so until bubbles ceases for removing the excess of H$_2$O$_2$ followed by the addition 10-15mL of concentrated H$_2$SO$_4$ (in order to avoid the turbidity of the solution, during the process of oxidation of Fe(II) to Fe(III)) . The solution quantitatively transferred into a volumetric flask (250mL), the volume is completed with distilled water. 

**Apparatus**

Ayah 3S$_{BGR}$X3-3D solar cell microphotometer was used in this work as a homemade instrument that measures the absorbance of any different sample segment color which is capable of absorption in the visible region of the spectrum by uses three sources of irradiation : Blue (470nm), Green (525nm), and Red (635nm) with three solar cells as a detector at range of 450-1150nm. The instrument is composed of a block of brass having the dimensions of 20(width), 20(thickness) and 90mm(length). Flow cell with ID=2mm and OD=4mm that embedded inside a metal block. Nine source of light emitting diodes were used as an array arrangement act as emission sources at 100mm distance with three solar cell as a detector. The output of measure by solar cells was used without any further amplification of the transmitted light signal as shown in fig.1-A(X,Y-t potentiometric recorder,(Kompsono, Graph C-1032, Siemens, Germany, 1-500 volt, 1-500mV) ).

Fig.1-B shows the manifold system that uses flow system represent by peristaltic pump (An ISMATEC, Switzerland, type ISM796 peristaltic pump, two channels), six ports rotary injection valve (Six ports medium pressure (model,V-450)(upchurch, scientific INC) valve (Teflon) was used with a variables sample volumes) and (Homemade Y liquid junction point. made of poly methylmethacrylate (PMMA)).

![Figure 1:A- 3D-representation of the brass metal housing of the used LED$_s$, their location, flow cell, and the three solar cell; each collect light from one set(single colour) of LEDs](image-url)
B- Schematic diagram of flow system for the determination of paracetamol

Methodology

A manifold system used in this research consist of two line flow feed unit: first line supplies Fe(III) (0.03mMol.L\(^{-1}\) with flow rate 2.4mL.min\(^{-1}\)) which passes through injection valve carrying the paracetamol sample(0.03mMol.L\(^{-1}\) with sample volume 160µL) which lead to reduction of Fe(III) to Fe(II) then combined with the second line (1,10-phenanthroline, 0.3mMol.L\(^{-1}\) with flow rate 2.5mL.min\(^{-1}\)) at a liquid junction point (Y-junction) that will produce orange-reddish color which passes through delay reaction coil (32cm,0.25mL) to completed formation of colored species and then to Ayah 3S\(_{BGR}\)X3-3D to measure absorption process at green light emitted diode(LED) as a source. A proposed mechanism for the reaction occurred in the manifold system expressed in sketch number 1.

Sketch number 1: A proposed equation of reaction between Fe (III) and paracetamol with 1,10-phenanthroline

Results and Discussion

Chemical Variables

A spectroscopic study for colored species (orange-reddish color) was monitoring by a homemade Ayah 3S\(_{BGR}\)X3-3D solar cell CFIA microphotometer at three different super bright light diode (LED) as a source (blue 470nm, green 525 nm, and red 635 nm) using paracetamol(0.03mMol.L\(^{-1}\),130µL)- Fe(III) (0.01mMol.L\(^{-1}\))- 1,10-phenanthroline (0.07mMol.L\(^{-1}\)) system with flow rate at 2.3 and 2.4 mL.min\(^{-1}\) of the line no.1 (carrier stream) and line no.2 (reagent stream) respectively. Fig.2 shows the maximum response measured in mV was obtained using green light emitting diode so it used for the determination of paracetamol in next studies.

Effect of Fe(III) concentration

Fe(III) solutions of different concentrations were prepared (0.005-0.07mMol.L\(^{-1}\)) using physical parameters : flow rate 2.3 and 2.4 mL.min\(^{-1}\) for the Fe(III) stream and 1,10-phenanthroline(0.07mMol.L\(^{-1}\)) stream respectively , sample volume 130µL(0.03mMol.L\(^{-1}\) paracetamol) and open valve mode. The maximum response of the colored species obtained was noticed at 0.03mMol.L\(^{-1}\) of Fe(III) concentration (more than 0.03mMol.L\(^{-1}\) could due to restriction of the passage incident light due to. small. colored colloidal. precipitate.
which be formed in front of solar cells). So it was found that 0.03mMol.L\(^{-1}\) of Fe(III) was the most suitable.

**Effect of 1,10-phenanthroline concentration**

Solutions containing 0.03mMol.L\(^{-1}\) Fe(III) and 0.03mMol.L\(^{-1}\) paracetamol with different 1,10-phenanthroline concentrations(0.05-0.7mMol.L\(^{-1}\)) were prepared. It was noticed at more than 0.3mMol.L\(^{-1}\) a decrease in response which can be attributed to increase of the colored species density which work as, internal filter that really prevent the remaining light intensity, after absorption. process.so it was chosen 0.3mMol.L\(^{-1}\) of 1,10-phenanthroline concentration for optimum sensitivity and reproducibility response.

**Physical variables**

**Flow Rate**

Using chemical variation for : paracetamol(0.03mMol.L\(^{-1}\))- Fe(III)( 0.03mMol.L\(^{-1}\))-1,10-phenanthroline(0.3mMol.L\(^{-1}\)) system and physical parameters including : sample volume (130µL) and open valve mode with variation of flow rates (1.9-2.7) ,(1.9-2.7) mL.min\(^{-1}\) for Fe(III) line and 1,10-phenanthroline line respectively. A flow rate of 2.4 and 2.5 mL.min\(^{-1}\) for Fe(III) and 1,10-phenanthroline line respectively was chosen as better flow rate because it was noticed at flow, rate ranged 1.9-2.1mL.min\(^{-1}\) there is an increase in area of colored segment in front of detector (increase in \(\Delta t_B\) (base width) versus peak height and dilution factor) while at higher flow rate (>2.4 and 2.5 mL.min\(^{-1}\) for Fe(III) and 1,10-phenanthroline stream respectively) the response is not very high because departure of reactant from measuring cell before to completion of reduction Fe(III) to Fe(II) (decrease time in front of detector and \(\Delta t_B\))

**Sample Volume**

Different sample volume (50-200µL) with fixing all previous experimental parameters (chemical and physical parameters) with 525nm as a source for irradiation were used. The results shows that increase in sample loop, led to an increase in S/N and \(\Delta t_B\) (base width) up to 160µL (above 160µL, there were a broadening at the peak height and \(\Delta t_B\)) so as a comparison between \(\Delta t_B\) , peak height and sensitivity , 160 µL could be used as best sample volume for the determination of paracetamol in next studies.

**Purge Time**

The purge time (time for purging of the paracetamol segment from the six port injection valve) was carried out in this work(5-30sec). It was noticed from results obtained that open valve mode at 30 sec was chosen as most suitable purge time for the totally departure of colored species from the injection valve to obtain better response for determination of paracetamol.

**Effect of reaction coil length**

Variation coil length (0-57cm) was used for the study of effect the reaction delay coil (after Y-junction point) on S/N peak profile , \(\Delta t_B\) and concentration of paracetamol after dilution . It was noticed that best coil length for the homogenization and completion of the reduction Fe(III) to Fe(II) with suitable base width (\(\Delta t_B\) , decrease dilution effect and regular response was 32cm(0.25mL).

**Preparation of calibration graph**

Various concentrations (0.001-0.09mMol.L\(^{-1}\)) of paracetamol was prepared using the parameters achieved above. Each measurement was repeated three times. Regression analysis gave r (correlation coefficient ) 0.9801, r\(^2\) (coefficient of determination ) 0.9606 , and R\(^2\)% (linearity percentage ) 96.06 as tabulated in table 1.

**Limit of detection and repeatability**

Gradual dilution of low concentration in the calibration graph and depend on the linear equation(numeric value of slope) was used for the calculated of detection limit. The repeatability studied for using Ayah 3S\(_{BGR}\)X3-3D analyser by paracetamol-Fe(III)- 1,10-phenanthroline system at concentration 0.01 and 0.07mMol.L\(^{-1}\). All calculated obtained was tabulated in table 1.

### Application

Ayah 3S<sub>BGR</sub> X3-3D solar cell CFI analyser was used for the analysis of paracetamol using paracetamol- Fe(III)-1,10-phenanathroline system in the different drug manufactures (SDI-Iraq, Advance- United Kingdom, and Kernadol, Kern pharma-Espain). A series of solutions were prepared of each paracetamol drug (20mMol.L<sup>-1</sup>) (0.3023g) by transferring 0.01mL to each 10mL volumetric flask, followed by the addition of step wise volumes (0.0, 0.01, 0.02, 0.03, 0.04 mL from 10mMol.L<sup>-1</sup> standard solution) to obtain 0.0-0.04 mMol.L<sup>-1</sup>. Table 2 shows all results obtained of standard calibration graph, practically content of paracetamol in each sample of drug and efficiency of determination using developed method at confidence level 95%.

The standard addition method in this research work was put into individual t-test between x (mean) and quoted value, (500mg). There is a significant difference between claimed value of each company with t calculated at α=0.05 (95% confidence interval).

Conclusion

The method in this research work described for the determination of paracetamol by reduction of Fe(III) to Fe(II) and then combination with 1,10-phenanthroline to formation orange-reddish colored species. Homemade Ayah 3S BGR X3-3D solar cell CFI analyser was used for the measurement of absorbance at 525nm green light emitted diode (LED)as a source. The new technique was applied successfully. for the determination of sample (paracetamol) in three different drugs.

²Biotech. Lab., College of Education for Pure Sciences, University of Mosul, Iraq

Abstract

In this investigation hairy roots were induced on leave petioles of *Ruta graveolens* L. plants. These roots were white in color and negative geotropism. Paper electrophoresis of hairy roots extract resulted in the separation of black spots of agropine. These transformed roots were cured from *Agrobacterium rhizogenes*, some cultures of these roots were directly produced shoots, and other was orientated to produce callus. Subsequently this callus was capable to produce numerous regenerates. Both groups of shoots were rooted easily and successfully adapted to field conditions. Evidences of molecular biology assessment, including isolation and amplification(PCR) of DNA of each transformed tissues and plants coupled with DNA electrophoresis data proved the transfer of *rol*-genes, except *rol B*, in the regenerated plants.

Conclusion: The genetic modified *R. graveolens* plants possess unique characters due to the conservation of *rol*-genes in their genomes.

**Key words:** *Ruta graveolens*, *Agrobacterium rhizogenes* R1601, Agropine, PCR, *rol*-genes.

Introduction

A recent study reported that *Ruta graveolens* L. plants reacted easily in culture, acceptable to many *in vitro* techniques and possess high regeneration capability (¹). Also plants were regenerated from leaf segments derived callus (²) and from axillary shoot multiplication (³). It is well-known that this medicinal plant is rich with different industrial plant products, such as alkaloids, coumarine, flavonoids (⁴) and rutin (⁵). The present study was designed whether *Agrobacterium rhizogenes* R1601, the natural vector, is efficient to create genetically modified tissues and whether genetically engineered plants can produced from them. In such studies experiments involved to demonstrated the transfer of T-DNA, synthesis of agropine, isolation of genomic-DNA of plant, amplification plant DNA by PCR coupled with gel electrophoresis of the amplified DNA (⁶). The aim of this research is to specify and confirm which *rol*-gene(s) was transferred and expressed.

Materials and Method

Preparation of bacterial suspension.

Agropine type *Agrobacterium rhizogenes* R1601 harboring Kana<sup>Res</sup> and Carb<sup>Res</sup> genes, as genetic markers, on Ri-plasmid was supplied from Prof. E.G. Nester(Washington university, U.S.A.). This strain was grown in agar solidified APM medium (⁷), provided with 100 mg.L<sup>-1</sup> of each Kanamycin and carbencillin. Agrobacterial suspension was prepared using single colony used to inoculate 50 ml of liquid APM medium supplied with the same above antibiotics. Cultures were kept on rotary shaker 100 rpm for 72 h. Inoculum was harvested and the precipitated bacterial cells was resuspended in 10 ml liquid APM. Optical density was adjusted to 1.90 (⁸).

Direct injection of leaf petioles with *A. rhizogenes* R1601.

Leaves petioles of 3.0 cm length were excised from two years old Rue ( *Ruta graveolens* L.) plants, washed with water and surface sterilized through soaking in the sterilizing solution consist of 1:2 (v:v) of sodium hypochlorite NaOCl: water for 15 min.. Explants were washed thoroughly with sterilized water three times 5 min./each time (¹). The tip needle tip was immersed into the inoculum and directly inject the top ends of the sterilized petioles in 2-3 sites. Each inoculated petiole was
cultured in vertical position into 25 ml of agar solidified MSO medium contained in 100 ml glass vessel. Hairy roots developed on inoculated samples were excised and transferred to agar solidified MSO medium containing gradual conc. of Cefotaxime to eliminate the habitant agrobacterium, as previously reported\(^9\).

Detection of agropin in hairy roots by paper electrophoresis.

Samples of bacterial-free young hairy roots were cut from their cultures and grinded in eppendorf tubes in the presence of 100 µl 0.1N HCl. The mixture was centrifuged at 6000 rpm for 20 min., volumes of 30 µL of each clarified sample and of standard agropin were spotted on the chromatography paper as described\(^10\).

Plant regeneration from transformed tissues.

Cluster of young hairy roots were transferred to 20 ml of agar solidified MS medium. Friable callus of white-yellow color was developed. Subsequently this callus was differentiated producing number of shoots. In other cultures shoots were produced from the green-tips of hairy roots. Both types of shoots were excised and each shoot was plunged vertically in the rooting medium MS+0.5 mg.L\(^{-1}\) IBA\(^11^,12\). All shoots were readily rooted, and adapted using peat-moss medium.

Conservation of \textit{rol-genes} in genomic DNA of transformed plant.

This involved intensive laboratory work including:

\textbf{Isolation of DNA:} The extraction solution CTAB (Cetyltrimethyl Ammonium Bromide) was used for DNA isolation from transformed plant\(^13\). Purity and concentrations of the isolated DNA were determined at 260 and 280 ηm\(^14\).

\textbf{Gel electrophoresis of the amplified isolated DNA:} One gram of agarose (Vivantis LE grade Agrose, USA) was dissolved in 100 ml of IX TBE solution. The melted agarose at 40°C was carefully poured in the tray. Gel layer thickness was 8 mm and of dimension 8.5×10cm. After complete solidification of gel the plastic comb was removed carefully, and the layer was put in the tank (Electrophorasis MS MINI U.K.) in the presence of 250 ml of the extraction solution 1X TBE. The loading samples was each consisted of 8.0µL of DNA mixed with 2.0 µL of loading buffer. One of the terminal well was loaded with 3.0 µL of the ladder λ DNA 50 bp DNA, total size 1350pb. At the end of samples loading electrical current of 50 volt for 90 min. was pass through. Then, remove the layer and transfer to dish containing 500 ml of ethidium bromid stain solution of final conc. 0.5 mg.ml\(^{-1}\) for 40min.. Finally examine the layer by UV light of 300 ηm to visualize the separated bands.

\textbf{Polymerase Chain Reaction test:} To detect the putative transfer of \textit{rol-gene(s)}, from T-DNA and their integration into plant genomic DNA the specific primers mentioned below (Table 1) used.

\begin{table}[h]

\end{table}
The reaction mixture was prepared in premix tubes containing 5.0 µl of the mixture (Taq DNA polymerase + dNTPs + Tris-HCl + KCl + MgCl₂ buffer X10). To this added 1.0 µl of the specific essential primer of conc. 10 Becamol Microliter -1. Similar volume and conc. of the reverse primers and of the temple DNA at conc. 50 ng µl -1. Complete the final volume to 20 µl by addition 9.0 µl of distilled, deionized sterilized water. Tubes were inserted into the thermal polymer to begin the amplification reaction following the same conditions previously mentioned (15).

### Results

- Establishment of cured hairy roots cultures.

The response of petiole explant to direct injection by *A. rhizogenes* R1601 resulted in the formation of adventitious roots on both inoculated and non-inoculated sites (Table 2)

#### Table 2: Induction of hairy roots on leaf petiole explants of *R. graveolens* to direct injection by *A. rhizogenes* R1601.

Hairy roots began to form as tiny bodies (Fig. 1: A), developed to white and fine hairy roots (Fig. 1: B). These hairy roots were excised as cluster or single root. They cultured on agar-solidified MS medium and were negatively geotropism as growing producing mass of these hairy roots. They grew rapidly on the surface of solid MSO medium (Fig. 1: C), whereas samples of excised normal roots failed to continuing their growth. Data indicated that gradual transfer of hairy roots culture three times on 100, 200 and 300 mg.l⁻¹ of cefotaxine led to the production of bacterial free culture of hairy roots (Fig 1: D). Overall these results considered the first signs of transformation of these roots.

![Fig. 1: Production of “agropine-positive” transformed hairy root of *R. graveolens* by *A. rhizogenes* R1601. (A): Formation of small bodies (arrowed) on inoculated petioles. (B): Development of single hairy roots (arrowed) from bodies in (A). (C): Cluster of hairy roots grew on the surface of agar-solidified MSO medium. (D): Development of hairy roots in (C) note their negative geotropism growth.](image-url)
Detection of the synthesized agropine.

Examination of electrophorctogram proved the separation of agropine that synthesized in these hairy roots. The black spots (approx. 2.0 cm diam.) were corresponded in positions and diam. to spots of standard agropine. This result represent an additional proof that this type of roots and their derived callus are genetically transformed by agropine type *A. rhizogenes* R1601 used in this study.

**Regeneration of plant from transformed tissues.**

The results revealed that culture of ‘agropine positive’ hairy roots of *Ruta graveolens* grown on solid hormone-free MS medium express their totipotency and producing number of shoots. Other cultures of hairy root were orientated to the spontaneous formation of callus, Subsequently, this type of callus acquired the green color and numerous shoots were differentiated.

The results indicate that shoots regeneration from bud developed on hairy root culture (Fig. 2. A), also regenerated directly from hairy roots (Fig. 2. B), and from hairy-root derived callus (Fig. 2. C,D). All types of shoots were readily rooted in agar-solidified MS medium supplemented with 0.5 mg L\(^{-1}\) IBA (Fig. 2. E). Plantlets were adapted and successfully acclimatized to field condition (Fig. 2. E). As they continuing growth clear morphological variations were found comprised the leave size, flower number, shape and flowering period.

**Fig. 2: Regeneration of genetically transformed *Ruta graveolens* L. from “agropine-positive” hairy roots induced by *Agrobacterium rhizogenes* 1601.**

(A): Shoot bud(arrowed) emergence hairy root grown on solid MSO medium start producing shoots (B): Direct shoot regeneration(arrowed) from hairy roots grown on MSO. (C): Spontaneous callus(arrowed) formation from hairy root grown on MSO. (D): Indirect shoot regeneration(arrowed) from callus grown on MSO. (E): Rooting of shoots(arrowed) in (A), in MS medium provided with 0.5 mg.L\(^{-1}\) IBA. (F): Transfer and acclimatized plants to field conditions.

**Concentrations and purity of DNA.**

Data showed that concentrations of DNA of transformed plants regenerated directly from transformed hairy roots and callus was exceed the conc. of DNA isolated from normal callus and plants (Table 3).
Table 3: Concentrations and purity of genomic DNA of *Ruta graveolens* L. plants transformed by *Agrobacterium rhizogenes* 1601.

<table>

</tbody>
</table>

Detection of *rol*-genes in genomic DNA of transformed *Ruta graveolens* plant.

Examination of electrophoresis gel layer of PCR products showed the separation of single band of amplified DNA of callus produced from transformed hairy roots. Its M.wt. was equal to the M.wt. of the specific primers for each of Kana \( \text{Res}^+ \) *rol A, rol B, rol C, and rol D* genes as single bands. The separation of these bands confirmed the presence of the responsible genes in cells genome of transformed hairy root, callus and plants regenerated from this type of callus. In the mean time the absence of such bands of amplified DNA isolated from non-transformed callus and plants donate an additional evidence in this aspects (Fig.3).

Fig. 3: Gel electrophoresis showed the presence of Kana \( \text{Res}^+ \), *rol A, rol B, rol C and rol D* genes in amplified genomic DNA isolated from leaves of genetically transformed *Ruta graveolens* L. by *Agrobacterium rhizogenes* R1601.

Lane (M): Lambda DNA.

Lane (1, 4): amplified DNA isolated from seedling leaves.

Lane (2, 5): amplified DNA isolated from leaves of genetically transform plant.

Lane (3, 6): amplified DNA isolated from seedling roots.

Those results strongly ensured that transformed hairy roots and callus conserved Kana \( \text{Res}^+ \) and *rol*-genes group except *rol B*. This indicate their transfer from the bacterial vector to genome of the recipient cells. The
expression of $Kana^{\text{Res}^+}$ gene enable hairy root derived callus to continue growth on MS medium contained with kanamycin. Whereas expression of $rol$-genes encouraged synthesis of agropine and the development of some variations on plant morphology.

**Discussion**

The production of genetically modified Rue, *Ruta graveolens* L., plant via *A. rhizogenes* 1601 mediated transformation probably explained the capability of this bacterial vector the rapid transformation of many plant species such as *Vigna radiate*\(^{(12)}\), tomato and potato\(^{(16)}\). In this study data proved the successful interaction between *A. rhizogenes* and petioles leaf, and the incidence of hairy roots pointed out the first sign of biotransformation\(^{(17)}\). During this stage acetosyringone compound release induce the transfer of T-DNA to plant cells\(^{(18)}\). Additionally, this compound stimulate T-DNA genes, of Ri-plasmids, to fuse with cell genome producing a genetically transformed clone\(^{(19)}\). This is supported the spontaneous induction of callus\(^{(20)}\) on hormone –free MS medium as occurred with *Solanum nigrum*\(^{(21)}\) and *Rubia akane* L.\(^{(22)}\) plants. Bacteria was eradicated by the use of cefotaxime antibiotic which recommended by several studies\(^{(15)}\). The expected explanation of agropine synthesis in hairy roots and its callus emphasized that $rol$ $D$ gene controlled it’s synthesis when *Agrobacterium*-plant functional interaction only take place\(^{(23)}\). In the present work production of genetically- transformed Rue plants from “agropine-positive” tissues is an expected status. At the same time it represented an advanced interested phenomenon. The expectation was not to obtain high transformation frequency (TF) as occurred with carrot\(^{(15)}\) plants.

Assessment of Bioactive Resin-Modified Glass Ionomer Restorative as a New CAD/CAM Material. Part I: Marginal Fitness Study

Huda A. Abdulla¹, Manhal A. Majeed²

¹Department of Conservative Dentistry, College of Dentistry, Tikrit University, Saladin, Iraq, ²Department of Conservative Dentistry, College of Dentistry, University of Baghdad, Baghdad, Iraq

Abstract

The objective of this in vitro study was to evaluate and compare the marginal fitness of monolithic crowns fabricated from a newly developed bioactive CAD/CAM resin block and reinforced resin CAD/CAM block pre- and post-cementation with adhesive and self-adhesive resin cements. Bioactive CAD/CAM block were fabricated from ACTIVA BioACTIVE-RESTORATIVE (Pulpdent Corporation, USA) using a clear rectangular Teflon mold. Thirty-two human maxillary first premolar teeth were prepared to receive full crowns then divided into two main groups of 16 teeth each according to the type of block used to fabricate the crowns: Group A: crowns fabricated from the bioactive resin block, Group B: crowns fabricated from reinforced composite block (BRILLIANT Crios, Coltene). Each group was then subdivided into two subgroups according to the type of resin cement used for cementation, Subgroups (A1, B1): RelyX Ultimate cement, Subgroups (A2, B2): ACTIVA BioACTIVE-cement. The prepared teeth were scanned using CEREC Omnicam digital intra-oral and the crowns were then designed using CEREC Premium software (version 4.4.4) and milled using CEREC MC XL milling unit. The marginal gap of each crown was measured before cementation at four points on each tooth surface using a digital microscope at a magnification of 230x. Each crown was then cemented on its respective tooth according to the manufacturers’ instructions of each cement, and the marginal gap was measured again at the same aforementioned points. The results of this study showed that the marginal gap of all groups are below the clinically acceptable limit. Meanwhile, the marginal gap of the crowns fabricated from both block types increased significantly after cementation with both types of cement. Pre-cementation, student’s t-test revealed that there is no statistically significant difference in the marginal gap of crowns fabricated from both block types (p > 0.05). Post-cementation, a statistically highly significant difference was seen between both block types with both types of cement (p < 0.01). From the results of this study, the newly developed bioactive resin block seems a promising material for CAD/CAM applications in terms of marginal fitness.

Keywords: resin block, ACTIVA BioACTIVE, BRILLIANT Crios, CAD/CAM, marginal gap.

Introduction

Marginal adaptation is a vital factor for long-term longevity and clinical success of dental restorations⁰¹,². Marginal discrepancies may lead to cement exposure to oral fluids, resulting in marginal microleakage and luting agent dissolution with percolation of bacteria, food and oral debris, potentially causing secondary caries, and periodontal disease³,⁴.

Numerous restorative materials for CAD/CAM systems differing in chemical structure and indications are now available on the dental market⁵. However, ceramic material has many disadvantages such as fragility, requirement of excess time for fabrication and abrasive effect. Additionally, low modulus of elasticity of ceramic material makes it unable to absorb the pressure of mastication. These disadvantages of ceramics have led to increased interest in resin composites CAD/CAM blocks⁶,⁷. Their exceptional machinability, edge stability and reduced brittleness relieve some of the drawbacks of ceramic CAD/CAM blocks.
Bioactive materials have been used in almost all fields of dentistry. However, bioactive materials have not yet been implied in the field of CAD/CAM materials. ACTIVA BioACTIVE-RESTORATIVE material is a resin-modified glass ionomer that delivers all the advantages of glass ionomers in a strong, resilient, resin matrix. As claimed by manufacturer, it chemically bonds to teeth, releases more calcium, phosphate and fluoride and is more bioactive than glass ionomers. Moreover, this material is claimed to be more durable and fracture resistant than resin composites. ACTIVA material contains a rubberized resin component that makes them tougher and more resistant to fracture and chipping than composites. It doesn’t contain Bisphenol A, Bis-GMA and BPAdervatives.

These positive characteristics of ACTIVA material encouraged the idea of developing a bioactive resin block for CAD/CAM applications that can release favorable ions and stimulate apatite formation in response to pH changes in the oral cavity.

The aim of this study was to assess the marginal fitness of crowns fabricated from the newly developed bioactive CAD/CAM blocks and compared with those fabricated from one of the commercially available resin blocks (BRILLIANT Crios) pre-and post-cementation with adhesive and self-adhesive resin cements.

**Materials and Method**

Bioactive resin blocks were fabricated from ACTIVA BioACTIVE-RESTORATIVE (Pulpdent Corporation, USA) using a clear rectangular Teflon mold. The internal dimensions of the Teflon mold size are in accordance with size 14 CAD/CAM block. The material was injected directly in the mold using disposable auto-mixing tips. A celluloid strip was then placed on the top surface of the mold and a glass slab was placed above. A 500 gm weight was placed above the glass slab to release air bubbles and remove excess material. A period of 30-seconds was waited to allow for the self-curing reaction to start. The mold was then placed in the chamber of UV light curing box (Vertex Eco Light Box, Netherlands, Holland) for 10-minutes. The block material was then separated from the mold by unscrewing of the base of the mold. A metal holder specially fabricated for this study was then fixed to the fabricated block.

Thirty-two sound human maxillary first premolar teeth extracted for orthodontic purposes were selected. Each tooth received tooth preparation for full crown in accordance with the guidelines of tooth preparation for full crown made from resin block. The prepared teeth were divided into two main groups of 16-teeth each according to the type of block used: Group A (study group): crowns fabricated from the bioactive resin block, Group B (control group): crowns fabricated from the reinforced composite block (BRILLIANT Crios, Coltene/ Whaledent AG, Switzerland). Each group was further subdivided into two subgroups of 8 teeth each according to the type of cement used for the cementation of the crowns: 

- **Subgroup 1**: crowns cemented with adhesive resin cement (RelyX Ultimate, 3M ESPE, USA),
- **Subgroup 2**: Crowns cemented with self-adhesive bioactive resin cement (ACTIVA BioACTIVE-Cement, Pulpdent Corporation, USA). The prepared teeth were scanned using CEREC Omnicam digital intra-oral scanner. Crowns were designed using Sirona inLab CAD SW 15.1 and milled using inLab MC XL machine. Each crown was then seated on its respective tooth under a standard static load of 5 Kg. The vertical marginal gap of each crown was then measured using a digital microscope at a magnification of 230x. Measurement was done at four points predetermined on each surface of specimen using image-J software. Sixteen measurements were obtained for each specimen and the mean of these measurements was taken which represented the pre-cementation marginal gap. Each crown was then cemented on its respective tooth with either type of cement after surface treatment of the internal surface of the crown and the tooth following the manufacturers’ instructions of the two types of cement. Crowns of both groups were sandblasted with 50 μm aluminum oxide. For group A, the internal surface was etched with phosphoric acid gel. For group B, ONE COAT 7 UNIVERSAL light-cured dental adhesive (Coltene/ Whaledent AG, Switzerland) was applied to the internal surface of the restoration according to the manufacturer’s instructions. Teeth of subgroups A1 and B1 (cemented with RelyX Ultimate cement) were etched with phosphoric acid gel for 15 seconds, rinsed and dried, then Single Bond Universal Adhesive (3M ESPE, USA) was applied according to the manufacturer’s instructions. On the other hand, teeth of subgroups A2 and B2 (cemented with ACTIVA cement) didn’t receive any surface treatment prior to cementation. The internal surface of each crown was loaded with either type of cement and each crown was seated on its respective tooth using a dental surveyor under a constant static load of 5 Kg, followed by light curing for 20 seconds per surface.
after removal of the excess cement. The specimen was then removed and kept on bench for one hour and then stored in distilled water for 24 hours (13). Marginal gap was then measured again at the same points used for pre-cementation measurement. The recorded measurements were then statistically analyzed using students’ t-test at level of significance of 0.05.

**Results**

The descriptive statistics of the vertical marginal gap in μm of the two groups and their subgroups pre- and post-cementation are shown in Table (1) and Figure (1).

**Table (1): Descriptive statistics of the marginal gap (in μm) of the different groups between blocks pre- and post-cementation.**

From this table and bar-chart, it can be seen the lowest mean of marginal gap was recorded by subgroup A2, in which crowns were fabricated from ACTIVA block and cemented with ACTIVA cement (49.718), while the highest mean of marginal gap was recorded by subgroup B1, in which crowns were fabricated from Crios block and cemented with RelyX Ultimate cement (85.925). On the other hand, there was an overall increase in the marginal gap of all groups post-cementation.

The comparisons between the marginal gaps of both groups pre-cementation and post-cementation using student’s t-test at a level of significance of 0.05 are shown in Tables (2) and (3), respectively.

The use of the ACTIVA cement resulted in significantly less mean marginal gap of crowns fabricated from the bioactive block than the RelyX Ultimate cement ($p < 0.05$).
Discussion

The vertical marginal gap measurement is the most frequently used method to quantify the accuracy of fit of the restorations (14). It is well-agreed among studies that marginal gaps less than 120 μm are considered clinically acceptable (15-17).

The results of this in vitro study showed that the marginal gaps of all groups pre- and post-cementation were below the clinically acceptable limit.

Before cementation, the statistically non-significant differences in the marginal gap between the two block types could be attributed to the standardized process in the fabrication of crowns (including standardized tooth preparation, scanning, designing, and milling), and the relative similarity in the basic composition of both block types as they belong to the same category of all-ceramic materials which is resin composite block. However, evaluating the marginal gap of crowns without luting them on their respective teeth is not reflective of clinical reality because the cement and cementation process play a relevant role in the final discrepancy achieved (18).

In this study, two types of resin cements that differ in their chemical composition and adhesive strategies (adhesive and self-adhesive) were selected.

After cementation, there was an increase in the marginal gaps of crowns fabricated from both block types and cemented with the two types of cements. This result is in agreement with other studies that found that the cementation procedure causes a significant increase in the vertical marginal discrepancy (18-20). This might be due to the hydraulic pressure developed during cementation that is going to push the cement upward.

In the designing software of CAD/CAM system, the marginal spacer was set “zero”, while the radial and occlusal spacer was set “100μm” starting 1mm above the finishing line. Therefore, when the crown carrying the cement is placed on the prepared tooth and pressure was applied, as the crown approaches the final position, there is no space for escapement of cement through the cervical marginal collar, resulting in great amount of luting cement to be accumulated on the occlusal surface of the prepared tooth that might interfere with proper seating of crown restoration, increasing the vertical marginal discrepancy (21).

The results of this study showed that the marginal gap of crowns fabricated from ACTIVA block and cemented with both types of cement were lower than those of crowns fabricated from Crios block with statistically highly significant differences. This could be attributed to that the cementation of restorations fabricated from Crios requires the application of one coat 7 universal adhesive to the inner surface of the restoration prior to cementation after sandblasting according to manufacturer’s recommendations, owing to the high degree of polymerization of these blocks. This forms an additional interfacial layer between the restoration and the tooth that might interfere with adaptation of the restoration.

Concerning the type of cement, ACTIVA BioACTIVE self-adhesive cement exhibited less increase in the marginal gap with both block types than the RelyX Ultimte adhesive cement. This may be due to the difference in the bonding strategy between the adhesive and self-adhesive cements. Cementation of indirect restorations with self-adhesive cements reduces the number of application steps as compared to adhesive cements that require multiple interfacial bonding layers that may compromise adaptability. Additionally, it has been found that light curing of the adhesive prior to placement of resin cement produces thicker adhesive film thickness that may interfere with the seating of the restorations (21).

Conclusions

1. Crowns fabricated from the bioactive resin blocks showed better marginal fitness post-cementation than those fabricated from Crios blocks regardless of the type of cement used.

2. The marginal gaps of crowns fabricated from both block types increased significantly post-cementation.

3. Crowns cemented with the self-adhesive cement showed better marginal fitness than those cemented with adhesive cement irrespective of the type of block material.

Study Genotoxicity of Ciprofloxacin in white rats

Mustafa Ahmed Shihab1, WAJDI Sabeeh Sadek1

1Biology department, College of Science, Tikrit University, Tikrit, Iraq

Abstract

The genotoxic and cytotoxic effects of ciprofloxacin drug on the bone marrow of white male rats were assessed by the Micronucleus test (MN) in polychromatic Erythrocytes (PCEs). The DNA damage was assessed by the Comet assay technique in bone marrow, liver and spleen. The white male rats were administered by oral gavage of single doses (93.5), (187) mg.kg\(^{-1}\) of body weight with twice a day for 7 consecutive days, while the negative control group was administered distilled water. The results showed a significant increase in the number of micronuclei corresponding to the duration of exposure, there was a change in the percentage of immature erythrocytes in bone marrow. This increased with an increase in treatment duration. As for the number of immature erythrocytes containing micronuclei, there was a significant increase corresponding to the treatment duration. When using the comet assay technique, the values of DNA damage increased in a dose-related manner.

Keywords : Ciprofloxacin, Comet Assay, Micronucleus.

Introduction

Ciprofloxacin (CFX) is a broad spectrum antibiotic belonging to the fluoroquinolone family \([1]\). It is regarded as the second generation of this family and has a wide spectrum and efficacy compared to other types within this family. Ciprofloxacin is considered the most commonly known antibiotic, used to treat many bacterial infections in the respiratory tract, skin, bones, joints, urinary tract infections and diarrhea \([2]\).

It is an antibiotic that kills bacteria by altering the efficiency and function of the DNA gyrase enzyme, which is responsible for bacterial DNA vas damage. This inhibition of the DNA gyrase efficiency causes rapid bacterial death \([3, 4]\).

Test design:

5 rats for MMC positive control, 5 rats for negative control distilled water, 5 rats for each treatment with doses of 93.5 and 187 mg.kg\(^{-1}\) of body weight.

Table (1) shows the micronuclei in the bone marrow of white male rats after treatment with different doses of CFX, negative control and positive control (MMC)

* Significance at the probability level P≤ 0.05 (t-test)

** Significance at the probability level P≤ 0.01 (t-test)

This test was used in the current study to assess the genotoxicity and cytotoxicity of ciprofloxacin drug (CFX). The table shows an increase in the percentage of polychromatic erythrocytes (PCEs) in bone marrow of white rats at treatment with dose 93.5 mg.kg⁻¹ of body weight by 11.13%. Treatment with a dose of 187 mg.kg⁻¹ of body weight gave a slight increase by 11.22%, and these are results which show a little change from the negative control of 9.84. This indicates that the abovementioned drug may have a cytotoxicity. It also indicates to the effect of the mentioned two doses of the drug in stimulating the cells generating erythrocytes to increase division in order to produce more cells and replace lost cells as a result of the toxic effect of the drug in the treated animal. As for the positive control, it was the largest percentage compared to the negative control and treatment with a percentage at 18.93%. The results of the table showed that the arithmetic mean of micronuclei with the dose 187 mg.kg⁻¹ of body weight was (4.91 ± 49.60) which is of significance compared to negative control (0.860 ± 6.800) and the arithmetic mean with the dose 93.5 mg.kg⁻¹ of body weight was (21.40 ± 1.50) which is of significance compared to negative control 0.860 ± 6.800. This indicates that the drug may be genotoxic because it caused an increase in the frequency of micronuclei, and this increase is related to the increase in the concentration of the drug.

The results of the table showed that the arithmetic mean of polychromatic erythrocytes containing micronuclei when treated with the dose 187 mg.kg⁻¹ of body weight was of significance at (2.91 ± 32.60) while the treatment with the dose 93.5 mg.kg⁻¹ of body weight was of less significance with (14.80 ± 1.07) compared to negative control of (4.400 ± 0.400). This leads to the assumption of genotoxicity of the drug by its ability to develop micronuclei in polychromatic erythrocytes. These results are consistent with studies conducted to assess and measure the genotoxicity of the drug [7-9].

It is possible that the mechanism for the formation of micronuclei by ciprofloxacin drug in the bone marrow of treated rats is that the drug inhibits Topoisomerase II enzyme in the treated rats. Ciprofloxacin is known to be anti-bacterial by inhibiting DNA gyrase. And this enzyme is not present in eukaryotic cells but may be functionally and precipitatively connected to Topoisomerase II enzyme for eukaryotic cells [10]. The Topoisomerase II and DNA gyrase are essential for life, as they play a role in the formation of active chromatin synthesis, limiting strand twisting and dismantles of interlocking strands during DNA replication, and contributing to chromosome depletion during mitosis and chromosomal separation during the anaphase [11]. Inhibition of the Topoisomerase
II enzyme prolongs the metaphase and interferes with the dissociation of sister chromatids in the anaphase, but does not prevent the cell from that causing chromosomal abnormalities and indivisibility, thus leading to the formation of fine micronuclei \[12\]. The micronucleus test is widely used in many exploratory research to understand the potential underlying mechanism of genotoxicity. Its simplicity and applicability to a wide range of cell types inside and outside the body makes it a flexible tool for understanding the keys to genotoxicity and its effect on humans. The micronucleus test has shown to be one of the preferred methods for estimating chromosomal damage since it has been able to measure both total chromosomal loss or chromosomal fractions in a reliable manner because only micronuclei can be expressed in cells that have completed nuclear division. There is a hypothesis stating that micronuclei can have predictive value for cancer, as well as genetic mutations, and therefore replace chromosomal aberrations as a life indicator of cancer risk \[13\].

Single Cell Gel Electrophoresis technique or Comet Assay technique is a direct method for identifying DNA damage in interphase cells. The tail represents the amount of damage done in DNA. This technique is particularly sensitive in the recognition of individual sequence fractures, and the locations of repair by cutting in single cells compared to conventional ways of identifying DNA damage. It is useful to show DNA damage in a single cell. It is a direct, sensitive, simple, fast, and effective technique used in studies of genotoxicology. It has been generally assumed that SCGE technique, which is conducted under alkaline conditions, recognizes the individual sequence fractions and the location of the alkalines in DNA [14]. The ability of DNA to migrate depends on the size and number of fractures in the molecule as a result of a particular factor [15].

The comet estimation technique requires high-level viability cells approximating 95%, and low levels of DNA damage were found in the negative control group during the experiment.

The results of Table (2) show the percentage of cells with comet tails that represent the affected DNA cells for both negative and positive control and treatment
groups with dose 93.5 and 187 mg.kg\(^{-1}\) body weight of ciprofloxacin in bone marrow cells. The results showed an increase in percentages of damaged DNA cells and the two groups treated with 187, 93.5 mg.kg\(^{-1}\) body weight respectively.

The results of the table also show mean values of DNA damage in bone marrow cells of white male rats. The results clarified that the treatment with the dose 187 mg.kg\(^{-1}\) of body weight was significant with (19.80 ± 2.92) compared with the negative control (0.510 ± 2.400), while the treatment with the dose 93.5 mg.kg\(^{-1}\) of body weight was significantly less than (2.03 ± 13.20) compared to the negative control of (0.510 ± 2.400).

The results of Table (3) show the percentage of cells with comet tails that represent the affected DNA cells of both negative and positive control and that treated with doses 93.5 and 187 mg.kg\(^{-1}\) of body weight with ciprofloxacin drug in spleen cells. The results show an increase in the percentage of damaged DNA cells for the positive control group (treated with MMC drug) and the two groups treated with the drug 187, 93.5 mg.kg\(^{-1}\) of body weight respectively.

The results of Table (4) show the mean values of DNA damage in the spleen cells of white male rats. The results clarify that the treatment with dose of 187 mg.kg\(^{-1}\) of body weight was significant with (21.20 ± 2.58) compared to negative control with (0.66 ± 3.20), while the dose treatment of 93.5 mg.kg\(^{-1}\) body weight was less significant and reached 2.51 ± 14.00 compared to negative control with (0.510 ± 3.600). These values are higher than those of DNA in bone marrow and spleen. This means that both the percentage of cells with comet tails and damage to the liver cell DNA are higher than in bone marrow and spleen cells. This may be due to the fact that the detoxification device is present in the liver which is a chromosomal device and is part of the defense system of the body. Most of the material is metabolized inside the liver, therefore, it converts it by introducing chemical changes so that it can be destroyed and get rid of its poisonous effect and highlighted in several operations as a useless metabolic material. This drug is partially metabolized in the liver by modifying the pepirazinel group into at least four metabolites. These metabolites, identified as diethylene ciprofloxacin, sulfo-ciprofloxacin, oxo-ciprofloxacin and cyprofloxacin N-acetyl, show a weaker microbiological activity than the initial form of the drug, but a similar or stronger activity for some other quinolones [16].

The results of the tables for MMC treatment were significant for liver cell DNA, and bone marrow and spleen cells DNA. Rjiba et al. have shown in their study that the effect of MMC drug was high [17]. The DNA damage caused by CFX drug may be due to its ability to release free radicals (void of oxygen) [18]. The oxygen free radicals attack the DNA causing mutations [19].

Abstract

Yeast isolates were grown on CHR OMagar Candida medium to detect different types of the yeast species, and then the unidentified isolates were diagnosed by using molecular analysis of ITS region. From a total of 54 yeast isolates, 37 isolates appeared as different species of the genus Candida, the rest of species belong to Hanseniaspora, Kazachstania, Kluyveromyces, Magnusiomyces, Pichia and Saccharomyces. 13 yeasts species in this study reported as new strains in Gen Bank, also species belong to C. pronicula, H. uvarum, K. exigua, K. marxianus, M. capitatus, Magnusiomyces sp., P. kudriavzevii, P. manshurica and S. bayanus x S. cerevisiae isolated for the first time in Iraq. We concluded that there are new emergent species of the yeasts inhabit the oral cavity of cancer patients undergoing chemotherapy, and the results showed that the molecular method provide a good approach for the identification.

Key words: yeasts, cancer patient, molecular identification.

Introduction

Certain fungi, notably some of Candida species, are inhabited the oral cavity as a commensals, but the alteration of mouth environment with certain virulence determinants lead to overgrowth of fungal species causing oral infections. The incidence of oral candidiasis has been reported to be ranging from 7-52% among patients with different types of malignancies (1,2).

Cancer patients undergoing chemotherapy treatment are prone to higher risk for fungal infections because of the host immunosuppression as the action of these drugs, the identification of the causative agent requires rapid and accurate methods to identify the pathogen for guiding appropriate therapy. Molecular identification of fungal pathogens often involves polymerase chain reaction (PCR) for ITS1-5.8S-ITS2 rDNA gene (3). The non-coding complex ITS region is evolved more rapidly and variable among different species within a genus, therefore it is appropriate for taxonomy and identification than the coding and conserved 5.8S rDNA gene. ITS region has typically been most useful for molecular systematics at the species and strains level. (4,5).

The present study was conducted to detection and discrimination of the yeasts at the strains level, isolated from oral cavity of cancer patients, by using molecular genetic analysis of ITS region.

Materials and Method

500 samples were obtained from the lining of the oral cavity of patients (195 males and 305 females) with different types of cancer, were submitted to chemotherapy at Al-Sader Teaching Hospital-Basrah, Iraq, in the period between December 2014 to February 2015.

The yeast isolates were identified by CHRO Magar Candida medium to distinguish between the different species by type and color of the colonies (6).

From the total isolates which identified by conventional methods, there were 54 isolates their identification still uncertain at the species level, so we used the molecular methods for the purpose of accurate identification.

According to (7), the DNA extraction and PCR amplification has been accomplished, to amplify the internal transcribed spacer regions (ITS) of ribosomal
DNA with a 19 base forward primer, ITS1 (5'-TCC GTA GGT GAA CCT GCG G-3') and a 20 base reverse primer, ITS4 (5'-TCC TCC GCT TAT TGA TAT GC-3'). The result of PCR technique yielded distinctive products size of approximately 400-850 bp. The purification and protocol of PCR products for 54 samples were carried at MACROGEN Company http://dna.macrogen.com. All the alignments were observed by Clustal Omega www.clustal.org/omega/ and identified using Blast program.

Results

The amplified ITS regions were appeared in all 54 yeast isolates accurately. The identification of gene sequences showed 15 yeast species belong to 7 genera (Table 1).

Discussion

The accurate and timely species identification is important for clinical management of patients because the yeast species have different antifungal susceptibilities, that is why the choice of the ITS1-5.8S-ITS2 rDNA gene sequencing for discrimination of the species is important (8,9,10).

The universal primers ITS1 and ITS4 were used for amplifying ITS1 and ITS2 regions in yeast species, these primers showed high efficiency appeared in the identification of 13 new yeast strains, some of them have been isolated and reported for the first time from the oral cavity of cancer patients such as C. prunicola, K. exigua, K. marxianus and P. manshurica that could be due to the changes of the mouth environment and/or influence of chemotherapy drugs which acts as immunosuppressive then alteration the lining of oral cavity that upset the healthy balance of the oral microorganisms allowing to fungal infection (11,12).

Also, to our knowledge, different uncommon yeasts were isolated as new record species from oral cavity for the first time in Iraq: C. pronicula, H. uvarum, K. exigua, K. marxianus , M. capitatus, Magnusiomyces sp., P. kudriavzevii, P. manshurica and S. bayanus x S. cerevisiae, this appearance could be due to the suppression of the host immune system as a result of the cancer disease, use of chemotherapy drugs which suppressed oral/mucosal immunity, salivary gland dysfunction and alteration in oral flora leading to change the quantity and quality of saliva that encourage infection by opportunistic fungi as well as lack of physical activity and a high carbohydrate diet (2,13,14).

This identification were agreed with previous studies of (1,9,15,16), which isolated different species of Candida based on ITS region sequencing. The present study showed similar results to those observed from (17), who reported six of Candida species from cancer patients.

H. uvarum is considered as opportunistic yeast and its occurrence in clinical isolates is unusual, but in this study, the appearance of this species in the oral cavity is considered the first recording as a result of malignancies and chemotherapy impact. It was first isolated in Spain by (18) from the oral cavity of a 70 year old women with lesions produced by the dentures, and they suggested that the source of infection was associated to handling and consumption of raw fish (19).

Although K. marxianus is less frequently in clinical samples but its prevalence has increased over the past decade. The anamorph form of this species (C. kefyr) is an emerging pathogen with hematological malignancies (11), while in current study the result was not consistent with that previous study because two strains of K. marxianus were isolated from the oral cavity of females with breast cancer.

C. prunicola, P. manshurica and S. cerevisiae were isolated from clinical samples by (20), but to our knowledge, the present study considered the first work to isolate them from the oral cavity of cancer patients and identification them through molecular methods.

In spite of the teleomorph species K. exigua is unlikely to be human pathogen because it did not grow at 37°C but in this study it was isolated for the first time from oral cavity. The fungal sexually reproduction in human body have a higher enzymatic activity and thus greater the virulence of the host tissues, that explains the increased appearance of teleomorph conditions in clinical samples (22).

P. kudriavzevii, which a teleomorph state of C. krusei, is abundant in the environment and mainly associated with food spoilage. Many studies have shown that P. kudriavzevii is the 5th most common cause of candidemia in immunocompromised patients (23). To our knowledge, this study consider the first work that isolated the teleomorph condition of C. krusei from oral cavity of cancer patients.

Conclusions

Many yeasts species showed a high similar phenotypic features, so molecular methods by using amplification of ITS1-5.8S-ITS2 rDNA gene provide a good alternative approach for the identification of pathogenic yeasts.

Evaluation of Effectiveness of *Boswelliaserrata* (Kundur) Gum Extract on Some Biochemical Parameters in Male Rats Induced Chronic Renal Failure (CRF)

Ahmed Neema AL-Mosawy¹, Saatar Jasim Hatroosh¹
¹Department of Biology, College of Education for Pure Science, University of Karbala, Iraq

Abstract

**Objective:** The study was to test water extract of Kundur by treating chronic renal failure that induced by Cadmium chloride CdCl₂.

**Method:** CdCl₂ at a concentration of 5 mg /kg body wt./day of rat at chronic level with drinking water for six weeks as animal model. Measuring some predicate biomarkers functional common kidney was done serum creatinine and novel biomarker measured KIM-1 and NAGL, Cystatin C, demonstrate that a regular oral intake of CdCl₂ solution (in drinking water) for 45 days.

**Results:** There is significant increase of Serum Urea, creatinine, KIM-1, NAGL and Cystatin C, when compared with control group, also indicate there is significant increase in serum biomarkers for kidney injury. After the treatment with water extract of Kundur by different concentrations 10, 20, and 30 mg/kg all these Urea, Scr., KIM-1, NAGL and Cystatin C were significantly decrease when compared with CdCl₂ group, compared with control group and after the treatment the damages were not found or minimize. At this exposure of CdCl₂.

**Conclusion:** The biomarkers KIM-1, NAGL and Cystatin C may be good predictive indicator of chronic renal failure, plant extract may be having a highly effect for treating the renal failure and showed highly response to treatment.

**Keywords:** Kundur, renal failure, KIM-1, NAGL and Cystatin C

Introduction

Changes in renal function are one of the most common manifestations of severe illness. Their importance is reflected in the routine physiological and biochemical monitoring of kidney function via urine output measures and blood laboratory measurement in critically ill patients. Chronic kidney disease is associated with high morbidity and mortality. The kidney contains many metabolizing enzymes and plays a central role in metabolizing drugs and foreign compounds in the body. Different studies persist to discover new biomarkers that are identification the kidney disease, and understanding the intensity and development of renal failure when examination noninvasively in urine and blood. The biomarker includes Cystatin C, KIM-1, NGAL. KIM-1 is a type I transmembrane glycoprotein which is not found in normal kidneys. The elevation in releasing of this protein was found at highly levels on the proximal tubule cells specially on the apical membrane after nephrotoxic or ischemic injury, and in rats it is widely induced in the tubules after ischemic or toxic injury. KIM-1 is released into the circulation where kidney injury in rodents and humans with CRF.

Cystatin C is a 13 kDa cysteine protease inhibitor that is produced by cells throughout the body. Cystatin C is abundant in serum/plasma and is readily filtered at the glomerulus. Serum levels of cystatin C have been proposed as a useful marker to estimate glomerular filtration rate. Unlike creatinine, cystatin C is not secreted by the proximal tubule. Instead, filtered cystatin

Correspondence author:
Ahmed Neema AL-Mosawy
E-mail: almosawy748@gmail.com
C is taken up through a megalin-dependent process and then completely catabolized in proximal tubule epithelial cells. Serum levels of cystatin C are much less likely to be affected by factors such as gender, metabolic status or disease states than are levels of creatinine. Cystatin C has recently received some attention as a potential biomarker of Cd nephrotoxicity those studies focused primarily on the measurement of serum levels of cystatin C as an indicator of glomerular function and they yielded equivocal and somewhat conflicting results. Most of these studies did not include data on the possible effects of Cd on the urinary excretion of cystatin C. Medicinal plants and their derived bioactive phytochemicals have been gaining recognition in the treatment of neurological diseases. Kundur is an oleo-gum resin of Kundur. Various pharmacologically active chemical constituents were isolated from Kundur. Kundur is exhibit antifungal. Anti-inflammatory, Nephroprotective Activity and Antimicrobial Activity and (polyuria).

Method

Al-Kundur gum was obtained from Al-Razi Center for Alternative Medicine, Baghdad, Iraq the gum plant was identified by the National Herb in Abu Ghraib, Baghdad. The gum powder was moistened with 1:5 water (50 g of powder was mixed with 250 ml of distilled water). A horizontal shaker was used for 30 minutes, the sample was left stationary, then filtered using filter paper 3 times. Centrifuge (3000 rpm) was then used for 15 minutes. Concentrate the extract using rotary evaporator, and dry at 45 °C in the oven. The water extract was used in the study of animals.

Experimental design and treatments: Thirty adult male Rattus norvegicus weighing 200-240 g were used in the present study. The animals were obtained from the animal house in the biology department of College of Science of Thiqar University and were housed in well-aerated cages at normal atmospheric temperature and normal 12-hour light/dark cycle. The animals had free access to water and a standard diet of known composition. All efforts were done to reduce the number and suffering of animals and all animal procedures were in accordance with the recommendations of the animal ethics committee of Karbala University. The experimental animals were divided into five groups as follows:

- **Group I** positive control group: Induced renal failure by cadmium chloride (15 animals) 5 animals per week.

- **Group III** Treatment group first (T1): group of animals induced renal failure and treated with a water extract of gum Kundur 10 mg / kg body weight and the number of 5 animals per week.

- **Group IV** Treatment group Second (T2): group of animals induced renal failure and treated with a water extract of gum Kundur 20 mg / kg body weight and the number of 5 animals per week.

- **Group V** Treatment group third (T3): group of animals induced renal failure and treated with a water extract of gum Kundur 30 mg / kg body weight and the number of 5 animals per week.

At the end of the experiment, rats were sacrificed under mild anesthesia and blood samples were obtained for serum preparation. Kidneys were rapidly excised and immediately perfused with ice-cold saline. Samples from the kidney were homogenized in cold phosphate buffered saline (10% w/v), centrifuged and clear homogenate was separated and stored at -20°C. studies parameter was measured according to the instruction of the Elabscience company.

Statistical Analysis

Statistical analysis was performed using SPSS (v.25). Results were expressed as mean ± standard deviation (SD) and all statistical comparisons were made by means of the one-way analysis of variance (ANOVA) test followed by Tukey’s test post hoc analysis. (P value less than 0.05 was considered significant).

Results

Serum Urea & Creatinine levels for male rat

The results of the development of experimental chronic renal failure in laboratory animals by cadmium chloride Cdcl2, shown in Table 1(&2), show that serum urea & creatinine levels in male rats in the form of mean ± SD mean, Had a significant difference at a probability level of P< 0.05 in the cadmium chloride dosage group compared to the control group. It was found that the treatment of animals induced in chronic renal failure with the water extract of bitter gum and the dose of
10, 20, and 30 mg/kg and at a rate of once a day for (first, second and third week) at a value of P≤ 0.05 levels of serum Urea & Creatinine compared to the cadmium chloride group, but the level of decline did not reach the level in the control group. It was also shown from the table that the dosage period had an effect on serum Urea & Creatinine levels for male rats. The difference was statistically significant at P≤ 0.05 after (first, second, and third week) of the dosage of water extract of Kundurgum after six weeks of chronic renal failure.

Serum levels of KIM-1, NAGL, and Cystatin C for male rats

Table 3,4,5 showed that the development of experimental chronic renal failure in experimental animals led to an increase in serum of KIM-1, NAGL, and Cystatin C levels respectively, in the treated group with cadmium chloride compared to the control group. It was found that treatment of chronic renal failure patients with water extract of myrrh gum and dose 10, 20, (P <0.05) at KIM-1, NAGL, and Cystatin C levels compared with the control group, showed a significant effect (P <0.05) on KIM-1, NAGL, and Cystatin C in the serum of male rats where the decrease was significant (P <0.05) after (first week, second and third) of the dosage of the water extract of the gum compared with six weeks after Chronic renal failure.

Discussion

Urea assessment in rats’ groups of induced chronic renal failure; Cdcl2, Control, treated with water extract at doses 10, 20 and 30 mg/kg.

The renoprotective activity shown by Kundur and its MS (Methanol soluble) fraction against Gentamicininduced nephrotoxicity during current study, may be attributed to the chemical constituents of Kundur having antioxidative potential. During the experiment it is fully justified that Kundur possesses renoprotective effect and further studies are warranted to explore itsmechanism of action (12).

Creatinine assessment in rats’ groups of induced chronic renal failure; Cdcl2, Control, treated with water extract at doses 10, 20 and 30 mg/kg.

Our current findings indicate that exposure to cadmium chloride has led to kidney failure, which is the significant increase in Creatinine and Urea concentration in the groups treated with cadmium chloride in the first and second weeks compared to control groups. Creatinine concentration shown significantly elevated in adenine group by comparisonwith the control group, this our data agrees with (17) in rat, that found, significant increase in serum creatinine and urea concentration by comparison with control group. It could therefore be suggested that the phytochemical constituents of aqueous stem bark extract of *Boswellia papyrifera* such as alkaloids, tannins, flavonoids, saponins and cardiac glycosides may be responsible for the nephrocurative effect of the aqueous stem bark extract of the plant. They are super antioxidants and free radical scavengers which prevent oxidative cell damage and have strong anti-cancer activity and protects against all stages of carcinogens.

Kidney injury molecule -1 concentration in serum of male rats induced chronic renal failure treated with the water extract 10, 20 and 30 mg/kg.

Explanation could be that the physiological stress of renal dysfunction, lead to non-renal cells, expressing KIM-1 to shed this molecule into the circulation. Another possibility is that with renal decline, KIM-1 is less efficiently scavenge from the circulation. Patients with the lowest eGFR have the highest plasma KIM-1 concentrations (18).

The concentration of KIM-1 after treatment with tomato powder at dose 10% and 20% from diet cause significant decrease when compared with adenine group. Tomatoes could supply almost 85% of the lycopene in the diet.

Lycopene contains a high level of antioxidant, to help preventing different kinds of oxidative damages in cell and tissues (17).

Cystatin C concentration in serum of male rats induced chronic renal failure treated with the water extract 10, 20 and 30 mg/kg.

Cystatin C is an emerging marker of both ischemic andnephrotoxic kidney injury. Serumlevels of cystatin C have been proposed as analternative to traditional markers such as BUN andcreatinine for the estimation of glomerular filtration rate (17). At the same time, increases inthe urinary excretion of cystatin C have been proposedas a sensitive indicator of proximal tubular injury. The fact that cystatin C is rapidly being accepted as a measure of renal function in the clinic makes it extremely important to understand the effectsthat specific nephrotoxic agents, such as Cd, have on serum and urinary levels of cystatin C.

Conclusion

From current study conclude that the biomarkers Urea, Creatinine, KIM-1, NAGL and Cystatin C may be good predictive indicator of renal failure, plant extract may be having a highly effect fortreating the renal failure and addition to biomarkers tests whichreveal the induced CRF groups showed high response to treatment.

The effect of Toxoplasmosis on Hematological and Biochemical Parameters in Pregnant Women in Thi-Qar Province

Dawood S. Mahdi1, A.H. Awad2, Abeer T. Ali1
1Dept. of Medical Lab.Tech./ College of Health & Medical Technology/ southern Technical University/ Republic of Iraq, 2Dept. Biology/ College of Pure Science/ University of Basrah/ Iraq

Abstract

The aim of the present study was to detect the effect of infection with Toxoplasma gondii on hematological and biochemical parameters in pregnant women. Blood samples (103) were collected from emergency unit of Bent Al-Huda Hospital in Thi-Qar province during the period from October 2018 till March 2019. Samples gave agglutination results with latex test (79) were tested with ELISA test. Ten blood samples were collected from healthy pregnant women as control. Concentration of blood hemoglobin (Hb), total WBCs count, liver enzymes Glutamate Oxaloacetate Transaminase (GOT) and Glutamate Pyruvate Transaminase (GPT), lipid profile (total Cholesterol and Triglycerides) were estimated during this study using different commercial Kits.

Keyword: T. gondii, GOT, GPT, WBCs, Cholesterol, Thi-Qar

Introduction

Toxoplasma gondii is one of the most common parasite of warm- blooded vertebrates including human with high prevalence. The parasite causing either acute or chronic infection(1).

About 40% of the pregnant women have Toxoplasmosis. The fetus is got congenital toxoplasmosis during mother pregnancy. Transplacental transmission usually takes in the course of an acute infection (2). Indirect diagnosis is obtained by serological and biochemical technique (3).

Toxoplasmosis induces several immunological changes in the body of infected women which are characterize by the production of immunoglobulin’s IgG,IgM and IgA (4,5).

The replication of the toxoplasma inside the parasitophorus vacuole need substantial amount of the specific lipids for membrane biogenesis (6). (7) found an association between toxoplasmosis with hepatomegaly and some abnormal liver function test.

Materials and Method

Blood samples (103) of abortive women with Toxoplasmosis aged 17-46 years (at third month of pregnancy) were collected from emergency unit of Bent-Al Huda Hospital, in Thi-Qar province during the period from October 2018 till March 2019. Five ml. of blood samples were collected from each abortive woman with different number of abortion (1-3) times. Ten blood samples were collected from healthy pregnant women had similar age of infected women, which considered as control group. Three ml. of blood placed in gel tube, centrifuged and then the collected blood were used in serological test (Latex and ELISA).

Each serum sample collected was tested with latex agglutination (Spinarect company from Spain).The result is consider positive if the agglutination appeared after the serum and latex solution added to each other on the slide.

Samples gave agglutination result (79) were tested with ELISA test Kit (forsight company in Germany) to detect the antibodies of T. gondii according to the manufacturers’ instruction.

Concentration of blood hemoglobin (Hb) and total WBC count were carried out. Liver function was evaluated by the estimation of GOT, GPT and AlP enzyme. Spectrophotometer was used at 520 nanometer.
Level of lipid profile test (Total Cholesterol and Triglyceride= TGS) were estimated during this study using commercial Kits. Statistical analysis of the result were done using t-test, P value was considered significant when it was P≤ 0.05.

**Results**

1- Prevalence of *Toxoplasma gondii* antibodies:

Table (1) shows the higher prevalence of *T. gondii* antibodies IgG (84.8%) and 15.2% of IgM antibodies with high significant differences P≤ 0.05.

**Table (1). Prevalence of *Toxoplasma gondii* samples of aborted women according to IgM +, IgG+ antibodies**

Discussion

The results of the present study shows the higher prevalence of *T. gondii* antibodies IgG 84.8% and 15.2% of IgM with significant difference with P≤0.05. (8) showed that high prevalence 68.75% antibodies of IgG, while in IgM 31.25% with high significant difference.

Increasing in the rate of Hb of aborted infected women in the present study may be due to physiological and immunological status pregnant women infected with Toxoplasmosis, while the decreasing in WBCs might be due to the affected of these cells by the parasites which regarded as the most important factors controlling the cellular and humeral immunity response in the body of pregnant infected women (9,10).

The decrease in mean of cholesterol and Triglycerides in the present study compared with control might be due to the infection with parasites which make huge variation in lipid parameters. In general cholesterol play a main role in cellular membrane organization dynamics function and categorization(11). The parasites need cholesterol biosynthetic enzyme and must take it from its host (12).

The main function of the liver enzyme is the storage and movement of nutrition detoxication and metabolism of water and electrolytes. *T. gondii* causes significant and progressive changes in the liver owing to remarkable proliferation of organisms (3).

It was found from the present study that *T. gondii* affect the liver function which is cleared by decreasing GOT and GPT levels. (13) recorded an increase in GOT and GPT enzymes. No significant difference in the severity of the infected mice and control one was showed by (14).

The enzyme activities of GOT and GPT in the serum of aborted women indicating decrease in protein catabolism (1).

The present results show a decrease of both enzymes which reflecting the degree of damage to the liver function. Regulation of hepatocyte metabolism depend either on increasing anabolism or decreasing catabolism (15, 16).

Paper Based Glucose Biosensor Depending on SPCE Modified with Hemoglobin and Silver Nanoparticles

Ali Saad Elewi¹, Shatha Abdul Wadood¹, Abdul Kareem Mohammed Ali¹

¹Iraq/University of Baghdad/College of Science/Department of Chemistry

Abstract

In this study, new strategy intended for rapid glucose detection utilizing disposable glucose oxidase (GOD) paper disk integrated with screen-printed carbon electrode (SPCE) modified with hemoglobin (Hb) and silver nanoparticles (AgNPs). The GOD adsorbed on the surface of paper disk and after drying it placed on the surface of the modified SPCE and 16µL of glucose solution were added for the testing. Different parameters such as applied potential, concentration of enzyme, pH, size of paper disk, and the volume of buffer were optimized to improve the efficiency of this glucose biosensor.

Key Words: Hemoglobin, Silver Nanoparticles, Glucose Biosensor, SPCE

Introduction

Glucose monitoring is a requisite tool in clinical trials where glucose concentration is a definitive indicator in type 1 and type 2 diabetes mellitus and other diseases such as endocrine metabolic disorders. Most patients with diabetic need to test their blood sugar periodically. Thus, great interest have been aroused from industrials and marketers people to develop glucose sensor with more time-saving, much reliable, easy, cost-effective and can be utilized in home-based care (¹). Paper-based biosensor has drawn much interest in analytical and clinical chemistry due to its discerning properties; cheap, simplicity, presorted reagent and not required special user, which can be largely used in the diagnostic field. Moreover, GOD is widely used in practical applications for glucose analysis, where it catalyzes glucose oxidation according to the following equation

Where, the glucose level can monitored by the detection of H₂O₂ generation or O₂ consumption. Overwhelmingly, electrochemical glucose biosensor based on O₂ detection but the detection of H₂O₂ was found to be more sensitivity.

Several analytical techniques have been employed for H₂O₂ analysis, such as spectrometry, fluorimetry, titrimetry, chromatography and electrochemical technique. Among these techniques, because of their rapid response, low cost, selectivity, simplicity and high sensitivity; the electrochemical method have been extensively utilized for this purpose (²).

Recently, with the large development in nanomaterial’s science, SPEs became more utilized in smart and modern biosensor applications to avoid some common problems of classical solid, in addition to it is characterized with; low cost, disposable, convenience, flexibility in design, easy to chemical modification and reduction of sample volume required (³). Different modifiers have been added in to screen printing ink to progress the sensitivity and selectivity of SPEs such as enzymes, mediators and nanomaterials (⁴). Hemoglobin (Hb) has considered a suitable model for H₂O₂ biosensor because hemoglobin could act as peroxidase-like to reduce H₂O₂, commercially available with moderate cost and excellent stability and it has a well-known structure (⁵). Nanoparticles attracted specific interests in the field of enzyme immobilization, due to unique properties, such as high electrical conductivity, good chemical and thermal stability, and large surface area (⁶).

In this study, we developed highly sensitive and stable paper based glucose biosensor by of utilized the previously fabricated hydrogen peroxide biosensor based on Hb immobilized on SPCE modified with AgNPs, and integration with GOD paper disk. Where,
in this paper based biosensor, glucose concentration can be electrochemically detected by using 16µL of sample. In addition, the analytical efficiency of present biosensor was evaluated in terms of repeatability, stability, sensitivity, and reproducibility after optimization of applied potential, pH, concentration of enzyme, and volume of buffer as the important parameters for biosensor development.

**Experimental part**

**Apparatus and measurement**

A potentiostat/Bipotentiostat (type DY2300, Digi-Ivy, Austin, U.S.A) was used to carry out the cyclic voltammetry, linear sweep voltammetry and Amperometric measurements, a screen-printed carbon electrode (SPCE) from Digi –Ivy (USA) with three electrodes was employed, consists of carbon electrode as working and counter electrodes, while pseudo Ag/AgCl was acted as a reference electrode. All the electrochemical experiments were done at room temperature (25 °C). The pH of the buffers was carried out using a HANNA pH meter. In cyclic voltammetry (CV) and linear sweep voltammetry (LSV) measurement, 16µL of 0.1M PBS (pH 7) was added onto the paper disk, with this volume a good contact was obtained between the paper disk and the modified-SPCE.

**Reagents**

Silver nanoparticles (0.02 mg/mL, suspension in aqueous buffer, 10nm), and Nafion (5%) were purchased from Sigma-Aldrich. Hb, and H2O2 from Sigma (USA), chitosan (CS) from Shanghai Biochemical (China), Glucose oxidase (GOD, 40IU/mg) from Fluka. A stock solution of 0.2M Na2HPO4, NaH2PO4 was used to prepare phosphate buffer solution (PBS, 0.1M) at various volume ratios and the pH was adjusted with 0.1M phosphoric acid or sodium hydroxide. All chemicals were of analytical reagent grade, and were used without further purification. Double distilled water (DDW) was used in all experiments. The stock solutions were stored at 4°C for further analysis.

**Preparation of GOD paper disc**

Grade 1 Whitman filter paper was carefully cut into round sheet with about 1 cm diameter using a paper punch. Then, 6µL of GOD solution (180 IU/mL) was carefully spotted on the center of each paper disk and left to dry at 25°C. The paper disk was placed onto the surface of the modified-SPCE to completely cover the working, reference and counter electrodes. Furthermore, GOD and glucose solutions with different concentrations were prepared and diluted with PBS (pH7).

**Results and Discussion**

**Electrochemical investigation of paper-based analytical devices**

The CV of modified SPCE integrated with GOD-paper disk and blank paper disk were examined by swept the potential in window of -0.6 V to +0.3 V at scan rate 0.1Vs⁻¹ in PBS (pH 7) with and without 1mM glucose solution, as shown in Figure (1).

No change in the cathodic and anodic peak current of modified SPCE was observed when blank paper was used in the presence of 1 mM glucose solution, in comparison with CV in PBS (pH 7) without glucose solution. Which refers to no H2O2 was produced in the absence of GOD in the reaction medium; also, the same result was obtained when GOD-disk paper was used in the absence of glucose solution.

While, there was an increase in the cathodic peak current of modified SPCE when glucose solution was added to paper disk pre-loaded with GOD, which is due to oxidation process of glucose, where the produced H2O2 in this reaction can be detect by the present modified SPCE.

![Figure 1: Cyclic voltammogram of modified SPCE integrated with GOD-paper disk and blank paper disk in the presence and absence of 1 mM glucose solution.](image-url)

Direct electrochemistry behavior of GOD disk paper with modified SPCE was investigated in the detection of glucose level with different modified electrodes using LSV method in potential range from +0.3 to -0.6 V at scan rate of 0.1Vs⁻¹. As shown in Figure (2), no reduction peak was observed for GOD-disk on the bare-SPCE in the presence of 1mM glucose solution, while, a weak peak current at -0.33 V was observed in Hb-
SPCE with GOD-disk paper. The reduction peak current was increased by 4.2 times when AgNPs was used in the modification of the electrode (NF-Hb-AgNP-CS-SPCE). Thus, GOD-disk paper integrated with NF-Hb-AgNP-CS-SPCE has a good electrocatalytic activity for oxidation of glucose, attributed to the high conductivity and high surface area of electrode that provided by using silver nanoparticles in modification of SPCE. In addition, it was demonstrated that Hb has a good electrocatalytic activity towards H$_2$O$_2$ reduction.

When the amperometric response of the paper based analytical devices is typically affected by the enzyme loading (7). Therefore, the amperometric experiment was investigated in 1 mM glucose solution for 60 s at scan rate of 0.1Vs$^{-1}$ with several GOD-paper disks prepared by immobilized different concentration of enzyme 0.2 IU/disk - 1.2 IU/disk. The optimum sensitivity of biosensor was recorded with an enzyme concentration of 0.8 IU/disk. While, excess loading of the enzyme resulted unchanged in sensor response for glucose detection, which is identity with enzyme kinetics.

In this amperometric study, PBS (pH 7) used as a carrier solution of analyte as well as supporting electrolyte. The volume effect of PBS containing constant concentration of glucose solution 0.1 mM on the amperometric response of GOD paper-based glucose biosensor was investigated in scan rate of 0.1 Vs$^{-1}$. Where, a suitable PBS volume was found to be 16 µL. In this volume of buffer, the contacting between the three electrodes of the modified SPCE and the wetting GOD paper was the best.

The pH value of the target buffer is a vital factor for the sensitivity of glucose biosensor, where two enzymatic reactions interested in the response of GOD paper-based NF-Hb-AgNP-CS-SPCE to glucose solution. An optimum pH rang influence both the electrochemistry of Hb and the bioactivity of the GOD. The extreme pH may change the kinetics of glucose measurements as a result of confusing the redox state of glucose oxidase reaction (8). For this matter, the effect of pH on the amperometric response of paper-based glucose biosensor to 1 mM glucose solution was investigated in 0.1 M buffer solution between 3 to 8 pH. From Figure (3), it can be deduced that the optimum enzyme activity was found at (pH 7) and in pH value above or below that, there was clear drop in response of fabricated glucose biosensor that may be due to denaturation of enzyme in these pH value. Based on the above results, a concentration of GOD with 0.8 IU/disk, a potential of -0.33, 16 µL of PBS with pH 7 were selected to obtain the optimum sensing.

The characteristics of biosensor response

Amperometric method is very suitable method for determination of glucose concentration, since its utilization is characteristic with fast and simple. By employing the optimum experimental conditions as
described above, the calibration graph of the biosensor response to the concentration of glucose solution was shown in Figure (4). It can be seen that the present glucose biosensor enabled us to determine the glucose concentration from 1.2 mM to 5.2 mM, with regression equation

\[ Y = 0.9059X + 3.0631 \]

Where \( Y \) refer to the response (current) in \( \mu \text{A} \) and \( X \) refer to the concentration of glucose in mM, with a correlation coefficient of 0.9905.

The limit of detection for glucose was calculated as 0.6 mM (based on LOD =) and the sensitivity of biosensor was found to be 11.91 \( \mu \text{A.mM}^{-1}.\text{cm}^{-2} \). The LOD value obtained was below 0.86 mM in Rungsawang, et al. study (9) and 3.12 mM in Li, et al. study (10). Meanwhile, the sensitivity is higher than the previously reported glucose biosensor (11). In addition, the resulted linear detection range of glucose that obtained by GOD paper disk integrated with NF-Hb-AgNP-CS-SPCE was 1.2-5.2 mM was almost the same as in other glucose biosensor, such as up to 5.7 mM in GOD-Au electrode (12), up to 6mM in GOD-AuNPs-NF-GC (13).

![Graph showing calibration curve](image_url)

a substrate saturation was observed when the glucose concentration is over than (5.2 mM), showing the characteristics of Michaelis-Menten kinetic (typical enzymatic reaction kinetics). The value of the apparent Michaelis-Menten constant \( K_m \) was calculated to be (4.4 mM), this value was significantly lower than 35mM in GOD-AuNPs-PA (14). Which implying that the GOD in our experiment exhibits a remarkable affinity for glucose.

**Stability and reproducibility of glucose biosensor**

In this work, the reproducibility of the biosensor was monitored by using 10 GOD paper disks prepared independently for testing 2 mM glucose solution, R.S.D was calculated to be 3.53%, while the bio electrocatalytic signal reached 90% of the steady-state value in 15 s.

The stability of the newly prepared GOD paper disks was evaluated at optimum conditions, by monitoring the signal decrease with storage time. The response of GOD paper based NF-Hb-AgNP-CS-SPCE was decreased to 62% of initial response after (20 days) of storage at 4°C. Thus, in this work the designed GOD paper based glucose biosensor can detect the concentration of glucose in small volume of sample with high sensitivity, good stability and low cost technique.

**Selectivity of biosensor.**

Selectivity of the glucose biosensor is important feature for practical applications, where in the amperometric biosensor, the electroactive compounds have been a problem in testing the biological or industrial samples. Eight possible potential interference species that may be influences the amperometric response of the proposed glucose biosensor were studied. The paper-based glucose biosensor response for a fixed concentration of glucose 2 mM was compared to that obtained for 1 mM of the possible interfering compound in the presence and absence of 2 mM glucose solution. As can be seen in Table (1), the paper-based glucose biosensor does not give response to any one of the interference compound that studied in the absence of glucose solution (close to background), that due to the specificity of enzyme.

However, in the presence of 2mM glucose solution plus fixed amounts of interfering species 1mM, the amperometric response is changes lower than 7% with exception of cysteine, where the registered signal decreased 12.3% that may refer to its interaction with some amino acid resides in the glucose oxidase molecule. Hence, our fabricated paper-based glucose biosensor are very suitable for the selective glucose determination in biological or industrial samples.

Conclusion

The paper-based biosensor comprised a linear response range for glucose over 1.2 mM to 5.2 mM with detection limit of 0.6 mM at signal to noise ratio of 3. While, the sensitivity and the apparent Michaelis-Menten constant (k) were calculated and found to be 11.91 µA.mM⁻¹.cm⁻² and 4.4 mM. In addition, the stability, reproducibility, repeatability and selectivity of present glucose biosensor were monitored in this study.

Evaluation of Noise Pollution Levels in Hospitals and its Effects on Staff Health in AL - Najaf City in Iraq

Ahmed Abdel Hamid A. Hamoud¹, Zaid Makki Mohammed H. AL-Hakkak¹
¹Ecology Department, Faculty of Science, University of Kufa, Iraq

Abstract
The aim of the study was to determine levels and sources of noise pollution in the hospitals and its effects on staff health in AL - Najaf city in Iraq. The study included measure sound levels in all wards in three hospitals (Al-sadr teaching hospital, Al-hakeem general hospital and Al-zahraa’ teaching hospital) using a digital sound level meter. The present work also examined distribution of symptoms caused by noise in employees of three hospitals and main sources of noise in hospitals by using prepared questionnaire through direct interview in the workplace. The results showed that the average measured A-weighted equivalent continuous level ($L_{Aeq}$) in all hospitals and in different shifts was more than recommended level (20 – 35 dB) of World Health Organization (WHO). The study revealed that the main sources of noise in inside the wards rooms of hospitals Al-Sadr Teaching Hospital, Al-Hakeem General Hospital and Al-Zahraa’ Teaching hospital were “staff conversation” (91%); “maneuver-patient treatment” (83%); “doors opening or closing” (77.5%); “mobile phone ringing and conversation” (76.5%). Moreover, it was observed that (32%) of respondents were headache by noise in hospitals. Moreover, the type of noise health effects that most complained among employees were vocal fatigue (31%), dizziness (30.5%), and feeling sick at the end of the workday (28.5%). This study concluded that the noise level in three hospitals was higher than the WHO rating; therefore, this problem causes raising the noise annoyance on of hospital staff.

Key words: Noise pollution, Hospitals and Staff health.

Introduction
Noise in hospitals has become a subject of growing concern in recent years, since it is often cited as a major complaint by patients in hospitals (¹, ²) reported that noise levels in hospitals averaging 72 dBA during the day and 60 dBA at night. Environmental noise present in hospitals all over the worlds is a common exertion and is recognized as a serious health hazard and not just as a nuisance (³).

Noise pollution has many health effects, e.g., increased blood pressure, noise-induced hearing loss, sleep disorders, annoyance and irritability (⁴). In addition; high noise can also leave adverse effects on work activity and events. It can also cause impaired sleep and behavior, increased gastric intestinal activity, heart rate, blood pressure, respiratory rate, and oxygen consumption (⁵).

Noise may elevate blood pressure, increase heart rate, stimulate the release of epinephrine (adrenaline), increase pain, and alter quality of sleep (⁶)(⁷).

Noise has been increasing over the years, specifically in large metropolitan areas. This increase is also perceived inside hospitals. Different noises originated from distinct sources, such as the operation of different devices and conversation among professional cause noise pollution in the hospital environment and this may affect the individual’s physical and emotional health (⁸).

In general, the problem of hospitals’ noise pollution is a global issue and because of its negative health impacts, it requires and deserves further attention (⁹) endeavors to prevent medical errors and risks stemming from the presence of patients and employees only in the hospital environment are very important in terms of patient and employee safety (¹⁰). In addition, working
performance is also affected by noise pollution. The aim of this study was to assess noise levels and sources and its effects on staff health of three hospitals in AL-Najaf city in Iraq.

**Materials and Method**

This study was carried out in three large hospitals: Al-Sadr Teaching Hospital, Al-Hakeem General Hospital and Al-Zahraa’ Teaching hospital in Al-Najaf AL-Ashraf city in Iraq from November 10, 2018, to January 12, 2019.

**Workplace noise assessment:**

The noise levels measurements were conducted using Noise measurements were recorded by using digital sound level meter model: UNI-T; UT352, China in three major hospitals Al-Sadr Teaching Hospital, Al-Hakeem General Hospital and Al-Zahraa’ Teaching hospital. In each hospital, several locations were chosen to measure various noise parameters at different time intervals.

Noise level assessments were performed at four time periods include morning time (09:00 am–12:00 am), afternoon time (12:00 am–04:00 pm), evening time (04:00 pm–06:00 pm), and night time (06:00 pm–09:00 pm).

In this study, noise level was recorded in every measurement in Decibel (dB): A-weighted equivalent continuous level (L_{Aeq}). In order to obtain a realistic recording of noise levels, neither the staff nor patients in the four institutions were aware of the recordings. The time for each measurement was 5 minutes, recording was repeated for two times in each location, and then the average reading was recorded.

**Questionnaire surveys:**

The questionnaire has been applied to 200 employees selected from three hospitals. Structured questionnaires were used to assess the staff response on noise pollution in all locations of the hospitals. All participants completed a researcher-made questionnaire. It included two parts:

First part: noise sources inside and outside the wards rooms in hospital: The second part: sources of noise pollution inside and outside the ward rooms such as (television and radio sets, mobile phone ringing and conversation, doors opening or closing, medical equipment, heating, ventilation, air-conditioning or cooling system, bed creak, maneuver-patient treatment, patients moaning or crying, staff conversation, conversation of patients visitors, wheelbarrows).

Second part: symptoms caused by noise on hospital employees: symptoms caused by exposure to noise pollution such as (headache, anxiety/jitters, dizziness/dizzy, annoyance, tension or irritability, discomfort, uncomfortable around loud noise, sleep alterations, experience difficulty sleeping, inability to sleep, inattention, low concentration, unable to concentrate in work, gastric changes, problem in speech, difficulty hearing what people say, tinnitus, ear ache, hearing deficiency, blocked ear, vocal fatigue, and feeling sick at the end of the workday).

**Statistical analysis:**

The data were statistically analyzed by using SPSS (statistical package for social sciences). The independent sample t-test, ANOVA (analysis of variance) . All values were expressed as mean ± Standard Error of Mean. P-value less than 0.05 and 0.01 were considered statistically significant.

**Results**

**Sound levels in three hospitals:**

The results recorded that the average A-weighted equivalent continuous sound levels (L_{Aeq}) in different locations of Al-sadr teaching hospital was (62.80 ± 2.14 dB). In addition, it can be observed that the average A-weighted equivalent continuous sound levels (L_{Aeq}) in different locations for Al-hakeem general hospital was (61.50 ± 2.12 dB). Also, The study found that the the average A-weighted equivalent continuous sound levels (L_{Aeq}) in all locations of hospital Al-zahraa’ teaching hospital was (61.64 ± 2.11 dB) (Table 1).
Table (1) Average A-weighted equivalent continuous sound levels ($L_{Aeq}$) in Al-sadr teaching hospital, Al-hakeem general hospital and Al-zahraa’ teaching hospital.

**Sources of Sound levels in hospitals**

The present study revealed that the main sources of noise in inside the wards rooms of hospitals Al-Sadr Teaching Hospital, Al-Hakeem General Hospital and Al-Zahraa’ Teaching hospital were “staff conversation” (91%); “maneuver-patient treatment” (83%); “doors opening or closing” (77.5%); “mobile phone ringing and conversation” (76.5%) (Figure 1). Moreover, it was observed that the “talking of visitors or patient’s family members in corridors” (94.5%) and “Staff conversation” (92%) were the major noise sources outside the wards rooms in hospitals Al-Sadr teaching hospital, Al-Hakeem general hospital and Al-Zahraa’ teaching hospital (Figure 2).
Figure (1) Sources of noise inside wards rooms in in three hospitals according to hospitals employees.

Figure (2) Sources of noise outside wards rooms in in three hospitals reported by hospitals employees.
Distribution of symptoms caused by noise in employees of three hospitals:

The study indicated that (32%) of respondents were headache by noise in hospitals (Figure 3). Moreover, the result also showed increment in percentages of vocal fatigue (31%), dizziness (30.5%), and feeling sick at the end of the workday (28.5%) in employees of three hospitals (Figure 3).

Discussion

Sound levels in hospitals:

The results recorded that the average A-weighted equivalent continuous sound levels ($L_{Aeq}$) in different locations of Al-sadr teaching hospital, Al-hakeem general hospital and Al-zahraa’ teaching hospital were (62.80 ± 2.14, 61.50 ± 2.12 and 61.64 ± 2.11 dB respectively). In the present study, the mean equivalent noise levels observed on all wards exceeded the recommended WHO guidelines for hospitals (11).

Eivazzadeh, M. et.al. (2017) found the higher levels of noise in a emergency ward (69.65 ± 1.68) were linked to a higher the working procedure of this ward compared to other wards; Moreover, the data recorded that the highest mean $L_{max}$ and $L_{min}$ (94.43 and 50.43, respectively) in the emergency ward. This might be due to the emergency care unit does not have a fixe time for treatment activities and clinical operations take place on demand all day (12).

In addition, the result observed that no significant elevation in mean ($L_{Aeq}$) of Al-sadr teaching hospital during morning, afternoon, evening comparison with Al-zahraa’ teaching hospital and Al-hakeem general hospital in the same period in the same period time. The findings agreed with results of previous study by (13) conducted a measurement of noise levels in Mosul medical city center teaching hospitals and concluded that the mean equivalent noise level (94.35 dBA) during morning time was higher than level (90.14 dBA) during afternoon. Furthermore, the study also recorded mean equivalent noise levels were higher on the weekdays (94.05 dBA) than on the weekend (88.57 dBA).

Pai, et.al. (2007) observed increase of noise level in the wards and locations was between 50.3 and 68.1 dB in Taiwan hospital which exceeded the suggested hospital ward sound level. The study also found The quietest units were the Surgical Intensive Care Unit and recovery rooms with a noise level lower than 50 dB during the night. Moreover, The higher noise levels were in the hall and pharmacy which were highly populated areas (14).

Sources of Sound levels in hospitals:

This study recorded that that the main sources of
noise in inside the wards rooms of hospitals Al-Sadr Teaching Hospital, Al-Hakeem General Hospital and Al-Zahraa’ Teaching hospital were “staff conversation” (91%); “maneuver-patient treatment” (83%); “doors opening or closing” (77.5%); “mobile phone ringing and conversation” (76.5%) . Similar results obtained by (15) who found that the daily average sound levels measured inside these hospitals during daytime were between 52.6 and 64.6 decibels. They also reported that most nursing staff members expressed that “talking of visitors or patient’s family members” is the major source of noise inside the wards, whereas “talking of visitors or patient’s family members” and “children playing” are the two major noise sources outside the wards.

Furthermore, the study showed that the “talking of visitors or patient’s family members in corridors” (94.5%) and “Staff conversation” (92%) were the major noise sources outside the wards rooms in hospitals Al-Sadr teaching hospital, Al-Hakeem general hospital and Al-Zahraa’ teaching hospital. Similar findings were recorded by Similar results obtained (16) indicated that many studies have shown that noise levels in most hospitals in USA are much higher. They pointed out two general sources of noise in hospitals. The first one includes paging systems, alarms, bedrails, telephones, staff voices, ice machines, pneumatic tubes, carts, and noises generated by roommates. The second source includes the surfaces of the floors, walls, and ceilings which usually are hard and reflect sound rather than absorb it.

Distribution of symptoms caused by noise in employees of three hospitals:

The results indicated that (32%) of respondents were headache by noise in hospitals (Tables 1, and 2). Moreover, the type of noise health effects that most complained among employees were vocal fatigue (31%), dizziness (30.5%), and feeling sick at the end of the workday (28.5%). This finding agreed with (17) who measured noise level in different environments of a public hospital and to analyze its effects on staff from reporting complaints. The study results showed that the minimum sound level 52.5 decibels in the intensive care unit (NICU) and a maximum sound level 85 decibels in the emergency room. They also observed staff feel discomfort to loud sounds (74.4%) and (35.5%) feel sick after hours due to stress caused by noise that is produced by multiple devices combined with the sounds of alarms, works, visits and schedules conversation between the hospital employees.

Montes-González, et.al (2019) reported that one of the main hospitals in the Extremadura region (Spain) is presented here to allow a global assessment of the acoustic impact of outdoor sound sources. Taking into account the results obtained, the noise impact on this hospital is primarily influenced by three sound sources: road traffic, cooling towers of the hospital and the emergency helicopter(18).

Fillary, et.al. (2015) exposure to excessive noise is associated with sleep disturbance, and symptoms such as dizziness, confusion, fatigue, high blood pressure, digestive problems, heart arrhythmias and neuropsychological disturbances. Moreover, noise is considered as the most common cause of discomfort, imposes stress and disrupts communication(19).

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq

Conflict of Interest: The authors declare that they have no conflict of interest.

Influence of Emotional Intelligence on Academic Achievement among Students at Secondary Schools in Babylon City

Hadeel Sahib Ali¹, Qahtan Qassim Mohammed¹
¹University of Baghdad /College of Nursing, Iraq

Abstract

Objectives: The main aim of the study is to determine the influence of emotional intelligence on academic achievement among the students. A descriptive study is carried to assess the influence of emotional intelligence on academic achievement among Students at secondary schools in Babylon City. A systematic random sample of (586) students are selected throughout the use of probability approach. The study sample selected from (4) secondary schools, which divided into (2) schools for female and (2) schools for male. The selection of sample divided into (141) students for each of male school and (152) for each female school. The schools were randomly chosen by lottery in the purpose to select 4 schools out of 28 schools (15%) and 25% of the students in these schools, which was convenient to the investigator. A total of (650) secondary school students, they were met the study criteria and agreed to contribute in the study. The finding reveals that there is a significant influence of students’ emotional intelligence on academic achievement at p-value = 0.01.

Key Words: Emotional Intelligence, Academic Achievement, Students, and Secondary Schools.

Introduction

Emotional intelligence (EI) defined as “the ability to perceive accurately, appraise, and express emotion; the ability to access and/or generate feelings when they facilitate thought; the ability to understand emotion and emotional knowledge; and the ability to regulate emotions to promote emotional and intellectual growth”. EQ consists of four domains of abilities which are the perception, use, understanding and regulation of emotion. Emotional intelligence is claimed to affect various aspects of human performance, namely in physical and psychological health, social interaction and performance at school and in the workplace. Unlike Intelligent Quotient (IQ), emotional intelligence (EQ) is associated with career and personal life success, including success in the academy. Emotional intelligence (EI) is defined as the ability to monitor one’s own and other people’s emotions, to discriminate between different emotions and label them appropriately, and to use emotional information to guide thinking and behaviour and to manage and/or adjust emotions to adapt to environments or achieve one’s goals. Emotional intelligence comprises interpersonal and intrapersonal intelligence. Interpersonal intelligence is the outer intelligence one uses to understand and manage relationships with other people. This is important for developing qualities like empathy and building up effective relationships. Intrapersonal intelligence is the inner intelligence one uses to know and understand oneself which is important for self-awareness, self-regulation and self-motivation. It can be postulated that management of interpersonal and intrapersonal emotions is vital for an individual’s academic and professional success. Those with higher EI are more likely to understand, regulate and manage emotions better both in themselves and in others. Low and Nelson (2006) claimed that EQ is crucial to a student’s personal health and success. They claimed that students with emotional intelligence skills are better able to cope with demanding and complex college experience. When individuals are able to lead their life successfully in the academy, they can focus on their learning and perform academically. Students who follow the lessons by integrating emotional intelligence will show significantly higher increase in Math scores. They have been integrated the ten aspects of emotional intelligence in teaching Math namely emotional awareness, self-esteem, self-confidence, self-control, motivation, communication, cooperation, empathy, problem solving and joy. Integration of emotional intelligence significantly increases the student’s attitudes.
toward Mathematics as a whole. Students who accept the integration of emotional intelligence significantly increase confidence, enjoyment and motivation towards math\(^4\). Apart from its contribution to academic success, a person with high emotional intelligence is also said to function better as a worker citing reasons such as being able to be a team player, work under pressure, and contribute to organization’s productivity\(^5\). It is becoming more evident that employers nowadays are no longer looking for employees with good grades alone but they are more interested in applicants who can meet the demands of a working world and adapt to the forever changing climate and needs of their organization. This is especially true in profession that requires the employees to be highly emotionally intelligent. An increasing amount of research is being carried out to examine stress in workplace including in learning institutions involving educators such as teachers and lecturers. This is because teaching profession is recognized to be one of the most stressful professions\(^5\).

**Materials and Method**

A descriptive study is carried out to assess the influence of emotional intelligence on academic achievement among students at secondary schools in Babylon City. The study has been conducted at the following secondary school in Babylon City; Mariam Al-Athraa Secondary School, Al-Batool Secondary School, Beirut Secondary School, and Al-Sadah Secondary School (2018-2019). A systematic random sample of (586) students are selected throughout the use of probability approach. The study sample selects from (4) secondary schools, which divided into (2) schools for female and (2) schools for male. The selection of sample divided into (141) students for each of male school and (152) for each female school. Through review of the related literature and previous studies, the questionnaire is constructed as a mean of data collection. It was consisted of (2) major parts:

**Part I:**

The first part is concerned with student’s socio-demographic characteristics which include (gender, age, students’ sequence in the family, students’ brothers number, students’ sisters number, residency, fathers education, mothers education, monthly income, scholastic stage and academic achievements (average)).

**Part II:**

This part is concerned with student’s emotional intelligence. It consist of (41) items (always, often, sometimes, rarely, never). These items were rated according to the Likers’ scale; always (5); often (4); sometimes (3); rarely (2); never (1) for the positive items, and vice versa for the negative items. The score estimation for the study scale has been evaluated according to responses’ percentages of the items. Each always answered item was assigned a score of 5. often answered items were assigned a score of 4. Sometimes answered items were assigned a score of 3. Rarely answered items were assigned a score of 2 and those never answered were assigned a score of 1. Total scores were summed and ranged in percentages. Score was assessed in percentages of the mean depending on the Likert scale as follows:

- High score: 3.67-5, (> 74 %).
- Moderate score: 2.34-3.66, (47 – 73 %).
- Low score: 1- 2.33, (<47 %).

A pilot study is carried out on December 22\(^{th}\) 2018 to December 30\(^{th}\) 2018 and it is conducted on (64) students who are selected randomly from the the chosen secondary school in the Babylon City. Finally, the sample of the pilot study is excluded from the original study.

The validity of the questionnaire was adjudged using Cronbach’s coefficient alpha calculated to test the reliability and internal consistency of the responses obtained from the respondents.

The data is collected through the use of a developed questionnaire (Arabic version) and student’s self-administration as a mean for data collection.

**Results and Discussion**

The descriptive analysis of the sample shows that more than half of the sample was females (51.9%) while the males were (48.1%), the distribution of the sample according to their age; the finding reveals that most of students are between (15-17) years old (41.0%) followed by a lesser proportion for those who were at age between (12-14) with (33.4%) and (25.6%) were more than 18 years old. The findings reveal that about, (28.0%) of participants were the first child in the family while
(22.2%) as second one. On the other hand, (18.1%) of students have third ordinary in the family. Also (15%) reported as fourth child. Additionally, (15.4%) fifth and more. Distribution of students’ brothers number shows that (4.4%) of students haven’t brothers, (20.8%) of students have one brothers, (27.3%) of students have three brothers, (27.6%) of students have three brothers, (12.3%) of students have four brothers and (7.5%) of students have five and more brothers. The findings show that (10.6%) of students haven’t sisters, (21.8%) of students have one sister, (28.7) of students have three sisters, (17.4%) of students have three sisters, (10.2%) of students have four sisters and (11.3%) of students have five and more sisters. The majority of participants live in urban areas (53.9%) while (46.1%) of participants live in rural areas. About (1.4%) of students’ father not read and not write, (3.4%) of students’ father can read and write, (22.2%) of students’ father have finished the elementary school, (31.7%) of students’ father have finished the secondary school, (36.5%) of students’ father have finished the diploma or bachelor study and (4.8%) of students’ father have higher education, while (7.2%) of students’ mother not read and not write, (9.9%) of students’ mother can read and write, (32.8%) of students’ mother are elementary school graduates, (21.5%) of students’ mother are secondary school graduates, (22.5%) of students’ mother are diploma or bachelor graduates and (6.1%) of students’ mother with higher education. more than a half of participants have a sufficient monthly income (60.4%). the distribution students according to scholastic stage were (17.1%) selected for each of first and second stage followed by equal numbers of students percent for each of (third, fourth, and sixth stage) with (16.4%) ; while (16.7%) for fifth stage.

This table indicates that (9.2%) of the students are have low level of Emotional Intelligence, (45.7%) of them were showing moderate level, and just (45.1%) show high level of Emotional Intelligence.

**. Correlation is significant at the 0.01 level (2-tailed).
This table reveals that there is a significant influence of students’ emotional intelligence on academic achievement at p-value= 0.01.

The findings also reveal that there are no significant association between students’ emotional intelligence and their Gender, Age, Residency, and Scholastic Stage on the other hand there are significant association between students’ emotional intelligence and their Sequence in the Family, Brothers Number, Sisters Number, Fathers Education, Mothers Education, and Monthly Income at p-value=0.05. The descriptive analysis of the sample shows that more than half of the sample was females (51.9%) while the males were (48.1%). These results agree with findings of Mohzan et al (2013)\(^1\), who found that the female in the sample are more than males. The results in also show that most of students are between (15-17) years old (41.0%) followed by a lesser proportion for those who were at age (12-14) with (33.4%) and (25.6%) were more than 18 years old. These findings are supported by a study conducted by Ream & kurt (2010)\(^7\) who stated that more than half of his sample was about (15-17) years old. These findings are also supported by a study conducted by Cooper (2017)\(^8\) who stated that mean age of (16.1) years old. The results reveal that about, (28.0%) of participants were the first child in the family while (22.2%) as second one. On the other hand, (18.1%) of students have third ordinary in the family. Also (15%) reported as fourth child. Additionally, (15.4%) as fifth and more, this agrees with Rust (2014)\(^9\) who found that most of his participants were as first child in family. Majority of participants in study live in urban areas (53.9%) while (46.1%) of participants live in rural areas. The current finding is supported with findings of Fitch (2015)\(^10\) who reported that more than half of the sample was living in the urban areas. (1.4%) of students’ father not read and not write, (3.4%) of students’ father can read and write, (22.2%) of students’ father have finished the elementary school, (31.7%) of students’ father have finished the secondary school, (36.5%) of students’ father have finished the diploma or bachelor study and (4.8%) of students’ father with higher education. These findings agree with a study of Neo (2012)\(^11\) who stated in his study that most of student father with graduated education. The findings shows that (7.2%) of students’ mother not read and not write, (9.9%) of students’ mother can read and write, (32.8%) of students’ mother are elementary school graduates, (21.5%) of students’ mother are secondary school graduates, (22.5%) of students’ mother are diploma or bachelor graduates and (6.1%) of students’ mother with higher education. In Iraq, according to the researcher’s point of view, as a result of the payment of the so-called customs and traditions sometimes or the harsh conditions at other times and neglect always can lead to low level of mothers educations. Actually more than a half of participants have a sufficient monthly income (60.4%) followed by (28.7%) of participants also have a somewhat sufficient monthly income, While (10.9%) of participants have an insufficient monthly income. The current finding is also supported with findings of Wijekoon, (2017)\(^12\) who found that 50% of his sample with sufficient monthly income. Additionally support by Neves (2016)\(^13\) who found that more than half of his sample with sufficient monthly income (63.8%). The distribution students according to scholastic stage were (17.1%) selected for each of first and second stage followed by equal numbers of students percent for each of (third, fourth, and sixth stage) with (16.4%); while (16.7%) for fifth stage. The current finding is supported with findings of Fitch (2013)\(^10\) who reported that the distribution of student according to scholastic stage were almost equal. According the level of academic achievement the findings indicates that (10.6%) of the students are have failed level of academic achievement, (43.7%) of them were showing accepted level, (27.0%) of the students have adequate level of academic achievement, (12.8%) of the students have good level of academic achievement, (4.4%) of the students have very good level of academic achievement, and just (1.5%) show excellent level of academic achievement. These findings are supported by a study conducted by Neves (2016)\(^13\) which stated that (55%) of them were showing accepted level of achievement scores. There are no significant association between students’ emotional intelligence and Residency at p-value=0.01. This finding agreed with a study established by Goodwin (2016)\(^16\) who stated that there are no significant association between students’ emotional intelligence and Residency.

**Conclusion**

There is a significant influence of students’ emotional intelligence on academic achievement. There are no significant association between students’ emotional intelligence and their Gender, Age, Residency, and Scholastic Stage. There are significant association between students’ emotional intelligence and their Sequence in the Family, Brothers Number, Sisters Number, Fathers Education, Mothers Education, and Monthly Income.
Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the University of Baghdad/College of Nursing, Iraq and all experiments were carried out in accordance with approved guidelines.

Evaluation of Biochemical Health Measurements to Predict Backpack Achievement (50m)

Imad Kadem Yasser¹, Ali Khalif Ali²

¹Physical Education and Sports Sciences / Thi-Qar University, ²Directorate of Education Thi-Qar

Abstract

The tests and measurement is one of the most important scientific subjects that seek to achieve the requirements of research by linking to the delicate aspects that are objective through the results of measurements that carry the scientific side, and swimming on the back is very important in the field of sports and biochemical indicators scientifically shows us the amount of potential To predict the level of achievement of young swimmers indicate the amount of safety of different devices and reflect the positive side of the level of real achievement.

Key words: Biochemical Health Measurements, Predict Backpack.

Introduction

Measurements are tools that can be identified on many indicators through the analysis or quantification of the components that indicate the knowledge of the scientific facts and the amount of prediction between them during what is required of the performance of the athlete, which achieves development rates in the side that works by To create a scientific experience for trainers or employees within their specialties and thus we may reach the desired performance of the best in the movement of sports according to a scientific measure which is a direct goal in this aspect. The research in the field of tests and measurement in the field of sports proved qualitative changes in order to secure the requirements of athletic achievement and raise the physical and functional level of athletes by giving us a precise description and analysis of different responses to the current or cumulative variables that occur to different body cells when practicing sports activity. Physical or functional for athletic effectiveness There are characteristics imposed on the various body devices depending on the nature of performance Sports efficiency characterized by high speed and maximum strength in a short time will inevitably impose different responses and functional adaptations, each depending on the nature of the actor And swimming is one of the activities that are not limited to a particular age or age, considering that all ages are suitable for development, but this level and its speed varies from age to stage and from one stage to another due to physiological, physical and dynamic reasons and whenever these qualities and elements are available at a high level When individuals learn the easier and better, The importance of research is one of the field indicators in most of the research and in this research is a scientific evidence shows us the amount of biochemical potential of the swimmers on which the safety of different devices and reflected positively on the level of real achievement. And the main problem of this event is the lack of scientific research that dealt with the prediction of swimming in terms of some biochemical indicators, and the lack of observation measurements that can be a scientific indicator in this area, which examines the most accurate details of the level of achievement, in addition to that we find that most swimmers do not have The scientific idea of biochemical measurements, which is one of the factors important for this type of swimming or other, and also noted the weakness of the researchers to achieve the new figures when most young swimmers in the country, and the reasons that the researchers see is the lack of interest most of the trainers in the note These measurements as possible to be one of the factors causing the failure of to achieve the required level, all of these reasons prompted the researchers to study this subject so that in front of

Corresponding author:
Dr. Imad Kadem Yasser.
Physical Education and Sports Sciences / Thi-Qar University; E-mail: imadkadhim@pe.utq.iq.
employees and athletes in this area of work under the results that will be obtained by the researchers, and the most important goals seen by the researchers.

1- Identify the level of completion of the swimming pool (50) m for young swimmers.

2 - Identification of the measurements of some biochemical indicators in the members of the research sample.

3 - The conclusion of predictive equations for some biochemical indicators of enzymes studied.

Research methodology and field procedures

Research Methodology:

That «research in all scientific fields resort to the selection of a curriculum that is appropriate to the problem, so the use of the descriptive method of surveying methodas this approach is an appropriate approach to the study of social phenomena as it provides data on the reality of these phenomena and the relationship between the causes and results and analysis, In which it would be useful to draw conclusions and recommendations thereon.»

Research community and design:

The researchers are interested in selecting the community and the sample they choose. Hence, the research community was identified. They are young people in the province of Thi-Qar (20) swimmers for the sports season (2018-2019). The researchers chose the research sample. (100%). The two researchers conducted homogeneity in the studied indicators in order to derive scientific equations for prediction as shown in Table (1)

Table (1). Shows the values of the computational circles, standard deviations and torsion coefficients of the research sample.

Field research procedures:

**Measurements and Tests Used:**

* - Measurement of biochemical indicators:

* Metabolic measurement (CPK) and (LDH) in the blood

Objective of the test: an enzymatic measurement (CPK) and (LDH) in the blood before and after the voltage.

Used equipments :

* A link to the area of the humerus - medical cotton, sterile materials - syringe (syringe).

A blood-free tube to prevent anticoagulation (EDTA) - to determine the level of serum (CPK) concentration in the blood - to determine the level of LDH concentration in the blood - the centrifuge.

Performance: The special test for the measurement of CPK and LDH enzymes in the blood was carried out at one stage. At the time of rest, the blood was withdrawn from the sample of the research sample in the morning and before any effort was made (in the case of rest) by calling the swimmer on the chair And extends one of his arms as shown in Figure (13), the analyst lends a compressive ligament in the humerus to limit the blood in the vein of the humerus then sterilize a small area of the vein and injects the syringe in the vein (the attachment area) and begins to withdraw blood by (5C) Which is sufficient quantity according to the instructions indicated with the book, after which the analyst pulls the syringe from the swimmer Sterilize the area and decompose the compressive ligament and then empty the blood in a plantub and leave the blood at room
temperature to clot and then place the blood sample in the centrifuge to extract the serum and then place the necessary material in its position in the Copas machine as shown in Figure 14.) By placing CPK and LDH materials in the space assigned to the Kopas device. We put the sample of the test through placing 50 ml of the special nematocyst syrup and placing it in the space assigned to it, The device then gives the device an order to do a CPK and HDL scan and then the device analyzes them until the results appear on the device screen Twenty minutes later.

Second Test: The completion of a swimming pool (50) meters:

* Purpose of the test: Measurement of the level of achievement of swimming on the back (50) m.

* Test instruments: swimming pool (50) m - stopwatch number (8) - whistle - registration form.

* Method of performance: The laboratory begins to perform the moment of hearing the whistle start and jump to the specified area and be in accordance with the movement of successive arms by the consensus of the feet and start from the jump to water in the opposite direction so that the back of the swimmer in the water, which consists of stages:

1 - Hate: Enter the swimming pool in the opposite direction with the movement of the arms outside and the shoulders are going out slightly.

2 - Tensile and push: The elbow must be attached and is higher than the shoulders, and the water tightens back and ends the movement before the arms bend slightly on the body to be complemented by a strong and fast movement of the sponsors back in the back and the arm must reach behind the shoulder level during tension.

There should also be a continuation of the end-of-tensile movement to the back-forward through the compatibility between the movement of the arms and legs, in which the hand faces both individually and sequentially when the two arms move forward. 1. Body position: The body should be extended in a straight horizontal position, hands down and slightly outwards, legs moving sequentially with the arms at the push, with a small part of the shoulder appearing above the surface of the water. The movement begins from the position of the adjacent extended men and the combs outstretched. The movement starts by pushing the articulation of the thighs and knees to the abdomen in a sequential manner, so that the angle between the thigh and trunk is approximately 55 because the angle is greater, affecting the flow of the body, which reduces the speed of movement in the water.

Calculation of grades: Calculates the time of the swimmer within a distance of (50) m.

Main experiment: The main experiment was conducted on 23/6/2018 after the completion of the exploratory experiments and the validation of the devices and tools. This experiment was conducted on the swimming pool of the Sumer Youth Forum in Dhi Qar Governorate. The test was applied to the research sample and with the help of cadre Auxiliary work where the time to test the swimming pool was measured (50) meters for the sample of the research. On the second day, biochemical measurements (LDH-CPK) were performed by the specialized physicians in Dhi Qar Governorate.

Statistical Methods: The researchers used SPSS ver20 to process data.

d. Table (4) shows the results of the statistical treatment of the significance of the regression of the variable (CPK) and the completion of (50) meters on the back in the test (F), where there are significant differences between the two variables with the value of (F) calculated at (5.675) 0.02b) and at degree of freedom (19). This confirms the predictability of the variable (CPK). The researchers believe that the reason for this is that the exercise of physical activities varies from one activity to another and the body gets Atp. Since swimming is one of the high-effort activities, requires quick compensation to the energy, which leads to the speed of the processes of representation within the body and also this works at the speed of nerve impulses. The release of various control mechanisms leads to an increase in the work of more than a device such as myocardial nervous system and this leads to a group of rapid reactions to meet the body’s need of energy needed during physical exertion through these chemical reactions decomposes (CP) the muscle stock that is decomposed by phosphate during the cycle. One in the cell that generates the energy needed during physical exertion. The enzyme CPK is a group of transferable enzymes. It transfers the phosphate group to the receiving nitrogen group, also called the CK. This enzyme is excreted into the blood and is increased in case of injury or after exertion. Blood CPK is an energy-rich chemical that plays an important role during the effort. This enzyme helps release a large amount of energy and rebuild the ATP, which is the first energy back. ADP is regenerated into a system called ATP-CP, Energy in the physical activity of oxygen, which lasts for about 10 seconds[^1]. The enzyme CPK is important in the preparation of the interactions of energy production necessary for physical activity, so we see concentrated in the skeletal muscle and heart muscle, which is an important parts of sports movements and it is known that most muscle cells have phosphocrytin CPK is two or three times greater than ATP and it is transformed in a small fraction of a second into ATP for the purpose of continuing consecutive muscle contractions[^4]. Thus, CPK can be used for young swimmers. Based on the above, (CPK) And the level of achievement of young swimmers to detect the significance of the regression between the two variables.

Table (4) Shows the significance of the degree (T) and the equation of the prediction of achievement in terms of (HDL)

a. Dependent Variable: Achievement
b. Predictors: (Constant), LHD

Table (6) shows the results of the statistical treatment to show the significance of the regression between the variable (LDH) and the completion of (50) meters swimming on the back in the test (F), where there are significant differences between the two variables as the value (F) calculated at (5.081) (0.03b) and the degree of freedom (19) This confirms the possibility of predicting the variable (LDH), and researchers believe that this enzyme is the most important characteristic of the chemical reactions that get directly between athletes from others through access to energy sources needed during work, (ATP) by anaerobic glucose analysis through a series of reactions ending with the conversion of pyrofil from glucose to no Which leads to the production of energy needed during physical work, assuring that “the conversion of pyruvace to lactic acid in the case of O2 in the muscles working at the large muscle activity through the processes of biodegradation of pyrofearc to lactic by hydrogen”6, as the high level of enzyme Lactate dehydrogenase (LDH) after exertion in some sports practices, including swimming, is due to its vital role in the biochemical reactions of the anaerobic system 8. It is the system on which the players depend on performing the physical efforts associated with the pills that require high physical exertion. Is consistent with Atwell et al. 1991. At the same time, the continuation of a high-intensity controlled physical load for 60 s produces a significant increase in blood LDH immediately after performance. In addition, LDH stimulates the conversion reactions Pyrenees to Lactate, which is consistent with what he reached. “LDH works to stimulate interactions of conversion of pyrons into lactat 7-9.

Conclusion

Determination of equations to predict the level of achievement depending on some measurements of some biochemical indicators through: The prediction of the enzyme C.P.K according to the following equation: Y = ax + b = 42.15. Predicting the enzyme (LDH) according to the following equation Y = ax + b = 42.70. Safety of devices Function in the composition of energy through the results of prediction of enzyme (cpk). Improve the time period of energy production after fatigue through (ck) and the unity of calcium.

Road Traffic Fatalities in Babylon Province – Six Years Epidemiologic Study

Hasan Alwan Baiee¹, Karim Al-Araji², Ahmad Jawad Mohammed³
¹University of Babylon /Hammurabi College of Medicine, Iraq, ²Professor of Surgery, University of Babylon, Iraq, ³Babil Health Directorate, Iraq

Abstract

Road Traffic Accidents are the fifth leading cause of morbidity and mortality worldwide. In Iraq, traffic accidents are increasing continuously leading to more fatalities that rank Iraq as number four in the world. Objectives: To assess the epidemiological features of fatal Road Traffic Accidents in a time, place, person epidemiologic model and to identify the trend of Road Traffic mortalities in Babylon province during six years. This was a descriptive cross-sectional study included a analysis of the forensic medicine data presented in the records of forensic medicine department in Babylon Health directorate for the period 2010-2015. After the approval of the study protocol by the local health ethical committees, a structured questionnaire was used to collect data according to the descriptive epidemiologic model (person, place, time model). During the period 2010-2015 mortality rates were higher in males than females with male to female ratio of 3:1. Higher mortality rates reported in the year 2015 and the highest frequency of mortality was in the age group (16-35) years (34.9%) followed by the age group (6-15) years (14.7%) the lowest rate was among the age group (46-55) years, the highest mortalities reported among Wage earners (58.8%).

Key words: Road Traffic Fatalities, Babylon Province, Epidemiologic Study

Introduction

Globally, Road Traffic Injuries (RTIs) have increased in the last twenty years, this makes RTIs one of the main five causes of morbidity and major cause of fatality all over the world particularly in the low- and middle-income countries¹. The RTA is defined as any vehicle accident occurring on a public road or highway and includes accidents where the place of occurrence is unspecified². The growth in the global economy in the last century has changed many aspects of people’s lives including their use of various means of transportation, this leads to a corresponding increase in the number of automobiles usually resulting in an increase in RTAs and consequent injuries and deaths³,⁴. The overall global RTIs fatality rate estimated to be 19.5 per 100 000 population, middle-income countries have the highest annual road traffic fatality rates, at 20.1 per 100 000, while the rate in high-income countries is the lowest, at 8.7 per 100 000. There is a wide variety in road traffic death rates in different regions of the world; the highest rate was reported in African regions, 24.1 per 100 000 and lowest in the European Region 10.3 per 100 000. Also, there is a considerable disparity within each region⁵. In the Eastern Mediterranean Region, one of the major challenges to the region is the constantly increasing incidence of RTIs⁶. This region has one of the world’s highest traffic fatality rates, mostly due to a lack of simple measures to reduce RTIs⁷ and inadequate pre-hospital medical emergency systems⁸. The available data referred to different death rates due RTIs in some Arab and regional countries; moderate to high fatality rates reported in United Arab Emirates⁹, Saudi Arabia 10 and Kuwait 11. However, road traffic injury fatality rates range from 9 in Turkey to 44.75 per 100 000 population in Iraq¹². In Iraq, traffic accidents are increasing continuously leading to more fatalities¹³. According to the WHO data about Iraq, road traffic fatality rate is preceded only by Namibia, Swaziland and Malawi⁵,¹². It is worth mentioning that in 2011 the injury toll from RTIs is almost four times greater than that from acts of terrorism in Iraq¹⁴. According to the agreement between Iraq and WHO, the Ministry of Health and the Ministry of Interior with the full cooperation of the WHO, Iraq launches the Decade of Action for Road Safety 2011-2020 and pledges to reduce
the level of road traffic fatalities by 2020. Accidents, therefore, can be studied in terms of agent, host and environmental factors and epidemiologically classified into time, place and person distribution. Previous studies referred that majority of the victims are within the age 15 to 50 years, furthermore, children account for approximately 13% of fatalities. The main victims of RTIs are males. The global burden of morbidity is estimated that around 20 to 50 million individuals are being injured or disabled each year with considerable social and economic losses. One million and three hundred thousand deaths are reported globally each year. The World Health Organization stated that without efforts to prevent these accidents, it is predicted that 1.9 million person in the world die annually by 2020 more than 90% of deaths due to traffic injuries occur in low-and middle-income countries including Iraq. In 1990, road accidents ranked 9th in the list of the most important factors threatening the health of the community but it is predicted that by 2020 they will rank the third cause of mortality. Another bitter fact about these reports is that 50% of the killed are individuals with a role in the economic development of societies. The frequencies of road accidents are rising in developing countries and are higher compared to those in developed countries. According to World Health Organization, the average standardized annual death rate due to road traffic accidents in Iraq is 44 per 1000000 population) and this is ranking Iraq as number 4 in the world. Because pre hospital transit times are long, most trauma deaths in these countries occur during the pre-hospital phase; hence efforts to improve survival rates should focus on better care outside the hospital.

**Objectives of the study:**

- To assess the epidemiological features of fatal RTIs in a time place person model in Babylon province.
- To identify the epidemiological trend of RTI mortalities in the province.

**Methodology**

The study protocol was approved by the ethical committee in Hammurabi college of medicine University of Babylon. The acceptance of ethical committee of Babel health directorate was taken as well. This was a cross-sectional descriptive study depended on a retrospective analysis of RTIs mortalities that were recorded in the forensic medicine department for the years 2010 – 2014. The time needed to conduct this study from 1st of February to end of May 2016. Data for the five years were reviewed by the researchers. The data for each victim include, age, gender, occupation, marital status and residence of the victims, in addition to the place of accident, date of accident (in day and month) and the site of injury in the body. Statistical analysis was done using Spss version 17 to calculate the Chi square test to evaluate the significant of difference between variables, P<0.05 considered as the statistical significant level.

**Results and Discusion**

Table (1) shows the distribution of mortalities for the six years according to gender, higher number of mortalities was reported among males at each year and over the whole period; out of the 2340 mortalities, males constituted 1791 (76.5%) while females were 549 (23.5%) with a male to female ratio of (3:1).

In Iraq, there are lacking in the reliable data on the incidence of RTIs, nonetheless, it is one of the public health priority of Iraq that will need to be investigated. Analysis of these data revealed that the total mortalities for six years period in Babylon province years were 2340 victims with male predominance this finding is similar to the finding reported by other study. On the other hand it had been noticed that the death numbers increased during the years 2011 and 2012 then declined in the next two years, this decline in the trend of mortalities might be attributed to the increase of the public and the drivers awareness about the traffic safety and the monitoring program applied according to the agreement between Iraq and WHO, where, Iraq launches the Decade of Action for Road Safety 2011-2020 and pledges to reduce the level of road traffic fatalities by 2020 towards achieving the objectives of the decade at the national and international levels, additionally, the traffic police in last three years enforced in some areas of Iraq the use of seatbelt, helmet, and having driving license particularly in the safe zones of Iraq. Despite this decline reported in the current study, the death numbers still higher than what were reported in neighboring countries such as Saudi Arabia, and Iran. This study showed that more than half of the victim’s lives in urban areas, higher proportion of victims were unemployed and the majority of deaths occurred on the main roads, which consistent with other studies. The high rate of deaths in the current study might be attributed to different factors such as no speed limit on the roads in urban areas and inside the cities, crowded roads, presence of different types of vehicles (two wheels, three wheels and four wheels vehicles), absence of road signs, additionally, other possible reasons for the higher RTI related fatalities such as insufficient government policies that promote cycling, walking and investing in public transport as it found in some countries in the region, lack of education about the safety measures, like seat belt, helmets and periodic safety check for the vehicles. The highest death rate was noticed in December, almost, similar finding was reported in previous Iraqi study, however, this might be due to cold or rainy weathers as in December. The current study found that head was the dominant site of injuries among victims, during the whole period which account for 93.7%, followed by lower limbs and upper limbs.

Conclusion

Most fatalities occurred among males, in their productive age group and among wage earners, the highest rates of deaths occur during December. Head and lower limbs were the commonest sites of injuries.

A Comparative Evaluation of Gutta-Percha and Sealer Removal of Rotary Niti File Retreatment Systems

Mirvet M. Rashad 1, Noor H. Fadhil 2, Raghad A. Al-Hashimi 3

1Lecturer, Department of Restorative and Aesthetic Dentistry, College of Dentistry, University of Baghdad, Baghdad, Iraq, 2 Assistant lecturer, Department of Restorative and Aesthetic Dentistry, College of Dentistry, University of Baghdad, Baghdad, Iraq, 3 Assistant Professor, Department of Restorative and Aesthetic Dentistry, College of Dentistry, University of Baghdad, Baghdad, Iraq

Abstract

Forty lower premolars with single root canals prepared with ProtaperNext files to size 25, and obturated with GP/sealer using lateral compaction. Teeth divided randomly into four groups (group n=10). Protaper universal retreatment kit (PUR), D-Race desobturation files (DRD), R-Endo retreatment kit (RE) and Hedstrom (H) files (control) were used to remove GP/sealer in each group. Removal effectiveness assessed by measuring the GP/sealer remnants in the roots after sectioning them into two halves. Stereomicroscope with a digital camera used to capture digital images. Images processed by ImageJ software to measure the percentage of GP/sealer remnants surface area in total, coronal, middle and apical areas of the canal. In the coronal area, PUR had significantly lower R% than RE and H groups, respectively (p<0.05). Also, DRD had significantly lower R% than RE (P<0.05). There was no significant difference between PUR and DRD (p>0.05), as well as no significant difference between RE and H groups(p>0.05). In the middle, apical and total root areas, Both PUR and DRD had significantly lower R% than RE and H groups, respectively (p<0.05). There was no significant difference between PUR and DRD (p>0.05). Also, there was no significant difference in R% between RE and H groups (p>0.05).

Keywords: DRace, Hedstrom, REndo, retreatment, Protaper

Introduction

Retreatment of endodontically treated teeth after the failure of the initial endodontic treatment is a common and a conservative procedure compared to tooth extraction and endodontic surgery. Retreatment procedure involves removal of the root canal filling materials such as gutta-percha and sealer which are the most frequent materials to be used for root canal filling. The success of retreatment is directly related to the effectiveness of any file system to remove the old filling materials, which may harbor bacteria and debris. 1 The techniques used for removal of gutta-percha from root canals include Hedstrom (H) instruments with/without chloroform, ultrasonics, lasers, heat carrying instruments, as well as NiTi rotary instruments. 2 Recent advances in NiTi rotary files systems used in removal of gutta-percha and sealer enable better cleaning, less time and less fatigue to patient and operator compared to the conventional stainless-steel files because of super elasticity, shape memory and resistance to torsional fracture, which enhancing their accessibility to distant parts of root canal and their removal effectiveness. 3-5 Many NiTi rotary systems introduced for gutta-percha/sealer removal such as Protaper universal retreatment (PUR) system (Dentsply Maillefer, Ballaigues, Switzerland), Re-Endo system (RE) (Micro-Mega, Besancon, France), D-Race desobturation system (DRD) (FKG Dentaire, La Chaux-de-Fonds, Switzerland). A modified guiding tip, triangular convex cross-section and progressive increase in tapers are the main characteristics of ProTaper universal retreatment files. This system consists of D1, D2 and D3 files which have sizes and tapers of 30/0.09, 25/0.08 and 20/0.07, respectively. D1 file has an active tip, D2 and D3 have non-active tips in order to reduce root canal retreatment mishaps. 6 D-Race retreatment files consist of DR1 and DR2 files with sizes and tapers of 30/0.10 and 25/0.04, respectively. Length of DR1 and DR2 are 15mm and 25mm, respectively. DR1 used in the straight and coronal section of the canal as it has
an active tip to penetrate the filling materials followed by DR2 which is used to reach the full length of the canal. R-Endo retreatment files consist of four files, Re, R1, R2, and R3 in addition to an optional finishing file Rs. Retreatment of root canals with R-Endo retreatment system start with coronal conditioning followed by repreparation of the canal using the mentioned sequence of files. Determining the effectiveness of different rotary NiTi systems in removing gutta-percha/sealer may help dentists to choose the best system that enables the greatest/fastest removal of gutta-percha/sealer. Previous studies had controversial findings regarding the best effective rotary NiTi system in removing obturated GP/sealer.

Materials and Method

Sample Preparation:

Forty extracted single canal teeth were selected for the study. To standardize the samples, all teeth were decoronated to obtain root segments of 12mm length, working length was established by subtracting 1 mm from the real root length determined by introducing a number 10 K-file (Dentsply Maillefer, Ballaigues, Switzerland) until it was visible through the apical foramen. Root canal instrumentation was performed using Protaper next system (Dentsply Maillefer, Ballaigues, Switzerland), as recommended by the manufacturer, up to size 25 using a crown-down technique and a standardized amount of 2.5% NaOCl was used to irrigate the canal. then each root canal was obturated with gutta-percha (Protaper next cones, Dentsply Maillefer, Ballaigues, Switzerland) and Endoﬁll sealer (PD, Switzerland) using the lateral compaction technique. The temporary filling was used to seal the coronal orifice, then the teeth were stored for one week in 37°C at 100% humidity. The roots were randomly divided into four groups (n=10/group) according to each retreatment file system was used:

Group I

The X-smart endodontic motor (Densply Sirona, Ballaigues, Switzerland) alongside the Protaper universal retreatment (PUR) system (Dentsply Sirona, Ballaigues, Switzerland) were used to remove the root canal filling materials. The PUR system was employed using D1 (size 30, .09 taper) in the cervical and beginning of middle thirds of working length. D2 (size 25, .08 taper) was used to remove GP from the middle and apical thirds until the working length was reached. D1 and D2 were used only without using D3 ((size 20, .07 taper) files. Speed setting used to remove gutta-percha/sealer from the canals was 500-700 rpm, gutta-percha/sealer removal was considered complete when no more remnants were detected in the file.

Group II

The DRD system (FKG Dentaire, La Chaux-de-Fonds, Switzerland) was employed using DR1 (size 30, .10 taper) and DR2 (size 25, .04 taper) files to remove gutta-percha/sealer from the coronal and apical half areas, respectively, until the working length was reached. The DR1 and DR2 files were used at slowest speed dictated by the manufacturer (600 RPM) and the torque was adjusted at 1.5 Ncm. The verification of complete gutta-percha/sealer removal was as previously described.

Group III

Re-Endo system (Micro-Mega, Besancon, France) files (Rm, Re, R1, R2, R3) were used as per the manufacturer’s instructions. The Rm stainless steel manual file (17 mm, 25/.04 taper) was used first to its full length. It was followed by nickel-titanium rotary instruments Re (25/.12 taper) orifice opener, R1(25/.08 taper) till cervical third, R2 (25/.06 taper) till middle third, R3 (25/.04 taper) to full working length at a speed of 300 rpm and a torque of 1.2 N cm.

Group IV

H files were used to remove the obturating material, H-files of sizes 20, 25 were used in a circumferential quarter turn push-and-pull motion until WL was achieved. The retreatment procedure was considered to be complete when no material could be visualized in the canal or file flutes.

Gutta-percha/sealer remnant quantification

Roots were grooved longitudinally in a buccolingual direction, then split into two halves using a chisel. Canals walls were examined under the stereomicroscope; and imaged at 25x magnification using a digital camera (Nikon, Tokyo, Japan) stabilized at a fixed distance using a holder. The images were magnified 100% using a digital zoom tool. The images were analyzed with ImageJ software (version 19 windows). The canal surface was divided into coronal, middle and apical areas digitally. The percentage of the area of remnants GP/sealer (A) was calculated using the following equation:

\[ A = \frac{\text{area of the remnants GP/sealer} \times 100}{\text{area of the root canal at either coronal, middle, apical thirds}} \]
total area of the root canal and remnant GP/sealer were calculated by summing the data of the coronal, middle and apical thirds. SPSS 24 was used to analyse the data. Inferential statistics included Kruskal Wallis H test and Man-Whitney U test, the significance level was assumed at \( p \)-value less than 0.05.

**Results and Discussion**

Table (1) shows the mean of the percentage of the area of remnants GP/sealer (R%) in coronal, middle and apical areas of the root canals, also, it shows the mean of the percentage of the area of remnants GP/sealer in the total surface area of the root canals. The lowest R% in coronal, Middle, apical and total root areas achieved in PUR, DRD, DRD and DRD groups, respectively. In each one of the tested groups, there was no significant difference in R% between coronal, middle, apical and total root areas, except in the H file group, there were significantly lower R% in coronal compared to middle areas of the root canal (\( p < 0.05 \)). In addition, there were significant differences (\( p < 0.05 \)) in R% between groups in each of the levels (the coronal, middle, apical and total root areas), respectively. In the coronal area, PUR showed the lowest R% compared to other systems. PUR had significantly lower R% than RE and H groups, respectively (\( p < 0.05 \)). Also, DRD had significantly lower R% than RE (\( P < 0.05 \)). There was no significant difference between PUR and DRD (\( p > 0.05 \)), as well as no significant difference between RE and H groups (\( p > 0.05 \)). In the middle, apical and total root areas, Both PUR and DRD had significantly lower R% than RE and H groups, respectively (\( p < 0.05 \)). There was no significant difference between PUR and DRD (\( p > 0.05 \)). Also, there was no significant difference in R% between RE and H groups (\( p > 0.05 \)), as shown in Table (1).

</table>

Identical small letters superscript in the same row represent significant differences between relevant groups.

Periapical inflammation and failure may be occurred postoperatively because of the inadequately prepared and obturated root canal systems that harbor bacteria and necrotic tissue that need to be eliminated therefore removing as much sealer and gutta-percha as possible in retreatment procedure seem necessary. This study aimed to assess and compare the effectiveness of PUR, RE, DRD and H files in removing gutta-percha and sealer in natural single root canals by measuring remnant GP/sealer surface area percentage. As reported by other authors, none of the techniques tested was able to irradiate all GP/sealer remnant from retreated root canals\(^4,11,12\)

To simplify the standardization of the specimens, premolars with straight roots and relatively wide canals were selected for this study. The use of a longitudinal split to obtain images to inspect the root canal walls was advocated by several authors.\(^9,10,12\) Longitudinal sectioning together with the use of the stereomicroscope has been shown to be more efficient for detecting the remaining root canal filling material compared with radiographic techniques.\(^13\)
In the present study, speed and torque used were adjusted according to the manufacturer’s instruction for all tested groups. However, in order to standardize the size of the final instrument used to remove GP/sealer in the canals, the files with size 25 tip in each system were the final instrument used to remove GP/sealer, therefore, D3 file of PUR was not used to remove GP/sealer. No solvent was used to help remove the root canal filling materials with the rotary NiTi systems, as they generally plasticize gutta-percha through the heat generated by friction. Also, the solvent was not used with H files in order to minimize the number of variables involved in the study. In addition, using a solvent would generate a thin film of gutta-percha on the root canal walls that would be difficult to identify and remove. Similarly, we did not use Gates Glidden burs with H files, which are known to be effective in removing GP/sealer in the coronal part of the root canals. Also, three-dimensional visualization of the root canal after retreatment was not used, which would provide superior quantification of the filling remnant and prevent remnant loss during the splitting procedure as reported by.  

The present study showed that root filling materials could not be completely removed from the root canal walls. This observation was in agreement with those of the previous studies on retreatment efficacy in which various retreatment technique and root filling materials were used. The results of the present study revealed that PUR and DRD showed the lowest R% compared to other groups. There were no significant differences between PUR and DRD (p>0.05) in R% at all levels (the coronal, middle, apical and total areas, respectively). These findings agree with that of Colaco and Pai 2015 and Ibrahim et al. 2018, they have reported that there are no significant differences between PUR and DRD regarding GP remnants. However, both PUR and DRD were more efficient than R-Endo and H files in removing GP/sealer by leaving less amount of remnant GP/sealer, this higher efficiency of PUR and DRD may be attributed to the design of the PUR and DRD files. PUR files have a convex triangular cross-section, a larger internal mass and area, and variable helical pitch and taper. Which result in effective removal of GP coronally in the canal. DRD files exhibit smooth surface because of a special electrochemical surface treatment, in addition to a triangular cross-section, which enhances removal efficiency of GP from the canal and superior sharpness.

Conclusion

The amount of GP/sealer remaining after root canal retreatment with PUR and DRD was not significantly different but showed better retreatment efficiency than Re-Endo and H files. However, because all experimented techniques showed remnants of filling materials on the canal walls, additional measures such as the combination of manual and rotary techniques can help completely remove GP during endodontic retreatment.

Clinicopathological Study of Oral Giant Cell Fibroma

Fatimah J.Ismael1, Bashar H.Abdullah1
1Department of Oral Diagnosis, College of Dentistry University of Baghdad, Bab-Almoadham, P.O. Box 1417, Baghdad, Iraq

Abstract

Giant Cell Fibroma (GCF) is a relatively rare oral mucosal lesion, so named due to the characteristic giant cells present within the fibrous stroma of the lesion, limited number of clinicopathological studies were performed in previously published literature. This study was performed to evaluate the clinicopathological features of Giant cell fibroma in a sample of Iraqi patients. Formalin-fixed paraffin-embedded sections from 22 giant cell fibroma in period between 2010 and 2018 were retrieved from the laboratory of oral pathology of Baghdad University/College of Dentistry. Clinical data and microscopic features were reviewed and analyzed according to the available surgical reports. The mean age of patients at the time of diagnosis was 29.68 years with slight female predilections (1.4:1), the gingiva is the most common site of occurrence (36.4%), the lesions were 2-10 mm in greatest dimension. The most frequent provisional diagnosis is fibroma (54.5%) and papilloma (27.3%). Histologically, the distinctive diagnostic feature is the presence of mono, bi or multinucleated large stellate giant cells with a mean of 48.59 which is most numerous in the lamina propria beneath the epithelium.

Key words: Clinicopathological, oral giant, cell fibroma

Introduction

The giant cell fibroma is an oral soft tissue lesion with distinctive clinicopathological features. It was first described as a separate entity among fibrous hyperplastic soft tissue lesions by Weathers and Callihan in 1974 when 108 out of 2000 fibrous hyperplasia specimens fulfilled the criteria for GCF 1 . Unlike the traumatic fibroma, it does not appear to be associated with chronic irritation, 2 . GCF is an asymptomatic nodular mass less than 1 cm frequently occur in the gingiva, the surface may be smooth, lobulated or papillary so the lesion takes on the clinical appearance of a papilloma, almost occur before age 30 years, with a slight female predilection 3 . Histologically, the surface is stratified squamous epithelium, covering loose or dense fibrous stroma with numerous large stellate mono-bi or multinucleated giant cells. With well-demarcated cytoplasm, dendritic processes and surrounded by an artificial space or separation of the collagen fibers from the cell boundaries.

Materials and methods

The study sample consisted of 22 GCF tissue blocks with their surgical reports retrieved from the files of the laboratory of oral pathology of Baghdad University/College of Dentistry, from 2010 to 2018, the available clinical data (age, gender, site, provisional diagnosis, size of the lesion) was reviewed and analyzed. All tissue sections were processed routinely for H and E stain and examined under a light microscope (Olympus CH3), The clinical features were assessed in relation to site, sex, size, and age. number of giant cells was calculated in each case in 5 fields of a tissue section by experienced pathologists and correlated to the clinical information. Statistical analysis was performed using Statistical Package for Social Sciences (SPSS) version 25. The data presented as mean, standard deviation and ranges. Categorical data presented by frequencies and percentages. Independent t-test and Analysis of Variance (ANOVA) (two-tailed) was used to compare the continuous variables accordingly. Pearson’s correlation test (r) was used to assess the correlation between continuous variables accordingly. Chi-square test was used to assess the association between provisional diagnosis and certain information. A level of P – value less than 0.05 was considered significant.
Results and Discussion

As showed in (table 1) The demographical and clinical data of 22 GCF cases revealed that the mean age was 29 years. A slight female predilection was recorded (59.1% versus 40.9%) with female to male ratio of 1.4:1. Gingiva is the most frequent site representing (36.4%), followed by tongue (27.3%), palate (18.2%), buccal mucosa (13.6%), and Lip (4.5%). The size of the lesion ranging from 2 to 12 mm with a mean of 4.8 mm and the largest lesion was seen in the posterior upper gingiva and buccal mucosa.

Oral Fibrous Hyperplasia(fibroma) is the most frequently missed provisional diagnosis (54.5%) followed by papilloma in (27.3%) which is mostly located on the tongue and palate of young aged patient, peripheral giant cell granuloma (P.G.C.G) and pyogenic granuloma in (9.1%), however, As showed in (table 2) statistically there is no significant association detected between provisional diagnosis and age, gender, and site as P value (0.121, 0.336,0.151) respectively.

The gross examination of the specimens of GCF (incisional and excisional biopsies) revealed white soft tissue lesions, the surface of the mass often appears papillary, the size of specimens ranged from 0.2 cm to 1.2 cm in diameter (figure 1) Microscopically sections showed a keratinized stratified squamous epithelium showing mild to moderate hyperplasia pseudo epitheliomatous hyperplasia was seen in 7 out of 22 cases with elongated and thick rete ridges, the underlying stroma consisted of dense collagenous fibrous tissue made of haphazardly arranged dense fiber bundles with mild to moderate amount of mixed inflammatory cells infiltrate (figure 2).

The most characteristic histological feature is the stellate shaped giant cells which are mono-bi or multinucleated with large hyperchromatic nuclei, these cells were mostly present in the subepithelial and interpapillary region and may have Short dendritic cytoplasmic processes and surrounded by an artifactual space or separation of the collagen fibers from the cell boundaries (Figure 3). The mean of the total number of giant cells in our study was 48.59 with 27.30 standard deviations. Statistically there is no significant association was detected between the number of giant cells and age, sex, and site of the lesion P value (0.8, 0.331, 0.077) respectively. The clinical features of GCF were described by five previous large-sample clinicopathological studies, GCF can occur at any age. The mean age of the patients was reported previously to be approximately 28 years in two studies (7,8), which was very close to the mean age of 29 years reported in the present study. The peak incidence is in the second decade of life, with about 60% of the lesions occurring in the first three decades. (1, 8,7) Our study found the highest incidence in the second and third decade, and approximately 60% of GCFs were in the first three decades. However, two previous studies have reported the highest incidence to be in the fourth decade of life. (9, 10) this discrepancy may be attributed to the asymptomatic nature of the lesion, genetic and racial differences. A slight female predominance for the occurrence was found in our study (59.1%) which is agreed with Four studies (1,7, 9,10) whereas disagreed with other studies that demonstrated no significant sex predilection. (8,11)

All previously mentioned studies stated that the most common location for GCF is the gingiva While The tongue is the second most common location followed by the buccal mucosa or palate that is in agreement with our study (1,7,9,10), the reported size of the lesion is 0.5-1 cm which is matching our results, however, the most accepted explanation to the largest size of lesion in the upper posterior gingival and buccal mucosal area is presence of trauma from occlusion in this site which lead to inflammation that may increasing the size. No GCF was diagnosed correctly at initial clinical presentation, GCF is misdiagnosed most often as fibroma, fibroepithelial polyp, or papilloma. (1,7,10) Comparable results were also found in the present study. The fibroma was reported in any location specially in buccal mucosa while the papilloma was frequently anticipated when the lesion appeared on the tongue or palate of the young and middle-aged patients because of the similarity in the shape, age, and site of these two lesions.

The histopathological features were in agreement with all previous literature; however, the presence of these peculiar giant cells and whether these cells were differentiated from a fibrous, histiocytic or neural lineage remains to be controversial. The pathogenesis of PEH Pseudoepitheliomatous hyperplasia (PEH) is still unclear, Pathologically, PEH arises due to the release of various cytokines produced by the tumor cells or inflammatory cells subsequently resulting in the proliferation of the overlying epithelium. 12 therefore, the presence of PEH in GCF may be associated with inflammation that presented mostly in traumatic areas inside the oral cavity specially gingiva and buccal mucosa, however, in our
study, in addition to the mentioned anticipated sites, the PEH was noticed in GCF from different sites such as palate, tongue, and lip.

**Conclusions**

Though the clinicopathological features of giant cell fibroma are similar to the conventional fibroma/fibroepithelial polyp there are discriminative histopathologic features for giant cell fibroma that still a controversial issue in pathological literature that need further clinicopathological, immunohistochemical and molecular verification. A high index of suspicion and appropriate investigative workup is necessary for separate lesions to achieve a suitable diagnosis and offer appropriate therapy.

Impact of Health Education Program on Health Status of Heart Failure Patients: A Quasi-Experimental Study

Younus Khudhur¹, Yousif Mohammed¹
¹Department of Adult Nursing, College of Nursing, Hawler Medical University, Erbil, Iraq

Abstract

Heart failure, is a major cause of morbidity and mortality, especially in ageing people, it affects and kills a large number of people. Objective: The study aims to evaluate the effectiveness of an education program on the health status of patients suffering heart failure. The study design is quasi-experimental. The patients were allocated into either the experimental group (taking the program, n = 200) or the control group (not taking the program, n= 200). The extent of samples knowledge about the disease was tested at both the pre and post education stages. A structured teaching program for imparting knowledge on various aspects of nutritional status was developed based on an extensive review of the literature and expert opinion. The results of the study were elicited based on two statistical approaches, first, descriptive statistics and the second is an inferential statistical analysis. The shows that health status sub main domains at pre-period in case and control groups was non significant, while the health status sub main domains at post period in both groups were high significant. Regarding the study global main domains in both groups along pre-post period were high significant.

Keywords: Education, Heart failure, Mortality, Knowledge

Introduction

Heart failure (HF), is a state in which the cardiac muscle is unable to push enough blood to body. As the heart does not push enough blood to all the body, it cannot meet the metabolic demand which must require.¹ The improper blood supply to the body result in subsequent incompetent supply of oxygen to the body tissues, and symptoms such as fatigue or activity intolerance appear as well as developing shortness of breath.² Heart failure lead to a major public health problem in the world with a significant risk of the disease on population and the individual, this burden of disease can be measured in terms of mortality, increase readmission rate, as well as the healthcare costs. Frequent HF hospitalization is a burden on the healthcare system and adversely affect patients and state outcomes.³,⁴ The most common causes of heart failure are cardiomyopathy, hypertension, heart valve disease, coronary artery disease, congenital heart disease and alcohol consumption.⁵ The usual symptoms are shortness of breathing, frequent cough, swollen extremities, abdominal swelling, fatigue, dizziness and sudden death.⁶,⁷ Risk factors for heart failure patient may be divided into two classifications; compliant and non-compliant risk factors. Compliant risk factors are those that a person can correct it, including high serum cholesterol level, a diet high in saturated fat, obesity, physically inactive, hypertension, cigarette smoking, and alcohol consumption. And non-compliant risk factors are those that an individual can’t change, such as age, gender, ethnicity and heredity.⁸ Heart failure is usually managed with style of lives changing and medicines, eating habits changes to maintain an ideal weight, diminish salt intake, appropriate exercise, smoking cessation, reducing and alcohol consumption.⁹,¹⁰ Investigation has shown that approximately half patients who readmitted to the hospital could be stopped if HF patients were compliant to their management regimen, and meet symptom monitoring.¹¹ Clients, as well as their caretakers, level of knowledge, is significantly related to their level of adherence to recommended care regimens.¹²,¹³ Patients knowledge is an essential component for the treatment of their disease.¹⁴ Studies focus on the education of patients and their families to improve their knowledge of self-care and compliance.¹⁵,¹⁶ Also studies checking HF patients’ knowledge and the outcomes of patient education recorded that health literacy was associated with higher HF knowledge and
Methodology

Design and Sample

A quasi-experimental design was applied to achieve the goal of the study. Non-probability, purposive sample, with the use of pre-post test approach for both study and control group. A sample of (400) heart failure patient chosen among patients who attended to three main hospitals; Hawler teaching hospital, Rojhelat emergency hospital, and Rizgary teaching hospital. The samples were divided into two groups; (200) patient as a study group was exposed to the health education program and the other (200) patients are not exposed to the health educational program, considered as the control group with the same demographic characteristic for both groups.

The Educational Program

A structured teaching program for imparting knowledge and nutritional status of heart failure was developed by the authors. The content of the educational program was designed based on an extensive review of the literature and expert opinion. The program composed of a set of modules related to health status, these modules include physical status, psychological status, nutritional status, exercise status, social status, economical status, medication status, as well as smoking status. Models content was created and edited by the researchers. Before the nutritional program is finalized, it has been presented to a group of experts. Those experts were asked to review the education program as well as the instrument for their content, clarity, and adequacy. After the review, some items were excluded and some others are added after face to face discussion with experts and the instrument considered valid after taking all the comments and recommendations in considerations.

Procedure

After ensuring informed consent from the patients, they were given the pre-test questionnaire before the administration of the educational program. Each patient was given a serial number to be followed in the second assessment (post-test). After administration of the pre-test questionnaire, the patients were imparted with a education program by face-to-face interview with the primary author. The face-to-face interview lasted ‘30-35 minute-sessions’ with using booklets and short videotapes. As a reminder, each participant heart failure patient was provided with a copy of the education booklet prepared and designed by the primary author and reviewed by other authors. The content of the booklet was similar to that of the educational program and it summarized the most important points in the program. For preventing bias recall, one month later, patients were asked by telephone to complete the same questionnaire a second time (post-test).

Data Analysis

The statistical data analysis approaches were used in order to analyze and assess the results of the study under the application of the statistical package (SPSS) ver. (22.0):

1- Descriptive data analysis: Frequencies, percentages, Mean of the score (MS), Standard Deviation (SD), Relative Sufficiency (RS%), as well as scoring scales of two categories, such that (Yes, and NO)and are responding with integer numbers (1, and 0) respectively.

2- Inferential data analysis: Alpha Cronbach, The Independent-Samples t-test, Matched Paired-Samples t-test (MP t-test), Pearson’s correlation coefficient.

### Discussions

Respect to subjects of studied socio-demographic variables in table (1), results shows that socio-demographic variables in studied groups had recorded no significant differences at P>0.05, except in age groups, and levels of education, which represented significant different in at least at P<0.05, rather than most of studied group’s individuals distribution concerning age, and levels of education are very similar. For summarizing preceding results in table (2), and due to an overall assessments, it could be conclude that suggested educational program could be applicable for case group, since the absence of significant differences between the two groups regarding health status of people with heart failure. Regarding the descriptive statistics of case and control groups in light of post period in table (3) , the result shows that the two groups in the light of sub main domains are recorded highly significant differences at P<0.01, with exception of no significant differences between the two groups concerning “Psychological Status of Heart Failure Patients, Social Status of Heart Failure Patients, and Economical Status of Heart Failure Patients” at P>0.05. For summarizing preceding results, and due to an overall assessments, it could be conclude that the suggested educational program has had a significant impact in improvement their health status.

Abstract
Hepatocellular carcinoma (HCC) globally ranked fifth common cancer and the third-leading cause of death. This study aimed to characterize the new mouse hepatocellular carcinoma cell line (HCAM) for some of the most important proteins involved in cell cycle regulation P53, HER2/neu, and EGFR by immunocytochemistry. Also, to measure the sensitivity of the cells to some common chemotherapeutic agents such as cisplatin and docetaxel by the MTT cell viability assay. The findings of immunocytochemistry appeared that HCAM cells proven to express the p53 and EGFR positively when compared with the negative control. Furthermore, showing nuclear only low expression for the HER2/neu. For evaluation of the chemotherapeutic agent’s efficiency, the cells of hepatocellular carcinoma (HCAM) were treated for 72 hours using different concentrations for Cisplatin and Docetaxel. The IC50 values of docetaxel and cisplatin after 72 h exposure for HCAM was 12.82 and 10.74 respectively. Our in vitro results demonstrate that Docetaxel and Cisplatin are toxic to HCAM cell line in a concentration-dependent manner. In conclusion, our results showed positive expression of p53, EGFR, and weak HER2/neu. Also, HCAM cell line showing to be sensitive to docetaxel and cisplatin, which inhibit cell proliferation.

Key words: Hepatocellular carcinoma, cisplatin, docetaxel

Introduction
Over the past several years, tumor cell lines have occupied significant parts in cancer researches to demonstrate molecular characteristics and evolving new therapies together ¹. Drug experimentation in cell lines of cancer is typically some of the initial steps in drug development. It permits the entrance of potential drugs numbers before committing to large scale expensive in vivo experimental approaches ². Cancers can develop resistance to particular therapeutics. The most type of primary liver cancer is hepatocellular carcinoma, which is cancer easily acquiring resistance to drug therapy. Therefore, many active anticancer agents available, some are associated with high levels of toxicity. For example, docetaxel agent is beneficial as microtubule depolymerization inhibition, and it has shown a strong influence against cancer ³. Also, Cisplatin, cisplatinum, or (cis-diaminedichloroplatinum) is a recognized chemotherapeutic agent; it is active against cancers types, including cancer of germ cell, carcinomas, and sarcomas. Cisplatin method of action through to its capability to linking with the purine bases on the DNA; causing DNA damage, intervening with DNA repair mechanisms, and then inducing apoptosis of cancer cells ⁴. Immunocytochemistry (ICC) analysis is a beneficial tool not only for cell characterization but in some cases, also for cell lines authentication ⁵. The suppressor gene of the tumor (p53) is mutated mostly in 50% of tumors. The p53 ability for various biological roles can be returned to its ability to act as a sequence-specific transcription factor to the regulation of different targets expression, and thus to manage multiple cellular processes including DNA repair, cell cycle arrest and apoptosis ⁶. These proteins (EGFR) are found on the surface of some cells of cancer and normal cells types and mediate cell survival, invasion, proliferation, and angiogenesis ⁷. A

type I tyrosine kinase receptor encodes by HER-2/neu proto-oncogene; Also, HER2/neu stimulates the factors that facilitating cell motility and induces cell division. The aim of the work to evaluate proteins expression and analyzed the cytotoxicity assay of docetaxel and cisplatin against the new hepatocellular carcinoma cell line (HCAM).

**Methodology**

**Cell line and Cell culture**

The cell line of (HCAM) Murine Hepatocellular Carcinoma Ahmed Majeed was supplied from Iraqi center of cancer, and medical genetics research (ICCMGR) and cultured in vitro in RPMI-1640 media supplemented with 10% fetal bovine serum (FBS), 100 µg / ml for ampicillin and streptomycin. The suspension was then transferred to a culture flask for 37°C incubation.

**Immunocytochemistry**

The Cells of HCAM were grown in RPMI-1640 supplemented 10% FBS to a confluent monolayer on glass coated with coverslips in a six-well plate and sustained in a humidified incubator at 37°C with 5% CO2. Before fixation, monolayer cells were washed using PBS twice. With 4% cold acetone, the cells on a coverslip were fixed for 10 min, rinsed gently in PBS. Endogenous peroxidase activity was neutralized by incubation for 10 min in a solution consisting of 3% H2O2 blocking reagents for 45 min firstly and then primary antibodies selection (anti -Her neu2, anti-P53, and anti-EGFR) (Santa Cruz Biotechnology), for 2 hours at 4°C for detection of markers for hepatocellular carcinoma. The antibodies dilution was (1:50–100) according to the recommendations of manufacturers. The color operation was achieved with the chromogen diaminobenzidine (0.6 mg/ml) in a 0.02% H2O2 solution. Cells were examined with a Leica light microscope after counterstaining of nuclei with hematoxylin.

**Quantitative image test**

ICC images were used for quantitative analysis protocol for the hematoxylin – DAB staining slides were taken by Leica inverted microscope and camera (Leica Microsystems, Germany), three different staining zones of immunocytochemistry images of each slide were analyzed in this study. Firstly, un-mix the DAB by color de-convolution technique, the areas of hematoxylin stained were leaving a complimentary image. As we take three new images. The first image is the hematoxylin stain, the second one is the DAB image, and we quantify the DAB image. The number of pixels of a specific intensity value vs. their respective intensity was raised using “Fiji” version of Imagej from http://fiji.sc. The intensity numbers in the results window were converted to Optical Density (OD) numbers with the following formula:

\[ OD = \log (\text{max intensity}/\text{Mean intensity}), \text{where} \ \text{max intensity} = 255 \text{ for 8-bit images} \]

**Cytotoxicity assay**

**Reagents**

Cisplatin and Docetaxel were obtained from the pharmacy with a concentration of (cisplatin 50 µg/ml, Docetaxel 100 µg/ml) and stored at 4°C. The preparation of the stock solution was accomplished by dissolving the reagents in distilled water. Before each experiment, this solution was diluted in the free serum medium and immediately used in the tissue culture.

**Cell viability assess**

The examine of cell proliferation, cells were plated in 96-well plates (Sarstedt, Denmark) with 200 µl of cells in each well and incubated at 37°C. At monolayer, cells exposed with concentration of Cisplatin (50µg/ml), prepare series dilution (50, 25, 12.5, 6.25 and 3.125) µg / ml, and Docetaxel (100 µg/ml), prepare series dilution (100, 50, 25, 12.5 and 6.25) µg / ml which were diluted with RPMI-1640 free serum medium. Then 200µl of each dilution of chemotherapy described earlier were added to each well. The microplate was incubated at 37°C for 72 hours. After 72 hours of the exposure the viability of cells was assessed and treatment by removing the medium, adding 100 µl of 2 mg/ml solution of MTT and incubating for 2 hours at 37°C, and dissolving of insoluble formazan crystals in 150 µl of dimethyl sulfoxide (DMSO).

The optical density (OD) was measured at 490 nm of the wavelength by a microplate reader. The cell growth inhibition rate calculated using the following formula: \( (IR) = (A-B)/A\times100 \). Where A: mean of the optical density of untreated wells, and B: optical density of treated wells.

**Morphological study**

The chemotherapy exposed and non-exposed...
control hepatocellular cells were photographed at 72h and fixed in 4% paraformaldehyde in phosphate buffer (10 min) at room temperature. The cell was stained with hematoxylin and eosin (H&E) stain. The cells were examined using the Leica inverted microscope. The affected cells were recognized according to cytological features 15.

**Statistical analysis**

The data was displayed as mean ± standard deviation. For ICC experiment, n = 3 images were used. One-way (ANOVA) analysis of variance multiple comparisons were done to show variations between groups. The statistical analyses were done using (GraphPad Prism, version 6.07 for Windows, GraphPad Software, San Diego, CA, USA), and p < 0.05 as statistically significant.

**The Results**

**Immunocytochemistry assay**

The result of immunocytochemical staining for some biomarkers was shown in figure 1. The P53, EGFR, and Her-neu2 expression in the HCAM cell line of hepatocellular carcinoma were noticed using an anti-mouse IgG immunocytochemistry kit. The findings presented that HCAM were positive for EGFR, weakly for Her-neu2, and p53 proteins expression. Her-neu2 showed nuclear expression when compared with control cells. The control cells were exposed to the secondary antibody only, without primary antibody (negative control).

**Digital Image Scoring**

Images of ICC stained HCAM hepatocellular carcinoma cells were analyzed using ImageJ software. Figure-1E displays demonstrative pixel and zones intensity analysis of ICC images. The analysis showed that P53, EGFR, and Her-neu2 proteins were significantly expressed when compared to control, not stained cells using ANOVA one-way multiple comparison test.

**Morphological study**

Cytopathic effect of Docetaxel and Cisplatin on HCAM cell line was studied after 72 hours of exposure. Light microscope unstained and H&E stained images for control untreated cells were relatively uniform in size and shape (spindle) in monolayer culture with and without H&E stain (X20).

Figure (1): Immunocytochemistry stain of HCAM cell line. A) EGFR-positive staining of HCAM cancer cells (magnification 20×). B) P53-positive staining of HCAM cancer cells (magnification 20×). C) Her/neu2 weak positive nuclear expression of HCAM cancer cells (magnification 20×). D) Negative control of HCAM cancer cells (magnification 20×). E) Digital Image Scoring is showing significant proteins expression when stained with relative mAbs against the markers that analyzed using ImageJ program.

Figure-2: Bar chart for the mean values of growth inhibition rate and ic50 of HCAM cell line (GI%) induced by Docetaxel and Cisplatin after 72 h of exposure.

(A) The IC50 value of docetaxel for HCAM cells.

(B) The IC50 value of Cisplatin for HCAM cells.
(C) The effect of Docetaxel (100 µg /ml) for HCAM cells.

(D) The effect of Cisplatin (50 µg /ml) for HCAM cells.

**Figure (4): cytotoxicity effect of Docetaxel and Cisplatin on HCAM cell line after 72 hours.**

(A, a) Untreated cells, HCAM cells were relatively uniform in size and shape (spindle) in monolayer culture with and without H&E stain (X20).

(B, b) Effect of docetaxel 100 µg /ml, (C, c) Effect of Cisplatin 50 µg / ml.

The cells tended to grow in clusters and arranged irregularly, cells detached and appeared as oval forms with and without (H&E) stain (X20).

**Discussion**

The ICC study presented that most of the HCAM cells were positive for EGFR, HER2/neu, and P53 proteins. The p53, EGFR, and HER2/neu genes expression impact the management of cancer cells due these genes provide both prognosis and therapeutic information \(^{16}\). HCAM cells were positive for P53 and EGFR as nuclear and cytoplasmic expression while for HER2/neu was very weak nuclear expression only. Positive expression of the cytoplasm and nucleus suggests mutation in p53, HER2/neu, and EGFR because it has important role in cell cycle control and DNA repair \(^{17-19}\). Several epigenetic and genetic alterations involved in the molecular pathogenesis of HCC as a somatic mutation of the tumor suppressor gene (p53) \(^{20}\).

In addition, \(^{21}\) shown that HCC models in both human and mouse, EGFR are upregulated in macrophages of the liver, where it acts as a tumor-promoting function. HER2/neu expressed weakly in non-neoplastic normal epithelia \(^{22}\). Otherwise, some researchers showed that development and modulation of HER2/neu oncogene in hepatocellular carcinoma is a rare event \(^{23}\). In agreement with our findings of HER2/neu nuclear expression in our HCAM cell line, another researcher \(^{24}\) found that hepatocytes with altered metabolic and cell cycle may have nuclear HER2/neu expression.

In the current study, MTT viability test was used to evaluate the cytotoxic effect of docetaxel and cisplatin on the growth rate of the cell line (HCAM) in vitro. Docetaxel and cisplatin can inhibit the growth of HCAM cells in a concentration-dependent manner. Docetaxel enhances the assembly of tubulin into stable microtubules and prevents their assembly that leads to a reduction of free tubulin and cancer death \(^{25}\). Our results demonstrated that docetaxel showed a cytotoxic effect of HCAM growth rate with high concentration 100, 50, and 25 µg/ ml at 72 hours. Docetaxel with high concentration level, can effects on cell cycle kinetics, apoptosis, or increased ROS level. \(^{26}\) Our data presented that cisplatin significantly inhibited the growth of HCAM cell with concentration (50, 25 and 12.5 µg/ ml) at 72 hours, which is consistent with a previous study \(^{30}\) that found hepatocellular carcinoma treated with cisplatin significantly inhibited the growth rate and induced apoptosis.

**Conclusion**

Our results suggest that HCAM cell line express p53 and EGFR proteins in both nuclear and cytoplasm, but weak nuclear HER2/neu expression. Also, HCAM cell line is sensitive to cisplatin and docetaxel that induces a significant cytotoxic effect. HCAM is a new important mouse model that can be used for anti-hepatic cancer drug development.

Abstract

Breast cancer is heterogeneous disease. From this; a special group of tumors, triple negative tumors, has a distinct interest from having its unique behaviors regarding biological, clinical, histological, hormone receptors status, Her2/neu expression, and therapeutic modalities. We made a study on Iraqi women, with triple negative tumors, focusing on some important parameters in this group of patients, comparing our results with the others (from the world). We conclude that most of these parameters are identical except the tumor grade, where we found that it is significantly low. Results from studies done before on Iraqi women, for the same purpose, showed some differences from ours. These differences include percentage of these tumors among other types of breast tumors (our results looked less), grade of tumors (our results showed medium grade), and lymph nodes metastasis which looked less in our study.

Key words: Breast cancer, Triple negative tumors, Tumor grade, Er, Pr , Her2/neu

Introduction

Obviously; the breast cancers are the most killing cancers in women. According to this fact, these cancers were studied thoroughly. From many studies on this subject, it was found that; breast cancer is a heterogeneous disease. Many types were mentioned according to morphologic, immunologic, and molecular studies. Immunohistochemical studies, namely hormone receptors (estrogen receptors ER, progesterone receptors PR, and others like ki 67 and Her2/neu) showed important prognostic parameters.1 These parameters were found to affect strongly the planed therapy for breast cancers (1,2) Recently it was found that, a specific group of breast tumors called triple negative tumors, (1,3) this term was used for those tumors with estrogen hormone receptor negative, progesterone hormone receptor negative, and Her2/neu negative. (1, 3) They found that this group has some specific manifestations regarding age of patient, histological grade, lymph nodes involvement, response to therapy, and survival time after taking therapy. (4,5,6,7,8,9,10) Some authors found that these tumors account for 10-17% of all breast carcinomas. (4, 5, 6, 7, 8, 11, 12) Many authors defined that they occur in relatively younger age group (< 50 years age) (4, 5, 6, 13) and even they are more prevalent in African American women. (7, 12, 13) Most of the studies agreed about the similarity between triple negative tumors and basal-like tumors. (1, 2, 3) Though not all basal-like tumors are triple negative tumors and vise versa (only 77% of cases classified by gene expression profiling as basal-like show a triple negative phenotype, while only 72% of cases of triple negative cancers exhibit a basal-like gene expression profile). (3, 14, 15) It was also found that the triple negative tumors are with high grade (4,8) just like basal like tumors. Most of triple negative tumors are of high grade invasive ductal carcinoma (9,10,16) like that of basal-like tumors. Though one study found that there is high prevalence of lymph nodes metastasis in triple negative tumors, (4) other studies did not find this result. (5, 8) Some found that; there is
no correlation between size of the tumor and presence of metastases in triple negative tumors. In Iraq; the breast cancer is important cause of death. This cancer is usually presented with high stage and grade and in relatively younger age group at diagnosis. It was noted (in comparative study) that; triple negative tumors in Iraqi patients are higher (about 3 folds) than English patients. In another study, done on Iraqi patients, it was found that triple negative tumors constituted about 15.6%.

Generally speaking; triple negative tumors is of high percentage in Iraqi women with breast cancers, and this indicates a bad prognostic sign, as shown before.

Methodology

A retrospective study was performed on 477 female patients with breast cancers who visited the Medical City-Oncology Center during years 2014 and 2015 for sake of cancer therapy. Patient’s data, from records of the oncology center, were collected to study different parameters like patient age at time of diagnosis, histopathology diagnosis, grade of tumors, lymph nodes involvement, hormone receptors (ER, PR) status, and Her2/neu expression. Those data were processed to define whether these tumors belong to triple negative group or not and a statistical study were done to detect behaviors of triple negative tumors in this sample of Iraqi patients. For all cases in this study; a histotechnique using paraffin embedding technique and a staining by routine Hematoxyline and Eosin (H&E) staining protocol for initial diagnosis were adopted. Then an immunohistochemistry technique was used according to College of American Pathologist (CAP) Breast Biomarkers template, especially for estrogen receptors (ER) and progesterone receptors (PR). Her2/neu study was done by immunohistochemical technique initially, while equivocal cases needed to be confirmed by fluorescence in situ hybridization (FISH) technique (a molecular cytogenic technique) according to American Society of Clinical Oncology (ASCO) Guideline Update.

Statistical studies for those parameters, mentioned above, were done by using Chi square depending on P-value (p< 0.01 is regarded as significant).

**Results**

At the end of this study and according to statistical data, we had the following results.

On studying the parameters (ER, PR, and Her2/neu) of breast tumors of those 477 patients, we found that 46 women were with triple negative tumors, and this number constitutes about 10.4% of all patients in the study.

The average age of the women, with triple negative tumors, was about 49.4 years (32-67). This means that most of those patients are below the age of 50 years (table no. 1), and this average is significantly lower than that of all patients (P<0.01).

In our study, we found nearly all triple negative tumors were of invasive ductal carcinoma, not otherwise specified. 2 cases were with additional intraductal carcinoma in situ of high grade.

Regarding the lymph nodes involvement, we found that only 13 cases (28.3%) were with lymph nodes involvement (table no. 3). This result is not significantly different from all patients in this study (P>0.01).

**Discussion**

The results of this study were compared to other studies in the world and in Iraq, mentioned in the introduction.

The number of Iraqi patients, in this study, was 477, so those results can give us information about Iraqi women with breast cancers, but they are not necessarily represent all Iraqi women with breast cancer.

We found that triple negative tumors group in this study constitutes about 10.4% (46 patients). This finding looked similar to other studies in the world. (4, 5, 6, 7, 11, 12, 13) But this result is different significantly (P<0.01) from
previous results on Iraqi women (17, 19).

Average age of women with triple negative tumors in this study was 49.4 (< 50). This finding looked similar to other findings in the world (4, 5, 6, 13).

Most triple negative tumors in this study (76%) were of grade II, and others (24%) were with high grade (III) and no case with low grade (I). This finding looks different from the belief that triple negative tumors are usually with high grade (III). (3, 4, 8) Though some authors found that 10% of these tumors were with low grade. In Iraq, one study on triple negative tumors defined high grade histology. 17

The histological diagnosis of all cases in this study showed invasive ductal carcinoma with no specific histology. These findings are the same to what others, in the world, said, (9, 10, 16) and even in Iraq. 17

13 cases (28.3%) from the triple negative tumors in this study were presented with lymph nodes metastasis. This finding is highly different from one study 4 (p<0.0001), while it looked similar to others, (5, 8) with no significant difference (P>0.5). While one study from Iraq 17 showed significant difference from our result (P<0.001).

Conclusion

At the end of this study, we conclude that the triple negative tumors group, in this study, has nearly the same findings and behaviors to those seen in the worlds, except the grade of tumors. And there were some differences seen from other previous Iraqi results.

Seroprevalence of Toxoplasma gondii (IgM,IgG) among Aborted Women in Some Karbala Hospital by using ELISA Technique and Microscopic Examination.

Bahaa Alaa Farhan
Department of Basic Medical Sciences /College of nursing /University of wraith Al-anbiya’a, Iraq

Abstract
In this study, 100 pregnant women experiencing unnatural birth cycle go to the Karbala Maternity and Children Hospital from October/2018 to April/2019. These women submit to a history and physical examination. Blood tests from pregnant ladies were tried for IgG and IgM. Antibodies and suicide Mo graphic information’s were gathered. Their normal age was 29 years. The investigation demonstrated that enemy of Toxoplasma IgG, IgM, and by and large seropositivity of all antibodies were 42.85% and 57.14% separately. There was noteworthy impact of age on extent rate. The most noteworthy disease rates were found at 20-25 age gathering, while the least contamination rate found at 36-40 age gatherings. The all out predominance was more in Second Trimester of pregnancy (12.22%). IgG was increasingly amassed in Second Trimester (13.33%) than IgM (11.11%). No noteworthy distinction was found among residency and the commonness of Toxoplasma gondii antibodies in both rustic and urban territories. Watchwords: Toxoplasma gondii Infection, Toxoplasmosis. Using a microscopic sample of blood samples, 14 positive blood samples from 100 were found and the infection was identified by its characteristic characteristics.

Key words: Toxoplasma gondii, IgM, IgG, Aborted Women

Introduction
Toxoplasma gondii that causes the malady toxoplasmosis is a commit intracellular parasitic protozoan. Serological investigations assess that up to 33% of the worldwide populace has been presented to and might be constantly tainted with T. gondii, in spite of the fact that disease rates contrast essentially among nations. Transmission of toxoplasma gondii happens generally by the ingestion of debased crude/half-cooked meat with tissue blisters, just as nourishment borne route through the ingestion of tainted vegetable/water with oocysts. The European Food Safety Authority (EFSA) has archived toxoplasmosis as parasitic zoonosis with the most elevated human rate. Analysts consider the eating of half-cooked contaminated meat as the greatest hazard and suspected ovine meat, to be a noteworthy hazard factor for human disease. Protein connected immunosorbent measure (ELISA), otherwise called a chemical immunoassay (EIA), is a biochemical strategy utilized by and large in immunology to distinguish the nearness of a neutralizer or an antigen in an example. In straightforward terms, in ELISA, an obscure measure of antigen is attached to a surface of wells, and after that explicit counter acting agent is connected over the surface so it can tie to the antigen. This counter acting agent is connected to a compound by utilize conjugated (catalyst Ab), and in the last stage a substance is included that the protein, and this can change over to some perceptible flag, most ordinarily a shading change in a synthetic substrate. The location of explicit IgM and IgG antibodies has been utilized serological marker for diagnosing ongoing toxoplasmosis. The reason for this examination was to decide the rate of Toxoplasmosis in pregnant ladies in karbala city from October 2018 to April 2019.

Materials
In this examination 100 blood test of pregnant ladies experiencing premature deliveries were gathered from patients who go to the Karbala Maternity and Children Hospital from October/2018 to April/2019. These ladies submit to a history and physical examination to ponder event of T. gondii.. The period of patients extended between (19-50) years of age. Five ml blood tests were
gathered by vein cut from every single contemplated lady subsequent to cleaning the skin with 70% liquor. Blood tests were gathered in plastic cylinders and left to cluster for around 30 min. at room temperature, at that point they were centrifuged for five minutes at 3000 rpm and isolated sera were moved into different cylinders. The gathered sera were put away at -20°C until utilized for the required test in the Central Public Health Laboratory/Karbala; where the ELISA test has been finished. For assurance of T.gondii antibodies (IgM and IgG), we utilized a third-age of compound immunoassay packs for T.gondii IgM and IgG ELISA units/BioCheck-USA.

Parasitological examination

One drop of blood placed at the end of one slide and by the other slide in angle of forty five touched the drop of blood by the end of the slanted slide so the blood run the space beneath it. The slanted slide was drawn quickly and the blood was pulled behind as previously mentioned (Zweygarth et al., 2002). The blood smear was died in air, fixed by absolute methyl alcohol and was stained with Giemsa 10% for 20 minutes in neutral phosphate buffer saline then was washed and dried. The slide was then allowed to dry prior to microscopic examination at 100x magnification.

Results

From 100 abortion women 21 (21%) serum sample were positive for anti- Toxoplasma antibodies and this positive results were diagnosed as 9 (42.85%) for anti IgM antibody and 12 (57.14%) for anti IgG antibody from 100 abortion women 21 (21%) serum sample were positive for anti- Toxoplasma antibodies and this positive results were diagnosed as 9 (42.85%) for anti IgM antibody and 12 (57.14%) for anti IgG antibody, microscopic sample of blood samples, 14 positive blood samples from 100 were found and the infection was identified by its characteristic characteristics. Table (1) showed IgG and IgM anti-toxoplasmosis percentage in patients distributed over different age groups; the highest percentage of acute infected patients was (18.91%) in the age group (20-25) years old, while the lowest percent was (5.55%) in the age group (36-40) years old while the highest occurrence of chronic infection were (11.76%) at the age groups (26-35) years.

**FIGURE 1.** Giemsa stained thin blood smear showing Toxoplasma infection bradyzoit

**FIGURE 2.** Giemsa stained thin blood smear showing Toxoplasma infection tacyzoit

**FIGURE 3.** Giemsa stained thin blood smear showing Toxoplasma infection tacyzoit
The commonness of T. gondii contamination in the present investigation was (21%) in Karbala area and ; the most noteworthy level of intense tainted patients was (18.91%) in the age gathering (20-25) years of age, while the least percent was (5.55%) in the age gathering (36-40) years of age while the most elevated event of unending disease were (11.76%) at the age gatherings (26-35) years. There were likenesses and distinction between the recorded outcomes and numerous others from various area around Iraqi region. In AL-Mosul, 6 announced 69.2% seropositive for this illness in similar patients gatherings, while 49.85% were certain by 9 in Duhok, and 60.21%, by 1 and by 8 80.6% in Baghdad. 17 in Babylon who detailed 43% positive outcome. Such contrasts were normal as the malady event relied upon the ecological conditions what straightforwardly influences on the survival and spread of this parasite. Other examination likes 7 alludes to the nearness of more than one hazard factor may impact the event of toxoplasmosis as the clean conditions and propensities for individuals. In Arab nations, for example, Egypt, El Deeb, et al. (2012) has revealed that (67.5%) are seropositive for T. gondii and in Saudi Arabia are (38 %) 4 and (30.8%) are seropositive in Qatar (Marawan, 2010). In different zones of the world, the present outcomes are about like what announced in Nigeria, 46% in Tanzania and 47% in France (rustic region) 12. Be that as it may, they are higher than what in joined kingdom, (22%) and in South Korea, (43%) as detailed via Carl (2006). This high commonness of the sickness might be because of the high number of hazard factors and numerous springswells of disease which incorporate the half-cooked meat sufficed with growths, eating unwashed vegetables or crude meat ingestion of sporulated oocyst in soil (for example amid planting eating). such finding might be because of distinction in the immunological status of ladies under examination at the time of tests accumulation and this concurs with 14. The percent of affiliation antibodies is 13 (7.14%) from the seropositive, while it is 15 (12 %) by 7 . The investigation of 5 in Egypt alludes to the percent of IgM (27.3 %) and (36.4 %) for IgG counter acting agent. While this examination appears (42.85%) for against IgM and (57.14%) for hostile to IgG antibodies. It has seen that altogether more prominent frequency of premature birth happened in patients with high immune response titters of IgM counter acting agent. This outcome is upheld by 13. The nearness of against T. gondii (IgG) antibodies in the example of serum isn’t adequate to initiate the way that the patient has been contaminated 15, while the nonappearance of IgG early or before pregnancy permits distinguishing proof of ladies in danger for getting the disease 18. In any case, IgG class of antibodies is commonly useful in the analysis of intensely displaying sicknesses on the grounds that these antibodies take 1-9 weeks to create 13 and proceeds for a considerable length of time or years. The high level of contamination is in the second trimester of pregnancy 11.11 % and 13.33 % separately. No noteworthy impact of trimesters on the frequencies of toxoplasmosis is showed up amid the ongoing examination. Regardless of the quantity of patients from provincial territories is higher yet it is a piece of the aggregate; country ladies are sure for hostile to Toxoplasma counter acting agent and this outcome might be because of the way that numerous ladies in rustic locales live in low close to home cleanliness, poor sterile, insufficient legitimate treatment and low instructive dimension about hazard factors, such lead to transmission of T. gondii. The job of wellbeing instruction is considered by 16 as a fundamental factor in diminishing the event of this contamination. The urban regions in Babylon region demonstrate a blend of various financial classes. Such a large number of ladies in downtown area live in poor sterile and low financial state as or even not exactly a significant number of country regions incorporated into the present investigation; this brought about huge likenesses in the quantity of tainted prematurely ended ladies. This outcome is reliable with 2 in Tikrit, who has discovered that the seropositivity is higher in country zones (36.36%) than focus ones (32.05%), 19 in Kirkuk who found that the seropositivity is higher among pregnant ladies from rustic zones (50.0%) than those in focus regions (33.5%). This might be ascribed to the nearness of indoor felines, or even the stray one in the rustic regions more than in the city, which is considered as a last host for T. gondii and a primary hotspot for spreading the irresistible oocyst in the dirt, water, vegetables and natural products utilized for every day expending. Be that as it may, it isn’t steady with an investigation in Ninewah by 3, who has discovered a higher pervasiveness among the city inhabitant (38%) than the country one (29%), likewise in Osorno (Chili) by 23. who has discovered a slight higher commonness in the urban territories than the rustic ones.

**Conclusion**

The investigation demonstrated that enemy of Toxoplasma IgG, IgM, and by and large seropositivity of all antibodies were 42.85% and 57.14% separately. There was noteworthy impact of age on extent rate. The
most noteworthy disease rates were found at 20-25 age gathering, while the least contamination rate found at 36-40 age gatherings. The all out predominance was more in Second Trimester of pregnancy (12.22%). IgG was increasingly amassed in Second Trimester (13.33%) than IgM (11.11%). No noteworthy distinction was found among residency and the commonness of Toxoplasma gondii antibodies in both rustic and urban territories. Watchwords: Toxoplasma gondii Infection, Toxoplasmosis. Using a microscopic sample of blood samples, 14 positive blood samples from 100 were found and the infection was identified by its characteristic characteristics.

Estimation of the Serum Concentration Levels of Ferritin and Vitamin D for Hypothyroid Patients

Amera Kamal Mohammed1, Thanaa Abdulmahdi2, Zainab Nasser Nabat2

1College of Pharmacy, Kirkuk University, 52001, Kirkuk, Iraq. ORCID ID: 0000-0002-8984-6824,
2Babylon Technical Institute, Al-Furat Al-Awsat Technical University, 51015, Babylon, Iraq.

Abstract

The paper investigates the serum concentration levels and the association between the levels of ferritin or vitamin D with thyroid dysfunction in Hypothyroid Patients. 90 participants were involved in this study; 47 healthy people (controls) (18 males and 29 females) and 43 hypothyroid patients (16 males and 27 females). Both groups have a mean age (age ± standard error) and body mass index (BMI) (BMI ± standard error) of 34.36. ± 1.19 years and 27.55± 0.52 kg/m2, respectively. The obtained results indicated that the age of participants played an ignorable role in this investigation (P ˃0.05), while significant differences were noticed between the patients and controls (P <0.05) in terms of BMI, 25(OH) vit D, ferritin, TSH, T3 and T4. There was also a significant difference (P<0.05) between male and female patients in terms of ferritin, TSH, T3 and T4 in comparison with the controls.

Keywords: Hypothyroid; vitamin D; ferritin; TSH; BMI.

Introduction

Thyroid hormones are very essential and have various actions, for instance, they maintain normal growth and regulate metabolism. Therefore, hypothyroid patients usually suffer from fatigue and cold, and easily gain weight due to their altered metabolism 1. There are two thyroid hormones in the human body, Thyroxin (T4) and triiodothyroxine (T3); these hormones are produced in the thyroid gland 2. The latter converts the iodine in food, in a series of reactions, into thyroid hormones. Although a disorder of the thyroid hormones, which is also known as hypothyroidism, can be easily diagnosed and treated, late diagnosis and consequently late treatment could cause adverse effects, such as slowed metabolism, and changes in the levels of serum ferritin and vitamin D 3. Previous studies have confirmed that hypothyroidism is directly related to the concentration of iodine, as the ability of the thyroid gland to produce the required amount of T3 and T4 is limited by the concentration of iodine in the body, where excess or lack of this element could result in disorder of thyroid hormones 4. Hypothyroidism is mainly diagnosed by investigating the inverse relationship between TSH and T4 and T3, where it is expected that a normal person will have a low level of T4 or T3 and a high level of TSH 5. It is estimated that hypothyroidism occurs in from 3.8% to 4.6% of the world’s population 6. However, some studies have indicated that the occurrence of hypothyroidism varies according to the area of the study and ages of the studied people, where it could reach 8.4% 7. Moreover, the clinical indicators of hypothyroidism are highly influenced by different factors, such as the duration and the deficiency level of the thyroid hormones. Generally, hypothyroidism gives a set of associated symptoms such as tiredness, cold, weight increase and dryness of skin, which could be used to diagnose this disease 8. Thyroperoxidase enzyme, which is a thyroid hormone, plays an important role in the synthesisation of thyroid hormones 9. Recent studies have demonstrated that the synthesisation process of the thyroperoxidase enzyme requires a certain amount of iron, which explains the association between the disorder of thyroid hormones and the ferritin level 10. For example, both Takamatsu, Majima 11 and Sachdeva, Singh 10 have demonstrated that the thyroid profile is highly influenced by the ferritin.

levels. It is noteworthy to mention that ferritin is an iron storage protein, with a diameter ca 10–12 nm; it is essential for physiologic and pathologic activities (12-14).

**Materials and Method**

The current study involved 90 participants; these participants were divided into two groups: healthy (controls) and hypothyroid patient groups. The hypothyroid patient group consists of 16 Males (37.21%) and 27 Females (62.79%), while the healthy people group consists of 18 Males (38.30%) and 29 Females (61.70%). The members of the control group were not suffering from any chronic diseases, and had no history of thyroid disease, nor were they on any medication that may interfere with the obtained results. They were living in Babylon Governorate, Iraq. They were examined at the laboratories of Marajan hospital and at Ibn al-Nafis specialist laboratory during the period of study (September 2017 to January 2018). The mean of their ages was 34.36 ± 1.19 years (mean ± S.E), and the mean of their body mass index (BMI) was 27.55± 0.52 kg/m2 (mean ± S.E). The BMI was calculated using the formula BMI= weight (kg)/ height2 (m)2. Vitamin D (25-hydroxyvitamin D), ferritin, T3, T4 and TSH levels were measured using the ELFA (Enzyme Linked Fluorescent Assay, Model: bioMérieux). It is noteworthy to highlight that the normal limit for vitamin D is ranging between 30 and 100 ng/ml. while the limits of ferritin are: male: 20-434 ng/ml, cyclic women: 20-159 ng/ml, menopausal women: 20-278 ng/ml. Finally, limits for serum T3, T4 and TSH thyroid dysfunction patients (hypothyroid) are: T3 between 0.9 to 2.33nmol/l, hyperthyroid <0.15, hypothyroid T4 between 60-and120 nmol/l, TSH thyroid 0.25->7.0. It is noteworthy to highlight that the results were analysed using SPSS package (version 18).

**Results and Discussion**

The obtained results showed that there was no relationship between the age of participants and the thyroid disorder, while the rest of the studied parameters showed a significant relationships (P<0.05). For example, it has been found that the values of BMI, 25(OH) vit D, ferritin, T3, T4 and TSH in the patients were 23.93± 0.39, 32.01±2.76, 33.16 ±3.02, 2.26 ± 0.18, 3.60 ± 0.12 and 19.04 ± 0.66, respectively. In contrast, the values of these parameters in the healthy people (controls) were 31.48 ± 0.56, 18.29 ± 1.54, 24.46±1.90, 11.82 ± 0.56, 1.18 ± 0.07 and 9.20 ± 0.18, respectively, as shown in Table 1. These differences indicate a significant association between these parameters and the thyroid disorder. Table 2 shows that the sex of the participants did not cause any a significant differences in the Age (years), BMI (kg/M2) and in the levels 25(OH) vit D (ng/ml). However, a significant variation was observed in the levels of ferritin(ng/ml), TSH(µu/ml), T3 (nmol/L)and T4(nmol/L) in male and female patients in comparison with the controls.
Table 1: Comparison between hypothyroid patients and control subjects for both sex.

In the hypothyroid patients the linear regression analysis showed there was a significant negative correlation between TSH(µu/ml) and 25(OH) vit D(ng/ml) (r = -0.41, P=0.007), as shown in Figure 1, and between TSH(µu/ml) and ferritin (ng/ml) (r = - 0.35, P= 0.02), as shown in Figure 2.
Figure 1: The linear regression analysis of the thyroid-stimulating hormone (TSH) (µu/ml) with 25(OH) vit D (ng/ml) for hypothyroid patients.

Figure 2: The linear regression analysis of the thyroid-stimulating hormone (TSH) (µu/ml) with ferritin (ng/ml) for hypothyroid patients.

Discussion

The outcomes indicated a significant correlation between the level of vitamin D and the thyroid disorder. A decrease in the average of vitamin D was noticed as the average of TSH increased. This relationship could be related to the increase in bone turnover in hyperthyroid patients that increases the calcium level, which in turn alters the synthetisation of both parathyroid hormone and vitamin D\(^{19}\).

The outcomes of the current study agree with those of\(^ {20}\), which indicated that deficiency of vitamin D is responsible for low thyroid hormones. Mackawy, Al-Ayed\(^ {21}\) found two facts, firstly the level of serum 25(OH) vit D in hypothyroid patients is less than its level in healthy people. Secondly, the authors noticed a clear correlation between serum 25(OH) vit D and TSH,\(^ {1}\), which agrees with the results of Shilpa, Mishra\(^ {22}\) that showed a clear reduction in the level of vitamin D in hypothyroid patients (≤ 20 ng/ml). Additionally, the literature showed that treatment of the vitamin D deficiency in thyroid patients has enhanced thyroid functions\(^ {23}\). The literature also indicated an inverse relationship between the levels of vitamin D and TSH\(^ {24,25}\).

Conclusion

The results showed that hypothyroidism, represented by the high level of TSH, was associated with high BMI and low level of 25(OH) vit D, ferritin, TSH, T3 and T4, and age does not play a significant role.

Impact of Nutritional Milk for Lactating Mothers upon Efficiency of Breast Feeding for Iraqi Mothers at Maternity Hospital in Baghdad City

Hawraa Hussein Ghafe1, Bahaulddin Hassan Abbood2
1Lecturer at, Maternal and Neonate Nursing Department, College of Nursing, University of Baghdad, 2Master Student of Pathology, College of Medicine, University of Kufa

Abstract

Objective: This study conducted to find out: The impact of nutritional milk for lactating mothers upon efficiency of breast feeding 2. The impact of nutritional milk for lactating mothers upon the number of breastfeeding 3. The impact of nutritional milk for lactating mothers upon the babies’ weight. This study conducted at AL-Elwaya Maternity Hospital in Baghdad City. The study started in January 2019 to March 2019. The study sample included (100) lactating mothers that feed their newborns by breast feeding only despite of the method of delivery (normal vaginal delivery & caesarian section) this sample divided in two groups the first one is the (study group) consist of (50) lactating mothers that consumption nutritional milk for three weeks and the other (control group) consist of (50) lactating mothers that not consumption nutritional milk and then comparison between the two groups to detecting the impact of nutritional milk on the efficiency of breast feeding. Results showed that the nutritional milk have impact upon the efficiency of breast feeding for the lactating mothers who were consumption the nutritional milk for at least three weeks and have impact upon their babies’ weight and growth.

Keywords: Nutritional milk, Lactating mothers, Breast feeding, Maternity hospital.

Introduction

Most studies regarding the lactation have focused on the quality and quantity of breastfeeding or on the benefits of the breast milk on infants. Far fewer studies have targeted the effects of lactation on short- or long-term maternal health. The breastfed infant doubles its weight in the first 4 to 6 months after birth and has additional energy demands beyond the gains in energy stores associated with growth. The metabolic adjustments that redirect nutrient use from maternal needs to milk synthesis and secretion involve nearly every maternal organ system1. Breast feeding results in a number of physiological adaptations which exert direct effects on maternal health. Nutrient needs during lactation depend primarily on the amount and composition of milk produced and on the mother’s initial nutrient needs and nutritional status. Among women exclusively breastfeeding their infants, the energy demands of lactation exceed pre-pregnancy demands by approximately 640 kcal/day during the first 6 months postpartum compared with 300 kcal/day during the last two trimesters of pregnancy (NRC, 1989). In contrast, the demand for some nutrients, such as iron, is considerably less during lactation than during pregnancy2. Breast milk is the best food for newborns and infants. The nutritional stores of a lactating woman may be more or less depleted as a result of the pregnancy and the loss of blood during childbirth. Lactation raises nutrient needs, mainly because of the loss of nutrients, first through colostrum and then through breast milk. Breast milk volume varies widely. The nutrients present in this milk come from the diet of the mother or from her nutrient reserves. The conversion of nutrients in food to nutrients in breast milk is not complete. To have good nutritional status the breastfeeding woman has to increase nutrient intake. Human breast milk has a fairly constant composition, and is only selectively affected by the diet of the mother. The fat content of breast milk varies somewhat. The carbohydrate, protein, fat, calcium and iron contents do not change much, even if the mother is short of these in her diet3.
Methodology

Experimental design was carried out throughout the present study with the application of a pre-test and post-test for the study group. The study was conducted at AL-Alwaya Maternity Hospital which is located at the center of Baghdad city, in Al-Rasafa sector. Non-probability (purposive sample), the study sample consists of (50) lactating mothers who were selected from Hospital, the study group was consumption nutritional milk for at least three weeks, nutritional milky that used in this study was (naktalia mama) is drink specifically formulated to meet the needs of mothers wishing to get pregnant, and those who are already pregnant or breastfeeding that supported with vitamins and essential minerals such as (calcium carbonate, potassium phosphate, magnesium carbonate, ferrous lactate, zinc sulphate, manges sulphate, cupper sulphate, sodium selenite, potassium iodide, Fer/iron) Fish oil, soya lecithin, antioxidant, fructose, oligofructose vitamins (C, E, PP, D3, B8, B5, A, B6, K1, B9, B1) and the control group consist of (50) lactating mothers who were do not consumption the nutritional milk; the criteria of this sample was lactating mothers in reproductive age, with different educational levels, who were feeding their babies with breastfeeding only. Data for such assessment was collected from the maternity hospital through the presence of the researcher in maternity hospital and her contact with lactating mother during one month period from 12 January 2019 through 12 March 2019. The criteria of this sample were Lactating mothers, Feeding their baby with breast feeding only and they delivered with normal vaginal delivery or C/S. The exclusion criteria Mothers who were feeding their baby by mixed or bottle feeding and Lactating mothers who were not persisting in consumption the nutritional milk for at least 3 weeks.

f: Frequency, %: Percentage

The highest percentage among study group is present a mothers with age group of 30-39 years old (36%), while 60% among the control group are mothers with age group of 20-29 years old. Regarding occupation, most of mothers in both group; study and control are housewife (98% and 94%); and also fathers are free job in both group (study=74% and control= 60%). The socio-economic status indicates a moderate among the subjects...
in the study group (68%) and in the control group (64%). 82% of mothers in both groups; the study and control are living in urban areas. Previous studies have found that factors such as socioeconomic and employment status, maternal and child characteristics, maternal/family intention and health care management contributed to breastfeeding initiation and/or duration. Among those factors, the effect of maternal age on breastfeeding practice is one of the most interesting research targets. This is because in the past 20 years, increasing maternal age at first childbirth in most developed countries has been observed (4,5,6). The present findings that both older maternal age of ≥ 35 and primipara were negative factors of success of EBF initiation (7,8). The findings reveal that half of mothers in the study group are got 2-4 pregnancy (50%), the mothers in the control group are having pregnancy 2-4 and more then 5 (34%). 56% of mothers in the study group and 44% in the control group are associated with 2-4 gravida. Regarding number of abortion, the highest percentages are showing no previous abortion (study=60% and control=82%), but 38% in the study group and 18% in the control group showing they have 1-4 abortion. More than half of mothers are confirmed they have cesarean section as type of delivery (study=62% and control= 60%). Most of mothers in both groups; the study and control showing that their gestational age were 27-40 weeks (100%). In previous study, 20–30% of mothers who did not initiate EBF at the time of discharge eventually turned out to have successful initiation at one month. Dewey et al. (2003) indicated that lactation difficulties during the first week postpartum are not uncommon, even among women who are highly motivated to breastfeed exclusively and receive good lactation guidance; and that early lactation success is strongly influenced by parity, but may also be affected by potentially modifiable factors such as labor medications; therefore, all breastfeeding mother-infant pairs should be evaluated at 72 to 96 hours’ postpartum (9,10). 84% of mothers in the study group and 72% in the control group are not taking a herbal supplements for increasing their milk and the remaining were used. Most of mothers in both groups have negative history of allergy toward foods (study= 96% and control= 90%). 54% of mothers in the study group are eating less than three meals per day while more than half of mothers in the control group are eating more than three meals per day (60%). Those mothers in the study group reveal that they not take vitamins supplements (78%) and only 22% taking vitamins; the mothers in the control group taking those vitamins (52%). More than two third of mothers in the study group and control group are showing a difficulties in breast feeding (72% and 74%). Half of sample in both groups showing that they have normal nipple (50%); and the remaining show a protruded nipple (30% and 28%). Maternal diabetes was a strong predictor of diabetes in children. Maternal preeclampsia was associated with increased risk for early and later onset of diabetes. 11 The World Health Organization recommends early initiation of breastfeeding (within the first hour after birth) and exclusive breastfeeding (no water, other fluids or foods) for 6 months 12. Breastfeeding reduces their risk of type 2 diabetes. This could be due to improving glucose hormones 13. Reduces their risk of developing hypertension and cardiovascular diseases (14,15). Helps them to lose weight, especially while their infants are being exclusively breastfed. 16.

Conclusion

The study showed that the nutritional milk have impact upon efficiency of breastfeeding. The study showed that nutritional milk have impact upon the number of breastfeeding. The study showed that the babies’ weight of lactating mothers who were consumption nutritional milk have increasing in their weight.

Risk of Osteoporosis in Patients with Crohn’s Disease Not Respond to Infliximab Therapy Undergoing Surgical Intervention

Fatima A. Mohammadⁱ, Fatin Fadhel ALkazzaz⁰, Sura A. Abdusattar⁴

¹Department of Chemistry, College of Science, Mosul University, Iraq, ²Department of Chemistry, College of Science, AL Mustasiyriah University, Iraq, ³Chemistry and Biochemistry Department, College of Medicine, AL Mustasiyriah University, Iraq

Abstract

Osteoporosis is one of the most common complications of Crohn’s disease (CD). Proper history with blood samples were collected from (30) healthy control group, (30) Crohn’s disease patients have been respond to biological therapy (infliximab IFX) (response group) and (30) CD patients with (non-response group) to biological therapy undergoing surgical intervention for the estimation of some biochemical parameters. This study demonstrate a significant decrease in FGF-23 (fibroblast growth factor 23) and vitamin D Levels between (non-response group) and control group (p< 0.01). Similary, parathyroid hormone (PTH) Levels were increased significantly (p< 0.01) in (non-response) group. Moreover the calcium (Ca) and phosphours (P) decreased significantly (p< 0.01) in same group. While in CD patients that have been treated with infliximab only vitamin D and FGF 23 decreased significantly (p< 0.01) compared with control group. Levels of Serum FGF23 are considerably lower in CD patients, It is independent pattern was not affected by type of treatment (medical or surgical). Hypovitaminosis common finding in CD patient’s. Although CD is not disease of vit D deficiency but it clearly is a disease whose pathogenesis seems closely related to vit D Level.

Keyword: Osteoporosis, Crohn’s disease, Infliximab, Vitamin D

Introduction

Inflammatory bowel disease (IBD) includes two lasting intestinal disorders, which are: CD and Ulcerative colitis (UC) ¹. CD is a chronic inflammatory disorder that could involve any part of alimentary tract from mouth to anus ². These disorders were first described by Dr. Burril Crohn’s and his team in 1932 ³. Although its aetiopathogenesis is still not clear, it has been well recognized that CD is one of the complicated disorders which result from interaction of environmental, microbial, and genetic factors.⁴ Patient that have Crohn’s disease are under increased risks of the metabolic bone disease, which includes osteoporosis and osteopenia ⁵. They seem to be one of the most important complication since osteoporosis has been reported in (30%-50%) of patient with CD which may be a silent disease until a fracture occurs ⁶. BMD (Bone mineral density) is less in patients that have CD ⁷. The mechanism which is underlying the lower BMD hasn’t been clearly understood ⁸. None-the-less, various risk factor including increasing age ⁹ disturbances of calcium homeostasis, malabsorption and vitamin D, smoking and the actual inflammatory process by releasing cytokines that interact with bone metabolism ¹⁰. Malabsorption and the deficiency of vitamin D which results from the involvement of the small intestinal of disease and or surgical resections are usually found in patients that have CD ¹¹. Which is why, the deficiency of vitamin D may result in hypocalcemia in patients that have Crohn’s disease with short bowel syndrome, also hypocalcemia might be resulting from deficient parathyroid hormone which stimulates bone resorption resulting in bone loss ¹². On the other hand, regulation of the phosphate in bone homeostasis hasn’t been entirely explained, regulation of the phosphate includes interaction of a complicated kidney–intestine–bone parathyroid gland hormonal axis that remains insufficiently comprehended. A lately discovered phosphatonia, FGF23 disclosed now. Pathways in mineral metabolism pathophysiology ¹³. FGF23 is a new phosphaturic hormone which is
mainly generated by osteoblasts/osteocytes in bones, and with lower levels in other types of tissue, they target the kidneys for regulating vitamin D metabolism and phosphate homeostasis. Infliximab anti-body directed against TNF (tumor necrosis factor alpha), has been the first TNF antagonist which has been approved for patient that have CD. It was an important advance in the treatment of the disease due to their proven efficacy in inducing and maintaining clinical symptoms remission. 74% of all CD patients will require surgery. Surgical management typically with intestinal resection remains considered as a significant modality of treatment because of disease symptoms nature and complication namely strictures and perforation obstruction, starts so hard to be sufficiently controlled.

**Aim of study**: Aim of this study are characterize serum PTH, Ca, P, vit D , and FGF 23 levels at Crohn’s disease patient’s compared with controls , and to identify correlates of changes in these parameters levels following therapy.

**Material and Methods:**

**Study subject**

This research has been approved by the Ethics committee, department of chemistry, college of science, Mustansiriyyah University, Bagdad, Iraq. and the Iraqi Ministry of Health approved this work as well. The blood samples were taken after informed consent of participant were recruited from Gastroenterology and Hepatology teaching hospital at Bagdad Medical city, while the healthy group were volunteers. All the patients were diagnosed by senior doctors specialist in gastroenterology field, (60) sixty unrelated Iraqi Crohn’s disease patient’s divided in to two groups according to response to biological therapy (infliximab) the first group (30) patients was respond to infliximab according to classical regimen (loading dose 5mg/kg at week 0,2,and 6 followed by repeated infusion of 5mg/kg every 8 weeks) and (30) patients not respond to infliximab undergoing surgical intervention as well as (30) unrelated healthy person termed as control group without any systemic disease. All the patients and control aged between 18 and 64 years. As well as the two groups of patient’s and control were measured by electronic balance and measuring body mass index (BMI). Five milliliters of venous blood was obtained from patients and control group by 5 ml disposable syringe (without tourniquet) drained into get plain tubes and left in room temperature (25°C) for 15 minutes, Then it was centrifuged at 2000 xg for 10 minutes in order to collect sera. Sera aliquots were placed in eppendorf tubes and stored at -40C° until used.

**Biochemical analysis**

The human FGF-23- was measured in the sera for the all patient and control group using the double sandwich (ELISA) kit according to manufactures instruction (Cat No.MBS 263043, My bio source / USA). PTH was measured using the protocol of ELISA kit (Cat No.MBS2505074,My bio source /USA). And vitamin D was measured using the competitive (ELISA) kit principle (Cat No.MBS 2503525 , My bio source / USA). While Calcium and phosphorus determined by automatically performed by the Dimension ® Clinical chemistry system (SIEMENS, Germany).

**Statistical analysis**

The statistical analysis system SAS program has been utilized to compare between control and two CD patients groups ( response and non-response to biological therapy) in study parameters. (Analysis of variation-ANOVA) was used to compare between means (P value of 0.05 and 0.01 has been considered to be statistically significant).

**Result and Discussion**

Mean ± SD value of age and BMI were recorded from all subscribers as shown in table 1. Results of this study shown in table 2 there were a non-significant differences in mean age between all age of the studied group at (p<0.05). Age at the onset of CD was in the range between early childhood to beyond 70 years of age. Although the peak incidence of diseases between ages 20 to 39, about 25% of patients with Crohn’s is present before 20 years of age—among children with Crohn’s disease, 4% present before 5 years of age. 21. a second peak is recognized between ages 50-70. Age definitions of early and elderly onset of Crohn’s in literature are different and are usually dependent on local clinical practice (such as age of referring from pediatric to adult Crohn’s disease care), and that makes comparisons between population complicated. In addition to that, heterogeneity in the approaches of data collection and case ascertainment (such as, diagnostic criteria, access to diagnostic procedures) – and as a result, differences in the capability of capturing each case of Crohn’s disease in the population- might result in bias in any of those
comparisons also shown that CD patients have a significant BMI decrease (P<0.01) from (26.743±2.699) Kg/m² to (22.816±2.025) Kg/m² in (non-response group) patients need surgical intervention compared with control healthy group this could be represented with malabsorption, decreased dietary intake, metabolic disturbances like increased expenditure of energy, increased substrate oxidation rates, and decreased respiratory quotient, could as well be one of the reasons that cause patient’s protein, glucose, and fat loss. To some extent, medical therapy including corticosteroid, mesalamine, TNF- alpha antagonists, and azathioprine, could enhance the BMI of CD patients.

The laboratory examination data in the three groups are shown in table( 2),also table (3) illustrated the statistics comparison of different biochemical analysis among the studied groups. Serum parathyroid hormone, calcium and phosphate were not significantly charged in patient response to infliximab group compared with healthy control group. The FGF23 and vitamin D significantly decreased (P>0.01) between the same groups. A research in the animal model TNF- mediated bone erosion have showed that treating mice with anti-TNF factor combined with osteoprotegerin or PTH results in repairing local bone erosions. There for the treatment with infliximab or adalimumab have an advantageous impact on bone metabolism in patients that have CD.

Abreu, etal. have reported that patients that have Crohn’s disease have appropriately increased Levels of active hormonal form of vitamin D 1,25 (OH)₂D. Those Level are inversely correlated to BMD probably due to the fact that 1,25 (OH)₂D mobilizes the stores of skeletal calcium, the mechanism for increasing 1,25(OH)₂ D is via increased 1-α hydroxylase expression by activated lamina propria macrophage, that some other way in which IFX has a positive impact on bone metabolism is via inhibiting macrophage activation in gut and decreased expression of 1,α-hydroxylase on the other hand vitamin D is essential for absorbing calcium in small bowel over time, vitamin D deficient generates hypocalcemia and consequently a secondary increase in the PTH Level also the regulation of calcium and phosphate metabolism, as physiological correlation between the levels of its main regulators PTH and vitamin D.

While there is significantly increase (p>0.01) in PTH levels and significantly decrease (p>0.01) in Levels of Ca, P and vitamin D in(non-response group) patients that surgical treated compared to control group in this study parathyroid hormone is released from parathyroid cells as a response to low extra cellular concentration of free calcium. Secondary hyperparathyroidism has been detected in more than 1/3 of patients that have Crohn’s disease who have operated on with small bowel resection, increased levels of PTH were related to increased bone turnover and decreased BMD preferentially in cortical bone.

**Conclusion**

The conclusions that have been drawn in this paper have stated the fact that Levels of serum FGF23 are considerably lower in patients that have Crohn’s disease, it is an independent pattern not affected by type of treatment (medical or surgical). Also hypovitaminosis D was common finding in CD patients Although Crohn’s is not a condition of the deficiency of vitamin D but it
is clearly a disease whose pathogenesis seems closely related to the Level of vitamin D. in addition to that, patients that have CD subjected to surgical intervention are under a risk to develop low Bone mineral density and secondary hyperparathyroidism.

Abstract

The success of endodontic therapy is relied on radicular system cleaning, shaping, elimination of microorganisms, and three dimensional filling of the radicular complex. This study was conducted to develop and assess new root canal sealer incorporating nano-sized bioactive glass into Gutta Flow II. The following concentration was used depend on a pilot study included adding (3%) of 45S5 bioactive glass into the Gutta Flow II. These materials were tested through assessment bioactivity. bioactivity test was undertaken after immersion of the tested samples into PBS for three days, seven days, fourteen days, and twenty eight days using FTIR too. study was found that it’s peaks was appear at level 800-1000 cm⁻¹. The results showed that GFII group revealed no peak at the 910 cm⁻¹, while, while BG3% revealed 179.85 pixel height, in conclusion the newly developed sealers exhibited apparent apatite and apatite precursor forming ability significantly with BG 3% while GuttaFlow II sealer showed no apatite layer forming ability.

Key words: bioactivity, chemical analysis, 45S5 bioactive glass

Introduction

Although gutta-percha based silicon sealers like Gutta Flow II is characterized by many advantages like simplicity of handling, setting expansion that may improve its sealing ability, in addition to certain extent of anti-microbial activity due to the effect of silver particles which were added as fillers 1 but generally gutta percha still has shortcomings, involving the inability to re-enforce the root canal treated tooth 2. Furthermore, the ability of gutta-percha to provide hermetic seal is still controversial as it does not capable to bond with root dentine 3. Specifically, Gutta Flow II still has considerable cytotoxicity, insufficient antibacterial activity, no bioactivity 4. Calcium silicate–based materials are classified as bioactive substances due to their ability to stimulate hard tissue remineralization and regeneration in both the dental pulp and bone 5. Silicone-based endodontic sealers showed relatively good biological features 6. The silicone-based sealer GuttaFlow II (Coltene Whaledent, GmBH + Co KG) constitutes a blend of polydimethylsiloxane and gutta-percha powder with nanometer-sized silver particles incorporated as a preservative. GuttaFlow II, a development of its predecessor GuttaFlow, is also a cold thixotropic flowable system. Both GuttaFlow and GuttaFlow2 are silicone-based root canal sealants that have variable forms of the silver particles used 7. A novel formula of polydimethylsiloxane with gutta-percha powder joined with calcium silicate particles was introduced in late 2015 and named GuttaFlow Bioseal (Coltene/Whaledent AG, Altstatten, Switzerland). In the present study nano-sized bioactive fillers of 3% were incorporated and distributed mechanically into gutta flow II sealer in order to develop bioactivity. Nano-sized 45S5 bioactive glass were chosen to be used in this study to lower the percentage of the incorporated powder in order to keep the physical characteristics of the original sealer regarding solubility and flow ability. In addition, to keep the newly developed material clinically applicable.

Materials and Method

Sample grouping:

Group 1 (control group): ten samples were prepared from Gutta flow II sealer.

Group 2: ten samples were prepared from Gutta flow II incorporated with nano sized 45S5 bioactive glass particles of optimum percent by weight according
to the optimization results of the pilot study.

**Preparation of bioactive glass containing Gutta Flow II 3%:**

The sample was prepared by mixing 0.3 mg of 45S5 bioactive glass with 7.7 mg of gutta flow II base. The pistons of both base and catalyst were separated by diamond disc that mounted on engine driven straight hand piece at their connected base. The gutta flow II was extruded on sterile screw cup, then 0.3mg was removed from the base to be replaced by 0.3 mg of bioactive glass. The mixing procedure was accomplished by adding the 0.3 bioactive glass carefully, and the mixture was mixed well by using disposable plastic spatula which was installed into INGCO cordless drill till complete homogenization of the mixture. The mixing time was 2 minutes and the speed was 750 R.P.M. Then the newly mixed material was reloaded in the base tube of the syringe carefully by using plastic spatula. The base piston was re-inserted into the base tube and pushed down to the level of the catalyst tube and rejoined at their base by using adhesive liquid.

**Assessment of apatite forming ability (bioactivity) using Fourier Transform**

**Infrared Spectroscopy**

Disk samples were impregnated into phosphate buffered saline solution (PBS) to mimic tissue fluid immersion and examined at 3, 7, 14, 28 days post immersion. At each period, samples were displaced from storage solution. The pH of the saline solution was usually checked by pH meter to keep its pH at 7.2. 0.1 mg of each disc was taken from its surface and tested by FTIR according to the manufacturers instructions to detect the development of carbonated hydroxyapatite layer at each sample surface.

**Results and Discussion**

**Chemical analysis using FTIR**

According to the chemical structure of the gutta percha figure (5) and its other included materials gutta flow II, the FTIR spectra range was 400 – 4000 cm⁻¹. The spectra of 50 Nano meter sized particles of 45S5 was 910 cm⁻¹, in which the primary peaks in correspond to the Si-O vibrational modes of the bonds in the glass network, the stretching vibration at 1090 cm⁻¹ and the rocking vibration at 450 cm⁻¹. The broad peaks in the 750-950 cm⁻¹ region correspond to Si-O-Si vibrational modes associated with the Ca⁺² and Na⁺ ions in the glass network as shown in the figures (2). The chemical groups in the FTIR spectrum of HA are PO₄³⁻, OH¹⁻, CO₃²⁻, as well as HPO₄⁻² that are characteristic of non- stoichiometric HA. PO₄³⁻ group forms intensive IR absorption bands at 1000 –1100 cm⁻¹. CO₃²⁻ intensive peaks between 1460 and 1530 cm⁻¹ which represent HA as shown in the figure (2).

![Fig (1) shows FTIR chart of GF II which appears no peak at 910 cm⁻¹ level](image1)

![Fig (2) shows FTIR chart BG3% which appears a peak of 63.95 pixel at 910 cm⁻¹ level](image2)

**Bioactivity test:**

According to the structure of the carbonated layer figure (4) the FTIR study was found that it’s peaks was appear at level 800-1000 cm⁻¹

According to the results of the present study, GFII showed no development of carbonated hydroxyapatite layer

The peak of carbonated material start to appear in the BG 3% group at the third day with obvious increment of it’s length figures (3).

Apparently BG 3% group reach to the maximum concentration of the carbonated HA layer which was indicated by increase the length of the peak at day 28,
Fig (3) shows FTIR chart of BG3% after 14 days which appears a peak of carbonated hydroxyapatite at 900 cm$^{-1}$ level.

Fig (4) shows FTIR chart of BG3% after 28 days which appears a peak of carbonated hydroxyapatite at 900 cm$^{-1}$ level.

Discussion

Throughout the obturation step of endodontic remedy, periradicular tissues may contact the root canal sealents via extrusion through the apical foramen. When sealers are in intimate contact with the periapical tissues for extended periods of time, their breakdown toxic products may hamper the periapical healing process by inhibiting the proliferative capability of the periradicular cell population. Therefore, apart from good physical and chemical characteristics, endodontic sealers should be biologically compatible. Several methods have been recommended for filling of root canals. Use of gutta-percha, a semi-solid root filling material, in combination with sealer is the most commonly performed method of root filling. Low dose of bio-active material is needed because the nano-particles allowed more surface area that may provide better activity, this may prevent adverse effect on the sealer flow characteristics. Incorporation of nano-

...
sized bioactive materials enhance bioactivity of already available endodontic sealer this is agreed with 13.

Particulate size has been proved to have effect on biomineralization; nanoparticles showed better performance than microparticles in induction of biomineralization 14. Paying attention to this fact, there might be still potential for enhancement of the performance of bioactive features.

there is no specific information on the osteogenic and cementogenic potential of calcium silicate-based sealers on mesenchymal progenitor cells through out the repair of periodontal ligament and relative surrounding tissue, and the molecular mechanisms underlying the osteogenesis and cementogenesis induced by various dental substances are unclear 15. This report is disagree with the present study. While

16 stated that calcium silicate-based sealers are new root canal sealers that have demonstrated apatite forming ability. This studies are agree with the present study.

Biomineralization and formation of hydroxyapatite (HA) begin with release of ions, especially calcium ions from the inorganic calcium-silicate particles and continue with formation of Si-OH groups at the material’s surface. The Si-OH groups on the surface function as ideal site for nucleation of HA. HA, i.e. Ca10(PO4)6(OH)2 precipitates first as an amorphous layer with the stoichiometric ratio Ca/P 1.67 and later crystallized into carbonated hydroxyapatite (CHA). HA precipitation is favored by an increase in the pH of the surrounding solution. The increase of the pH of the interfacial solution to around 7.9 and above around the dissolving BG has been shown. The combination of adequate physical charateristics containing silicone-based sealer and bio-active bioactive glass-ceramic (BG) particles is a prospective option to conventional root canal sealers. Silicone-based endodontic sealers also showed advantages against mineral trioxide aggregate (MTA) cements in manipulation and clinical application. This study explores in detail the potential of GB, a new endodontic sealer containing BG particles to induce biomineralization. The aim was to demonstrate apatite forming ability, the influence of the BGC on the surface structure and examine ion dissolution patterns of the endodontic sealer GB more widely that is currently available in the scientific literature. Most of the data in similar studies are now limited to concern only calcium ion release. In addition, change of pH in the surrounding media. This is agreed with 17.

BGs gradually dissolve when exposed to aqueous media. The degree of dissolution depends on the ratio of the surface area of the glass in contact with a certain volume of solution. However, the Ca/P ratio levelled off rather slow. This is agree with 18. The rather weak intensities of the HA reflections are indicative of a thin HA layer, which also results in strong interfering signals from the crystalline filler materials inside the underlying matrix 17. Biomineralization requires excess of mineral forming ions to be present in the solution and in this case, the ions originated from the dissolution of BG particles and from the SBF. In this study, the carbonated HA was measured by using FTIR analysis. Although Ca ion release is strongly related to bioactivity most of the studies in current scientific literature ignores the release of other ions which also have biological interest. Different BG compositions used as bioactive fillers in composites are known to have different dissolution behaviours. The newly developed materials showed low number of BG particles in the PDMS matrix, but despite of that, biomineralization, and more importantly increase of pH to the bacteriostatic level was seen. Therefore, it can be assumed that the sealer may have beneficial effects also in vivo conditions where ratio of surface area/volume favors the emerging local alkalinity. This is agreed with 17. FTIR has been intensively used in the study of the surface reaction of bioactive materials after immersion in simulated body fluid (SBF) solution 19 and after implantation 20. Both diffuse reflectance and specular reflectance can be used for monitoring the formation of the HCA layer at the surface of bioactive materials. The HCA layer is characterized by the P=O bending vibration peaks at 560 and 604 cm⁻¹ and the P=O asymmetric stretching vibration bands between 1000 and 1150 cm⁻¹ 21. The peaks corresponding to the bending vibration are most used to discriminate between HCA and bioactive material since the P=O stretching band is superimposed on the Si=O stretching band corresponding to bioactive glasses while the absorption band corresponding to Si-O bending is between 400 and 500 cm⁻¹ 21, at lower frequencies compared with P=O bending in HCA. The magnitude of HCA peaks at 560 and 605 cm⁻¹ increases relative to the foam Si-O peaks at 450 cm⁻¹ as the immersion time is longer. This indicates that the HCA layer is thicker for the samples soaked in simulated body fluid (SBF) solution for longer times. However, the signal-to-noise ratio of the reflection spectra is poor due to the porous surface,
600 interferograms being needed to obtain the spectra. Therefore, the easiest application of FTIR is the study of bioactive powders with a KBr diffuse reflectance device. In this case, the signal is much stronger and the preparation time is less. Carbonate peak at 875 cm$^{-1}$ developed at 0.005 g ml$^{-1}$ and increased in intensity with prolonging the time of immersion into SBF. In particular, the band around 500 cm$^{-1}$ can be related to the longitudinal optical (LO) Si–O–Si vibration, indicating a strong distortion of the SiO4 tetrahedra at high content of glass network modifiers (i.e. Ca$^{2+}$ and/or Na$^+$) 22. The next band at 600 cm$^{-1}$ can be attributed to either the P–O bending vibrations of PO4$^{3-}$ groups present in the amorphous phosphate, or pseudolattice vibrations of the PO4 tetrahedra with at least one bridging oxygen 23.

The bands in the 732–805 cm$^{-1}$ range were attributed in the literature to the Si–O–Si bending mode. The band in the 1000–1050 cm$^{-1}$ range could be related to stretching vibrations of the Si–O–P 24. A higher intensity of the bands at around 930 and 854 cm$^{-1}$ for the 45S5 glass indicates an increased degree of depolymerization of the silicate network. The FTIR spectra of the bioactive glass confirm the beginning of crystallization, while the band at around 930 cm$^{-1}$ becomes more intense and sharper, indicating the crystallization of the major Na$_2$Ca$_3$Si$_3$O$_9$ phase (combeite). Additionally, a weak band at 696 cm$^{-1}$ can be ascribed not only to Si–O–Si stretching mode, but also to P–O bending. This is agreed with 26.

**Conclusion**

Abstract

Objective: this study designed to assess self-care of patients’ undergoing hemodialysis with end stage renal disease and to determine out association between self-care of patients with end stage renal disease and their socio-demographic characteristics. Descriptive cross-sectional design is adopted in the recent study to perform the early stated objects. Started the study from (October 1st, 2016 until May, 6th, 2017). A Non-Probability (Accidental Sample) of (61) ESRD patients, those who visit dialysis centers of Al-Sadder Medical City in Al-Najaf Al-Ashraf., are included in the study sample. Analyzed data by descriptive analysis contains (Frequencies & Percentages) and statistical figures (Pie Charts) and Pearson’s Correlation Coefficients. The outcome of the present study that the self-care activities are interdependent and there is a positive relationship between the patients’ self-care with their age, income and marital status. While there is a non-significant difference between self-care activities and their clinical data in all items except there number of admission to emergency is a high significant difference. The study concludes that most patients with ESRD need moderate assistance in performing in dietary, exercise and other activities.

Keywords: assessment, self-care, patient, End Stage Renal Disease (ESRD).

Introduction

End-stage renal disease (ESRD) is irreversible and a progressive chronic disease reasons a main health crisis worldwide. The occurrence of ESRD is rising by 7% every year ¹. It is a chronic, life-threatening condition has been emerged as a main public health problem around the world (², ³). ESRD is a growing public health problem, given the raising prevalence international. It is estimated that by 2020 the number of patients ESRD will increase by 60% when compared with the number of patients recorded in 2005. Data from 150 countries showed that over 3 million patients were treated for ESRD worldwide by the end of 2012 ⁴. Hemodialysis is the process used to removal fluid and waste products from the body when the kidneys are notable to doing. The object is to maintain the life and well-being of the patient until the renal function is repaired. Mechanism of the dialysis working on the principles of the diffusion of solutes and ultrafiltration of fluid transit a semi-permeable membrane. There are three types of dialysis i.e. hemodialysis (primary), peritoneal dialysis, hemofiltration, as well as there are two secondary types of dialysis which are hemodiafiltration, and the intestinal dialysis ⁵. Self-care defined as an active participation in own health care, it is about learning what to do to take care of on self and when to decide to ask for help; it is an achievement, and measures persons get to enhance their health and well-being, to prevent and reduce the likelihood of disease, and to restore health after injury or illness. According to Orem (1998) self-care theory is founded on the philosophy that “all patients wish to care for themselves” if the patients are allowed to perform their own self-care requisites to the best of their ability, it will recompense more rapidly and holistically. The theoretical frame-work of Orem’s self-care theory was taken as a base for carrying out the current study aiming at assessing self-care practices of patients’ on maintenance hemodialysis at one of teaching hospital ⁶.
Methodology

Design of the Study

Descriptive cross-sectional design is adopted in the current study to achieve the early stated objectives. The study started from October 1st, 2016 until May 6th, 2017. A Non-Probability (Accidental Sample) of (61) ESRD patients, those who visit dialysis centers of Al-Sadder Medical City in Al-Najaf Al-Ashraf, are included in the study sample.

An assessment tool is adopted and developed by the researcher to assess of self-care activities for patients’ with ESRD. The final study instrument consists of three parts:

- **Part 1: Demographic Data:**
  
  This part consists of (7) items, which involve, age, gender, level of education, monthly income, residence, marital status, occupation status.

- **Part 2: Clinical Data:**
  
  This part consists of (6) items: (number of admission to emergency, previous hospitalization/day, problems begin since: years, hemodialysis begin since: years, number hours hemodialysis sessions/week, heart disease, diabetes mellitus, hypertension and respiratory disease)

- **Part 3: Self Care:**
  
  This part of the questionnaire comprised of (4) domains: (dietary, exercise, psychological and general care)

Collected the data by applying of the developed questionnaire with aid of structured interview technique with the subjects as they were individually interviewed. The study subjects are interviewed in a similar way. The interview technique spends about 20-25 minutes for each subject.

Statistical Analysis

The data were analyzed by using statistical methods to evaluate the study result:

- **Descriptive Data Analysis:** This approach includes the following measurements: A- Frequencies and Percentages. B-Mean, Mean of scores (MS) C- through using Split Half.

- **Inferential data analysis:** include Pearson’s Correlation Coefficients to determine the reliability of questionnaire (Internal consistency).

Ethical consideration:

This is one of the most essential principles before collecting the data, to keep the patient’s morals and self-esteem. The researchers achieved this agreement from the ethical committee at the Faculty of Nursing / University of Kufa. The researchers promised to keep the patient’s information confidential, and use these data for this study only then he explained the purpose of this study to each participant without affecting the routine visiting and care. In addition to above the researcher told each participant that this is an involuntary work, and they can leave any time even the interview process is not completed.

NS: Non-Sig. at P>0.05, S: Sig. at P<0.05, HS: high significant at p-value less than 0.01.

The table reveals that there is a highly significant association among the patients (self-care activities) and their (age and emergency), at p-value < 0.01 and significant in relation with (income and marital status) at p-value <0.05. While there is a non-significant association with remaining demographic and clinical data.

This study is the effort to investigate Personal care for dialysis Patients in Najaf Governorate Iraq in general. That the majority of the study subjects (26.2%) are within the age group (more than 60 years). This finding comes along with 7. Whose results indicated that the thirty five percentage were age group of 60 and over years. Concerning to the study subjects gender, the results indicate, that the higher percent of the study sample are males. This result comes along with 8, 9. Concerning educational levels, the higher percentage (24.6%) are able to read and write. This result is in agreement with other studies Al-Garni, (2006) and Anees, et al. (2011) in their studies found that the majority of the study subjects are able to read and write 10, 11. Most of the sample results indicate that (45.9%) of the study sample are insufficient monthly income. This come is consistent with another study of Mahmoud and AbdElaziz, (2015) and Halle, et al. (2015) reveals in their studies that most of the study sample hasn’t enough monthly income 12, 13. Regarding residency, the current study results show that most of the sample (59%) is live who at urban area. This result in agreement with Crews, et al. (2014) they indicated that the majority (98.4%) patients of ESRD is living in urban area. Concerning to marital status, majority of subjects (80.3%) are married 14. Table (2) shows that the majority of the study subjects (55.7%) are admitted to the emergency department for 1-5 days annually. While the number of hospitalization days, the study results indicates that the majority of the subjects (42.6%) are hospitalized for 1-5 days annually 19. In addition to that and in regarding to the period when the renal problems appear, the results show that the (80.3) are equal or less than (5 years). While for the hemodialysis duration, about (91.8%) from the study subjects were meeting dialysis for more than 5 hrs weekly. This finding agrees with the result 20. In addition to the problem, the higher percentage (85.2%) of study results had no heart disease then diabetes mellitus (62.3%) which represent the highest percentage of other included problem followed by hypertension (70.5%) and (86.9%) are no suffering respiratory disease. This result is supported by 21, 22. The study findings indicate that the overall assessments for patients’ self-care activities
are interdependent. It shows that the sample responses to the following self-care activities are interdependent which mean they need some assistance in performing these activities, while the sample self-care activities were independent in general care domain which means they do not need any assistance. These results agree with 6. According to the study results indicate that the high-significant relationship between the patients self-care activities and their (age and emergency), and significant in relation with (income and marital status) while there is a non-significant relationship with other demographic and clinical data. Present study is in agreement with (10, 23).

Conclusions

All the patients with ESRD are completely independent in General Care themselves in their daily self-care activities and Most patients with ESRD need moderate assistance in performing in dietary, exercise and psychological in their daily self-care activities.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Faculty of Nursing, University of Kufa and all experiments were carried out in accordance with approved guidelines.

Hypertension in Relation with Smoking in Azadi Teaching Hospital at Kirkuk City

Saad S. Mustafa¹, Taghlub H. Ryhan², Ali A. Ismail³

Abstract

Background: smoking and hypertension are two common health problems effecting body organs and increasing morbidity and mortality.

Aim of Study: determining the relationship between smoking and hypertension, the affect of the amount and duration of smoking on the severity of hypertension and complications of smoking among hypertensive patient.

Patient and Method: the study is cross sectional, in which 200 hypertensive patient were collected in Azadi Teaching Hospital in Kirkuk. There blood pressure was measured and the patients were asked about smoking habits, and if they have complication of hypertension.

Results: hypertension is more common among male, married, illiterate and primary educated, intermediate socioeconomic state, physically inactive and more in urban than rural area. Uncontrolled rate of hypertension is high in both smokers and non smokers and this rate increase with increase with increasing duration of smoking. Heart and cerebrovascular complications of hypertension is very high in smokers compared with non smokers. P-value less than 0.05 regard as significant relationship.

Conclusion: very low control rate of hypertension in both smokers and non smokers. We recommended public health education via mass media regarding the side effect of smoking combined with hypertension and it’s complications.

Keywords: Smoking, Hypertension, Blood pressure, Tobacco

Introduction

Elevated blood pressure and tobacco smoking are, respectively, the first and second leading causes of preventable mortality worldwide(1). Hence, from both a population perspective and a patient perspective, the joint occurrence of tobacco smoking and elevated blood pressure has enormous health consequences. Worldwide, the absolute number of tobacco smokers has increased because of population growth, despite a decrease in the age-adjusted prevalence of smoking(2). In the United States, the estimated number of tobacco smokers has dropped, as a result of tobacco-control efforts, from 45.1 million in 2005 to 36.5 million smokers in 2017 (3) . However, while use of tobacco products has decreased, use of electronic cigarettes (e-cigarettes) has increased substantially in the United States, along with concerns about their potential health risks(4). Tobacco smoking and e-cigarette use may raise blood pressure and accelerate atherothrombotic processes though a variety of potential mechanisms, including deleterious effects on endothelial function, inflammation, lipids, and thrombosis(5) . The effects of smoking on blood pressure and hypertension are discussed in this topic. Hypertension control and smoking cessation to prevent cardiovascular disease and the approach to smoking cessation are discussed elsewhere.

The effects of tobacco smoking on blood pressure are complex, with evidence that tobacco smoking increases blood pressure acutely and increases the risk of renovascular, malignant, and masked hypertension. Passive (or secondhand) smoke exposure also appears to raise blood pressure(6).
The aims of the study:

Clarify the relationship between smoking and Hypertension.

Identify the relationship between the amount and duration of smoking and the severity (Stage) of hypertension in comparing with non-smokers.

Identify the cardiovascular complications of smoking in hypertension patients.

Patients and methods:

The design of the study: The design of the study was cross-sectional study. The place of study was the center of Azadi Teaching Hospital in Kirkuk city.

The duration of the study: The duration of the study was extended from March 2018 till September 2018.

Sample/population: Patients were visiting Azadi Teaching for diagnosis, treatment and follow-up purposes. The sample size was 200, all patients were hypertensive with two criteria of diagnosis: First one any patient with blood pressure more than 140/90 mm Hg in two different occasions (each 10 minutes apart); The second criterion was any patient on antihypertensive drug even with normal blood pressure. Information was also taken from patients about smoking habits, to determine the relationship between smoking and severity (stage) of hypertension and the effect of smoking on hypertension complication like cardiovascular and cerebrovascular complications.

The systolic and diastolic blood pressure was measured by a random zero mercury type sphygmomanometer on both arms (each five minutes apart). The mean value of the two readings was calculated. The blood pressure measuring was after asking patients to rest for 30 minutes, and if the patient was a smoker, to stop smoking for 30 minutes before measuring blood pressure.

The questionnaire: The questionnaire was designed to contain the following major questions that meet with the aims of the study:

Sociodemographic questions: -

Sociodemographic questions, which contains the name of the patients, age, sex, marital status, physical activity, residence, educational level, and economic state.

Questions about history of medical diseases:- Questions about history of medical diseases to determine the secondary causes of hypertension, and to exclude the other risk factors for the major complications of hypertension. These questions include asking about diabetes mellitus, ischemic heart disease, drug history, bronchial asthma, cerebrovascular accidents, chronic obstructive pulmonary disease, and surgical history.

Questions about the complications of hypertension:- Questions about the complications of hypertension including ischemic heart disease, left ventricular hypertrophy, atrial fibrillation protein urea, renal failure, stroke, and retinopathy.

Questions about smoking: - Questions about smoking, including the number of smoking per day and the duration of smoking.

The questionnaire also contained the measuring of vital signs: - The questionnaire also contained the measuring of vital signs including systolic and diastolic blood pressure, heart rate, and respiratory rate.

Statistical methods: - The sample was chosen by simple random sampling, the data was analyzed with the using statistical package for social sciences (SPSS Ver.23) program, standard methods were used to obtain summary statistics such as means, prevalence and other measures.

Ethical consideration: - All the studied individuals were asked whether they were interested in the study or not. All agreed voluntarily to participate.

Results

In this study we explored 200 hypertensive cases, the mean age was 55, the range of the age was from 32 – 88, the high portion of age from 43 – 64 year with a percentage of 64% male more than female, married more than single, the urban area more than rural, not educated more than educated as it is illustrated in (Table 1), with high proportion of intermediate economical state and low physical activity.

Smoking and hypertension: From total 200 cases, 143 was non-smoker in a percentage of 71.5%, and 57 was smokers in a percentage of 28.5%. The relationship between smokers habit and different stages of hypertension is showed in (Table 2).
The effect of duration of smoking on stages of hypertension: In this relationship we notice that the uncontrolled systolic BP group are in the duration of 10 – 19 years, while the larger number of controlled diastolic BP group in the duration of less than 10 years, and this adverse relationship between duration and hypertension can be clarify by the effect of another factors like physical inactivity or inappropriate pharmacological treatment as showed in (Table 3).

The effect of the amount of smoking on stages of hypertension: The uncontrolled hypertensive cases increase with the amount of smoking with larger number in those who smoke more than 20 cigarette per day as in (Table 4).

The effect of smoking on heart and cerebrovascular complications in hypertensive patients in relationship with non-smokers: In both (Table 5) and (Table 6), it is very clear that both heart and cerebrovascular complications increase in smoker patients. The percentage of heart complications in smokers to non-smokers are 47% to 0.6%, also the same percentage regarding the cerebrovascular complications.

Discussion

This study clarified several findings in the relationship between smoking and hypertension, the effect of smoking on the complications of hypertension, and the relationship of sociodemographic characteristic and hypertension. All these facts are important in controlling of hypertension and reducing the complications of hypertension in relationship with smoking.

In the study the main age group of patients are between 43 – 64 years with a percentage of 64%, the mean age is 55, the proportion of male is higher than female with a percentage of 53%, these results are similar to those in USA(7) that hypertension prevalence increase with age and more in male due to reduced vascular compliance that the prevalence of hypertension increases greatly with age, changing from 15.2% of 18 – 24 years – olds to 60.2% of 65 to 74 years.

The study showed that all 143 non-smoker were poorly controlled hypertension, i.e., all of them with blood pressure more than 140 / 90 mmHg, while within 57 smoker patients there are 15 cases with control blood pressure. This poor controlled blood pressure among non-smokers may related to other factors like physical inactivity, obesity, stress, inappropriate treatment.

The amount and duration of smoking affect adversely on the controlling of blood pressure, the study clarified that the uncontrolled rate for those patients smokes more than 20 cigarette / day is 76% for systolic and 91% for diastolic blood pressure, and similar uncontrolled rate for those smoking for more than 20 years with a percentage of about 88% for both systolic and diastolic blood pressure. This result is similar to that study in Vietnam(8) that smoking rises blood pressure acutely and the level return to baseline in about 15 minutes. And if a person smokes more than 30 cigarettes / day this can elevate the blood pressure continuously(8).

The study clarified that the cardiac complications of hypertension (including angina and myocardial infarction), and cerebrovascular complications (mainly transient ischemic attack and cerebral infarction) are very high in smokers with a percentage of 47% in comparing with very low percentage of 0.6% in non-smokers.

Conclusions

The major conclusions of the study are: Poor blood pressure control present in the majority of the patients with a percentage of 93% the uncontrolling blood pressure was mainly in males, married, illiterate and primary educated, low physical activity persons, intermediate socioeconomic state and more in urban than rural areas. High blood pressure was in both smokers and non-smokers. The heart and cerebrovascular complications of the hypertension increase in smokers compared with non-smokers.

Determination of Some Volatile Organic Compounds in the water produced at Al-Ahdab oilfield in the Governorate of Wasit, Iraq using Headspace SPE-GC-FID

Najla Mohson Hammod¹, Khalid Waleed S. Al-Janabi², Salam Abbas Hasan¹

¹AL-Mustansiriya University, College of Science, Chemistry department. ²The University of Baghdad, College of Education for Pure Sciences/ Ibn Al-Haitham (Correspondant author:

Abstract

The study was conducted over the period of Oct 2018 to Apr 2019 and is aimed for the detection and estimation of four hazardous Volatile Organic Compounds VOC (benzene, toluene, ethylbenzene, and xylene) so-called (BTEX) in samples collected from the produced water in the Al-Ahdab oil field in Iraq also to track their availability in the important natural water sources around the field. These compounds pose a risk to human health as well as environment. To avoid the laborious and tiresome conventional extraction methods, water samples were collected and concentrated using solid-phase extraction technique (SPE) which is a robust and cost-effective method of sample extraction with minimal exposure and handling of solvents and then to be analyzed via a gas chromatograph with a flame ionization detector (GC-FID). All of the collected samples were found contaminated with the BTEX compounds by unacceptable limits exceeding the recommended percentages. BTEX compounds were also found in the aquatic samples outside the field. Standard deviation (SD) was ranging from 0.01-0.73. The purpose of this study was to track and monitor the BTEX concentrations in the water produced by the Al-Ahdab oilfield and compare it with the BTEX levels in the water sources near the oilfield. Which is very important to control the impact of the discharged waters on the environment.

Keywords: BTEX, Al-Ahdab oil field, Al-Dalmaj Marsh, General Downstream Canal (GDC), Main Outfall Drain (MOD)

Introduction

Most oil fields often yield petroleum from underground reservoirs accompanied by what is called produced water, which is brine or water that necessitates disposal. Treatment of this water is of great importance to make it safe to be discharged to the environment (1,2). The produced water³(PW) usually contains different hazardous materials especially high concentrations of dissolved BTEX organic compounds, i.e. (benzene, toluene, ethylbenzene, and xylene)⁴. BTEX compounds are harmful to plants and toxic for other livings. Direct contact with benzene including inhalation may affect the central nervous system of the human body. However, prolonged exposure to it consequentialy leads to alteration in hemopoietin tissue appears as anemia and leukopenia⁵-⁷. Furthermore, high lipophilicity of BTEX made it possible to leak to the brain and causing brain damage, cardiac depression, dizziness, and nausea. While moderate exposure affects the function of kidney and liver⁵-⁷. When benzene and other BTEX compounds discharged to the environment they can leak to groundwater toxify it with concentrations much higher than those usually detected in surface water due to evaporation suppression⁶. There are different analytical procedures to measure the availability and concentration of BTEX in water⁸-¹⁰ and in air¹¹-¹³. However, a pretreatment is often necessary for water specimen to separate the components of interest from sample matrices. Solid Phase Extraction (SPE) become a common technique for the analysis of water samples, as it can retain volatile and semi-volatile compounds from the aqueous medium. It is environmentally benign as it requires minimal volumes of solvents and doesn’t require any special or complicated equipment¹⁴. The General Downstream Canal¹⁵ (GDC) [Appendix-2] or the Main Outfall Drain¹⁶ (MOD), known before the year of 2003 as Saddam River or the Third River. With more than a 565 Km long¹⁷, it is upstreaming from Baghdad.
north and downstream into the Shatt Al-Arab in Basrah. It was an old project since the 1950s then re-implemented into the 1990s. It is the main source of water for the marshes in southern Iraq\(^1\). The Al-Ahdab oilfield is located in the Al-Kut governorate and takes the required quantities of water from the MOD close to wetlands of Al-Dalmaj marsh\(^2\). As well as the Al-Ahdab oilfield discharges the produced water to the MOD. Any contaminations discharged to the MOD will reach and toxifying the natural environment and the aquatic life of the wetlands. Thus, it is very vital to regularly examine the water quality released to MOD\(^3,4\). The produced water samples were collected directly pipelines and reservoirs from the Al-Ahdab oil field then extracted using SPE cartridges for later analysis with GC-FID for the determination of BTEX toxic compounds those may go with the drainage to reach the water resources affecting the environment. The presence of such harmful compounds in both water produced from the oil fields and water sources close to the fields must be examined and supervised regularly to control it and to prevent any bad consequences on humans and biodiversity around the area.

**Experimental**

**Chemicals and materials:**

- Gas chromatograph, Shimadzu GC-2014 (Kyoto, Japan) equipped with a flame ionization detector FID.
- Certified standards of BTEX (benzene, toluene, ethylbenzene, and p-xylene) were purchased from ChemService at a concentration of 2000 μg/mL in methanol (West Chest, PA, USA).
- Intermediate solutions were prepared by diluting the standard mixture at concentrations of 1 and 20μg/ml in methanol, Hydrochloric Acid (HCl) 6N(BDH).
- Solid Phase Extraction Tubes (SPEC-R31930B), SiliaPrep SPE Cartridges CleanENVI (Silicycle inc, Canada).

**Locations of the collection of PW samples:**

PW water samples were collected in 1-liter bottles from three sites within the Al-Ahdab oilfield and five sites on the Main Drain river outside the field in Wasit province, Iraq. The sample bottles were sealed with Teflon then transported on the same day to the laboratory under refrigerated conditions.

In the laboratory, samples were preserved at a temperature of 4° C, and then were filtered through a 0.45μm Millipore filter and diluted for the analysis of BTEX. Figure (1) showing the location of the Ahdab oilfields in Iraq. The Al-Ahdab oilfields campus dimensions are about 10 Km long by 3 Km. The oilfield area is located among three Secondary Surface Drain canals (SSD) and a Main Surface Drain canal (MSD) those dispense directly into the MOD which flows toward the southern marshes. While table (1) specifies the spatial coordinates of the sample collection sites.

![Figure 1. The location of the Al-Ahdab oil fields mediated among SSD(s) and MSD those discharge directly into the MOD\(^2\).](image-url)

Sample injection parameters GC/FID conditions:

A cold trap (cry focus) cooled with a flow of liquid nitrogen (LN2), mounted prior to the separating column RTX-624,20m,0.18mm,1μm for the purpose of re-concentration of the VOCs.

The aqueous samples were extracted and concentrated (5ml) then placed into 20ml headspace vials. The injected volume was set to 1 ml (the split ratio was 5:1 and the linear velocity was set to 45 cm/sec. The GC oven temperature started from 50 °C for 1 min, gradient temperature, ramping 35 °C/min up to 280 °C. The water samples were purged with helium (99.995% purity) at a flow rate of 40 ml/min for 11 min at 26 °C. The volatiles was thermally desorbed and transferred to the GC which attached to a Flame Ionization Detector (FID) via a heated transfer line. After desorption, the trap was cleaned by heating it up to 200 °C for 8 min.

The analysis was adapted according to the EPA method 624 for the measurement of VOCs in water. The usage of an (Elite 624 capillary column 30m x 0.25mm, 1.40μm) as a separating phase with such narrow bore column enables the reduction of the analysis time (fast GC) nonetheless maintaining the chromatographic resolution successfully.

The vaporized samples were injected from the headspace to the column quite slowly as per the normally small split ratio (5:1) implemented in favor of sensitivity. However, the application of fast GC approach in combination with the slow headspace sampling has compensated the lateness in analysis duration.

Results and Discussion

One liter of each PW aqueous sample was extracted and retained on SPE cartridges then retrieved by desorption from the sorbent bed of the SPE cartridge by 1 ml of dichloromethane. Which increased the limit of detection and sensitivity of the method by concentrating the samples 1000 times. The resultant extract has been placed in a 10 ml headspace vial (5 replicate vials for each sample). Direct injection in headspace HS mode was performed at the temperature of 280 °C in programmed temperature vaporization (PTV) injector for a GC-FID.

The BETX levels in water samples were expressed in the unit of μg/ml. The limit of detection (LOD) for benzene has turned out to be 0.001 µg/ml. Figure (2) exhibited a GC-FID chromatogram of a standard mixture of BTEX at the concentration of (1 μg/ml) of each component. The total chromatographic runtime was less than 8 minutes. While table (2) listed common chromatographic values for the analysis of (1 μg/ml) standard BTEX samples.
Figure 2. An HS–GC–FID chromatogram for the standard solution of BTEX at the concentration of (1 μg/ml) for each component.

While those samples collected from outside the oilfield were represented into five main sets (Group 4 to 8); directly from MOD before Injection water supply line, from Al-Ahbad Injection water supply line from MOD, from less than a kilometer next to Al-Ahbad Injection water supply line, from Al-Ahbad Injection water supply ponds, and after it respectively as listed in Table (4) below. The data listed in the table concluded, there was no contamination with BTEX for the water samples taken from Al-Ahbad Injection water supply line from MOD (group 5) and directly from MOD before Injection water supply line (group 4). While the water samples collected from less than a kilometer next to Al-Ahbad Injection water supply line (group 6) as well as those collected from Al-Ahbad Injection water supply ponds and after it (groups 7 and 8) respectively have shown some contamination with BTEX compounds which confirm our suspicions that the oilfield may get rid off some untreated PW directly to the MOD which may pollute to the marshes in the southern area of Iraq those fed from MOD steam and the serious impact on the environment and biology.

**Table 4. The average concentrations of BTEX found in aquatic samples collected from MOD. The BTEX levels in samples of the groups (4, and 5) were undetectable. Analyses were taken place using HS-SPME-GC-FID**

</table>

Average concentrations of BTEX were found within the range of μg/ml. These findings point out the are of the same order of magnitude as those reported by other authors, such as in the effluent of produced water from platforms of two different petroleum production units located in the Campos Basin, State of Rio de Janeiro, Brazil (283–1855 mol/ L for benzene, 87.04–2224 mol/L for toluene, 16.77–1220 mol/ L for ethylbenzene and 67.35–5969 mol/ L for xylenes)\(^2^6^)\) and in Norway total BTEX of 8000 μg/L was measured\(^2^7^)\).

**Conclusion**

BTEX pollutants were successfully collected from water samples inside and around Al-Ahbad Oilfield using the environmentally friendly technique of SPE. The extracted water samples were accurately quantized by GC-FID. Reliability and performance of the method of determination were validated by working out the detection and quantification limits, precision and accuracy. Concentration levels ranged from 0.21 and 1.62 μg/mL for BTEX in the PW samples collected from inside Al Ahbad oilfield.

Abstract
Many domestic and Newcastle disease is a contagious bird disease affecting wild avian species, it may be transmissible to humans. Detection of Newcastle virus confirmed by rapid test technique (Immunochromatography). ten sample (10%) out of 100 faeces sample collected from chickens were positive. Twelve mice used in this study devided into two groups, first group consist of six mice induced with 0.2 ml from one positive sample of Newcastle virus suspension to evaluate some histopathological changes caused by Newcastle virus in small intestine and stomach of mice, second group induced with 0.2 ml from phosphate buffer saline only. The results revealed that histopathological changes in small intestine (duodenum) induced by using 0.2 ml from the positive Newcastle virus suspension to complete necrosis and fragmentatin in the villi. Jejunum of mice treated with this concentration of Newcastle virus has partial necrosis for villi with filtration of villus core while ilium of mice treated with same concentration has wide spread of villus necrosis. Stomach of treated mice has oedema in submucosa layer and partial necrosis in gastric glands.

Key words: Histological changes, Newcastle virus, digestive system

Introduction
Newcastle disease is caused by avian paramyxovirus serotype-1 (APMV-1), which is also disease virus (NDV). It is a highly contagious viral diseases that affects domesticated and wild bird species throughout the world as well as NDV is a human pathogen and the most common sign of infection in humans is conjunctivitis that develops within hours of NDV exposure to the eye (1,2). However, disease host species and in different geographical locations. NDV is classified in the genus Avulavirus within subfamily Paramyxovirinae, family Paramyxoviridae and order Mononegavirales. This enveloped virus has a negative sense non-segmented, single stranded RNA genome has 15198 nucleotides in length. The genome encodes six structural and two non-structural proteins. Based on the fusion (F) gene strains are classified into lineages or genotypes; however the discrepancies between the two classification systems are nominal. NDV is spread primarily through direct contact between healthy birds and the bodily discharges of infected birds. The disease is transmitted through infected birds’ droppings and secretions from the nose, mouth, and eyes. Clinical manifestation or severity of the ND depends largely upon the isolates involved in disease outbreak. Based upon pathogenicity, these strains are commonly categorized into velogenic (mesogenic and lentogenic types). The varying level of pathogenicity is attributed to amino acid sequence motif present in protease cleavage site of the precursor F protein.

Materials and Method
Samples collection:
A total of 100 faeces samples were collected from chicken suffering from clinical signs and symptoms of severe greenish watery diarrhea. Detection of Newcastle virus performed by rapid test (Immunochromatography) supplied from Biochek company – USA. The positive samples for Newcastle by rapid test were diluted with phosphate buffer saline or normal saline and stored at -20 °C in freeze. One positive samples of Newcastle was further used for the experimental study on laboratory animals (mice) for evaluation the effects of Newcastle disease on histologicalsections of these
Experimental study: A total of 12 males mice species Balb/c have aged two months and weight 100-120 g divided into two groups. The first group consists of six mice injected orally with 0.2 ml of Newcastle virus suspension for one positive sample. The other control group received 0.2 ml of sterile phosphate buffer saline (PBS) according to methods (12,13). After 4-6 days, clinical signs were recorded in infected animals, whereas observed Experimental mice were sacrificed after anesthetization by chloroform and open abdomen cavity by medical scissors. Tissue from small intestine, stomach, liver were collected from the experimentally infected mice and placed in formalin 10% for histopathological examination in later. Histological sections and staining were prepared according to methods described by 14. The histopathological changes were observed by Dr. Nemah H. Al-jabori/college of medicine / Babylon university under the magnification power 10X and 40X of light microscope.

Results

Histological changes observed in stomach and small intestine which infected with 0.2 ml from Newcastle virus suspension, these changes shown in figure 1,3,5,7. Figure (1) Stomach of mice treated with 0.2 ml from Newcastle virus suspension shows edema in submucosa layer and partial necrosis in gastric gland. The results in figure (3) small intestine of mice (duodenum) treated with 0.2 ml concentration from virus Newcastle suspension revealed to complete necrosis and fragmentation of the villi. Figure (5) small intestine of mice (jejunum) treated with 0.2 ml concentration from Newcastle virus suspension revealed to partial necrosis of villi with filtration of villi core of lymphocytes. Ilium of mice treated with 0.2 ml concentration of virus suspension indicated to widespread villus necrosis.

While the figures 2,4,6,8 revealed to stomach, small intestine (duodenum), small intestine (jejenum) and small intestine (illium) respectively for control mice treated with...
Figure (5) : jejenum of control mice. The slide shows the normal histology of the duodenum with normal villi core. H&E 20X.

Discussion

The authors consider lesions of Newcastle virus most prominent duodenum jejunum and ileum. Even in birds showing neurological signs prior to death, little evidence is found nervous system. Lesions are usually present in the respiratory tract when clinical signs indicate involve men 15. The results of present study about effects of Newcastle virus on stomach and small intestine of mice which experimentally infected with this virus revealed to histopathological changes within stomach and small intestine including duodenum, jejunum and ileum in the mice infected with 0.2ml from Newcastle virus suspension. These histopathological changes were observed in figure 3,5 were indicated histopathological changes in small intestine including duodenum, jejunum and ileum of mice treated 0.2ml viral suspension. Other reports mentioned the occurrence of villi atrophy and atrophy with blunting of the villus tips in the ileum and jejunum of pigs infected with rotavirus 13. Similar findings were reported by 16 which mentioned the severe necrotic and degenerative lesions of the villous enterocytes in piglets. Stomach of mice treated with 0.2ml from Newcastle virus suspension had macroscopic and microscopic changes in the stomach, histopathological changes in stomach and small intestine of mice which treated with Newcastle virus suspension due to most replication for newcastle virus in small intestine. Causes of histopathological changes in small intestine of mice due to enterovirus replicates predominantly in the cytoplasm of differentiated small intestinal villous epithelial cells and thus the virus induces changes that are restricted to the small intestine and these viruses induced epithelium cells destruction and inflammatory response to these parts of intestine 21, 22.

Conclusion

In Conclusion the Newcastle virus suspension caused clear histological changes in stomach and small intestine of mice (Balb/c).

The Effects of Newcastle virus Histologically Suspension on Some Organs of White Mice (Balb/c)

Alaa Abd Alzahraa¹, Ahmed Obaid Hossain¹, Abbas Abd Sherhan¹

¹College of biotechnology, Al-Qasim Green University, Iraq

Abstract

Newcastle disease is a contagious bird disease affecting wild avian species and many domestic, it may be transmissible to humans. Detection of Newcastle virus confirmed by rapid test technique (Immunochromatography). Ten sample (10%) out of 100 faeces sample collected from chickens were positive. Twelve mice used in this study divided into two groups, first group consist of six mice induced with 0.2 ml from one positive sample of Newcastle virus suspension to evaluate some histopathological changes caused by Newcastle virus in small intestine and stomach of mice, second group induced with 0.2 ml from phosphate buffer saline only. The results revealed that histopathological changes in liver induced by using 0.2 ml from the positive Newcastle virus suspension as hyperpalsia in kupfer cells. Lung of mice treated with this concentration of Newcastle virus has partial pneumonia and thicking the intra alveolar walls. While brain of mice treated with same concentration suffering from increase in number of glial cells (gliosis) and apoptosis in brain cells.

Key words: Newcastle virus, histologically suspension

Introduction

Newcastle disease is caused by avian paramyxovirus serotype-1 (APMV-1), which is also disease virus (NDV). It is a highly contagious viral diseases that affects domesticated and wild bird species throughout the world as well as NDV is a human pathogen and the most common sign of infection in humans is conjunctivitis that develops within hours of NDV exposure to the eye (1,2). However, disease host species and in different geographical locations. NDV is classified in the genus Avulavirus within subfamily Paramyxovirinae, family Paramyxoviridae and order Mononegavirales. This enveloped virus has a negative sense non-segmented, single stranded RNA genome has 15198 nucleotides in length. The genome encodes six structural and two non-structural proteins. Based on the fusion (F) gene strains are classified into lineages or genotypes; however the discrepancies between the two classification systems are nominal (5,6,7). NDV is spread primarily through direct contact between healthy birds and the bodily discharges of infected birds. The disease is transmitted through infected birds’ droppings and secretions from the nose, mouth, and eyes. Clinical manifestation or severity of the ND depends largely upon the isolates involved in disease outbreak. Based upon pathogenicity, these strains are commonly categorized into velogenic(mesogenic and lentogenic types). The varying level of pathogenicity is attributed to amino acid sequence motif present in protease cleavage site of the precursor F protein (10,11).

Materials and Method

1-Samples collection:
A total of 100 faeces samples were collected from chicken suffering from clinical signs and symptoms of severe greenish watery diarrhea. Detection of Newcastle virus performed by rapid test (Immunochromatography) supplied from Biochek company -USA. The positive samples for Newcastle by rapid test were diluted with phosphate buffer saline or normal saline and stored at -20°C in freeze. One positive samples of Newcastle was further used for the experimental study on laboratory animals (mice) for evaluation the effects of Newcastle disease on histological sections of these mice.

2-Experimental study: A total of 12 males mice species Balb/c have aged two month and weight 100-120 g divided into two groups, the first group consist of six mice injected orally with 0.2 ml of Newcastle virus suspension for one positive sample. The other as
control group was received 0.2 ml of sterile phosphate buffer saline (PBS) according to methods of (12,13) after 4-6 days clinical signs were recorded in infected animals. were observed Experimental mice were sacrificed after anesthetization by chloroform and open abdomen cavity by medical scissors, tissue from small intestine, stomach, liver were collected from the experimentally infected mice and placed in formalin 10% for histopathological examination in later. Histological sections and staining were prepared according to methods described by (14). The histopathological changes were observed by Dr. Nemah H. AL-jabori/college of medicine / Babylon university under the magnification power 10X and 40 X of light microscope.

Results

Histological changes of current study observed in liver, lung and brain of mice infected with 0.2ml from newcasstle virus suspension, these changes shown in figure1,3,5, while figures 2,4,6 represented control group of mice treated with 0.2ml phosphate buffer saline. In this results figure (1) represented the liver of mice treated with 0.2ml from Newcasstle virus suspension shows hyperpalsia in kufper cells. The results in figure (3) indicated to lungs of mice treated with 0.2ml concentration from virus Newcasstle suspension revealed to partial pneumonia and thicking the intra alveolar walls. While the figure (5) revealed to the brain of mice treated with 0.2ml concentration from newcasstle virus suspension revealed to increase in number of glial cells (gliosis) and apoptosis in brain cells. Finally the figures 2,4,6 revealed to liver, lung and brain respectively for control mice treated with phosphate buffer saline. No histological changes observed in liver, lung and brain of control mice group

Discussion

The authors consider lesions of Newcasstle virus most prominent duodenum jejunum and ileum. Even in birds showing neurological signs prior to death, little evidence is found nervous system. Lesions are usually present in the respiratory tract when clinical
signs indicate involvement\textsuperscript{15}. The results of present study about effects of Newcastle virus suspension on liver, lung, and brain of mice which experimentally infected revealed to histopathological changes within liver, lung and brain of mice infected with 0.2ml from Newcastle virus suspension. These histopathological changes were observed in figure 1,3,5. Figure (1) showed histological changes in liver represented in hyperpalsia in kupfer cells. This results similar to recent studies mentioned that Newcastle virus outbreaks in a poultry facility in Japan was characterized, among other lesions, by hepatic necrosis\textsuperscript{16}.

The results of lung mice infected with same concentration of this virus revealed to partial pneumonia and thicking the intra alveolar walls. This results accept with other reported mentioned that some Newcastle virus strains have been shown experimentally to cause moderate lesions in the respiratory system, these changes were obtained only through aerosolization or use of very high viral titers direct air sac instillation of the virus\textsuperscript{(17,18)}. While the results of lung mice infected with same concentration from Newcastle virus suspension recorded increase in number of glial cells (gliosis) and apoptosis in brain cells. This results agreement with some studies mentioned finding Interactions between the Newcastle disease virus and mouse tissues\textsuperscript{(19,20)}. Causes of histopathological changes in liver, lung and brain of infected mice perhaps due to virulence of Newcastle virus and rapid replication effect on three systems are digestive system (e.g: liver), respiratory system (e.g: lung) and nervous system (e.g: brain)\textsuperscript{(21,22,23)}.

**Conclusion**

The Newcastle virus suspension caused clear histological changes in liver, lung and brain of mice (Balb/c).

Abstract

The current study was conducted to investigate dissemination of gastrointestinal Ascariasis in local pigeons (*Columba livia domestica*) living in Kerbala province. Forty domestic pigeons with different ages were purchased from different markets. Each bird was examined for intestinal parasites. Out of 40 birds examined, the prevalence of gastrointestinal Ascariasis in examined birds were (12.5%), Ascaris sp. was detected in 100% of intestinal contents using macroscopic and microscopic examination assays, molecular diagnosis from bird belly, with the emphasis on primer designed specificity it used in our study.

**Key words:** Ascaridia columbae, pigeon, primer design

Introduction

The rock pigeon (*Columba livia domestica*) is subspecies of the rock pigeon (*Columba livia*) which is a free-living in environment and live side by side with human and other animal species in the environment. The rock pigeon (*Columba livia*) belong to the order Columbiformes and spread widely in all the world. Columbiform pigeons were infect with *Ascaridia columbae* and causes significant infection. Untile now only ~25,000 species have been detected although bilateral animals with an estimate of 1–10 million species. The gastrointestinal helminth (*ascaridia spp*) that infect chickens, pigeons and parrots. Pigeons may be consider reservoirs for many of helminth infections of veterinary importance especially *ascaridia spp* to other avian. *A scaridia spp* infestations have a major role and effect direct or indirect on health status of birds lead to economic losses in the production of poultry meat and eggs. *A scaridia spp* are one of the most common gastrointestinal helminth problems of pigeons. They harbor *Ascaridia columbae* and *Ascaridia galli*. The infected pigeons suffer from various clinical signs which differ from loss of weight, growth, egg production, elementary canal disturbance and gastrointestinal blockage with increase mortality rates. The aim of the present study to investigate prevalence of gastrointestinal helminth in healthy local pigeons in Kerbala province.

Materials and Method

Ethics statement

This experiment was approved by Veterinary medicine Animal Care and Animal Ethics Committees, Faculty of veterinary Medicine, University of kerbala, Iraq.

Study areas and Parasitological analysis

Forty local domestic pigeons (*Columbia livia domestica*) with dubious clinical emaciated signs which include (inability to fly properly, Sitting too still, Drooping wings or slouched and Head listing to one side) were admitted to the Department of Veterinary Parasitology, Faculty of Veterinary Medicine, Kerbala University. In this current study, several suspected Ascaridia eggs were examined in the sample stool of each emaciated bird, then was directed to the veterinary parasitological Laboratory, Faculty of veterinary Medicine, University of kerbala Iraq, from February till the end of April 2019. After the stool was mingled with 0.85 % physiological salt solution in order to refine it from several separate
particles and all pigeon were stool examined according to the. The infected birds were isolated and killed by neck dislocation in order to isolate the infected intestines from the belly of the birds, later on, the intestine was opened longitudinally from esophagus to cloaca. The intestinal contents were examined macroscopically for the presence of adult nematodes or other parasites. Microscopical examinations were included direct smear, sedimentation and floatation methods and the ultra structures for both male and female. A scaridia spp. that were presence in various places of intestine were collected and put it into Petri dishes then transferred in labeled bottles contain tap water. Amplification of specific DNA sequences by PCR and restriction endonuclease analysis of PCR products have been used for identification and characterization of ascariasis. The aim of this study was to determine the prevalence of pigeon ascariasis and to design a specific primer selection of identified Ascaridia columbae in kerbala province.

**DNA extraction:**

Adult Ascaridia columbae were collected from luminal content in the pigeons were harvested, single worm was harvested using a procedure carried out according to. The DNA of worm obtaining was extracted by genesig Easy DNA/RNA Extraction Kit (Southampton, UK) according to the manufacturer company.

**Primer designing:**

Dual nucleotides primers were designed according to sequencing that obtained from NCBI website(https://www.ncbi.nlm.nih.gov), PerlPrimer was used in the design of primers and calculates primer melting temperature (http://perlprimer.sourceforge.net). Table 1.

The primers were manufactured by (Alpha DNA, Montreal, QC, Canada). PCR amplification was carried out with a thermal cycler (Analytik Jena’s Biometra thermal cycler, Germany.) and by using a premix PCR kit (AccuPower® PCR PreMix, Korea) and by following the instructions of the manufacturer instruments, PCR reaction assay were formed with a dual primers designed on the basis of the published nucleotide sequence of the Ascaridia columbae complete Cytochrome oxidase 1 Cox1 gene (length, 1,563 bp; GenBank database accession JX624729 and NC_021643.1). Briefly, A product of mixing PCR consisted of 5 μl of a sample containing DNA was added to each premix well, 7 μM each primer, and double-distilled water to a final volume of 25 μl. PCR optimizations were denatured at 94°C for 5 min. thirty five cycles were run under the following processes: DNA denaturation at 92°C for 3 minutes, annealing temperature at 52°C for 1 min, and extension process at 72°C for 1 min. After the final cycle, the reactions were terminated by an final extension at 72°C for 7 min. The PCR products were analyzed by Safe-Red™-agarose gel electrophoresis.

**Results and Discussion**

Ascariasis can probably affect any mammal. Its occurrence is sporadic and worldwide. Birds, particularly pigeons, often carry the agent in their intestinal contents and contribute to its reservoir (figure 1). They are rarely affected clinically, and then mostly on mucous surfaces, there were no clear signs of the birds unless they were weak, shivering emaciated and ruffled feathers, The internal organs are not clear due to the multiplication of worms forming almost like a cover enriched with roots of tree that cause intestinal blockage (figure 1). Ascariasis most frequently affects the mucous surfaces on which the worm is abnormally found, possibly the digestive tract of pigeon; it typically remains confined to areas of villus epithelium due to blunting of the villi.

Pigeon is often associated with ascariasis (through eggs) or intensive exposure. The infestation of pigeon
has an important role in causing significantly reduce due to the economic losses in the eggs production. Also, they may have essentially harmful or lethal effects on birds infections, especially small birds (small squares), causing growth delay, intervention in healthy development, and making older birds susceptible to secondary infection.

Microscopically and macroscopically methods were used to determine the difference between males and females, the male’s posterior end is curved ventrally and has a bluntly pointed tail with copulatory spicules which help the worm to dialate the vulva and can also work as a canal for the spermatozoa (figure 2). There was no apparent difference in parasite anterior end, so, this ends are more slender than the posterior ends. Males have pineal, spices or spine like extensions nears its posterior opening whereas females lack these structure.

A female sediment from intestinal contents is mixed with an equal amount of ddH₂O on a slide and a cover slip is added. Microscopically, the internal organisms appear as bright circular lacunae in a dark field, containing the eggs in their centers.

Avian Ascariasis affects chickens, turkeys, pigeons, and other birds. It resembles ascariasis of humans involving the anterior digestive tract. In the young, it can be a blocking digestive disease and cause considerable mortality.

We searched the Cytochrome oxidase 1 Cox1 site, on the Ascaridia columbae genome Acession number (JX624729) using NCBI Nucleotide BLAST for complete sequences (http://www.ncbi.nlm.nih.gov/BLAST/) limited by the Entrez query ‘Ascaridia columbae’. among data obtaining, the study was selected the target gene containing the Cytochrome oxidase 1 in the Ascaridia columbae, and also tested the specificity of the 1563 bp sequence of the target, the selected 263 bp Cytochrome oxidase 1 and the 22 and 20 bp for forward and reverse primer regions, respectively, at both ends among the target region using NCBI Nucleotide BLAST figure 3.

In PCR-based parasite identification, PCR-product amplified was also be shortly and appropriately detected. As a general, the amplify DNA sequences can be determined by agarose gel electrophoresis after Polymerase chain Reaction assay amplification. Numerous identification systems for specified of parasite investigation such as Ascaridia columbae based on the combination of PCR and gel electrophoresis have been already progressing and commercialized.

The primer design and aligned method was based on a number of available sequencing that upload on the the NIH genetic sequence database, unfortunately, in our current study, we found only two available
GenBank sequence database for Ascaridia columbae mitochondrion, complete genome which included two accession number (JX624729 and NC_021643.1) They belong to researchers who record that accession number (NC_021643.1) has not yet been subject to final NCBI review and confirmed this reference sequence is identical to JX624729.

Our results was used gel electrophoresis is an easy method of PCR products, according to our knowledge, this primers can used to differentiate between specific PCR amplification products and non-specific ones (figure 3), In our current study, we have not observed any convergence and alignment of the nucleotides sequences used between the Ascaridia columbae wit other ascariasis except for some animals or the parasite far from an pigeon infestation, Therefore, we can say that this primer is considered as a specific diagnosis of the this strain.

Figure 3: Align of Ascaridia columbae with more sequences with other prokaryotic and eukaryotic cells using BLAST

Conclusion

In conclusion our study was demonstrated the rapid and specific detection of PCR DNA amplified from an Ascaridia columbae genome using a specific primer sequences.

Effect of Addition of Composite Polyamide Micro Particles and Silicone Dioxide NanoParticle on Some Mechanical Properties of Room Temperature Vulcanized Maxillofacial Silicone Elastomer Before and after Artificial Aging

Bahaa F. Alanssari¹, Bayan S. Khalaf²
¹ M.Sc. Student (Prosthodontics Department, College of Dentistry/ University of Baghdad, Iraq), ² Asist. Prof. (Prosthodontics Department, College of Dentistry/ University of Baghdad, Iraq)

Abstract

Background: The most common reason for re-making a maxillofacial prosthesis is the degradation of the mechanical properties of the silicone.

Aim of this study: To assess some mechanical properties of VST-50F maxillofacial silicone reinforced with a composite of silicon dioxide nanoparticle and polyamide-6 microparticle before and after artificial aging.

Material and Method: Preparing 240 samples tested for tear strength, tensile strength and elongation percentage, hardness, and roughness before and after aging. The Silicon dioxide was added in concentrations of 1% by weight and Polyamide-6 in the concentration of 0.25% and 0.5% by weight to the VST-50F RTV maxillofacial silicone. The one-way ANOVA and post hoc tests were used for inferential statistics.

Results: The one-way ANOVA showed a highly significant difference between all tested groups. The effect of the addition of composite fillers showed an increase in tear strength, hardness, and surface roughness but a decrease in tensile and percentage of elongation. However, the effect of artificial aging showed increased in tear strength, Percentage of elongation, and surface roughness, but a decrease in tensile strength and hardness.

Conclusion: Addition of composite of fillers into the silicone elastomer allowed enhancement of some mechanical properties. The composite of different types of filler reinforcement improves the anti-aging properties of silicone and maintain some of the mechanical properties to enhance the service life.

Keywords: Composite, silicone dioxide, polyamide, Maxillofacial silicone, Mechanical properties, artificial aging.

Introduction

The distortion in appearance and function could be restored with a maxillofacial prosthesis that reproduces the natural features of the lost tissues from acquired, developmental, and congenital head and neck defects. The first treatment of choice is plastic surgery. However, when a medical procedure is ill-advised, because of undesirable conditions, restoration with maxillofacial prosthesis could be an alternative method for improving patient’s appearance and confidence and encouraging their resumption to society. Rahman et al. after systematic review for various researches concluded that there was no ideal maxillofacial material that could resist different aging conditions. Liu et al. concluded that merging two types of micro-particles in specific percentages could give a maxillofacial prosthesis closer to ideal properties. On the other hand, Nano- and micro-filler mixture is a practical approach to improving the strength and the features of material.

This study assessed some mechanical properties of VST-50F maxillofacial silicone reinforced by a composite of silicon dioxide nanoparticle and...
Materials and Method

The materials used in this study were the VST 50F RTV silicone (Factor II Inc., USA), SiO2 (Sky Spring, Inc. USA) and PA-6 (Changfeng Chemical Co., Ltd. China).

The SiO2 was added in 1% by weight and PA-6 in the 0.25% and 0.5% by weight to the VST-50F silicone.

A total of 240 samples had been prepared and separated into four groups according to the performed tests, so each test included 60 samples and each test group further subdivided into six sub-groups (Control, Control/aged, 0.5PA+1SiO2, 0.5PA+1SiO2/aged group, 0.25PA+1SiO2, 0.25PA+1SiO2/aged) with ten samples for each sub-division.

The shapes and dimensions of the molds for the test samples were designed utilizing AutoCAD 2013 and fabricated with CNC machine into which the silicone poured. The two templates had dimensions of 30 cm length x 20 cm width x 2.2 ± 0.05 mm thickness for tear and tensile strength test and 6 ± 0.05 mm thickness for hardness and roughness tests.

The fabrication of the samples for each of the experimental groups started by weighing the fillers in the mixing bowl then the silicone base added and mixed for 10 min. The mixing was conducted under vacuum to eliminate air entrapment in the mix for the first three minutes. The vacuum was switched off to prevent the suction of the nanoparticles and then it was switch on for the last 7 min. The vacuum pressure was -28 inch Hg, and the speed of the mechanical mixer was 140±10 RPM. Before adding the catalyst, the mixture was left for 2 minutes to cool — the catalyst mixed with the base mixture for 5 minutes ± 5 seconds.

Pouring of the material was carried out under a temperature of 23 ±2°C, and the humidity around 50±10% 6. The homogeneous mixture was dispensed carefully into a plastic-syringe of 60 mL (Figure 1). The acrylic mold placed over a dental vibrator working at a low vibration and the mixture poured in an excess amount from the disposable syringe. The cover was placed over the poured material in the matrix, starting from one end part of the cover by resting the margin and lifting the margin of the other end part. Then the lid was gently lowered slowly and carefully onto the matrix to allow for the escape of the excess material out of the mold. After that, a load of one kilogram placed over the middle part of the mold’s cover, and the cover secured in place with nuts and G-clamps, then the weight was removed (Figure 2). The mold was fixed firmly until the samples hardened 1.

All the samples organized, and the tests performed according to ISO 23529 6 specifications.

The following four tests were performed to assess the various mechanical properties of the VST-50F maxillofacial silicone:

1. Tear strength test: According to ISO 34-1 specifications, the samples had been prepared and tested by the universal testing machine clamps (Laryee Technology Co., Ltd., China). The tear strength sample was the type C tear sample.

2. Tensile strength and elongation percentage tests: The testing procedure accomplished according to ISO 37 8 specifications with dumbbell-shaped.

3. Hardness Test: According to ISO 48-4 9 specification, the testing procedure accomplished. The samples marked with five points, one at the center and the others 6mm away at each direction around the center point. Shore A hardness durometer mounted on the mechanical stand used for measurement. The device was forced firmly by hand clamp on a mechanical stand over the surface of the sample for 1 second with a 1Kg load according to specification, and the mean of 5 reading recorded 9.
4. Surface Roughness Test: All samples prepared according to ISO 48-4 specifications. Portable digital roughness tester with (0.001μm) accuracy was used to conduct a surface roughness test. The device mounted on a stand and adjusted in a way so that the stylus just contacted the sample surface in 3 various places so that three measures obtained for each sample and their mean value represented the roughness value 10.

SEM (AIS2300C, Angstrom Advanced Inc, USA) scanning the dispersion of the composite fillers within the silicone matrix.

SPSS software v23.0 used for data analyzes for the descriptive and inferential statistics with a confidence interval of 95%.

Results

ANOVA test showed that a highly significant difference between all tested groups.

The results showed no significant increase in the tear strength after fillers reinforcement.

The effect of artificial aging for 150 hours showed that the tear strength of the control group decreased significantly, but for the reinforced silicone increased. It was a highly significant difference for 0.5PA+1SiO2 and a non-significant difference for the 0.25PA+1SiO2 group in comparison to the control group.

The results showed a non-significant decrease in the tensile strength after fillers reinforcement.

The effect of artificial aging for 150 hours showed that the tensile strength decreased highly significantly for the control group and the reinforced silicone. It was a highly significant difference for 0.5PA+1SiO2 and 0.25PA+1SiO2 groups in comparison to control group before aging and the non-significant difference in contrast to the control group after aging.

The results showed a significant decrease in the percentage of elongation after 0.5PA+1SiO2 fillers reinforcement and a highly significant decrease after the 0.25PA+1SiO2 fillers reinforcement.

The effect of artificial aging for 150 hours showed that the percentage of elongation of the control group decreased non-significantly, but for the reinforced silicone increased highly significantly. It was a non-significant difference for both percentages in comparison to the control group before and after aging.

The results showed a highly significant increase in the hardness after filler reinforcement.

The effect of artificial aging for 150 hours showed that the hardness of the control group increased non-significantly, but the reinforced silicone decreased highly significantly. It was a non-significant difference for both percentages in comparison to the control group before and after aging.

The results showed a highly significant increase in the surface roughness after 0.5PA+1SiO2 fillers reinforcement and non-significantly increased after the 0.25PA+1SiO2 fillers reinforcement.

The effect of artificial aging for 150 hours showed that the surface roughness increased non-significantly for the control and the reinforced silicone groups. It was highly significantly different for 0.5PA+1SiO2 group in comparison to the control group before and after aging.
and also highly significantly different for the 0.25PA+1SiO2 group, in contrast to control before aging, but it was only significantly different in comparison to control after aging (Table 1 and 2).

The SEM results showed a good dispersion of the Nano-fillers within the silicone matrix (Figure 3),

Discussion

Many types of research showed that most of the commercially present materials had not satisfied all of the required, ideal properties and the highest chance of early deterioration was the major limitation of silicone material that may exhibit reduced tear strength, somewhat fitting margin, discoloration of material and modified texture. It clarifies the constant increase in the number of researches to develop enhanced maxillofacial silicone material, by changing the formulation of previous materials or by reinforcement with various types of fillers in different percentages \(11\). Silica particles can adsorb polydimethylsiloxane chains to its surface and form strong hydrogen bonds between its surface hydroxyl group and the oxygen in the polymer chain. These bonds increase polymer chains resistance to rupturing when subjected to tearing forces due to high shear strength between the nanofiller and the polymer chains \(12\). Also, the PA-6 could form multiple hydrogen bonds among adjacent elements because of the high polarity natural of fillers due to the amide (-CO-NH-) groups. It is leading to an alteration in the whole density and more tear resistance of the polymer due to the formation of fillers with a three-dimensional network in the polymer matrix. On the other hand, rubber can scatter stress-energy close the apex of the growing cracks and thus increasing the strength in elastomers. So, this may explain the increase in tear strength after SiO2 and PA-6 filler reinforcement \(13\). The hardness increase might be referred to the difference in the crosslink density with filler contents; the filler particles may cause a reduced in the distance among the crosslinks of the polymeric matrix thus the reduction of the softness of the material.
contributed to the polymer and filler interaction. As mentioned early, the SiO2 nanoparticles increase the cross-linking network that leads to improve the overall stiffness of the polymer and increase its resistance to tearing, but the higher cross-linker tightened the net to upper limit so reducing the flexibility and deteriorating tensile properties obtaining extremely brittle samples. The decrease in elongation could also be clarified by the reduction in the space between the fillers aspect ratio and contents. Therefore the elongation at fracture was decreased by the relatively reduced distance of rubber molecules. On the other hand, the cross-linking was reversible for PA-6 particles with temperature and UV light inside the Weather-Ometer chamber and could result in a polymer with altered physical and mechanical properties. The decrease in cross-linking leads to a reduction in tensile strength and an increase in the percentage of elongation. It may be because of chain scission that results from the generation of free radicals which react with oxygen leading to the formation of polymer oxy- and peroxy radicals via the enhanced chemical reaction (photo-oxidation). It influences the distribution of molecular weight and reducing the density of the network structure by breaking the bonds, commonly C-H bonds, between two diverse chains or within the same main chain due to strength value of material reduced.

The particles of the nanofiller (SiO2) may be associated strongly with the polymeric chains even after severe condition. If these particles were detached, an increase in the porosity of the polymer and reduction in the hardness would be expected. So the surface roughness increase results from the formation of microcracks and pits on the surface level of material.

Conclusions

Within the limitations of the study, the following were drawn: The addition of various types of fillers in appropriate proportions to silicone elastomer could enhance some of the mechanical properties. The composite of Nano-SiO2 and micro PA-6 fillers tend to increase in tear strength, hardness and surface roughness but a decrease in tensile and percentage of elongation. The composite of different types of fillers reinforcement is promising to improve the anti-aging properties of silicone and maintain some of the mechanical properties to enhance the service life.

The Elements of the Crime of Copyright Infringement on the Internet

Ammar Ghali Abdulkadhim

Faculty Member, Faculty of Law, University of Babylon, Iraq

Abstract

With the creation of the human mind, the intellectual production of such machine created by the Creator began to appear in various forms starting from drawing and engraving on stones, the manufacture of clothing from plants leaves and animal skins, and making fishing rods and eventually to all cognitive sciences known by the world today and the evolution reached in all fields and aspects. Intellectual property rights are among the most important forms of human rights related to his intellectual production in the scientific, literary, artistic, and all forms of intellectual production in the different aspects of human life. It is clear to all that this production has its material and moral fruits. The intellectual property rights have become one of the most important forms of material rights that entitles its holder to dispose them, give them up and invest them. This right can be defined from the researcher point of view as a set of ideas that are written and issued by the human mind, and that can be accessed and identified just as tangible material objects. It includes all rights resulting from the intellectual activities of man in the literary, artistic, scientific, industrial, commercial and similar fields.

Keywords: Crime, Elements, internet

Introduction

Through this research, we address a number of points by study and interpretation: What works are covered by criminal protection ¹, in terms of definition, conditions to be provided, and the elements of the work. The corpus delicti of the Crime of copyright infringement on the internet. Criminal Punishment for such crime in the Light of Iraqi Legislation ². The research was conducted on four themes, in the first of which the researcher addressed the works covered by the legal protection in three sections. Section one introduces the definition of works, section two addresses conditions to be provided in the work covered by legal protection and section three provides the elements of the works subject to the crime in question. The second theme handles the physical corpus delicti of the crime of copyright infringement on the internet. It is introduced in three sections: the first of which is concerned with the criminal activity, the second of which deals with the criminal result, the third of which provides for the causal relationship ³. The third theme handles the moral corpus delicti of the crime of copyright infringement on the internet. It is introduced in two sections: the first of which is concerned with premeditation in the crime of copyright infringement on the internet, the second of which deals with the motive of the crime of copyright infringement on the internet ⁴-⁶.

Methodology

Conditions to be provided in the work subject to such crime

The author copyright related to his work, due to all of the above mentioned reasons, may fall as a victim of counterfeiting and illegal imitation, so the right holder (the author) incurs physical and moral damage. Thus, the legislator must intervene to the extent necessary for providing the legal protection sufficient for the author and guarantee his rights with regard to his work in order to hive him reassurance and thus give more room for creativity and intellectual production.

The elements of the works subject to the crime

Neither jurisprudence nor law, nor even the judiciary system, interferes in the development of certain elements that are required to establish the literary, social, scientific, artistic or cultural value of the digital work, so that it can be considered a subject of crime. In other words,
the purpose of the work is not significant in determining whether or not legal protection should be available.

The elements to be available in the work so as to be covered by legal protection are two elements that are:

1. Creation: The legal jurisprudence considers innovation to be an essential element for the protection of intellectual property. The French jurisprudence considers innovation the essence of originality and seriousness, so that the work reflects the personal nature of the work author, which appears in the stage of creation and expression during the creation and production of the electronic work. This is evident by its definition of innovation as (the personal imprint placed by the author on his work). The Egyptian jurisprudence defines innovation as (the work being characterized by originality in terms of construction or expression). The Iraqi jurisprudence defines innovation as “the emergence of the personal effort of the author of the idea, regardless of its literary or material value 6. This does not differ if work is created by the author, in whole or in part, through different elements being collected and arranged in a particular form that reflects the character of the author through the production of the work covered by legal protection).

2. Material physical form: An abstract idea is not enough for providing legal protection, even if it is innovative and new, since this idea must have a tangible physical existence. Therefore, the digital works covered by legal protection should have a tangible physical existence that commensurate with the prevailing trend in jurisprudence and legal legislation of the expression of material physical existence. The latter limits range of the legal protection of digital works to a large extent, especially those that take the form of public performance such as Quranic recitation, musical melody or poetic poems

**Section (1): Criminal Activity**

The most prominent element of the crime corpus delicti in general is the first material notice of the crime existence to the outside tangible world, and as far as the crime of copyright infringement on the internet is concerned, the criminal activity here means the act of infringement of the author literary and financial copyright, either by the imitation of the work wholly (total reproduction) or in part as when some of the ideas contained in the work that belong to the author are attributed to another person, who is usually the perpetrator of the imitation crime.

Imitation within the framework of intellectual property rights is all the forms of action against these rights, and since the criminal legislator 7 has avoided setting the definition of imitation along with mentioning the acts that are considered, the legal jurisprudence defined it as making something new less valuable than the original one or similar there to with the aim to benefit from the value of the difference between the two things.

**Results and Discussion**

It is the second element of the crime corpus delicti, since the criminal conduct entails consequential effect, and this effect is the criminal result. There is no doubt that such an effect is required for the legal establishment of the crime, since a crime can never be established unless there is a criminal conduct and consequences arising there from. Therefore, the extent of such legal effect conformity to that effect specified in the legal model of crime shall be considered. The effect of the criminal conduct in the infringement of copyright on the Internet crime represents an infringement of the interests and rights protected by law. This is the conventional legal concept of the criminal result as an element of the crime corpus delicti. The right of the legal author related to his work falls within the intellectual property rights. It is also the general right of the human right to preserve his intellectual life away from the intervention of others and grant him the right to lead this life as he pleases within the limits of the law. The criminal result in accordance with this concept is a legal idea based on the moral damage affecting the interest or right protected by the law in its text. According to this legal idea, the crime may have occurred even if the criminal conduct did not lead to material damage at the time of such conduct occurrence because the normal course of events foresees that such damage will inevitably occur in the future, and this possibility of the damage incurred by the interest protected by law is the criminal result. The legal provision that criminalizes certain conduct has been established only for the wisdom of the legislator 8, and the latter has not established the legal provision merely to avoid tangible material damage, but rather to seek punishment for the same criminal conduct. The mere fact that the criminal conduct leads to the criminal result, even if it does not occur, is sufficient to punish those whoever commits such conduct. This applies to the crime of infringement of the author legal rights on the Internet, since the perpetrator violates the intellectual
property right of the victim, protected by the law, without the need to investigate the external material effects resulting from such conduct. Such crime is a risk crime that are sometimes called formal offences. The causal relationship means the association that links the criminal conduct to the criminal result is one of the elements of the crime corpus delicti and is considered the link between the two other elements (the criminal activity and the criminal result). The issue of causation and its significance is clearly manifested when other factors interfere with the criminal activity of the perpetrator, contributing to the criminal result. The latter have already been given a general description as the violation of the victim rights through unlawful means. The question how is this convenient as far as the crime of copyright infringement on the internet is concerned? If other factors interfere with the criminal activity of the perpetrator, contributing to the criminal result, does this negate the causal relationship, and therefore one of the elements of the crime corpus delicti is missing or this does not affect the existence of the causal relationship, which is proved along with the rest of the crime elements to form together the corpus delicti of the crime? The establishment of a criterion for proving the causal relationship between the criminal conduct and the criminal result is subject to the discretion of the competent court and its experience and precedents that enable it to give precedence to one of the criteria of proving the causal relationship and to judge its availability as an element of the crime corpus delicti or not. This did not prevent the criminal legislator in other criminal legislation from establishing a specific criterion for determining the availability of the causal relationship or not. The Iraqi judiciary has different positions in the cases considered between the period between the old Baghdad penal code and until after the issuance of the Penal Code in force no. 111 of the year 1969, since before the issuance of the current Penal Code and because the Baghdad Penal Code lacks any text that determines a criterion for establishing the causal relationship, the judiciary went to follow the theory of direct cause, influenced by the trend of the French judiciary and jurisprudence and some of the Egyptian judiciary decisions. However, the Iraqi judiciary has committed itself to apply the causal relationship criterion adopted by the theory of equivalence of conditions as stipulated in article (29) of the Iraqi Penal Code after its promulgation. One of the decisions issued by the Court of Cassation in Iraq, clearly demonstrate such trend in its this decision, stating that: the kidnap attempt, apart from assault, is a crime in itself and is indeed an act that comes in contravention of law, which caused the victim extreme agitation, and since she was suffering from heart disease, this has resulted in her death. The penal code held the perpetrator accountable for the crime, offence that did not result from his criminal conduct but he is responsible for that offence if, together with his criminal conduct, some other prior, contemporaneous or subsequent cause, even though he was unaware of it, played a part in its commission. Whereas the expert doctor mandated in the case has stated that the psychological agitation or irritability makes the patient heart unable to carry out its task and leads to the acceleration of death, so the court decided to confirm the decision issued in the case, convicting the defendants and sentencing them according to such conclusion.

The mental element of the Crime of copyright infringement on the internet

The mental element is the second pillar of the crime, and it means that the intention of the perpetrator goes to committing the criminal activity and the violation of the law either intentionally or inadvertently. The mental element of the crime has two forms: the first of which is the so-called criminal intent (the vicious will) in which the perpetrator has directed his or her will to committing the criminal conduct aiming to reach the criminal result consequent thereto. The mental element of the crime cornerstone on which the criminal legislator and the judiciary rely in ensuring legal justice and achieving the social purposes of the penalty, since the legal nature of the criminal liability and the penalty sufficient there for are determined based on such element.

Conclusions

The author shall be given two types of rights on his electronic work that are the literary and financial rights, and one of them is likely to over weigh the other considering the different nature of the beneficiary whether the author during his life or his heirs or successors after his death. The crime of infringing legal copyright as other crimes has its corpus delicti and mental element. Committing such crime entails the imposition of original and consequential penalties, and the crime of the author copyright infringement on the internet is deemed as a misdemeanour. Most of the
comparative legislations included controls that clearly describe the outstanding work of the author in the field of arts, literature or other cognitive sciences so that it can be considered as a work covered by legal protection. The author’s copyright is not subject to prescription, but this does not necessarily mean accepting the notion of permanence or eternity. If we accept that the permanent right is not subject to prescription, which means that the right holder or his successor has the right to defend his right before the infringer at any time, and the infringer may not use prescription as a basis for pleading the lapse of the copyright of the author or his successor. However, this idea is different from the permanence, which is intended to protect the right of the author related to his work that applies on an eternal basis and is not limited to any period of time, even if such period lasts for long.

Effect of Iron Oxide Nanopaticlal on The FSH, LH and Testesteron Hormones in The offspring of Albino Rats

Reyim Hameid Kamel 1, Amel Ali AL-Taee 2
1Collage of Science, Babylon University, Iraq, 2Professor/Biology Dep., Collage of Science, Babylon University, Iraq.

Abstract

The study was carried out to investigate the effect of iron oxide nanoparticle(NP) on FSH,LH and Testosterone hormones in the offspring of albino rats. The study included twenty (20) offspring divided into two groups, treated and control group. The results of the hormonal study showed the existence of significant increase (P≤ 0.05) in the mean levels of FSH,LH, Testosterone of offspring treated groups compared with controls.

Keywords: Iron Oxide Nanopartical, FSH, Testesteron Hormones

Introduction

Nanotechnology can be defined as a branch of engineering and science, technology dealing with nanoparticles ultrafine objects in a range between (1 – 100) nm in dimension, the shape and size of these nanomaterial’s can be controlled by finding its way in a wide range of applications 1. Nanoparticles (NPs) are at the forefront of rapid development in nanotechnology, their exclusive size-dependent properties make these materials indispensable and superior in many areas of human activities 2. Being the most current transition metal in the Earth’s crust, iron stands as the backbone of current infrastructure in comparison to group elements such as cobalt, nickel, gold, and platinum are some what neglected 3. Iron and oxygen chemically combine to form iron oxides (compounds), and there are ~16 identified iron oxides, in nature iron (III) oxide is found in the form of rust 4. Generally, iron oxides are prevalent, widely used as they have an imperative role in many biological and geological processes, they are also extensively used by humans, e.g. as iron ores in thermite, catalysts, durable pigments (coatings, paints, and colored concretes) and hemoglobin 5. The three most common forms of iron oxides in nature are magnetite (Fe3O4), maghemite (γ-Fe2O3), and hematite (α-Fe2O3) 6. Hematite is extensively used in gas sensors, catalysts and photocatalysts, magnetism and electrochemical capacitor 7,8,9. Iron oxides with different particle sizes and morphologies have been obtained by a variety of physical and chemical approaches such as chemical precipitation, solvo thermal, pulsed layer ablation, electro-spinning, hydrothermal and sol-gel methods 10,11. Since NPs are incorporated more and more in a variety of consumer products, it is likely that the general public may be exposed to NP-containing products such as personal care products, food and food packaging materials, textiles and medicine 12,13. To develop such insights toxic properties of NPs should be identified and dose-response relationships established, despite the fact that there are a number of publications concerning undesirable effects of NPs various gaps still exist in the knowledge on the intrinsic hazards of NPs the potential human exposures to NPs and the relationship between exposure and adverse health effects (risks) of NPs 14,15,16. Existing information on potential adverse health effects is mainly based on animal experiments although in vitro studies with cell lines have recently added to the insight in potential hazards of NPs, these particles have been shown for example to induce cytotoxic, genotoxic, inflammatory and oxidative stress responses in different mammalian cell lines 17,18,19

Material and Method

Animals:

Thirty six healthy adult female albino rats weight (225±10gm), age (10-12)weeks were purchased from Iraqi Center for Drug Research/ Baghdad. All these animals were housed during the period of experiment in the animal house unit in science college of Babylon University, under controlled temperature (21 ± 1°C)
and constant light-dark schedule (12 hours light and 12 hours dark cycle), food and water were available. The pregnant rats administrated orally (150 mg/kg) of B.W. iron oxide NPs by gavage tube for 21 days of pregnancy until they give birth, they offspring left for tow months until they became adult and then killed, the serum was taken from the offspring for hormonal study.

**Experimental Design:**

Twenty offspring were randomly divided into two groups.

**Group 1:** Control group (n=10).

**Group 2:** Treated group (n=10).

**Blood Samples Collection and Serum Preparation**

To perform the blood biochemical tests, blood sampling was collected from adult offspring (male and female). The blood samples were centrifuged and the serum of samples were separated at 3000 RPM for 10 minutes. The concentrations of LH, FSH and Testosterone of serum specimens were measured according to Cusabio Elisa kit.

**Statistical analysis:**

All data were subjected to a one-way analysis of variance (ANOVA) to determine the level of significance between control and the treated groups. The significance was tested by finding LSD. Data are reported as mean ± standard error (±SE).

**Results**

**Follicles Stimulating Hormone (FSH) level**

The results of our study showed that FSH levels increased significantly (P≤0.05) in the offspring (females and males) (1.581±0.017b, 1.309±0.009b) respectively as compared with control groups (0.814±0.011a, 0.809±0.008a) (Table 1-1).

**Luteinizing Hormone (LH) level**

The results of study revealed significant increased (P≤0.05) in the level of LH in the females of treated groups (1.3608±0.440b) compared with control (0.825±0.220a) while males had non-significant change in the treated groups (1.004±0.1003b) compared with control groups (0.832±0.121b) (Table 1-1).

**Testosterone Hormone level**

The results of our study showed no significant change in the level of testosterone in the offspring of both females and males groups (2.081±2.885a, 0.826±0.005a) respectively compared with control groups (0.510±0.014a, 0.517±0.006a) (Table 1-1).

Discussion

The present study results showed that there were significant increases (P≤ 0.05) in the levels of FSH, LH and testosterone in offspring. NPs may effect hormone secretion in two ways: 1. NPs pass through the blood-brain barrier into the hypothalamus and secretory cells of the pituitary altering the secretion of GnRH, LH and FSH, thus undermining the normal positive and negative feedback of the hypothalamic-pituitary-gonadal axis and affecting the normal secretion of ovarian estrogen and progesterone. 2. NPs enter the ovaries through circulation and accumulate in theca cells and granulose cells, which effects steroidogenesis. Some in vitro studies showed that some NPs could be swallowed by granulose cells resulting in changes in the secretion of hormones and dysplasia of the ovum, another studies showing that NPs can enter both thecal cells and granulose cells and affect their normal function particularly relating to their key role in hormone secretion. Before ovulation, androgens and androstenedione secreted by theca cells diffuse into granule cells and are transformed into steroid hormones, during this process NPs can directly affect the secretion of sex hormones by destroying these secretory cells in the ovaries. In vivo studies have shown that long-term (90 consecutive days) exposure to titanium dioxide NPs (TiO2 NPs) in female mice results in an imbalance of sex hormones and mineral element distribution leading to a reduction in pregnancy rate and oxidative stress and disruption of ovarian gene expression. Moreover, in vivo experiments in rats showed that silver NPs could get transferred from the mother to offspring through the placenta and breast milk. The neurohormones such as GnRH, follicle stimulating hormone (FSH) and luteinizing hormone (LH) secreted by the hypothalamus and pituitary play crucial roles in positive and negative feedback regulation during oogenesis, NPs may indirectly effect oogenesis and ovarian health by disturbing the balance of these sex hormones. In which the treated female groups showed significant differences in this parameter comparing to the related control. Those results agree with who found that iron oxide nanoparticle treatment led to increases in the levels of the serum LH in female mice. In contrast to study used copper nanoparticle revealed decrease in the level of sex hormones FSH, LH and testosterone in male rats. In this study, iron oxide nanoparticle treated groups in female and male rats showed significant increases in production of reproductive hormones as compared to control. Another study showed significant increases in the levels of LH and FSH in males of Wister rats using gold nanoparticles. Alterations in testosterone levels leading to impaired male reproductive function that have been investigated in numerous in vivo studies that observed inhalation rats to nanoparticle-rich diesel exhaust (NRDE-NPs) significantly increased testosterone, these findings suggest that the increased levels of testosterone due to the disrupted balance between androgen-metabolizing and testosterone biosynthetic-enzymes. Another attempting to clarify the mechanism responsible for the rise in testosterone levels, research group confirmed that increased testosterone biosynthesis could be attributed to an increase in the mRNA expression of StAR and cytochrome P450 side-chain cleavage (P450scc) an enzyme responsible for the conversion of transported cholesterol to pregnenolone in Leydig cells. Another study investigated the effect of silver nanoparticles consumption instead of drinking water animals from each group were selected and the levels of sex hormones were evaluated also and the level of testosterone increased with “testicle hyperactivity.”

In our study Fe2O3-NPs might have interfered with hypothalomo-hypophyseal-testicular axis as a potential endocrine disruptor contributing to the increased serum testosterone levels as reported by. As evidenced from our results the iron content in the serum and testes revealed that Fe2O3-NPs accumulated in both, therefore the Fe2O3-NPs crossed and entered the blood tested barrier as reported in mice by.

Conclusion

The study included twenty (20) offspring divided into two groups, treated and control group. The results of the hormonal study showed the existence of significant increase (P≤ 0.05) in the mean levels of FSH, LH, and Testosterone of offspring treated groups compared with controls.

Genetic variability of the Mite *Varroa destructor* Isolated from Honey Bees in Iraq and Some Middle Eastern Countries

Muntasser S. Mahdi¹, Mahmood B. Ali¹, Aqeel N. Al-Abedy²

¹Department of Geography/ Faculty of Arts/ University of Kufa, ²Department of Plant Protection/ Faculty of Agriculture/ University of Kerbala.

Abstract

This study was conducted to isolate and diagnose different isolates of *Varroa* parasite collected from different regions of Iraq, Iran, Turkey, Syria, Egypt, and Jordan. The different *Varroa* isolates were identified using the polymerase chain reaction (PCR) technique to amplify the mitochondrial cytochrome oxidase gene I (mtCOI) to determine the nucleotide sequences generated from these isolates. These nucleotide sequences were analyzed to identify the similarities and differences in the amplified gene regions. The results obtained from the nucleotide base-sequence analysis indicated that all isolates of *Varroa* parasite collected in this study were *Varroa destructor*. Furthermore, the results showed differences in the nucleotide sequences resulting from the amplification of the target mtCOI by PCR. The isolates from Egypt (No.12) and from Syria (No.14) were the most genetically different among the other isolates in this study (17 samples). By the phylogenetic tree analysis, isolates of parasites numbered with 12 and 14 appeared in separate clades from the other clades of isolates under study. Besides, these isolates (No.12 and No.14) showed differences to other isolates of the same parasite formerly recorded at NCBI. The *V. destructor* isolate of Egypt (12) and Syria (No.14) showed a genetic similarity of 99%.

Key words: Honey bees, *Varroa destructor*, Apiculture in Iraq, Polymerase chain reaction.

Introduction

Bees have an important role in the environment by pollinating both wildflowers and many agricultural crops as they forage for nectar and pollen, in addition to producing beeswax and honey. Like all other living organisms, honey bees are subject to many pests and pathogens that harmfully affect their behavior and production. Among the most important of these pests is Varroa (Varroa destructor), which invaded Iraq for the first time in 1985 and was officially registered as an epidemic pest to honey bees (Apis mellifera L.) in 1987, known then as Varroa jacobsoni (M.H.E.S.R, 1987, 12). The registry was modified afterwards to Varroa destructor according to 16. The Varroa parasite is affected by geographical location and natural climatic conditions, especially temperature, humidity, and others. This may lead to genetic mutations that contribute to causing morphological, physiological and behavioral changes allowing for their continual reproduction (1,7,10,13,17). According to observations by beekeepers, there are new species of Varroa as confirmed by the Iraqi Ministry of Agriculture could be because of imported bees infected with Varroa parasite. 16.

Materials and methods:

Sample Collection

Seventeen samples of *Varroa* parasites were collected directly from the infected bee colonies of ten living parasites from adult *Varroa* females for each sample. They were placed in a separate tube of ethyl alcohol (95%), brought to the Department of Plant Protection/ Faculty of Agriculture/ University of Kerbala, and kept at 4°C until the DNA was extracted.
The samples were collected from different regions of south, central and northern Iraq, as well as samples of bees imported into Iraq. Other samples were obtained from some countries of the Middle East, including neighboring countries (Iran, Turkey, and Syria), where bees can enter Iraq naturally by swarming or male travelling (Table 1 and Fig. 1). The other method of transmission is the beehive trade, often from three countries (Iran, Turkey, and Egypt), while a few bees enter from Jordan, often bee queens, often in informal ways.

Figure (1) Map shows sites of Varroa Sampling, Source: The researcher by GIS software, ArcMap 10.5
Genomic DNA Extraction and PCR Amplification of mitochondrial cytochrome oxidase I (mtCOI) in Varroa genome

To extract DNA from the Varroa parasite, a DNA extraction kit (Favorgen, Cat No. FAPGK 001) was used following the steps recommended by the manufacturer. PCR was performed using the Maxime PCR PreMix (i-Taq) kit (Cat. No. 25026) with the primer pair (CO1-F: TTGATTTTTGTCATCCAGAAGT and CO1-R: TCCAATGCCTAATCTGCCATATTA) to amplify the mitochondrial cytochrome oxidase I (mtCOI) gene.

The target region of Varroa genome was amplified for all samples to be diagnosed using the following PCR steps and conditions: Initial DNA denaturation for 5 minutes at 94°C, followed by 35 cycles each consisting of final denaturation for 30 seconds at 94°C, primer annealing for 30 seconds at 58°C and then an initial extension of the amplified PCR product for 1 min at 72°C with the completion of PCR steps by one cycle of the final extension at 72°C for five minutes. PCR-amplified products were electrophoretically separated on a 1% agarose gel for 140 min at 80 V, 400 mA and visualized with ethidium bromide staining under UV illumination and images were captured using Vilber Lourmat, Taiwan gel documentation system.

Nucleotide sequence analysis of DNA of Varroa Samples

To identify the nucleotide sequences of the PCR-amplified products of the various Varroa samples, the PCR products were sent to the Korean Macrogen company with both forward and reverse primers (CO1-F/R) used in DNA amplification to determine the species of Varroa parasite in the sample collection sites, and the degree of similarity and difference in the sequences of the nucleotide sequences of the amplified DNA of Varroa. The nucleotide sequences of the DNA product was processed into the database available at the National Biotechnology Information Center (NCBI) using the Basic Local Alignment Search Tool (BLAST). The phylogenetic tree was constructed using the MEGA6 program, using the Neighbor-joining method.

Results and Discussion

Molecular diagnosis of Varroa Isolates

The results of DNA extraction from Varroa isolates and their processing (PCR) showed the possibility of replicating the PCR-amplified products and the expected size (approximately 880 nitrogen bases) using the forward and reverse buffer (mtCOI_F/R) (Fig.2).

Figure (2) PCR-amplified products, using the mtCOI_F / mtCOI_R (PCR) pair of Varroa isolates from Duhok (1), Najaf (2), Sulaymaniyah (imported bees) (3), Turkey (4), Karbala (5), Al Muthanna (6), Basrah (7), Diwaniyah (8), Iran (9), Erbil (10), Jordan (11), Egypt (12), Najaf (imported bees) (13), Syria (14), Thiqar (15), Wassit (16), and Kirkuk (17). M= 1Kbp DNA ladder marker. NC: Control treatment (without adding DNA to the other PCR components). The results of the nucleotide sequence analysis of the amplified DNA products for Varroa isolates using BLAST showed that all isolates of the current study belong to V. destructor. The isolates from Egypt (No.12) and Syria (No.14) gave the most different in the nucleotide sequences with 99% similar with the other isolates belonging to the same parasite isolated in this study from different regions in some Middle Eastern countries (Table 2 and Fig. 3).
Figure (3) Similarity and difference in nucleotide sequence alignments of PCR-amplified products of isolates from Duhok (No. 1), Egypt (No. 12), and Syria (No. 14)
The results of the nucleotide sequence analysis for *Varroa* isolates from Egypt (No.12) and other isolates recorded at NCBI indicated that there is a difference in the nucleotide sequences, wherein the genetic similarity ranges between 86-99%. The Neighbor-joining tree analysis showed the isolate (No.12) was appeared in a separate clades from other isolates previously recorded at NCBI (Figure 5).

The results also of the nucleotide sequence analysis of the PCR-amplified mtCOI gene of *Varroa* isolates from Syria (No. 14) showed the presence of a clear genetic variation in the nucleotide sequences with the nucleotide sequences of the other isolates previously recorded at NCBI giving a similarity of 99%. The Neighbor-joining tree analysis showed that the isolate No.14 was appeared in a separate clade from the other clades of the same parasite previously registered in NCBI (Figure 6).

In the current study, PCR was used to diagnose 17 different isolates of the *Varroa* parasite collected from different parts of Iraq and some Middle Eastern countries by targeting the mitochondrial cytochrome oxidase I (mtCOI). PCR has been used efficiently in the diagnosis of many organisms; microorganisms (such as fungi) and insects (*Bemisia tabaci*) to avoid diagnostic problems based on morphological characters. Although phenotypic diagnosis is useful in categorizing the organisms under study into smaller groups before starting other methods of diagnosis, there are many problems associated with the phenotypic diagnosis of organisms, including the need of the diagnosis conductor to the high experience, especially for similar fungal species as well as the need for long time and substantial efforts. There are also other factors that may affect these morphological characters, including the type and nature of growth, moisture and light that can affect some of the morphological characteristics of the insect. Several researchers have also used the difference
between the mtCOI-based sequence to diagnose Varroa isolates from different regions of the world using PCR technology (6,8,22,23).

**Conclusion**

The results obtained from the nucleotide base-sequence analysis indicated that all isolates of Varroa parasite collected in this study were Varroa destructor. Furthermore, the results showed differences in the nucleotide sequences resulting from the amplification of the target mtCOI by PCR. The isolates from Egypt (No.12) and from Syria (No.14) were the most genetically different among the other isolates in this study (17 samples). By the phylogenetic tree analysis, isolates of parasites numbered with 12 and 14 appeared in separate clades from the other clades of isolates under study.

Effect of Preoperative Breathing Exercise on Postoperative Patients’ Lung Functions

Dhiaa A. Al-Reda1, Rajha A. H1
1Adult Nursing, University of Kufa. Faculty of Nursing, Iraq

Abstract

Pulmonary complications after surgery are a major cause of morbidity and mortality and therefore are a source area of concern in both developed and developing countries. Presently, surgical patients didn’t acquire education about deep breathing activities that were adequate and many of them only received some education post operation. Aim of the study: To investigate the Effect of Preoperative Breathing Exercise on Postoperative patients’ Lung Functions. A quantitative quasi-Experimental, Pre-Test and Post-Test design. A non-probability (purposive sample) of (60) patients divided into two equal groups distributed as the case and control groups (30) patients for the case group are exposed to the breathing exercise program, Pursed-lip method, and (30) patients without exposed to the breathing exercise program categories as control group. The study have been carried out in Al-Diwaniyah teaching hospital, This study conducted from 22nd of October 2018 to 25th of June 2019. There were statistically significant difference between case and control groups, patients in the case group had improvement in all parameters of lung functions than control group (P < .05) in the two periods of measurement post-operatively. The program show obvious difference between the lung function for both study and control groups during the post-test.

Keywords: Preoperative, Breathing Exercise, Postoperative, patients’ Lung Functions.

Introduction

Impairment in lungs functions after surgery are one of important postoperative complications, strength of respiratory muscles could be decreased and that one reason lead to lung function change 1.

During surgery, using of general anesthetics can affect the central regulation of breathing by changing the neural drive to respiratory muscles such as the diaphragm and because of this, the respiratory function cannot be separated from anesthesia 2. The components that can alter the pulmonary function contain unconsciousness, ventilation (whether its mechanical or spontaneous), a patient’s position, anesthetics drugs, that were used during the anesthetic process on the respiratory muscles 3. General anesthesia can alter mucociliary function, promoting retention of secretions, causing bronchoconstriction, decreased surfactant production, inhibition of alveolar macrophage activity. Moreover, anesthesia may cause atelectasis instantaneously in majority of the patients as an outcome of chest wall deformation, decreased inspiratory muscle tone, and reduced functional residual capacity (FRC) which may considerably influence gas exchange 4.

The effect of these factors on pulmonary function are appear in the early postoperative period. Lung function, measured as vital capacity (VC) and forced expiratory volume in one second (FEV1), is usually decreased by 35-60%, and a 6-13% Decreased lung function can linger for four months. In the first days following an operation, a decreased lung function can impact impaired gas exchange, and the strength of the respiratory muscle will also decrease during the first days after surgery 5. This may be explained by insufficient diaphragmatic breathing or by the respiratory fatigue that some patients experience during the post-operative period 6. The complications that related to anesthesia, tissue damage, immobilization, inhibition of cough, and incision of abdominal muscles which results in postoperative pain, major causes to decreased the lung volumes and limited airway clearance, which can lead to Post-operative pulmonary complications(PPC) 7-9.

Methodology

Study Design:
A quantitative quasi-Experimental, Pre-Test and Post-Test design have been carried out to study the effect of preoperative breathing exercise on postoperative patients’ lung functions, in Al-Diwaniyah teaching hospital, This study conducted from 22nd of October 2018 to 25th of June 2019.

Setting of the Study:

The study is conducted in Al-Diwaniyah City, Al-Diwaniyah Health Directorate, Al-Diwaniyah teaching hospital, Surgical Wards. This hospital is a governmental, and the largest general hospital, and presents different of the medical therapeutic services in Al-Diwaniyah city.

Study Sample:

A non-probability (purposive sample) of (70) patients undergoing abdominal surgery. (10) patients of the sample for pilot study and (60) patients of the sample is divided into two equal groups distributed as the case and control groups (30) patients for the case group are exposed to the breathing exercise program, Pursed-lip method, and (30) patients without exposed to the breathing exercise program categories as control group.

Criteria for Including the Sample:

1. Adult patients age from 20 years and above.
2. Patients undergoing abdominal surgery under general anesthesia.
3. Stable condition as reported by the physician.
4. Patients with normal respiratory and cardiac functions.

Validity of the Instrument:

The face validity of the study instruments are determined by a panel of (16) experts, have experience more than ten years, from different specialties from nursing faculties.

Reliability of Instrument:

In order obtains the reliability of the study instrument five patients undergoing abdominal surgery are selected from Surgical wards for the purpose of testing the instrument their lungs capacities (FEV1, FVC, FEV%) was measured in preoperative period by used two spirometers at one time, one of them is used in the present study and the other used at Al-Diwaniyah teaching hospital. A comparison between the results of them, The result indicate, spirometers which used in present study is a reliable instrument to measure the purpose of the study.

Through developed questionnaire for Arabic version, demographic and clinical data were collected. While physiological data (Lungs volume) are collected by using the pulmonary function test machine (Portable Diagnostic Spirometer, Mir, Italy) through preoperative and postoperative assessment. During preoperative phase, the assessment was obtained ( before one day of surgery for case group and, in the same day for control group), while in the post-operative phase, the assessment was done at 8th hours and 24th hours after surgery based on the previous scientific references such as Regarding case group the assessment of the lungs volumes applied before and after the application of the program. For the control group, the assessment was performed only without the application of the program. The data collection process has been performed from 11th January to 14th March 2019.

The data have been collected through the use of a constructed questionnaire tool. The data analysis was done through statistical package of social science (SPSS) version (25). The methods of analysis of data include; Descriptive Data Analysis and Inferential Data Analysis

</table>
Table (1) represent the clinical data of the case and control groups. Regarding body mass index (BMI) the table shows most of the sample in both groups are overweight (46.7%) in control group while (43.3%) in case group. In smoking status condition the table shows the majority in control group (76.7%) is nonsmoker and (70%) in the case group. Regarding type of smoking in both groups are cigarette smokers with duration of smoking (66.6%) with period of (10-19) years for control group and (57.1%) for case group who spend more than 30 years in smoking. Regarding chronic disease the study results presents that chronic disease (60%) of case group with chronic disease and (66.7%) in control group with chronic disease(50%) of both group with hypertension. Regarding previous surgery (50%) in case group have previous surgery (20%) of them with Caesarian surgery and about control group (56.7%) have previous surgery (16.7%) of them with Caesarian surgery. Regarding type of present surgery the majority of the case group (40%) have cholecystectomy surgery, and (26.7) of control group have share cholecystectomy and hernia surgery. Concerning duration of surgery (80%) in control group is more than 1:30 hours while the case group is (66.7%).

Discussion

Regarding Table (1) there was a high percentage of patients at age groups (50-59) years old, and the majority of study samples were male. This could be agreeable with their study have the same range age group, and the gender was also mainly male. The present results show
that most patients are primary school graduate, many people might live with number of social and economic barriers to stressful and conflict environment, this can prevent them for achieving higher educational levels, this result could be supported by 12 majority of their study are primary school graduate were (78.5%). It is show that there is non-significant difference between both groups in the baseline pulmonary functions parameters mentioned in the pre-operative period. This may be due to both groups were had resemble characteristic and functionally comparable to each other. The present result is similar to a study conducted by (13,14) are similar with the result of present study, and the pulmonary function test parameters did not differ between two groups before operation. After the application of the breathing exercise pursed lip methods through the present study, the results indicated that there is an improvement in the case group lungs volumes compared with those patients in the control group. The result shows that there is a significant difference between groups. Patients in the study group who demonstrate breathing exercise had a higher pulmonary function in all parameters than in control group at P- value less than 0.05 in all the post-operative periods. The applied method is an effective way to improve the post-operative patients’ lung function. The results of this study agree with the observations of 15, they concluded that the pre-operative deep breathing exercise improves the pulmonary functions, with significantly improved for lungs parameters such as FVC, FEV1 at P-value = 0.003, and P- value less than 0.001 respectively). The study shows that there is a relationship between the patient’s lung volume with their age and body mass index at p-value less than 0.05 after 24 hours postoperatively, while the other results indicate there is no relationship between patients lungs volumes and other demographic and clinical data at p-value more than 0.05. Pulmonary function may decrease and affected by age. The rate of respiratory and blood circulation are increases in childhood and become in a maximum level at age group between (20–30) years, then decline again in the older age. About high body mass index there are some reasons for decline the lung function. Firstly, the diaphragm position in the thoracic cavity is elevated obviously when individual increase weight. Secondly, it appears that fat accumulation on the chest wall will impede the movement of thoracic cage by a direct resistance or the abnormal function of intercostal muscle (16,17).

**Conclusion**

There were no differences between lung function in both case and control groups in the pretest. There is an improvement in the postoperative patients’ lungs function in study group after exposure to an educational breathing exercise program. The program show obvious difference between the lung function for both study and control groups during the post-test. Control group does not present any modification in their lung function post-operatively. In addition, there is relation between study groups and demographical data in age and body mass index only.

**Conclusion**

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** All experimental protocols were approved under the University of Kufa. Faculty of Nursing, Iraq and all experiments were carried out in accordance with approved guidelines.

Glomerular Diseases: Systemic Lupus Erythematosus is Most Common Finding: A Cross-Sectional Study

Fadhil Handhal Khleif 1, Haider Jebur Kehiosh 2, Salman Azeez Aljuborî 3, Sabah Nemah Alfatlawi 4

1 M.Sc. Microbiology/Al-Hindiyah Primary Health Care Centre/ Karbala Province / Iraq, 2 Ph.D. Pathology Consultant / Al-Hussein Teaching Hospital / Karbala Province / Iraq, 3 Ph.D. Microbiology / Professor / Department of microbiology / Faculty of Medicine / University of Kufa / Al-Najaf province / Iraq, 4 Ph.D. Pathology / Consultant / Al-Sader Teaching Hospital / Al-Najaf province / Iraq

Abstract

The objective of this study was to assess the connection amongst’s immunological and histopathological findings of renal biopsy acquired from patients with glomerular diseases. This cross sectional study was done in Al-Kafîl private hospital and included 110 patients who were diagnosed by nephrologist as having glomerulonephritis as per clinical introduction, physical examination and laboratory findings of biopsy. The age scope of patients enlisted in the present investigation was between 2.8 to 72 years. The study included 67 male patients (60.9%) and 43 female patients (39.1%). The examination began at January 2016 and reached out through January 2017. At the point when clinical introduction and the entire workup of examination were at long last joined, with exceptional accentuation on histopathology and immunofluorescent tiny examination, the accompanying classification was gotten. Cases with glomerular association optional to foundational lupus erythematosis represented 27 out of 110 (24.5%). Consequently lupus nephritis is the most incessant reason for glomerulonephritis observed in the present examination. As indicated by the International Society of Nephrology (ISN)/Renal Pathology Society (RPS) grouping of lupus nephritis, the most incessant compose was ISN/RPS class IV (A/C) represented 14 case (12.7%), trailed by ISN/RPS class III (A/C) (8 case, 7.3%)

Key words: Glomerular disorders, SLE, immunoflourescent, Iraq

Introduction

The kidney in spite of the fact that being moderately little size in examination with add up to body weight plays out a great deal of capacities that keep human body at ideal physiological conditions. These capacities incorporate water and electrolyte adjust, corrosive base direction, endocrine capacities and discharge of waste items, for example, urea and creatinine 12. Infection influencing the kidney may include the veins, glomeruli and tubulointerstitial compartments. Glomerular sicknesses represent a huge extent of dreariness and mortality in the populace 11. Glomerular sicknesses are regularly because of of some type of immunological affront. Immunological bases for glomerular damage can be expected do humeral or cell invulnerable reaction 7. Humeral resistant reaction includes a counter acting agent that is independent from anyone else poisonous to certain segment of the glomerulus, for example, Good Pasteur disorder in which the immunizer is coordinated against glomerular cellar layer 15. Then again humeral reaction might be because of affidavit of insusceptible edifices that are either framed in situ or effectively flowing in blood, for example, glomerular damage found in relationship with foundational lupus erythematosis (SLE) 13. Likewise, humeral insusceptible reaction might be because of enactment of elective supplement pathway 4. The established introduction of glomerular sickness is as proteinuria and/or hematuria 5. The time of beginning is exceptionally factor and is amazingly wide so glomerular ailment might be found in youngsters, immature, youthful grown-up and elderly people. The
particular order of the sort of glomerular damage is basic for both treatment system portion and guess of the sickness to be cleared up. For distinct conclusion of glomerular ailment, renal biopsy ought to be performed. Three principle steps take after renal biopsy got for suspected glomerular ailments; these are normal and extraordinary histological stains, electron minute examination and immunofluorescent tiny examination. The innovation of tissue immunofluorescent strategy, by Coons and Kaplan in 1950 and its application on renal biopsy by Mellors in 1955, constrained the requirement for electron microscopy in symptomatic renal biopsy. Immunofluorescence allows the recognizable proof of the guilty party immunoglobulin (IgG, M and An) and furthermore the included supplement segment (C3 and C1q) and furthermore allow the distinguishing proof of safe testimony whether membranous or mesanginal. In Iraq there is extremely set number of concentrates that managed this subject and the greater part of studies took a set number of cases and was constrained to a solitary or various glomerular issue. The vast majority of these examinations featured the histological adjustment as well as clinical angles. The absence of an Iraqi immunologic investigation that arrangements with extensive example and different sorts of glomerular infections defended the conduction of the streams think about.

The Aim of this study was to assess the connection amongst’s immunological and histopathological discoveries of renal biopsy acquired from patients with glomerular infection.

Patients and method

This cross sectional examination was done in Al-Kafif private doctor’s facility and included 110 patients who were analyzed by nephrologist as having glomerulonephritis as per clinical introduction, physical examination and discoveries of research center examinations. The age scope of patients enlisted in the present investigation was between 2.8 to 72 years. The example included 67 male patients (60.9%) and 43 female patients (39.1%). The examination began at January 2016 and reached out through January 2017. The procedure of patients’ determination begun at the nephrology meeting room. Any patient having the accompanying highlights was incorporated into the present investigation:

- Patients with regular picture of nephritic disorder
  - Massive proteinuria, summed up edema, hypoalbuminemia, hyper-lipidemia and lipiduria.
- Patients with regular highlights of nephritic disorder
  - Hematuria, hypertension, azotemia and oliguria
- Patients with highlights that are not suggestive of glomerular association; in any case, urinalysis of them indicated critical proteinuria as well as glomerular hematuria
- Patients with intense or constant disappointment with extra clinical highlights suggestive of glomerular malady

Any patient with highlights that are not suggestive of glomerular sickness and have no proof of huge proteinuria and/or glomerular heamturia was barred from the investigation. Routine histological appraisal, immunoflourescent ponder were the fundamental examination to which all patients were subjected, adjacent to hematological, serological, biochemical examinations and urinalysis.

Results

Demographic characteristics of the study sample

The present study included 110 patients with glomerulonephritis, 67 male patients (60.9%) and 43 female patients (39.1%) with a male to female ratio of 1.56:1. Mean age of patients enrolled in the current study was 31.28 ±13.83 years and it ranged from 2.8 to 72 years, as shown in table 4.1. According to 10 years age intervals patients were distributed as following: 2 patients less than 10 (1.8%), 21 patients from 11.20 (19.1%), 39 patients from 21.30 (35.5%), 23 patients from 31.40 (20.9%), 13 patients from 41.50 (11.8 %), 6 patients from 51.60 (5.5%), 5 patients from 61.70 (4.5%) and a single patient older than 71 (0.9%), as shown in figure 1.
Mean duration of disease is $1.88 \pm 1.66$ years and it ranged from 2 weeks to 7 years. Patients with disease duration of less than one year accounted for 34 (30.9%), patients with 1 to less than 2 years accounted for 19 (17.3%), patients with disease duration of 2 to less than 3 years accounted for 17 (15.5%), patients with disease duration of 3 to less than 4 years accounted for 22 (20%), patients with disease duration of 4 to less than 5 years accounted for 9 (8.2%), patients with disease duration of 5 to less than 6 years accounted for 7 (6.4%), patients with disease duration of 6 to 7 years accounted for 2 (1.8%).

**Lupus nephritis**

Cases with glomerular involvement secondary to systemic lupus erythematosus accounted for 27 out of 110 (24.5%). Hence lupus nephritis is the most frequent cause of glomerulonephritis observed in the present study. According to the International Society of Nephrology (ISN)/Renal Pathology Society (RPS) classification of lupus nephritis, the most frequent type was ISN/RPS class IV (A/C) accounted for 14 case (12.7%), followed by ISN/RPS class III (A/C) (8 case, 7.3%) and lastly by ISN/RPS class III (A) (5 cases, 4.5%). Immunofluorescent study is shown in figure 2 and 3 in which there was mild diffuse segmental granular mesangial deposition of IgG and mild diffuse segmental granular mesangial deposition of IgM.

**Discussion**

In this investigation Cases with glomerular association optional to foundational lupus erythematosis were the most regular and represented 27 out of 110 (24.5%); the most incessant write was ISN/RPS class IV (A/C) represented 14 case (12.7%), trailed by ISN/RPS class III (A/C) (8 case, 7.3%) and ultimately by ISN/RPS class III (A) (5 cases, 4.5%). In one Iraqi investigation, it was demonstrated that 25 (45.5%) cases were because of lupus nephritis and in another Iraqi examination just two cases (3.4%) satisfied the clinical, serological and histopathological criteria of lupus nephritis. We concur with that lupus nephritis is the most incessant reason for glomerulonephritis in Iraq and can’t help contradicting who depicted a predetermined number.
for lupus nephritis in his investigation. In another examination in India, 3 assessed the clinicopathologic parts of crescentic glomerulonephritis and found that 14.7% of cases were because of SLE. Lupus renal malady gives off an impression of being more common in certain ethnic gatherings 10, and this may clarify the high rate of lupus nephritis in Iraqi patients. A similar investigation of SLE in three ethnic gatherings announced that renal malady, which is characterized by American College of Rheumatology (ACR) criteria as persevering every day proteinuria of >500 mg within the sight of cell throws or biopsy proof of lupus nephritis, happened in 45% of African Americans, 42% of Chinese, and 30% of Caucasian patients, individually 10. Another multi-ethnic US companion of SLE patients revealed that renal malady happened in 51% of Africans and 43% of Hispanics however in just 14% of Caucasians 2. In a planned investigation of 216 Chinese patients with new beginning SLE, 31% patients had dynamic renal sickness as the underlying introduction. 8. The general combined frequency of renal sickness was 60% at 5 years post-SLE finding. These investigations delineated that lupus renal association is more typical in Africans, Hispanics, and Chinese than in Caucasians 9.

Conclusion

At the point when clinical introduction and the entire workup of examination were at long last joined, with exceptional accentuation on histopathology and immunofluorescent tiny examination, the accompanying classification was gotten. Cases with glomerular association optional to foundational lupus erythematosis represented 27 out of 110 (24.5%). Consequently lupus nephritis is the most incessant reason for glomerulonephritis observed in the present examination. As indicated by the International Society of Nephrology (ISN)/Renal Pathology Society (RPS) grouping of lupus nephritis, the most incessant compose was ISN/RPS class IV (A/C) represented 14 case (12.7%), trailed by ISN/RPS class III (A/C) (8 case, 7.3%) and in conclusion by ISN/RPS class III (A) (5 cases, 4.5%). In Iraq, SLE is the fundamental driver of glomerular damage.

Synthesis of Diimidazole Has Pyrazole, Isoxazole and Pyrimidine Derivatives and Evaluation as Antibacterial

Sahar Abdullah Kadham 1, Abdul Jabar Kh. Atia 2

1 Department of Biology, College of Science, Mustansiriyah University, Baghdad, Iraq, 2 Department of Chemistry, College of Science, Mustansiriyah University, Baghdad, Iraq

Abstract

New diimidazole contains pyrazole, isoxazole and thiopyrimidine were synthesized by using simple methods. All compounds were synthesized by using hippuric acid (1) as stating material which was obtained from benzoyl and glycine with. pyrazole derivatives (6a – b ) was obtained from reaction (5a – b) with hydrazine hydrate while reaction of (5a – b) with hydroxyl amine isoxazole derivatives (7a – b) were obtained, finally reaction of thiourea was reacted with 5a – b thiopyrimidine derivatives were get (8a –b) . FTIR and 1HNMR spectra were used to characterized derivatives several bacterial species like Pseudomonas aeruginosa, Staphylococcus aureus, and Acinetobacter baumanii were used to tested antibacterial activity

Keywords: pyrazole, isoxazole, imidazole, thiopyrimidine

Introduction

Heterocyclics were found good biological molecules like imidazole 1 molecules with five and six membered rings mostly are high activity 2. All natural products with heterocyclics are important in biologically active system 3 and medicinal to approved drugs. imidazole derivatives in heterocyclic chemistry considered most important compounds and drugs 4 such as Antioxidant activity 5 anti-microbial (6-7), antiangiogenic 8 , antitumor 9 , analgesic 10 . pyrazoles and isoxoles play important role to synthesis biologically active drugs like Antifungal 11 , antimicrobial 12 anticancer 13 , analgesics 14 , Ant helminthic 15 , Ant pathogenic 16, anti-inflammatory 17

Method

Synthesis of [(phenyl carbonyl)amino]acetic acid(1)

Glycine (0.1mol ) in 15ml of 1N NaOH was cooled to 5 and then benzoyl chloride (0.1 mole ) was added to cold drop wise . The reaction mixture was stirring for one hour. The aqueous layer was acidified with 2N HCl and the product was collected and recrystallized from ethanol and product was collected as white powder

Synthesis of (Z)- 2-phenyl -4-benzylidene oxazol-5(4H)-ones (2a - d)

To a mixture of compound (1) ( 0.01 mole ), acetic anhydride (20 ml) and acetic acid (5 ml), (0.01 mol) of aromatic aldehyde was added. And the mixture was refluxed for 4hr and the temperature was reached to 80°C. The reaction mixture was allowed to cool. , then poured into crushed ice and it was allowed stirred for 30 min. the product was recrystallized from ethanol.

Synthesis of 3-(2-amino)-5-arylidine-2-phenyl-3,5-dihydro-4H-imidazol-4-one (3a – d)

To a mixture of (2a – d) derivatives (0.01 mole) in (20ml) triethyl amine , (0.01 mole) of hydrazine was added. And then it was refluxed 2 h. after that the mixture was cooled to RT. And the desired compound was obtained after recrystallizing from ethanol.

Synthesis of 1-[(4Z)-4-(arylidene) -5-oxo-2-phenyl-4,5-dihydro-1H-imidazol-1-yl] thio urea (4a – d)

Potassium thiocyanate was added to a mixture of compounds [3a - d] (0.01 mole) in ethanol (27 ml) and then stirred for 30 min. the mixture was  poured in to could water and then filtered, the solid (desired compound) was recrystallized from ethanol.

Synthesis of (5Z)-5-(4-chlorobenzylidene)-3-(4-oxo-2-thioxoimidazolidin-1-yl)-2-phenyl-3,5-dihydro-4H-imidazol-4-one (5a – d)
To solution of (4a – d) (0.01 mole), in 30 ml of dry benzene chloro acetyl chloride was added and the mixture was heated in water bath at (60 OC) for 3 hrs. with stirring after that the solvent was evaporated, and the product desired compound was recrystallized from appropriate solvent.

**Synthesis of 1-[3-(Aryl)-5-phenyl-3,3a-dihydroimidazo[4,5-c]pyrazol-6(2H)-yl]-2-thioxoimidazolidin-4-one (6a – b)**

To solution of (5a – b) (0.01 mole), in 20 ml of acetic acid hydrazine hydrate was added and the mixture was heated (refluxed) for 5 hrs. with stirring after that mixture poured to water (200ml), and the product desired compound was recrystallized from appropriate solvent.

**Synthesis of 1-[3-(Aryl)-5-phenyl-3,3a-dihydro-6H-imidazo [4,5-c]isoxazol-6-yl]-2-thioxoimidazolidin-4-one (7a – b)**

To solution of (5a – b) (0.01 mole), in 20 ml of acetic acid hydroxyl amine hydrochloride was added and the mixture was heated (refluxed) for 5 hrs. with stirring after that mixture poured to water (200ml), and the product desired compound was recrystallized from appropriate solvent.

**Synthesis of 1-[6-(4-chlorophenyl)-8-phenyl-2-thioxo-1,2,5,6-tetrahydro-9H-purin-9-yl]-2-thioxoimidazolidin-4-one**

To solution of (5a – b) (0.01 mole), in 20 ml of acetic acid thiourea was added and the mixture was heated (refluxed) for 5 hrs. with stirring after that mixture poured to water (200ml), and the product desired compound was recrystallized from appropriate solvent.

**Results and Discussion**

Scheme (1) shown all compounds were synthesized

Ar = p-NO$_2$, p-Cl, p-Br, p-NMe$_2$

Synthesis of target (1) was done by the reaction of amino acid with benzoyl chloride through nucleophilic mechanism. (93%). m.p (186-188), color (White). The FT-IR spectrum of compound (1), shows stretching vibration of (OH) of carboxylic acid at (2610-3390) cm$^{-1}$ and appearance of new band at (3350) cm$^{-1}$ for NH.

Compound (1) was treatment with aryl lead to formation of compounds (2a - d)

2a :yield (79%), FT-IR cm$^{-1}$ C=N(1646), C=O(1729), (C=)ar (1601,1551), (C-H)ar (3083), (NO)$_2$,(1534-13), 1H-NMR(ppm), s,(6.92) for(C=CH) , (7.25-7.76) (m, aromatic protons).

2b :yield (82%), FT-IR cm$^{-1}$ C=N(1657), C=O(1721), (C=)ar (1603,1500), (C-H)ar (3035), (C-Cl) , (1097) , 1H-NMR(ppm), s,(6.88) for(C=CH) , (7.44-7.89) (m, aromatic protons).

2c :yield (75%), FT-IR cm$^{-1}$ C=N(1704), C=O(1640,1509), (C-H)ar (3050), (C-Br) 975. 1H-NMR(ppm), s,(6.76) for(C=CH) , (7.54-7.91) (m, aromatic protons).

2d :yield (80%), FT-IR cm$^{-1}$ C=N(1632), C=O(1720), (C=)ar (1603,1508), (C-H)ar (3066), (C-H)alph (2884-2987), 1H-NMR(ppm), s, (3.11) for(NMe$_2$) , s,(6.35) for(C=CH) , (7.47-7.81) (m, aromatic protons).

Treatment of (2a – d) with hydrazine gives (3a – d)

3a :yield (78%), FT-IR cm$^{-1}$ NH$_2$ ( 3345,3213 ), C=N(1656), C=O(1701), (C=)ar (1610,1503), (C-H)ar (3079) , (NO)$_2$,(1545-1330). 1H-NMR (ppm), s, (5.66) for(NH$_2$) , s,(6.48) for(C=CH) , (7.51-7.77) (m, aromatic protons).

3b :yield (69%), FT-IR cm$^{-1}$ NH$_2$ ( 3401,3234 ), C=N(1651), C=O(1709), (C=)ar (1600,1500), (C-H)ar (3060), (C-Cl) , (1109), 1H-NMR (ppm), s, (5.23) for(NH$_2$) , s,(6.31) for(C=CH) , (7.51-7.77) (m, aromatic protons).

3c :yield (73%), FT-IR cm$^{-1}$ NH$_2$ ( 3389,3143 ), C=N(1666), C=O(1712), (C=)ar (1599,1501), (C-H)ar (3069), (C-Br) 977. 1H-NMR (ppm), s, (5.46) for(NH$_2$) , s,(6.76) for(C=CH) , (7.55-7.92) (m, aromatic protons).

3d :yield (61%), FT-IR cm$^{-1}$ NH$_2$ ( 3345,3207 ), C=N(1643), C=O(1718),(C=)ar (1607,1500),(C-H)ar (3070), (C-H)alph (2879-2980), 1H-NMR (ppm), s, (3.61) for(NMe$_2$) , s, (5.66) for(NH$_2$) , s,(6.48) for(C=CH) , (7.11-7.69) (m, aromatic protons).

Reaction of compounds (3a – d) with KSCN in ethanol, compounds (4a – d) was formed

4a :yield (71%), FT-IR cm$^{-1}$ NH$_2$ ( 3311,3225 ), NH ( 3112), C=N (1646), C=O(1731), (C=)ar (1601,1551), (C-H)ar (3083) , (NO)$_2$,(1534-1330), 1H-NMR (ppm),
Compounds (6a – b) , (7a – b) and (8a – b) were obtained by cyclizing compounds (5a – b) with hydrazine , hydroxyl amine and thiourea respectively.

6a : yield (65%), FT-IR cm⁻¹, NH (3213), NH of pyrazole, (3171), C=N (1645), C=O thio imidazole (1735), (C=)ar (1611,1500), (C-H)ar (3060), (NO₂), (1555-1535). 1H-NMR (ppm), s, (4.29) for (CH₂ , thio imidazole ) , s, (9.22) for (NH ) , s,(8.27) for(NH , pyrazole), (7.53-7.98) ( m ,aromatic protons).

6b : yield (61%), FT-IR cm⁻¹, NH (3269), NH of pyrazole, (3199) C=N(1661), C=O thio imidazole (1739) (C=)ar (1600,1501) , (C-H)ar (3071) ,(C-Cl), (1021). 1H-NMR (ppm), s, (4.19) for (CH₂ , thio imidazole ) , s, (9.82) for (NH ) , s,(8. 79) for(NH , pyrazole), (6.89-7.24) ( m ,aromatic protons).

7a : yield (71%), FT-IR cm⁻¹, NH (3245), C=N (1651), C=O thio imidazole (1743) , (C=)ar (1605,1516), (C-H)ar (3079) , (NO₂), (1532-1530) . 1H-NMR (ppm), s, (4.02) for (CH₂ , thio imidazole ) , s, (9.46) for (NH ) , (6.92-7.48) ( m ,aromatic protons).

7b : yield (77%), FT-IR cm⁻¹, NH (3211), C=N(1670), C=O thio imidazole (1728) (C=)ar (1609,1511), (C-H)ar (3079),(C-Cl), (1011), 1H-NMR (ppm), s, (4.10) for (CH₂ , thio imidazole ) , s, (9.32) for (NH ) , (6.89-7.24) ( m ,aromatic protons).

8a : yield (57%), FT-IR cm⁻¹, NH (3311), NH of pyrimidine , (3165) C=N (1649), C=O thio imidazole (1741) , (C=)ar (1601,1511), (C-H)ar (3092) ,(NO₂), (1539-1535) . 1H-NMR (ppm), s, (4.20) for (CH₂ , thio imidazole ) , s, (9.71) for (NH ) , s,(8.16) for(NH , pyrimidine), (6.72-7.30) ( m ,aromatic protons).

8b : yield (54%), FT-IR cm⁻¹, NH (3302), NH of pyrimidine, (3190) C=N(1644) , C=O thio imidazole (1733) (C=)ar (1600,1500) , (C-H)ar (3085) ,(C-Cl), (1077) . 1H-NMR (ppm), s, (4.51) for (CH₂ , thio imidazole ) , s, (9.76) for (NH ) , s,(8.36) for(NH , pyrimidine), (6.99-7.59) ( m ,aromatic protons).
Table 1. Antibacterial Activity of derivatives (4a – d, 5a – d, 6a – b, 7a – b and 8a – b).

Antibacterial activity of derivatives

It might be observed that derivatives which that tested were active but 8a, 8b, 4b and 6a have high activity toward all types of tested bacterials while compound 5a and 5d have weak activity toward all types of tested bacteria compound 8a was showed high inhibition with E. coli and Proteus mirabilis.

Novel Approach and Cloud Point Extraction Method for Determination of Acetazolamide Drug

Muna Iskandar Mahdi¹, Kassim Hassan Kadhim¹
¹Chemistry Department, College of Science, Babylon University, Iraq

Abstract

Acetazolamide was hydrolyzed to primary aromatic amine by using (0.4) M NaOH under reflux. The product was evaluated by two a ways. The first way, Diazotization coupling reaction (approach) as simple, sensitive, rapid and selective Spectrophotometric method, using 8-hydroxyquinoline as Chromogenic reagent to give Azo dye (red) in basic medium. The second way involves applying Cloud point extraction, using Triton-x₁₁₄ as surfactant. The Azo dye was diagnosed by FT-IR, ¹HNMR and UV-Visible technique. The analytical data for Approach and Cloud point extraction method, involve concentration rang (5-150), (0.5-6) µg.mL⁻¹, molar absorptivity (2.3×10³), (1.3×10⁴) L.mol⁻¹.cm⁻¹, Sandall’s sensitivity (0.096) µg.cm⁻² (0.017) µg.cm⁻² and detection limits (0.952) µg.mL⁻¹ and (0.043) µg.mL⁻¹ respectively. In addition the measurement enrichment factor (100) and preconcentration factor (6.30), The proposed methods don’t affect by the existence of excipients so the methods were applied successfully in determining Acetazolamide in pharmaceutical preparations.

Keywords: Hydrolysis Acetazolamide, spectrophotometric determination, Cloud point extraction, Diazotization coupling reaction, 8-Hydroxyquinoline.

Introduction

Acetazolamide a carbonic anhydrase inhibitor, which is used primarily to reduce intraocular pressure by decreasing aqueous humor formation, therapeutically for treatment of glaucoma, epilepsy and as a diuretic and has been used clinically since 1954 ¹⁻⁴. Acetazolamide in either medicinal forms or biological fluids were estimated in several techniques and methods have been declared in the literature, including HPLC for the quantification of acetazolamide in human and rat plasma ⁵⁻⁷, LC/MS and GC/MS ⁸⁻¹⁰, LC-UV ¹¹⁻¹³, and spectrophotometry for determination acetazolamide and other sulfonamide drugs ¹⁴⁻¹⁹. Applications of cloud point extraction techniques for estimation of some elements and drugs ²⁰,²¹. The present paper involves a novel determination of acetazolamide in pure and pharmaceutical formulations by Diazotization coupling reaction (approach) and Cloud point extraction spectrophotometric method, depending on basic hydrolysis of acetazolamide to primary aromatic amine, and coupling the product with 8-Hydroxyquinoline as a chromogenic reagent to give Azo-dye in alkaline medium.

Experimental

Instruments

The scanning of all spectrums and measurements of the absorbance at selected wavelengths achieved by T80 UV-Visible Spectrometer PG Instrumental Ltd, UK, with quartz cell matched 1 cm, Infrared spectra were registered using FT-IR, Shimadzu, Japan, ¹HNMR spectrum was registered using NMR Burker DPX 400 spectrophotometer operating at 300 MHz. the chemical shift δ is quoted in ppm relative to DMSO-d⁶, while the pH was adjusted using 340i pH-meter WTW, Germany, and Heating-Cooling Water Bath – Haak Fe, Sartorius

Chemicals and reagents

Highest purity of Acetazolamide (C₄H₉N₆O₃S₂) was gained from state company for drug Industries and Medical Appliance-(SDI) Samarra-Iraq, 8-hydroxyquinoline (C₉H₇NO),Sodium nitrite (NaNO₂),Absolute ethanol(C₂H₅OH),Sodium hydroxide (NaOH), Sodium carbonate (Na₂CO₃) were gained from the BDH Company with Purity 99.00%. Hydrochloric acid (HCl) was gained from a BDH Company with
concentration 37.00%. Triton X-114 from Arcos organics, New Jersey, USA with purity 100%. Pharmaceutical preparations that were used in this study were Cidamex and Diamox 250mg/acetazolamide from CID Egypt and France respectively.

**Hydrolysis of Acetazolamide**

0.1 g of Acetazolamide was hydrolyzed in alkaline medium by using 0.4 M NaOH under reflux for 2 hours. During the reaction, the secondary amide is converted to the primary amine. The synthetic path of the product is shown in Scheme I. The hydrolysis product was cooled and diluted to suitable volume using distilled water to obtain a stock solution (2000 µg·mL⁻¹). More dilute solution was prepared daily by neutralizing of stock solution with dilute hydrochloric acid and dilute to final suitable volume using distilled water. The tablet sample (Cidamex and Diamox 250mg/acetazolamide) were prepared in the same manner.

2 mol. from the hydrolysis product was converted into dizonium salt ion by using 0.3 mL HCl 1 M and 0.2 mL NaN₂ 1%. The dizonium salt ion was coupled with 1 mol. 8-hydroxyquinoline in alkaline medium to give azo-dye. The synthetic path of the azo-dye is shown in Scheme II. The azo-dye was precipitate, purified and diagnosed by FT-IR, ¹H-NMR and UV-Visible technique as shown in Fig.2, 3 and 4.

**General procedure**

**General procedure of Approach method**

The calibration curve of acetazolamide was constructed by using a series of (10 mL) volumetric flask. Increasing volumes (0.1-3 mL) from Acetazolamide solution after hydrolysis (500 µg .mL⁻¹), mixed well with (0.3, 0.2 mL) from Hydrochloric acid (1 M) and (1%) Sodium Nitrate respectively, and stand for (5 min) to complete formation of dizonium salt. Then added (2.5 mL) 8-Hydroxyquinoline (0.03M) and (0.7 mL) Sodium Hydroxide (0.4 M). The volume was made up to mark with distilled water. The absorbance for all solutions was measured at (502 nm) at (25°C) against solution blank.

**General procedure of Cloud point extraction method**

A series of (10 mL) volumetric flask, increasing volumes (0.05-0.6 mL) from a solution of Acetazolamide after hydrolysis (100 µg .mL⁻¹) mixed well with (0.1, 0.2 mL) from Hydrochloric acid (1M) and Sodium Nitrate (1%) respectively, and stand for (5 min) to complete formation dizonium salt. Then added (0.5 mL) 8-Hydroxyquinoline (0.005M) at pH=7.2 by using Sodium carbonate (0.2 M). The volume was made up to the mark with distilled water. The solutions were transferred into a centrifuge tube with added (0.5 mL) Triton X-114. The mixture was transferred into hot water bath about (10 min) at (55°C) to form a cloud solution. The mixture separated into two phases by centrifuge (10 min) at (3500 ramp), The aqueous phase decanted and the surfactant-rich phase diluted with (0.3 mL) absolute ethanol. The absorbance of final solutions was measured at (502 nm) against blank solution was prepared in the same away.

**Result and Discussion**

**Identification of the prepared drug and Azo Dye**

Identification of the Hydrolysis product and Azo Dye. The hydrolysis product was prepared as explained in paragraph 2.3. The qualities experimental were involved tests for amine group by using Nitrous acid test and Azo-dye test. The hydrolysis product (5-amino-1,3,4-thiadiazole-2-sulfonamide) give yellow solution result from a reaction between a primary aromatic amine with concentrated HCl and NaNO₂ to formation diazonium salt ion, while the acetazolamide before hydrolysis not reaction. The two compounds were tested also by azo-dye test. The hydrolysis product after formation diazonium salt ion was coupled with 8-Hydroxyquinoline in alkaline medium to give azo-dye, while the Acetazolamide before hydrolysis not reaction. This azo-dye was prepared by taking a stoichiometric amounts was precipitate, purified and diagnosed by FT-IR, ¹H-NMR and UV-Visible technique.

IR spectrum of azo-dye showed in Fig.1. one peak at 3417 cm⁻¹ assigned for stretching (O-H) of phenolic group, peak at 1426 cm⁻¹ assigned of stretching (N=N), and other peak 1575,1145 and 879 cm⁻¹ assigned for stretching (C=N) thiadiazole, (S-C) and (C-S-C) groups respectively. This mean the formation of the aromatic primary amine group by hydrolysis of Acetazolamide and converted the amine in to diazonium salt in the presence of HNO₂ and coupling the last with 8-Hydroxyquinoline in alkaline medium. The ¹H-NMR spectrum (DMSO-d6, 400 MHz) of azo-dye complex showed chemical shifts at δ 1.66 (1H, -SO₂NH₂), Singlet broad band at δ 3.5 refer to water in the solvent, DMSO, where its band δ 2.5, δ 5.5 (1H, aromatic -C=O-H), δ 7.1(2H,C-H₆₅)
quinoline), δ 7.4 and 7.5 (3H,2H, C-H\textsubscript{22} quinoline), δ 8.3 and 8.85 (2H,1H, C-H\textsubscript{21} quinoline)\textsuperscript{26-28} as shown in Fig.1. The qualitative and quantitative study of drug after hydrolysis, also done by UV-Visible technique. The Azo-dye complex (color product) scanned at (700-400 nm), and give a maximum absorption λ\textsubscript{max} at (502 nm) versus blank solution. While the scan of the blank solution versus water doesn’t give any absorption at λ\textsubscript{max} for colored product as shown in Fig.3. This property was adopted in the estimation of trace amounts from Acetazolamide in pure and pharmaceutical preparations. The effect of various experimental conditions as concentration, volumes from 8-Hydroxyquinoline reagent, volumes of HCl (1M), volumes of (1%) Sodium Nitrate, different types of bases, various volumes of Sodium Hydroxide (0.4 M) and temperatures of formation of (40 µg.ml\textsuperscript{-1}) azo dye were studied. The starting point involves using (0.5mL) from (1M) Hydrochloric acid with (0.5 mL) from (1%) Sodium nitrate, stand for (5 min), then (0.5mL) from (0.05M) 8-Hydroxyquinoline, and (0.5mL) from (0.4 M) Sodium hydroxide were added in (10 mL) volumetric flask. The absorbance of the solutions was measured at (λ\textsubscript{max}=502nm) against blank solutions after (5 min) since the beginning of the coupling reaction. The effect of various experimental conditions shown in Fig.2.

Selection Optimal Experimental Conditions of CPE method

The effect various concentrations, volumes of 8-Hydroxyquinoline reagent, volumes of HCl (1M), optimum pH value, volume of Triton X-114 5%, also effect of temperature and incubation time on formation of surfactant of (5 µg.ml\textsuperscript{-1}) azo dye were studied. The starting point involves (0.3 mL) of Hydrochloric acid (1M) fellow (0.2 mL) of Sodium nitrate (1%), stand for (5 min ), then (0.3 mL) from 8-Hydroxyquinoline (0.005M), at (pH = 7) Sodium carbonate with (0.3 mL) Triton X-114 5% were added in (10 mL) volumetric flask. The mixture was heated (10 min) at 55°C in water bath. The mixture was separated by centrifuge Ramp=3500 at (10 min). The surfactant rich phase was diluted with (0.3 mL) absolute ethanol and the absorbance of the solution was measured at (λ\textsubscript{max}=502nm) against the blank solution The effect of various experimental conditions shown in Fig.2.
Calibration curve

After fixing all the optimum conditions for the reaction of acetazolamide after hydrolysis with 8-Hydroxyquinoline of approach and cloud point extraction method the calibration curves were constructed as shown in Fig.3. The all analytical values were calculated with accuracy and precision result are summarized in Table.1. The results shown each method has a good accuracy and precision.

Stoichiometry of Reaction and mechanism

The methods of Mole ratio and Continuous variation, Jobs method were used to detect the stoichiometry of azo-dye formation from reaction 8-Hydroxyquinoline reagent with acetazolamide drug. The results obtained in Fig.4 shown that 2:1 acetazolamide to 8-hydroxyquinoline was formed at 502 nm. And The average conditional stability constant of the colored products in water at optimum conditions was $6 \times 10^{12}$ L² mol⁻². The azo dye has high stability because the acetazolamide have electron with drawing group (sulfonamide) makes $\text{O} \rightleftarrows \text{N}$ group more positive charge and 8-Hydroxyquinolnic have electron donating group makes ring very active so easy formation of high stability azo-coupling reaction between acetazolamide and 8-hydroxyquinoline[26]. The proposed mechanism of reaction illustrated in Scheme.II.
**Pharmaceutical applications**

The proposed methods approach and cloud point extraction were applied successfully for determination three concentrations form Acetazolamide in (Cidamex and Diamox 250mg) tablets as shown in the Table 3, after studying the effect of additives by adding separately excess amounts about (10:1) from additives to (40 µg.mL⁻¹) acetazolamide solutions under optimum reaction conditions followed in the calibration curves. As shown in a Table. 2.

The Effect of Pilates Exercises in the Repair of the Aberration and Balance of the Muscles of Shoulder Girdle as a Beginning for the Fitness

Hussein Ali Kadhim¹, Haidar Shmkhi Jabar¹

¹Physical Education and Sports Sciences, Thi-Qar University, Iraq

Abstract

Fitness refers to the good health of athletes, then, it is necessary for every athlete to duty the importance of management and agreement in the training of muscle groups then everything related to the substratum and muscle balance and evaluate it by using the Pilates way to identify its elements and secrets so as to raise the substratum of the athlete and rehabilitation of distortions and deviations, creating healthy habits, and spreading fitness awareness among athletes through working to improve strength, lengthening and muscular balance of the shoulders. Thus, the researcher used the experimental approach by using the experimental design with one suitable group of the research, while, the sample of the research that made up of (12) athletes, that has been chosen by the researcher by using the intentional method for those who are suffering from the aberration of the shoulder fall. The researcher made sure to applied the Pilates exercises by using repeat contraction that aims to improve muscle balance, strength and flexibility of the sample of the research, with (8) weeks and consists of (24) Training modules, (3) modules a week, the most important conclusion in the research is that the using of Pilates contribute to reduce and rehabilitation the aberration of the shoulder fall, if the essential strength of the shoulder girdle muscles that assist in developing the muscular balance, it can be concluded that these exercises agreed with the aberration of shoulder fall and muscle balance.

Keywords: Health of Athlete, Fitness, Muscle Balance.

Introduction

Allah the almighty is giving the health to mankind to be crown for them, Allah the almighty says in the Glorious ¹. We have indeed created man in the best of moulds, the human body is very accurate and complex, it is created to the fullest level to be ready to adapt to all the requirements of the environment, Fitness refers to the good health of athletes, then, it is necessary for every athlete to duty the importance of management and agreement in the training of muscle groups, which required to planning in order to achieve a high ² level of muscle balance whether it is in the body parts (right – left) or in one part for the muscles (stretching and shrinking), especially in the joints and extremities that work in the activities of flinging balls and beating on the basis of the muscles of the shoulder girdle, then ignore the muscles experiences of balanced force of the left and right shoulders through the performance ³ of movements of the main goal leads to appearance of the aberration of shoulder fall, the favorite arm in the activities of throwing and beating in the two games (volleyball - handball) ⁵. Therefore, the existence of such a kind of aberrations in the body changes its mechanics in the performance of these different skills and dispersion of power in the side paths do not work in the same skill then it be the deviation of the area that is the most at risk and cramp ⁶. The significance of research lie in the study of all concerning with the substratum and muscle balance and evaluate it by using the Pilates way to identify its elements and secrets so as to raise the substratum of the athlete and rehabilitation of distortions and deviations ⁷, creating healthy habits, and spreading fitness awareness among athletes through working to improve strength, lengthening and muscular balance of the shoulders. The balance of muscle is the main part to make a good health (fitness), also this method prepares the body type to another perfect body.
The Methods and Practical Procedures of the Research:

The Methodology of the Research

The researcher used the experimental method by using the experimental design with one group which is suitable for the research.

The Sample of the Research

The sample of the research that made up of (12) athletes of first club athletes (volleyball- handball) in Thi-Qar, that has been selected by the researcher by using the intentional method for those who are suffering from the aberration of the shoulder fall. The researcher made a similarity of the following variables:

Table 1: Shows the Coefficient of Skewness to Measure Pre-Test of the Research Sample in Some Main Variables

</tbody>
</table>

The previous table shows that all the values of the Coefficient of Skewness between (-1,1), so this indicates to the similarity of samples in the research variables before make the main experience.

The Research Tests

The Aberration of the Shoulder Fall: It is detected by drawing a line between the two non-sticky papers placed on the lateral top of the shoulder joint (anatomical points) on both sides of the body. If the anatomical point forms a current angle (0 °) with the frontal axis (axial axis), that means this is not aberration, however, if the degree of angle increases, this indicates that there is a quantum deviation and the angle is measured in degree by the program (Kinovea) as in Fig. (1).

The Tests of Muscle Balance of Muscles That is Working on the Shoulder Joint

The maximum strength of the underlying muscles (capture, rumbles, dimensions, roundness, internal rotation, external rotation) of the shoulder joint was calculated by way of the number of times a movement was performed with a load of weight 5 kg, and then the maximum force value of the right shoulder and shoulder (1) and then calculate the balance of muscle balance through equation (2) the closer the ratio of 100% indicates that there is a balance between the muscles of the body (shoulders):

\[
RM-1 = \frac{\text{raised weight} \times 100}{\text{Number of repetitive repetitions} \times 2} \quad (1)
\]

Muscular balance = high shoulder force ÷ strength of low shoulder × 100 \( \ldots \) (2)

The Main Experience

The exercises were conducted after reviewing a number of sources related to sports training related to the subject of the research. After presenting it to the experts, the exercise was started in the form of repetition contract to improve the muscle balance and development of muscle strength and elasticity for the members of the research sample on 15/1/2019 until 20 (3) units per week (Sunday - Tuesday - Thursday) for all muscles and in the method of directing the endurance (3-1) between the weeks while the orientation between the days (2-1), “The number of repetitions (3-5) and the number of groups
of (3-5) groups may be included researcher intensity training by giving exercises on both sides and then per party either using different frequencies or varying intensity of training for each side of the body where focused The researchers were trained to maintain the strength and increase the lengthening of the low shoulder while the shoulder training was high by increasing the strength and maintain the level of muscle extension and since the training intensity used in the development of flexibility is (100%) the intensity of performance will be using the researcher to use endurance guidance based on the maximum exercise time intensity (100%) directed by hard training.

The Analysis and Discussion of the Results

Explain and discuss the results of differences in shoulder fall deviation for pre and post-tests of the groups

The Experimental Research:

We see that the values of shoulder fall deviation of the research group have evolved by (39.534) as it appears that the value of the deviation of the shoulder fall by the dimensional test has evolved significantly from what it was in the tribal test and the researchers attribute the reason for this ratio of evolution to the physical awareness played by the researcher in educating those affected by the deviation of the fall The shoulder has led to positive results for the research, and this is confirmed by raising awareness of the dictionary is one of the methods used in preventing deformities, especially deformities that did not reach the stage of composition. By presenting the table for the deviation of the shoulder fall, we found there a clear decrease in the degree of this deviation and the researchers attribute the reason for this and generally to the practice of the sample members to the training of the rehabilitation using the method of Pilates, and that this improvement was attributed by the researchers the full commitment of the members of the sample performance all Pilates training vocabulary, which contained physical exercises that means devices and aids to treat and rehabilitate this condition, has been repeated (3) times a week for twelve weeks. Hence it can be said that the goal of the research was achieved and was recognized the effect of exercises using the method Pilates prepared to correct the deviation of shoulder fall which contributed to the body’s correct ability, as well as improving the muscular balance of the shoulder girdle and increasing its flexibility, and strengthening the muscles, it is a comprehensive exercise that works to rehabilitate the body from all aspects.

6 The muscular balance of the outer rotation muscles of the shoulder % Pre 79.399 7.908 13.132 Post 91.403 9.584 9.417

We can see that the values of muscle balance of the shoulders of the post-test has evolved significantly from the post-test and attributed the researchers cause this development to increase the growth of muscle strength in a balanced balance of the right shoulder compared to the left shoulder and thus contributed to modify the body from the previous situation to the ideal situation which should be. The two researchers attributed this to the nature of exercises applied by the research group Pilates exercises performed by the research sample on a regular basis and within different frequencies and times of constancy specified, contributed to increase the muscle balance in the muscles of the shoulder girdle as well as to get the ideal shape of the shoulders, Musculature between the underlying motor muscles (rounded to the inside) and the corresponding muscles (rounded out) not only happens in the force but also occurs in the lengthening, The essence of the exercises applied by the research sample was to focus on an ideal combination of strength and length, which achieves the goal of researching that the proposed program of balance in muscle strength has an important effect on the development of muscle balance in general that compatibility between fist muscle groups and relaxed muscle groups will helps to increase the equal strength of the muscles of the body in order to achieve an acceptable physical balance of the body, meaning the shape or position taken by the body during movement or stillness helps to maintain the center of the body’s weight within the base of the balance of the parts of the body, especially the shoulders in a hierarchical form from the top down as a result of the development of the balanced strength of the shoulder girdle muscles, which in turn help to move the weight of these parts gradually, balanced and equal between the bones, joints, muscles and ligaments of the body.” Keeping the muscles in balance with increasing strength is the first requirement to develop the muscle’s ability to produce maximum strength in the maximum range of motion at the highest possible rate of speed, as well as to increase the muscle capacity of the left arm (non-strike or aimed) during the technical performance of the events of throwing and beating Has a significant impact on the improvement of the ability of the strike arm or as a result of the principle of the transfer of the impact of training from the arm of non-working to the labor force, and also find that the rate of progress of the arm is preferred than the preferred arm due to neglect in the previous training programs and the varying levels of strength and ability of the shoulders agree with the main goal of research is to balance the muscle strength between muscle groups working and non-working and this is what achieved exercises for balance in muscle strength.

Conclusions
Through the results between the pre and post-tests, the application of the exercise Pilates therapeutic treatment on the devices and tools helped significantly improve the strength and flexibility of the shoulders of the muscles of the shoulder girdle as well as reduce the degree of deformity of all injured. That is, the curriculum was in line with the deviation of the shoulder fall. The rate of development between the results of the pre and post-tests of the variables during the study was effective and in favor of the post-test of the deviation of the shoulder fall and muscle balance.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Effect of Specific Tactical Exercises in Some Biochemical Indicators and Psychological Endurance and Achievement of 400 M Hurdles for Young Players

Mahmoud Nasser Radi, Ali Bukheet Hassan, Muntadher Mohammed Ali

Faculty of Physical Education and Sports Sciences / University of Kufa

Abstract

This study dealt with several topics including the introduction of the research and the importance of the use of specialized tactical training during the training units, which are manifested in the development of biochemical indicators, psychological tolerance and performance of the effectiveness of 400 m hurdles, so researchers thought to conduct this study and go in the process to identify the results that will be achieved. In the results to the lack of the use of specialized lactic exercises, which are based on scientific foundations and that would make adaptations functional, in addition to the effectiveness of this need of self-sufficiency of large runners because it is a difficult activity that requires the will and determination to win, if The research problem involves two main axes: the first is the low speed restriction and tolerance of the special speed in the 400 m hurdles, and the second axis in the search is to obtain a high level of functional efficiency of some biochemical indicators associated with special speed and the tolerance of the speed Therefore, the researchers considered going into this experiment.

Keywords: biochemical indicators, psychological endurance, achievement

Introduction

The achievement of sport requires the use of the scientific method of modern planning in various fields, where it began to take a large space to create a sophisticated world using it in all methods and scientific methods and in all areas of life 1, including sports, which is one of the important areas that reflect the culture of peoples. The emergence of modern science in the field of sports, especially in the science of training and physiology, the great impact in the development of the sports side and thus the evolution of athletes by upgrading their levels to the best compared to the previous level 2. The effectiveness of the arena and the field of sports events reflected the scientific progress achieved and reflected on most of the activities 3, including digital levels of times in track (running, jogging, walking, barriers and barriers) and distances in the field (jump, throw and jump) and points in the composite competitions (Decathlon for men – sevenfold for women) 4. Including the 400 m hurdles, which are very difficult to perform and their skills, and therefore require skill and physical training to suit the difficulty of the players during the competitions. Hence, it was necessary to use specialized lactic training because it has a positive effect on the development of functional efficiency 5 and upgrading the level of training of the player and the training and psychological state as the exercise exercises used, which is one of the most important factors of success and progress in performance provided that it is built on the basis of scientific correct to contribute In order to increase the efficiency of the athlete to achieve the best achievement, hence the importance of research in the use of tactical training specialized during the training units, which are reflected in the development of biochemical indicators and psychological tolerance and performance of the effectiveness of 400 m hurdles. So researchers thought to conduct this study and go into the process to identify the results that will be achieved. The 400 m hurdles are difficult games that require integration of physical elements and skill performance as well as
They were divided into two groups (experimental and control) equally by random method. Table (1) builds the community and the research samples.

Sampling homogeneity and equivalence of the two research groups:

**Homogeneity of the sample:**

In order to adjust the variables that affect the accuracy of the search results, the researchers sought to verify the homogeneity of the research sample, which is related to the morphological measurements (length, mass mass, temporal age). The researchers used the torsion factor before applying the main experiment to the control and experimental groups, As shown in table (2).

**Measurement method:**

1. Five minutes after the player’s 400m hurdles test, this is the best time to measure lactic.

2 - The measuring tape is placed in the location assigned to the device.

3. After placing the tape, the code number of the tape will appear. A blood sample will then be taken through the use of a complaint through which a finger is pricked and then pressed to allow us to extract the blood drop.

4. Note through the screen device and after raising the finger for a few seconds will appear on the screen the proportion of lactic acid in the blood and according to the specified percentage.

The record: A blood drop from the finger that has been pricked by a LACTATE PRO 2 device is used to obtain the drop of blood and place it in the measuring tape placed in the device . The blood is drawn by the medical staff, And in recent years used modern devices and simple can be carried by hand to measure the amount of lactic acid in the blood after the implementation of the
physical effort for about five minutes according to the consensus of expert experts after the implementation of the physical effort required to know the movement of the escalation of the amount of lactate blood and landing after the physical effort to ensure the transfer of the largest amount of The lactic acid from the muscles to the blood and put this sample of blood in the device, measuring the amount of lactic acid after several seconds and read the figure that appears in the screen of the device, which represents the measurement (Mmol / L³), and Yoshida, 1984 that lactate responses in The veins are better responsive to lactate arteries. 2

2- Measuring the level of concentration of dehydrogenase (LDH) in the blood:

The concentration of the enzyme dehydrogenase (LDH) was measured after the completion of the 400 m hurdle test. The laboratory sits on a chair immediately after 5 seconds, and the venous blood is withdrawn by (2 cc) by the chemist from The research community (14) hostility, which is sufficient amount as indicated by the instructions attached with the measuring tape, which is placed in the tubes (medical) written on the name of the player and number, and was transferred to the laboratory of Sadek Specialist directly, where the analysis of the enzyme By the specialist doctor.

Second - Psychological Endurance Scale:

In order to reach the goals that were developed, the researchers adopted the psychological stress scale prepared by 3.

The scale may be from (64) paragraphs, see Appendix (2).

Third: Test run 400 m hurdles:

- Objective of the test: measuring the real achievement of the competition.

As for the difference in the experimental group of the variable (heart rate after the effort), the researchers attributed to the use of the special lactical training that was prepared and applied to the members of the experimental group, because the runners were exposed to the effort (anaerobic), seeing 11 Physical exertion is considered the most important factor affecting the heart rate, as the rise of the pulse during the effort is normal in response to the effort exerted to meet the body’s energy needs, which the heart and circulatory system to provide them by increasing the heart rate or the size of the blow “ . 12

moral
The differences between the control and experimental groups were due to the quality of the exercises. The results showed that there were significant differences between the two groups (control and experimental) in the concentration of lactic acid in the blood and for the benefit of the experimental group. The specialized lactic prepared and designed by the researchers according to the physiological bases, which is compatible with the prevailing energy exchange system for the effectiveness of 400 m. Based on the scientific foundations of sports training and sports physiotherapy, as these exercises were prepared according to the system of lactic energy and this helped the athletes to get rid of lactic acid quickly, and researchers believe that sports training leads to increase the work of organizations to eliminate the biological increase of lactic acid, The exercises resulted in these differences after the effort between the two groups and after training for the concentration of lactic acid in the blood, which led to a state of improvement in the experimental group and thus an improvement in the work of the functional devices we note the low concentration of lactic acid. The concentration of lactic acid in the blood of well-trained athletes is less comparable to non-trained or less effective training if they do the same training or effort.

**Conclusions**

Based on the research results reached within the research community, the following conclusions were reached: specialized lactic exercises helped to develop the concentration of lactic acid in the blood. The specialized lactic exercises contributed to the high concentration of the enzyme (L.D.H) in the blood. The specialized lactic exercises were in the level of achievement in the sample research.

Comparative Molecular Study between Some Plant Extract and Tinidazole of Hydatid cysts in Basrah, Southern Iraq

Jalal Y. Mustafa1, Ghaz Y. Azzal1, Suzan A. Al-Azizz1, Fatin A. Muatafa2, Arwa R. Lazim2

1Veterinary Medicine colleges / Basrah university, Iraq, 2Education colleges of Biological science / Basrah University, Iraq

Abstract

Hydatid disease or Echinoccosis is one of the serious public health problems. This study was designed as a comparative molecular study between some plant extract and tinidazole of sheep hydatid cysts in Basrah province. In this study, 213 sheep were examined and the number of those infected with hydatid cysts was 75 (35.2 %). The results showed that hydatid cyst were detected successfully by performing PCR technique. In addition, *Quercus aegilops* has been shown the best plant extract for destroying all genes, the second plant extract which is *Capparis spinosa* showed destroying of two genes (*G6-7, COI*) and failed to destroy (*sh4-1*). Furthermore *Prosopis fracta* has shown to destroy only (*G6-7*) and tinidazole failed to destroy any of these genes used in this study.

Key words: Comparative Molecular Study. Plant Extract with Tinidazole.

Introduction

Hydatidosis is one of the very important parasitic defect of domestic animals that cause economic losses and public health disease worldwide. It is caused by adult or larval stages of cestodes (metacestodes), which is belonged to the genus *Echinococcus* and the family *Taeniidae*, also known as Hydatid Disease, is an infection caused by the larval stage of the flat worm *Echinococcus granulosus*. It has a worldly distribution and is one of the most general parasitic zoonosis. The metacestodes progress are fluid - filled hydatid cysts, in which protoscoleces are construct as the following generation of tapeworms. In liver and lung, cyst develop. Their growth cause acute defect and death in the intermediate host. Protoscoleces inside entire hydatid cysts in organs of perished or slaughtered animals stay infectious for up to 2 weeks, according to the temperature and other conditions. It has been observed that tinidazole has the ability to rupture the helix structure of DNA and prevent building of nucleic acid which leads to destroy the cells and the parasite. Many types of medical plants have been used to treat some parasitic infection. Arab people have traditionally used *Quercus sp.* to treat dysentery (which is caused by *Entamoeba histolytica*), stomach cancer and bloody vomiting, as well as many disorder like eczema, cancer healing and vomiting. This is due to the presence of active substance (Phenols and Tannins) in the plant. Acorns serves an paramount role in early human history and it were a source of food for many cultures around the world. In the past, the poorer would origin eat acorns in their food. According to Edible and Useful Plants of California, by Charlotte Clark, “people who use acorns today concur that they resemble other nuts in oiliness and taste”. In general, acorn flour contains significant quantities of calcium, magnesium, phosphorus, potassium, sulfur, fat and protein. Many species of *Capparis spinosa* extract, many of these species are reported from Iraq, northern to southern of the country. The plant is well known for the edible buds and fruits (caper berry), which are consumed pickled. *Prosopis fracta* is belonged to Memosaseae family. It is a grapple shrub with 30-100cm height, grows extravagantly in Iraq.

Materials and Method

In this study, A total 213 organs (lung and liver) of sheep infected with hydatid disease were examined to determine the effect of some plant extract comparing with drug used for treatment (tinidazole) from the period between October 2018 to March 2019. The hydatid cysts were taken from the infected organs and
put in a clean container with 70% ethyl alcohol and transported to the laboratory of Veterinary Parasitology at College of Veterinary Medicine / University of Basrah. The samples were divided to five groups, each group has 10 samples as follows: group one was a control, represented by cyst without any treatment, group two was treated by tinidazole, group was three treated by *Capparis spinosa*, group four was treated by *Prosopis fracta* and group five was treated by *Quercus aegilops*. The extract or tinidazole after prepared to the plain tube were added to each group, followed by adding part of the germinal layer of the cyst for 24 hours. A part of cyst of each group was processed for DNA extraction.

The aqueous extract was prepared by distal water and plant extract according to with some modification. Twenty five gram of plant powder were added to 100ml distal water, and left for 24 hours on magnetic stirrer (IKA-combinimag) type RCT, the extract was then filter by vacuum pump using special filter paper type Whatman No-1. The extracts were concentrated and streams by rotary vacuum evaporator in type Rota Vapor-RE, Buchi, at Biochemistry Laboratory colleges of science / University of Basrah. After drying them, they were kept in dark bottle until used.

**DNA Extraction:**

DNA was extracted from liquid (Protoscolices) and germinal layer using Wizard® Genomic DNA Purification Kit (Promega/USA) following the manufacturer’s instructions. The concentration of extracted DNA was determent by NanoDrop spectrophotometer at 260 nm and 280 nm and stored at -20°C.

**Polymerase Chain Reaction:**

DNA of hydatid cyst was amplified by performing PCR technique using (GoTaq Hot Start Green Master Mix, Promega) following the manufactures instructions. Three pairs of primers were used for the detection of *Echinococcus* were used in this study: 

- **COI:** F: 5’ TTGAATTTGCCACGTTGGAATGC 3’, R: 5’ GAACCTAACGACATAATGA 3’ with product size 792bp
- **sh1-4:** F: 5’ GTTATAAGGCGCTTCGTTGTTGG 3’, R: 5’ CGTACGATTAGTTTCACAATATATGA 3’ with product size 295bp
- **G6-7:** F: 5’ TGGGGTAGTTACAATAGTTATTC 3’, R: 5’ CATATTCAATGAGTACGATTA 3’ with product size 234bp. The annealing temperature for all PCR are 56°C.

The PCR conditions are as follows: initial denaturation for 5min at 95°C, followed by 35 cycles of 95°C for 30sec, 56°C for 30sec, 72°C for 30sec. The reaction was then held at 72°C for 10min, and then cooled down 4°C for 5min (table 2). The PCR product was then detected on agarose gel stained with ethidium bromide, used 100-1000bp (KAPA BIOSYSTEM) and 1kb DNA ladder (Promega).

**DNA Sequencing and Sequences analysis**

PCR product was sent to Macrogene (Korea) company, for sequencing. The sequences were edited and aligned using Parbi-Doua and NCBI BLAST programs. Contrasted the results with data gained from Gene Bank published ExPASY program which is available at the NCBI online. Phylogenetic analysis was performed by using the NCBI program.

**Results and Discussion**

This study showed that the total number of the examined sheep was 213 and the total number of infected sheep was 75. The total percentage of infection was (35.2%) which is agreed and disagreed with who showed that the prevalence of infection was 1.5%, 5.9% in north and middle of Iraq, respectively. The result of infected liver and lung in sheep by hydatid cyst is -shown in figure (1, A and B). This difference could be accounted on the basis of differential management practices, natural resistance, drug treatment and nutrition. The live and dead protoscolices were stained with green and red color, respectively (Figure 1, C).

The results of this study showed that the percentage of infection is high in sheep in Basrah province. Greater endeavor is wanted to control the transmission of hydatid cysts from slaughter house by the suitable disposal of infected residue, especially in sheep. This will reduce the transmission of cysts from slaughter house to potential hosts in this region. Now, veterinary authority put rules to control this disease through the creation good standardization abattoirs system to raise knowledge of farmers about hydatid cysts and removal stray dogs from Basrah province.

The results of the present study are compatible with other studies in different parts of the world which showed that the sheep strain is the most important pattern accountable for human injury and a broad range of intermediate hosts.
No effective chemotherapy is presently accessible for the medical treatment of cystic and alveolar hydatid disease in human \(^{29}\). However recently several anthelmintic drugs (which have shown encouraging results in the reduction to the larval cystic mass) \(^{30}\), there is an evidence effect of the drug tinidazole and praziquantel on lethal the protoscolices \(^{31,32}\).

**Fig. (1): Sheep infected by hydatid cyst (A) in liver (B) in lung.**

(C) Live and dead protoscolices isolated from sheep.

**Molecular study**

In this study, the effect of plant extract or drug against *Echinococcus* was evaluated through the determining of specific genes of three groups: control, extract and treated by tinidazole.

Three genes, including strain *G6-7* (234bp), strain *sh4-1* (295bp) and strain *COI* (792pb) were detect in this study.

Fig.(2) showed the results of PCR (*G6-7, sh4-1, COI*) in group one (control group) and group two (treated by tinidazole), the result showed PCR amplification for *G6-7* 237bp, *sh4-1* 295bp and *COI* 792bp. While fig. (3) showed group four (treated by *Prosopis fracta*), the results of PCR the amplification for *sh4-1* 295bp and *COI* 792bp and absent for *G6-7* because the effect of plant extract. Fig.(4) appeared the results of PCR (*G6-7, sh4-1, COI*) in group three (treated by *Capparis spinosa*), the result showed that *sh4-1* 295bp was amplified but absent in *G6-7, COI* because effect of plant extract. The same figure showed the last group (group five) appeared treated by *Quercus aegilops*, the result showed absent of any amplification because effect of plant extract. The high efficacy of *Quercus aegilops* come from phenol and tannins properties \(^{33}\), Tayler study pointed out because tannins polar properties give the inhibition effect many type of microorganism, as well as limited the inhibition effect of protease enzyme \(^{33}\). For all that, this study reported the *Quercus aegilops* is the best extract against three genes used in current study, table (4) appeared all the result of genes in all groups.
Fig. (2): Results of PCR of control and tinidazole groups. lane (1) is the ladder 1kb DNA ladder (Promega), lanes (2,8) for G6-7, lanes (3,6,9) for sh4-1, lane (10) for COI. Samples treated with tinidazole are represented in lanes (11,13,15,17,19) for G6-7, lanes (12,14,18) for sh4-1, lanes (16) for COI.

Fig. (3): Results of PCR for the fourth group (treated by Prosopis fracta), lanes (1,20) is the ladders 100-10000bp (KAPA BIOSYSTEM), lanes (9,10,12,13) for sh4-1, lanes (15,16) for COI.

Fig. (4): Results of PCR for the third and fifth groups (treated by Quercus aegilops). lanes (1,21) is the ladders, lanes (2-20) show no PCR product. Group three (treated by Capparis spinosa), lanes (22,41) is the ladders, lanes (24,25,27) for sh4-1.
The results of this study agree with Hosseinzadeh in sheep genes strain \((G6-7, \, sh4-1, \, COI)\) \(^{34}\), these authors extracted DNA and used \(G7-6\) and \(sh4-1\) genes in order to detect \(E. \, granulosus\) in sheep. \(COI\) gene aligned \((792\text{bp})\) sequence matrix of partial of gene \(cox1\) which contained 124 variable sites \((15)\). \(COI\) gene was used for the determination and identification of \(Echinococcus\) \(^{16}\).

The results showed that the effect of \(Quercus \, aegilops\) extract on hydatid cyst was big in the absence of all genes in PCR product. On the other hand, the effect of \(Capparis \, spinosa\) extract was observed on only two genes \((G6-7\, \text{and} \, COI)\), whereas the effect of \(Prosopis \, fracta\) extract was observed only on \(G6-7\) gene (Table 1). \(Prosopis \, spp.\) were also known to have medicinal effects. It was demonstrated to have cytotoxic effects on its fruits, which has a significant activity against lung carcinoma \(^{35}\). The very important point was in the tinidazole group which gave positive amplification results for all genes which means the frailer to brake any of the gene.

### Table (1) Effect of tinidazole, \(Capparis \, spinosa\), \(Prosopis \, fracta\), \(Quercus \, aegilops\) against three genes with control group.

### Sequencing

The results of sequencing determined the identity of \((COI, \, G6-7, \, sh4-1)\) genes. Sequence similarity of \(G6-7\) was 97\% with Austria isolation, while the \(sh4-1\) was 99\% with Oman isolation, 79\% with Estonia isolation which was recorded in GenBank in accession number \(\text{KX039965.1}\) and the partial gene recorded by \(^{36}\) and \(COI\) was 99\% identical with Australia isolation.

### Phylogenetic Analysis

The phylogenetic trees were constructed using NCBI website according to the compartment between sequences published in a recent study and other sequences of the other \(E. \, granulosus\) which were published in GenBank. Figure 5 show the phylogenetic analysis of gene \(COI\) for \(E. \, granulosus\), rooted neighbor joining phylogenetic tree. This tree shows the distribution and phylogenetic relationships between \(E. \, granulosus\) in Iraq and other countries.

### Conclusion

The results showed that hydatid cyst were detected successfully by performing PCR technique. In addition, \(Quercus \, aegilops\) has been shown the best plant extract for destroying all genes, the second plant extract which is \(Capparis \, spinosa\) showed destroying of two genes \((G6-7, \, COI)\) and failed to destroy \((sh4-1)\). Furthermore \(Prosopis \, fracta\) has shown to destroy only \((G6-7)\) and tinidazole failed to destroy any of these genes used in this study.

Histological, Histochemical And Immune Histochemical Study of Effect Aging on the Parotid Salivary Glands in Buffalo

Dhuha Adel Kareem¹,  Hiba M. Abd Alrahman¹, Fawzi-Alasadi¹
¹Department of Anatomy and Histology, College of Veterinary Medicine, University of Basra, Basra, Iraq

Abstract
The present work were carried out on twenty parotid salivary glands were collected from head of buffalo (slaughtering of Basra) and divided into two equal groups (one year age and five year age). The results were showed that the parotid salivary gland consist of spherical serous acini connected with branched ducts, intercalated ducts which attached with striated ducts, these duct involved the intra lobular ducts. The larger duct named interlobular duct, myoepithelial cells located between the basal membrane and secretory acini and ducts. The results revealed that the effect of aging on the histological structures of parotid salivary gland by using routine stain, histochemical stain stereiological histologically, and immunohistochemistry. The high intensity of connective tissues in the parotid salivary glands with age of five years as compared to the age of one years (normal intensity), also showed fibrosis in the parotid gland of five year age as compared with parotid gland of one year no appear any fibrosis, stereological histologically of the mean diameter of acini for parotid gland of five years age increased significantly p<0.05 (13±0.33 micron) while acini of one years age (10.4±0.02 micron), the mean diameter of intercalated duct for parotid gland of five years age increased significantly p<0.05 (40.13±2.61 micron) as compared of intercalated duct for age one years (26.56±1.22 micron). The histochemical results by using PAS stain showed low intensity of glycogen for parotid gland of five years age as compared to the group of one years age. The immunohistochemistry (VEGF) showed decrease in the parotid salivary gland of five year age as compared to the group of one years age.

Keywords: salivary glands, aging, hypo salivation.

Introduction
The salivary apparatus consist of three major salivary gland and several minor salivary glands ¹. The parotid glands were the one and largest of the three major salivary glands located at the side of maxilla opposite to ear and resemble to pancreas ². The parotid salivary glands divided in to lobules by connective tissues, each lobules contain several secretory serous acini, these acini attached to striated ducts which led to inter lobular duct. The parotid salivary gland secret serous saliva which act as protection, antimicrobial, mineralization, lubrication, epithelial repair and buffering ³. The aging is term used in human, animals, plants and fungi caused by many factor, the first is free radicals which attack the cells and damage the DNA, the second is the imuno system depression which promote the cells and tissues for attack. The third cause is the glycation and oxidative stress ⁴. The glycogen consider as the main storage unit of glucose in the tissues and play an important role in the salivary glands ⁵ in rat. The aim of this study is to investigate the effect of aging on the histology, some histochemistry and immunohistochemistry of the parotid salivary glands.

Materials and Method
Twenty parotid salivary glands were collected from buffalo (slaughtering of Basra) and divided into two equal groups. Group I with one year age and Group II with five year age. The deparrafinized sections were stained with hematoxyline eosin for routin histological study and PAS reaction for glycogen content ⁶, as well as some deparrafinized section were processed for VEGF immunohistochemistry. The mounted section were photographed with light microscope evaluated statistically using t-test program ⁷.
Results

The present study showed that parotid salivary gland consist of spherical serous acini connected with branched ducts. There were intercalated ducts which attached with striated ducts, these duct involved the intra lobular ducts. There were larger duct named interlobular duct(Fig.1). There are two type of secretory cells (mucous cells and serous cells, the secretory granules were located in the upper part of cell. There were myo epithelial cells located between the basal membrane and secretory acini and ducts, there were connective tissue dividing the glands to lobes and lobules by trabeculli which contain nerves and blood vessels(Fig.2(B)). When comparing the two group ,the intensity of connective tissues were increased in the parotid salivary glands with age of five years as compared to the parotid salivary gland with age of one years (normal intensity)(Fig.2) .There were a few fibrosis in the parotid salivary gland of five year age as compared with parotid salivary gland of one year which showed no any fibrosis(Fig.3).

The steriological histologically of the mean diameter of acini for parotid gland of five years age observed increased significantly p<0.05 (13±0.33 micron) as compared to the parotid of one years age(10.4±0.02 micron). The steriological histologically of the mean diameter of intercalated duct for parotid gland of five years age observed increased significantly p<0.05 (40.13±2.61 micron) as compared to the parotid of one years age(26.56±1.22 micron) (Fig.1).

The intensity of PAS reaction(glycogen content) were decreased in the parotid salivary glands of five years age as compared to the group of one years age(Fig.4).

The VEGF immuonohistochemistry showed that VEGF distributed in the basal membrane around the acini, ducts and around the blood vessels in connective tissues in the parotid salivary glands. The results showed that the intensity of VEGF which showed as brown color were decreased in the parotid salivary gland of five year age as compared to the group of one years age (Fig.5).
Discussion
The present study showed that parotid salivary gland consist of spherica serous acini connected with branched ducts. These result coincide with\(^8\) in buffalo;\(^9\) in goat and sheep;\(^10\) in rhesus monkeys;\(^11\) in barking deer;\(^12\) in human and rodent;\(^13\) in local rabbit;\(^14\) in rat;\(^15\) in mice and\(^16\) in rabbits. These result disagreed with\(^17\) in castrated donkey;\(^18\) in dog;\(^19\) in mammals;\(^20\) in dog, cat and ferret, who observed that parotid gland was a mixed gland serous and mucous.
There were intercalated ducts which attached with striated ducts. These results agree with the study of the African palm squirrel, who reported the presence of a large number of intercalated duct in the parotid gland with only serous cells. These duct involved the intralobular ducts. There were larger ducts named interlobular ducts. These results agree with study of 21 in camel; 22 in castrated donkey and 8 in buffalo, who reported the intercalated duct and striated duct were referred to intralobular duct, disagree with 23 in buffalo who reported that the intralobular ducts in buffaloes without striated duct.

There were myoepithelial cells located between the basal membrane and secretory acini and ducts agree with study of 24 in Dungarian hamster, disagree with 25 in rat who reported that, the serous acini lack myoepithelial cells.

The intensity of connective tissues were increased in the parotid salivary glands with age of five years as compared to the parotid salivary gland with age of one year agree with 26 and Scott and co-workers e.g., 27,28 in human; 29 in rats; 30 in human; 31 in rats, who said the major salivary gland tissue represented by acinar cells with age, serous and mucous acinar cells are lost or decrease in the number and replaced by fat, connective tissue due to aging. The increase in adipose tissue by aging may be attributed to the reduction in the hormone Testosterone which associated with aging 32 in human; 33 in rats.

There were a few fibrosis in the parotid salivary gland of five year age as compared with parotid salivary gland of one year which showed no any fibrosis, the result agree with 1 in human; 34 in human; 35 in rat.

The mean diameter of acini for parotid gland of five years age observed increased significantly p<0.05 (13±0.33 micron) as compared to the parotid of one year age(10.4±0.02 micron) increase in the diameter of both the serous and mucous acini has been shown in this study agree with 36 in human; 37 in rats.

The mean diameter of intercalated duct for parotid gland of five years age observed increased significantly p<0.05 (40.13±2.61 micron) as compared to the parotid of one year age(26.56±1.22 micron) This observation agrees with 38 in rats; 39 in human, who stated that there is an increase in the ductal diameter with aging.

The intensity of PAS reaction(glycogen content) were decreased in the parotid salivary glands of five years age as compared to the group of one years age agrees with 40 in mice, who mentioned that the fibrotic regions were rich in collagens and it has been investigated that the total collagen density was lower in young mice than in older mice. In addition, acinar atrophy and dilated interlobular ducts were observed in old mice.

The results showed that the intensity of VEGF which showed as brown color were decreased in the parotid salivary gland of five year age as compared to the group of one years age agrees with (5,6) in rat, they observed that there were age-related decreases in the number of acinar cells, increase in eosinophilic zymogen granules in cells, collagen accumulation in fibrotic areas and dilatation in interlobular ducts. Also, while type I collagen and MMP-2 immunoreactivity were moderate in the salivary glands of the young mice, they were high in the salivary glands of the old mice.

Study the Protective Role of Vitamin (B6 and B12) on the Some of the Blood Physiological, Biochemical Parameters and Histological Induced by Treatment of Sodium Fluoride Male White Rat

Alyaa Neamah Al-Saidi 1, Zainab Shnewer Al-Turfi 1
1Assist. Prof. Physiology/ College of Education for Girls University of Kufa

Abstract
The study was conducted in the Faculty of Pharmacy / Karbala University for the period from 12/2018 to 7/2019. The first group was orally injected with a saline solution with a concentration of 0.9 ml and was considered as a control group. The second group was injected with sodium fluoride at a concentration of 20 mg / kg body weight (Positive), while the third group was injected with sodium fluoride with the same previous concentration with vitamin B6 leaves Group G was also injected with sodium fluoride with the same previous concentration with vitamin B12 at a concentration of 25 μg / kg body weight. In the fifth group, sodium fluoride and vitamins B6 and B12 were injected with the same concentrations mentioned above with 1 mg / kg body weight. Ml of each of the solutions above and for all groups where the duration of the dosage lasted 21 days and once a day. a significant decrease in the ratio of body weight, red blood cells, hemoglobin, hematocrit, high density lipoprotein and glutathione peroxidase, whereas white blood cells, platelets, cholesterol, triglycerides, low density lipoproteins and Malondyaldehyde increased significantly in the sodium fluoride treatment group with control group.

Keywords: vitamin (B6 and B12) , blood physiological , biochemical parameters

Introduction
Vitamins are organic compounds essential for improving the functioning of the human body including biotin, folic acid, niacin, pantothenic acid, riboflavin, thiamine, vitamin A, pyridoxine, copolamine, vitamin C, vitamin D, vitamin E and vitamin K. The body needs small amounts and is obtained from a healthy diet 22. As for the importance of water-soluble vitamins, vitamin B6 had a role in the prevention of cardiovascular disease 16, immunological functions and memory diseases 43 and kidney stones. In addition, it may also be useful in the treatment of gastrointestinal diseases such as premenstrual syndrome (PMS) 55, side effects of oral contraceptives, nausea and vomiting during pregnancy (26,52), depression and carpal tunnel syndrome. Vitamin B12 also helps prevent certain diseases, especially neural tube defects 32, cardiovascular disease 37, cancer 14, depression, Alzheimer’s disease and dementia 12.

Fluorine is a rare natural element and is often found in the soil and is flammable, calcined, toxic, with fluorine compounds forming about 0.08% of the earth’s rocks 42. Fluorides in general are highly toxic to cells and tissues of the body because they cause calcium deposition. They also cause high blood pressure, respiratory failure and general paralysis. They also have a relationship to cancer. They inhibit the effectiveness of the enzyme necessary for protein synthesis and DNA synthesis. Medical research on the effect of fluoride ion on the human was found to be cancer of the treated cells. It was also found that mice injected with additional doses of fluoride ion had liver cancer 23.

Material and Methods:

Blood tests
The Automated Cell Counter (Sysmex-800, Japan) is used to calculate the blood count of different blood cells.

The sample (tube containing the blood and anticoagulant) is injected into the designated area of the
device. The blood parameters of WBC, red blood cell count (RBC), platelet count (PLT), hematocrit ratio (HCT), and hemoglobin level (Hb) are estimated by using a small amount of sample Blood and with high accuracy and short period of time.

**Measure serum cholesterol level:**

According to what he described

Measuring the concentration of high-density lipoprotein cholesterol (HDL-c):

It was measured according to what he described.

**Measuring the concentration of low-density lipoprotein cholesterol LDL-c.**

Its concentration is calculated according to the following equation:

\[
\text{Concentration of LDL} = \text{total cholesterol} - \left(\frac{\text{triglyceride}}{5} + \text{HDL concentration}\right).
\]

**Assay of Glutathione Peroxidase (GPx) Activity:**

Measuring the concentration of malondyaldehyde (MDA) in the serum.

According to what he described.

Table (1) shows different blood standards in different treatments

**Result and Dissection**

**Change blood standards**

The results of Table (1-1) showed a significant decrease (P <0.05) in the number of red blood cells (RBCs) of G2 and G3 compared with the control group G1 and the other groups G4 and G5., G4, G5 when compared with G2.

In terms of hemoglobin Hb, there was a significant decrease (P <0.05) in G2 and G3 compared to control group G1. When comparing groups G3, G4 and G5 among them except control group G1 with G2, <0.05) for hemoglobin.

In terms of hematocrit HCT, P <0.05 was also observed in G2 and G3 compared with G1. When comparing G3, G4, G5 with G1, G2 with significant G (P) <0.05) for the hematocrit ratio.

The results of the white blood cell count (WBC) differed with the previous results. A significant increase was observed (P <0.05) in groups G2, G3, G4 but did not reach the level of significance in group G5. When comparing totals except G1 with G2, Moral decline (P <0.05).

The number of platelet plaques was significantly higher (P <0.05)

A significant difference between the treated groups with control below the probability level of 0.05

b, c significant difference between the treated groups below the probability level of 0.05
The results of the present study showed a significant decrease in the number of red blood cells and the proportion of hemoglobin and hematocrit (which is the proportion of the volume of red blood cells packed to the full volume of blood) while increased the proportion of white blood cells and platelets. Reduced numbers of red blood cells, hemoglobin and packed red blood cells may be due to deficiencies in hematopoietic factors (iron, folic acid, folate B9 and vitamin B12), which are essential factors for normal blood formation and crucial for the manufacture of DNA. In the cellular divide, a deficiency of vitamin B12 and folic acid will cause dysfunction in the process of cell multiplication, especially in the red blood cell manufacturing system, leading to anemia (17, 40).

The results of the microscopic examination of the tissue sections of the liver, kidneys and rats treated with sodium fluoride have enhanced the morphological growth of white blood cells and platelets, which can explain why this was reported when exposure to high concentrations of substances and compounds increases the number of pellets The white blood of lymphocytes increases due to the immune system’s sense of fluorine ion as a defense against inflammatory processes in the liver, kidneys, spleen and bone marrow.

Our current findings agree with many previous studies that the interaction of toxic substances (sodium fluoride) with red blood cells may affect their ability to carry Hb and thus reduce its content. reported a slight increase in WBC values, while our results did not agree with what observed a decrease in white blood cell count.

B6, B12, G3, G4 and G5 were treated to modify the levels of blood parameters studied by having an important role in the formation of red blood cells and in the synthesis of hemoglobin, which is important for red blood cells to transport oxygen and therefore increase the proportion of hematopoietic as the amount of percentage volume (%) of red blood cells in the blood.

Vitamin B6 deficiency has an important role to play in the weakness of the immune system and resistance to inflammation, as it reduces the body’s ability to secrete white blood cells responsible for regulating the functions of the immune system.

**Change in the values of cholesterol, triglycerides, high-density lipoproteins and low-density lipoproteins**

Table (1-2) showed elevated cholesterol. In the G2 group was significantly higher (P <0.05) than the control group G1, while the rest of the groups were between high and low, not reaching the moral level.

When comparing the G3, G4, and G5 groups with the G2 poisoning group, they observed a significant decrease (P <0.05).

TG triglycerides in G2 were significantly higher (P <0.05) and G3, G4, and G4 were higher than G1, but did not reach the moral level.

When comparing the results in the same groups with the G2 poisoning group, a significant decrease was observed (P <0.05).

The low HDL ratio was also significantly decreased (P <0.05) in the G2 poisoning group for the control group. The other G3, G4 and G5 groups were also high but slightly higher than the G1.

When comparing the results of the same groups with the G2 poisoning group, the increase was significantly higher (P <0.05).

There was also a significant increase in LDL (P <0.05) in the G2 poisoning group from the G1 control group. It was also observed that the results of the other values were slightly higher, not reaching the moral level.

When comparing the results of these groups G3, G4, G5 with the G2 poisoning group, the results were significantly lower (P <0.05).

The results of the present study showed a significant increase in the concentration of cholesterol, triglycerides and LDL with a significant decrease in HDL level in males of adult rats treated with sodium fluoride at a concentration of 20 mg / kg compared to G1 control group. In his study of the blood and tissue effects of sodium fluoride in local rabbits.

The results of the present study differed with the results of the study of with low blood cholesterol level in pigs treated with sodium fluoride at a concentration of 150 mg / kg body weight.

While the treatment groups G3, G4, G5, sodium fluoride, vitamin B6 and B12 were separated once and again, they led to a marked improvement in the values of cholesterol and triglycerides. If LDL levels are high, they are deposited on the walls of the blood vessels, leading to narrowing and reducing their elasticity,
which leads to blockage. As a result, there is a problem in blood flow, which is called atherosclerosis. When it occurs in the arteries that feed the heart, it increases the risk of heart attack. It is worth mentioning here that HDL helps to prevent the deposition of LDL cholesterol on the walls of the blood vessels and take it out of the circulatory system as vitamin B12 contributes to the reduction of cardiovascular disease and levels Low-density lipoprotein, high blood pressure, low levels of high-density lipoprotein, obesity and diabetes.

The role of both vitamin B6 and B12 as antioxidants and in the repair of hepatic tissue cells will thus rid the body of excess cholesterol. Its role in liver cell repair leads to the liver’s return to its normal state, secretion and regulation of the levels of important lipoproteins necessary for blood plasma.

Outcome Following Medical and or Surgical Intervention (ESPAL) for the Treatment of Epistaxis in ENT Unit in Al-Diwaniyah Teaching Hospital: Cohort Study

Ali Najm Abdullah Alibadi1, Wasam Abbas Abdulhsen Albusalih1

1ENT specialist / Al-Diwaniyah Teaching Hospital / Department of surgery / Al-Diwania / Iraq,

Abstract

Aim of the study: In the current study the aim was to evaluate a sample of Iraqi patients with epistaxis regarding medical and surgical interventions and their outcomes. The study was carried out in Ear Nose and Throat (ENT) unit in Al-Diwaniyah Teaching Hospital, Mid-Euphrates region, Iraq. The study started on January 2018 and ended on June 2019. The main variables included in the study were age, residency, level of education, occupation, clinical presentation (cold versus emergency), severity of bleeding, type of intervention (Medical versus surgical), presence or absence of associated disease and response to treatment. Medical intervention included, direct pressure, anterior nasal packing and chemical cauterization with silver nitrate; whereas, surgical intervention included transnasal endoscopic sphenopalatine artery ligation (TESPAL). Bleeding was more frequently of emergency presentation rather than cold in association with surgical group, more severe in surgical group and characterized by more frequent attacks per month in surgical group in comparison with medical group. Response to medical and surgical intervention was good and satisfactory in all patients even after follow up for 6 months at least. There were negligible adverse effects in association with surgical intervention.

Key words: transnasal endoscopic sphenopalatine artery ligation, epistaxis, Iraq

Introduction

One of the most frequent emergencies daily faced by ENT specialists is epistaxis (nose bleed) 1. Basically nose bleeds are classified into anterior and posterior ones. Anterior bleeding is the most common variety and the source of bleeding is often from Little’s areas (Kiesselbach plexus). On the other hand, posterior nose bleeding is the least common and the most likely source of bleeding is the sphenopalatine artery (2, 3). The disease may be primary in which no cause can be identified or secondary for some other conditions such as trauma and coagulopathies (1-3). Epistaxis is most often in children between 2 and 10 years and elderly between 50 and 60 years of age. It is estimated that 60 % of population experienced epistaxis at some point of their life. However, only 10 % of cases deserve medical intervention since most of cases are mild and self-limited 4. From etiological perspective, local causes include trauma, septal deviation, local steroids and cannulation; whereas, systemic causes included alcoholism, coagulopathies (hemophilia and von Willebrand disease) vascular malformations and hypertension (5-7). Epistaxis may associate the use of a number of medications such as anticoagulants (warfarin), non steroidal anti-inflammatory drugs (ibuprofen) and platelet aggregation inhibitors (clopidogrel). Neoplastic disorders should be suspected in case of headaches, facial pain, unilateral nasal blockage and facial deformity (5-7). Nosebleeds are the consequences of blood vessel rupture within the nasal mucosa. Rupture of mucosal blood vessels may be spontaneous, caused by trauma, secondary to use of a number of medication, or secondary to other neoplastic or non neoplastic disorders. When blood pressure is abnormally high, the duration of bleeding may be prolonged. Similarly the use anticoagulant medications and having coaglupathies increase the duration of bleeding 8. The most important step in management includes the identification of bleeding site whether anterior or posterior. Medical interventions such as direct pressure, anterior nasal packing, chemical cauterization with silver nitrate, anterior nasal balloon
and thrombogenic gels are usually effective in controlling anterior nasal bleeding. If these measures fail to control bleeding, a posterior source will be suspected and treated properly. Posterior nasal packing may be helpful, surgical intervention and ligation of sphenopalatine artery may be needed to control posterior nasal bleeding (9-11). In the current study we prospectively evaluated a sample of Iraqi patients with epistaxis regarding medical and surgical interventions and their outcomes.

Patients and Methods

The present cohort study included 65 patients of epistaxis who were treated medically and or surgically and followed up for at least 6 months. The study was carried out in Ear Nose and Throat (ENT) unit in Al-Diwaniyah Teaching Hospital, Mid-Euphrates region, Iraq. The study started on January 2018 and ended on June 2019. The age range of included patients was form 4 to 65 years. The main variables included in the study were age, residency, level of education, occupation, clinical presentation (cold versus emergency), severity of bleeding, type of intervention (Medical versus surgical), presence or absence of associated disease and response to treatment.

Medical intervention included, direct pressure, anterior nasal packing and chemical cauterization with silver nitrate; whereas, surgical intervention included transnasal endoscopic sphenopalatine artery ligation (TESPAL).

The study was approved by institutional ethical approval committee and a verbal consent was obtained from every participant after full illustration of the study aim and procedures.

Obtained data were transformed into SPSS (version 23) spread sheet. Numeric data were expressed as range, mean and standard deviation, whereas, categorical data were expressed as number and percentage. Independent sample t-test was used to evaluate mean difference between two groups; while chi-square test was used to study association between categorical variables. The level of significance was considered at $P \leq 0.05$.

Results

The present study included 65 patients with epistaxis. Those patients were categorized according to type of intervention into two groups. The first group included 52 patients who responded well to medical treatment and considered as medical intervention group. The second group included 13 patients who failed to respond to proper medical treatment and needed surgical intervention in the form of endoscopic sphenopalatine artery ligation. The latter group was considered the surgical intervention group. The demographic characteristics of patients enrolled in the current study are demonstrated in table 1.

The age range of all patients was from 4 to 65 years, that of medical intervention group was from 4 to 65 years and that of surgical intervention group was from 9 to 40 years. Mean age of medical intervention group was more than that of surgical intervention group, 26.15 ±8.13 years versus 18.02 ±16.55 years; however, the difference was statistically insignificant ($P = 0.095$), table 1. The study included 38 (58.5 %) males and 27 (41.5 %) females; there was no significant difference in the frequency distribution of patients according to gender between medial group and surgical group ($P = 0.378$), table 1. There was also no significant difference in the frequency distribution of patients according to residency, urban versus rural, between medial group and surgical group ($P = 0.378$), table 1. In addition, there was no significant difference in the frequency distribution of patients according to occupation between medial group and surgical group ($P = 0.318$), table 1. The distribution of patients according to level of education was also shown in table 1.

Idiopathic cases were seen in 44 (67.7 %) patients. Most of cases belonging to surgical group had idiopathic cause (93.3 %). Associated disorders were encountered mainly in patients with medical intervention and included trauma, chronic hypertrophic allergic rhinitis, dryness of nasal mucosa, common cold, diabetes mellitus, hypertension and immune thrombocytopenic purpura (ITP), as shown in table 2.

The characteristics of bleeding episodes are shown in table 3. Bleeding was more frequently of emergency presentation rather than cold in association with surgical group, more severe in surgical group and characterized by more frequent attacks per month in surgical group in comparison with medical group, as shown in table 3.

Response to medical and surgical intervention was good and satisfactory in all patients even after follow up for 6 months at least. There were negligible adverse effects in association with surgical intervention.

Discussion

Nose bleeding is common in daily clinical practice and some cases are true emergency that needs prompt and rapid intervention in order to prevent further complications (1-4). Anterior nasal bleeding is usually easy to control using conventional medical approaches than posterior nasal bleeding. These medical interventions included direct pressure, anterior nasal pack and silver nitrate cauterization. However, posterior nasal bleeding frequently associated with severe and recurrent attacks of bleeding that requires surgical intervention, often in the form of endoscopic sphenopalatine artery ligation. Posterior epistaxis often arises from the posterior septum and the posterior lateral nasal wall, which constitutes 5 to 10% of patients. Due to the difficulties in spotting the location of bleeding, its treatment is more difficult than anterior epistaxis (9-11).

In the current study we included 65 cases of epistaxis that have been managed in the unit of ENT in Al-Diwaniyah teaching hospital and then we categorized them according to type of intervention into medical group and surgical group aiming at identifying possible demographic characteristics, associated disorders or characteristic of nose bleed that can predict the need for surgical intervention.

In the current study, regarding demographic characteristics, those patients who required surgical intervention were relatively young; however, the difference in mean age between both groups did not reach statistical significance. Probably those young patients has posterior nose bleeding more than those older patients; however, the lack of statistical significance makes this observation related to chance factor rather being a significant association. Indeed, several authors reported that those who need inpatient treatment are usually older than those receiving outpatients treatment (12, 13).

In the present study, associated diseases were more frequent in group of medical intervention and the majority of cases of surgical group were idiopathic. These findings seems contradictory to majority of previous reports (17-20); however, it may be merely statistical finding and increasing sample size in the future may reveal better idea regarding the impact of primary and secondary nasal bleeding on treatment approach.

In the current study following up of patients revealed significantly more attacks in association with surgical intervention in comparison with medical interferences; however, we believe that the source of this recurrent attacks is attributed to secondary infection and subsequent mucosal abrasion evidenced by that bleeding severity is much less than original one before operative interference reflecting mucosal oozing rather than true arterial bleeding.

In the current study both medical and surgical interventions were efficient in producing high rate of satisfactory good results. However, some cases did not respond to medical intervention and needed surgical intervention to control nose bleeding.

Conclusion

when medical treatment fails to control nose bleeding, transnasal endoscopic sphenopalatine artery ligation is effective and safe procedure with negligible adverse outcomes.

Abstract

Aim of the study: we planned and conducted the current cohort study to evaluate the safety and efficacy of this new contraceptive method in a sample of Iraqi women.

Patients and Method: This cohort study was carried out at some governmental health institutes such as Al-Diwaniyah Maternity and Child Teaching hospital and Al-Shamiyah teaching hospital and some private clinics. The beginning of the study is dated back to the 2nd of January 2016; the study continued till end of June 2019 and included 53 women. Inclusion criteria included any women with implanon implant that was recently implanted. The variables to be evaluated included age, residency, gravidity, parity and abortions in addition to principal outcomes, complications (amenorrhea, bleeding and development of ovarian cysts) and pregnancy six months following removal of the implant. All women participating in the current study were followed up till at least six months after implant removal.

Results: The outcome of implanon use was assessed following a period of follow up that ranged from 2 to 3 years with a mean of 2.89 years, as shown in table 2. Contraceptive failure was no seen in any case with a failure rate of 0.0 %. Amenorrhea was the most frequent side effect and it has been seen 18 (34.0 %). Ovarian cyst was seen in 6 cases accounting for (11.3 %) and bleeding was seen in 2 cases only accounting for (3.8 %). Complications, amenorrhea, ovarian cysts and bleeding were not significantly correlated to any of demographic or obstetric characteristics of the study group (P > 0.05).

Key words: safety, efficacy, implanon implant, Iraqi women

Introduction

Control of the number of family members and regulation and timing of child birth become well accepted issue in our community since decades. This because of economic concern partly, as increasing family size is by itself an economic burden (1-3). In addition some cultural attitudes have been positively directed toward the quality of siblings, their education and their positive participation in the society (4). So that having little number of well educated children and of good socioeconomic status becomes the goal of Iraqi family since 80s of the previous century. Thus various methods of contraception became sought by Iraqi couples. Indeed, none of contraceptive methods is free from failure rate or adverse health issues (5,6). The methods of contraception are diverse; however, they can be grouped into two major groups, hormonal and non hormonal methods. Hormonal methods include oral birth control pills (7), skin patches (8), vaginal ring (9) and hormone releasing contraceptive coils (10). Non hormonal methods included male condom, female condom (11), copper coils (12), diaphragms (13), chemical creams, gel or suppositories (14) and natural control methods (15). The intrauterine device (IUD) is on top of the list of contraceptive methods used worldwide and it is estimated to be used by more than 168 million women globally (16). Recently in the United States, IUD gains wide acceptance by women within all ages and parities as an efficient method of avoided unintended pregnancy (17). In addition, researchers have shown that pregnancy rates in association with oral contraceptive pills and implants are about 20 times more frequent when
compared with IUD. As it was mentioned previously, there are basically two forms of contraceptive methods, hormonal based and non hormonal ways. Implanon is one of the relatively newly introduced hormonal based contraceptive methods. It is an etonorgestrol implant. It is composed of a single rod that is to be inserted in the upper arm. Etonorgestrol is a synthetic active metabolite derived from a synthetic progestin and has high affinity to bind progesterone receptors. It acts to prevent pregnancy by several ways including the inhibition of luteinizing hormone (LH) secretion, an important hormone for natural ovulation, making the cervical mucus more viscous thereby inhibiting passage of sperm, and rendering the uterine mucosa less receptive for embryo thereby interfering with implantation. Implanon was recently introduced into our country and its efficacy and safety is yet to be determined since published national research work with this regard is somewhat lacking. Therefore, we planned and conducted the current cohort study to evaluate the safety and efficacy of this new contraceptive method in a sample of Iraqi women.

**Patients and methods**

This cohort study was carried out at some governmental health institutes such as Al-Diwaniyah Maternity and Child Teaching hospital and Al-Shamiyah teaching hospital and some private clinics. The beginning of the study is dated back to the 2nd of January 2016; the study continued till end of June 2019 and included 53 women. Inclusion criteria included any women with implanon implant that was recently implanted. The variables to be evaluated included age, residency, gravidity, parity and abortions in addition to principal outcomes, complications (amenorrhea, bleeding and development of ovarian cysts) and pregnancy six months following removal of the implant. All women participating in the current study were followed up till at least six months after implant removal. The study was approved by the institutional approval committee and verbal consent was obtained from all participants following full illustration of the aim and procedures of the current study. Data were then transformed into an SPSS (version 23) spread sheet. Numeric data were expressed as mean, standard deviation, median, interquartile range (IQR) and range, whereas, categorical data were expressed as number and percentage. Correlation was calculated using Spearman correlation test and the level of significance was chosen at \( P \leq 0.05 \).

**Results**

The demographic characteristics of women enrolled in the current study were demonstrated in table 1. The study included 53 women with an age range of 17 - 40 years and a mean age of 26.70 ± 6.27 years. Women less than 20 accounted for 5 (9.4 %), women between 20 and 39 accounted for 42 (79.2 %) and women older than 40 accounted for 6 (11.3 %). According to residency there were 47 (88.7 %) women from urban areas and 6 (11.3 %) from rural areas. Regarding obstetric history, the range of gravidity was from 0 to 9 with a median of 4, the parity was ranging from 0 to 8 and the median was 3 and abortion ranged from 0 to 5 with a median of 0. Regarding mode of delivery the range of vaginal delivery was from 0 to 9 with a median of 1 per woman, whereas, the range of cesarean section was from 0 to 5 with a median of one cesarean section per woman, as shown in table 1.

The outcome of implanon use was assessed following a period of follow up that ranged from 2 to 3 years with a mean of 2.89 years, as shown in table 2. Contraceptive failure was no seen in any case with a failure rate of 0.0 %. Amenorrhea was the most frequent side effect and it has been seen 18 (34.0 %). Ovarian cyst was seen in 6 cases accounting for (11.3 %) and bleeding was seen in 2 cases only accounting for (3.8 %), as shown in table 2.

Complications, amenorrhea, ovarian cysts and bleeding were not significantly correlated to any of demographic or obstetric characteristics of the study group \((P > 0.05)\), as shown in table 3. Pregnancy after removal of the implant was seen in 17 women (32.1 %).

Discussion

The avoidance of unintended pregnancy by Iraqi couples became well known trend in our community and the search for a suitable method for contraception with minimal adverse effects and almost zero percent failure rate became an urgent need in daily obstetric clinical practice. For that reason, now and then new modalities of contraception enters into daily obstetric practice, but basically they are always of either hormonal or non-hormonal principle of action.

Implanon is well recognized as an effective mode of contraception in developed countries. It is a single road etonorgestrol implant that is can be inserted in the upper arm and remains for a period of 3 years. The active ingredient is Etonorgestrol which is a synthetic active metabolite derived from a synthetic progestin and has high affinity to bind progesterone receptors. It produces its effects by several mechanisms such as the inhibition of luteinizing hormone (LH) secretion, an important hormone for natural ovulation, making the cervical mucus more viscous thereby inhibiting passage of sperm, and rendering the uterine mucosa less receptive for embryo thereby interfering with implantation.

In the current study, Impalnon use was evaluated in a cohort study and women were followed up for a period that lasted for an average of 2.89 years. The use of Implanon was associated with zero percent failure rate and minimal anticipated side effects such as amenorrhea and bleeding in addition to 6 cases of ovarian cyst that have resolved spontaneously. In addition, pregnancy was successful after Implanon removal in 32.1% of cases with in a period of six months after implant removal.

In addition, the cost of Implanon was also satisfactory for all participants. The safety and efficacy of Implanon has been reported by several previous reports. Some side effects have been previously reported. Damage to antebrachial cutaneous nerve at time of insertion or removal has been observed by Wechselberger et al. Damage to ulnar nerve at time of insertion has been seen by Osman et al. There was spontaneous extrusion of Implanon in one case 3 days after insertion. Extrusion has also been seen by Harrison-Woolrych and Hill. Splitting of Implanon in 2 halves in situ more than one year after insertion has been observed by Agrawal and Robinson; however, none of these adverse outcomes has been seen in our study.

Therefore, in view of available data of the current research and previously published data about Implanon single rod contraceptive implant, a conclusion can be inferred as following: Implanon is effective and safe mode of contraception and recommended to be used in daily obstetric practice in our community.

Conclusion

The use of Implanon is highly effective as a contraceptive mode since it was associated with 0% risk of contraceptive failure and it was safe because of minimal tolerable side effects in almost all included women.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Al-Diwaniyah child and maternity hospital / Department of Obstetrics and gynecology / Al-Diwania / Iraq and all experiments were carried out in accordance with approved guidelines.

Sperm Activation of Asthenospermic Infertile Patient by Using Swim-up and Swim-down Techniques

Rana F. M. Al- Dulaimi
Directorate of Education Babylon, Iraq

Abstract
The study included ten semen samples collected from infertile patients with asthenospermia. Each sample was divided into two equal parts where the sperm were activated by swim up techniques up on a part of the sample while the second part was used to activate the sperm by swim down. The results showed a significant decrease \((p < 0.05)\) in both the recovered sperm concentration and the concentration of leukocytes after activation with both techniques compared with their values before activation. A significant increase was observed in the percentage of sperm motility style A+B and a significant decrease in sperm motility percent style C after activation compared with their values before activation. The significant difference was not observed \((p >0.05)\) when comparing between the two techniques. There was also no significant difference \((p > 0.05)\) in the percentage value of the abnormal sperm percent before and after activation. The study concludes that the techniques of swim up and swim down are effective in activating the sperm of infertile patients who are infected with asthenospermia.

Key words: swim up, swim down, sperm activation

Introduction
Assistive Reproductive technologies have developed rapidly in recent years. These technologies have grown and became with therapeutic value for the infertile couples in both developed and developing countries. According to statistics on Intra cytoplasmic sperm injection (ICSI), the number of children are that borne by using ICSI was only 237809 in 2004. Intra Uterine Insemination (IUI) technique using which is the sperm of the husband is another technique of assisted reproduction which is the first choice for its ease, efficiency and low costs. IUI is used for infertility due to cervical factors, male infertility factors, mild endometriosis, and unexplained infertility. The high pregnancy rates resulting from the use of the IUI technique with the husband’s sperms and the low rates of failure and risk made it the most common; pregnancy rates reached 8 – 20% per cycle. In IUI technique, is injected recovered motile sperms after activation. IUI is acceptable when the activated sperm concentration is 0.8 -5 million / ml and pregnancy rates may be increased if the number of motile sperm are higher than the amount mentioned. A recent study confirmed that the pregnancy ratios index is based on the total number of motile sperm which is deposed in the uterus, the age of the wife, the appropriate timing of insemination, the duration of sperm preparation and the choice of appropriate and technique for infertility factor.

Swim up technique is the most common technique of sperm activation to suit most male infertility factor, while activation of the sperm by using the swim down technique is effective as it is the natural movement of the sperm. Asthenozoospermia is the most important factor of male infertility. Therefore, the present study aimed to activate the sperm of infertile patients who suffer from asthenospermia by using swim up and swim down techniques to compare the efficiency of two mentioned techniques for activation the sperms of the asthenospermia.

Material and Method
Ten samples of seminal fluid were collected from infertile patients who suffered from asthenospermia by masturbation after a period of interruption of intercourse for three days. Seminal Fluid Analysis was performed for all semen samples according to the WHO method. Each semen sample was divided into two equal parts to perform sperm activation with Swim up and Swim down...
techniques.

1- Swim up technique

Placed 1 ml of semen with 1 ml of activation medium (Ham`F-12) in a tube and mix well to be tilted at a 45° angle in an incubator at 37 c° for half an hour. The top of the medium layer was transferred to a new tube to be centrifuged rapidly at rpm 2000 for 10 minutes. The upper layer was discharged and covered the sperm pellet in the bottom of centrifuged tube with 0.5 ml of Ham`F-12 medium. They were left for half an hour in the incubator at 37 c° and then a drop was taken from the top centre and examined under a microscope to evaluate the studied sperm parameters.

Swim down technique

It was placed 1 ml of semen with 1ml of the activation medium of the Ham`s F-12 in a tube and mix well to be placed at 37°c in a incubator vertically at 90° angle for half an hour. The upper layer was discharged, the lower layer was centrifuged with 2000 rpm for 10 minutes. The upper layer was then ignored and sperm pellet deposited in the bottom of the centrifuge tube was covered with 0.5 ml of Ham`s F-12 where it was left for half an hour in the incubator at 37°c , then a drop was taken from the upper medium center and examined under a microscope to evaluate the studied sperm parameters.

Results

The results revealed in table-1- a significant decrease (p< 0.05) in the concentration sperm after sperm activation by the swim up and swim down techniques compared to the sperm concentration before activation , while significant difference was not observed in the concentration sperm between the two techniques, but the sperm concentration recovered by using swim down technique was insignificant (p>0.05) higher than those recovered by swim up technique . In terms of sperm motility at grade activity A+ B, a significant increase (p < 0.05) was observed in the sperm motility percent after activation by using swim up and swim down techniques which was compared to the values of sperm motility before activation. While the percentage for the sperm motility percent of grade C , the results were showed a significant decrease (p<0.05) in percentage of the sperm motility grade with swim down technique compared to its values before activation, while there was insignificant differences (p>0.05) was observed in swim up technique compared to sperm motility percent grade C compared to before activation . No significant difference (p>0.05) was observed in the percentage for abnormal sperm after activation compared with before activation . A significant decrease (p<0.05) was observed in the leukocytes concentration after activation by using swim up technique and swim down technique compared with value before activation , while no significant difference (p>0.05) was observed between the concentration of leukocytes between the two techniques which is used to activate sperm infertility patients who are suffering from asthenospermia.

**Discussion**

With the progress of reproductive technique in human, the need is required for improved sperm activation and development the increasing of the highly active motile sperm for contribute in improved external fertilization processes. For example, IUI requires activation of the sperm and isolating of the active sperm from the rest of the sperm\(^7\).

There are several effective ways to separate active sperm such as swim up technique, glass wool column technique, and density gradient\(^8\). All of these technique effectively separate active sperm from seminal plasma, but their efficiency varies with the variety of sperm parameters. The ratio of active sperms normal sperm morphology and the degree of DNA of the recovered sperm were differed significantly with difference of the techniques\(^9\). The swim up technique is represented to isolate the sperm from the sperm pellet after washing and centrifugation, it is the considered a basic and standard technique for normospermia and infertility patients, as well as for the treatment of female infertility factors\(^10\).

The washing process is necessary to remove prostoglandins, inflammatory agents and pus cells\(^11\). The technique of swimming up and other techniques are designed for obtaining motile and normal sperms. It is not necessary for these sperms to be of the highest quality, but it is important that they be able to produce acceptable pregnancy rates\(^12\).

Swim up technique does not require much experience or many rare and complex materials, so it is most practical technique for its ease and low cost\(^13\). The increase in the number of motile sperms after the activation of sperm naturally leads to an increase in the number of normal sperm morphology\(^14\). Another positive aspect of swim up technology is the removal of immotile sperms, pus cells and immature cells, which enhances the benefits of activation and preparation technique of sperm for artificial insemination\(^15\). The results of the current study showed an increase in the total number of motile sperm, the percentage of forward motile sperms (grade A+B) in the swim up technique was 23% while in the swim down it was 30%. One study has indicated that the effect of the concentration of total recovered motile sperm after perform of swimming techniques and IUI processes when less than 10 million / ml is low, and when the concentration of recovered motile sperm is more than 30 million / ml, pregnancy rates are very high and mild ratio when the concentration of recovered motile sperm is between 10 and 30 million / ml\(^16\).

The swim down technique is considered the best in term of removal of the abnormal sperm, dead sperm and other cell residues. The swim down technique shares with the other technique to got a small number of motile sperm, so this technique is preferred for people with normal sperms parameters and couples whose wives suffer from female infertility factors\(^17\).

The results of the present study showed that there was an insignificant increase in the percentage of motile sperm with progressive motility (A+B pattern) and a significant decrease in the percentage of motile sperm with no progressive motility (C pattern) when using swim down compared to swim up technique and this resulte consistently agree with the results of other study which is indicated that there was a significant increase in the number of sperm of the forward motility when using the technique of swim down compared to those sperm obtained by using swim up technique\(^18\). The swim up and swim down techniques considered as easy and highly efficient in terms of sperm activation and high-quality sperm separation for Artificial Insemination\(^19\). It was concluded from this study that the recovered sperm which is obtained after activation of the sperm by using swim up and swim down techniques with a high degree of activity qualify them for use in Artificial Insemination and the possibility of obtaining good pregnancy ratios.

**Conclusion**

A significant increase was observed in the percentage of sperm motility style A+B and a significant decrease in sperm motility percent style C after activation compared with their values before activation. The significant difference was not observed (p >0.05) when comparing between the two techniques. There was also no significant difference (p > 0.05) in the percentage value of the abnormal sperm percent before and after activation. The study concludes that the techniques of swim up and swim down are effective in activating the sperm of infertile patients who are infected with asthenospermia.

The Impact of Both Types of Leukemia on the Concentrations of Alpha-TNF and serum C and Serum Immunoglobulin in Both Sexes

Thamer Ismail Ahmed1, Mounif Saab Ahmed2
1University of Kirkuk, Iraq, 2University of Tikrit \ Faculty of Education for Pure Sciences, Iraq

Abstract

Vascular leukemia is a malignant disease that affects the tissues that form the blood cells. These cells are carcinogenic and occur due to the deficiency of cells to differentiate and develop to be normal blood cells. The acute leukemia includes two types of acute and chronic, the seriousness of the disease on human life and its ability to infect all age groups, Gender The research is demonstrated to evaluate the level of tumor necrosis factor, active C protein and total white blood cells and their types in the blood of the study groups (leukemia patients and control) The research is conducted in the period from September 2018 until the end of April 2019 in the center of the province of Kirkuk specialized for tumors and blood diseases. Blood samples are collected from 141 patients with leukemia and 30 normal subjects (control group) in different age groups.

Keywords: leukemia, alpha-necrotic factor, active C protein, white blood cells

Introduction

Lungemia is a group of malignant diseases that begin in the bone marrow, infect cells that generate blood cells and multiply in the bone marrow and circulatory system. The number of red blood cells and platelets in the blood decreases. Excessive egg blood but these abnormal cells are abnormal and do not perform normal functioning. There are two types of leukemia, the first type acute leukemia, which is characterized by spleen swelling and bleeding or inflammation of the gums, and then symptoms of fatigue, exhaustion, lupus and general weakness due to anemia and appear to stained purple color on the parts of the body due to lack of platelets as well as enlargement lymph nodes (Tamimi, 2007). The condition of the patient worsens quickly and affects children (under 15 years of age) more than the elderly. The second type is chronic renal leukemia, which is the result of anorexia nervosa. It is characterized as one of the disorders of the immune system. It has about 15% of the total number of different leukemia diseases and affects all age groups, but its incidence in the elderly is more common. The causes of both types of infection are not yet known to be definitive, but scientists have attributed the causes of the disease to several factors, including viral, genetic or environmental factors such as smoking, exposure to chemicals or nuclear explosions. Of cancers, including leukemia, and that the chance of leukemia increases with aging because of the high level of free radicals in the body as age increases and the ability of the immune system to remove toxins from these free radicals. For example, laboratory tests, for example, a smear test or a full blood picture, a decrease in the proportion of hemoglobin in the blood, and a rise in total blood cells Eggs, high blood cells, lymphocytes, and only the search for aromas in the blood smear (salaf), and then the bone marrow test and the search for the aromas, and the spasms in the white blood cells are lower than in the normal state (Hoffbrand, 2006). French, British and American scientists have categorized each of the above species into several branches. Acute acute leukemia with nine branches or subtypes, acute and undifferentiated acute leukemia and leukemias, primary growth aromas, leukemias, complete growth aromatics, leukemias, leukemias, leukemias, purulent leukemia, leukemia, and chronic leukemia was categorized into leukemia with the presence of the Philadelphia chromosome and leukemia, the absence of the Philadelphia phytochemical leukemia (Hofbrand et al, 2006). The treatment of the disease lies in early
detection of the disease. Treatment immediately after the diagnosis begins by blocking the abnormal cells and then eliminating them and the stage. The first step is to strengthen and stabilize the first stage. For example, anthraxycin and cytosine compounds are used for 3 and 7 days respectively, and then Cytarabine is treated with one of the drugs. All these drugs attack normal blood cells. Bone, In addition, there are other methods of treatment, including targeted therapy, radiotherapy and biologic therapy. Materials and Methods of Work: The study was conducted at the Kirkuk Specialized Center for Oncology and Hematology. The samples are collected from patients from the beginning of September 2018 until the end of April 2019. Blood was collected from 141 patients diagnosed with leukemia by a blood diseases specialist and 30 healthy people (control) after conducting routine laboratory properties to ensure their safety from any diseases were different ages and both sexes. And withdraw 5 ml of each person’s blood and separated into two parts Part 1 2 ml Put in a test tube containing anti-clotting for tests on the total white blood cells and types and add the second part 3 ml in a glass tube and leave it for 20 minutes at room temperature and then Place the centrifuge at 3000 RPM for 15 minutes to receive the serum For the testing of the tumor necrosis factor and the effective C protein, put the first part of the blood in the Ruby autoanalyzer and give the device instructions to withdraw blood and read the full blood image The result appears on the screen G and tender instruct the device to pull the result of a tethered printer and knowledge of it after we write down the patient’s information on (name, age, sex, date) The second part of the blood after we get the serum of it we begin to conduct test checks tumor necrosis factor alpha and by the steps:

1. Prepare the solutions according to the instructions of the processed company and according to the information received from DRG International, Inc., USA,

2. Reading absorption at a wavelength of 450 nanometers by an ELISA reader

Write the results in the questionnaire for each person (patients and control).

We also carried out the effective protein c test as instructed by Spanish company Linear.

Statistical analysis: Perform all statistical analyzes in this study and calculate the mean variables and frequency distribution of the variables and compare them between the study groups through the T-Test.

Results

The results of the statistical analysis showed a high morale (p<0.01) for both the level of the tumor necrosis factor and the active c protein in the serum of patients (mean 8.79 ± 4.20, 1.90 ± 0.381) respectively, (P<0.05) in the total number of white blood cells (WBC) in the blood group of patients compared with the control group at an average of (21.6 ± 6), 15 and 6.18 ± 1.46 respectively, and showed a high morbidity of both lymphocytes and only blood cells in patients with an average of 42.7 ± 5.95 and 7.4 ± 11.9 respectively In comparison with With mean control group (mean 34.7 ± 5.9 and 1.8 ± 1.3) respectively, while a significant decrease in blood white blood cells was observed in patients’ blood with an average of 48.4 ± 19.6 compared to The control group recorded an average of 61.1 ± 6,7

</table>
While no significant difference was observed in the proportion of white blood cells of the menstrual and acid between the average group of patients compared with the control group.

**Discussion**

In this study the results of the white blood cell count were significantly higher in the group of patients compared to the control group and this result can be interpreted according to 14. When leukemia occurs, a female proliferation of leukemia cells occurs at any stage of its maturation in the bone marrow. This works on the elevation of abnormal white blood cells in the bone marrow and peripheral blood. This result can be explained according to 14 and works to reduce the performance of the work of these cells and thus reduce the immunity of the patient and therefore infected the patient at this stage microbial infections and this explains the high rate of factor necrosis alpha is a cytokine protein involved in the process against inflammation in the body in this case needs to increase by 15 C-reactive protein (C) is an anti-inflammatory protein that collects on the surface of dead, diseased or carcinogenic cells and around different types of microbes. It is present in the blood at elevated levels depending on the inflammatory state and is installed in the liver in response to factors released from the thrombocytopenia 16.

**Conclusion**

In the statistical analysis of the tumor necrosis factor alpha and b-C, the significant increase is significantly increased (p00.01) in the serum of patients with leukemia (8.79 ± 4.20, 1.90 ± 0.381 respectively) compared with the control group, (0.76 ± 1.76 ± 0.1) respectively. There is also a significant increase in the total number of white blood cells (WBCs) and lymphocytes (P00.01) Control group while white blood cells recorded a significantly lower morale compared to the control group while no significant difference may be observed in white blood cells as well as the acidity between the mean group of patients and the mean control group, the results under study show a positive relationship between the alpha-prophylactic factor C and the total number of white blood cells.

Psychological Factors Affecting on Performance in Speaking Skill

Raziqa Aliwy Naser Al-Khafaji¹, Jalal Azizi Farman Al-Barqawy¹, Muneer Ubeid Najem Al-Jiboory¹
¹College of basic education/ University of Babylon, Iraq

Abstract

The aim of this research paper is to evaluate performance during styles of simple perspective sensible learning due to VARK model which identifies four primary types of learners: visual, auditory, reading/writing, and kinesthetic. The study sample consists of (140 teachers of both sexes) who are distributed according to the school kind (for boys or for girls) and location, for elementary schools. The research paper is descriptive, the paper tool is a form of 25 teaching skills of learning styles. The statistic means are used in the centigrade scale, weighted average and Pearson Correlation Coefficient (PCC). The study has concluded results like visual and auditory control because of getting the highest degrees in the statistic means.

Key words: Psychological, Performance, Skill

Introduction

This language is evaluated because it is the language of Quran and it deserves a lot of interest. It is the language of Quran and Sunnah (Prophetic Tradition) as well as a language of learning and education as assured by the study of (Al-Musawi, Fatima). Al-Musawi study refers that Arabic language is a gift from God to human beings to be a means for the human to know himself. one of the factors that effects in the human and social development of the society and unites the cultural and intellectual frames of education. Most of other carriers are obliged to confess that their basic preparation is insufficient. What makes a teacher successful and distinguished is the work based on educational theories and concepts and the full understanding of educational operation sides and indicators. The successful teacher has to apply procedures that assist learners to learn and acquire targeted skills and experiences. One of the most important issue for the teachers is his knowledge about learning styles which enable him to build and design the learning units and introduce the appropriate means for his pupils rather than what is appropriate to him as a teacher. The teacher mustn’t depend on a specific method in teaching but he must be creative of his style and flexible in taking the appropriate style to achieve the educational and learning goals. Choosing the learning style is connected with the text book and teacher’s ability to use the appropriate style of the educational situation that makes the learners accept the information. This is assured by the study of which shows the sets effect in listening of pupils of English language. Some believe that factors and psychological, physical, mental and social readiness are connected with each other and considered as important factor in the achievement process. So if a pupil desire to any kind of studies increased, his achievement or degree will be increased and vice versa. It is necessary to make use of any teacher according to his competence because each teacher has something to introduce, as a part of his professional responsibility, in textbook development on the basis of continued professional preparation. The teachers’ preparation will remain as a difficult task because of the limited textbooks and educational means unless we have the efficient teacher. So it is necessary to identify the learning styles to improve the learning performance including the class interaction which leads to positive effects in the educational process. The study problem is identified by the following questions:

1- How could we know the style of each pupil of the elementary school?
2- What is the relation between the learning styles and teachers’ of Arabic language performance?
3- What is the benefit for the teacher and the pupil of elementary school to know the learning styles?
Expressions Identification:

Evaluation, as an expression, is identified by (Al-liqani and Al Jamel) as a judgment issue towards a subject (Al-liqani, 82:1996).

Al-Qala identified the evaluation as the procedures through which the data of the scientific material or a project or an occurrence or an individual is collected and studied depending on a scientific style that assures the achievement of the limited goals to take the appropriate decisions.

The performance:

It is identified by Al-Dulaimi as “a personal activity made by an individual when facing a specific task to achieve successful results”.

Learning styles:

VARK identified them as “the way in which the learner can receive knowledge”

Atiyah identified them as “motivating the learner’s mental forces and self-activity to change his behavior resulted from internal and external effects”.

Methodology

The researcher chose the descriptive method to adapt with the current study nature. That method was considered as one of the most used one in the educational and psychological researches.

Research community:

It is divided into two parts:

a- The community of governmental elementary schools in the center of Babylon province.

b- The community of teachers (of both sexes) of Arabic language in the elementary schools.

The research tool:

The research aims to evaluate the performance of teachers of Arabic language during the learning styles. So it needs monitoring form as a tool of performance evaluation. Direct monitoring is considered as one of the most appropriate means to measure the learning styles for students. It is also important to monitor the teachers educational methods due to the students kinds and interests. Direct monitoring provides a clear image about the educational behavior of teachers.

Tool validity:

Validity is considered as one of the basic conditions that should be existed in the research paper. The tool will be valid if it achieves the purpose for which it exists and can measure what is required.

Tool stability:

The research tool should be stable and it won’t unless it gives the same results when applied on individuals under the same circumstances.

Tool application:

The tool is applied as the following:

1- Making interviews with all teachers of Arabic of the fourth and fifth class and inform them about the visit purpose which is serving the scientific research.

2- The researcher makes (109) visits to the teachers of Arabic, each teacher has one or more visits.

3- Not up to the standard note is included in the notice form prepared previously.

Research results:

The researcher concluded many results, prominent among those was:

1- Students Individuals differences are not taking into consideration due to the learning styles preferred by students.

2- Visual and auditory style is controlled on most of teachers’ performance and this will lead to the lack of performing the other two styles (reading/writing, and kinesthetic).

Conclusion

The study sample consists of (140 teachers of both sexes) who are distributed according to the school kind (for boys or for girls) and location, for elementary schools. The research paper is descriptive, the paper tool is a form of 25 teaching skills of learning styles. The statistic means are used in the centigrade scale, weighted average and Pearson Correlation Coefficient (PCC). The study has concluded results like visual and auditory control because of getting the highest degrees in the statistic means.

Effectiveness of an Instructional Programs on Patient’s Knowledge Regarding Self-Care Management after Ischemic Heart Disease

Ahmed Abdul-Hussein Kittan¹, Rajha Abdul Hassan Hamza²

¹Adult Health Nursing Department / College of Nursing / University of Thiqar / Iraq,
²Adult Health Nursing Department / College of Nursing / University of Kufa / Iraq.

Abstract
Cardiovascular disease remains the leading cause of morbidity and mortality worldwide, and there is a rising global burden. The effects of diet on cardiometabolic risk factors have been studied extensively. Healthy habit as a cost-effective approach to risk reduction in post-ischemic heart disease patients is proven to be beneficial. A quasi experimental study design is carried out at An Nasiriyah Heart Center in AL-Nasiriyah City, from 15th of September, 2018 to the 2nd July, 2019. A non-probability (Purposive sample) of (100) patients diagnosed with myocardial infarction divided into two group (50) patients as control group and (50) patients as study group. The data were collected through the use of questionnaire designed by researcher, which comprised of (2) parts: Part I: related to the Socio-demographic characteristics and Part II: Clinical characteristics. Part III: Assessment self-care management of IHD patients’ knowledge. Reliability of the questionnaire is determined through a pilot study and the validity through a panel of experts. The descriptive and inferential statistical procedures were used for analysis of data. Findings of the present study indicated that the instructional program recorded positive and meaningful results in improving patients’ knowledge with self-care management.

Keywords: Effectiveness, Instructional Program, Patients, Knowledge, Self-Care Management.

Introduction
Cardiovascular diseases is considered as one of the most common chronic diseases and mortality reason in the world. It is estimated that due to cardiovascular diseases, 20% of healthy life years of people will be lost by 2020. In 2000, CVD is accountable for more than 1.9 million of death in the European Union, 4.35 million deaths in Europe, responsible for 43% of all deaths in male and 55% of all deaths in female. Cardiovascular disease is developing and has become the leading reason of death in developing countries. Furthermore numerous risk factors have been linked to the development of CVD including: poor dietary habits, overweight and obesity, hypertension, insulin resistance or diabetes mellitus, alcohol consumption, smoking, poor physical activity levels, and dyslipidemia. Many of these risk factors are related and reversible through a healthy diet and increased physical activity. Adopting a healthy lifestyle can lower cholesterol, reduce recurrent myocardial infarction, need for surgery or angioplasty. One of the ways to do this is to reduce the amount of saturated fats, salts, and meats consumed. Studies have established the benefits of therapies, such as self-care management, at reduction risk factor in secondary prevention of IHD. In his study, Yancy et al. has shown 73.3% of patients felt limitation and isolation, 62% gave up hope and accepted that they did not look after themselves, 66.6% of them had frequently been hospitalized and they believed it happen due to lack of knowledge about looking after themselves. Nowadays, developing the technology has decreased the duration of diagnosis, cure and hospitalization days and patients don’t have enough time to obtain information about their disease during hospitalization. According to a study, 20% of hospitalized patients said that they have received enough information and consultation about their health conditions, while 20% of them were not satisfied about their received information and 60% have said information must be presented better. Learning self-care can direct person toward maintaining the health and cause to increase of adaptation and ability of self-
Material and Method

A quantitative research approach has been used for this study. The quasi-experimental design (two-dimensional demonstration of two-group pre-test-post-test design) conducted on patients with ischemic heart disease towards education program with application of pre-post-test approach for the study group and control group in assessing their knowledge and the application of education program for the study group. It carried out in order to achieve the initial stated objectives. The study was started from 15th of September, 2018 to the 2nd July, 2019, mission to carry out the study. A non-probability (purposive) sample of (100) patients was selected. All the patients diagnosed with ischemic heart disease and they had a medical records and they review cardiac outpatient clinics An Nasiriya Heart Center. The sample was divided into two groups each one contained (50) patients as control group and case group. The study group was exposed to an education program about knowledge of self-care management, while the control group was not exposed to such instructional program. To accomplish the study, the researcher constructed the questionnaire based on the review of previous related literature and related studies. Data were analyzed through the use of SPSS application version 0.22. Descriptive data analysis including Frequency, Percentage, Mean of score (M.S) with their Standard Deviation (S.D). Percentile Grand Mean of Score (PGMS), Percentile Global Mean of Score (PGLMS), and Relative Sufficiency (RS %). Inferential data analysis includes Chi Square statistic of the contingency, Test (ANOVA) Data, T-test (independent sample t-test), T-test (paired t-test).

For the abbreviations of the comparison significant (C.S.), we used the followings

- □ NS : Non-significant at P>0.05
- □ S: Significant at P<0.05
- □ HS : Highly significant at P<0.01

The study limited by different factors including: difficulty to reach to the national studies and previous studies regarding educational programs about nutritional regimen for myocardial infarction patients, Limited research population that could affect the generalization of research findings in all Iraqi governorates. As well as difficulty to attend some education sessions by some patients.

Table (1) shows that studied groups recorded no significant differences at P>0.05, and this reflects the validity of the selected subjects due to their similar status in the light of those variables, as well as preceding results indicating that two studied groups are thrown from the same population in the light of, and this is more reliable for this study, since any meaningful deviation between studied groups should be interpreted according to the effectiveness of applying the suggested program. Statistical distribution of case group and control group by their socio-demographic data, it explains that the highest percentage (case group 60% and control group 82%) of patients are with ages above 60 years old, and (68% of case group and 70%of control group) of them are male patients, the majority of case group (86%)and control group (82%) are married, most of the sample live in urban residents (case group74% and control group 68%), while (24% of case group and 50% of control group) are illiterate, most of (76% case group and 84% of control group) have insufficient monthly income, and are (38% of case group and 60% of control group) retired.

Discussion:

The case results show that the most frequent age group for patients’ with IHD are (60 years old and more). This result agrees with (Jernberg, et al.,) 8., they concluded in their study that (60 years old) are the dominant age group of the case sample Many studies claimed that the elderly patients’ over 60 years of age have more chances of having IHD, This fact may be related to many factors such as decrease metabolic rate for these patients’ and increase catabolic rate. Concerning the gender of the sample , the study results reveal that the majority of subjects are males. This result agrees with Tomaszewski, et al., 9 in their study they found that the dominant gender are male. In addition, the differences in sex in the broad scope of wellness and illness have been the matter of general investigation, Men consider themselves as responsible for their families and they react to ward solving any problem they face or stress without expressing of their problem to others this may become as one of the risk factor for IHD and other chronic disease, on the other hand women can be relieved from their problems by many ways for example crying, talking about the problem to friends or relative. Regarding educational level, The results of the study indicate that most of the patients’ were illiterates. This result agrees with Singh, et al., 9 their study results indicate that most participants are illiterate this may be due to the socioeconomic reasons. This may be related to culture and knowledge deficit resulting from economic and social causes related to poor living conditions. The study results show that majority of the study subjects are married, these results agree with many other studies Malik, et al., 10; Manfredini, et al., 11 their results indicated that the majority of case subjects are married, The Iraqi people are well socialized and have habits and customs they follow and one of these customs is having married in early age. Young men can face many psychological stress after many years throughout marriage. Regarding occupational status, the results show high percentage of case group are retired people. Regarding patients’ clinical data, the case results reveals that most of patients are diagnosed with angina, as it is the first signs that may occur for patient before myocardial infarction due to vasoconstriction of the coronary vessels not death part of heart muscle tissue. This finding is in agreement with finding of a previous case of Wang, et al., 18he found that there are poor knowledge level of the patients before application the educational program. A study concluded that communities need to be aware of educational programs in relation to heart diseases to reduce complications and increase knowledge of the disease. Concerning the result related to associations between post-test and demographical data. The present case reveals that there is non-significant association between post-test and demographic data of case group in relation to (Marital status, Monthly income, residency, Period of diagnosis, Suffering from the disease, training sessions and No. of admissions). The results of the present case are supported by other studies that indicated no significant difference between demographic data and post-test (Aziz & Lafi, 2013; Wigmans, 2018).

Conclusions

The majority of IHD patients are males with age 60 and above, also they are illiterate, with not enough monthly income, and most of them live in urban areas. Instructional program an appropriate and effective way to improve the patient’ knowledge about IHD self-care The study group have significant modification in relation with self-care management toward IHD at pretest and posttest The control group does not present any significant modification related to knowledge toward IHD at pretest and post test There is strong effect between the study group knowledge in pre-test and their (marital status, body mass index, Smoking Period, number of cigarettes, Number of hospital admissions).

Abstract

In this paper, a cellulose paper was impregnated with silver nanoparticles (AgNPs) for the purpose of removing Enterococcus faecalis from drinking water. AgNPs papers were prepared by chemical reduction of silver nitrate (AgNO3) with various concentrations (0.005 M, 0.01 M, 0.015 M, and 0.025 M) using sodium borohydride (NaBH4) as a reducing agent. Two ratios of NaBH4/AgNO3 of 2:1 and 10:1 were used to show the effect of reduction on the formation and removal efficiencies of AgNPs. AgNPs papers were characterized using SEM and TEM. TEM images showed that the silver nanoparticles size in the papers varies from 1.3 to 75 nm.

Keywords: Enterococcus Faecalis, Drinking Water, Silver Nanoparticles.

Introduction

Disinfection of potable water is the specialized treatment for destruction or removal of organisms capable of causing disease; it should not be confused with sterilization, which is the destruction or removal of all life. Although disinfection methods currently used in drinking water treatment can effectively control microbial pathogens, researches in the past few decades have revealed a dilemma between effective disinfection and formation of harmful disinfection byproducts (DBPs). Three categories of human enteric pathogens are of concern in drinking water: bacteria, viruses, and ameobic cysts. Disinfection must be capable of destroying all three. Destruction or removal of these organisms is essential in providing a safe potable water supply. Some bacteria, viruses, protozoa, and larger organisms ingested from contaminated water cause diseases varying from mild illnesses to life-threatening. The Enterococcus genus is placed in the Enterococcaceae family and consists of species that occur in human and animal gastro-intestinal (GI) tracts, as well as in the guts of insects traditional fermented food and dairy products, and in various environments including plants, soil and water. Enterococcus faecalis is a non-spore-forming, fermentative, facultatively anaerobic, Gram-positive coccus. Enterococcus faecalis cells are ovoid and 0.5 to 1 μm in diameter. They occur singly, in pairs, or in short chains, and are frequently elongated in the direction of the chain. They typically have an optimum growth temperature of 35°C and a growth range from 10 to 45°C. They currently rank among the most prevalent multidrug resistant hospital pathogens worldwide as the third most commonly isolated healthcare pathogen, and are capable of causing a variety of infections including endocarditis, sepsis, surgical wound infections, and urinary tract infections. The organism has the natural ability to acquire, accumulate and share extrachromosomal elements encoding virulence traits, which help to colonize, compete with other bacteria, resist host defense mechanisms and produce pathological changes directly through production of toxins or indirectly through induction of inflammation. Nanotechnology and its application is one of the rapidly developing sciences. Silver nanoparticles have proved to be most effective as it has good antimicrobial efficacy against bacteria, viruses and other eukaryotic microorganisms.

Experimental Procedure

Sampling

The samples were taken from Shatt al-Hilla, at Al-Hilla city/Iraq and during the period (November 2018 – March 2019). 500 ml of water as grabbed and kept
in precleared plastic bottle. The samples were analyzed immediately to prevent any change in their quality that may occur.

**Preparation of AgNPs papers**

A (10 cm * 10 cm * 0.8 mm) off-white paper, 100% alpha cellulose was used to be embedded with silver nanoparticles. AgNPs papers were prepared by in situ reduction of AgNO3 with various concentrations (0.005 M, 0.01 M, 0.025 M and 0.05 M) with two reduction ratio of 2:1 and 10:1. Each paper was soaked in 40 ml of AgNO3 solution for 30 minutes, then it was washed with ethanol for 1 minute to remove the excess Ag ions which not absorbed by the paper. To form AgNPs, the paper was placed in 40 ml of NaBH4 solution for 1 hr. After that, the paper was soaked in de-ionized water for 30 minutes. Then the paper was dried in the oven at 60 °C for 2.5 hrs.

**Characterization**

The synthesized AgNPs papers were characterized by Scanning Electron Microscopy (SEM), type Quanta 450 available at the University of Babylon/ College of Pharmacy and Transmission Electron Microscopy (TEM) available at Al-Nahrain University/ College of Medicine.

**Acid Digestion**

To determine the silver content in the AgNPs paper, an acid digestion of the paper was performed and then analyzes the amount of dissolved silver with an Atomic Absorption Spectrometer (AAS) (AA320N) available at the University of Babylon/ College of Material Engineering. Approximately a 100 mg of the dried AgNPs paper was reacted with 5 ml of nitric acid (HNO3) and 5 ml of water. The mixture was boiled until the paper was disintegrated. 5 ml of 30% hydrogen peroxide (H2O2) was added to the mixture to assist in the complete oxidation of the organic matter to release additional metals into the solution. The mixture was boiled again and left to be cooled, then filtered through a filter paper and then diluted by adding a 100 ml of water. The diluted mixture was tested for silver content using an AAS.

**Microbiological Test**

The raw water samples were cultured using serial dilution method, 1 ml of the sample was diluted in 9 ml of distilled water (1:10 dilution). 1 ml of 1:10 dilution mixed with 9 m; of distilled water (1:100 dilution), etc.
the filtered water samples were cultured without dilution. 0.1 ml of each sample was spread over a media plate and then the plates were incubated in 37 °C for 48 hrs in an incubator (LIB-030M).

**Results and Discussion**

**Paper Characterization**

The AgNPs papers were characterized by SEM and TEM. Fig.2 represents the images obtained by SEM to show the presence of AgNPs in paper fibers. Fig. 3 represents the images obtained by TEM to determine the particles sizes of AgNPs. Table 1 represents the particles sizes of AgNPs obtained by TEM test.

![Fig. 2: Images obtained from SEM. (a) 2:1 NaBH₄/AgNO₃ ratio. (b) 10:1 NaBH₄/AgNO₃ ratio.](image)

![Fig. 3: TEM images. (a) 2:1 NaBH₄/AgNO₃ ratio. (b) 10:1 NaBH₄/AgNO₃ ratio.](image)

</tbody>
</table>

TEM images showed that an excess of sodium borohydride reductant (10:1 ratio of sodium borohydride to silver nitrate) gave more uniform and smaller nanoparticles.

Acid Digestion

Acid digestion was performed to determine the silver content of the paper. The results were obtained by using AAS (AA320N). Table 2 shows the results of the AAS test.

Table 2: Silver content of each paper

<table>
<thead>
<tr>

<tr>
<td>0.05</td>
<td>7.8669</td>
</tr>
</tbody>
</table>

The acid digestion of AgNPs papers showed silver content ranging from 3.9 to 8.7 mg Ag per dry gram of paper. The increase in silver content of the paper correlates with the increase in precursor silver ion concentration of the solution in which the papers were soaked, prior to reduction. For the same concentration of AgNO₃, the NaBH₄/AgNO₃ ratio of 10:1 resulted in more silver content than 2:1 ratio.

Bactericidal Effectiveness of AgNPs papers

Fig. 4 shows the effect of the silver content in the AgNPs paper on the removal efficiency of Enterococcus faecalis of filtered water samples and raw water samples with a NaBH₄/AgNO₃ ratio of 2:1 and 10:1 respectively.

Fig. 4: Effect of silver content on the removal efficiency of Enterococcus faecalis of raw water samples with a: (a) NaBH₄/AgNO₃ ratio of 2:1. (b) NaBH₄/AgNO₃ ratio of 10:1.
Fig. 4 shows that removal efficiency Enterococcus Faecalis of the raw water samples for both ratios ranges from 99.9% to 100% for all silver contents.

**Analysis of silver content in the effluent**

Due to possible human health effects from silver exposure, the silver content in the effluent water was analyzed by AAS. Table 4 represents the relationship between the silver content in the paper and silver release in the effluent.

**Table 4: The relationship between the silver content in the papers and silver in the effluent water.**

<td>0.043</td>
</tr>
<tr>
<td></td>
<td></td>
<td>10:1</td>
</tr>
</tbody>
</table>

As shown in Table 4, the average silver content in the effluent water for the three replicates range from 0 to 0.082 which meets the United States Environmental Protection Agency (US-EPA) guideline for drinking water of less than 0.1 mg/L [EPA, 2018]. This was due to the stability of silver nanoparticle in the cellulose paper. Sodium borohydride acts not only as a reducing agent but also as an ion stabilizer, which prevents silver ions from aggregation. Moreover, hydroxyl and ether groups in the cellulose fiber play an important role in the stabilization of metal nanoparticles.

**Conclusions**

Silver nanoparticles used in this study were well dispersed and stabilized on the paper fibers. Chemical reduction of AgNO3 by using NaBH4 as a reducing agent resulted in spherical silver nanoparticles. The NaBH4/AgNO3 ratio of 10:1 resulted in smaller sizes of silver nanoparticle and more silver content than the ratio of 2:1 for the same AgNO3 concentration. (99.9-100)% inhibition of Enterococcus Faecalis was obtained with all the concentrations of AgNO3 and NaBH4 and for both NaBH4/AgNO3 ratios.

**Financial Disclosure:** There is no financial disclosure.

**Ethical Clearance:** All experimental protocols were approved under the College of Water Resources Engineering/ Al-Qassim Green University and all experiments were carried out in accordance with approved guidelines.

Assessment of the Correlation between the Salivary Flow Rate and Dental Caries Experience among Children with β-Thalassemia Major

Mudhafar Fadhil Jaddoa¹, Alhan Ahmed Qasim²
¹M.Sc. Student, ²Assistant Prof., Department of pediatric and preventive dentistry/College of Dentistry/Univ. of Baghdad, Iraq.

Abstract

Thalassemia constitutes a group of congenital blood disorders which characterized by a defect in synthesis of one or more globin chains of human hemoglobin molecule and the resultant microcytosis and hypochromia of the RBCs. It is of two main divisions, α- and β-thalassemia and several other subdivisions. The study group composed of 40 patient years previously diagnosed with β-thalassemia major attending the thalassemia center in Thi-Qar province/Iraq. The control group, matching the age and sex of the study group, and consisted from 40 child selected from a number of primary schools. Unstimulated salivary samples was taken from each subjects under standardized conditions. The mean value of flow rate of saliva was lower among β-thalassemias (0.466±0.024) than for controls (0.829±0.048). The (mean±SE) for the primary teeth (dmfs) in β-thalassemias (1.450±0.324) was higher than that for controls (1.250±0.808), this difference was not significant (P> 0.05). The (mean±SE) of the caries experience (DMFs) in β-thalassemias (6.850±0.782) was higher than for the control group (3.600±0.489).

Keywords: β-Thalassemia major, Salivary flow rate, Dental caries experience (dmfs/DMFs).

Introduction

Thalassemia is a very worldwide common autosomal and recessive genetic disorder with a large geographical incidence difference, it is a so severe and incurable disease because prevention is the only way to evade the disease [1]. Thalassaemias are caused by markdown or complete absent in the synthesis of one or more of the globin chains that constitute the hemoglobin (Hb) unit [2,3]. About 60,000 to 70,000 newly born children are born yearly with a severe form of thalassaemias around the world [4], and unfortunately most affected children are those who born in areas of low sources of income [5], β-Thalassemia major is the most severe type of thalassemia and occurs due to a defect in the synthesis of β-globin chain [6]. Beta- homotetramers in α-thalassemia are more stable than alpha- homotetramers in β-thalassemia; therefore, in beta thalassemia α-homotetramers tend to precipitate priorly in the RBCs life span, producing marked RBCs haemolysis [7]. Few of the pro-erythroblasts beginning their maturation and can survive [8,9], the resultant few RBCs will bear an inclusion bodies that identified in the spleen, shortening the RBC lifespan and producing severe haemolytic anaemia [10]. The produced anaemia stimulates the production of erythropoietin stimulating hormone from the kidney and liver with a compensatory erythroid hyperplasia, but the marrow response is disrupted by ineffective erythropoiesis. [11]. Later on, massive bone marrow expansion will happened and the end result is skeletal deformities [12]. In thalassemias, high caries index, pallor of oral mucosa, atrophic glossitis, sialadenitis, retained deciduous teeth, shortened and spiked roots of teeth and thinning of the lamina dura could be seen [13]. Oral health, on the other hand, can also affect child’s personality, knowledge, and social relationships [14]. Dental caries is a chronic disease resulted from a complex intercommunication of a mass of cariogenic oral microorganisms which grow on the teeth surfaces within the dental [15]. Dental caries is widely spread and can affecting all ages. The experience of dental caries could

Corresponding

e-mail: moadhafar_f@yahoo.com.
Saliva is a heterogeneous mixture of fluids mainly produced via the major and minor salivary glands and contains oral bacteria and food debris from the gingival crevicular fluid. Saliva have an important role in the maintenance of a healthy oral environment through a variety of physicochemical and biological properties. Unstimulated (resting) saliva includes secretions that enter the mouth without any exogenous stimuli. Flow rate is the most important salivary parameter affecting oral health status and it represents the rate of salivary secretion and it is expressed in milliliters per minute. Flow rate is very important protective factor against dental caries throughout its washing and buffering effect, any minimization in the normal salivary flow rate can results in establishment of dental caries. Al-Jobouri and Al-Casey and Kataria et al.

Materials and Method

The total sample included in this study was (80) subjects. The study group was consisted of a (40) child suffering from β-thalassemia major and aged (11-12 years old). The control group, the non-thalassemic children, matching the age and gender of the study group, and consisted of a (40) child selected from the primary schools. An ethical approval was firstly obtained from the Ministry of Health and the Ministry of Education to perform the clinical examination and laboratory biochemical analysis. Also, a written consent form as well as patient information sheet were provided to each participant for gaining the acceptance of the child’s parents or his/her caregiver. Children having other diseases whose known to affect the experience of dental caries or the characteristics of saliva such as diabetes mellitus, were excluded. The oral examination was performed under standardized conditions of oral health surveys (WHO 1997). During examination, a suitable chair is used with noticing that it supports the head of the child. Clinical examination was performed using plane mouth mirror and dental probe. The reported caries experience was based on the criteria suggested by Manjie et al. Unstimulated salivary samples was taken from each subjects under standardized conditions suggested by Navazesh and Kumar. Statistical analyses were done using SPSS computer programme, version 21. Descriptive statistics including (the mean and SE) of each clinical variable were determined for all the subjects. Student t-test was used to compare the caries experience between the study and control groups. Pearson’s correlation coefficient (r) was used to assess and compare the correlations among the variables. (P> 0.05) was considered statistically not significant. (P≤ 0.05) was considered statistically significant and (P≤ 0.01) was considered to be statistically highly significant.

Results

Table (1) illustrates the results showed that the (mean±SE) in β-thalassemias (1.450±0.324) was higher than that for the control group (1.250±0.808). This difference was not significant (P> 0.05).

Discussion

In the present study, the mean value of salivary flow rate was founded to be lower among β-thalassemias (0.466±0.024) than in their control subjects (0.829±0.048). This result was also documented previously by Norri [28] and by Al-Jobouri and Al-Casey [24]. This minimization in the salivary flow rate among the study group might be attributed to the fact that the salivary glands function in thalassemic patients can be affected directly by the excessive iron deposits, and the resultant painful inflammation of the salivary glands, with either regular or diminished salivary flow [23]. However, Siamopoulou et al [29] concluded in their study that the difference in salivary flow rate between the two groups is not significant. These results were in disagreement with Luglie et al. [30] and Greenberg et al. [31] whose showed in their studies that salivary flow rate was similar in both study and control groups.

The present study also concluded that the mean value of caries experience by surfaces in primary dentition (dmfs) among β-thalassemias was higher than that recorded in their controls. This result was corresponding with Gomber et al. [32], Kaur et al. [33], Dhote et al. [34]. On the contrary, this result was disagree with Scutellori
et al. [35], Qureshi et al. [36] and Arora et al. [37] who were concluded that there is no difference between the two groups.

Furthermore, the results of the present study revealed that the mean value of caries experience by surfaces in permanent dentition (DMFs) among β-thalassemias was higher than that recorded in their controls. This results was in agreement with Hattab et al. [38], Al-Raheem et al. [39] and Al-Hadithi [40], while it was in disagreement with the results of Scutellori et al. [35] and Arora et al. [37] who were founded a similar mean value between the two groups.

In present study, there was a negative correlation between salivary flow rate and caries experience. Salivary flow rate may play an important role in relation to dental caries in which the flow rate of saliva exert cleansing activity which is critical in the clearance of food remnants and bacteria [41]. It was documented that the caries experience is obviously increased when salivary flow rate is stunted and this fact sign that the chronic decrease in flow rate is a risk factor for dental caries initiation and progression [42]. In thalassemic patients, reduced salivary flow rate can help in colonization of cariogenic S. mutans, which may have a role in the higher caries experience. Al-Zaidi [43] has documented an indubitable correlation between oral mutans streptococci and dental caries in β-thalassemia patients.

However, the higher caries experience in β-thalassemias than the normal controls can be related to factors other than a reduced salivary flow rate. This could be explained on the idea that these patients are less concern with their oral health, their parents are more worried about the serious physical condition, they paying less care to the oral health care, and seeking professional oral care just when the child experience severe pain [23, 44].

Al-Wahadni [45] and Gomber and Dewan [32] concluded in their studies that skeletal changes as enlargement in maxillary arch that occur in thalassemias in could result in protrusion of anterior segment, increased space between upper and lower teeth, overbite or open-bite which all could predispose to dental caries.

**Conclusion**

Dental caries experience was higher among beta thalassemias compared to the control group. The salivary flow rate among β-thalassemias was lower among β-thalassemia patients than for their control subjects. The reduced salivary flow rate detected in β-thalassemia major patients could be considered as a modifying factor for the increased experience of dental caries in these patients.

Abstract

Background: Diabetic foot is a serious complication of diabetes that aggravates the patient’s condition whilst also having significant socioeconomic impact. Increasing physicians’ awareness and hence their ability to identify the «foot at risk» along with proper foot care, may prevent diabetic foot ulceration and thus reduce the risk of amputation.

Objectives: 1. Determine the socio demographic data on diabetic foot and leg ulceration
2. Determine the relationship of socio demographic data on diabetic foot and leg ulceration
3. Determine the Effecteness of Carbothera therapy upon diabetic foot and leg ulceration improvement

Methodology: A descriptive study was conducted on a sample consisting of (50) patients is having diabetic foot and leg ulceration who were selected randomly from Endocrine and Diabetic Center in Nasiriya City. Diabetic patient who have diabetic foot and leg ulceration, carried out in Nasiriya city / endocrine and diabetic Center starting from January/ 2019 to July /2019

Results: 40% the age between 60-69 years, males was 68%, the patients residing in the city (urban) by 66%,78% of them consider that their monthly income is not enough, infected with diabetes For diabetes for a period of 10 years and more is 76%, the average age of patients was 59 years, patients discovered diabetes disease was 66% , improvement in their health through the carbothera therapy 66% indicated a positive effect on the patients, a significant mean relationship at level of 8% between the urban and rural environment variable with improved carbothera therapy indicates that therapy is more effective when the patient has a more urban than rural. In addition, a very weak and statistically insignificant relationship between the patients is other demographic data and the improvement of carbothera therapy

Keywords: Diabetic, Carbothera therapy, foot and leg ulceration

Introduction

Diabetic foot and leg ulceration is one of the most significant and devastating complications of diabetes, and is defined as a foot affected by ulceration that is associated with neuropathy and/or peripheral arterial disease of the lower limb in a patient with diabetes. The prevalence of diabetic foot ulceration in the diabetic population is 4–10%; the condition is more frequent in older patients 1-3. It is estimated that about 5% of all patients with diabetes present with a history of foot ulceration, while the lifetime risk of diabetic patients developing this complication is 15% 1. The majority (60–80%) of foot ulcers will heal, while 10–15% of them will remain active, and 5–24% of them will finally lead to limb amputation within a period of 6–18 months
after the first evaluation. Neuropathic wounds are more likely to heal over a period of 20 weeks, while neuro ischemic ulcers take longer and will more often lead to limb amputation. It has been found that 40–70% of all no traumatic amputations of the lower limbs occur in patients with diabetes. Furthermore, many studies have reported that foot ulcers precede approximately 85% of all amputations performed in diabetic patients. The risk of foot ulceration and limb amputation increases with age and the duration of diabetes. The prevention of diabetic foot is crucial, considering the negative impact on a patient’s quality of life and the associated economic burden on the healthcare system. Diabetic foot ulceration is a major health problem and its management involves multidisciplinary approach. This review aims to provide a synopsis of the current management strategies of diabetic foot ulcers, from prevention to the options for therapy. The authors believe that it may be useful to primary care physicians, nurses, podiatrists, dialectologists, and vascular surgeons, as well as all healthcare providers involved in the prevention or management of diabetic foot ulcers of skin integrity, providing a site vulnerable to microbial infection. Peripheral arterial disease is 2–8 times more common in patients with diabetes, starting at an earlier age, progressing more rapidly, and usually being more severe than in the general population. It commonly affects the segments between the knee and the ankle. It has been proven an independent risk factor for cardiovascular disease as well as a predictor of the outcome of foot ulceration. Even minor injuries, especially when complicated by infection, increase the demand for blood in the foot, and an inadequate blood supply may result in foot ulceration, potentially leading to limb amputation. The majority of foot ulcers are of mixed etiology (neuro ischemic), particularly in older patients. In patients with peripheral diabetic neuropathy, loss of sensation in the feet leads to repetitive minor injuries from internal (calluses, nails, foot deformities) or external causes (shoes, burns, foreign bodies) that are undetected at the time and may consequently lead to foot ulceration. This may be followed by infection of the ulcer, which may ultimately lead to foot amputation, especially in patients with peripheral arterial disease. Structural foot deformities and abnormalities, such as flatfoot, hallux valgus, claw toes, Charcot neuroarthropathy, and hammer foot, play an important role in the pathway of diabetic foot ulcers since they contribute to abnormal plantar pressures and therefore predispose to ulceration. Other risk factors for foot ulceration include a previous history of foot ulceration or amputation, visual impairment, diabetic nephropathy, poor glycemic control, and cigarette smoking. Some studies have shown that foot ulceration is more common in men with diabetes than in women. Social factors, such as low socioeconomic status, poor access to healthcare services, and poor education are also proven to be related to more frequent foot ulceration.

**Methodology**

Non-probability (purposive) sample application was conducted on a sample consisting of (50) patients having foot and leg ulceration who were selected from endocrine and diabetic center in Nasiriya city. An assessment format was constructed and designed depending on open format information and after reviewing the related literature, the objective of this assessment was to evaluate the need for the educational program. The assessment was conducted from January 2019 to July 2019 and the format was comp each respondent a period between 30-40 minutes. Researcher were fill out the format by himself. For those who were unable to ask to read and write, the researcher filled out the format herself with their original responses.

The data of present study were analyzed through the application of two statistical approaches, which may assist for the determination of the study results.

**Statistical analysis**

A statistical questionnaire on diabetic foot disease was prepared and a sample of 50 patients was selected. The form consisted of two axes: The first on the socio-demographic aspect of the patient and the second on the clinical medical aspect.

The data from the form were classified and the variables were coded according to the requirements of the statistical program SPSS.

Since the variables used are qualitative and not quantitative, the correlation coefficient has been used to measure whether there are links between some variables and their analysis. The Spearman correlation coefficient is based approximately the vocabulary of each of the descriptive variables in question, with each given numeric value showing its order. Using these ranks, the correlation coefficient, called “grade”, can be calculated. The correlation coefficient can be calculated through the following formula:
\[ R_s = 1 - \frac{\sum D^2}{n(n^2 - 1)} \]

Where \( n \) = number of observations

\( D \) = differences between two ranks of two observations

Table (3) showed that the majority of patients discovered diabetes through their reviews, not the same thing. The proportion of patients diagnosed with the disease was 66% of the total sample. The percentage of patients who reported an improvement in their health through the therapy of carbothera therapy 66% indicated that the therapy had a positive effect on the patients, the form of the number of patients who responded to exercise daily, which is very useful to them, the number of patients who responded that they are walking Which were very useful to them, constituted a high rate of 82% of the patients in the sample.
Table (4) showed the majority of patients (23 patients and 46% of total patients) who responded to therapy were among the 1 to 15 session sessions supporting the patient’s response to therapy after attending only one and a half sessions (two sessions a week). The relationship between Spearman and (0.248) indicates that a significant mean relationship at an error level of 8% between the urban and rural environment variable with improved carbothera therapy indicates that therapy is more effective when the patient has a more urban than rural environment. The patient to the consequences of disease in the city be committed to therapy and get better results. While the relationship between the mean and moral level of error does not exceed 9 per cent between the variable and the presence of monthly salary of the patient due to lack of improvement in the therapy of carbothera, indicating that the therapy is more effective when the patient a monthly salary. This result is for the patient’s mental state and the state of safety provided by the continuous monthly salary.

The correlation is very weak and there is no daily walk to the patient with improved therapy of carbothera through the value of the link (Spearman) and the amount (0.007), may appear this way because the patient has difficulty walking because of the disease and declare that he walked but did not exceed the steps were not simple you remember.

Discussion of the Results

The study comprised 50 participants with confirmed diagnosis of diabetes mellitus. Were more males than females, age between 60-69 years that is (due to the customs and traditions that require men to accompany women during their visit to the hospital for therapy). The patients residing in the city (urban), Which indicates that the incidence of the disease may relate to the nature of nutrition in the city and the natural nutrition in the countryside, the adequacy of the monthly income of the patient or not, of them consider that their monthly income is not enough, which indicates that insufficient income leads to “malnutrition and the lack of a suitable environment for living”. Improvement in their health through the therapy of carbothera therapy indicated that the therapy had a positive effect on the patients, the form of the number of patients who responded to exercise daily, the number of patients who responded that they are walking Which were very useful to them, constituted a high rate of the patients in the sample, but the statistical results did not show a correlation with the improvement of their health condition due to their inability to walk already and the decline of a few daily plans, which makes it useless healthily. This agree with the study by Bakker et al. 2016 (International Working Group on Diabetic Foot Editorial Board. The development of global consensus guidelines on the management and prevention of the diabetic foot.

Conclusion

The management of diabetic foot and leg ulcers remains a major therapeutic challenge, which implies an urgent need to review strategies and therapy in order to achieve the goals and reduce the burden of care in an efficient and cost-effective way. Questions remain as to which types of intervention, technology, and dressing
are suitable to promote improvement, and whether all therapies are necessary and cost-effective as adjunctive therapies. Diabetic foot ulcers should be carefully evaluated and the gold-standard therapy should be strictly applied in order to prevent amputation. Further clinical studies are needed to support the existing evidence regarding the clinical benefit of new approaches for the therapy of diabetic ulcers, and these approaches should be used only as add-on therapies to the gold-standard wound care.

Abstract

Cerebrospinal fluid rhinorrhea occur when there is communication between skull base and the nasal cavity. Nowadays endoscopic endonasal repair of CSF rhinorrhea become the preferred surgical intervention.

Setting: ENT department at Ghazi AL Hariri Hospital for specialised surgeries, Medical City, Baghdad, Iraq.

Aim: To assess the effectiveness of fascia lata as sealing graft in the endoscopic endonasal repair of CSF rhinorrhea.

Patients and Method: Fifteen patients present to our department with possible clinical diagnosis of CSF rhinorrhea. The patients submitted to full history, examination including nasal endoscopy, radiological investigation (CT and MRI) of the nose and paranasal sinuses and skull base and CSF analysis. Operative technique was endoscopic endonasal repair using fascia lata graft. With monthly follow-up.

Results: Successful rate noted in 93% of the patients. No recurrence of meningitis attacks among those who reported meningitis on their presenting illness.

Conclusion: Endoscopic endonasal repair of CSF rhinorrhea has less operative and postoperative complication. Fascia lata graft offers a good choice for the repair.

Key words: CSF rhinorrhea, fascia lata graft and endoscopic endonasal repair.

Abstract

A number of important etiologies may result in CSF rhinorrhea. The most common include accidental trauma, surgical trauma, congenital, tumors, and spontaneous (or idiopathic). Careful understanding of these etiologies is a prerequisite prior to devising a comprehensive diagnostic and management strategy for effective surgical repair of CSF rhinorrhea. Approximately 80% of all cases of CSF rhinorrhea occur in the setting of accidental trauma, mostly in the form of closed-head injury. Conversely, CSF rhinorrhea is noted in only 2% to 3% of cases of serious head trauma. It is imperative to establish the diagnosis of CSF rhinorrhea beyond doubt before considering surgical repair. If this is not done, patients may be subjected to unnecessary surgical intervention and its attending morbidity.

Contraindications to the endoscopic treatment of CSF fistulas include the presence of an intracranial lesion; a fracture of the posterior wall of the frontal sinus; lateral extensions of the frontal and sphenoidal sinus, and CSF rhinorrhea from a temporal bone defect. Aim of the study is to assess the effectiveness of fascia lata graft in the endoscopic endonasal repair of CSF rhinorrhea.

Patients and Method

Across sectional study was conducted between March 2014 and November 2015 at ENT department,
Ghazi AL-Hariri for specialised surgeries Hospital, Medical City Complex, Baghdad, Iraq. Fifteen patients (eight males and seven females) were with a possible clinical diagnosis of CSF rhinorrhea. The duration of symptoms ranged from two months to twelve years. All patients had failed conservative treatment.

All patients underwent a thorough clinical history, endoscopic examination of nasal cavity, and the glucose concentration of the nasal discharge (CSF) was analyzed. All our patients underwent computed tomography (CT) and magnetic resonance imaging (MRI); CT scan was helpful in showing fracture site in post-traumatic CSF rhinorrhea while MRI was beneficial in detecting meningocele. Inclusion criteria was both the traumatic and non-traumatic CSF leak. Patients with skull base tumor were excluded from the study. Endoscopic examination where done using local decongestant and topical anesthesia using 0 degree rigid scope and the findings were difficult to localize the exact site of CSF leak, but the leak was noted coming from sphenoethmoidal recess or frontoethmoidal area other patients with an obvious meningocele was noted specially in pediatric age group. Our surgical option was endoscopic endonasal repair of CSF rhinorrhea using tensor fascia lata as sealing graft. All surgeries done under general anesthesia with oral endotracheal intubation. Patients lie in slightly reverse trendelenberg position. In cases were the defect in the cribriform area or from sphenoethmoidal area ,we lateralized the middle turbinate to get access to those areas sometimes we did complete ethmoidectomy to get access to the fovea ethmoidalis, In cases were a meningocele is present we follow it till reaching its neck and visualize the defect which coming from. The most critical step in the repair was to cauterize all the mucosa surrounding the defect and denuded the bone by using a bipolar suction diathermy to help get a good ground for the graft. A fatty tissue which obtained from the patient thigh plugged into the defect (underlay) ,after that an appropriately sized tensor fascia lata graft ( 30% larger than the defect due to later shrinkage of the graft ) is insinuated into the defect a few millimeters.then a gelfoam sponge was inserted to support the graft and a Merocil (Kennedy) pack was inserted and it was removed at third or fifth day; once the packs were removed; an endoscopic examination is done to remove any crustation and to get the first look after the surgery .The patients were instructed to minimize their daily activity like weight lifting, upstairs, sex, and avoid constipation by eating rich fiber diet . Patients were advised for monthly visit for endoscopic examination and assessment.

**Results**

Fifteen patients were with diagnosed of CSF rhinorrhea their age range from two years to fifty five years. Duration of symptoms range from two months to twelve years, eight patients were male and seven patients were female (figure 1); six patients experienced CSF leak from the left side while the other nine patients had the leak from the right side (figure 2).

![Figure 1](image1.png) **Figure (1) Gender ratio**

![Figure 2](image2.png) **Figure (2) Eight patients had history of head trauma (of those, three patients had previous nasal surgery) while the remaining seven patients had non traumatic CSF rhinorrhea (figure3).**

![Figure 3](image3.png) **Figure (3) Traumatic versus spontaneous CSF leak**

Of those fifteen patients, five patients reported history of meningitis (ranging from one to several
attacks during their illness); the other patients had no such history, figure (4).

Figure (4) meningitis rate

Eight patients were founded have a meningocele during the surgery; five meningocele were originated from cribriform plate, two meningocele were originated from fovea ethmoidalis, while one patient had a sphenoidal meningocele, figures (5),(6)

Figure (5) rate of meningoceles

Regarding CSF rhinorrhea without meningocele; the sites of the leaks were; three patients had leaks from cribriform plate; three patients had leaks from fovea ethmoidalis and one patient had leak from frontal sinus.

Figure (6) origin of meningoceles

Discussion

In our country; CSF rhinorrhea had been treated surgically by neurosurgeons using open approach (craniotomy) for many years with its highly morbidities and mortalities. In the last few years a great move done in our otolaryngology department Ghazi AL Hariri hospital to treat such cases with CSF rhinorrhea by endonasal endoscopic approach. In our study male with CSF rhinorrhea more common than female. Yong-Gang Kong et al (2013), found seventeen male and five female among 22 cases with CSF rhinorrhea. 

Thibaut Van Zele et al (2013), found five female and one male among six patients. Majority of our cases (53.3%) were traumatic, which is similar to most other study. S. Schmerber et al (2006), found six pateintns had spontaneous leak and sixteen patientns had traumatic CSF leak. Muhammad Umar Farooq and Murtaza Ahsan Ansari (2011), also found the same rate. In our study all patients submitted MRI, Bernardo Cunha Araujo Filho et al (2005), Order MRI only for suspected cases of meningoencephaloceles. José Alberto Landeiro et al (2004), ordered MRI for all patients. We had five cases of meningitis, Bernardo...
Cunha Araujo Filho et al (2005), report one case among 44 cases. 9. Yong-Gang Kong et al (2013) found four cases among twenty two patients (5). Mazhar Husain et al (2006), found three patients had meningitis among nine patients. 11. Antibiotics cover used for all our patients, Friedman JA et al (2001), adopted antibiotics for all patients. 12. We have eight cases with meningocele among our patients, Yong-Gang Kong et al (2013), had two cases among 22 patients. 5. In our study, majority of our cases had leak from lateral lamella of cribiform plate 53.33%. Bernardo Cunha Araujo Filho et al (2005), found the same. (9) Silva et al (2006), found sphenoid bone involved more commonly than ethmoid bone. (13) The success rate was of CSF closure in our study was 93.33%. Kirtane et al (2005), had success rate of 96.63%. (14) Bernardo Cunha Araujo Filho et al (2005), 80% success rate. (9) Schick et al (2001), report success rate of 80%. (15)

**Conclusion**

Nowadays endoscopic endonasal repair of CSF rhinorrhea become the preferred option for the repair of CSF rhinorrhea with fascia lata graft offer a good choice for the repair in both traumatic and spontaneous CSF leaks with high successful rate.

Genotype and haplotype of HLA- class II in Type I and Type II Diabetes Mellitus in Iraqi Patients

Abeer Mazin1, Abdalnabi J Abid 2
1Postgraduate, 2Professor , Department of Microbiology, College of Science for Women, University of Babylon

Abstract

Background: Diabetes is one of the common complicated disease associated with multiple influenced factors, immunological serological and molecular factors play a great role in susceptibility and diagnosis of this disease. HLA genotyping were reported to have an influencing in both types of diabetes.

Aim: The current study was conducted to investigate the association of human leukocytes genotypes in Diabetes patients.

Method: Case-control study enrolled 225 blood samples collected from patient attended to the Marjan Teaching Hospital- Hilla and 25 apparently healthy from October 2018 to May 2019. Class II HLA genotyping was performing for 60 patients with diabetes mellitus and 25 healthy unrelated controls by means of the PCR-SSP method. The diagnosis of T1D and T1ID was set up according to American Diabetes Association criteria.

Results: both types of diabetes were significantly associated with HLA-DR3.  Associations were also observed with HLA –DQA105:01, the appearance of these two alleles differs in both TID and TIID . Conclusion. Certain HLA class II alleles, haplotypes, and genotypes have related to diabetes mellitus so it can be dependent as a genetic marker for susceptibility of this disease in Iraq.

Keywords: Type II diabetic, Type I diabetes, HLA classII, genotype, haplotype.

Introduction

Diabetes mellitus (DM) is a group of metabolic disorders characterized by a chronic hyperglycemic condition resulting from the defects in insulin secretion, insulin action or both.1 Type 1 and type 2 diabetes consider the two main types, with type 2 diabetes constituting for the majority (>85%) of the total diabetes mellitus prevalence, According to the latest estimates, there are 425 million people with diabetes in 2017 and this number is expected to rise in 2045 to 629 million.2 The genetic loci involved in the rejection of foreign organs knew as the major histocompatibility complex (MHC), and the MHC encodes highly polymorphic cell surface molecules. The human MHC is representing as the HLA (Human Leukocyte Antigen) system because these antigens first identified and characterized using alloantibodies against leukocytes.3 The encoding of HLA-DQ proteins are belongs to HLA-DQ genes and expressed on α and β chain at cell surface.4 The DQ region of HLA include two gene clusters, DQA1 and DQB1.5 The polymorphism of HLA had serologically significant impact and the Polymorphism at the HLA-DQB1 locus used to be determined serologically and recognized the specificities DQ1, DQ2, DQ3 and DQ4.6 The use of DNA typing techniques has increased the number of alleles. The allelic sequence diversity is also predominantly present in exon 2 and, except for DQB1*0201 and DQB1*0202, all alleles can be discriminated by PCR-SSOP in this exon. A large number of studies have demonstrated that specific alleles at the DRB1, DQA1, and DQB1 loci are strongly associated with diabetes.7,8 However, allelic variation at these loci cannot account fully for the pattern of HLA haplotype sharing among affected sib pairs.9
Material and Method

Patients and controls

Two hundred twenty-five blood samples were collected from clinically diagnosed diabetes patients who regularly admitted by medical committee specialized diabetic center of marjan hospital (Babylon) from October 2018 to May 2019, the age of patients between (2-80) years including both sex male (112) and female (113), in addition to (25) samples were taken from apparently healthy human were taken from Babylon province as control. The study was approved by the Research Ethics Review Boards of the University of Babylon. This work was done by self funding and it is a part of M.Sc project for the first author with the agreement of university.

All participants provided written informed consent. Case Ascertainment. Patients with diabetes were diagnosed by a physician on the basis of the following criteria: a fasting glycemia ≥ 1.26 g/dL, an unexplained weight loss, signs of hyperglycemia (polyuria, polydipsia, polyphagia, and asthenia). These criteria were defined according to the recommendations of the American Diabetes Association.10.

Blood sampling

For each individual enrolled in the study, 3 ml of venous blood was collected in EDTA-treated tubes for DNA extraction, which performed according to the protocols recommended by the manufacturer (Favorgen/Taiwan).

HLA genotype analysis

HLA –DQA105:01 and HLA-DR3 genotyping was performed with PCR-sequence-specific primers (PCR-SSP).11 In a 20 µl mixture of 2.5 µl DNA, 1.5 µl from each forward and reverse of the primer, 5 µl master mix and 9.5 µl nuclease free water. The DNA amplification for HLA-DQA1 is includes an initial denaturation of 2 min in 94°C, 32 cycles of amplification (every cycle consists of a denaturation of 30 s in 94°C, a hybridization of primers during 30 s in 63°C, and an extension of 30 s in 72°C), and a final extension of 10 min in 72°C.11 While the process of DNA amplification for HLA-DR3 is same as DQA1, (exception the hybridization temperature was 52°C), then the PCR products were separated in 1.5 % agarose electrophoresis system using ethidium bromide then visualized with the gel documentation, with 100 bp-ladder (Bioneer, Korea) and photographed. The sequences of primers used for the amplification of the genes are presented in table 1.

Statistical Analysis

All data were statistically analyzed according to software program version 20 SPSS statistical software (version 17; SPSS, Inc., Chicago, IL, USA). The association between TID, TIID and each identified HLA-DR/DQ alleles, haplotypes, and genotypes was assessed using the odds ratio with its 95% confidence interval (OR, CI 95 percentage).

Results

The present study reveals a noticeable variety with HLA haplotype among type I and type II diabetes. HLA alleles discriminated by PCR assay. The distribution of HLA-DQA1 show high appearance in both types, out of 30 samples 26 show positive result 86.66% in type I and out of 33 samples 26 show positive result 78.78% in type II finally, statistical analysis showed no significant differences comparing diabetes patient and control subjects table 2.

**Discussion**

Diabetes mellitus is a combined metabolic disorder that includes several complications and the incidence of diabetes has been increasing worldwide therefore various are relentlessly working out the possible role of a vast number of genes associated with this disease. Human leukocytes antigen represented many proteins that encoded by HLA genes, therefore HLA-DQ genes expressed as heterodimers of alpha and beta chains at the cell surface.

The distribution of HLA-DQA1 in the present study show high appearance in both types, out of 30 samples 26 show positive result 86.66% in type I and out of 33 samples 26 show positive result 78.78% in type II finally, statistical analysis showed no significant differences comparing diabetes patient and control subjects.

Although the high appearance of this HLA-DQA1 type in both types of diabetes TID and TIID, statistical analysis show no significant differences between patients and control, this led to conclude that this haplotype had no risky effect on this population sample of diabetes patients.
HLA allele and haplotype frequencies vary considerably across ethnic groups. Researchers pointed that HLA-DQA1∗05:01, HLA-DQA1∗03:01 play a role in diabetes susceptibility particularly TID.

The analyses of HLA disease associations in different ethnic populations, due to differences in allele frequency distributions and patterns of linkage disequilibrium, can allow important general inferences of disease risk associated with specific alleles and their combinations.

The distribution of HLA-DR3 in type I and II showed that type I diabetes revealed percentage 46.66% and type II revealed a percentage 36.66% whereas the control revealed percentage 32%. Statistical analysis showed significant differences comparing two types of diabetes patient.

On contrary of HLA DQA, HLA DR3 appear in less percentage in diabetes patients particularly in TIID. This may be due to the protective role of this haplotype in the population samples of diabetes. The increased risk of DR3/4-DQB1*0302 heterozygotes relative to DR3/3 and DR4/4 genotypes has led to the hypothesis that the trans-complementing DQ heterodimers are more effective in presenting diabetogenic epitopes to T-cells.

Type I diabetes has the strongest association with HLA-DQA1 and DR3 similar result were also reported by.

Studies on DRB1 and DQB1 allele distributions and the importance of genotype context support the genetic associations observed in previous studies.

Variable results on DQA1 and DR3 genotypes in this study observed the risky and protective role of these genotypes in TID, TIID and healthy individuals. This is compatible with the of DQ heterodimer encoding by DQA1∗0501 and DQB1∗0302 explanation.

**Conclusion**

This study was designed to assess the associations of HLA class II alleles, haplotypes, and genotypes with the risk of developing T1D and T2D in Iraq. Certain HLA class II alleles, haplotypes, and genotypes were related to diabetes and may be used as genetic susceptibility markers to diabetes. Further studies of HLA and diabetes mellitus in Iraq are needed to confirm the present results and to provide data for the development of screening assays and for better management of patients with diabetes at the onset of disease.

Cloud Point Extraction, Preconcentration and Spectrophotometric Determination of Co (II) and Cu (II) using 15-Crown-5

Yussra O.Mussa1, Azhar A. Ghali2, Ashwaq S.Hussei1

1Department of Chemistry, College of Education, University of AL-Qadisiyah, Diwaniyah, Iraq,
2College of Pharmacy, University of AL-Qadisiyah, Diwaniyah, Iraq

Abstract

In the current study, a cloud point extraction (CPE) with UV-vis spectrometry for detection of Cu (II) and Co (II) ions with 15-crown-5 as a chelating agent was developed to be more selective and sensitive. The CPE method is improving the analytical signal and permits the preconcentration of metals ions. After phase separation induced by change temperature to become higher more than the temperature of the cloud, the point is performed with centrifugation. The Co (II) and Cu (II) ions are determined in the enriched phase by UV-vis spectrometry. Several factors affecting the extraction efficiency were optimized, e.x. pH, the concentration of the chelating agent, non-ionic surfactant concentrations, and cloud point temperature. Under optimum conditions, a linear calibration graph in the range of 0.5-5 μg mL⁻¹ of Co (II) in the initial solution with r² = 0.9994 (n=8) and 0.2–7μg of Cu (II) in the initial solution (mL⁻1) with r² = 0.9991 (n=8) were obtained. Detection limits of 0.4and 0.1μg are for Co(II) and Cu(II) along with preconcentration factors (66 and 50) for these ions, respectively. The method was used for detection of Co(II) and Cu(II) in some food samples.

Keywords: Cloud point extraction, preconcentration, spectrophotometric

Introduction

CPE Cloud Point Extraction method which is interest with the separation method metal ions field by forming small volume of the surfactant-rich phase (colloidal system) as a result of heating non-ionic aqueous solution of surfactant to a certain temperature at which the solution become turbid ,then the colloidal solution is separated into a small volume of surfactant-rich phase and an aqueous phase(1-6). A list of advantages of this method than other analytical methods because of i-it green method to avoid hazardous solvents ii- its selectivity for obtaining high coefficient of preconcentration iii- its economic for capital cost iv- its rapidity for reduce the time(7-9) iiv-simplicity application for separation and purification of a variety samples of pharmaceutical products, vital and solid,and enviromental(10-16).

A previous study used CPE methodology coupled with flame atomic absorption,(17-22) high performance liquid chromatography,(23) Ultrasonically modified Amented,(24-25) Ultrasound,(26-27) atomic absorption spectrometry,(28)spectrophotometric technique(29) and total reflaction X-ray fluorescence(30).

Supramolecular chemistry are strong linked to molecular recognition chemistry ,which investigates now host molecules that do the recognizing quests molecules that are recognized ,although molecular recognition chemistry is sometimes called host-guest chemistry ,the main concept associated with molecular recognition is the “Lock and Key “concept proposed by Email Fisher at the end of the nineteenth century 31. According to the structures and sizes of various crown ethers are forming stable and selective complexes with metal ions including alkali and alkali earth metal catoin ,although ability of these macro cyclic ligands as electron pair donors towards neutral molecular iodine and with δ- or π- acceptors(35-37).In this present work we report the formation of complex 15Crown5 with copper and cobalt in ethanol solution. This work focused on the suitability of CPE combination with UV-Visible spectrophotometr

The experimental
The apparatus

Spectrophotometer (A Shimadzu UV–vis 2101) was used for making experiment studies. Determinations of pH were measured using a (Wellhem, Model 7110) (Germany) digital pH meter. The water bath is used for studying temperature (OPTIMA co, made in Japan). A centrifuge (Hettich co., made in Germany) was used to the separation.

Reagents and Solutions:

Doubly Distill water was used in the study. The nitrate salts of cobalt and copper (Merck) solution of 1000 μg. mL⁻¹ were prepared by dissolving the appropriate amount of nitrate salt. The solutions were produced by dilution by doubly distill water. The nonionic surfactant Triton X-114 was provided (Acros Organics company, New Jersey, made in the USA).

Suggested methods for Cloud point extraction

For making cloud point extraction, it requires 10 ml aliquot solution containing 0.5–5μg mL⁻¹ of Co(II), 0.2–7μg mL⁻¹ of Cu(II). Then, a solution containing 15C5 dissolved in Triton X-114 was added to the aliquoted solution at a suitable pH. The phase separation occurs when heated the solution in the water bath at 60°C for 15 min, So accelerating phase separation by using centrifuging the solution at 5000 rpm for 10 min. Then cooling, the surfactant-rich phase changed to viscous, and the aqueous phase was easily removed using a syringe pipette. The surfactant-rich phase was made up to 1.0 mL by adding ethanol and Trans to a quartz cell to the determination of the absorbance at 290,252 Nanometer.

Application of foods samples:

Heating spinach sample (40) gram for three hours in silica crucible on heater and the charred substances was moved to oven for heating 24 hours at 650°C. then cooled, after that treated by nitric acid (10) mL and H₂O₂ (3) mL at concentration (30) and return to the oven for two hours at 650°C, and shouldn’t any organic compound. Treatment of final residue by nitric acid (3) mL and convert by evaporated to the fumes. Final solid was kept in distal water, then keep at pH (4) made up to 25mL. Black tea one gram, green tea one gram and tomato sauce one and a half gram were digested with the mixture of 8 mL concentrated nitric acid, H₂O₂ (2) ml at a concentration (30%) in microwave and dilution it by deionized water (50) mL. Also, the blank digest too submitted for the same way. The CPE methods were used to the final solutions. The analyte ions levels were determined by the procedure provided in section 2.3.

The Results and the Discussion

Absorption spectra and Characteristics of the method:

The absorption spectra of Co (II)-15-C-5and Cu (II)-15-C-5 complexes in the surfactant-rich phase after CPE procedure against reagent blank are shown in Fig. 1 the detection wavelengths were chosen to be 290 and 252 nm. The stoichiometry of 15-Crown-5 complexes with Co (II) and Cu (II) was examined by mole ratio method, and the continuous variation was found to be 1:1. The preconcentration factor results in by dividing aqueous phase volume to the preconcentrated phase volume. Table 1 summarizes the analytical characteristics of the method under the optimum experimental conditions.
Table (1): showed parameter methods that used for detection values of cobalt and copper by using CPE.

Optimizing of CPE parameters:

**Effect of pH:**

The separation of ions includes primary production sufficient hydrophobic with metal-chelate to be extraction of a little amount of surfactant-rich phase\(^{(38)}\). PH test is the main parameters\(^{(39)}\). PH effect to the CPE method was applied in (1–5) range. Adjusting of PH values is with HNO$_3$. Figure (2) showed a pH effect on the percentage of extraction; it included the extraction percentage increasing with nitric acid decreasing. The final results, pH (4) were chosen.

**Effect of 15-Crown-5 concentration:**

The effect of 15-Crown-5 on the extraction and determination of Co (II) and Cu (II) complexes were investigated in the range $2.0 \times 10^{-3}$-$2.0 \times 10^{-4}$ mol L$^{-1}$, the results present in Fig. 3. The extraction will result in high concentrated of 15-Crown-5 and remained almost constant. That explains that micelles are filled by the chelating agent. At higher concentration, extraction efficiency was decreased. That due to the free 15-Crown-5 competes with the complexes in extraction to surfactant-rich phase results in low extraction\(^{(40,41)}\). Therefore, a concentration of $1.0 \times 10^{-2}$ and $9.0 \times 10^{-3}$ mol L$^{-1}$ of 15-Crown-5 was selected as the optimum concentration Co (II) and Cu (II).
Triton X-114 Effect:

One of a critical factor that in the CPE is the concentration of surfactant, Triton X-114 is non-ionic surfactant wide using in CPE due to its achieves a good cloud point extraction that means increase the extraction efficiency by reducing the phase volume ratio, results in improvement of concentration factor. Where Triton X-114 present in markets at high purity, with low point temperature, low cost and toxicity and the surfactant-rich phase (high density)\(^{(42,43)}\). The preconcentration efficiency depends on the Triton X-114 level (0.001-0.015) as range M, as shown in Fig. 3. At lower concentrations of the surfactant, the highest extraction efficiency for cobalt and copper ions was obtained with 0.007 and 0.009 M Triton X-114. The extraction decreases with increasing of the surfactant amounts. That may be belonging to increasing in viscosity and volume of the micellar phase leading to poor sensitivity\(^{(44)}\). An amount of 0.4 and Triton X-114 (0.5 MI) were selected for subsequent experiments.

Effect of time and temperature of Equilibration Incubation:

Determination of incubation is done by temperature and time. As well as, the extraction process depends on temperature. Figure (5) showed the influence time and temp of the incubation of Cobalt and copper. The cloud point temperature of Triton X-114 is (23-25)°C in (0.1–5) weight percentage, heating more than ten °C is important for getting good separation\(^{(45)}\). When temperature or incubation time is an increase, it will increase Co (II) and Cu (II) extracted amount in the surfactant-rich phase with quantitative separation after fifteen minutes in 60 °C (water bath). The prolonged times is necessary to apply it at high temperatures for satisfactory mange extraction\(^{(46)}\).

Wide ranges are used in our study (30–70) °C as temperature degree and (5–30) minutes as a time. Time (15) minutes and temperature (45) °C were optimum conditions for extraction.

The effect of centrifuge conditions:

Centrifugation was accomplished for separating the aqueous and surfactant-rich phase in the suggested procedure. (5000) recycled per minute and ten minutes are best phase separation\(^{(47,48)}\).

Effect of foreign ions:

The interferences are studied in the preconcentration stage, 15-crown-5 react cations or analytes may react with species and the extraction efficiency become low. The solution (10) ml consist of (3) \(\mu\)gmL\(^{-1}\) Co (II) and Cu(II) as Table (2).

Applications and Accuracy:

The suggested procedure was used to determination of the Co(II) and Cu(II) according to Section 2.4 in Spinach, Tomato Sauce, Green tea and Black tea provided from local markets. The results are shown in Tables 1. The values measured by at ranged (96-101) %, the results indicate that confirm the accuracy of the procedure.

**Conclusion**

Extraction of ions of cobalt and copper is done with 15-crown-5 in non-ionic surfactant Triton X-114 phase. Extraction of complete elements was done by 15-crown-5 because of the hydrophobic production. The molar ratio is determined. Simplicity, Ecological safety, metrological characteristics, the sensitivity and convenience of are procedures used for extraction of the organic compounds. The results found these methods could use it for preconcentration and separation of cobalt and copper ions.

Hormonal and Immunological Study in Serum of Pregnant albino rats Treated with Nickel Oxide Nanoparticles

Haneen M. Alsoltane¹, Amel A. Altaee¹
¹Babylon University/College of Science, Iraq

Abstract

The present study was aimed to elucidate the effect of Nickel oxide nanoparticle (100mg /kg b.wt) on some parameters in pregnant Albino rats which including serum reproductive hormonal level, Leutinizing Hormone (LH), Follicle stimulating Hormone (FSH) and Testosterone (Test), and some Immunoglobulin levels (IgA, IgG, IgM) for different period of pregnancy (12 and 14 days). The hormonal results showed significant (P≤0.05) increased of treatment groups as compared with control groups. Immunological results showed significant decreases in treated groups as compared with control groups, It could be concluded that increasing concentrations of NIO- NPs and durations of exposure leads to negative effects on the pregnant albino rat.

Key words: NIO, nanoparticles, albino rats, hormones, immunoglobulin.

Introduction

Nickel is a silver-white metallic chemical element that is naturally present in the Earth’s crust. Because of its unique physical and chemical properties, being tough, harder than iron, ferromagnetic, having good plasticity and highly resistant to rusting and corrosion, nickel and its compounds are widely used in industry. Nickel is an essential element for at least several animal species. These animal studies associate nickel deprivation with depressed growth, reduced reproductive rates, and alterations of serum lipids and glucose. Nickel is known as a potentially harmful element for humans. Its concentration in the environment can rise due to industrial activities. Human exposure to nickel or its compounds has the potential to produce a variety of pathological effects, which may include cutaneous inflammations such as swelling, reddening, eczema and itching on skins, and may also include allergy reactions and teratogenicity in the human body. Nickel is capable of evoking dual responses in the human immune system. Experiments conducted in humans and in rodents have shown that nickel exhibits both immune modulatory and immune toxic effects, Number of immunological and lymphoreticular effects have been reported in humans and animals exposed to nickel. In 38 production workers exposed to nickel (compound not specified), significant increases in levels of immunoglobulin G (IgG), IgA, and IgM and a significant decrease in IgE levels were observed. Significant increases in other serum proteins, which may be involved in cell-mediated immunity (including α1-antitrypsin,α2-macroglobulin, ceruloplasmin) were also noticed. Nickel and chromium significantly depressed the circulating antibody response of rats immunized with a viral antigen, with the greatest decrease in antibody titers noted in animals receiving the metal two weeks before the initial antigen dose. Several studies have examined the relationship between nickel exposures and acquired immune function. Exogenous chemicals can interfere with the normal functioning of the HPG axis, resulting in reduced fertility or even infertility in both females and males. Ni NPs effect the serum sex hormone levels (FSH, LH, E2 or T) in female and male rats. Some study demonstrate that Ni NPs increased significantly the level of serum FSH and LH, and decreased E2 this effect associated with dose-dependent in females. The results indicate the effects of Ni NPs on the female rat ovarian reserve. It is probably an indication of the decreased level of serum E2 and ovarian hormone secretion following ovarian damage with Ni NPs, which increased the level of serum FSH and LH by negative feedback. Meanwhile, the male

Corresponding Author:
Haneen M. Alsoltane

rat serum FSH, LH and T content analysis showed the levels of FSH and T were decreased significantly by Ni NPs treatment.

**Materials and Method**

**Animals**

Animals with weight of 195-280 gm and aged of 2.5-3 months were obtained from the animal house of the Biology Department/College of Science at University of Babylon. Animals were put inside special cages for breeding with length of 25 cm, 18 cm width and 19.5 cm height and stayed about 30 days. The cages were covered with sawdust, which replaced three times weekly with the care of hygiene and sterilization. The animals were provided with food and water ad libitum. The animals were housed in special rooms with controlled conditions of temperature (24±10°C) and natural light periods (12 hours light/dark).

Each two females were put with one male (for mating) in special plastic cages and strung metal caps with dimensions of 40 cm length, 25 cm width and 19.5 cm height. After ensuring the pregnancy by observing vaginal plug and vaginal smear, this day regarded as 0th day of gestations (GD=0). Pregnant rats divided in five groups (n=4). Each two females were put with one male (for mating) in special plastic cages and strung metal caps with dimensions of 40 cm length, 25 cm width and 19.5 cm height.

**Nanoparticles Dose Preparation**

Determination of Nickel oxide doses were depended on the animals body weight. 25-PPM doses of nanoparticle suspension was prepared and mixed with distilled water.

**Animals Anesthesia**

The pregnant rats were anesthetized with chloroform in 12 and 14 days of pregnancy. Pregnant rats were put after anesthesia on dissection bowl, the fore and hind limbs were fixed by fine pins, the pregnant’s abdomen was opened by a sharp scissors and take blood sample by heart puncture.

**Blood collection:** Blood samples were collected via the left ventricular cardiac puncture into sterilized EDTA tubes and gel tube to separate the serum quickly and then centrifuged at 3000 rps for 5 minutes. The serum samples were stored frozen until used.

**Hormonal Assay:** Serum Follicle Stimulating Hormone (FSH), Luteinizing Hormone (LH) and Estradiol were measured by using ELISA (Monobind Company, USA) for both control and treatment animals.

**Results**

Effect of Nickel Oxide nanoparticles on Luteinizing Hormone in Pregnant Albino Rats for 12, 14 Days of Pregnancy.

The result of the present study showed that the LH hormone means increases significantly (P≤0.05) in treated group (12, 14 days) with NIO (100 mg / kg b.wt) (1.1 ±0.010, 1.28 ± 0.043) (pg/ ml) respectively, as compared with control group (0.8263 ± 0.02512, 0.836 ± 0.0251) for 12, 14 days respectively (Figure-1).

![Figure 1](image1.png)

**Figure (1):** Effect of Nickel Oxide Nanoparticles on Luteinizing Hormone in Pregnant Albino Rats for 12 and 14 Days of Pregnancy.

Effect of Nickel Oxide Nanoparticles on Follicle Stimulating Hormone in Pregnant Albino Rats for 12 and 14 Days of Pregnancy.

FSH means in present study increases significantly (P≤0.05) in treated group with NIO (100 mg / kg b.wt) (1.023 ±0.032, 1.16 ± 0.051) (pg/ml) as compared with control group (0.8 ± 0.004, 0.8 ± 0.003 pg/ml) 12 and 14 days respectively (Fig.2).

![Figure 2](image2.png)

**Figure (2):** Effect of Nickel Oxide Nanoparticles on Follicle Stimulating Hormones in Pregnant Albino Rats for 12 and 14 Days of Pregnancy.
Effect of Nickel Oxide nanoparticles on Testosterone Hormone in Pregnant Albino Rats for 12 and 14 Days of Pregnancy.

The present study showed significant increases (P≤0.05) of Testosterone in treated group with NIO (100 mg / kg b.wt) (0.61 ±0.001, 0.63 ±0.001 pg/ml), as compared with control group (0.541 ±0.013, 0.52 ±0.08 pg/ml) for 12 and 14 days respectively (Figure-3).

Effect of Nickel Oxide nanoparticles on Immunoglobulin A in Pregnant Albino Rats for 12 and 14 Days of Pregnancy.

The result in (Figure-4) revealed that the IgA, showed significant (P≤0.05) decreases in the treated group with NIO (100 mg / kg b.wt) (16.29 ± 0.292, 14.3 ± 0.22 pg/ml) as compared with control group (19 ± 0.386, 18.63 ± 0.52 pg/ml) for 12 and 14 days respectively.

Effect of Nickel Oxide Nanoparticles on Immunoglobulin G in Pregnant Albino Rats for 12 and 14 Days of Pregnancy.

The result in (Figure-5) revealed that the IgG, showed significant (P≤0.05) decreases in the treated group with NIO (100 mg / kg b.wt) (95 ± 1, 82.66 ± 1.52 pg/ml) respectively, as compared with control group (119 ± 1, 118.3 ± 1.52 pg/ml) for 12 and 14 days respectively.

Effect of Nickel Oxide Nanoparticles on Immunoglobulin M in Pregnant Albino Rats for 12 and 14 Days of Pregnancy.

The result in (Figure-6) revealed that the IgM, showed significant (P≤0.05) decreases in the treated group with NIO (100 mg / kg b.wt) (16.35 ± 0.19, 14.46 ± 0.21 pg/ml) respectively, as compared with control group (19.62 ± 0.06, 18.24 ± 0.02 pg/ml) for 12 and 14 days respectively.

Discussion

Effect of Nickel Oxide Nanoparticles on Luteinizing, Follicle stimulating and Testosterone Hormones in Pregnant Albino Rats for 12 and 14 days of pregnancy.

The present study showed significant (P≤0.05) increases in treated group with NIO (100mg / kg b.wt) as compared with control group for 12 and 14 days of pregnancy this change of hormones could be resulted from the hypothalamic–pituitary–gonadal (HPG) axis is the hormone system whereby the hypothalamus secretes so-called releasing hormones, which are transported via the blood to the pituitary gland. There, the releasing hormones induce the production and secretion of gonadotropins (i.e., LH and FSH), which in turn are transported by the blood to the gonads (i.e., the ovaries and testes).

Generally speaking, in females, LH and FSH stimulate the ovarian follicle that contains the maturing egg to produce estradiol. After ovulation has occurred, LH also promotes production of progesterone. Both hormones participate in a negative feedback mechanism through most of the menstrual cycle, suppressing GnRH release from the hypothalamus and LH release from the pituitary (11).

Exogenous chemicals can interfere with the normal functioning of the HPG axis, resulting in reduced fertility or even infertility in both females and males, the effects of Ni NPs on aspects of serum sex hormone levels (i.e., FSH, LH, E2 or T) in female and male rats. Increases of Ni NPs level in serum FSH and LH, with significant and
dose-dependent in females. It is probably an indication of the decreased level of serum E2 and ovarian hormone secretion following ovarian damage with Ni NPs, which increased the level of serum FSH and LH by negative feedback 12.

The change of hormone reproductive levels indicates the abnormal reproductive axis function, which correlated with male and female infertility 13. However, the mechanisms by which NPs alter the functions of HPOA ultimately resulting in female infertility have not been investigated thoroughly 15. Meanwhile, the amount of studies about NPs having negative effects on HPOA is relatively small. It is certain that NPs with size of 36 nm were significantly accumulated in cerebrum and cerebellum translocation via the olfactory nerve and increased with the exposure time 16. The sizes of NPs less than 90 nm could disturb the balance of GnRH, FSH and LH, such as Ni, PEG-b-PLA (17) 18.

Other study showed that gold nanoparticles reduced the level of testosterone. Another assumption is that the nanoparticles could affect the gene expression of the protein that is involved in the transport of cholesterol into the inner membrane of mitochondria and increased the synthesis of steroids. It is also possible that nanoparticles by reducing the gene expression of the mitochondrial membrane protein Star, inhibit the cholesterol transportation into the inner membrane of mitochondria, and eventually inhibit the conversion of cholesterol to pregnenolone and reduced the level of testosterone. Karpenko (2013) studied toxic effects of cerium oxide nanoparticles on sex hormones and concluded that nanoparticle reduced glandular and testosterone secretion, the gold nanoparticles reduced the level of testosterone 19.

Effect of Nickel Oxide Nanoparticles on Immunoglobulin A, G and M in Pregnant Albino Rats for 12 and 14 Days of Pregnancy.

The results of the current study as in the table (1) revealed that the IgA, IgG and IgM, showed significant (P≤0.05) decreases in the treated group of (12, 14) days with NIO (100mg/kg b.wt), as compared with control group. The decreases of Immunoglobulins levels in pregnant females due to that the nanoparticles can also suppress the immune system which can weaken immune response against infections and cancerous cells. These immunosuppressive properties, on the other hand, can make nanoparticles useful in preventing transplant rejection, in treating inflammatory and autoimmune diseases, and in delivering immunosuppressive drugs 20.

Nanoparticle properties are responsible for immunosuppressive effects. While some nanoparticles are used to deliver immunosuppressive drugs, others have their own immunosuppressive properties. Shen et al. 22 have shown that Fe3O4 nanoparticles weaken the antigen-specific humoral response and T cell cytokine expression in ovalbumin-challenged mice. Mitchell et al. 23,24 reported that multi-walled carbon nanotubes (MWCNTs) suppressed systemic humoral immunity in mice. Some nanoparticles have been shown to possess anti-inflammatory properties. CeO2 nanoparticles were reported to reduce ROS and the level of inflammatory cytokines IL-6 and TNF-α in murine macrophages 25. After the immunization of mice with a C60 fullerene derivative conjugated to bovine thyroglobulin, they produced IgG antibodies specific to fullerenes. Other researchers were not able to detect fullerene-specific antibodies, even when they used a carrier molecule 25.

Conclusion

The hormonal results showed significant (P≤0.05) increased of treatment groups as compared with control groups. Immunological results showed significant decreases in treated groups as compared with control groups. It could be concluded that increasing concentrations of NIO- NPs and durations of exposure leads to negative effects on the pregnant albino rat.

Assessment of Mental Health of Healthcare Professionals Working in the Infectious Diseases Units: Comparative Study

Maysaa Niama Aboalshon¹, Hayder H. AL-Hadrawi², Ammar Abbas Shalan²

¹ MScN, ² PhD, College Nursing, University of Babylon

Abstract

Background: Health care professionals working in infectious diseases units or hospitals are at higher risk for being affected by certain contagious pathogens than other professional groups through direct contact, equipment, and contaminated supplies; therefore, they are working under ongoing stress that negatively impacting their psychological well-being.

Aims: This study aims to assess the mental well-being of healthcare professionals working in infectious diseases units and compare these results to the score of other healthcare professionals working in other units.

Methodology: A comparative study design using a convenience sample of (N=300) healthcare professionals (150 working in the infectious diseases units and 150 working in different units). The General Health Questionnaire-28 was used to assess the mental health of study subjects.

Results: Recent findings indicate a statistically difference between study group and comparative group (p<=0.05), which means that healthcare providers working in the infectious disease units are at higher risk for psychological disturbance than the comparative group. Moreover, other work factors are found to have significant relationship with professionals’ mental health, such as infection prevention trainings, years of experience in infectious diseases units, availability of personal protection equipment and hand hygiene, and number of patients in the unit.

Conclusion: Working in high risk work environment increases the concern about personal safety and impose ongoing stress, which negatively influence professional’s mental well-being. More training about infection prevention and provide personal protection materials help reducing the risk of disease transmission among patients and to health care providers.

Keywords: Emotional Intelligence, Work-related Stress, Psychiatric Nurses

Introduction

Most healthcare professionals are vulnerable to the risks of workplace; especially those who expose to blood, body fluids, and injuries that could be contaminated with infectious microorganisms (15,20). Death rates are more likely to be higher among healthcare professionals (especially nurses and doctors) who work in infectious diseases units, as a result of their role as frontline professionals in caring for clients with different infectious diseases (14). Health care professionals working in infectious diseases units or hospitals are at higher risk for being affected by certain contagious pathogens through direct contact, equipment, or contaminated supplies; consequently, they are working under an ongoing stress that affects their psychological health. Working in such units increases the demand on health professionals to increase the quality of hospital care, controlling infection, and protecting themselves at the same time, which impose additional stress and impact the professionals’ general health outcomes (4). The purpose of study is to assess the mental health outcomes of healthcare professionals working in the infectious diseases units and measure the difference in the mental health outcomes among healthcare professional working in the infectious diseases units and other units. Mild stress is consider essential to promote professionals’ productivity and responses; however, when the stress level is high, it negatively impact the
health of individuals. Workplace challenges do not often reported to psychological complaints; however, psychological health of professionals is impacted when they are unable to adapt effectively with these challenges. Stress is described an imbalance among the perceived needs, understand resources, and ability to cope with those needs, which can cause physical and psychological distress. Stigma is not only affecting clients with infectious diseases, it is another issue that faces healthcare professional who care for those clients as a result of the possibility of infection transmission to healthcare care employees. Consequently, it is also considered one of the main causes of perceived stress, depression, and anxiety. Professional mental health is directly and indirectly influenced by the stigma associated with infectious diseases through stress. The Importance of risk awareness and patients safety have been indicated in several research. According to, “nurses are expected to maintain a high level of awareness towards an infectious disease outbreak and ensure the safety of the public.” This critical role highlights the reason behind the high level of stress among nurses who work in communicable diseases units. Identifying the risk factors that cause professional stress among health professionals is a crucial approach to create healthy workplace environment and maintain professionals’ mental well-being.

### Methodology

#### Study Design and Sampling Plan:

Comparative study design using a convenience sample of 300 healthcare professionals for both groups (150 in the study group and 150 in the comparative groups). Health care providers who participated in this research study were selected regardless of their gender group, specialty, or work time. This strategy was used to clarify the general characteristics of healthcare providers of either group. About 400 healthcare providers received the questionnaire and agreed to be a part of the study; however, only 310 subjects responded to the questionnaire (150) subjects from the first group and (160) subjects from the comparative group. To make the sample size equal in the both groups, 10 subjects were randomly excluded from the comparative group.

#### Study instrument:

The General Health Questionnaire (GHQ28) is used to assess the mental health of healthcare providers working in the infectious diseases units and the mental health of the comparative group. This scale was a developed as a screening tool to detect those likely to have or to be at risk of developing psychiatric disorders. This screening tool was developed by Goldberg in 1978. It is a 28-items that is measure a four levels scale ranged from (0 to 4) respectively; 0 indicates no, 1 indicates less than usual, 2 indicates more than usual, 3 indicates more often than usual. The levels of psychological distress among healthcare providers are determined based on the sum of items scores (minimum score 0 and maximum score 84). The cut score is 23/24 and individuals with higher scores are considered having higher level of psychological distress. This scale is includes four subscales in which each scale consist 7 items, divided as follow: 1) Items (1-7) measure somatic symptoms; 2) Items (8-14) measure anxiety/insomnia; 3) Items (15-21) measure social dysfunction; 4) Items (22-28) measure severe depression. The Arabic version of the scales had good reliability level, Cronbach’s alpha level (0.89).

### Ethical Considerations

Healthcare professionals were asked for voluntary participation. Research objectives, risks, and benefits were explained to participants to help them decide whether to participate or not. After they agreed to be a part of the study, participants were given anonymous questionnaire to maintain participants’ confidentiality.

### Results and Discussion

The recent study indicates that there is a statistically significant difference between study group (healthcare providers working in infectious diseases units) and comparative group (healthcare providers working indifferent units) in respect to their mental health. More than half of the healthcare professionals working in the infectious diseases units were symptomatic for psychological distress; whereas, 30% of the comparative group (working in non-infectious units) were symptomatic for psychological distress. indicate that nurses working in high demand or high risk environment anticipated a greater likelihood of developing depression and stress symptoms as a consequence of the continuous concern about their safety. mentioned that healthcare professional who work in hospitals settings are more likely to be vulnerable to depression, and the risk is greater than the risk compared to the general population. However, highlighted that healthcare workers who are in contact with communicable diseases are at higher risk.
Health practitioners need to emphasize the importance of using personal protection equipment for infection prevention and control, as well as studies have highlighted the importance of providing control, availability of the personal protective working conditions, including training about infection control, risk perception. Significant relationships were indicated that those employees who had higher baseline depression and anxiety than those who care for clients with non-communicable diseases. These psychological effects related to the nature of environment as a high risk, loss of social support (isolation), stress attached to their role, and risk perception. Health care professionals who had direct contact with the affected patients were at great risk for physical and psychological risks. Even though, providers uses personal protection equipment, they still experience barriers of communication and difficulties in diagnosis and caring process, which extent the time needed for each patients and increase the risk for stress. Working in such conditions indicated considerably higher social isolation and felt considerably more vulnerable to somatic symptom, sever anxiety, depression, and fatigue. Analysis of variance (ANOVA) was used to find the differences among healthcare providers in response to psychological disturbances as a result of working in high risk environment. The findings indicate that technicians had the highest mean score than other groups of professionals, which represents their vulnerability to psychological disturbance, followed by physicians and nurses. The study of compared the phenomenon of burnout among healthcare professionals working in the same situation. Researchers indicate a significant difference across professional groups in terms of being subjected to burnout and emotional disturbance. The difference was explained by several factors, including the responsibilities and roles assigned for each group, as well as the type of patients they care for. Being at the frontline in contact with patient can also increase the vulnerability of work stress. In addition, training programs can have positive impacts on reducing work-related stress. Significant relationships were found between psychological health and professionals’ working conditions, including training about infection control, availability of the personal protective equipment, and availability of hand hygiene. Several studies have highlighted the importance of providing training for infection prevention and control, as well as the importance of using personal protection equipment for all healthcare professionals working in the infectious diseases units to prevent the potential risk and reduce work stress. The study that carried out by showed that healthcare professionals who had not received infection prevention training were less likely to have knowledge of infection prevention than those who had received infection prevention training. Therefore, lack of knowledge increases their vulnerability to stress. Moreover, training has positive impact on the attitude of the respondents in the study group compared to the control group. Health practitioners need to safeguard themselves with barriers such as gloves, face masks, gowns, protective eyewear and face shields to reduce work-related microorganism transmission. Despite that, the threat cannot be secured completely, such as the threat results from needlestick injury, using personal protective equipment (PPE) regularly can protect both the professional and the patient from potentially infectious body fluids. The research of linked the increased risk for professionals’ infection to their noncompliance in using hand hygiene before and after caring process. Most providers of healthcare underestimate the significance of hand hygiene as it is not correctly stressed. As a result, many nurses lack the expertise and resources necessary to promote their compliance. Re-education; therefore, enables them by emphasizing the importance of compliance with hand hygiene, which increases the quality and safety of provided healthcare services. In addition, studies have also shown that personal protection equipment are not all available for healthcare professionals; however, even with the availability of required equipment, some professionals are careless to use the protective materials. Therefore, hand hygiene is critical to reduce the risk of infection transmission among patients and prevent the risk for healthcare providers.

**Conclusion**

This study aims to assess the mental well-being of healthcare professionals working in infectious diseases units and compare these results to the score of other healthcare professionals working in other units. Workplace stress has been found in all healthcare providers as a result of various types of stressor factors, which impact their mental health. However, healthcare providers who are in contact with infectious diseases are at higher risk for depression, stress, anxiety, and sleep disturbance than others who work in different healthcare settings. Consequently, feeling stressed and concerned about personal safety impose a negative effect on professionals’ mental health. More training

---

The reference text in the document: [1]. A literature review study was conducted on the workplace factors that influence the psychological health of healthcare professionals involved in caring for clients with various infectious diseases. This research discovered that those employees had higher baseline depression and anxiety than those who care for clients with non-communicable diseases. These psychological effects related to the nature of environment as a high risk, loss of social support (isolation), stress attached to their role, and risk perception. Health care professionals who had direct contact with the affected patients were at great risk for physical and psychological risks. Most providers of healthcare underestimate the significance of hand hygiene as it is not correctly stressed. As a result, many nurses lack the expertise and resources necessary to promote their compliance. Re-education; therefore, enables them by emphasizing the importance of compliance with hand hygiene, which increases the quality and safety of provided healthcare services. In addition, studies have also shown that personal protection equipment are not all available for healthcare professionals; however, even with the availability of required equipment, some professionals are careless to use the protective materials. Therefore, hand hygiene is critical to reduce the risk of infection transmission among patients and prevent the risk for healthcare providers.
about infection prevention help raising professionals’ knowledge and practice of preventing infection from being transmitted to other patients or to the healthcare providers. Likewise, using personal protective equipment and hand hygiene play an important role in reducing the risk of infection among healthcare professionals. Therefore, it is important for healthcare professionals to be aware of the effective strategies that reduce their vulnerability to the risk of infection. More training about infection prevention and provide personal protection materials help reducing the risk of disease transmission among patients and to health care providers, which indeed helps reducing the psychological stress among healthcare professionals.

Emotional Intelligence and Work-related Stress among Nurses Working in Psychiatric Hospitals

Zaman Ahmed Hrefish¹, Hayder H. AL-Hadrawi²

¹MScN, College of Nursing/University of Babylon, ²PhD, College Nursing/University of Babylon

Abstract

Background: Emotional Intelligence is a broad concept that connects various personality and cognitive traits of human beings. The concept of emotional intelligence is described as the individual’s capability of recognizing their own emotions and the emotions of others, and practice this understanding to navigate important interactions successfully.

Aims: The purpose of this study is to assess emotional intelligence among nurses working in psychiatric hospitals, as well as the relationship between emotional intelligence and workplace stress.

Methodology: A descriptive correlational study design using a convenience sample of (N=109) nurses working in two main psychiatric hospitals. Two separated scales (The Emotional Intelligence Scale-34 items and The Work-related Stress scale-24 items) was used to meet the study objectives.

Results: The study findings indicate that emotional intelligence levels were ranged between moderate to high among study participants. However, the majority had moderate work-related stress about (61%). Nurses’ work stress was found to have significant relationship with their emotional intelligent level.

Conclusion and Recommendations: Despite the positive levels of emotional intelligence nurse have, working in psychiatric hospitals is still cause of stress for nurses. The statistical relationship found in this study highlights the importance of enhancing emotional intelligence among nurses working in psychiatric hospitals settings by engaging them in effective training programs to maximize their abilities of adjustment and reduce their levels of work-stress.

Keywords: Emotional Intelligence, Work-related Stress, Psychiatric Nurses

Introduction

Emotional Intelligence (EI) is a broad concept that connects different personality and cognitive traits of humans, including emotional processing, emotional understanding, integrating affects and management of feeling states, ¹⁶. The concept first introduced by Salovey and Mayer in 1990, and it was defined as cognitive skills that introspectively can detect and regulate affective states and assess the emotional state of others. In general, emotional intelligence is described as the ability of an individual to recognize own emotions and others emotions, and to practice this understanding to navigate important interactions successfully. A clear understanding of EI and its difficulties is helpful in the practice of nursing; due to the understanding of how emotions merge with cognition. Generally, EI helps nurses to improve relationships, manage their patients more effectively, make better decisions, and positively affects the quality of care provided to patients and families. The study aims to assess emotional intelligence among nurses working in psychiatric hospitals, as well as the relationship between emotional intelligence and workplace stress. Emotional intelligence is mainly focus on people with the ability to express, evaluate, and adjust enthusiasms and emotions of themselves and others, as well as those who can properly guide and control the thought and performance. Therefore, emotional intelligence is considered as an effective power to deal with job stressors. Also, nurses with high emotional intelligence and emotional managements are able to direct positive feelings exchanged by healthcare individuals to decrease the negative effects of job stress.
experience and suffer from stress and health problems have less traits related of their work characteristics and less contact with patients (1, 8). Emotions can have an impact on job outcomes and emotional intelligence, which could explain the differences among individuals in dealing with work stress. 8 Emotional intelligence can have a direct influence on the quality of the provided healthcare services or indirect influence, through other mediator, variables such as individual's job satisfaction and professional conflict. Studies have shown that nurses communication skills and job satisfaction play significant role in the emotional intelligence of nurses and the quality of the provided services 3. Moreover, work-related outcomes are more likely to be impacted when nurses feel stressed and insecure in their work environment. 15.

Methodology

Study Design and Sampling Plan:

A descriptive correlational study design using a convenience sample of (N=109) psychiatric nurses working in the main psychiatric hospitals in Baghdad Province. Both male and female nurses were included regardless of their working shift. Their age ranged between 20 – 60 years old, with at least one years of experience in the psychiatric hospital.

Study instrument:

Two separated scales were used to meet the study objectives. The first scale is the Revised Emotional Intelligence Scale-(34) items. The original emotional intelligence scale was developed by 4, which contains (65 items); then, it was reduced to (34 items). The revised scale is widely used to measure the emotional intelligence cross-cultures. This scale is a self-reported instrument that is measured and rated on three levels rating scale; 1= not applicable to me, 2= applicable to some extent, 3= highly applicable. The levels of emotional intelligence are determined based on mean scores of the total items as follow: 1) nurses with means scores of (1 - 1.66) are considered having low emotional intelligence; 2) nurses with means scores of (1.67 – 2.33) are considered having moderate emotional intelligence; 3) nurses with means scores of (2.34 - 3) are considered having high emotional intelligence. The second scale is the Karasek Professional-Related Stress Scale was adopted and modified to be used in this study to assess workplace stress among psychiatric nurses. The original scale was developed by Karasek in 1980 2. This scale is also a self-reported instrument; however, it is measured and rated on four levels rating scale; “1=strongly disagree, 2= disagree, 3= agree, 4= strongly agree”. Coding for negative statements was reversed for statistical purpose. The levels of work stress are determined based on total scores of the scale items as follow: 1) nurses with total scores of (58 – 69) are considered having high work related stress. 2) nurses with total scores of (70 – 81) are considered having moderate work-related stress; 3) nurses with total scores of (82 - higher) are considered having low level of work-related stress.

Scale Validity and Reliability

The Revised Emotional Intelligence Scale and The Karasek Professional-Related Stress Scale were translated to Arabic by two bilingual content experts. The Arabic versions of both scale were presented to panel of content experts related to the fields of mental health, psychology, and community health to maintain the validity of the Arabic versions. Both scales had good reliability levels with a Cronbach’s alpha level (0.89) for the emotional intelligence scale and a Cronbach’s alpha level (0.78) for the work stress scale.

Ethical Considerations

Nurses were asked for voluntary participation. Research objectives, risks, and benefits were explained to participants to help them decide whether to participate or not. After they agreed to be a part of the study, participants were given anonymous questionnaire to maintain participants’ confidentiality.

Results and Discussion

This study indicates that majority of the study sample (60.6%) had high level of emotional intelligence, and (39.4%) had moderate level. The results of this study show that female nurses have higher level of emotional intelligence, than male nurses. Recently, there are some studies have been conducted to study nurses’ emotional intelligence in several fields. Empathy, emotional awareness, and problem solving were the most common attributes of emotional intelligence that have been reported by nurses. Researchers discovered that nurses’ emotional intelligence was higher than other professionals. This difference is related to the fact that nurses get more training about caring process and spiritual care (12,14). Another research was conducted in the Netherlands showed higher emotional intelligence scores among mental health nurses compared to the
general population. Engaging in more ethical behavior have been indicated by nurses who reported high levels of emotional intelligence. Moreover, it has been found that the high level of emotional intelligence among clinical nurses play a role in organizational justice, specifically regarding interpersonal and informational aspects of relationships. The outcomes of this study show moderate level of work-related stress was identified in (60.6%) of psychiatric nurses; while (14.7 %) had high level of stress related to their workplace. Nursing personnel are considered as professionals with increased level of stress, anxiety, and depression due to their daily routine, which is particularly demanding since they are forced to cope with pain, sadness, and death. Stress also comes from the fatigue resulted from an increased workload, as well as the inability of nurses to cope with the emotional needs of patients and their families. Nurses who work in psychiatric settings are more likely to experience work violence than other nurses who work in different healthcare settings. Violence is negatively impact the provided quality psychiatric care and increase the level of stress among nurses. Shu-Fen Niu et al. (2019) have highlighted alarming percentages about the experienced violence by nurses that cause higher level of work-related stress among nurses population. Researchers indicates that more than 50% of the psychiatric nurses involved in their study experienced physical violence and more than 80% experienced psychological violence by psychiatric patients. Resilience of nurses is another concept could explain the work-related stress among psychiatric nurses participated in this study. Most recent systematic review study was conducted on 38 articles that targeted nurses resilience and work-related factors. Researchers pointed out that “Job demands (stress, burnout, posttraumatic stress disorder, and workplace bullying) were negatively associated with resilience, while job resources (coping skills, self-efficacy, social support, job satisfaction, job retention, and general wellbeing) were positively related to resilience”. A significant inverse relationship between emotional intelligence and work-related stress was identified among psychiatric nurses, in which that stress decreased when emotional intelligent increased. Several studies have highlighted the link between emotional intelligence and work-related stress among nurses. Nurses who have a high level of emotional Intelligence build relations within an organization and with the people they serve; whereas, those with low level of EI may tend to create problems for the organization through their individual behaviors. Therefore, developing emotional intelligence should be emphasized in order to overcome stress at workplace and accomplish goals and cope with stress. The study of represent that emotions play an important role in a profession that requires not only technical expertise, but mainly relies on the psychological and physical care of human beings. The positive effects of EI with respect to the quality of nursing work and the ability to mitigate the impact of a difficult working environment via the contribution of emotional self-management and the personal stress management capacity in environments that is full of stress. EI enables nurses to effectively manage and deal with stress at work. Furthermore, the ability of individuals to regulate emotion can have positive effect on group cohesiveness and that the emotional intelligence level of team leaders can improve team empowerment and minimize stress among workers. It has been found that longer careers, job retention, and participation in clinical ladder programs are related to higher emotional intelligence scores of clinical staff nurses. Moreover, there is relationship between emotional intelligence and nurse reports of self-compassion that affect positively on their performance, and higher nurse emotional intelligence is associated with lower levels stress and less burnout. In addition, less confrontational anxiety was associated with the ability to regulate emotion.

Conclusion

The recent study aims to measure the phenomenon of emotional intelligence among nurses working in psychiatric hospitals and the relationship with their stress at work. The findings show that more than half of nurses working in psychiatric hospitals had high emotional intelligence level. However, despite the positive results, working in psychiatric hospitals is still a source of stress for nurses. The statistical relationship appears in this study between emotional intelligence and workplace stress highlights the importance of enhancing EI among nurses, as it improves the capacity to exercise skills in a manner that benefits patients, families, peers, and themselves as practitioners. Furthermore, increased emotional intelligence can lead to more successful management, job satisfaction, organizational commitment, better patient health outcomes, and less workplace stress.

The Relationship between Smoking and Urokinase Gene 3’-UTR T/C Expression on Occurrence of Bladder Cancer

Zainab Nizar Jawad 1, Kamal Abdul Rasool 1, Weaam Awad 2

1Department of Biology, College of Education for Pure Sciences, University of Kerbala, Kerbala, Iraq,
2College of Medicine, University of Kerbala, Kerbala, Iraq

Abstract

Bladder cancer (CA Bladder) is the malignancy that affects the lining of the bladder (which is the most common types of urinary epithelial cancers that associated with the most invasive types of cancers and has the highest incidence of recurrence and infections). This study was designed to investigate the role of cigarette smoking on expression of urokinase gene that has a prominent role in the incidence of CA bladder. The samples were collected from 90 patients after being clinically diagnosed by the specialist surgeon of Imam Hussein Center for Cancer Diseases, Holy Kerbala, Iraq who were heavily smokers (more than one pocket/day). These patients were compared to 90 non-smoker patients with CA bladder and 90 persons who apparently healthy individuals as a control groups, DNA was extracted from all blood samples. The level of gene expression was correlated with cycle threshold value calculated by using real time PCR.

The results showed significant association between smoking and occurrence of CA bladder (by increased expression of urokinase 3’-UTR T/C gene) in comparison to both control and non-smoker patients groups.

Keywords: CA bladder DNA, cigarette smoking, Urokinase gene 3’-UTR T/C, real time PCR.

Introduction

The genetic investigations for polymorphisms help to distinguish between the different inherited forms of the gene and their impact on the occurrence of many human diseases include cancer 6. The extent of the risk factors like smoking and genetic predisposition of many affect the occurrence of many diseases such as cancer, heart disease and diabetes 1. The urokinase-type plasminogen activator uPA system is a responsible for transforming plasminogen into plasmin, which has different physiological functions 10. It additionally assumes a key signaling protein in disease intrusion and metastasis both locally and spread away for far destinations 4.

The urokinase gene is located at chromosome 10q24 9. Polymorphisms of a C/T transversion at the 3’ UTR (+4065 nucleotide) were demonstrated by C/T substitution in exon 6 and a T/C substitution in intron 7 8. Among the risk factors that participate in the occurrence of CA bladder, smoking was detected as one of major one 3. High levels of urokinase have been depicted in bladder tumors especially in those who were heavily smokers 5.

Methodology

Blood samples were collected from males of age group ranging from 50-60 years old by the Imam Hussein Center for Cancer and Hematology at the Imam Hussain Teaching Hospital in Holy Karbala province, Iraq. The samples were include a 90 heavily smoker patients after the clinically determination of bladder malignancy (transitional cell carcinoma) by authorized specialist, 90 patients with CA bladder with no history of smoking for at least the past 25 years, and 90 apparently healthy non-smoker individuals as a control group. Both patients and control groups were matched regarding age, body weight, past medical history and any associated confounding factors. This study was extended for period from January to August 2018. DNA was extracted from all blood samples by DNA extraction kit (Bioneer,Korea). Polymerase chain reaction (PCR) was adopted for amplification of gene, The Premieres
were Designed by STS Accession No. G27040: forward primer 5'-CCGCAGTCACA-C-CAAGGAAGAG-3' and backward primer 5'GCCTGAGGGTAAAGCT-ATTGTCGTGCAC-3'.

The RT-PCR protocol involve the following steps: (a) initial one cycle of denaturation for 5 minutes at 95°C, (b) followed by annealing at 58°C for 40 seconds, (c) then extension at 72°C for 40 seconds, (d) with final step of holding the specimen at 8°C. Real time PCR was used for quantitative assessment of urokinase gene 3'-UTR T/C expression by measuring cycle threshold (cT) value (which is inversely proportional to the level of gene expression).

Statistical Analysis

Data were statistically represented as mean±SD and analyzed by detection of variance of significance using ANOVA test by sigma plot software version 12.5.

Results and Discussion

Smoking was thoroughly studied as a predisposing factor for many human disease include cardiovascular disorders, respiratory diseases malignancies, neurological deficits and many other organic dysfunction. In current study, the aim was to demonstrate the Table (1): the cT value of urokinase gene 3'-UTR T/C (expressed as Mean±SD) estimated by real time PCR.

<table>
<thead>
<tr>
<th>Group Name</th>
<th>No.</th>
<th>Mean±SD</th>
</tr>
</thead>
<tbody>
<tr>
<td>CA smokers</td>
<td>90</td>
<td>12.584±2.692</td>
</tr>
<tr>
<td>CA non smokers</td>
<td>90</td>
<td>23.213±3.569</td>
</tr>
<tr>
<td>Healthy non smokers</td>
<td>90</td>
<td>24.865±2.861</td>
</tr>
</tbody>
</table>

The difference in cT values were quite significant between smoker patients as compared to both non-smoker patients and non-smoker healthy persons (12.584±2.692 versus 23.213±3.569 at P<0.001 and 12.584±2.692 versus 24.865±2.861 at P<0.001 respectively). On the other hand, no significant difference was detected between non-smoker patients in comparison to non-smoker healthy individuals (23.213±3.569 versus 24.865±2.861). These findings suggested that smoking has potential inducing effect for expression of urokinase gene 3'-UTR T/C which has crucial role in occurrence of CA bladder in heavily smokers. Other finding was noticed that the occurrence of CA bladder in non-smoker patients may be attributed to other sort of predisposing factor or gene.

This association was mentioned in certain study, which suggested that chronic exposure to cigarette smoking had strong association with development of urothelial carcinoma.

In another study done to evaluate the effect of smoking on soluble 3'-UTR isoforms (regulatory pathway of bronchial epithelial cell function), similar results were founded supporting the potential role of smoking as predisposing factor for CA bladder in our study.

This effect of smoking was explained in certain study as a result of the effect of smoking on p53 pathway that mediate apoptotic signaling that responsible for eradication of cancer cells.

Abstract

This study aimed to investigate the effects of 7,12 dimethylbenz[a]anthracene (DMBA) on some blood parameters and hepatic histopathology in rats and antioxidant enzyme. twenty female Wistar albino rats, weighing 180–200 g, were randomly divided into two group. DMBA group (positive group) who received 20 mg DMBA/kg body weight/ (single Douse). Control group (negative group) don’t received any thing. The animals in the groups were sacrificed at the end of the 90 days: The histological structure of the liver tissues in the control group was normal. the liver exhibited hydropic degeneration and coagulation necrosis in hepatocytes, severe dilation in the sinusoids, congestion in the central and portal regions, DMBA groups, was degenerative and necrotic changes were detected. MDA levels increased in the DMBA group , compared to the control group, Antioxidant activity CAT, SOD and GPX, the results showed increased enzyme activity in positive control compared with negative groups, ,the hematological parameter was increase in WBC, PLT, GRA, and LYM and decrease in RBC value .

Keywords: 7,12-dimethylbenz[a]anthracene (DMBA); Blood parameters; Antioxidant enzyme; MDA; Rat.

Introduction

Cancer, also termed as malignant neoplasm, is a type of diseases where in a group of cells show abnormal proliferation, invasion and sometimes metastasis 1. Cancer begins when cells in a part of the body start to grow out of control 2. There are more than 100 types of cancer have been identified 3. The substances that promote cancers are called carcinogens, and agents that have the ability to change DNA in ways that are inherited by daughter cells are called mutagens. Most cancers are related to environmental, lifestyle, or behavioral exposures 4. The term “environmental”, as used by cancer researchers, refers to everything outside the body that interacts with humans 5. Other chemicals, like benzene, ketones, vinyl chloride, ethylene bromide, and dichloro-diphenyl-trichloroethane (DDT), are known carcinogens 6. The accumulation of multiple factors, carcinogens and altered genes, transform a normal cell into a cancerous one. Carcinogens that have the ability to promote cancer have various sources 7. The factors responsible for cancer development are classified as exogenous and endogenous 8. The first group includes nutritional habits (food preservation and preparation), socio-economic status, lifestyle, physical agents (ionising and non-ionising radiation), chemical compounds (natural and synthetic) and biological agents (Helicobacter pylori, Epstein Barr virus, human T lymphotropic viruses I and II, human papilloma virus and the hepatitis B virus 9.

Material and Method

Experiential animals and Tumor induction in rats:

Twenty female of Wistar albino rats and aged between (7-8) weeks were weighing between 150 – 250 g used in this study. All they were kept in ventilated cages, with temperature of 25±2°C. A 12:12 h light:dark cycle
is also regulated for these animals. Balanced rodent food pellet and water is provided. The rats were randomly assigned to 2 groups of 10 rats each.

The groups were as follow:

Group 1: Received a single dose of DMBA (positive control) 20 mg DMBA/kg body weight/ (single dose)

Group 2: Did not received any treatment (negative control).

**DMBA administration:** Mammary tumors were induced by 7, 12-

Dimethylbenz (a) anthracene (DMBA) \(^{10}\). A single dose of DMBA dissolved in corn oil was given by oral gavage to two groups using the syringe and needles. DMBA was purchased from Sigma Aldrich and dissolved in corn oil. The concentration of the solution was 20 mg DMBA per 1 ml corn oil for each rat \(^{10}\).

**Preparation of tissue sample**

The liver was exteriorized and excised. All specimens were immediately fixed in 10% formaldehyde solution. After fixation they were processed in usual manner, and embedded in paraffin for subsequent histopathological examination for liver. A scoring system (of no abnormalities, mild, moderate, severe) was used to classify the liver changes according to the severity of the damage and extent of histological changes. The histological sections were evaluated by a pathologist without prior knowledge of the treatment given to the animals \(^{11}\).

Blood parameters were determined in whole blood by the using rat mode of veterinary practice with a blood cell counter (Abocus Junior Vet-5, Austria). Measurements of biochemical parameters were made with a Modular PP autoanalyzer (Mindray BS800, China).

**Results**

Histopathological findings: The control group showed normal histological structure in the liver tissue (Figure 1A). In the DMBA group, the livers exhibited dilatation of the sinusoids, cholangiohepatitis in the portal region, and congestion in the sinusoidal and portal regions (Figure 1B). Hematological parameters also change in negative group compared of positive group Table 1, in positive group : white blood cell (WBC) , LYM, MON, GRA and PLT while other parameter such as RBC was decrease. The state of free radicals and antioxidants is given in Table 2. As seen in Table 2, the levels of MDA increased in liver groups compared to the control group, also SOD, GSH-Px, CAT, and GSH values decreased.

**Figure1; A:** DMBA group showing cholangiohepatitis in portal region, mild dilation in sinusoids, hyperemia, and hydropic degeneration in hepatocytes;  
**B:** Control group showing liver tissue with a normal histological structure

**Discussion**

7, 12-dimethylbenz (α) anthracene (DMBA) is a well known carcinogen and immunosuppressor used in rodent models to study cancer. DMBA is reported to induce mutations by making DNA adducts. Although, it is a well known skin carcinogen, yet many researchers have reported the deleterious effect of DMBA in liver. Liver is the primary site of metabolism and is often prone to damage by xenobiotics. Evidently, liver cancer is the second most common cause of cancer deaths worldwide. Several haematological and haematochemical parameters were changed when treated with DMBA and found that DMBA induced hepatocellular carcinoma. Experimental studies showed that DMBA-induced skin, oral, mammary and ovarian tumors. The carciogenic and mutagenic effect of DMBA requires its metabolic activation by mixed function oxidases. The hydroxylation of DMBA at 7-methyl group is a crucial step towards its carcinogenesis. Further metabolism of DMBA leads to formation of a wide range of metabolites with varying toxicity. Among these, trans-3,4-dihydrodiol-1,2-epoxide is the carcinogenic product of DMBA. The metabolic products of DMBA, when present inside body, hampers ROS-antioxidant balance by overproduction of free radicals and the body in turn reacts by modulating activities of antioxidant enzymes to curb the damaging effects of an increased ROS. Hematological and biochemical parameters may be affected by a variety of factors such as race, age, gender, pregnancy, lactation, muscular activity, region, season, environmental heat, maintenance, and nutrition. In the present study, the effects on blood parameters and hepatic, histopathology of fluoride. Oxidative products derived from mutagen metabolism, such as DMBA, might impair vital cellular function by damaging proteins and lipid membranes. Consequently, these changes induced by the chemical carcinogen 7,12-dimethylbenz[a]anthracene, have been reported to be leukemia, and the development of anemia. Reactive oxygen species (ROS) are important pathological agents for many diseases. Increased oxygen radical production and lipid peroxidation are associated with the pathogenesis of many diseases and the toxic effects of a wide range of compounds increase in total leukocyte count (WBC), eosinophil, neutrophil and monocyte values for rats exposed to DMBA was also reported by. On other hand find MDA content increase significantly with rat treated with DMBA only.

¹University of Babylon / College of Basic Education, Iraq

Abstract

The questions are one of the most common and used methods in the educational process and in schools all over the world and are the most important educational strategies. Because questions are a great place in teaching, which is the mainstay of the dialogue method and is like the driving force in the lesson. The educators say (If you want to become a highly competent educator, it is important that you begin to apply and develop educational questions). These questions also occupy great importance in the educational process after which the standard means of knowing the readiness of the students and the level of information they received, in a good question, we achieve the desired goal and achieve a desirable educational product. Besides, the exams are a means to help educators to make different educational decisions, so that, there have been wide concerns calling for the reform of the test questions and the evidence of that conferences that discussed this problem, studies and research aimed at diagnosing them in order to address, improve and develop their defects to achieve best results in education.

Key words: evaluation, Arabic Language Questions, six Grade Students, Standard Specification Table.

Introduction

Education is the basis for the reform of humanity and its success. It is a force that can develop individuals, sharpen their talents, sharpen their minds and ideas. The education of the individual means comprehensive education that is integrated in all aspects, spiritual, mental, physical, psychological, social and aesthetic.¹ The method of education is the language that benefits the individual in understanding cultural aspects is the means of understanding and the means of education and the collection of cultures, a tool for the transfer of ideas, but is a tool of thinking and sense and feeling.² In summary: Language is one of the tools of public life, and it does not perform its duty unless fulfills its purpose for, and does not reach its real status with its people unless they are concerned about what they are and about.² Through this way, the Arabic language is one of the most important elements of our Arab nation. It is the language of the Holy Quran, which says: “We have sent down Arab villages” (Yousif / 2). The Holy Quran absorbed the characteristics of the language and it’s all stylistic features and its characteristic expression Until become the basis for the validity of the language and the state return to know the secrets and facts.³ Thus, Arabic is one of the most important elements of our Arab nation and by which the nation held fast and boycotted the sermons. As well as it is the language addressed by God Almighty Prophet Muhammad (peace be upon him and peace) as it is the language that came down the Koran by saying: (We sent down Arab villages that you may know) (Yousif / 2). The Holy Quran absorbed the characteristics of the language and it’s all stylistic features and its characteristic expression Until become the basis for the validity of the language and the state return to know the secrets and facts.⁵ The Arabic language is a branch of a large group called the Semitic languages, and the first to be known as the German orientalist Schlutzer in 1781.³ The evaluation of exam questions is a component of the curriculum, because it is the process of ensuring the achievement of goals, the relationship between the evaluation process and the educational goals, the evaluation process aims at knowing the extent to which these goals are achieved, or the extent of their progress towards the educational goals to be achieved. The importance of the evaluation is clear because of its great impact in the process of change and development in the educational process, because on the basis of a sound objective evaluation can be achieved a...
lot of educational principles, in addition to showing and treating weaknesses and showing positive aspects and strengthening them. There are some important terms that should be clarified as follows:

1. Evaluation: “It is the last stage that depends on measurement and decision-making, and then the feedback that makes teaching and teaching circular rather than linear.”

2. Questions: The field in which the student acquires knowledge and mental skills and intellectual capacities and works on their development and development.

3. Exam: A systematic objective method for measuring a sample of a person’s skills or abilities or a group of individuals in a particular time and place.

4. Bloom classification: A classification that contains a range of public areas, which include the possible educational data, and the expected educational process.

The theories and models of evaluation are very numerous and difficult to define each model that has many positives that make it suitable under conditions. And certain educational programs, and no matter how many calendar models, for the good qualities that should be characterized by any model of the calendar and any measure or any test are:

1. The Objectivity: - Objectively means that the procedures of evaluation and its components or measurements are accurate without falsehood away from self-impact and personal impressions of the transient to be true and consistent.

2. It is appropriate that the evaluation be appropriate in its tools, procedures and results for the subject of evaluation.

3. The Inclusion: - that the evaluation process is comprehensive so that the study programs or the subject to be evaluated in all its aspects and not by a certain aspect of it.

4. The Stability: that the evaluation process results in the same results if the results are re-analyzed or the application of measurement and evaluation tools is repeated.

5. The Honesty, ie, the evaluation means what is intended to evaluate it cannot study something and measure something else.

6. The Easiness: - That the evaluation and its tools process can be easily applied within the available material and human resources available and under the local conditions designed for them. The researcher will discuss the classification of Bloom and the criteria adopted in the analysis of the questions of Arabic grammar for sixth grade students. The scientific and literary branches in detail in the third chapter.

The results of the study are as follows:

1. The questions of reading subjects in the primary stage are markedly concerned with the level of understanding and remembering. The percentage of questions of comprehension (47.3%) and the level of remembering (40.8%). The levels of application, analysis, installation and evaluation were very small.

2. The questions of reading topics are concerned with the skills of direct understanding of the text, and the skills of understanding the conclusion of a greater interest in higher thinking skills such as the skill of criticism and taste, the proportions were respectively: (57.6%), the deductive understanding (34.5%), the critical comprehension (6.9%), and the final taste (1.7%). The test questions focused on the questions of understanding the direct meaning by 68% and the deductive questions by 32%.

3. Reading comprehension questions (50.3%), comprehension level (31.1%) and application (9.1%), followed by the remaining levels at low rates.

4. The predominant type of questions in subjects of reading is the most important questions (34.8%), while the balance of questions is (51.4%) compared with (48.6%) for the objective questions.

The research methodology and procedures:

It includes a presentation of the procedures that have been carried out to achieve the research objectives, starting with the research methodology and descriptive design, defining the research community and its design, preparing the research materials and tools, and presenting the statistical means used.

The Descriptive Design: The researcher followed descriptive research methodology to analyze the content.
of test questions because it is the appropriate method for analyzing questions, which is one of the research methods used in education and psychology. The aim of this approach is to provide data and facts about the problem of the subject to be interpreted and to identify its implications.

**The research community and design:**

The research society includes the general (ministerial) examination questions for the Arabic grammar for the third grade in the Republic of Iraq for the academic years of the academic year (2014/2015) to the academic year (2018/2019), and the first two and the third and the number of (11) exam paper, (5) papers for the first round and (5) exam papers for the second round examination paper for the third round and as Annex 1, as the research community represents the questions of the ministerial examinations of the sixth scientific grade therefore, the whole research community will be a basic sample that will be adopted by the researcher in his procedures.

**The research Tool:**

A - Sources of building the tool:

The structure of the criteria for the evaluation of the ministerial examinations of Arabic grammar through:

- Building an open survey questionnaire addressed to teachers and specialists in the methods of teaching Arabic language and measurement and evaluation.

- See a collection of previous studies and literature relevant to the current research topic that examines the standards of good questions. By means of exploratory resolution and the sources of tool construction, the orthodontic criteria that analyzed the test were built. The study consisted of six criteria and these criteria were analyzed by the questions of the ministerial examinations of the grammar of the Arabic language for the sixth grade in the scientific branches on the grounds that these criteria are the most important criteria that
should be available in the examination questions are:

- Independence.
- Direct and indirect questions.
- Objectivity.
- Inclusion.
- Bloom’s levels of knowledge.
- Technical aspects.

B - Tool credibility:

These criteria were presented to a sample of experts and arbitrators with expertise and experience for the purpose of identifying the validity and importance of each paragraph of the questionnaire, in order to achieve the apparent honesty. A standard was established to measure each paragraph (valid, not valid, observations). In this respect, Ebel points out that the test is true if its verbs measure what has been measured 13.

The researcher relied on the arbitrators to indicate the validity of the paragraphs of the questionnaire in their precise reference to the paragraphs, which is an indicator of the apparent authenticity of the questionnaire, and after collecting the questionnaires from the arbitrators, the researcher determined the proportion of agreement (90%) and more than the opinions of experts on the validity of the paragraph, because it represents the view of the majority, Agreement as follows:

- Independence 100%
- Objectivity 100%
- Bloom levels of the field of knowledge 100%
- Inclusive 100%
- Direct and indirect questions 95%
- Technical aspects 97%

In addition, some experts and arbitrators suggested that another criterion be increased, namely the proportion of correspondence to the textbook questions. The criteria were as follows:

- Independence
- Objectivity

- Bloom’s levels of knowledge
- Inclusion
- Correspondence to textbook questions
- Direct and indirect questions
- Technical aspects.

Steps to analyze the test questions:

A - Reading the contents of my book Arabic grammar rules for the sixth grade scientific reading good to know all content and topics.

B - Reading the questions a good reading and answer them as appropriate.

C) The question which contains several branches, each of which is treated as an independent question.

D - matching the questions to the criteria adopted by the researcher.

E) Unloading the results of the analysis into the criteria for analyzing the questions.

Evaluation criteria for ministerial examination questions:

There are scientific educational foundations that must be available in any exam to trust its results and benefit from it. The good exam is the one that is fit to perform the purpose for which it was set up in the fullest manner. Such a test will not be complete unless there is information on its validity for measurement.

Bloom’s Levels of Knowledge:

Many of the studies in Bloom’s classification (1956) indicate that this classification is one of the most important works that can help to analyze questions in general and in a procedural manner to contain all levels that reflect the desired objectives of the education process 14.

The Bloom classification is one of the most important attempts to address behavioral goals and the most widely used. It has an advantage in the identification and identification of educational goals 15.

Bloom’s classification helps teachers gain a clear idea of the patterns of behavior emphasized by a particular set of educational schemes. As well as it represents
an educational system and benefit for all teachers, administrators and those interested in education and researchers who are in the Department of specialization in the issues of curriculum and evaluation 16

Therefore, the researcher chose this classification because it is one of the most common classifications because it contains a very wide range of behavioral patterns of goals that most educational programs and systems are expected to achieve. It also benefits educators in general, and teachers who seek to define their educational goals in special behavioral terms. 17.

Those who are interested in measurement and evaluation, led by Bloom, set behavioral goals in three areas. A meeting of the University of Chicago in 1956 resulted in an agreement to classify goals into three areas:

(Cognitive / mental, emotional / emotional, and motor).

Statistical means:

The researcher used the following statistical means:

- percentage
- Equation (scott) to find the stability of analysis.

Conclusion

The ministerial examinations are of great importance, because it represents the boundary between the stage and the other, especially since each stage characteristics and advantages differ from the stage that precedes it, especially the transition from secondary level to university; The current research problem revolves around the validity of ministerial examination questions for the Arabic language for the sixth scientific grade and the extent to which the characteristics of good questions. In the light of the criteria standard and the analysis of questions according to this standard. The importance of the current research stems from the importance of the Arabic language and its importance to all the subjects, the importance of the ministerial examinations also stems from the fact that they are the most important evaluation tools currently used in our schools.

Abstract

Background: Transurethral resection of prostate has been regarded as the gold standard surgical management of benign prostatic hyperplasia (BPH). With the evolution of new technologies, laser prostatectomy emerged as an alternative.

Aim of the study: To compare the rate of outcome of diode laser vaporization of prostate and Transurethral Resection of Prostate in Al Diwaniya governorate.

Patients and Method: From October 2017 to October 2018, forty patients with surgical indications of prostatectomy were enrolled in this study. Their ages ranged from 60-75 years with a mean age 68.6 years and prostate size ranged from 40-80 ml with a mean size 62.175 ml. Twenty patients underwent diode laser vaporization of prostate and another 20 patients underwent Transurethral Resection of Prostate. The choice based on surgeon preference and patient ability. Preoperative evaluation was done for all patients by history, physical examination and investigations. International Prostate Symptoms Score, maximum flow rate, digital rectal examination, prostate specific antigen, abdominal ultrasound, urinalysis, blood urea, s.creatinine, complete blood count were all done preoperatively. One pint of compatible fresh blood prepared.

Results: The rate of significant bleeding and transfusion in diode PVP and TURP was (zero vs. 35% respectively), in PVP and TURP the mean irrigation amount perioperatively was (10.10 vs. 33.15 pints respectively), mean operative time was (70.80 vs. 50.00 min respectively), mean hospital stay was (16.03 vs. 30.09 hours respectively), mean time to urethral catheter removal was (24 vs. 81.71 hours respectively), postoperative complication rate (mainly dysuria) was (75% vs. 65% respectively), mean postoperative IPSS was (14.40 vs. 14.20 respectively), mean postoperative Qmax was (15.45 vs. 16.30 ml/sec respectively). There was no statistical difference between both groups in regard to lowering IPSS or increment in Qmax. The mean cost was (1500 vs. 500.42 dollars) in diode PVP and TURP respectively.

Conclusion: Diode laser vaporization of prostate is a good alternative to TURP with comparable results in treatment of BPH especially in patients taking anticoagulant drugs who cannot stop their medication. However, the high cost of this procedure and dysuria as a complication may prevent the common use of this technique.

Keyword: Diode photoselective vaporization of prostate, Transurethral resection of prostate, Benign prostatic hyperplasia.

Introduction

Benign Prostatic Hyperplasia (BPH) is a histologic diagnosis that refers to the proliferation of smooth muscle and epithelial cells within the prostatic transition zone and periurethral zone.¹ BPH is commonly characterized by lower urinary tract symptoms (LUTS).² The
prevalence of histologically diagnosed BPH increases from 8 percent in men aged 31 to 40, to 40 to 50 percent in men aged 51 to 60, to over 80 percent in men older than age 80. The prevalence of moderate or severe LUTS for men in the fifth, sixth, seventh, and eighth decades of life to be 26, 33, 41, and 46 percent, respectively. Patients often presents with LUTS as storage irritative symptoms (frequency, urgency and nocturia) due to bladder response to obstruction (increased pressure) and voiding obstructive symptoms (straining, weak stream, intermittency and feeling of incomplete bladder emptying). BPH is a progressive condition that can lead to serious long-term complications such as acute urinary retention (AUR), renal insufficiency, development of gross hematuria, bladder calculi, urinary incontinence, and recurrent urinary tract infections (UTIs). Medical history can establish the severity of LUTS by IPSS. PSA should only be performed if life expectancy is greater than 10 years and if a diagnosis of prostate cancer would modify the management approach. Medical treatment includes Alpha 1 antagonist, 5-alpha reductase inhibitors, Anti-muscarinic agents and Phosphodiesterase-5 inhibitors, when medical treatment fails to control patients complaints, surgical intervention is mandatory; however, surgery is associated with a number of complications. Surgical approach includes TURP. Laser prostatectomy is either coagulation or vaporization (or both), resection or enucleation depending on the wavelength applied. The usage of TURP is gradually decreasing (nearly 5%/year). Types of laser procedures includes HoLEP which can be used in large glands (100-150) and has comparable efficacy and good outcome compared to open prostatectomy and TURP but longer operating time. In this study, we want to compare the rate of intraoperative bleeding and the need for blood transfusion, the amount of irrigant, operative time, hospital stay, time of urethral catheterization, postoperative complications and the cost of diode laser vaporization of prostate and TURP in Al Diwaniya governorate.

Patients and methods

From October 2017 to October 2018, forty patients with surgical indications of prostatectomy were enrolled in this study. Their ages ranged from 60-75 years with a mean age 68.6 years and prostate size ranged from 40-80 ml with a mean size 62.175 ml. Twenty patients underwent diode laser vaporization of prostate and another 20 patients underwent Transurethral Resection of Prostate. The choice based on surgeon preference and patient ability. Preoperative evaluation was done for all patients by history, physical examination and investigations. International Prostate Symptoms Score, maximum flow rate, digital rectal examination, prostate specific antigen, abdominal ultrasound, urinalysis, blood urea, s.creatinine, complete blood count were all done preoperatively. One pint of compatible fresh blood prepared.

Results

Our patients data were comparable between the two groups with a mean age of 68.6±4.14 years (range 60-75 years) and mean prostate size of 62.175 ± 10.885 ml (range 40-80 ml). Their mean PSA was 3.615 ng/ml (range 1.5-8ng/ml). Regarding vesical stones, one patient (5%) of laser group was with 18 mm stone and 3 patients (15%) of TURP group with 18, 13 and 15 mm vesical stones which were removed before beginning of the procedure. Four patients (20%) were on anticoagulants who could not stop their medications (all of them on warfarin 5 mg, 2 patients with cardiac stents, 1 patient with prosthetic mitral valve and 1 patient with deep lower limb venous thrombosis). All of them were enrolled in laser group as shown in table 1.

The mean operative time in laser group was 70.8 min. (range 60-80 min.) , while in TURP group was 50 min. (range 40 – 60 min.) (figure 11). Regarding intraoperative complications, no patient developed significant intraoperative bleeding in laser group. In our study, we determined significant intraoperative bleeding as reduction in blood pressure that required transfusion, while seven patients (35 %) in TURP group developed significant intraoperative bleeding and required intraoperative blood transfusion. No patient in laser group developed obturator reflex in comparison with TURP group in which 3 patients (15 %) developed obturator reflex, as shown in table 3.

The mean follow up period was two months. All of the patients were assessed clinically by calculating IPSS and Q max .The mean pre-operative IPSS was 17.65 (range 13 – 27 ) and significantly decreased post operatively in both groups (mean IPSS 14.3 with range of 9-18 ), with the mean IPSS of laser group decreased from 20.1 to 14.4 and that of TURP decreased from 18.75 to 14.2.

Regarding post-operative complications: no patient in laser group had frank hematuria in the immediate post-operative period compared to 2 patients (10 %) in TURP group. TUR syndrome did not occur in neither group. Four patients (20 %) in laser group had UTI in comparison to 5 patients (25 %) in TURP group. Acute retention occurred in 3 patients (15 %) in each group. Eight patients (40%) in laser groups complained from dysuria compared to 3 patients (15%) in TURP group. The overall complications rate was 75 % vs. 65 % for laser and TURP groups respectively. As shown in table 6.

Discussion

In this study, we compared the rate of intraoperative bleeding, the amount of irrigation fluid needed, operative time, hospital stay, time to urethral catheter removal, postoperative complications, follow up results and the cost. In our study, no patient in laser group developed significant bleeding, while in TURP 35% of patients had significant bleeding and needed transfusion. Kuntz RM reported that bleeding and need for transfusion is reduced significantly in diode laser PVP compared to TURP. Erol A. et al reported 1 patient with diode PVP developed bleeding that needed catheterization and irrigation. Seitz M. et al stated no patient had significant bleeding in diode PVP. Our study is comparable to these results. Reich O. et al reported rate of 7.1% of blood transfusion in TURP in 10,654 patients, while in our study it is 35 %. This high rate may be due to small sample study. The amount of irrigation needed for laser group is much less (mean 10.10 pints) than TURP group (33.15 pints) and this is because less encountered bleeding in laser group. Mithani MH. et al had mean of 16.44 pints for laser group. In our study, the operative time of laser group is longer than that of TURP by about 20 minutes. Razzaghi MR also reported higher operative time of laser because the time it takes for the light energy absorption by water and Hb. In our study, the mean hospital stay for laser and TURP groups was 16.03 and 30.09 hours respectively. This less stay for laser can be attributed to less bleeding and uncomplicated procedure. Tugcu V. et al concluded also less hospital stay. In our study, the urethral catheter was removed after 24 hours for laser group, while in TURP the mean time to remove the catheter was 81.71 hours. This is an advantage. Cetinkaya et al reported 1.45 day for laser and 2.63 day for TURP which is comparable to our results. The overall complication rate of laser and TURP groups in our study was 75% and 65% respectively.

Conclusion

Diode laser vaporization of prostate is a good alternative to TURP with comparable results in treatment of BPH especially in patients taking anticoagulants who cannot stop their medication and this advantage make it better than TURP. However, the high cost of this procedure and dysuria as a complication may reduce the common use of this technique.

Tympanometric Findings among Adults with Chronic Nasal Obstruction Due to Sinonasal Pathology

Salim Hussain Ibrahim

Department of surgery-Otorhinolaryngology Head and neck surgery; Tikrit Medical College –Iraq

Abstract

Background: The nasal obstruction is one of the causes that affect the middle ear function, but the physiological mechanism of this effect is not well understood. This study aims at 1st; evaluation of the middle ear function among adults with chronic nasal obstruction due to sinonasal pathology using tympanometry, and 2nd, at comparison between the anatomical and mucosal inflammatory causes of nasal obstruction and its impact on the middle ear function.

Patients and methods: A prospective case study of (310) adult patients with chronic nasal obstruction were subjected to tympanometry for study of middle ear pressure in the private ENT clinic for a period of two years in the Salah Al-Deen governorate.

Results: this study found that (13%) of adults with chronic nasal obstruction had abnormal tympanogram (type B or C), (17.2%) was due to mucosal inflammation and (7%) due to anatomical and structural cause. Commonly one ear affected (unilateral) was (67.5%). Myringotomy and aspiration of middle ear found that (64%) had OME and VT was inserted.

Conclusion: The study statistically proved that adults with chronic nasal obstruction due to mucosal inflammation differs from others due to anatomical and structural causes in the followings; 1. The incidence of abnormal tympanogram (type B and C) is more. 2. The type B (OME) was more than type C (Eustachian tube dysfunction). 3. In the treatment, it was found that the need to VT insertion was more.

Keywords: Tympanometry, Chronic nasal obstruction, Otitis media with effusion, Nasal polyposis, Chronic rhinosinusitis.

Introduction

One of the major ENT complaints is chronic nasal obstruction. A definite relation between nasal obstruction and middle ear diseases, where Eustachian tube dysfunction (ETD) caused by nasal obstruction, that may cause middle ear hypoventilation resulting in otitis media with effusion (OME), that may be definitely diagnosed through use of otoscopic findings associated with a B tympanogram (1,2,3). Some previous researches have been carried out on how the nasal obstruction that influence middle ear function, but the physiologic impact of this effect is not well defined (4,5,6). The evaluation of the middle ear function with a high rate of success in the management and follow up of middle ear diseases can be carried out by Tympanometry, because of its compliance, flexibility of the ear drum to changing air pressure 7. This study aims at 1st; evaluation of the middle ear function among adults with chronic nasal obstruction due to sinonasal pathology using tympanometry, and 2nd, at comparison between the anatomical and mucosal inflammatory causes of nasal obstruction and its impact on the middle ear function.

Patients and Method

A prospective case study of 310 adult patients with chronic nasal obstruction (>3 months) were subjected to tympanometry (620 ears) for study of middle ear pressure in a private ENT clinic during a period from 1st January 2017– 1st January 2019, in the salah El-den
governorate. Iraq. Male were 184 (59%) and female were 126 (41%), age ranging from 18–63 years (mean age 31 years). The diagnosis of nasal pathology was based on detailed history taken, proper ENT examination includes nasal endoscopy and investigation includes computed tomography of the nose and paranasal sinuses. Ear examination includes otoscopic examination, Tuning fork tests. Tympanometry, PTA when abnormal tympanometry. Exclusion criteria includes nasoapharyngeal mass or tumor, recent history of acute rhinitis or middle ear infection, chronic suppurative otitis media, previous nasal or ear surgery, tympanosclerosis, no case with nasal malignancy. Patients were classified according to the causes of nasal obstruction in to;

1. Patients with nasal obstruction due to anatomical and structural causes includes Septal deviation, hypertrophied turbinates, concha bullosa, nasal valve collapse, synchia, choanal atresia.

2. Patients with nasal obstruction due to Mucosal inflammation, such as allergic rhinitis with or without nasal polyposis (NP), non allergic rhinitis, and chronic rhinosinusitis (CRS).

Tympanometry was carried out using viola middle ear analyzers from inventis audiology equipment / Italy to conduct automatic tympanometry tests at low frequency (226Hz)

The tympanometer probe was inserted into the clean ear canal. The types of tympanogram are classified according to Jerger/Fiellau-Nikolajsen in to the following;

1. Type A is a normal peaked curve with pressure between +50 and -99 daPa, Compliance from 0.3-1.5 ml. Suggests normal middle ear functioning

2. Type B is a flat curve without peak, Compliance less than 0.3 ml suggests middle ear effusion.

3. Type C is a peak curve with negative pressure (-100 or more negative), compliance from (0.3-1.5 ml). Suggest Eustachian tube dysfunction.

Treatment involves surgical correction of nasal obstruction according to the causes ,and myringotomy procedure was carried out for the ear with type B and type C tympanogram , when there is fluid aspirated and the ventilation tube (VT) is inserted.

Results

From total 310 patients with chronic nasal obstruction 40 patients (13%) had abnormal tympanogram (type B or C). (Table 1). An abnormal tympanogram was found in patients with chronic nasal obstruction due to the mucosal inflammation was 31/180 patients (17.2%), and in patients due to anatomical causes was 9/130 patients (7%),Which is statistically significant association p-Value 0.018. (Table 1). Patients complaining of nasal obstruction due to mucosal inflammation the type B/C tympanogram were as follows, in allergic and non-allergic rhinitis was 7/57 patients (10.5%), nasal polyposis (NP) was 17 /94 patients (18%), and in chronic rhinosinusitis (CRS) was 7/29 patients (24%), anatomical and structural causes 9/130 (7%) as shown in (Table 2). Patients who had an abnormal tympanogram in one ear (unilateral) were 27/40 patients (67.5%) and in both ears (Bilateral) were 13/40 patients (32.5%) (Table 2). Regarding the type of tympanogram, the normal type A was in 567/620 ear (91.5%), type B was 25/620 ear (4%),and type C was 28/620 (4.5%), this statistically very strong association p-value =0.005 (Table 3).

Patients who underwent surgical treatment were 31/40 patients (77.5%) (9 patients refused to carry out the operation or were missing). Total number of ears who have abnormal tympanogram was 39 ear ( 8 patients were in both ears and 23/patients in one ear). Those patients have undergone myringotomy and aspiration of middle ear and found that 25/39 ear (64 %) fluid was aspirated (OME) so that a VT was inserted. Shah VT was inserted in 23/39 patients (59%) and Good T-tube in 2/39 patients (5%) who had adhesive otitis media, this results was statistically significant association P-value =0.05 (Table 5) The study found that the Shah VT was inserted in 23/33 ear (70%) of patients with chronic nasal obstruction due to mucosal inflammation ,and in 2/6 ear (33%) of patients with anatomical causes. (Table 4) The research found that 24/40 (60%) of Patients who had abnormal tympanogram were complaining from hearing loss or fullness of ears and tinnitus and (40%) of patients deny the presence of such ear symptoms.

Discussion

The incidence and severity of middle ear diseases has been found to be related to the cause of nasal obstruction, whether anatomical and structural causes or mucosal pathologies. There are several suggested theories about the effect of nasal obstruction on the Eustachian tube, one theory suggest that nasal obstruction leads to turbulence of air flow in the nasopharynx. The turbulent air flow may leads to Eustachian tube dysfunction (ETD) by the following supposed mechanisms, 1. Dryness of mucosal film leads to increased viscosity of the mucous and the surface tension at the tubal orifice interfering the opening of the Eustachian tube. 2. The air pollutant and microorganisms deposited in the (ET) orifice causing tubal or pre tubal inflammation and obstruction. 3. Stimulation of the mechanoreceptors, leading to reflex alteration of (ET) function. Many studies have been conducted to assess the correction of nasal obstruction due anatomical causes and the study of its impact on the middle ear dysfunction. Nanda et al, & Osama G. et al have found that septoplasty improve hearing and middle ear function by improving ET function, but Şahin, et al found that no effect of septoplasty on middle ear pressure and ET function. The whole mucosa of the upper respiratory tract, including the nasal cavity, sinuses, nasopharynx, eustachian tube, and middle ear, which belong to a system called the rhino-pharyngotubal unit or the “unified airspace”. Therefore, the presence of inflammatory disease that affects the nasal and middle ear mucosa is considered the more likely physiologic mechanism that leads to middle ear diseases.

The mucosal inflammation in Allergic rhinitis, NP and CRS contribute to congestion, including increased venous engorgement, nasal secretions from nasal glands and tissue swelling (edema), the accumulated secretion and edema block the eustachian tube. This can reduced middle ear ventilation leading to negative middle ear pressure. There is a significant association between OME and persistent symptoms of allergic rhinitis, these results suggest a direct involvement of the middle ear mucosa. Parietti-Winkler et al reported an association between OME and nasal polyposis. They concluded that the mechanism causes of OME in NP and CRS is more likely the presence of inflammatory disease that affects the nasal and middle ear mucosa, and less likely the obstruction of the ET by polyps or by congestion of the nasopharyngeal mucosa. There is a study concluded that the OME seem to be an inflammatory disease that extends to the middle ear rather than a consequence of the nasal disease itself. Because even when the symptoms of nasal obstruction are well controlled, the OME can develop or persist.

The current study found that patients with CRS and NP are at greater risk of developing abnormal tympanogram (24%) and (18%) respectively (Table 2). as found by other authors Rennie et al, study on Eustachian tube dysfunction found that 69% were due to CRS with NP, 28% CRS without NP, and 14% due to allergic rhinitis. In CRS the mucopurulent or purulent Secretions pass over the pharyngeal end of Eustachian tube and it can lead to inflammation of ET and hypertrophy of tubal tonsil results in ET obstruction. Patel et al (2016) found that symptoms of ET dysfunction are frequent in CRS, and respond well to
endoscopic sinus surgery. The current study found that the VT was indicated in 70% of patients with sinonasal mucosal inflammation because of glue like aspirate of the middle ear (OME). While in the anatomical causes VT was indicated in (33%). This results goes with Mary, et al who found that by 4, where they found that patients with severe CRS with NP are at greater risk of developing OME, and often highly viscous middle ear effusion.

Limitation in this study that combined pathology may be found commonly septal deviation and/or hypertrophied turbinates with allergic rhinitis, nasal polyposis or chronic rhinosinusitis. In this study they were classified with mucosal inflammation causes. This study statistically proved that adults with chronic nasal obstruction due to mucosal inflammation differs from patients with nasal obstruction due to anatomical and structural causes in the followings; 1.The incidence of abnormal tympanogram (type B and C) is more. 2.The type B (OME) was more than type C (Eustachian tube dysfunction). 3. In the treatment, it was found that the need to VT insertion was more. This study has the following recommendations recommendation: It is preferable to do tympanometry for patients with chronic nasal obstruction ,especially when it is due to NP and CRS, even if they not complain of hearing loss, tinnitus or fullness in the ear.

The impact of Mindfulness Education on Elementary School Students

Rawaa Saadoun Al-Abedi¹, Rassem Ahmed Al-Jerayi²

¹Asst. prof. Dr. Ibtisam Al-Zaywaini, ²University of Babylon / College of Basic Education, Iraq

Abstract

The current research aims at evaluating the reading for the fourth grade of primary school in the light of the habits of mind and followed the researcher descriptive approach to suitability the current research procedures to achieve the research objective, the researcher prepared a list that included the criteria of habits of mind based on this researcher prepared a questionnaire (6) standards and (141) paragraphs after verifying the authenticity of the tool from its presentation to a group of arbitrators the stability of the analysis using Holistic equation (0.83) The tool consists of (128) paragraphs distributed in six areas The researcher has developed three alternatives (valid), (invalid), (need to be modified), and the researcher used the appropriate statistical means for their research. The data obtained from the analysis process are: Holistic equation, centimeter weight, square cay, and weighted mean.

Keywords: Evaluation, Arabic Reading Book, Habits of Mind

Introduction

The students are the real wealth of the nation and society must be prepared for life, including the development of writing and reading skills, the maximum extension of the hand of reform is the book must be a systematic evaluation of the curriculum to learn the extent to which the goals set for them ¹ Reading is very important in the elementary stage as a natural entry point for learning and primary school fails miserably if it fails to teach its students to read because the student’s success and progress in all subjects depend on his literacy ability is not material with content that can be taught separately from other subjects But is a fundamental part of every other material. It has become clear that there is a need for something new if schools are to start from a traditional mindset that is focused on capacity only so that students can have a kind of mind-set to create a productive self-fulfilling life and therefore the need for effective and effective mental habits such as the need to develop educational goals that reflect The belief that ability is a repertoire of skills that the individual stores and continues to be constantly expanding as one can increase the skill of thinking through man’s efforts. Education in its general form is a familiar process for all reflect an activity produced by human societies across many times and places, It is not only a reflection of social, economic and political life, but it is an important tool in the development and formation of this life, including from different social systems the prosperity of nations and the attainment of their goals are linked to their concerns. These nations raise and nurture a strong generation to take responsibility for the leadership of the nations and hand them over from fathers to sons, therefore, attention to education means providing the right direction and congratulating the environment for the emergence of righteous individuals. Language has a great role in the twenty-first century because it is a new world in which information prevails in all spheres of life as the individual is able to get the information he needs as quickly as possible in the least effort and language is the basic goal through which he knows what he wants ¹. One of these languages is the Arabic language that every speaker has the right to be proud of and is magnified by our Arabic language, which is characterized by the beauty of its methods and the strength of its expression and its vast wealth of words and meanings. reading is the means of the numbers of the individual scientifically and morally is a means of personal harmony and social assistance to the individual to autonomy and adaptation with others and reading helps to quickly understand and gain desired attitudes and behaviors. The textbook offers opportunities for the teacher to use many of the teaching methods, especially those that need to have a textbook in the hands of the student when the teacher assigned
a student or several students to read a paragraph of the book to develop information or a comparison with external information is the basic premise in front of students to the world of research, knowledge, thinking and knowledge.

**Methodology**

The researcher followed descriptive research methodology to analyze the book of Arabic reading for the fourth grade of primary school because it means describing the facts to identify the data related to a particular educational phenomenon and follow closely and analyze and interpret and investigate the relationships and connotations and then access to the explanatory and complementary instructions can be used. The researcher relied on the analytical descriptive approach because it is a method that is compatible with the nature of the research and its requirements. The descriptive approach is a method for studying scientific phenomena or problems through scientific description and then reaching logical explanations with signs and bar Yen and that research is descriptive of a wider use of research in educational and psychological field it is usually looking at the present and diagnose existing phenomena and the relationships with the discovery by classifying them and their works on the interpretation of those phenomena. 

**Identify the research community and its sample:**

The research community is identified and identified by the researcher to define their research community as well as to define their own identity so that the current research community is determined the fourth grade reading book in the Republic of Iraq, the tenth edition 1437/2018. Karim Obaid Al Waeli and Dr. Abdul Abas Abdul-Jassim and Turki Abdul Ghafoor Al-Rawi, the book consisted of (147) page excelled by the researcher’s title book title, the exclusion of these parts of the content is familiar to previous studies and does not affect the analysis procedures directed towards the content related to the objectives of the book and its subjects, which is the subject of physical and moral construction of the student and has the ability to achieve educational experiences, information and facts Concepts, values and trends. Here is a description of this book:

**The Research Tool:**

As regards to lack of a ready and appropriate tool to gather information commensurate with the purposes and objectives of the research, the researcher adopted the questionnaire as a tool for research and to prepare this tool, the researcher followed the following steps:

- **List habits of reason:**

In order to reach the list of habits of mind and use that list in the analysis of the book of reading for the fourth grade of primary The researcher adopted the following steps:
1 - Review previous studies on the habits of reason

2 - Access to literature and books that dealt with the habits of mind

3 - The preparation of the preliminary list of the habits of reason based on the researcher’s knowledge of past efforts

4 - Directing an open survey questionnaire for supervisors and teachers of the Arabic language in primary schools, including the following questions:
   - What habits should be read in the fourth grade reading books? Please specify in terms of relevance to the primary stage
   - Do you think that the book of Arabic reading meets the habits of mind appropriate for the primary stage?

5. Distribution of the preliminary list of the habits of the mind to a group of specialists in the Arabic language to analyze them and determine whether the principles and their sub-indicators belong to the domains received and have been compiled and studied and used to reach the final list.

The tool’s credibility:

Honesty is one of the important characteristics of educational tests and standards psychological and different and is one of the old concepts so it is subjected to a lot of modification and change as a result of the spread and the expansion of the movement of tests and standards in the various humanities and the truth of several types of the researcher has used what fits the nature of her research which is the apparent truthfulness of the initial examination of the content of the instrument and is reached by the consensus of the arbitrators’ assessment of the measure of the instrument to which it was prepared and to achieve the credibility of the tool based on the credibility of arbitrators and specialists in Arabic language and literature and curricula and methods of teaching as well as those who teach Arabic reading for the fourth grade of primary school. The researcher presented the tool in its initial form in order to ascertain the apparent honesty. The arbitrators expressed their observations about the tool and took the researcher. The researcher has adopted (80%) of the opinion of the arbitrators on the validity of the paragraphs, this is indicated by Bloom, as 80% and more of the arbitrators are evidence of an investigation virtual honesty.

The Analysis:

A – The analysis unit: The researcher used the unit of thought in its analysis of the book of Arabic reading, if it is one of the most important units of analysis and the largest and may be the unity of the idea or phrase contains the idea that revolves around the subject of analysis.

B- The analysis steps:

1- Reading each topic of the Arabic reading book for the fourth grade of the primary to identify the ideas contained in the subject in general

2 - Second reading of each line in the subject for the purpose of reaching the phrase or sentence that contains a particular idea

3 - The identification of the phrase containing a specific idea added by the researcher to the principles prepared in advance and work to determine the suitability of this idea with each paragraph of this principle in a special analysis form

4 - Give a repeat of each paragraph correspond to the idea extracted

5 - Calculate the frequencies obtained by each paragraph in one principle and then calculate the frequencies of each principle individually.

The stability analysis:

While the method of content analysis is a scientific tool, there is a need to satisfy the conditions of objectivity, and achieving objectivity requires knowledge of the stability of the analysis. In terms of consistency, the results obtained from applying the analysis tool to the same sample are not changed and one of the most prominent methods of verification of the stability of the most common analysis of the presentation of a sample of the analyzed article on a group of experts and specialists and the people of know-how and experience in the analysis of content.

So the researcher used two experts who have knowledge in the analysis of the content given each of them a random sample and 10% of the analyzed material from the topics of the book of reading and the researcher calculated the correlation between them and the two experts was the correlation coefficient between them and
the first analyst (92.0) And between them and the other analyst (85.0%)

The statistical means:
The researcher used the program (spss) statistical means to analyze the results as follows:
1 - The weighted average to measure the extent to which each concept of the questionnaire
2 - Square Kai to calculate the honesty of building concepts
3 - Holistic coefficient to calculate the stability of concepts
4 - Percent weight to be used in interpreting the results.

Results
The researcher reached the following results: Taking into account the book of Arabic reading of some habits of the mind, which means taking into account individual differences between students. The habits of the mind give a wide range in the educational process to help the teacher to understand the minds of students and enhance their role in providing opportunities for students to learn and think in different ways. The planning and preparation of lessons through the habits of the mind left a great impact on the students, which led to an understanding of the students to read and assimilate well.

Conclusion
The researcher has developed three alternatives (valid), (invalid), (need to be modified), and the researcher used the appropriate statistical means for their research. The data obtained from the analysis process are: Holistic equation, centimeter weight, square cay, and weighted mean.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the University of Babylon / college of Basic Education, Iraq and all experiments were carried out in accordance with approved guidelines.

Prevalence of Bronchiolitis among Hospitalized Children less than Two Years in Babylon Province

Maha. A. Kadim¹, Nuhad M. AL-Doori²

¹ M.Sc. Student in child and adolescent health nursing, College of Nursing, University of Babylon, Hilla City, Iraq.
² Assistant Professor, Ph.D. in child and adolescent health nursing, Babylon University, College of Nursing, Hilla City, Iraq

Abstract

Background: Bronchiolitis is one of viral lower respiratory tract infections that constitute a heavy burden to public health in the Pediatric population worldwide, which occurs most frequently before age 2 years in the winter and early spring months and most frequently induced by a viral infection (respiratory syncytial virus).

Settings and Design: A survey descriptive study conducted in Babylon Province through-out the period of “1st January 2019 to 30 March 2019” (three) special hospitals of pediatrics.

Method and Materials: Non-probability “purposive” sample consists of 3374 subjects, which collected through a review of patient records for (2016, 2017, 2018) in the statistical units in Babylon hospitals. The information of data was collected retrospectively through-out the special questionnaire obtained from the patient’s sheets in the statistical unit.

Statistical analysis used: The data are coded and tested by the application (SPSS) through the descriptive and inferential analysis.

Results: The analysis of the study indicated that the majority of the children (62.7%) were aged (1-6) months old who lived in rural areas, the male percentage was higher than the female. In addition, the study indicated that the prevalence of bronchiolitis progressed during the last three years.

Conclusions: The study concludes that the higher morbidity of bronchiolitis was in 2018, most of them admitted to the hospital in January months. Also, the duration of hospital stay was > 4 days.

Key-words: Epidemiology, Prevalence, Bronchiolitis, children.

Introduction

Respiratory disorder is considered the most frequent reason for hospitalization and illness in children¹. Bronchiolitis is the most relevant infection of the LRTI during infancy through the 1 year of life. “Respiratory syncytial virus” (RSV) is the main cause of this condition as it is considered a major leading cause of increasing the rate of morbidity and hospitalized patients number and cost³. As long as, the epidemiology of RSV in developing countries has identified that the most common viral cause of LRI globally⁴, bronchiolitis constitutes a heavy burden to public health in the Pediatric population worldwide, particularly in the United States, which causes significant morbidity and mortality in infants and young children⁵. Bronchiolitis mortality rate is roughly 2 per 100,000 infants and is higher in developing than in developed countries, and statistical data showed that globally there are 150 million new cases of bronchiolitis annually⁶. Also, it has been reported that hospitalization of children during seasonal Respiratory syncytial virus epidemics about 2-3% of all infants less than 1 year⁷. In the United States, there is significant season-to-season variation in RSV with the period of the peak prevalence varying by as much as 7 weeks (ranging from early January to late February) between seasons⁸. In Egypt, during the period between “October 2016 and March
found that most of the children 53.3% were diagnosed with bronchiolitis and 31.7% were diagnosed with pneumonia. The median duration of the hospital stay four days. Prophylaxis is considered the most effective and safe method that is used in the prevention of respiratory syncytial virus (RSV) disease in infants.

Methodology

The study aims to determining the prevalence of bronchiolitis among hospitalized children less than two years

Study design: A cross-sectional descriptive study that conducted through the period of 1 January 2019 to 30 March 2019.

Setting study: The study conducted in in Babylon province at “Pediatric Teaching hospitals”.

Sample of study: A total of 3,374 is selected by a convenience non-probability sample through a review of statistical records which were selected out from the main hospitals in Babylon province.

Study instrument: The information of data was collected retrospectively throughout the special questionnaire obtained through a review of patient records for (2016, 2017, 2018) in the statistical units in Babylon hospitals.

Data Analysis: The data are coded and tested by the application “statistical package of social science (SPSS)(Version 24)”. A descriptive analysis includes frequencies and percentage; inferential data analysis included the correlation coefficient, ANOVA test.

Results

Figure (1) the prevalence of bronchiolitis disease in Babylon province for the last three years (2016-2017-2018).

Table (1) reveals that the majority of children were male in the past three years which signified as (60.8%) with (62.7 %) of babies aged less than 6 months; most of
them admitted in January and recovered within a short period of hospitalization stay (less than 4 days). The highest percent 57.9% were lived in the rural area.

The findings in the table above also reported that the prevalence of bronchiolitis was raised in the last three years, particularly in 2018.

**Discussion**

**Prevalence of bronchiolitis disease for the last three years (2016-2017-2018)**

The findings in the figure (1) reveals that the higher morbidity of bronchiolitis was in 2018. The researcher indicated in the present study that bronchiolitis was increased gradually in the last three years (2016, 2017, 2018) consequently. This study go along with a retrospective study carried out in Italian about “Comparing of two different epidemic seasons of bronchiolitis”, which done to evaluate the differences of bronchiolitis frequency and characteristics of the bronchiolitis-related hospitalization between two seasons; S1(2015-16), S2(2016-17). The author indicated that the bronchiolitis morbidity rising from 17% in 2015-16 to 26% in 2016-17. Also, it showed an increased rate of hospitalization. Another study conducted at AL-Zarqa Government Hospital, Jordan. It’s goal to analyze the epidemiology of RSV infection on 271 children less than 24 months with bronchiolitis, from January 1997 and May 1999. The results indicated gradual rising with peak incidence were in 1999. Rationally speaking, Iraqi children’s displacement and migration, particularly during the winter season, live in a crowded situation with bad earnings and health facilities that increased the incidence of communicable diseases with missing or dropping out in the immunization follow-up timetable.

**Distribution of Bronchiolitis prevalence data from statistical records**

In related to the prevalence of bronchiolitis as shown in the table (4.6), the study underhand proved that the majority sample was males aged less than six months who lived in a rural area, admitted in January, 76.5% stayed less than four days in the hospital which increased within two years progressed. a prospective study at Al-Bashir Hospital, Jordan, on children’s admission < 24 months. The author mentioned that the majority sample 60% were male, (53%) were < 6 months, with the annual peak during January and February. In reason, low immunity and high incidence of RSV in children less than 6 months during the winter season. Furthermore, the research showed that the duration of hospital stay was 4 days, the length of stay as indices for the severity of bronchiolitis and linked with absence of breastfeeding, reduced age, greater viral load and sepsis. Certain study indicated that the length of hospital stay was 3 days. The period varied in this study from 4 days in 2010 to 3 days in 2015, and the mean length of stay similar to that reported in Spanish studies. In the term of discharge outcome in the present study, more than half 64.7% were well status. The outcome discharge and LOS are dependent on effective management. Evidence study conducted at Meherpur General Hospital, about the RSV outbreak to determine the etiology and explore possible risk factors. Which indicated that no death among analysing cases, (36%) Still sick after 5 days of illness and (39%) recovery within 5 days.

**Conclusion**

The study concludes that predominant age is (1-6) months with a majority to male than female, the higher prevalence of bronchiolitis was in 2018, LOS was less than four days in majority of children, with improved status.

Nanotechnology issues included in the subjects of the Department of Biology in the Colleges of Education

Mazen Thamer Shenif 1, Mustafa Abdel Amir Raheem Al-Zamili2

1 University of Al-Qadissiyah, College of Education, Iraq, 2 University of Al-Qadissiyah, College of Education, Iraq.

Abstract

This research aimed to: Recognize how much including in content of subjects in the Department of Biology College of Education in accordance with the Nanotechnology Issues. To achieve this aim, the researchers built a standard for the Nanotechnology Issues, were verified validity by presentation to a group of arbitrators specialists in the methods of teaching the Biology, and that standard is finalized be from (8) Nanotechnology Issues and emerged of them (90) sub- Issues, then the researchers analyzed the content of subjects of the Department of Biology in Colleges of Education for the academic year (2018-2019) in the light of this criterion as the number of analyst was (12201) page, and it adopted the explicit idea and implicit idea as units for registration and repetition unit of the census, The results were: weakness of subjects in the Department of Biology in Colleges of Education to contain Nanotechnology Issues compared with the ratio based on the opinions of experts (20%), (16) only of 90 terms were achieved, that was equal of (17.77%)

Keywords: Nanotechnology - Nanotechnology Issues - Understanding Students

Introduction

In the midst of rapid and successive developments in most fields of science and knowledge, university institutions and research centers are undertaking these developments as an important tributary to them and a rich resource for their productions in the invention, discovery or development, and therefore university education adopts those developments learning and education at the very least, and perhaps the most important science that split its path to global scientific interest is nanotechnology because of the science it has enormous applied fields in various sciences, including Biology, and the first to be the outcome of this science is abundant and based on university students, including students of Biology departments in the colleges of to be educators in the future and need to develop their understanding and awareness of scientific knowledge achievements and provide the latest science and cognitive transformations. Technological Despite its many applications, importance, challenges and gravity, it did not receive the required attention from the thought and educational research in Iraq, as it notes the weakness of educational institutions in keeping with the amazing development in this field through its programs and plans

4. Through the information obtained by the researchers from the exploratory questionnaire distributed to a group of teaching specialists in the departments of Biology in the colleges of education and the number (9) include a question on the importance of nanotechnology and the most important issues related to the content of subjects in the departments Biology in the colleges of education, the researchers found that there is a certain desire and urgency of the teachers to address the topics and issues related to nanotechnology because of its global interest in scientific institutions and research centers, and its impact on the intention of the cognitive process for students and their lives, and the above is determined by the following research problem by asking:

Second: The Importance of Research:

Human societies are striving to pay attention to future science in order to face the challenges and developments of the times. Today, our world is witnessing rapid and successive changes as a result of major technological and scientific developments in all fields of life and at all levels. Humanity, and education, and educational practices allow the learner to take advantage of technological innovations in the development of achievement and skills. Among
the technological innovations are nanotechnology which takes care of the study and characterization of nanotechnology materials and their properties at a size less than (100 nm), and precise control of the interaction of molecules and rearrange the atoms and place them in order to produce new materials unprecedented, so that it is possible to design smaller robots from the head of a pin can enter and movement in the blood vessels and be able to perform accurate operations within them and treat blood clots tumors and incurable diseases.  

Given the importance of nanotechnology in education, many conferences have been held, most notably one, Nanotechnology organized by the University of Jordan in Amman from 10-13 / 10/2008, in cooperation with the University of Illinois at Urbana-Shampeen, under the name of “developed nanomaterials” (14) In Iraq initiatives have emerged related to nanoscience and technology in light of the national education strategy and education that started work formulated and organized since (2009) and launched in (2013) for (10) years, and in this regard published the University of Technology (128) research in the field of nano, and the University of Baghdad with (120) research {15} and given all the above interest in technology Nano and its issues in all fields have emerged many studies and research, including the study Ahmed and others (2015) that sought to investigate the impact of an educational program – learning according to the concepts of renewable energy and know its impact on technological enlightenment in the Department of Chemistry, and showed results the program assists students in acquiring knowledge and concepts related to nanoscience and technology and in technological development.  

Nano materials:

Hijazi defines nanomaterials as “very small materials that are prepared in the laboratory or already present in nature and whose measurements of lengths or diameters of granules range from 0.1 to 100 nanometers.”  

Forms of nanomaterials: nanomaterials are prepared in various forms including:

The Fullerene: nanoparticles composed of triple bonded carbon atoms, which give the shape of pellets that have a structure similar to graphite, but instead of containing pure hexagonal form, they contain pentagonal forms and potentially sevenfold carbon atoms.  

Thin Films: a thin layer of a specific material, less than 100 nanometers thick, and their length and width may be in micrometers. These thin layers are used in the field of semiconductors such as silicon and gold bars.  

Nanofibres

Perhaps the most famous nanofibers are those made of polymer atoms because the ratio of surface area to volume is large in the case of nanofibers, and this gains those fibers characteristic mechanical properties such as rigidity and tensile strength and others, which can be used in biomedicine, and in organ transplantation such as joints, and transport of medicines.  

Nanoballs:

One of the most important carbon nanoparticles, which ends in the class of Foloreinat, of the material C60, but they differ slightly from the composition as they are multiple crust.  

Second: Field Applications in Pharmacy:

Nanotechnology is one of the most important scientific fields that scientists rely on in the development of drug mutations that change the concepts of treatment and medication for many diseases, and perhaps the most important applications of nanotechnology in pharmacy:

1- Nano-biotics: compounds that have the ability to identify bacteria and viruses, and then eliminate them without exposure to any other cell

2 - delivery of the drug to tissues: It depends on the manufacture of nanomaterials that work to improve the bioavailability of the drug (Bioavailability) This means the presence of drug molecules in the target place of the body  

Nanotechnology can offer drug delivery solutions in the following areas:

a- Drug Coating: Using pharmaceutical packaging materials such as liposomes and polymers (such as polylactide –PLA, and lactide combined with PLGA glycolide)

b- Drug carriers: Another type of drug delivery system, nanotechnology offers important, manageable solutions to link with the drug, the target and the imaging material.

Research Approach
The researchers adopted the descriptive analytical approach for the analysis of subjects in the Department of Biology in the Colleges of Education.

**Search procedures**

First: Research Community (Community of Subjects)

The community of subjects covered represents all subjects for the four stages of the Biology department in the Colleges of education.

Second: Research sample (sample content of subjects): The analysis process included the content of subjects in the Department of Biology in the College of Education, as the number of analyzed subjects (15) of the 35 articles, or 43% of the total community. The total analyzed pages are (12201) pages, (1689) pages of the first stage materials, (2291) pages of the second stage materials, (4367) pages of the third stage materials and (3854) pages of the fourth stage materials. The scientific, drawings, tables and charts after the indexes and glossary of terms for the analyzed materials were excluded.

**Analysis of the content of the subjects of the Department of Biology**

The researchers relied on the explicit idea and the implicit idea as the two recording units because the subjects in the Department of Biology are scientific materials and expressions are often clear and explicit, but their use of the idea implicit, because some topics can suggest ideas that reflect the issues or sub-issues of the standard nanotechnology.

**Validity of the analysis**

To ensure the validity of the analysis conducted by the researchers were hired two experts * in the methods of teaching Biology and presented to them three subjects (cytology, biology, algae) with the standard of nanotechnology issues that were built and ideas extracted from the content of analyzes to make sure The analysis was valid, and they unanimously agreed on the validity of the analysis, which was prepared by the researchers in truth to the analysis he conducted.

**Stability of analysis**

In order to be objective analysis and to obtain acceptable stability, the researchers used two types of stability:

1- Agreement over time

To calculate the stability coefficient in this way, the researchers re-analysis after thirty days as the value of the coefficient of stability calculated (0.98) using the Holste equation, a very high value and reflect a high degree of stability.

2- Agreement between analysts

The researchers used external analysts to analyze the content *. This was done by selecting a random sample of the total analyzed content of (12201) pages. The proportion of the stability sample represented about (20%) (2790 pages), which included books (cell biology, biology, algae) and using the equation (Holsti) was extracted the stability coefficients calculated in this way and was equal to (0.82) For the researcher with the first analyst and 0.80) For the researcher with the second analyst (0.83) between the first and second analyst, and thus the coefficient of stability is good, and some studies have indicated that the acceptable stability ranges between (0.50 or 0, 60) as in Table 1

**Table (1) values of stability factors**

Determine the spoken ratio to compare the results of the analysis

Depend that the percentage (20%) to be a hypothetical ratio to compare the results of the analysis based on the agreement of the arbitrators and experts on this ratio, the researchers presented a questionnaire to find out the ratio (2). The agreement was (80%) of the experts and arbitrators on this ratio.

The results will be presented according to the research objective and discussed as follows:
Identify the extent to which the content of subjects is included in the Department of Biology, College of Education for Nanotechnology Issues.

After the subjects were subjected to the four stages, the pages subjected to analysis included (12201) pages and the results were as shown in Table (2).

</table>

From the data recorded in Table (5) it is clear that the subjects in the third stage were the most interested in the contents and issues of nanotechnology, where it obtained 68.75% of the percentage out of (16) elements of the sub-issue extracted, followed by the first stage by 25% and the second by 6.25% and then the fourth by (0%) and the researchers attribute this to the algae materials and practical environment and educational laboratory. In the third stage, it received the most attention, followed by the first stage, which was the theoretical and practical biology and theoretical cell which focused on the issues of nanotechnology and microscopes. Then the second stage materials represented theoretical histology material while the fourth stage materials were weaker and poorest as it did not get any repetition despite the importance of the fourth stage materials in the formation of specialization for students of the Department of Biology in the colleges of education and this is a take on the materials of that stage, which was expected to the strongest of the four stages because the first stage represents the beginning of specialization and the second and third stages represent a transitional stage to the end of the specialization of the fourth stage.

As for the issues, the diversity of interest in the main and sub-issues and their components, as in Table (3).

</table>
Through Table (3) we note that the issues in general did not get sufficient attention in the subjects of the four stages, which indicates the weakness of keeping up with these materials to the developments of science and its applications, including nanotechnology, but when looking at the same table we note that the identification issues of nanotechnology have been obtained more interest of the subjects has obtained (11) repetitions out of (16) recorded for all subjects and the rate of (68.75%) and the researchers attribute this to the fact that most of the study material deals with these tariff issues as an introduction to nanotechnology as well as the standards and microscopes that adopt this technique.

**Conclusions**

Through the results of the research, the researchers reached the following conclusions: The subjects of the Department of Biology in the colleges of education were weak in their inclusion of nanotechnology issues. The subjects of the third stage in the Department of Biology got the highest frequency, followed by the first stage and then the second stage, while the fourth stage did not receive any repetition. The nanotechnology knowledge issues with the greatest interest in the content of the subjects were the four stages.

Color Stability of Different Aesthetic Resin Composite Materials: A Digital Image Analysis

Shatha Abdul-Kareem1, Ahmed G. Al-Maroof 2, Noor H. Fadhil3

1Lecturer, Department of Conservative and Cosmetic Dentistry, College of Dentistry, University of Baghdad, Baghdad, Iraq, 2Lecturer, Department of Conservative and Cosmetic Dentistry, College of Dentistry University of Baghdad, Baghdad, Iraq, 3Assistant lecturer, Department of Conservative and Cosmetic Dentistry, College of Dentistry, University of Baghdad, Baghdad, Iraq

Abstract

This study aimed to evaluate and compare the color stability of three commercially available resins composites after exposure to different staining solutions using digital image analysis. A total of ninety-disc shape specimens of a microhybrid composite (Amelogen plus), ultrafine hybrid composite (Essentia), and nanohybrid composite (Beautifil II) were produced in Teflon mould (n=30/resin composite type). Specimens of each resin composite were then divided into 5 subgroups (n=6/subgroup) and immersed in 200 ml of Pepsi, orange juice, tea, coffee and artificial saliva (control group), respectively. Digital images of the specimens were taken before (baseline) and after 28 days immersion against a black and white background. Adobe Photoshop CS6, Ver.13.0.1 graphic program (AdobeSystems Inc., San Jose, CA, USA) was used to analyze the digital images and calculate the change in color (ΔE). Data were submitted to statistical analysis using one-way ANOVA and Tukey Posthoc test at a significance level of p<0.05. This study concluded that all resin composites exhibited color changes after immersion in all staining solutions. However, Amelogene Plus showed better resistance to staining compared to Beautifil II and Essentia.

Keywords: aesthetic resin, composite materials, image analysis

Introduction

Composite restorative materials are the most popular esthetic materials used in dental practice. The color instability of composite materials may be the main reason for the replacement of restorations. Discoloration of composite resin caused by extrinsic or intrinsic factor. Intrinsic factors include physical-chemical discoloration reactions in the composite matrix, in surface and deeper layers of the material, triggered by heat, humidity, or UV irradiation. Chemical discoloration has been attributed to a change or oxidation in the amine accelerator, oxidation in the structure of the polymer matrix, and oxidation of the unreacted pendant methacrylate groups1. Extrinsic factors are related to the surface adsorption of staining agents from exogenous sources or due to the accumulation of plaque2. Consumption of certain drinks such as Tea and coffee may affect the physical properties and aesthetic of composite restoration. The effect of drinks on the properties of restorative resins may be directly related to the amount and frequency of its intake2. The aim of this study was to evaluate and compare the color stability of three commercially available resins composite: Amelogen Plus (Microhybrid), Essentia (ultrafine hybrid), Beautiful II (Nanohybrid) after exposure to different staining solutions for 28 days using digital image analysis. The null hypothesis tested was that there is no difference in color changes (ΔE) between the tested composite materials after 4 weeks of degradation of the restorative materials and their adsorption of staining agents3.

immersion in different staining solutions.

**Materials and Method**

One microhybrid composite (Amelogen plus, Ultradent), one ultrafine hybrid composite (Essentia, GC), and one nanohybrid composite (Beautifil II, Shufo) were evaluated in this study. For each brand, the enamel shade was selected. A total of ninety-disc shape specimens of composite materials were produced in Teflon mould (10 mm diameter x 1 mm thick). After filling the mould with the composite, the discs were covered with glass slides, to exclude atmospheric oxygen, and then cured by visible light for 40 s, using a dental curing unit (Optilux, Demetron Res Crop, Danbury, USA) with an irradiance of 850 mW.cm⁻², which monitored with a radiometer (Kerr/Demetron, Danbury, USA). Light-curing was repeated on the opposite surface for another 40 s. After which, specimens were stored in an incubator at 37°C for 24 hours. Specimens of each resin composite brand were then divided into 5 subgroups (n=6/subgroup) according to the immersion solutions represented by Pepsi, orange juice, tea, and coffee or artificial saliva which constituted the control group. The digital images acquisition of all specimen groups was taken before immersion (baseline) by digital imaging technique using an SLR camera (Nikon D5200, Nikon Corporation, Japan) with a 105mm camera macro lens (Sigma 105 EX Macro, Sigma, Japan). The camera was fixed perpendicularly on stand clamp holder (10 cm distance from the specimen) and set on manual mode, which allowed total control of shutter speed 1/6, ISO 1250, f-stop 3.5. These measurements were remained unchanged during taking shots and three images were obtained for each sample against a white as well as a black background. For the digital imaging method, four fluorescent tubes were mounted on a costume made photostand with tubes perpendicular to the front plane that hold the discs, being 20 cm away from the specimen and illuminating at an angle of 45°. Two 6,500-K fluorescent tubes (Philips PL-C 18W/865, Koninklijke Philips Electronics N.V., Eindhoven, Netherlands) were placed in the lower sockets and were combined with two 2,700 K (Philips PL-C 18W/827) fluorescent tubes placed in the upper sockets. After baseline images acquisition were made, specimens were then immersed in 200 ml of each staining solution and kept in an incubator at 37°C for 28 days. Staining solutions were changed every week to avoid bacteria or yeast contamination. After the staining period, the specimens were gently rinsed with distilled water and air-dried. Imaging measurements were repeated for each sample to determine the color variation.

The digital images were transferred to a personal computer (PC), saved as TIFF images and were analyzed using the Adobe Photoshop CS6, Ver.13.0.1 graphic program (AdobeSystems Inc., San Jose, CA, USA). For standardized calculations, a measurement template was created in the middle third of the samples that consisted of a square area of 50 pixels. The CIE L*a*b* values of these particular areas were calculated using the eyedropper tool. The color data obtained directly in color picker palette tab for (L, a and b) parameters (Figure1). Color changes (ΔE) were calculated as follows:

\[ \Delta E = \sqrt{(L_1^*-L_2^*)^2+(a_1^*-a_2^*)^2+(b_1^*-b_2^*)^2} \]

where \( L^* \) is lightness (0 = black; 100 = white), \( a^* \) is green-red component (\( -a^* = \) green; \( +a^* = \) red), \( b^* \) is blue-yellow component (\( -b^* = \) blue; \( +b^* = \) yellow), subscript 1 is the baseline measurement before the immersion and subscript 2 is the measurement after 28 days immersion in staining solution.

![Figure 1: Adobe photoshop program shows how to pick the color data from the sample (L=47, a=-8, b=10) red dotted area.](image)
Data of color change acquired from black, white backgrounds were submitted to statistical analysis using one-way ANOVA and Tukey Posthoc test for multiple comparisons between groups at a significance level of $p<0.05$. Statistical analysis performed using the Statistical Package for the Social Sciences (Version 24; SPSS Inc., IBM, Chicago, Illinois, USA).

**Results**

Tables 1 and 2 show $\Delta E \pm (SD)$ of all tested composite resins after 28 days immersion in different staining solutions on a black and white background, respectively. The lowest $\Delta E$ value observed for Amelogen Plus composite resin in artificial saliva on a black background (1.42±(0.45)), on the other hand, the highest $\Delta E$ value observed for Essentia composite resin in coffee on white background (28.0±(1.12)). Regarding staining solutions, coffee caused the highest $\Delta E$ in all composite resins, followed by tea, orange, Pepsi and artificial saliva, as shown in tables 1 and 2.

In the black background data set (Table 1), there were significant differences in $\Delta E$ in each brand of resin composite between the different staining solutions ($p<0.05$), except between the artificial saliva and Pepsi, there was no significant difference in $\Delta E$ in all brands of resin composites ($p>0.05$). Also, there were significant differences ($p<0.05$) in $\Delta E$ between the three composite resins in each staining solution except between Amelogen Plus and Beautiful II in artificial saliva, Pepsi, orange and tea ($p>0.05$), there was no significant difference in $\Delta E$. Similarly, there was no significant difference in $\Delta E$ between Essentia and Beautiful II composite resins in orange staining solution ($p>0.05$), as shown in table 1.

Discussion

As a composite restorative material are continuously exposed to saliva, food stains and beverage pigments, it is important to determine its susceptibility to color change. In the present study, we investigated the effects of beverages tea, coffee, Pepsi and orange juice on the color stability of different composite materials. The artificial saliva constituted the control group. The results of the present study showed that there is a difference in color changes $\Delta E$ between the tested resin composites after immersion in different staining agents.

For standardization of staining conditions, we perform an “in vitro” study to control all variables such as food or drinking habits, tooth brushing. All the tested composites were of enamel translucency A2 shade, enamel translucency was selected because it is used as the most external layer and being in contact with staining agents. The immersion time for each composite group was 28 days in accordance with previous studies. Ardu et al. in 2017 reported that the immersion time for 28 days simulated about 2 years of drink consumption. Ertas et al. considered 28 days is equivalent to about 2.5 years of clinical aging (24 h in vitro staining corresponds to 1 month in vivo).

Digital imaging system is a reliable method for determining the color of teeth and gingiva when used with the appropriate calibration protocols. In this study, the digital imaging system was selected to evaluate the color changes against white and black background which were used to allow a double evaluation to simulate two different clinical situations; black background can mimic the situation, where no tooth structure exists in the back. i.e., class IV composite filling. White background can mimic class I, II, III, V and veneers, where one of the walls is still present.

Results of this study revealed that all tested composite showed significant color changes after immersion in the tested solution. Amelogen Plus was more stain-resistant followed by Beautiful II, while Essentia seems to be the most prone to staining. It seems that Essentia extensively colored in these staining solutions. The slightly different ranking obtained with the two different backgrounds may be related to different opacity of the composites which might modify the color perception on different backgrounds. The general behavior trend of the tested composites is confirming that Essentia has less color stability than Amelogene Plus and Beautiful II.

Findings of this study may depend on the hydrophilicity of the resin matrixes of these three resin composites and their filler particles. The differences in the staining resistance between these resin composites may be attributed to the different filler size and load which may affect the overall resin content in the cured composite. Essentia contains prepolymerized filler of resin, which together with the resin matrix, may increase the resin content in the composite, hence the water sorption and staining susceptibility consequently. It has been reported that increased resin content in the composite may increase the water sorption significantly especially in the first week of immersion in the staining solution.

The structure of resin matrix and filler type may have a direct impact on the susceptibility to extrinsic staining. The presence of UDMA, Bis-MEPP, Bis-EMA in the Essentia resin composite in this study did not enhance the staining resistance as has been proposed by previous studies. This may be due to the concurrent presence of Bis-GMA and TEGDMA in resin composition, which were present in the other two tested resin composites in this study.

Regarding the staining solution tested, coffee showed the most staining capacity, followed by tea, orange, Pepsi and artificial saliva (Control group). Changes in $\Delta E$ value were greater for the tested staining solutions than for the control group, so the staining effect of a staining solution varied according to its ingredients. These results are in agreement with many previous studies which shown various staining potential of these drinks and this may be related to their composition and properties.

The highest values of $\Delta E$ reached was in coffee and this could be related to its acidity (pH 4.5), both adsorption and sub-surface absorption of coffee colorant. The degree of polarity of the staining agent determines their degree of penetration into the resin materials. Less degree of polarity, such as coffee, can easily penetrate into the polymer matrix. Both coffee and tea contain a large amount of staining agents like Gallic acid, which could be another reason for the staining capacity of these materials. This finding is in agreement with the study conducted by Ardu et al. Some studies reported that a solution with a lower pH can attack the composite material...
surface, causing some changes and increasing pigment absorption. Although Pepsi had a low pH, which can damage the surface integrity of the materials, it did not cause as much staining as coffee and tea. This may due to the absence of yellow colorant, which is abundant in coffee and tea, these findings were in agreement with other studies which found that coffee and tea produced more discoloration than cola.

Conclusion
This study concluded that staining solutions affected the color stability of the tested resin composites significantly in a clinically unacceptable level, except for Amelogene Plus and Beautiful II in artificial saliva and Pepsi, which were acceptable clinically. Also, Essentia resin composite performed inferior to Amelogene Plus and Beautiful II in terms of color stability.

Abstract

The aim of the current study is to evaluate the antifungal efficacy of several different percentages of Bergamot Essential Oil (BEO) incorporated into heat cure PMMA denture base material against Candida albicans.

Materials and Method: Eighty samples were divided into eight groups including six various percentages of BEO (2%, 3%, 4%, 5%, 6% and 7% by volume) and 0% BEO as a control group, in addition to 1.4% by weight of nystatin which represent the positive control group. All these additives were incorporated into heat cure PMMA denture material. After 48h incubation in distilled water, all samples were assessed by Candida albicans colonies viable count test.

Results: For Candida albicans activity test; the experimental groups (2%, 3%, 4%, 5%, 6% and 7% of BEO) showed highly significant decrease in the mean values of the viable count of Candida albicans when compared to the control group (0% BEO) (p<0.01). In contrast, a non-significant difference among experimental groups and 1.4% nystatin group.

Conclusion: Bergamot essential oil was successfully incorporated into heat cure PMMA denture base material and could act as potential antifungal agent with a drug delivery system against Candida albicans. It seemed that adding of 5% and 6% BEO was the most beneficial effects against the growth of fungi.

Key words: Heat cure PMMA, Denture base, Bergamot essential oil, Nystatin, Candida albicans

Introduction

Walter Wright discovered poly(methyl methacrylate) (PMMA) after publishing the results of his clinical evaluation of PMMA in 1937, since it is introduced has become most superior, popular and satisfactory of all polymeric denture base materials. Acrylic denture base is used in removable dentures fabrication, and its popularity and universal use has attributed to low cost, light weight, ease of processing, ease of reparation, low water sorption and solubility, biocompatibility, satisfactory aesthetic properties.

and accurate fit, in spite of that this material until now remain not ideal denture base material due to the presence of several drawbacks like susceptibility to microbial colonization and formation of biofilm on its surface and this make the denture a source of different infections because it harbor the microorganisms in addition to lack of manual dexterity among the old age patients which make the effective biofilm removal not possible. Denture stomatitis is a disease related to denture use, and considered chronic atrophic oral candidiasis, which affect up to 65% of denture wearer, its etiology is multifactorial, but Candida albicans considered the main pathological microorganism which is the mostly isolated type from the oral cavity in patient with denture stomatitis. The most common line that is used in treatment of denture stomatitis is prescribing of topical antifungal medicines, but maintaining optimal oral drug dose and lacking of motor dexterity of geriatric patient who had impaired cognition, limit their use
and make it challenging to get a maximum benefit of these topical drugs. To overcome these obstacles it is better to incorporate the antifungal drugs into denture base materials. Unfortunately fungal resistance and side effects of these drugs make it necessary to obtain naturally derived medicaments as a substitution to these synthetic drugs. Herbal medicines are a powerful alternative treatment for microbial infections in the oral cavity which have less or no side effects; and this made a worldwide trend to make a lot of researches about them in order to find biologically safe herbal-based medicines with effective antifungal properties. Plants oils are herbal medicines and various researches, recently, have been done to test their antifungal efficiency against Candida albicans and they reported that these oils are considered a promising line of therapy which have effective antifungal properties and can be used for treatment of denture stomatitis. One of the recent research was done through the incorporation of virgin coconut oil into heat cured acrylic-based denture soft lining and proved the antifungal efficiency of this oil against Candida albicans. Bergamot is the popular name for Citrus bergamia Risso et Poiteau, Citrusbergamia is defined as “a hybrid between a sour orange (C. aurantium L.) and lemon (C. limon L. Burm.F.) or a mutation of the latter. Other authors considered it a hybrid between a sour orange and lime.”

Materials and Method

Regular- conventional heat cure acrylic resin denture base material (Vertex, Netherlands) was utilized. Bergamot essential oil (bergaptene-free) from (Aura Cacia pure essential oils, USA) was added to the liquid part of acrylic resin in six different percentages (2%, 3%, 4%, 5%, 6% and 7%), these percentages were selected to discover which one is as effective as 1.4% nystatin group (positive control group). This proportion of nystatin was calculated by the conversion of International Units (U) to milligrams. Every 6079U corresponded to 1 mg of nystatin. Therefore, for this group (500,000U) the amount of nystatin used was 90 mg for every 6.6 g of acrylic powder. In general, 500,000 units was the most common concentration used by many authors and result in decreased yeast count compared to control group. Also this percentage of nystatin start to change the color of acrylic resin into orange so it is objectionable to use it above this percentage especially in aesthetic area.

Total of eighty samples were prepared, 10 samples for control group, 10 samples for each percentage of BEO groups (2%, 3%, 4%, 5%, 6% and 7% BEO) and 10 samples for positive control group. All samples were tested by viable count of Candida albicans colonies test at the same time and circumstances and they stored in distilled water for 48h prior to test procedure to reach the state of standardization.

Candida albicans colonies viable count test

Samples preparation

Plastic models were prepared with dimensions of 10×10×2.3 mm in length, width and thickness, respectively using laser cutting machine. Then, the models were invested in freshly mixed type IV extra hard dental die stone to create stone molds where the acrylic resin samples will be packed. For control group the acrylic resin denture base materials were proportionate and mixed as directed by the manufacturer instructions. Regarding BEO incorporated samples, the required amount of oil were measured by micropipette and subtracted from the volume of monomer, then mixed manually in dry clean glass beaker with monomer. Following which, the mixture was added to acrylic powder and mixed thoroughly.

Isolation and identification of Candida albicans

Candida albicans were obtained from oral cavity of patient with an indication of a denture induced stomatitis by using cotton swab which then cultured on the surface of a sabouraud dextrose agar SDA (Oxoid, United kingdom) plates and incubated at 37°C for 48 h. The identification of candida albicans was done according to the following order: Firstly, the colony morphology (macroscopic examination) in which the Candida albicans appear as creamy, pasty, smooth and convex colonies on SDA. Secondly, microscopic examination using Grams stain procedure, candida seen as small gram-positive oval or budding yeast cells. Thirdly, Germ tube formation. Fourthly, Biochemical identification using analytical profile index API Candida system (bioMérieux, France) and API 20 C AUX system.

Assessment of Candida albicans viable count

Candida albicans suspension of about 10^7CFU/mL which equal to 0.5 McFarland standards was prepared by diluting a small quantity of inoculums in a test tube.
containing normal saline and measuring this solution with McFarland densitometer device as shown in Figure 1(A). Then, 100µL of Candida suspension was added to each tube contain 9.9 mL of sabouraud dextrose broth (Oxoid, England) to obtain 10 mL broth mixture this done by using micropipette. The samples after that immersed in tubes (Figure 1 (B)) and incubated at 37 °C for 24 h. After incubation, about 100µL was taken from all tubes of broth mixture and added to other tube contain 9.9 mL normal saline so tenfold dilution obtained. A second dilution made from this dilution by the same procedure as in Figure 1(C). About 100 µL taken from the second dilution and spreaded on SDA plates by using disposable inoculation loops (Figure 1(D)). The SDA plates incubated aerobically at 37 °C for 24 h. This dilution was chosen because it demonstrated a countable range of 30-300 CFU.

Following incubation, the Candida albicans colonies were visible on SDA plates, all these colonies counted and this viable count analyzed statistically so the material antifungal efficacy (AFE) was calculated using following formula (Equation 1):

\[
AFE [%] = \frac{V_c - V_t}{V_c} \times 100 \% \quad (1)
\]

In this formula the number of viable colonies of control samples was represented by Vc and number of viable colonies of experimental samples was represented by Vt

Statistical Analysis

The data of this research were collected and analyzed using SPSS (statistical package for social science – version 21) computer software. Descriptive statistics were made which include Means, Standard deviation, Minimum, Maximum. Inferential statistics include ANOVA (one-way ANALYSIS OF VARIANCE) test which was used to evaluate the significance of difference among the mean values of all groups, then multiple comparison using Dunnett t-tests which treat one group as a control, and compare all other groups against it was used.
Results

The viable count of Candida albicans colonies test was performed on six experimental groups (2%, 3%, 4%, 5%, 6% and 7% BEO) and two control groups (negative control 0% BEO group and positive control 1.4% nystatin group for comparison). After 48 h of samples incubation in distilled water, the results of viable counts of Candida albicans showed a reduction in the mean values for experimental groups in comparison to negative control group. So 5% and 6% groups showed the lowest mean value among all groups, while other experimental groups (2%, 3%, 4% and 7%) revealed higher mean values than positive control group. Antifungal efficiency (AFE) for the experimental groups are as follows: 55.53% for 2% BEO group, 67.21% for 3% BEO group, 68.64 % for 4% BEO group, 76.43% for 5% BEO group, 74.18 % for 6% BEO group, 66.80% for 7% BEO group and 69.87% for 1.4% nystatin group.

Descriptive statistics (mean, standard deviation, maximum and minimum) and statistical test of viable count of C. albicans results using One- Way ANOVA for comparison of means of all studied groups listed in Table (1) the difference between groups was highly significant. For multiple comparison purpose the Dunnett t (2-sided) a test was used. In this test the 1.4% nystatin group taken as control group and all other groups compared against it. The 0% BEO group showed a highly significant difference while all other experimental groups showed a non-significant difference in comparison to 1.4% nystatin group as listed in Table (2).

a. Dunnett t-tests treat one group as a control, and compare all other groups against it.
Medicinal Plants extracts are very good replacement to antimicrobial drugs with less or without side effects, as a result this encouraged the worldwide tendency towards herbal-based medicines and a lot of researches were done to obtain herbal medicine that is biologically safe and have excellent antifungal properties. Essential oils are examples of naturally derived herbal medicaments which are concentrated, hydrophobic liquids extracted from plant and have wide spectrum of pharmacological activities, these essential oils considered as a promising therapeutic line for oral infections and in the last few decades a lot of kinds of oils have been tested for efficacy against Candida albicans, each one of them has special active component that affect the fungi in particular mechanism. Bergamot essential oil has been used for its antiseptic, anti-inflammatory, diaphoretic, appetizing, and analgesic effect.

**Figure 2**: Viable counts of Candida albicans after 48 hours incubation of: a) Control samples; b) some experimental samples with BEO; c) positive control sample (1.4% nystatin). Medicinal Plants extracts are very good replacement to antimicrobial drugs with less or without side effects, as a result this encouraged the worldwide tendency towards herbal-based medicines and a lot of researches were done to obtain herbal medicine that is biologically safe and have excellent antifungal properties. Essential oils are examples of naturally derived herbal medicaments which are concentrated, hydrophobic liquids extracted from plant and have wide spectrum of pharmacological activities, these essential oils considered as a promising therapeutic line for oral infections and in the last few decades a lot of kinds of oils have been tested for efficacy against Candida albicans, each one of them has special active component that affect the fungi in particular mechanism. Bergamot essential oil has been used for its antiseptic, anti-inflammatory, diaphoretic, appetizing, and analgesic effect.

**Conclusion**

Within the limitations of the present study; the following conclusions can be obtained that Bergamot essential oil was incorporated successfully into heat cure acrylic resin denture base material and worked as a powerful antifungal herbal medicament against Candida albicans that is comparable with the effect of nystatin. Moreover, the samples with 5% and 6% BEO revealed a better antifungal efficiency compared to all other control and experimental groups.

Antimicrobial Activity And Characterization of Some Oxazole, Thiazol And Quinoline

1Department of Chemistry, College of Science-University of AL-Mustansiriyyah- Baghdad-Iraq

Abstract

New Heterocyclic compounds derivatives comprising 1,3-oxazole, chalcone ,thiazole, pyrimidine, quinolone moieties are reported. New derivatives of Quinazolin-4 (3H)-one ring comprising Schiff’s bases,(1,3,4-Thiadiazole),(1,3,4-Oxadiazole) and (1,2,4-Triazole), Thiaurease moieties are reported. Compounds (1), (2) and (5) were synthesized by reaction of benzyol chloride with urea, thiourea and anthranilic acid respectively , then compounds (1)and (2) were converted into(3a-c) and (4a-c) derivatives. While compound (5) reaction with urea to convert to compound (6) which was converted to (7a-c) . chalcone derivatives (9a,b ) were readily obtained by reaction of compound (8) with different aldehydes, Compounds (9a , b) were converted into (10a,b) and (11a,b) The structure of these compounds has been established on the basis of their spectral data FTIR and 1H NMR. These compounds were tested for invitro antibacterial activity against Escherichia coli, Sepidermidis, S.aureusand Klebseillastandard methods. These synthesized compounds have been shown moderate to good antibacterial activity.

Keywords: 1,3 oxazole, chalcone, thiazole, pyrimidine, quinolone, antimicrobial activity.

Introduction

Heterocyclic compounds had been receiving considerable attention due to their pharmacological and pesticidal importance. The heterocyclic nitrogen compounds like quinazolinone derivatives has a vital role in synthetic drugs and biological processes. A Quinazolin-4-one derivative possessing broad spectrum of biological and pharmacological activities such as antifungal, antimicrobial, bronchodilator, antihistaminic, anti-inflammatory, 1,3-Oxazole and thiazole derivatives possess a broad spectrum ofpharmacological activities such as antibacterial, antiviral, anti-inflammatory, antitumor. The biological significance of the pyrimidine derivatives has led to the synthesis of substituted pyrimidineand their derivatives, pyrimidinederivatives have been important role in medical applications. One possible reason for their activity is the presence of a pyrimidine base in cytosine, thymine and uracil, which are essential building of nucleic acids ,RNA and DNA. Pyrimidine derivatives possess several interesting biological activities such as antimicrobial, antitumor, antifungal, antimalarial, anticancer, antiallergic, antitubercular activities and anti-inflammatory activities. Many Pyrimidinederivatives are used for thyroid drugs and leukemia.

Materials and Method

Apparatus

Melting point were determined in open capillary tubes and were uncorrected and the purity of the compounds were checked by TLC . The IR Spectra were recorded on a Perkin-Elmer 1600 series FTIR spectrometer, using KBr discs. 1H NMR Spectra of prepared derivatives were recorded in DMSO with TMS as internal standard on a Varian-Mercury 300 MHz Spectrometer the reaction were followed.

Procedures

Synthesis of N-(aminocarbonyl)-benzamide (1)

A mixture of benzyol chloride(1. 1 mole), and urea (1. 1 mole) in dry benzene(30ml) were mixed in round bottom flask and refluxed for 15 hrs, resulting mixture was poured in to crush ice and the solid filtered and
Synthesis of N-(aminocarbonothioyl)-benzamide (2)

A mixture of thiourea (1 mole) and benzoyl chloride were dissolved in benzene (30 ml) then refluxed for (16 hrs.), the mixture was cold and filtered to obtained the solid, and purified by recrystallization from appropriate solvent table (1).

Synthesis of N-substituted acetamide (General method)

In a dry and clean conical flask (0.01 mol) of substituted aromatic amine was dissolved in 15 ml dry benzene with continuous shaking and (0.015 mol) of chloro acetyl chloride was added drop wise by dropping funnel, the mixture was heated in water bath for (1 hr) after the reaction complete, the product which separated were filtered and washed with sodium bicarbonate (5%), water, dried and recrystallized from alcohol.

Procedure for Synthesis of derivatives(3a-c)

A mixture of compound (1) (0.01 mole) and (0.01 mole) of 2-chloro-N-(substituted phenyl)acetamide in ethanol were refluxed for 24 hrs and allowed to stand undisturbed over night, the product separated on cooling was filtered and purified by recrystallization.

General Procedure for Synthesis of derivatives (4a-c)

A mixture of compound (2) (0.01 mole) and (0.01 mole) of 2-chloro-N-(substituted phenyl)acetamide in ethanol were refluxed for 24 hrs and allowed to stand undisturbed over night, the product separated on cooling was filtered and recrystallized from appropriate solvent table (1).

Synthesis of (2-phenyl)-3-carboxamidequinazoline-4-(3H)-ones (5)

A mixture of benzoyl chloride (1.4 gm, 0.01 mole) and anthranilic acid (1.38 gm, 0.01 mole) in triethyl amine (30 ml) were stirred at 0-5°C for 1 hr, then further stirred for additional 1 hr at room temperature. A paste mass obtained which was washed thoroughly with sodium carbonate (10%) to remove unreacted acid, the solid separated by cooling and was dried and purified by recrystallization.

Synthesis of (2-phenyl)-1,3-benzoxazin-4(H)-ones (5)

A mixture of benzoyl chloride (1.4 gm, 0.01 mole) and anthranilic acid (1.38 gm, 0.01 mole) in triethyl amine (30 ml) were stirred at 0-5°C for 1 hr, then further stirred for additional 1 hr at room temperature. A paste mass obtained which was washed thoroughly with sodium carbonate (10%) to remove unreacted acid, the solid separated by cooling and was dried and purified by recrystallization.

Synthesis of (2-phenyl)-3-carboxamidequinazoline-4-(3H)-ones (6)

Compound (5) (2.23, 0.02 mole) and urea (0.6 gm, 0.02 mole), in pyridine 20ml, the reaction mixture was refluxed for (12 hrs) in oil bath at (180-200°C), then the reaction mixture was poured into to ice cold water containing conc. HCl. The separated solid was filtered, washed and recrystallized from appropriate solvent table (1).

General Procedure for synthesis of derivatives (7a-c)

2-chloro-N-(substituted phenyl)acetamide (0.01 mole) and (2-phenyl)-3-carboxamide quinazoline-4-(3H)-ones (6) (0.01 mole) of in ethanol were refluxed for 24 hrs and kept the product over night, the solid separated on cooling was filtered and purified by recrystallization.

Synthesis of N-(4-acetylphenyl)benzamide (8)

To a mixture of 4-amino acetophenone (0.01 mole, 1.39g) in 25 ml of benzene and benzoyl chloride (0.01 mole, 1.4g) was refluxed for 3 hrs according to literature procedure [12]. After that, mixture was kept overnight. The product thus obtained was recrystallized from appropriate solvent table (1).

Synthesis of N-(4-(3-4-substituted aryl) acryloyl) phenyl)benzamide (9a9b)

A mixture of (substituted benzaldehyde) (0.01 mole) and compound (8) (0.01 mole) and (20%) 10 ml NaOH in ethanol (30 mL) was stirring for 24 hrs at room temperature. After that, mixture was poured onto crushed ice to get precipitate. The product thus obtained was purified by recrystallization table (1).

Synthesis of N-(4-(2 mercapto-6-(substituted aryl)-1,6-dihydropyrimidin-4-yl)phenyl) benzamide (10a,b)

A mixture of required chalcone (9a,b) (0.01 mole) and thiourea (0.01 mole) in 1,4 dioxan (10 ml) and acatalytic amount of glacial acetic acid are taken in around bottom flask and heated under reflux for about 24 hrs. The reaction mixture was poured into cold water with stirring, the product was filtered and purified by recrystallization.
Synthesis of N-(4-(2-hydroxyl-6-(substituted aryl)-1,6-dihydropyrimidin-4-yl)phenyl)benzamid (11a,b)

A mixture of N-(4-(3-4-substituted aryl)acryloyl)phenyl)benzamide (9a,b) (0.01 mole) and urea (0.01 mole) in the presence of KOH (1gm) in 20ml ethanol was heated under reflux for 12 hrs, then cooled and poured in ice cold water, the solid mass was obtained by filtration, recrystallization table (1).

Results And Discussion

All compounds were prepared according to the following scheme:

The structures of prepared compounds were identified by FTIR (table 2) and $^1$H NMR spectra (table 3). All results spectral data were in correspondence to expected values. The purity of prepared compounds were checked by using TLC chromatography. The physical properties of compounds are listed in (table 1). Compound (1) was synthesized from benzoyl chloride and urea with dry benzene. The IR spectra of this compound, show the appearance of bands at 3360, 3342, 3225, 3068 and 1674 cm$^{-1}$ which could be due to v (NH$_2$, NH), v C-H aromatic and v C=O amide, respectively. The $^1$H NMR spectra measured in DMSO-d$_6$ at 25°C revealed a multiplet from 8.41 to 7.64 ppm for aromatic protons, a singlet at 11.58 ppm (N-H, 2H) and 3.7 ppm (NH$_2$). Also the reaction between benzoyl chloride and thiourea with dry benzene lead to the formation of compound (2). The spectroscopic observation of compound (2) is given show the appearance of bands at 3360, 3342, 3225, 3068 and 1674 cm$^{-1}$ which could be due to v (NH$_2$, NH), v C-H aromatic and v C=O amide, respectively. The $^1$H NMR spectra showed a singlet at 11.6 ppm (N-H, 2H), a singlet at 7.1 ppm (C-H oxazole, H), a multiplet from 8.4-7.84 ppm (ph-H, 9H). Compounds (4a-c) were synthesized by the reaction of compound (2) with 2-chloro-N- (substituted phenyl) acetamide in ethanol to give 5-membered heterocyclic system (substituted 1,3 thiazol). In compound (4a), the transformation is confirmed by observed the appearance 3257, 3088, 1672 cm$^{-1}$ which could be due to N-H, C-H aromatic and C=O as well as the appearance of C=N stretching band at 1626 cm$^{-1}$. The $^1$H NMR spectra, the signal of (N-H, 2H) and (C-H thiazole ring, H) protons were appeared at 11.7 and 7.1 ppm, as well as the signal of (ph-H, 8H) protons were appeared between 8.6-7.8 ppm. The reaction of benzoyl chloride with anthranilic acid in basic media lead to the formation of compound.

Antimicrobial activity

The activity of antibacterial and antifungal were studied by using cup-plate agar diffusion method. The inhibition zones were measured in mm. Amoxicillin and mefenamic acid (500mg/ml) were used as standard drugs for antimicrobial activity. The compounds were screened for antibacterial activity against klebsilliha, Escherichia coli, Pseudomonasaeruginosa and Staphylococcus aureus in Mullar Hinton agar, and the results are shown in the tables 4a, 4b, 4c and 4d. The results of antibacterial screening, indicate that compounds (4b, 7a, 11b) show activity against S. aureus and Sepidermidis than E. coli and Klebseilla and compared these results with standard drugs (mefenamic acid and amoxicillin). While only the derivative 10b show good activity against Klebseillamore the activity for standard drugs. The results obtained by antifungal activity, it is found that the compounds (3a, 4a, 7a and 7b) show good activity against conidid fungi and these results compared with standard drugs (mefenamic acid and Amoxicillin).

Conclusion

Different heterocyclic derivatives containing thiazole, quinazolin-4-one, oxazol and pyrimidine in structure were prepared and characterized using spectroscopy techniques. Four routes in the synthesis, the first synthesis of oxazol derivatives 3a-3c by reaction of benzoyl chloride with urea, after that cyclization product with (substituted phenyl) acetamids. In the same method prepared thiazole derivatives 4a-4c but with thiourea. The third route includes preparation of quinazolin-4-one derivatives 7a-7b by reaction of benzoyl chloride with anthranilic acid and reaction product with urea n de cyclization by (substituted phenyl) acetamids. In the final scheme synthesis was prepared pyrimidine derivatives 10a-11b. These derivatives have been evaluated in vitro for their antimicrobial activities against several microbes like klebsilliha, Escherichia coli, Pseudomonas aeruginosa and Staphylococcus aureus, addition of antifungal activity.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Department of Chemistry, College of Science-University of AL-Mustansiriyah-Baghdad-Iraq and all experiments were carried out in accordance with approved guidelines.

Nurses Staff Knowledge Regarding Standard Hand Hygiene Precautions in Rania City/Kurdistan Regional Government of Iraq

Blend B. Ameen
College of Nursing, University of Raparin,

Abstract
Objectives: -To assess nurses staff level of knowledge regarding standard hand hygiene precaution, and to find out the association between their level of knowledge and some of socio-demographic characteristics such as (gender, and level of education).

Method: Quantitative design, a descriptive study was carried out at Rania City. To achieve the objectives of the present study, non-probability purposive sample was used. The study sample was (66) nurses who were providing nursing services at two hospitals (Rania teaching hospital and Rania maternity and pediatric hospital). 10 of samples were excluded for a pilot study.

A questionnaire was constructed by the researcher for the purpose of the study technique and it was used as a tool for data collection. The data were collected through using an interview technique (face to face) approach.. Data were analyzed through the application of descriptive statistical analysis, such as: (frequency, percentage, mean of scores), and inferential statistical analysis (Pearson’s chi-square and correlation coefficient), by using the statistical package of social sciences (SPSS) version (20).

Results: The study indicated that the most of samples aged between 32-36 years old and represents 28.6% of the study samples. In addition, the highest percentages of the nursing staffs were female 73%. Concerning of the educational level, more than half of nurses graduated from the medical institute 66 %. And the largest study sample have 6-10 years of experiences 28.5%The findings of the study reveal that the nurses have a good level of knowledge about hand hygiene (HH) and appropriate time to do HH. The majority of the stay sample routinely used HH and they disinfectant their hands either by washing hands with water and soap or use alcohol-based jell for, while some of the nurses don’t wash their hands either because they are busy, they forget to do it or even the products are not available or not easy to reach. The study also approves that there was a statistically no significant association between the knowledge of nurses and gender and years of experiences.

Keywords: Hand hygiene, Hand washing, Alcohol-based hand rub, Knowledge, Nurses

Introduction
Nurses do hand hygiene even by washing hands with water and soap or using alcohol-based hand rub to prevent spread of infection to them or even to patients. With that there are many moments that the nurses do not do it either because they are busy, they forget to do it or the products are not available or not easy to reach. In addition, they do not wash their hands correctly because of lack of knowledge about standard HH. Hand hygiene is a simple, low cost and an effective way to prevent separation of infections. Cleaning your hands can prevent the spread of germs and safe the nurse and the patient lives. Hand hygiene refers to either hand washing with antimicrobial soap or hand disinfecting with an alcohol-based hand-rub. The aim of hand hygiene is to remove dirt and limit the microbial counts on the skin, to prevent cross transmission of pathogens between patients 1. The New England Journal of Medicine reports that a lack of hand-washing remains at unacceptable levels in most medical environments, with large numbers of doctors and nurses
routinely forgetting to wash their hands before touching patients, thus transmitting microorganisms\(^2\). One study done in ICUs in Michigan (2003), showed that proper hand-washing and other simple procedures can decrease the rate of catheter-related bloodstream infections by 66 percent\(^3\). The World Health Organization (WHO) has issued guidelines for procedural hand washing in order to reduce the prevalence of hospital associated infections, but lack of knowledge amongst health care workers is associated with poor compliance\(^4\). To reduce the spread of germs, it is better to wash the hands or use a hand antiseptic before and after tending to a sick person. All staff in hospital should deal with hand hygiene actively because this is one of the easiest ways to help keep patients as safe and healthy as possible. So there is a need to check up nurses’ knowledge and awareness toward hand hygiene periodically in order to ensure prevent spared of infection in health care setting and to stop patients and health care workers from getting infections.

**Method**

A quantitative design, descriptive study was carried out in in the Rania city from August 2, 2018 to the end of March 2019. In order to assess nursing staff level of knowledge regarding standard precaution (Hand hygiene) in Rania city. Rania is a city located in the Slimani Governorate Kurdistan Region/Iraq. A non-probability purposive sample of (66) nurses at the Rania teaching hospital and maternity and pediatric hospital. Who were providing nursing services at hospitals, 10 of samples excluded for a pilot study. Through an extensive review of relevant literature, and previous studies a questionnaire was constructed by the researcher for the purpose of the study and it is used for data collection. The questionnaire consisted of three parts: 1\(^{st}\) part includes socio-demographic characteristics of nurses, staff, 2\(^{nd}\) part consists of (7) question about HCWs compliance regarding hand hygiene, and 3\(^{rd}\) part includes (18) items, which include (2) sections. Section (1) consists of (11) items, about knowledge of study samples regarding the hand hygiene, section (2) consists of (7) items, about the most appropriate timing of hand hygiene actions that prevent transmission of germs to the patient. The data were collected through the use of interview technique (face to face). Items were measured by using two levels of (Likert) scale and rating as, the Yes answer (2), No answer (1)\(^5\). 1999). To content validity of the tool was established through penal of (5) experts. Reliability of the questionnaire was determined through the use of (test-retest) technique by using Pearson’s coefficient of correlation formula. (\(r = 78\)). This means that the questionnaire format was adequately reliable as a tool for data collection. Data were analyzed through the application of descriptive statistical analysis, such as: (frequency, percentage, mean of scores, Pearson’s chi-square and correlation coefficient and independent sample test), in addition use the statistical package of social sciences (SPSS) version (20). The mean of the score (1 - 1.33) was considered a low level of knowledge, (1.34 - 1.67) considered a moderate level of knowledge, and (1.68 – 2) considered a good level of knowledge.

**Results**

Figure (1). When nurses worked with his/her colleague and he/she forgot to disinfect their hands before touching the patient.

The bar indicate when the nurses worked with his/her colleague and he/she forgot to disinfect their hands before touching the patient, in what percent do you remind your colleague. The bar chart shows that (28.57%) percentage of nurses about (75-100%) remind his colleagues, (21.43%) says they will remind them in a percentage between (25-50%). (33.93%) give a percentage between (50-75%). In addition to (8.93%) says I never be reminded him to do hand hygiene and (7.14%) give between (0-25%).
Table (1): Level of knowledge of the study sample regarding the hand hygiene action with (2) levels of scale and frequency, percentage, mean of scores, and comparative significant.

Discussion

Hand hygiene is one of the essential ways to prevent or reduce the spread of infection in the health care setting. Periodically assessing knowledge of nursing staff regarding hand hygiene is an important ways to provide them with update information. In relation to the sociodemographic characteristics of the nurses’ the results show more than a quarter percentages of the nurses their ages between (32-36) years old. More than two-third of the study sample were female, due to Rania city has two hospitals; (Rania teaching hospital and Rania maternity and pediatric hospital). Most of the nurses in maternity and pediatric hospital were female. Concerning the level of education, more than half percentage of the samples are graduated from the medical institute, at the same time only a small percentage of the nurses were graduated from nursing college 12%. Regarding the years of experiences, above the quarter percentage of nurses’ has (6 - 10) years, while only five percentages
of nursing staff have (16 – 20) years’ experience. The result is an agreement with the Alireza Sharif study, the result of the study shows most of the nurses (38.5%) had working experience 5-10 years. But another study done in Mozambique which titled (Cold chain management: Knowledge and Practice in PHC facilities) that one-third of workers had between (2 to 5) years which constituted 32%. Concerning source of information, more than 70% of nurses had a self-reading either from reading books or from internet to increase or update their knowledge about HH. In addition, more than half of nurses took the training course about HH. The hospital administration, always tried to help their nursing staff to participate in course training in order to increase the staff’s knowledge and experiences about hand hygiene. While the diagram 1 shows that the more than seventy percentage of the study sample routinely used hand hygiene either by washing hands with water and soap or use alcohol-based handrub, but nearly 30% did not do hand hygiene routinely. This is not acceptable in hospitals because maybe they become source of transmission of infection. Healthcare workers’ hands are the source for the carrying of pathogens from patient to another and within the healthcare environment. The health care worker commitment to the highest degree of practices remains low. The study also shows the reason that makes the nurses did not do hand hygiene due to they are too busy, out of product or the product are way or located in an inconvenient location to get in time. In addition, they forget to do HH sometimes. Even though these excuses are not reasonable for nurses or other health care worker, they need to do hand hygiene in order to prevent or reduce the transmission of infection in healthcare facilities. Health experts say poor hand hygiene is one of element in hospital-borne infections that kill tens of thousands of Americans each year. One every 25 patients in U.S. hospitals get a hospital-acquired infection as part of his or her care despite modest progress in controlling those pathogens inside medical facilities, the Centers for Disease Control and Prevention (CDC) reported in its most comprehensive look at a stubborn and dangerous health care problem. The result of this study also shows depicted that no significant association between knowledge of nurses regarding hand hygiene with gender and years of experiences. The mean knowledge score was not associated with gender (p=0.82), and years of employment (p=0.63). This may back to some reasons like the small percentage of study samples, and this is out of hand of the researcher due to Rania city has only two hospitals, and only nurses includes in the study. Another reason is the most of the study samples have the same level of education (most of them graduated from the institute). There is consistent with a study done about the knowledge of hand hygiene among the healthcare workers of two teaching hospitals in Mashhad. The result shows there was no significant difference in the knowledge level of the participants who had received formal training in hand hygiene and those who had not. Also, the mean knowledge score was not associated with age, gender, department, and the profession.

Conclusion

According to the results of the study, nurse have good knowledge regarding HH, but they are not routinely aware to use HH due to they are too busy or because out of disinfect product or they forgot to do that. In addition, most of them, they did not remind other to disinfect their hands before touching the patient in case they forget to do that. Finally, the findings of the study also show there is no significant association between nurses’ knowledge regarding HH with gender, and years of experiences.

Risk Factors Increasing Prevalence of Type 2 Diabetes Under the Age of 40 Years attending Al-Diwanyia Teaching Hospital

Hassan Raji Jallab¹, Zahraa Abdul Ameer Kadhim¹
¹Department of Community and Family medicine, University of Al-Qadisiyah, College of Medicine, Iraq

Abstract

The present case control study of Iraqi people living in Aldiwanyia city to identify the attributable risk factors that leads to type 2 diabetes in younger age groups and the correlation of the most prevalence risk for developing diabetes. The study was designed to be a case control study includes 315 individuals, 150 is the number of controls, and the rest of the participants are patients that have been diagnosed by diabetes mellitus type 2 before or at age of 40 years. All these participants attended outpatient clinics at Al- Aldiwanyia teaching hospital in Al-Dewanyah province/ Iraq. The beginning of data collection was dated on the January 2019 and ended on June 2019. Mean age of patients with diabetes mellitus was significantly higher than that of control subjects. There was highly significant difference in the frequency distribution according to marital status, occupation, residency, level of education, economic status in patients and controls groups. It appears that the rate of overweight and obesity is comparable in patient and control group.

Key wards: diabetes mellitus; risk factors; prevalence; Iraq; young age.

Introduction

Type 2 diabetes mellitus (T2DM) is a complicated disease, the starting age of subjects is as early as 15 years old. Diabetes is widespread among people, ages and regions of the sphere due to changes in standard of standards of living, inheritance and environmental factors which all together in the disorder. Type 2 diabetes is a serious chronic disease resulting from a complex inheritance environment interaction along with different risk factors such as high BMI and sedentary lifestyle. Type 2 DM and its complications comprise a major worldwide public health trouble, affecting populations in both developed and developing countries with high rates of diabetes related morbidity and mortality. Diabetes mellitus is a clinical syndrome characterized by hyperglycemia caused by absolute or relative shortage of insulin. Lack of insulin affects the metabolism of carbohydrate, protein and fat, and can cause considerable disturbance of water and electrolyte homeostasis; fatality may result from acute metabolic decompensation. Long-standing metabolic derangement is associated with functional and structural changes in numerous organs, predominantly those of the vascular system, which guide to the clinical ‘complications’ of diabetes. In both of the common types of diabetes, environmental factors interrelate with genetic vulnerability to establish which group develop the clinical syndrome, and its onset. However, the fundamental genes, precipitating environmental factors and path physiology vary considerably between type 1 and type 2 diabetes. The prevalence of diabetes is rising in epidemic magnitude on a global basis. In the USA alone, it has been estimated that there are around 16 million people diagnosed with DM, representing about 6% of the population. Diabetes mellitus is becoming progressively more prevalent in developing countries, possibly due in part to alter in dietetic habits, diminished physical activity, and increase BMI.

The worldwide prevalence of DM has risen considerably over the last two decades, from an estimated 30 million cases in 1985 to 415 million in 2017. Based on current trends, the IDF projects that 642 million individuals will have diabetes by the year 2040. It is estimated that the greater part of patients with diabetes obtain their care from a family doctor. The complexity and chronicity of diabetes presents special challenges for family physicians, whose chief responsibility is the screening and avoidance of diabetes-related complications.
Patient and methods

The type of the design used in this study was a case control. This study was done in the Republic of Iraq, Aldiwayia governorate, in Aldiwayia general teaching hospital. Patient selected randomly throughout their attendance to outpatient clinic of diabetes in the former hospital. The study included period from January 2019 to July 2019. The patient introduce to this study were in the age under 40 years old or has been diagnosed with diabetes below 40 of age, and the study is only for type 2 DM. An arranged questionnaire was prepared by collecting any possible risk factors and Verbal consent was obtained from participant in the study. All diabetic patient with type two who were under the age of 40 or have been diagnosed with DM before that age we exclude patient that have been diagnosed after the age of 40 years and the patient with type 1 DM. The ethical approval of this study include the following:

- Acceptance of Scientific Committee of Community and Family medicine department in college of medicine/university of Al-Qadisiyah and acceptance of Committee of Ethical Scientific Researches in the college
- Verbal consent of individual participated in the study

Results

The Distribution of diabetic patients and control subjects according to age and gender is shown in table 1. Mean age of patients with diabetes mellitus was significantly higher than that of control subjects, 49.93 ± 9.95 years versus 34.68 ±12.56 years, respectively (P <0.001). No diabetic patient was under 20, 5 (3.1 %) were between 20-29 years, 15 (9.3 %) were between 30-39 years, 51 (31.5 %) were between 40-49 years, 32 (19.8 %) were between 60-69 years and 4 (2.5 %) were between 70-79 years, table 1. The mean age at diagnosis was 36.85 ± 4.48 years with a range of 20-40 years.

n: number of cases; SD: standard deviation; †: independent samples t-test; ¥: Chi-square test; HS: highly significant difference at P ≤ 0.01; NS: not significant at P ≤ 0.05
There was also highly significant difference in the frequency distribution according to occupation between patients and control groups (P < 0.001) in such a way that employee was less frequent in patients than in control group, 32.2 % versus 51.7 %, respectively, whereas the frequency of housewives and retired was more in patients than in control group, 45 % versus 32.9 % and 16.8 % versus 4%, respectively.

In addition, there was highly significant difference in the frequency distribution according to residency between patients and control groups (P = 0.005) in such a way that rural residency is more frequent in patients than in control group, 29.5 % versus 14.1 %.

Moreover, there was highly significant difference in the frequency distribution according to level of education between patients and control groups (P = 0.001) in such a way that illiterate and primary and secondary levels were more in patients than in control group, 32.9 % and 28.2 % versus 16.8 % and 16.1 %, respectively. Regarding economic status, there was also highly significant difference in the frequency distribution between patients and control groups (P < 0.001) in such a way that very poor and poor categories were more frequent in patients than in control group, 13.4 % and 45 % versus 1.3 % and 14.8 %, respectively. The comparison of body mass index (BMI) and waste circumference between diabetic and control groups is shown in table 3. Patients and control subjects were categorized into underweight (< 18.5), normal (18.5 -24.9), Overweight (25-29.9), class I obesity (30-34.9), class II obesity (35-39.9) and class III obesity (≥40 kg/m2), as shown in table 3. It appears that the rate of overweight and obesity is comparable in patient and control group; in addition, there was no significant difference in mean BMI between patients and control groups, 27.02 ±2.83 kg/m2 and 28.01 ±6.85 kg/m2, respectively (P = 0.091); however, mean waste circumference was significantly higher in diabetic patients than in control group, 105.85 ±14.26 cm versus 99.21 ±16.62, respectively (P <0.001).

Discussion

In the current study the mean age of patients with diabetes mellitus was significantly higher than that of control subjects. The mean age at diagnosis was 36.85 ± 4.48 years with a range of 20-40 years, which indicate significant relationship between DM and aging. This result has been supported by many studies worldwide including study have been done in UK, which prove that type 2 diabetes is more common in the middle-aged and elderly. It affects 10% of the population over 65, and over 70% of all cases of diabetes occur after the age of 50 years. Gender differences arise from sociocultural processes, such as different behaviors of women and men, exposition to specific influences of the environment, different forms of nutrition, life styles or stress, or attitudes towards treatments and prevention. In this study there is no significant relationship between gender and DM, the result have been supported by USA study that found no difference between male and female, study done in Pakistan revealed that there’s no difference in prevalence of diabetes mellitus with the gender. In Iran the prevalence of DM 12.1, with no significant difference between male and female, while the prevalence of diabetes in Saudi Arabia as demonstrated by Al-Nozhal show a higher ratio in females than in males, with 42%, and 37.2%, respectively. There was highly significant difference in the frequency distribution according to marital status between patients and control groups in this study in such a way that the frequency of married is more in diabetic than control which may be attributed to alteration of habitual life style. Study was done throughout Iranian urban population found that marital status was not significantly related to diabetes mellitus. In our study rural residency is more frequent in patients with DM, which has a similar result conducted from a cross sectional study using data from US centers for Disease and Prevention’s (CDC’s) Behavioral Risk Factor Surveillance, has found the increasing prevalence of DM in rural area more than urban that may be attributed to increasing poverty and lower education. highly significant difference in the frequency distribution according to level of education between patients and control groups. A case-cohort study in eight Western European countries nested in the EPIC study demonstrates the inequalities in the risk of T2DM in Western European countries, with an inverse relationship between educational level and risk of T2DM that is only partially explained by variations in BMI. Individuals within the middle socio-economic level, who are physically inactive and do not consume large amounts of fruit are at greatest risk of developing type 2 diabetes mellitus as explained by study has been done in Ghana. Individuals within the middle socio-economic level, who are physically inactive and do not consume large amounts of fruit are at greatest risk of developing type 2 diabetes mellitus as explained by study has been done in Ghana as well as in this study.

Conclusion

This study has been focused on the most important risk factors for the development of type 2 diabetes in young age patients and has assimilate other studies conducted throughout the world which puts the BMI, family history, lifestyle, hyperlipidemia, hypertension, and psychological insults in the top of these risks which necessitates the screening for diabetes in earlier ages. other risk must have further evaluation

Psychosocial Consequences of Children with Idiopathic Growth Hormone Deficiency in Baghdad

Adraa H. Shawq¹, Zaid W. Ajil¹
¹Lecturer, Pediatric Nursing Department, College of Nursing, University of Baghdad, Iraq

Abstract

Study aim: to evaluate psychosocial problems of children with growth hormone deficiency.

Methodology: A cross sectional study, of (80) children from both gender, (4 – 15) years diagnosed with idiopathic growth hormone deficiency, attending endocrine clinics in Baghdad city. Consent form taken from children and their guardians to participate in the study. Pediatric Psychosocial Symptoms Inventory (mood, behavioural, somatic, learning, and personality problems) was used to evaluate children psychosocial consequences. SPSS programme version 23 used for data analyses.

Result: children with growth hormone deficiency experience moderate psychosocial problems, especially personality and behavioural problems.

Recommendation: The researchers recommended details psychological assessment for children with growth hormone deficiency during their routine physical examination and provide suitable psychological support for them and their parent.

Keywords: psychosocial consequences, growth hormone deficiency

Introduction

Children with growth hormone deficiency usually followed up endocrine clinics for treated their short stature and improve their quality of life (¹, ², ³), they aware about their physical growth and feel with embarrassment about body differences from peers ⁴. As reported in the pediatric studies that children with health disorders may suffer from different negative psychosocial consequences ⁵. Those children and their parents influence by children`s short stature, in addition, to the burden of treatment regime (¹, ⁶). In Baghdad a study conducted in 2009 showed the prevalence of short stature only was 18.7%, while with underweight and short stature was 13.5% ⁷. The prevalence of short stature related to growth hormone deficiency was 1/4000 child and 60-80% of them with idiopathic causes ¹⁷. Many previous literature documented adverse effects of the short stature on children`s psychologically and socially ⁸.

Method and Materials

Research design: cross sectional study used, data was collected from first of May tile the first of November 2018.

Setting: study was carried out in outpatient endocrine clinics at two pediatric teaching hospitals and two specialized centres for endocrine disorders in Baghdad city.

Instrument of the study and procedure: Pediatric Psychosocial Symptoms Inventory PEPSI, parents reported scale, Arabic and English version. It has good reliability, developed from two famous pediatric psychosocial scales: strength and difficulties scale and child behavioral checklist scale by Dr. Al -Ayed and Al-Haider in their study about screening of children`s psychosocial problems in Riyadh ⁹. The approval obtained from the ownerships by electronic mail. PEPSI consists of (38) items, with five subscales: Mood symptoms subscale scored from (0-24), Behavioral symptoms subscale scored from (0-27), Learning problems subscale scored from (0-18), Somatic
symptoms subscale scored from (0-24), and Personality characteristics subscale scored from (0-21). Rating from 0-3: no symptoms= 0, rarely= 1, occasionally= 2, and frequently= 3. The total score ranged from 0-114 (0-38 = mild, 39-76 = moderate, 77-114 = severe).

**Statistical Analysis**

SPSS programme version 23 was used, frequency, percentage, and mean used in data analysis.

**Results**

Figure (1) Child’s Age and Gender Distribution

In these figures, the mean age of children with growth hormone deficiency is (8.41±2.7), most of them (75%) at school age (6-12) years, and mostly are boys (65%).

This table reflects that (84.75%) of children with growth hormone deficiency experience moderate psychosocial problems when assessed by PEPSI.

**Discussion**

The results of the present study showed that (48.75% and 22.5%) of children with short stature related to growth hormone deficiency experience moderate and severe psychosocial problems respectively. Their physical growth (height) interferes with social competence and body differences from normal peers which caused psychological disturbances. A study about psychosocial problems of children with growth hormone deficiency by using the Visual Analogue Scale for Children, support the present findings that those children showed negative self perception concerning physical appearance. Another longitudinal study about terminated treatment of adolescents with growth hormone deficiency showed that, their shortness affects negatively on their psychosocial status and their quality of life. Children with growth hormone deficiency suffer from psychosocial disturbances and their psychosocial functioning depending on various factors especially family support and school adaptation. Short stature associated with psychosocial distress and emotional deprivation. While another study about reviewing the psychosocial consequences of children with short statured that, those children showed negative social experiences but they have not psychosocial problems. However some studies mentioned the benefit of growth hormone treatment on their quality of life and self esteem after one year of successful treatment.

The present findings showed the aspects of children psychosocial problems according to pediatric psychosocial symptoms inventory PEPSI (learning, somatic, emotional, behavioural, and personality problems), in all aspects of children psychosocial problems children with growth hormone deficiency scored such problems. Mostly they scored behavioural...
and personality problems (60.4%, 65%). As parent reported their children have mood changes, fight with others, fidgety, tell lies, do not listen to rules, feel down, no hobbies, no friends, spend time alone, depend on others, and seem shy.

Most of children experienced teasing or juvenalization, these negative psychosocial consequences related to their shortness. Those children experienced behavioral and emotional problems, low self esteem. They exposure to bullying and could not adopt with their condition, the psychosocial burdens may also play role in developing short stature among some children. Short stature in children can lead to adverse psychosocial impact on those children and affects on their school performance and development of their personality. Children with short stature scored behavioural problems as a result of negative social relationships especially with their peers. Another study to measured behavioral and social problems of (195) children with short stature compared with normal children found that children with short stature experience higher score of school difficulties and behavioral problems. Children with short stature experienced different barriers in their personality development which affects negatively on their school and sport competence. Children’s psychosocial problems and school performance are the most concern of their parent.

As parent reported children with short stature have low social competence when compared with normal children, because of their unsatisfied appearance which affects on the social relationships and development their personality. Those children may face bullying in school or playing with younger children. A study in Japan about psychosocial problems of children with growth hormone deficiency by using Child Behaviour Checklist (CBCL) scale, the result of the study showed those children have higher scored than normal children, they also showed high scored on subscale of Child Behaviour Checklist scale such social problems, anxiety and attention. Previous studies showed school and psychosocial problems due to their appearance, they experience internalize problems and behavioral problems, and showed low health related quality of life. By using child behavior checklist scale for children with short stature, the findings showed those children scored high score of behavioral problems than normal developing children in addition to the somatic, attention, and social problems. In a study about reviewing children with short stature reported that those children scored lower in academic functioning, while another American study reported no differences form normal children. More than half of children with short stature experienced bullying and showed low quality of life. Children with growth hormone deficiency scored low neuropsychological test and impaired social relation. Those children recorded poor academic level due to effects of social relationships in spite of IQ score comparing with normal children.

Kranzler and his colleague in their study about psychosocial function of children with short stature that, those children scored externalize problems and inadequate social relationships. Children with growth hormone deficiency showed aggressive behavioral problems, attention, social, emotional problems and maladaptive. Prepubertal short children developed more social, internal, and external problems than children in the same age group. Children with short stature experience behavioral problems. Children with short stature scored low self esteem, bullying, juvenalization, and stigmatization because of their shortness. Previous studies reported those children have academic, internal, external, and behavioural problems due to their shortness. Those children have low quality of life. Psychosocial assessment of children with short stature is important in diagnosis and treatment of those children and well being. Some studies reported those children experienced low quality of life, and internal problems. Child health problems affects negatively on their parents.

Early children diagnosis and treatment reduce the risk of psychosocial problems and financial burden of treatment comparing with untreated children, in addition to the psychosocial advantages. Before treatment regimen the psychological profile should be assessed. The psychosocial services should also provide during treatment of children with growth hormone deficiency, those children experience sad feelings because of their shortness and puberty development delayed the psychological assessment of short adult showed some psychological disturbances. The setting and cultural attribute play a role in developing the psychosocial problems associated with certain health problems. The psychological health services will decrease and children well-being improved. Psychosocial improvement is one of the important goals for treated children with short stature.
Conclusion

Children with growth hormone deficiency were experience psychosocial problems, especially behavioral and personality problems.

Prevalence of Hepatitis B and Hepatitis C Viruses in β-thalassemia Major Patient in AD-Diwanya province, Iraq

Hassan Raji Jallab¹, Zahraa Muayad Eesa¹

¹Family medicine specialty, College of Medicine/ University of Al-Qadisiyah

Abstract

Background: transmission of infectious agent is still the most common cause of death and disability related to blood transfusion.

Objective: to estimate the prevalence of HBV and HCV in beta thalassemic major patients in Ad-Diwayah governatorate.

Method: The current study is a retrospective cross sectional study involving sample of 80 thalassemic major patients who regularly visit thalassemia center in Ad-diwuryah for treatment, data that required in the study had been collected from patients, their guardians and from the records.

Results: The prevalence rate of HBV was 2.5% (1 male and 1 Female ) which was significantly associated with family history of hepatitis ; while the prevalence rate of HCV was 3.8% (1 male and 2 female) which was significantly associated with age and family history of hepatitis.

Key words: prevalence; hepatitis; thalassemia; major.

Introduction

Thalassemia syndromes are characterized by varying degrees of ineffective hematopoiesis and increased hemolysis 1. Clinical syndromes are divided into α- and β – thalassemias, each with varying numbers of their respective globin genes mutated. There is a widen array of genetic defects and a corresponding diversity of clinical syndromes. Most –thalassemias are due to point mutation usually in both of the two β-globin genes (chromosome11), which can affect every step in the pathway of β- globin expression from initiation of transcription to messenger RNA synthesis to translation and post translation modification . A mutation in a single β- globin gene inherited along with triplicated alpha genes also may cause a β-thalassemia syndrome. Autosomal dominant forms of β–thalassemia also occur rarely 1 . β-Thalassemia major is caused by mutations that impair beta chain synthesis. Because of unbalanced synthesis of alpha and beta chains, alpha chains precipitate within the cells, resulting in RBC destruction either in the bone marrow or in the spleen . β -Thalassemia major is seen most commonly in individuals of Mediterranean or Asian descent. The clinical severity of the illness varies on the basis of the molecular defect. Signs and symptoms of β-thalassemia major result from the combination of chronic hemolytic disease, decreased or absent production of normal hemoglobin A, and ineffective erythropoiesis. The anemia is severe and leads to growth failure and high output heart failure. Ineffective erythropoiesis causes increased expenditure of energy and expansion of the bone marrow cavities of all bones, leading to osteopenia, pathological fractures, extra medullary erythropoiesis with resultant hepatosplenomegaly, and an increase in the rate of iron absorption. Treatment of β-thalassemia major is based on a hyper transfusion program that corrects the anemia and suppresses the patient’s own ineffective erythropoiesis, limiting the stimulus for increased iron absorption. This suppression permits the bones to heal, decreases metabolic expenditures, increases growth, and limits dietary iron absorption. Splenectomy may reduce the transfusion volume, but it adds to the risk of serious infection. Chelation therapy with deferoxamine or deferasirox should start when laboratory evidence of iron overload (hemochromatosis) is present an before there are clinical signs of iron overload (non immune diabetes mellitus, cirrhosis, heart failure, bronzing of the skin, and multiple endocrine
When it is certain that they require regular transfusion, they should be given washed red cell transfusions at monthly intervals; it is vital that the blood is screened for human immunodeficiency virus (HIV)/acquired immune deficiency syndrome, hepatitis B and C viruses. Most death and disability related to blood transfusion worldwide is still caused by the transmission of infectious agents. Despite the availability of a highly effective vaccine against hepatitis B, approximately 2 billion people worldwide are infected, 350 million with chronic active infection accounting for (600,000) attributable deaths annually worldwide. Hepatitis B is spread via blood and body fluid contact through heterosexual and homosexual relations, by sharing of needles by infected drug abusers, and by accidental needle sticks in the medical setting. In areas of high disease prevalence (e.g., Southeast Asia, China), transmission is primarily from mother to child during childbirth or in early childhood. The vaccination for hepatitis B uses recombinant DNA, requires three doses on a set schedule, and confers immunity in the majority of recipients. Patients with chronic infection can develop cirrhosis and end-stage liver disease. Hepatitis C affects more than 300 million people worldwide. At least six genotypes and 100 subtypes have been identified. The diagnosis is established with serum testing for HCVRNA antibodies; although an antibody is induced, it is not protective against disease contraction and progression. Transmission occurs via blood or body fluid contamination through IV and intranasal drug use, blood transfusions, and in health care workers (e.g., needle stick or skin disruption with contaminated instrument).

Patients and Method

The study has been designed as a retrospective cross-sectional study including a cohort of Iraqi patients having beta thalassemia major on regular transfusion therapy. No limitation for gender or age was proposed. An 80 patients were randomly selected in the study from the population of thalassemic patient regularly visit the thalassemia center in AD-Diwaniyah for transfusion therapy (at least once monthly). Any patient had been diagnosed with HBV or HCV infection before starting the first transfusion had been excluded from the study, also family history of HBV or HCV prior to infection of thalassemic persons was one of the exclusion criteria. The study had been done at AD-Diwanyah thalassemia center in AD-Diwanyah governorate in Iraq. The study had been started from first of April 2019 and ended on the third of June 2019. The study had been approved by the committee of ethical approval at Collage of Medicine university of Al-Qadisiyah. Verbal consent had been taken from the patients who included in the study if their age was more than 18 years or from their guardians if they were younger than 18 years old. The questionnaire had been designed to involve sociodemographic informations of patients included in the study like gender, age, residency; if it was rural or urban area and occupation. Socioeconomic state also was part of the questionnaire, the patients classified as high, moderate and low socioeconomic state; taking in consideration their level of education, income, residency, number of family member comparing with number of rooms and the house size, also if the house was renting or their own.

Results

Distribution of patients with beta thalassemia major according to age

The frequency distribution of patients with beta thalassemia major according to age is shown in table 4.1. Patients less than 10 years old accounted for 29 (36.2%), patients between 10 to 19 years old accounted for 38 (47.5%), patients between 20 to 29 years old accounted for 8 (10.0%) and patients between 30 to 39 years accounted for 5 (6.2%). The mean age of all participants was 13.38 ±8.26 years with a range of 2 to 39 years, table 1. Majority of patients were between 10 to 19 years and <10 years of age, as shown in figure 1.

Distribution of patients with beta thalassemia major according to gender

The frequency distribution of patients with beta thalassemia major according to gender is shown in figure 2. Male patients accounted for 41 out of 80 (51.2 %), whereas, female patients accounted for 39 out of 40 (48.8 %). The male to female ratio was 1.05:1.

Distribution of patients with beta thalassemia major according to residency

Distribution of patients with beta thalassemia major according to residency is shown in table 2. Patients from urban areas accounted for 27 out of 80 (33.8 %) and patients from rural areas accounted for 53 out of 80 (66.2 %), table 2.

Correlation between HBV or HCV infection and age of patients with beta thalassemia major

Mean age of patients with HBV were older than patients who were free of HBV infection, 20.00 ±2.83 years versus 13.21 ±8.29 years, respectively; however, the difference did not reach statistical significance (P = 0.253). Mean age of patients with HCV were older than patients who were free of HCV infection, 24.33 ±12.74 years versus 12.95±7.86 years, respectively; and the difference was statistically significant (P = 0.018), as shown in table 4.

Discussion

The current study had been designated in order to highlight the prevalence of HBV and HCV infection beta thalassemic patients in Ad-Diwanyah province since those patient need multi transfusion therapy for the rest of their lives, the fact that make them at higher risk to have blood transfusion transmitted infections, including HBV and HCV, and these infections can be transmitted to healthy persons by many routes other than blood transfusion and causing dangerous morbidity that reach hepatocellular carcinoma or even death. Also there is no other published study concerning about this topic in the mentioned area. Patients with beta thalassemia major had been targeted in the current study because those patients needs blood transfusion in a very early life time mostly in the first year of life so, if those patients had been infected with HBV or HCV, that would be most likely due to transfusion of contaminated blood.
Regarding age distribution in thalassemic patients who involved in the study, it was ranging from 2 to 39 years old with 83.7% of them less than 20 years old which could be due to high fatality rate of thalassemic patients comparing with general population. This result had been agreed by many other studies in the vicinity like Kamal Dumaidi and co-worker study about prevalence of hepatitis C and B viruses among patients with B thalassemia in Palestine which reveal that (75%) of patients involved in the study were aging 24 years and less. The mean of age in the current study was 13.38±8.26 year, this result was near but less than the mean age in the studies that done in the vicinity, as in the study that had been done in Iran by silos Mohammadi and Mazaher Khodabandehloo about the prevalence of HCV antibodies among Beta thalassemia major patients which revealed that the mean age was 18±8.05 years. Male to female ratio was 1.05:1 since the inheritance of thalassemia is autosomal which was agreed by Al-Naamani study in Oman. 66.2 % of patients who included in the study were living in rural areas. Regarding occupations of patients who enrolled in the current study; most of patients were either so small to attend school, students or having no job apart from single patient who was a nurse. Most of patients involved in the current study was classified as low or moderate socioeconomic state (87.5%) and the other 12.5% was classified as high socioeconomic state. 85% of patients’ parents were relative since most of them live in rural areas in which there is high rate of marriage between relatives. The rate of blood transfusion was ranging from 1 to 4 times per month patients with small age and patients who had splenectomy usually need transfusion 1-2 times per month while patients who didn’t have splenectomy and reaching adulthood or teenage, they usually needs transfusion 3-4 times per month. The prevalence rate of hepatitis B virus infection in patients participating in this study was 2.5% (two patients out of 80) which was less than the result of similar study done by Widad Yazaji in Syria which is a neighboring country, the study involved 159 patients, the study reveal that 13.2% of patients were seropositive for hepatitis B infection (21patients out of 159). The prevalence rate of HCV infection in the current study was 3.8% (3 patients out of 80) which was slightly higher than the prevalence rate of HBV infection which might be due to the availability of HB vaccine in the national vaccine program while there is no vaccine for HCV till the current day in the entire world. The prevalence rate of HCV infection in patients with thalassaemia in Zabol city of Iran; another neighboring country, was 8.5% which was higher than the current study which might be due to higher prevalence in general population in Iran (0.5%) comparing with Ad-Diwanyah population (< 0.3%). Regarding to relation of gender with HBV and HCV infection, there was no significant relation between them, this result going with study of Ansari et al. In the current study, there is no association between residency and infection with HBV and HCV. Also, no significant association between socioeconomic state and infection with HBV and HCV. This result had been agreed by Ghufranud Din’s et al study in Pakistan.

Conclusions

Prevalence of HBV and HCV infection is more in multitransfused beta thalassemia major patient than in the general population. Measures taken in the blood preparation and checking still not enough to prevent infections transmitted by blood transfusion. Risk of having HBV and HCV infection in multitransfused patients increase with progression of age. There was highly significant association personal and family history of HBV and HCV infection.

Deposition of TaN Film on Commercial Pure Titanium Disk by Modified Reactive Plasma Sputtering Technique

Hassan Jawad Farhan¹, Raghdaa Kareem Jassim², L. Thair³

¹Assistant lecturer Department of prosthodontics. College of dentistry. University of Karbala, ²Professor. Head of Department of Prosthodontics. College of dentistry. University of Baghdad, ³Chief researcher, Ministry of Science and Technology, Iraq

Abstract

Background: The new trend of implants is to find materials which accelerate bone formation at bone implant interface and improve Osseo integration to provide immediate or early loading after placement and eliminate waiting period which is uncomfortable and disturbs patients. Titanium as an implant material still need some improvement of surface properties physically and chemically. Tantalum which is gaining more attention as a new metallic biomaterial. Coating layer over implant is an important way for improvement of surface properties of titanium. Plasma used for surface modification, has several advantages such as changing surface topography, increasing surface roughness and in increasing the wettability of the surface.

Aim of study: To evaluate the effect of TaN coating by modified plasma sputtering technique of commercially pure titanium disk on wettability, surface roughness, surface chemical composition in comparison to non-coated surface.

Materials and method: Two groups were tested in this study which include non-coated commercial pure titanium disks and coated commercial pure titanium with TaN. Modified reactive plasma sputtering apparatus was used to coat CpTi with TaN at 4, 6 & 8 h. Surface characterization by x-ray diffraction (XRD) analysis, scanning electron microscope (SEM), energy dispersive spectroscopy (EDS), contact angle measurement, were carried out for coated and uncoated disks.

Results: The result of coating specimen with TaN at times (4, 6 & 8) h showed that 8 h coating time was the best time. And this was according to the results of X-ray diffraction analysis which show a new peak formation of TaN coated CpTi disk which was not present in non-coated CpTi disk. The results of wettability test for CpTi disk coated with TaN disk was more than wettability of non-coated CpTi disk. Surface Roughness was more and better distributed in CpTi coated with TaN disk than non-coated one which appear clearly in electron microscope.

Keywords: TaN film, pure titanium disk, modified reactive plasma sputtering technique

Introduction

Engineering and surface modification of dental implant material become much advanced than it was earlier ¹. Titanium shows a favorable combination of intrinsic properties for the fabrication of dental implants such as low specific weight, high strength to weight ratio, low modulus of elasticity, very high corrosion resistance, easy surface coating and excellent general biocompatibility ² enhancing the osseointegration of CpTi results in reducing the non-functional time period of the implant, increase its applicability in alveolar bone with low quality, cause minimum discomfort to patient, and minimize the failure rates. ³ Surface coating was one of the methods used in accelerating the Osseointegration process and this by increasing roughness and change surface properties physically and chemically. Chemically and physically reactive plasma discharges are widely used to modify the surface properties of materials. ⁴ The stable chemical element Tantalum (Ta) can exist in the surface layers of base materials. Ta is one of the promising materials used in medical and dental fields.
6. The stable TAN protective film can provide better corrosion resistance and bioactive property than that of TiO film. 7. The Ta components offer a low modulus of elasticity, high surface frictional characteristics, and excellent Osseo integration properties (i.e. Bioactivity and biocompatibility) 8. Surface-coated implants are reported to have less failure and can support heavier and more dynamic forces 9 surface coating with TaN by using plasma sputtering techniques was applied in this study on Cp Ti disk. In dental field especially in dental implant, plasma coating constitutes a simple, dry technique, which does not harm the environment, of low cost and does not comprise the intrinsic properties of the biomaterial, affecting only its surface. Many types of gases can be used in such technique to modify surface properties physically and chemically. Aim of our study to coat CpTi with TAN by using coat plasma sputtering technique.

**Material and Method**

**Sample preparation**

Titanium disks were prepared (10×5mm) diameter and thickness respectively which were cut from Cp Ti rod by using Bench Nibbling machine (TAURUS 7000-W6 CNC, Italy). All specimens were abraded successively using Si C grinding paper with different grits started from 80 grit, and continued by 120, 230, 400, 600, 800 and 1000 grit to get flat and scratch free surface. These disks were polished until a smooth and mirror polished surface was obtained. After that all specimens cleaned by using ultrasonic cleaning device with ethanol 99.8%.

**Surface coating with TaN:**

The procedure of sputtering was performed by using modify Dc glow discharge reactive plasma sputtering system. The total number of samples were 10 disk which divided as 1 uncoated and 9 coated disk. These coated disks were divided into 3 groups according to the time of coating (4, 6, & 8) h. The procedure of sputtering started with placing the clean and polished disks on the center of anode base. Then evacuating process of chamber to high vacuum (≈1x10⁻⁵mbar) by using high vacuum system which consist of rotary and turbo molecular vacuum pumps to ensure the complete removing of the heavy gases like hydrocarbons. After that Power supply negatively charged voltage of 3.5 kV applied. For sputtering process, the voltage was gradually applied using variac until the required energy achieved (applied voltage and current), The pressure was 2x10⁻² to 7x10⁻² mbar and this pressure was achieved by feeding the bombardment and reactive gases. The appropriate voltage and amber were adjusted precisely by regulator until intended sputtering glow (purple color, which standardized for each gas) is achieved. One of the most important modification done to convert normal plasma system to sputtering plasma system include replacement of electrode position, so the cathode placed in upper part and anode electrode placed in lower part of chamber. A Target (cathode) and anode stainless disk. The cathode faced the anode with 7 cm distance between them, which provides electric field for the gas to be discharged. The electrical electrodes and the associated dc-power supply of 5kV. The bottom of the stainless steel disk cathode electrode are covered with tantalum sheet which regarded as target. The clean and polished samples were placed on the anode in the center of base which regarded as substrate. All the samples were cleaned by argon plasma sputtering for 15 min prior to the TaN coating process by applying a bios dc voltage of 100 Von the anode. Parameters used for reactive plasma sputtering procedure: argon was used as bombardment gas and nitrogen as reactive gas. The process was carried out at various sputtering times (namely 4, 6 and 8 hours). The reactive gas nitrogen was introduced into the evacuated chamber and the flow rate was adjusted until the pressure was stabilized to the required pressure (1x10⁻² mbar), then the argon gas introduced to the chamber until the sputtering pressure of 5x10⁻² mbar achieved. After the sputtering process completed, the samples were kept until ambient temperature in the vacuum chamber was reached.

**Phase Analysis by using X-Ray Diffraction**

Surface analysis for Phase’s distribution was performed for non-coated CpTi, and CpTi coated with TaN. It done by using X-ray Diffraction Facilities (SHIMADzu 6000, Japan) using Cu Kα radiation. XRD analysis were performed at room temperature in the 2θ range from 30˚- 80˚ with a 0.05˚ step and counting time of 5 secs per step. The indexing of the data and the diffraction peaks were identified according to the powder diffraction files. (PDF), received from ICDD (Intimations’ Center for Diffraction Data).
Wettability test

In this test, non-coated and coated disk (10×5) mm diameter and thickness respectively were used. An equal amounts of normal saline (0.25ml) from graduated container dropped on each disk. Then after 20 second from putting the drop on disk, surface measurement for the angle formed between titanium disk surface and drop of normal saline done by taking a picture obtained from a digital camera.

Scanning electron microscope examination

All tested group were examined by using SEM (JEOL-JSM-5600). Samples were prepared as cross section and then mounted in double face metal tape (electrically conductive) to make the sample holder electrically conductive before entering the samples into the SEM Chamber. VEGA3 TESCAN, SEM HV: 20 KV, SEM MAG:7.50kx, VIEW FIELD:27.7

Energy dispersive spectroscopy analysis

Chemical structures and relative concentrations for non-coated CpTi and coated CpTi with TAN discs were assessed via energy dispersive spectroscopy (EDS). EDS use of the X-ray spectrum radiate a solid sample with a focused beam of electrons to obtain a localized chemical analysis. All elements from atomic number 4 (Be) to 92 (U) can be detected in principle. Qualitative analysis involves the identification of the elements in the spectrum and is fairly straightforward owing to the simplicity of X-ray spectra. Quantitative analysis determination of the concentrations of the elements.

Atomic force microscopy examination

Atomic force microscope able to detect both conductive and nonconductive surfaces on the atomic scale. The AFM relied on the scanning technique and provided a high-resolution 3D image from the surface of the sample. A sharp tip at the end of the cantilever is in contact with the surface of the development and the sample displaced with piezoelectric scanners. The force on the tip causes deflection to measure with tunneling capacitive or optical detectors such as interferometer laser in this technique, the standard pressure applied to the joint is zero (to prevent any surface deformation).

Result

Surface characterization by using X-Ray Diffraction.

A: Before Heat treatment:

XRD patterns of the non-coated Cp Ti specimen and TaN coated by modified reactive plasma sputtering after different sputtering time (namely 4, 6 and 8 hours) are demonstrated in Figure (1). And these data were indexed according to the Powder Diffraction Files (PDF) for the hexagonal αTi (JCPDS-ICDD file # 44-1294), TaN (JCPDS-ICDD file # 25-0922, 33-1391and 33-1390), and TaN (JCPDS-ICDD file # 34-0977). The diffraction peaks of the uncoated CpTi were found to be corresponding to (100), (002), (101), (102), (110), (200), (112) and (201) α-Ti at 2θ values 35.00°, 38.30°, 40.05°, 52.9°, 62.8°,70.6°, 76.25°and 77.35° respectively. The patterns of the plasma sputtered specimen for 4 and 6 hours show wide peak in the range of 2θ 20-30° which seems to be due to the formation of not fully crystalline TaN, whereas the pattern of the specimen sputtered for 8 hours show clear and prominent TaN peaks corresponding to the reflections (111) at 2θ 35.14 and (200) at 2θ 41.24°. Also its very clear there are a shift in the 2θ position of the CpTi reflections towards the higher 2θ indicting the change in titanium crystal cell volume.

B: After Heat treatment:

The CpTi specimen’s coated with TaN for sputtering time 8 hours before and after heat treatment are shown in Figures (2). The pattern of the heat treated specimen show prominent new peaks of 111 TaN at 2θ 36.00 and
developed one assigned as 200 TaN at 2θ \( \text{o} \) 41.24. also The XRD pattern of the heat treated specimen shows the formation of 110 of tantalum peak TaN at 2θ \( \text{o} \) 27.23.

The XRD pattern of the heat treated specimen shows the formation of 110 of tantalum peak TaN at 2θ \( \text{o} \) 27.23.

Figure (2): XRD patterns of uncoated Cp Ti and coated with TaN for 8 hours before and after heat treatment.

Surface characterization using Wettability test

From the result of wettability test, 8 hr. coated disk with TaN give more hydrophilic surface feature with contact angle formed less than non-coated disk as shown in Figure (3).

Fig (3) Wettability test for CpTi and experimental groups at 4.6 and 8hr

Material/Time

- A: Non coated
- B: 4h coating
- C: 6h coating
- D: 8h coating

Surface characterization using SEM 3.3

A: Topographic

The scanning electron microscopy images of CpTi disk before coating in (figure 4a) revealed a relatively flat and smooth surface. While the surface morphology of CpTi plasma sputtering samples with TaN for 8 h showed a fully arranged nanochips and uniformly distributed in (figure 4b).

B: Chemical composition by EDS

Regarding the analysis of the chemical structure of CpTi figure (5, A) show two titanium peaks with these values (\( \kappa \alpha 4.512 \) and \( \lambda \alpha 0.452 \)), these values represent alpha phase of titanium. For coated disk with TaN, there were five peaks, two peaks for titanium which represent alpha phase, two tantalum peaks and one peak of nitrogen with following values percentage (\( \kappa \alpha 4.512 \) and \( \lambda \alpha 0.452 \) (\( \lambda \alpha 8.146 \) and \( \mu \alpha 1.712 \) (\( \kappa \alpha 0.392 \)) respectively as shown in figure (5, b). Elemental composition of tested group as follow in (fig a) titanium was 100%, and in (fig b) percentage of titanium was 3%, tantalum was 22% and nitrogen was 75%.

A: CpTi disk B: CpTi disk coated with TaN

Fig (5): EDS.A/ CpTi disk without coating B/CpTi disk coated with TaN for 8 hr.

Discussion

The new trend in implant research is to increase and accelerate the osseointegration of Cp Ti\(^{11}\). One of the methods used in accelerating the osseointegration process is to modify the surface properties of the implant\(^{12}\). Chemically and physically reactive plasma is widely
used to modify the surface properties of materials. In this research, tantalum is a material with specific properties which is used as a coat material with nitrogen gas to develop TaN surface on CpTi disk by using modified plasma sputtering technique which has several advantages such as changing surface topography, increasing surface roughness, wettability of the surface. Reactive plasma coating constitutes a simple, dry technique, which does not harm the environment, does not comprise the intrinsic properties of the biomaterial.

The results of X-ray diffraction analysis revealed a new peaks formation towards the 20 direction in coated disk as a result of deposition of TaN material on the surface of CpTi, these new peaks were more prominent after heat treatment in coated disk as evidence to the more crystallinity of TaN. Surface properties and roughness of uncoated CpTi and TaN coated disk for 8 h were examined by Scanning electron microscope, showed fully arranged nanochips with uniform shape in coated layers, this might be due to difference of chemical composition of coated layer of non-coated and TaN disk, this shape of nanochips due to the deposition of TaN on the surface of CpTi. Contact angle of fluid drop in 8 hr. CpTi coated disk with TaN less than non-coated CpTi disk, which mean the coated disk more hydrophilic than non-coated disk. This may be due to more affinity of tantalum and nitrogen to fluid.

Abstract

This study designed to investigate the effects of 7,12 dimethyl benz[a] anthracene (DMBA) on some blood parameters and hepatic histopathology in rats and antioxidant enzyme. twenty female Wistar albino rats, weighing 180–200 g, were randomly divided into two group 1- DMBA group (positive group) who received 20 mg DMBA/kg body weight/ (single Douse) 2-Control group (negative group) doesn’t receive any item. The animals in these groups were sacrificed at the end of the 90 days: The histological structure of the liver tissues in the control group was normal. the liver exhibited hydropic degeneration and coagulation necrosis in hepatocytes, severe dilation in the sinusoids, congestion in the central and portal regions, DMBA groups, was degenerative and necrotic changes were detected. MDA levels increased in the DMBA group, compared to the control group, Antioxidant activity CAT, SOD and GPX, the results showed increased enzyme activity in positive control compared with negative groups, the hematological parameter was increase in WBC, PLT, GRA, and LYM and decrease in RBC value.

Keywords: 7,12-dimethylbenz[a]anthracene (DMBA); Blood parameters; Antioxidant enzyme ; MDA ; Rat.

Introduction

Malignant neoplasm, is that diseases in which a crowd of cells illustrate abnormal growth, invasion and sometimes called metastasis 1. This disease begins in the moment that cells in body start to grow without control 2. More than 100 kinds of neoplasm are identified 3. The stimulation of tumors is named carcinogen, that have the capacity to change DNA in behavior that are inherited by daughter cells which called mutagens. Most of these tumors are associated to ecological, life, or expected behaviors 4. The statement “ecological”, as used by cancer investigators, means everything outside the body that reacts with humans 5. On the other hand some chemicals, like benzene, ketones, vinyl chloride, ethylene bromide, and dichlorodiphenyl-trichloroethane (DDT), known as carcinogens 6. When multiple factors are accumulated, altered genes and carcinogens change a normal cell into a cancerous one. Carcinogens which promote cancer have various precursors 7. exogenous and endogenous factor lead to cause Cancer development 8 such as nutritional habits (food preservation and preparation), socio-economic status, way of life, physical agents (ionising and non-ionising radiation), chemical compounds (natural and synthetic) and biological agents (Helicobacter pylori, Epstein Barr virus, human T lymphotropic viruses I and II, human papilloma virus and the hepatitis B virus 9.

Material and Method

Experimental animals and Tumor induction in rats:

Twenty female of Wistar albino rats and aged between (7-8) week were weighing between 150 – 250 g used in this study. All they were kept in ventilated cages, with temperature of 25±2°C. A 12:12 h light:dark cycle is regulated for the animals. Balanced rodent food and water is provided. The rats were randomly assigned to 2 groups, every group of 10 rats.
The following groups:

Group 1: Taking one dose of DMBA (positive control) 20 mg DMBA/kg body weight/ (single dose)

Group 2: Did not received any treatment (negative control).

DMBA administration: breast cancer that induced by 7, 12-

Dimethylbenz (a) anthracene (DMBA) \(^\text{10}\). One dose of DMBA dissolved within corn oil and given orally to each groups with the syringe and needles. DMBA was taken from Sigma Aldrich and melted in corn oil. The concentration of the mixture was 20 mg DMBA per 1 ml corn oil for each rat \(^\text{10}\).

**Preparation of tissue sample**

The liver was exteriorized and excised. All samples in the same time fixed in 10% formaldehyde. And then they processed in known method, and placed in paraffin for histopathological testing for liver. A scoring system (of no abnormalities, mild, moderate, severe) was used to classify the liver changes according to the severity of the damage and extent of histological changes. The histological sections were evaluated by a pathologist without prior knowledge of the treatment given to the animals \(^\text{11}\).

Blood parameters were determined in whole blood by the applying rat method of veterinary practice with a blood cell counter (Abocus Junior Vet-5, Austria). Measurements of biochemical parameters were made with a Modular PP autoanalyzer (Mindray BS800, China).

**Result**

Histopathological findings: In the DMBA group, the livers exhibited dilatation of the sinusoids, cholangiohepatitis in the portal region, and congestion in the sinusoidal and portal regions (Figure 1A). The control group showed normal histological structure in the liver tissue (Figure 1B).

Hematological parameters also change in negative group compared of positive group Table 1, in positive group: white blood cell (WBC), LYM, MON, GRA and PLT while other parameter such as RBC was decrease. The state of free radicals and antioxidants is given in Table 2. As seen in Table 2, the levels of MDA increased in liver groups in compare with control group, also SOD, GSH-Px, CAT, and GSH values decreased.

**Figure 1:** A: DMBA group showing cholangiohepatitis in portal region, mild dilation in sinusoids, hyperemia, and hydropic degeneration in hepatocytes;

Discussion

7, 12-dimethylbenz (α) anthracene (DMBA) is a famous carcinogen and immunosuppressor used in rodent model to learn tumor. DMBA is report to make mutations by creation DNA adducts, while, it is a well known skin carcinogen, however lots of researchers have reported the harmful result of DMBA in liver. Liver is the main site of metabolism and is frequently prone to injury by xenobiotics. obviously, liver cancer is the second most general source of cancer deaths universal.

a number of haematological and haematochemical parameters were altered when treated with DMBA and establish that DMBA caused hepatocellular carcinoma. new studies showed that DMBA-induced skin, oral, mammary and ovarian tumors.

The carcinogenic and mutagenic effect of DMBA needs to its metabolic activation by mixed gathering oxidases. The hydroxylation of DMBA at 7-methyl collection is a critical step towards its carcinogenesis. additional metabolism of DMBA leads to development of a large range of metabolites with changeable toxicity. along with these, trans-3,4-dihydrodiol-1,2-epoxide is the carcinogenic result of DMBA. The metabolic products of DMBA, when present within body, hampers ROS-antioxidant balance by overproduction of free radicals and the body go round reacts by modulating activities of antioxidant enzymes to control the destructive effects of an enlarged ROS.

Hematological and biochemical parameters may be affected by a variety of factors such as race, age, gender, pregnancy, lactation, muscular activity, area, season, environmental heat, maintenance, and nutrition. a significant increase in the GPX, CAT, SOD level in rat treated with DMBA only was reported by. On other hand find MDA substance increase significantly with rat treated with DMBA only.

Immunohistochemical Expression of CD68, P53 and Bcl2 in Thyroid Tumors

Samar Abdul Raheem AL-Gharrawi 1, Ali Hussein Mohammed Ali Alkhafaji 2, Rana Zuhair Naji 3

1Department of Basic Science, College of Dentistry, Mustansiriyah University, Iraq, Baghdad, 2College of Dentistry, Privet Uruk University, Iraq, Baghdad, 3Department of Histopathology, Oncology Teaching Hospital, Iraq, Baghdad

Abstract

Background/aim: The aim of this study was to determine the expression of CD68, P53 and Bcl2 in thyroid tumors and correlation between them.

Materials and Method: The expression of CD68, P53 and Bcl2 was examined by immunohistochemistry on paraffin-embedded tissues obtained from patients with benign and malignant tumors between 2010 and 2015. Thirty three malignant thyroid tumors of variable subtypes and 10 benign tumors. The extents of staining and intensity were scored semi quantitatively.

Results: CD68 have shown strong positive score expression in (28.9%) in PTC while score was found in (18.5%). The higher percentage of strong weak positive score expression of P53 was in PTC (6.1%) Followed by (3.03%) strong score in FTC, (3.03%) moderate score in benign and (3.03%) in MTC. The expression of Bcl2 was higher in benign tumors (20%) than in malignant tumors were PTC (9.1%) followed by FTC (3.03%), the strong positive expression seen in MTC (9.1).

Keywords: Thyroid tumors, Immunohistochemistry, CD68, P53, Bcl2.

Introduction

The commonest type of endocrine malignancy is thyroid cancer, although it’s rare. Thyroid cancer accounting for about 1.5 of all newly diagnosed cancer in the United States, its occurrence being steadily increasing worldwide in the last three decades 1. It is categorized into three main histological types: differentiated including “papillary, follicular and hurthle» «medullary» and «anaplastic» (aggressive undifferentiated tumor) 12. Papillary thyroid carcinoma (PTC) represents 80.3% of malignant endocrine tumors and 65% of malignant thyroid tumors (12, 14) According to Iraqi cancer registry, it ranks the eight cancers from commonest ten cancers in general and the second cancer in female (Iraqi cancer registry, 2019). Combined with there are different cellular and molecular factors that plays a role in development and progression of thyroid cancer. One of the main cellular constituents in the stromal of many cancers is “tumor-associated macrophages” (TAM) 20. Advanced staging and poor prognosis in many human cancers including thyroid cancers related to tumorigenic role of “TAM” 17. TAMs have an essential role in tumor advancement at different levels, including stimulating genetic instability, nurturing cancer stem cells pavement the way to metastasis , taming defensive adaptive immunity 1. Transformations in the p53 gene are the most widely recognized in human cancer 11 and they express to the most frequent genetic changes in malignant transformation. P53 protein assumes an essential role in the regulation of the cell cycle. Wild sort p53 protein is capable of inhibiting cell proliferation and transformation and it has been observed to be latent in tumor cells 13. This gene mutation is the most prevalent genetic alterations in human tumors and has been found in over 15% of thyroid neoplasm. The p53 gene mutations are promoting more aggressive cancers. Bcl2 protein is a modular of programmed cell death and is involved in both lymphoid and epithelial malignancies. The reporting of bcl2 protein expression in thyroid cancer has been sporadic and some have shown a down regulation of bcl2 in papillary carcinomas 5. The present study aimed to evaluate level of CD68, P53 and Bcl2 expression in both malignant and benign thyroid
tumors, and to correlate the results with the variable clinicopathological parameters (taking in respect the age and sex of the patients combined with tumor types histopathological).

**Materials and Method**

Our study involved paraffin-embedded tissue blocks samples of 43 thyroid tumors patients, of which 33 thyroid carcinomas and 10 benign as control group. All these samples were collected from the Pathology Department of Teaching Laboratories /Medical city and Central Public Health Lab between the years 2010-2015. All Hematoxylin and Eosin stained tissue sections were reviewed by pathologist. Immunohistochemistry study was prepared on serial sections and the antibodies panel that has been used is shown in the table below (table 1).

CD68, P53 and Bcl2 immunohistochemical staining.

Immunohistochemistry: Four µm sections were cut from formalin-fixed, paraffin-embedded tissue blocks and placed on polylsine-coated glass slides. After overnight packing at 65°C, tissue sections were deparaffinized in xylene and rehydrated in descending grades of alcohol. Antigen retrieval was performed in a water bath for 15 min in 95 °C citrate buffer pH 9.0 for CD68, P53 and Bcl2. Endogenous peroxidase action was blocked by 3% hydrogen peroxide. The sections were incubated at room temperature for 1 hour with primary monoclonal antibodies.

Scoring of immunohistochemistry: The stained slides were observed microscopically by histopathologist using the p53, Bcl2 and semiquantitative criteria: 0 = negative; 1+ = <33% area of positive staining; 2+ =34-66% area of positive staining; 3+ = >67% area of positive staining. Positive staining was also graded on intensity, 0 to 2+. A combined score of 0 to 6 was allocated. Tumors assumed a score 0 to 1 were classified as negative; those given a score of 2 were ordered as weakly positive; a score of 3-4 was regarded as moderately positive; and a score of 5-6 was considered strongly positive.

Statistical Analysis

Data were analyzed by one -way analysis variance (ANOVA) followed by Fisher’s test for multiple comparison, using Statview version 5.0. Differences were considered “significant when p<0.05”. Reversion analysis was done by analysis of covariance (ANCOVA) likewise by Statview version 5.0.

Results and Discussion

**CD68**

In this study, the results of immunohistochemical analysis for CD68 have shown in table 2, 3 and 4. As shown in table 2 there significant correlation between CD68 with thyroid patients age less than (45 years) (P=0.01) and (P=0.0001) with thyroid patients age more than 45 years.

In table 3 and 4 the results recorded depended on scores weak positive and strong positive. There is significant difference between score of CD68 and gender (P. value: 0.058). (Table 3)

Score of CD68 showed associated with gender in table 2, from total 29 female were (20 cases, 98.9%) weak positive and (9 cases, 31%) strong positive while
from 9 male were (5 cases, 55.6%) weak and (4 cases, 44.4%) strong positive.

Table 4 showed CD68 score related with tumor type, PTC was appeared high associated with strong positive (11 cases, 28.9%) followed by MTC and Hurthle cell carcinoma (1 case, 2.6) in same score. While the weak score was found in (7 cases, 18.5%) in benign tumors, (10 cases, 26.4%) in PTC, (3 cases, 7.9%) in FTC and MTC and finally (1 case, 4.5) in ATC.

P53

Expression of P53 was related with age group, gender and tumor type summarized in table 5 Of 26 patients were less than 45 year, only (5 cases, 11.6%) were positive. These 5 cases were 4 female and 1 male which of them 1 benign tumor case, (2, 6.1%) PTC, (1, 3.03%) FTC and (1, 3.03%) MTC.

Table 6 showed significant difference between score of P53 and gender (p.value:0.001).

The results in table 7 show that high percentage of strong score was in PTC (2 cases, 6.1%), followed by 1 case 3.03% strong score in FTC, 1 case 3.03% moderate score in benign and 1 case 3.03% in MTC.

### Discussion

The host’s immune response to the tumor is represented by macrophage infiltrates in the context of or surrounding a variety of malignancies (4,7). The “tumor-associated macrophages” (TAMs) had fundamental jobs in tumor development and metastasis of various cancers, including advanced thyroid malignant growth (17). This study demonstrated the presence of CD68+ in benign and malignant thyroid tumors. But all (7 cases, 18.5%) of CD68+ in benign were in weak score. While (11 out of 21) 28.9% from PTC were strong positive score which came in similar with Qing et al.,(2012) who investigated TAM density in both benign thyroid tumors and PTC by CD68 immunostaining. They establish that overall density of TAM was higher compared with “thyroid goiter” and “follicular adenoma”. On the contrary to previous studies, (17) pointed to the expression of TAM in 36 PTC Patient with L.N metastasis using immunohistochemical staining with anti-CD68 antibody. And Ryder et al.,(2008) who recorded a higher TAM thickness in ineffectively separated PTC and ATC This different was explained by the mixed cell populates of macrophage with CD136 ,CD68 and undifferentiated monocyte/macrophage which are for all positive for CD68 ,these kinds of macrophages play special roles in the advancement and progression HNSC (18). Other study by (10) using CD68 immunohistochemistry, observed that TAM anticipated metastasis in a number of patients. Of 121 patients with PTC, 15% had TAMs (CD68) that seemed to have a phagocytic capacity on cancerous cells. These patients had fundamentally less blood vessel attack and remote metastasis and largely supplementary invasion lymphocyte and dendritic cells, than patients without a CD68 cells. Further, the findings of the current study are in similar with other study by (21) who observed expression of p53 was more frequently in malignant than in benign lesions. Since p53 has been known to be rarely mutated in well differentiated tumors of the thyroid where an frequently expressed in poorly differentiated or undifferentiated tumors which are of different number, in our study, however there is a concern of tumor suppressor gene where it plays an important role in cancer progression,yet a serious studies should that it plays a role in early stages different types of cancers including thyroid cancers. We found a moderate immunoreactivity of Bcl2 in cytoplasm of epithelium of the benign and well-differentiated PTC and these findings are accordance with other studies by (26 , 22, 2 , 24).

### Conclusion

CD68 + macrophages are key players in thyroid tumors microenviroment leading to thyroid tumor development where its indirectly correlated with BCL2 family oncoproteins where antiapoptotic pathway is down regulated leading to increased aggregates of CD68+macrophages and that CD68+macrophages are positively correlated with p53 gene mutation expression where both markers can explain the biological behavior of tumor. BCL2&P53 have an inversed correlation since both have an opposite functions (p53 represent cell death gene while bcl2 is an antidote to a programmed cell death ,bcl2 was more expressed in benign tumor in our study than in malignant tumors unlike to p53 where its more expressed in WDT (PTC 6%followed by FTC3.03%) indicating that expression of p53 may be a late event in thyroid tumor genesis and that there’s a mutual expression between both bcl2 & p53 in thyroid tumors.

Abstract

Background: Smoking is a well known risk factor that is implicated in a number of human malignant disorders.

Aim of the Study: To study the prevalence of lung cancer in a sample of Iraqi non smoker patients and the main risk factor implicated in such malignant tumor.

Patients and Method: In this hospital based study, in order to explore the prevalence rate of bronchogenic carcinoma in non smoker patients, it retrospectively collected data about those patients for the last four years, starting from January 2016 through June 2019. These information were retrieved from patients records that are already present in oncology and respiratory units in Al-Diwaniyah teaching hospital, Al-Diwaniyah province, Mid-Euphrates region of Iraq. The following variables were included in the questionnaire form: Age, gender, occupation, education level, residency, socioeconomic status, marital status, history of smoking, history of second hand smoking, number of household smokers, type of smoking, history of alcoholism, history of chronic illness, the main presenting clinical features and clinical features of carcinoma and finding in examination as well as those obtained from investigations.

Results: In the current study, the prevalence rate of all cases of lung cancer during the period of study was 61 out of 403 (15.1 %). the rate of lung cancer in none smokers, in the current study, was 39.3 %. Old age individuals were the main age group affected and there was female predilection. there was also no significant difference in the distribution of patients and control subjects according to residency, occupation, level of education marital status and socioeconomic status (P > 0.05). In the current study, the prevalence rate of passive smoking in patients was significantly higher than that in control subjects, 70.8 % versus 40 %. Moreover, the number of household smokers was significantly higher in patients group than in control group.

Conclusion: Lung cancer in non smokers appears to be significantly correlated with passive smoking in addition to increase incidence in old age and women.

Key words: Prevalence; Lung Cancer, Non Smoker, Iraq.

Introduction

The term, never smokers, refers to persons who have smoked fewer than 100 cigarettes in their lifetime, including lifetime nonsmokers. Most studies that track the trend of lung cancer rates often include both smokers and never smokers, and few studies independently study the trends over time for never smokers because of the limited longitudinal collection and the limited reliability of smoking information in population-based registries. From what is available, however, the overall global statistics estimate that 15% of lung cancers in men and up to 53% in women are not attributable to smoking, with never smokers accounting for 25% of all lung cancer cases worldwide ¹. If lung cancer in never smokers were considered separately, it would rank as the seventh most common cause of cancer death worldwide before cervical, pancreatic, and prostate cancer ². In countries in South Asia, up to 80% of women with lung cancer are never smokers ³. In the United States, one study estimated that 19% of lung cancer in women and 9% of
lung cancer in men occurs in never smokers\(^4\). The age-
adjusted rate for lung cancer in never smokers (ages 40–
79 years) ranged from 11.2 to 13.7 per 100,000 person-
years for men and from 15.2 to 20.8 per 100,000 person-
years for women. The rates are 12 to 30 times higher
in current smokers of the same age group. Lung cancer
included heterogeneous group of malignant epithelial
disorders that comprises squamous cell carcinoma,
adeno-carcinoma, small cell carcinoma and large cell
carcinoma as well as a number of rare histopathological
subtypes such as bronchoalveolar carcinoma. The most
common subtype by far is squamous carcinoma and is
mainly attributed to smoking but a number of cases have
been reported in life time non smokers. Because of the
shortage of Iraqi literatures dealing with lung cancer in
non smokers since most published Iraqi articles deal
with smoking related lung cancer, and because we are
interested in making an idea about the prevalence rate
of lung cancer in non smokers and to outline its possible
risk factors in our community we planned and conducted
the current study to one of leading articles in the Mid-
Euphrates region dealing with this important human
cancer.

Patients and Method

In this hospital based study, in order to explore
the prevalence rate of bronchogenic carcinoma in non
smoker patients we prospectively interviewed 5 cases
during 2019 and retrospectively collected data about
those patients for the last 3years, starting from January
2016 through June 2018. These information were
retrieved from patients records that are already present in
oncology and respiratory units in Al-Diwaniyah teaching
hospital, Al-Diwaniyah province, Mid-Euphrates region
of Iraq. However for purpose of comparison in order
to evaluate possible risk factors in association with
non smoker bronchogenic carcinoma we included in
the study 25 apparently healthy individuals serving as
control group. Records of all patients with established
diagnosis of bronchogenic carcinoma were included in
the present study. Variables were registered concerning
those patients who are never smokers. Although records
of smoker patients with bronchogenic carcinoma
were retrieved, information about them were used for
calculation of prevalence rate of lung cancer in non
smoker only, and the rest of information were excluded.
The total number of patients with all kinds of malignant
tumor was also obtained to calculate the prevalence
rate of broncogenic carcinoma out of all malignant
tumors. The following variables were included in the
questionnaire form: Age, gender, occupation, education
level, residency, socioeconomic status, marital status
history of smoking, history of second hand smoking,
number of household smokers, type of smoking, history
of alcoholism, history of chronic illness, the main
presenting clinical features and clinical features of
carcinoma and finding in examination as well as those
obtained from investigations. The study was approved by
the institutional ethical approval committee and formal
agreement was obtained from the directorate of Health
in Al-Diwaniyah province, the formal representative
of Iraqi Ministry of health. Data were collected and
transformed into a spread sheet of Microsoft Office
Excel 2010 and then into an SPSS (statistical package for
social sciences) version 23. Numeric quantitative data
were expressed as mean, range and standard deviation
(SD), whereas, qualitative data were expressed as
number and percentage. Comparison of mean between
any two groups was done according to independent
sample t-test, while chi-square test was used to evaluate
association between any two categorical variables. The
level of significance was considered at P ≤ 0.05.

Results

During that period the number of cases with
malignant tumors, including lung cancer, accounted
for 403. In addition, the total number of cases with
lung carcinoma during the period of study, irrespective
of smoking, was 61. Therefore, the prevalence rate of
all cases of lung cancer during the period of study was
61 out of 403 (15.1 %), out of which 24 cases were
associated with evidence of passive smoking (39.3 %).
Table .1 outlines the comparison of age between control
and patients group. There was no significant difference
in mean age between patient and control group, 61.63
±15.31 years versus 68.28 ±8.50 years, respectively (P
= 0.065). The age range of patients with bronchogenic
carcinoma was form 30 – 85 years. In addition the
frequency distribution of patients according to 10
years intervals was as following: 8.3 %, 16.7 %, 4.2
%, 41.7 %, 12.5 % and 16.7 % as 30-39 years, 40-49
years, 50-59 years, 60-69 years, 70-79 years and ≥ 80
years, respectively. Thus, the highest incidence rate was
observed at age interval of 60-69 years, table 1.

With respect to gender, women accounted to 15 out 24 patients with bronchogenic carcinoma thereby accounting for 62.5 %, making the male to female ratio 1:1.7. Control group included 12 men and 13 women; therefore there was no significant difference in the distribution of patients and control subjects according to gender, as shown in table 2. There was also no significant difference in the distribution of patients and control subjects according to residency, occupation, level of education marital status and socioeconomic status (P > 0.05), as shown in table 3. Regarding bad habits, none of patients or control subjects admit to be alcoholic of experience cigarette smoking.

Discussion

In the current study, the prevalence rate of all cases of lung cancer during the period of study was 61 out of 403 (15.1 %). It has been estimated that lung cancer accounts for about 16 % of all cancers, a proportion that is nearly similar and in total agreement with our finding. On the other hand, the rate of lung cancer in none smokers, in the current study, was 39.3 %. Most published articles indicated that the proportion of non-smokers with lung cancer ranges between 10 to 25 % (6,7, 8,9). This indicates that a significant proportion of patients with bronchogenic carcinoma, in our study, have acquired the disease irrespective with cigarette smoking. Therefore, identifying other possible risk factors in association with lung cancer in those patients was the main aim of the current study. Indeed, we supposed that passive smoking may play a principal role in the development of lung cancer in patients who are not habitual smokers. Unfortunately lung cancer in never-smokers has been studied far less extensively than tobacco-related lung cancer. This indicates that age by itself may be a risk factor. Indeed, most published articles dealing with lung cancer in non smokers has linked age as a potential risk factor for such malignant disorder (10, 11,12,13). Older age is associated with cancer development due to biologic factors that include DNA damage over time and shortening telomeres. Accordingly, the median age of lung cancer diagnosis is 70 years for both men and women 14. On the other hand and with respect to gender, in the current study, women accounted to 15 out 24 patients with bronchogenic carcinoma thereby accounting for 62.5 %, making the male to female ratio 1:1.7. There are conflicting data regarding the possibility that women may be more susceptible to developing lung cancer 15. There is a higher rate of lung cancer in non-smoking women compared with non-smoking men, a higher proportion of epidermal growth factor receptor (EGFR) mutations in female NSCLC, and a higher incidence of adenocarcinoma with lepidic features in women (16, 17). Some genetic mutations found to be more common in females may predispose toward lung cancer development in women, including over-expression of the CYP1A1 gene, mutation of the glutathione S-transferase M1 enzyme, mutations of the p53 tumor suppressor gene, and over-expression of X-linked gastrin-releasing peptide receptor (15, 16,17). Moreover, in the current study, there was also no significant difference in the distribution of patients and control subjects according to residency, occupation, level of education marital status and socioeconomic status (P > 0.05). In agreement with our results, a number of authors have denied any association between residency, rural versus urban and lung cancer (18,19). Exposure to pollutant in association with occupation is the main hazard precipitating to lung cancer. The occupational
and environmental exposure to carcinogenic agents is an everyday phenomenon.

Effects Hydrocortisone on the Body Weight of the Pregnant Rabbits and their Embryo with Histological Effects Skin, Stomach and Small Intestine of Embryos

Abid AL-Shammary¹, Rasha Noori Abid AL-Shammary¹
¹Dept. Anatomy and biology, College of Medicine. Univ. of Wasit – Iraq

Abstract

The aim of the study was to investigate the effects hydrocortisone of on the body weight of the pregnant rabbits and their embryo with histological effects pregnant skin, stomach and intestine of embryos for 45 days. The rabbit were randomly divided into two equal groups (control and one treated groups), and the animals were treated as follow: 1- Control group C. (n = 12) received Distilled water 1ml /kg b.w five times a week intramuscular for 26 days. 2- Treatment group. (n=12) treated daily with hydrocortisone 100mg/kg b.w/day/ intramuscular for 26 days. The body weight of the animals detected at the 1st, 7th, 14th, 21st and 26th days of the experimental period. At 26 days animals sacrificed and embryos weighted and skin, stomach, intestine were removed and taken for histopathological study. The present study showed that treatment with hydrocortisone causes a significant decrease in body weight of embryos and pregnant rabbits. As a conclusion: hydrocortisone cues decrease body weight of embryos and pregnant rabbits.

Keywords: Rabbits, hydrocortisone, skin, stomach, intestine

Introduction

Hydrocortisone belongs to a group of medicines called steroids. Their full name is Corticosteroids. These corticosteroids occur naturally in the body, and help to maintain health [1,2]. Hydrocortisone is an effective way to treat various illnesses involving inflammation in the body [3,4]. Indication and clinical use: Primary or secondary adrenocortical insufficiency [5]. Rheumatic disorders: As adjunctive therapy for short-term administration in: psoriatic arthritis, rheumatoid arthritis, including juvenile rheumatoid arthritis, ankylosing spondylitis, acute and subacute bursitis, acute non specific tenosynovitis, acute gouty arthritis, post traumatic osteoarthritis, synovitis of osteoarthritis and epicondylitis [6,7].

Collagen Diseases: During an exacerbation or as maintenance therapy in selected cases of systemic lupus erythematosus and acute rheumatic carditis [8].

Dermatologic Diseases: pemphigus, bullous dermatitis, herpetiformis, severe erythema multiforme, exfoliative dermatitis, mycosis fungoides and severe seborrheic dermatitis [9].

Allergic States: Control of severe or incapacitating allergic conditions intractable to adequate trials of conventional treatment: seasonal or perennial allergic rhinitis, bronchial asthma, contact dermatitis, atopic dermatitis, serum sickness and drug hypersensitivity reactions [10].

Ophthalmic Diseases: Severe acute and chronic allergic and inflammatory processes involving the eye and its adnexa such as: allergic conjunctivitis, keratitis, allergic corneal marginal ulcers, herpes zoster ophthalmicus, iritis and iridocyclitis, chorioretinitis, anterior segment inflammation, diffuse posterior uveitis and choroiditis, optic neuritis, sympathetic ophthalmia [11].

Respiratory Diseases: Symptomatic sarcoidosis, Löfgren’s syndrome not manageable by other means, berylliosis, fulminating or disseminated pulmonary tuberculosis when used concurrently with appropriate antituberculous chemotherapy, aspiration pneumonitis [12].

Hematologic Disorders: Idiopathic thrombocytopenic purpura in adults, secondary
thrombocytopenia in adults, acquired (autoimmune) hemolytic anemia, erythroblastopenia (RBC anemia), congenital (erythroid) hypoplastic anemia [13].

Neoplastic Diseases: For palliative management of: leukemias and lymphomas in adults, acute leukemia of childhood [14].

Edematous States: To induce a diuresis or remission of proteinuria in the nephrotic syndrome, without uremia, of the idiopathic type or that due to lupus erythematosus [15].

Gastrointestinal Diseases: To tide the patient over a critical period of the disease in: ulcerative colitis, regional enteritis [16].

CNS: Acute exacerbations of multiple sclerosis. Miscellaneous: Tuberculous meningitis with subarachnoid block or impending block when used concurrently with appropriate anti tuberculous chemotherapy, trichinosis with neurologic or myocardial involvement [17,18]. Hydrocortisone Injection can cause side effects although not everybody gets them. Steroids including hydrocortisone can cause severe mental health problems. These are common in both adults and children. They can affect about five in every 100 people taking medicines like hydrocortisone [19,20]. Feeling depressed, including thinking about suicide. Feeling high (mania) or having moods that go up and down. Feeling anxious, having problems sleeping, having difficulty in thinking or being confused and losing your memory. Feeling, seeing or hearing things which do not exist. Having strange and frightening thoughts, changing how you act or having feelings of being alone [21,22]. Corticosteroids have been shown to be teratogenic in many species when given in doses equivalent to the human dose. Animal studies in which corticosteroids have been given to pregnant mice, rats, and rabbits have yielded an increased incidence of cleft palate in the offspring [23]. There are no adequate and well-controlled studies in pregnant women. Corticosteroids should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus. Infants born to mothers who have received corticosteroids during pregnancy should be carefully observed for signs of hypoadrenalism [24].

The aim of the present study was to investigate the effects of hydrocortisone on the histological section of skin, stomach and intestine in embryo rabbits.

Materials and Method

Twenty for adult rabbit were obtained from market of Kut. Animals were placed at the animal house, College of science, Wasit University and fed with pellet during experimental periods, temperature was 25°C. Female was left in a separate cage with one male for the each cage ratio 2:1. Male and female couple were kept together in mating cage for six weeks.

The rabbit were randomly divided into two equal groups (control and one treated groups), and the animals were treated as follow:

1- Control group C. (n = 12) received Distilled water 1 ml/kg b.w five times week intramuscular for 26 days

2- Treatment group. (n=12) treated daily with hydrocortisone 100mg/kg b.w/day/ intramuscular for 26 days [25]. The body weight of the pregnant animals detected at the 1th, 7th, 14th, 21th and 26th days of the experimental period by electrical balance. At end of experiment period pregnant rabbit and embryo weighted and sampling skin, stomach, intestine of embryos preserved in 10% formalin buffer solution until preparation of histopathological section. Tissue was cut at 7-8µm and embedded in paraffin and takes sections of skin, stomach, intestine were stained with hematoxylin-Eiosin stain (H&E) for histopathological study [26].

Statistical Analysis:

Data were expressed as mean ± standard error of mean and were compared by one way ANOVA followed by LSD. P value more than 0.05 was considered as statistically significant [27].
Result and Discussion

The value represent Mean(gram) + Standard Error-The different small letters show significant effect while the same small letters show insignificant effect between different groups.

Table (1) showed a significant decrease of body weight in hydrocortisone compared with the control along time of the experimental periods. Except one day non significant between hydrocortisone compared with the control. The decrease body weight because hydrocortisone therapy have included gastrointestinal upset, nausea, vomiting, and peptic ulcer disease, pancreatitis, ulcerative esophagitis [28,29]. Or may be due to hydrocortisone that impair carbohydrate, protein and lipid metabolism [30].

When taken hydrocortisone in high doses and for long period of time can cross the placental parrier causing premature and low birth weight due to inhibition of metabolism and fetal glands [31,32].
Figure 1: histopathological examination of skin embryos (under fox 10x 0.25)

Histopathological examination of skin embryos in (fig. 1-A) control group no change in skin thickness (fig. 1-B) control group show normal dermal cell number and normal dermal collagenous fibres. (fig. 1-C) treatment group thinning of the skin. Hydrocortisone inhibition epidermis thickening and keratinization and remove a small amount of the outer layer of the skin which affect by passive diffusion. (fig. 1-D) decrease in dermal cell number and increase of dermal collagenous fibres [33, 34]. Hydrocortisone may cause primary irritant reactions which directly damage or kill epidermal cells and dermis [35, 36].

Figure 2: histopathological examination of stomach embryo (under fox 10x 0.25)
Histopathological examination of stomach embryo in (fig. 2-A) control group normal in the rate of epithelial cell formation (fig. 2-B) control group no reduction in stomach glandular epithelium (fig. 2-C) control group show normal size blood vessels (fig.2D) treated group reduction in the rate of epithelial cell formation due to hydrocortisone therapy had effect epithelial cell is rapidly turned over ,replaced with irritants leading to a stomach wall more susceptible to peptic disease(37,38). (fig.2-E)treated group a reduced in stomach glandular epithelium due to a reduced frequency of mitosis in glandular epithelium that incidence of gastric peptic ulcer is actually increased after hydrocortisone therapy [39,40]. (fig. 2-F treated group) hyperplasia blood vessels due to increase in mucosal blood flow secondary effect of hydrocortisone [41].

Histopathological examination of intestine embryo rabbits in (fig. 3-A) control group normal epithelial cell height with crypt height (fig. 3-B) control group increased in the number of goblet cells (fig. 3-C) control group increased in the number of the values with normal elongation of villi (fig. 3-D) treated group increased epithelial cell with crypt height and largamente mucosa. hydrocortisone therapy increases cell migration rate, thymidine kinase levels, and RNA and DNA content. The enhanced cell proliferation leads to mucosal hyperplasia and increases in intestinal weight ,crypt height which develops equally throughout the entire small intestine [42] (fig. 3-E)treated group decrease in the number of goblet cells . hydrocortisone inhibited the premature differentiation of goblet cells induced by thyroxine and lowered mitotic counts, as compared to control [43,44]. (fig. 3-F) treated group decrease in the number of the values with increased elongation of villi. Also higher doses of hydrocortisone had a marked suppressive effect on DNA , the values in the steroid-treated group being about one-half those of the control group . Also hydrocortisone acceleration villus maturation, including the formation of previllous ridges , elongation of villi, vascularization of villi [45].

Comparison of Preoperative Ultrasound Report with Intraoperative Findings of Laparoscopic Cholecystectomy in Gallstone Disease in Al-Diwaniyah Teaching Hospital

Adel Shakir Al-Timimi¹, Anwar Majeed Hussein¹
¹College of Medicine/Al-Qadisiyah University, Iraq

Abstract

Background: Gallstones constitute a significant health problem in developed societies, affecting 10% to 15% of the adult population, meaning 20 to 25 million Americans have (or will have) gallstones. The resultant direct and indirect cost of gallbladder disease represents a consumption of ~$6.2 billion annually in the U.S., constituting a major health burden that has increased more than 20% over the last 3 decades. The best diagnostic tool is ultrasound; however, several authors have raised the issue of inconsistency between preoperative ultrasound evaluation and laparoscopic operative findings.

Aim of the study: To compare preoperative ultrasound findings with operative findings in patients undergoing laparoscopic cholecystectomy in order to evaluate the accuracy of ultrasound in detecting gallbladder pathology.

Patients and Method: In this hospital based study, in order to evaluate the concordance and discrepancy between preoperative ultrasound findings and operative findings in patients subjected to laparoscopic cholecystectomy. At the end of study we were able to include 100 cases. The study started on January the 2nd 2019 and ended at June the 15th 2019. The study was carried out at laparoscopic unit in Al-Diwaniyah teaching hospital. Ultrasound findings were retrieved from available reports that are already kept with the case file sheet of each patient. Operative findings were obtained the surgery team and by the use of a special device which provide information about size of stone and gallbladder wall thickness.

Results: Regarding number of stones and for purpose of unification both ultrasound sound findings and operative findings were contrasted as single stone versus multiple stones, as shown in table 2. Indeed, there was almost complete agreement between ultrasound and operative findings since 22 patients were diagnosed as having single stone by both methods and 76 were diagnosed as having multiple stones by both methods. According to MeNemar test, there was no significant difference in distribution of patients into having single versus multiple stones (P = 1.000), a finding that was further supported by Kappa agreement statistic of 0.944 (P < 0.001), table 4.3.

Key word: Gallbladder Disease, Ultrasound, Gallstone, Laparoscopic Cholecystectomy.

Introduction

Gallstones constitute a significant health problem in developed societies, affecting 10% to 15% of the adult population, meaning 20 to 25 million Americans have (or will have) gallstones. The resultant direct and indirect cost of gallbladder disease represents a consumption of ~$6.2 billion annually in the U.S., constituting a major health burden that has increased more than 20% over the last 3 decades. With an estimated 1.8 million ambulatory care visits each year, gallstone disease is a leading cause for hospital admissions related to gastrointestinal problems. These numbers are likely an underestimate because laparoscopic cholecystectomy is often performed as a day procedure and thus not captured by hospital statistics that require overnight admission. Although the mortality rate for gallstones disease is relatively low at 0.6%, the high burden of disease imposes
troubling mortality figures, such as an estimated 1,092 gallstone-related deaths for 2004 in the U.S. Fortunately, case fatality rates have steadily diminished from over 5,000 deaths in 1950, falling >50% between the years 1979 and 2004. This decline represents the greatest decrease for any digestive disease. Gallstone disease per se also carries inherent risks. Prospective population-based surveys have revealed an increased overall mortality, particularly from cardiovascular disease and cancer, as seen in Americans and Pima Indians with cholelithiasis. Further, as the incidence of gallstone disease escalates, there is a concomitant increase in complications like gallstone-related pancreatitis. The best diagnostic test to confirm gallbladder disease is the abdominal ultrasound. It is noninvasive and is 90% to 95% accurate in detecting gallstones. Pericholic fluid and thickened gallbladder walls can also be identified as in acute cholecystitis. Gallbladder sludge and occasionally common bile duct stones can also be seen with abdominal ultrasounds. The gallbladder ultrasound may also be useful in detecting possible gallbladder neoplasms. The EUS or endoscopic ultrasound is not a first-line test for diagnosing gallbladder disease. There is no place for it as a diagnostic tool for cholecystitis. It is useful when evaluating and staging tumors of the gallbladder, pancreas, and bile ducts. Biopsies can also be done for tissue diagnosis. Ultrasound scanning has been the modality of choice for the clinical diagnosis of gallstone disease for the last 25 years. It is accepted to possess a higher sensitivity than oral cholecystography or computed tomography.

Patients and Method

In this hospital based study, in order to evaluate the concordance and discrepancy between preoperative ultrasound findings and operative findings in patients subjected to laparoscopic cholecystectomy. At the end of study we were able to include 100 cases. The study started on January the 2019 and ended at June the 2019. The study was carried out at laparoscopic unit in Al-Diwaniyah teaching hospital. The study was approved by the institutional ethical approval committee and formal agreement was obtained from the directorate of Health in Al-Diwaniyah province, the formal representative of Iraqi Ministry of health. Verbal consent was obtained from each patient after full illustration of the aim and procedures related to the current study.

Results

Patient’s demographics

The present comparative study included 100 patients who recently underwent laparoscopic cholecystectomy. The age range of those patients was form 14 to 85 years and the mean was 44.32± 14.53 years. With respect to gender, there was 19 male patients accounting for (19.0 %) and 81 female patients accounting for (81.0 %); therefore the male to female ratio was 1:4.26. Mean body mass index (BMI) was 29.28 ± 7.83 kg/m² and the range was from 24-33 kg/m² as shown in table 1.

n: number of cases; SD: standard deviation

The degree of agreement between ultrasound findings and operative findings

The thickness of gall bladder wall

It is obvious that approximately more than half of cases that have been labeled as normal thickness had actually operative measures that are comparable to that regarded as thin by ultrasound examination. On the other hand, most of cases that have been thick wall, according to ultrasound examination, had indeed operative measures that are the same as those considered normal by ultrasound examination. Added to that, the value of R² was 0.206 which in terms of accuracy means that the accuracy of ultrasound in comparison with operative findings is only 20.6 %, as shown in figure 1. Therefore, one can conclude that ultrasound examination is very undependable in estimation of gallbladder wall thickness.
The mean thickness of gall bladder wall according to operative notes was 2.95 ±2.08 mm with a range of 0.8 to 15 mm. There was almost complete agreement between ultrasound and operative findings since 22 patients were diagnosed as having single stone by both methods and 76 were diagnosed as having multiple stones by both methods, table 2. The mean size of largest gall stone according to ultrasound was 10.02 ±5.94 mm and that according to operative findings was 9.93 ±6.56 mm; the difference was statistically insignificant (P = 0.770). On the other hand the range of sizes of gall stone was 2 -27 mm according to ultrasound and 2 -26 according to operative findings; therefore, there was fair agreement between ultrasound and operative findings regarding stone size, as shown in table 3. In 71 patients there was agreement between ultrasound and operative findings in the absence of peri-cholecystic fluid. In 13 patients there was also agreement between ultrasound and operative findings in the presence of peri-cholecystic fluid. However, disagreement was seen in 16 cases; but McNemar test showed no significant difference (P = 1.000) and Kappa statistic indicated fair agreement of 0.518 (P < 0.001), as shown in table 4. There was complete agreement between ultrasound and operative findings with respect to presence or absence of stone impaction, as shown in table 5, in which stone impaction was seen in 5 patients according to both ultrasound and operative notes. The level of agreement was supported by lack of significant variation according to McNemar test (P = 1.000) and a kappa statistic of (1.000) with high significant level of (P <0.001), as shown in table 5.

Discussion

In the current study the degree of accuracy provided by US in measuring gallbladder wall thickness was extremely low (20.6 %). Therefore, one can conclude that ultrasound examination is very undependable in estimation of gallbladder wall thickness. Actually, as most patients are examined in the emergency setting, it has sometimes been questioned if the younger radiologists would perform as well as experienced radiologists, who are not always available at the time of examination7. prospectively evaluated the interobserver agreement in US examination of the gallbladder and the biliary tract performed by an experienced and a novice radiologist: they report that the novice radiologist’s expertise in the primary diagnosis of uncomplicated gallstone disease was as good as the one provided by the experienced colleague and the significant interobserver difference in the measurements of the thickness of the gallbladder wall and the common bile duct diameter might indicate that assessment of these parameters requires extensive practice. In the current study, there was almost complete agreement between ultrasound and operative findings since 22 patients were diagnosed as having single stone by both methods and 76 were diagnosed as having multiple stones by both methods and the Kappa agreement statistic highly significant 0.944 (P < 0.001). So the level of agreement in our
study was 98% and this is higher than that reported by\(^\text{11}\), who stated that the degree of agreement between preoperative US assessment of number of gallstones in comparison with operative findings was 82.7%. In another study, the degree of accuracy of preoperative ultrasound in estimating number of gallstones was 74%\(^\text{12}\) which is much lower than that of the current study. In the current study, ultrasound was able to agree with operative findings in 84% of cases; however, false results were seen in 16% of cases; therefore the degree of agreement was fair. Despite thorough search in available published articles, we failed to find an article that compares the accuracy of pre-operative ultrasound in the detection of pericholecystic fluid with that of operative findings as most of published articles have assessed gallbladder wall thickness and stone characteristic, compare ultrasound with other imaging modalities or evaluate the accuracy of pericholecystic fluid in predicting conversion to open surgery or difficult operation or in association with accurate detection of acute cholecystitis\(^\text{13,14,15,16,17,18}\). Therefore, this study may be regarded as the first one to raise the issue of ultrasound accuracy in detecting pericholecystic fluid in comparison with operative findings. In the current study, there was complete agreement between ultrasound and operative findings with respect to presence or absence of stone impaction and stone impaction was observed in 5% of cases. Despite thorough search in available published articles, we failed to find an article that compares the accuracy of pre-operative ultrasound in the detection of gallstone impaction with that of operative findings as most of published articles have assessed gallbladder wall thickness and stone characteristic, compare ultrasound with other imaging modalities or evaluate the accuracy of pericholecystic fluid in predicting conversion to open surgery or difficult operation or in association with accurate detection of acute cholecystitis\(^\text{13,14,15,16,17,18}\). Therefore, this study may be regarded as the first one to raise the issue of ultrasound accuracy in detecting impacted gallstone in comparison with operative findings. In the current study, adhesion was seen in 34 (34.0%) patients and operation was difficult in 12 (12.0%). Adhesion was significantly correlated to thick gall bladder wall, presence of pericholecystic fluid, dilated gall bladder and stone impaction; whereas, difficult operation was significantly correlated to female gender, biliary tree dilatation, presence of pericholecystic fluid and stone impaction. Actually these findings are in agreement with the vast majority of articles dealing with how to predict difficult laparoscopic cholecystectomy and may alter the decision of the surgeon to change into open surgery to avoid unnecessary complications\(^\text{19,20,21,22,23,24}\).

Frequency of Arrhythmia after Acute Myocardial Infarction During Admission to the Coronary Care Unit in Ad_diwaniyah Teaching Hospital

Radhi F. Shlash¹, Sarah Abdul Kareem Abdul Jabbar¹

¹Al-Qadisiyah University/ College of Medicine, Iraq

Abstract

Aims of the Study: To study the incidence of arrhythmias after Acute Myocardial Infarction (AMI) with respect to type of arrhythmia, risk factors, age and sex distribution, and location of infarction in a sample of patients during their admission in the coronary care unit in Ad Diwaniyah teaching hospital.

Patients and Method: This is a cross sectional study involving a cohort of 97 Iraqi patients diagnosed with acute myocardial infarction and admitted to the coronary care unit of Ad Diwaniyah teaching hospital in Ad Diwaniyah governorate / Iraq. All patients who admitted in the ccu for the period from January 2019 to July 2019 were followed by ECG records for any arrhythmia detected.

Result: Out of 97 patients diagnosed with AMI, 61 patients (62.88%) developed one type or more of arrhythmia, including 35 male (57.3%) and 26 female (42.6%), with the highest incidence (40.98%) above 70 years of age.

Reviewing the main risk factors in the past Medical History of those patients: hypertension was the most significant with 39 hypertensive patients (63.93%). The types of arrhythmias found in the patients included in this study were 27 cases with Premature Ventricular Contraction (27.8% of all patients with AML), 13 cases of Atrial Fibrillation (13.4%), 18 cases of Sinus Tachycardia (18.5%), 7 cases of premature Atrial Contraction (7.2%), 6 cases of Ventricular Tachycardia (6.2%), 3 cases with Ventricular Fibrillation (3.09%), 3 cases of Sinus Bradycardia (3.09%), 5 cases with accelerated junctional rhythm (5.1%), 3 cases of first degree A-V Block (3.09%), 2 cases with Complete Heart Block (2.06%), 7 cases of Right Bundle Branch Block (7.2%) and 5 cases with Left Bundle Branch Block (5.11%).

Key words: arrhythmia, acute myocardial infarction, coronary care unit

Introduction

Acute myocardial infarction (AMI) is myocardial necrosis in a clinical setting consistent with acute myocardial ischemia and detection of elevated values of cardiac biomarkers (CK-MB/troponin-I) above the 99th centile of the upper reference limit 4 hours after starting of symptom. Major risk factors for AMI can be classified as non-modifiable (e.g. genetic makeup) or modifiable (e.g. diet, cholesterol). In order to minimise the risk of AMI, modifiable risk factors should be identified and managed appropriately. In practice, the disorder is diagnosed and assessed on the basis of clinical evaluation, the electrocardiogram (ECG), biochemical testing, invasive and noninvasive imaging, and pathological evaluation. Diagnosis and treatment of patients with the hope of improving clinical outcomes depend on precise classification of infarction. In patients with myocardial infarction, 30-day mortality rates are between 7.8 - 11.4 percent (data reported by the American Heart Association in 2015). Of these, 18% men and 23% women (≥45 years of age) it is known that myocardial ischemia and infarction leads to severe metabolic and electrophysiological changes that induce silent or symptomatic life-threatening arrhythmias. Sudden cardiac death is most often attributed to this pathophysiology. Both atrial and ventricular arrhythmias may occur in the setting of ACS and sustained ventricular tachyarrhythmia’s (VAs) may be associated with circulatory collapse and require immediate treatment.
Atrial fibrillation (AF) may also warrant urgent treatment when a fast ventricular rate is associated with hemodynamic deterioration \(^7\). The incidence of sustained VT and VF occurring within 48 h of the onset of an ACS seems to have decreased over the past decades \(^8-10\). This is most likely due to the widespread availability of revascularization therapy, limiting the size of infarction and to an increased use of beta-blockers \(^11\). However, in a recent retrospective analysis of two randomized trials sustained VA occurred in almost 6% of patients in the very early phase of acute MI indicating the significance of VT/VF in this situation \(^12\).

**Patients and Method**

The study was designed to be a cross-sectional study involving a cohort of 97 Iraqi patients diagnosed with acute myocardial infarction and admitted to the coronary care unit of Ad Diwaniyah teaching hospital in Ad Diwaniyah governorate / Iraq. Patients were selected randomly through their admission in the ccu for the period from January 2019 to July 2019. ECGs used to follow the patients during their stay in the ccu to detect any arrhythmia and know the type of MI (STEMI or NSTEMI) and site of infarction.

The questionnaire form was based on the following:

- Sociodemographic characteristics of patients: Mainly age, gender and smoking.
- Past medical history of the patients regarding hypertension, diabetes and previous ischemic heart disease.

Data were collected, summarized, analyzed and presented using two software programs; these were the Statistical package for social sciences (SPSS) version 23 and Microsoft Office excel 2013. Numeric variables were presented as mean, standard deviation (SD) and range, whereas, categorical variables were expressed as number and percentage. Association between categorical variables was assessed using either Chi-Square test or Yates correction for continuity when more than 20% of cells have expected counts less than 5. The level of significance was considered at \( P \leq 0.05 \).

**Results**

Ninety seven patients admitted to the CCU with AMI included in this study: 57 of them were males (58.7%), and 40 of them were females (41.2%). Their ages ranged from 23 to 90 years with the mean age of the participants was 62.5 (±16.54 SD) years (\( p \) value <0.01 HS). Age distribution of patients was (3.09%) in the age group 20–29 years, (5.15%) 30–39 years, (11.34%) 40–49 years, (18.56%) 50–59 years, (27.84%) 60–69 years and (34.02%) above 70 years as shown in (Table 1).

Discussion

This study included 97 Patients admitted with AMI, 57 (58.7%), males patients and 40 (41.2%) females patients, so there is a clear male predominance. Acharya LD et al, also reported similar findings in accordance with the findings of this study. Siddique MB et al, also observed males (67%) predominance over the females (33%) 14. Overall incidence of myocardial infarction in this study was more common with the age group above 70 years (34.02%). Deshpande JD et al, in their study observed that, the incidence of AMI was highest i.e. 31% among the study subjects with 51 to 60 years. 17 Regarding risk factors In this study, we have concentrated on four main risk factors (Diabetes Mellitus, Hypertension, IHD and smoking) for precipitating AMI and its arrhythmic complications, Hypertension was a major risk factor for 62.88% of overall patients with AMI and 63.93% of those who developed arrhythmia following AMI, it is well known that uncontrolled and prolonged elevation of BP can lead to a variety of changes in the myocardial structure, coronary vasculature, and conduction system of the heart. 18. The second significant risk factor was DM, 55 patients (56.70%) of the total number of cases were diabetic and 32 patients (52.45%) of them developed arrhythmia, since Diabetes causes endothelial dysfunction, decreases endothelial thromboresistance, and increases platelet activity, thus accelerating atherosclerosis 19,20. Because there is a strong association between cigarette smoke exposure and heart disease, in the present study out of all AMI cases 38 patients (39.71%) were smoker, 14 (14.43%) ex-smoker, because Nicotine in Cigarette smoke produces a marked elevation in serum catecholamine concentration that is potentially arrhythmogenic, 22, smoking was found in 32.78% of patients and EX smoking 9.83% of AMI patients who develop arrhythmia. The maximum incidence (40.98%) of arrhythmias in this study was found in patients above 70 years of age (despite of p value 0.217 which is not significant statistically). The results of the study were in accordance with those of the American Heart Association, which showed 42% in age group of 60 or more. This is due to high prevalence of DM, dyslipidemia, atherosclerosis in age group of 60 or more. According to gender wise distribution incidence was more in males (57%) as compared to females (42%).

Conclusion

The frequency of arrhythmias and particularly premature ventricular contractions and sinus tachycardia following acute myocardial infarction was significantly high in this study patients sample. Increasing with age in both sexes. More common in extensive infarctions, while Hypertension, Diabetes Mellitus, previous ischemic heart disease and smoking are the commonest associated risk.

Sex Determination of in Vitro Produced Goat Embryos by Epididymal Spermatozoa Selected by Swim up Technique

Sura Shakir Hammood
Department of Surgery and Obstetrics, College of Veterinary Medicine/Baghdad University

Abstract
The study was conducted to determine the sex of the male and female goat embryos produced in vitro fertilization by Epididymal spermatozoa of local buck and separated by swim-up technique. The sex of produced embryo was identified by polymerase chain reaction (PCR). Results indicate that the fertilization by Epididymal spermatozoa selected using Swim-up technique at 200×g centrifugation showed that 48.70 ±0.62 % of spermatozoa were detected in the supernatant while the precipitate contained 42.1±0.70. Spermatozoa in the supernatant were used for IVF of matured oocytes. The sex of goat embryos produced in vitro fertilization was determined by polymerase chain reaction (PCR) using specific primers to detect the SRY gene. The percentage of male embryos recorded 71.73% while female embryos recorded only 28.26% from the total goat embryos obtained after IVF by sperms selected using swim-up at centrifugation force of 200×g. It was concluded that the use of swim-up technique up at centrifugation force of 200×g on Epididymal spermatozoa showed the ability of selection male embryos in caprine.

Key words: Swim up, Gender, Goat, Cauda, Epididymis, Embryo, SRY Gene.

Introduction
The animal manufacture depends upon increase in the number of productive livestock and a major concern is to increase the efficiency of offspring from them. The goat plays a significant role in socioeconomic development because of its contribution of milk, meat, skin and fur to humans and plant nutrition as farmyard manure, being small in size and having a short gestation period 1. Predetermining the sex of animals has been a central goal of producers for generations because of its economic advantage. The current development of state of the Assistant Reproductive Techniques (ART) has made it possible to predetermine the sex, involving the separation of X- from Y- chromosomes bearing sperms, used in artificial insemination (AI), in vitro fertilization, and embryo transfer 2. Sperm sexing has progressed from research to commercial application for humans and cattle 3. Sperm separation methods are capable to significantly improving sperm quality with a high rate of progressive motility and morphological normal spermatozoa 4. Several investigators have attempted to separate X- and Y spermatozoa using diverse techniques based on principles of differing mass and motility, swimming method, surface changes, centrifugal countercurrent distribution, immunologically relevant resources and volumetric differences (2,5). The potency of sex preselection in semen has been demonstrated for multiple species, including endangered species in zoos and aquarium animals 6. The objective of this research is the separation of X- from Y-bearing Epididymal spermatozoa of local goat by swim-up technique which with can be simply appropriated in small laboratory and with least laboratory appliances.

Materials and Method
Gonads of local goat were collected from Al-shu’alah abattoir and transported in a normal saline by cool box within 30 minutes to the laboratory. The ovaries were removed and washing three times with fresh normal saline and twice with a collecting media (TCM-199, TALP and MEM) and gentamycin to get out of contamination and were sliced into small pieces in fresh normal saline with a surgical blade. The oocytes have been collected in the Hood cabinet by aspiration, slicing or puncture from the normal saline solution to MEM according to procedures of Wani et al10. Aspiration of 2-8 mm size follicles were aspirated with 18 gauge needle attached with a sterile 3 ml disposable syringe containing 2 ml of collecting medium and the
slicing was performed by placing the ovaries in a sterile Petri dish containing 10 ml of collecting medium, held with forceps and the ovarian surface were incised with a scalpel blade while puncture visible follicles on the surface of the ovaries ranging from 2-6 mm in diameter with 18- gauge syringe needle. (7,8,9) The media with harvested oocytes were transferred to one petri dish (10,11). The wells of the dish were examined under inverted microscope and then the total number of oocytes was counted. Collected oocytes were examined and graded according to 12 as grade A, grade B and grade C on the foundation of cumulus cells and uniformity of cytoplasm.

Only grade A, and grade B oocytes were selected under a stereomicroscope, washed twice with cultured medium, and incubated in appropriate maturation medium at 39 °C, 5% CO₂ and 90% relative humidity for 24 hrs, the numbers of matured oocytes were calculated. Every 5 oocytes were placed in a well out of 24 wells dish containing 2 ml of the medium MEM containing HEPES buffer, sodium Bicarbonate, crystalline penicillin, streptomycin, fetal calf serum 10%, was used as maturation medium, presence of first polar body was the criteria of oocytes maturation. 13.

**Sperm separation by Swim-up technique:**

The procedure of the modified swim-up technique is essentially the same as that described by 12, Ham’s F10 (Euro-Lone, Italy) was used as an substitute media to estimate the effectiveness of the swim-up technique in separating X and Y chromosome bearing sperms. Sperms sample transferred to 10 ml centrifuge tube. Sperms washed twice using 0.5 ml Ham’s F-10 medium then centrifuged at 300×g or 200×g for 10 minutes. Supernatant removed and overly sperm pellets with 0.5ml of Ham’s F-10 medium in each tube. The tubes were put in the incubator, inclined at an angle around 45° and incubated at 37°C and 5% CO₂ for 60 minutes. By inclining the tubes at 45 to ameliorate the capability of the sperms to swim out of the sample and reaching the medium. Following incubation, the first 0.25ml was discarded and the final 0.25ml was used for IVF after sperm evaluation 12.

Groups of matured oocytes were kept in of 5 in petri dish containing media MEM supplemented with 10% heat inactivated estrus goat serum (EGS), BSA and antibiotics (Penicillin and Streptomycin) for fertilization with sperms and incubated at 39 °C, 5% CO₂ and 90% relative humidity for 24-27 hrs 13. After fertilization at 24-27 hrs, oocytes have 2nd polar body or oocyte with head of sperm in the cytoplasm was evaluated as fertilized oocyte. 13.

Cultures of fertilized oocytes were performed; embryos were cultured in MEM at 38.5-39 °C, 5% CO₂, and 90% humidity. Every 24 hrs, developments of embryos were perceived, 50% of the media volume was replaced with fresh medium at 24 hrs intervals according to 14 procedure, and then DNA extraction from embryos was applied.

**DNA extraction from cultured embryos:**

The primers (Promega, Germany) were used to detection SRY gene, they prepared according to the details of the producer. The sequences and product size of the primers are:

The forward primer sequence was: ATGAATAGAACGTTGCAATCG

(OD-260: 12.9, Microgram: 382, Pico moles: 58704)

The reverse primer sequence was: GAAGAGGTTTTTCCCAAAGGC

(OD-260: 11.7, Microgram: 363, Pico moles: 58842)

The Statistical Analysis System- SAS (2012) program was used to influence of difference factors in parameters of study. Chi-square test was used to significant comparison between percentage and least significant difference –LSD test (ANOVA) was used to significant comparison between means in this study.

**Results and Discussion**

Several techniques were used for the collection of oocytes from the ovaries in goats. The effect of collection methods on the recovery rate of oocyte is shown in table (1). Aspiration technique showed oocytes recovery rate of 62% (81/131) with a mean of oocytes per ovary and Perforation (puncture) showed oocytes recovery rate of 57% (71/125) while slicing showed oocytes recovery of 48% (55/114). There was a significant difference (p‹0.05) between different collecting techniques. Recovered ova via aspiration and puncture are statistically different than ova recovered by slicing. Similar observation was shown by 15 while 16 and 17 in the sheep. The results disagreed with 9 in goat and 12 in sheep. The aspiration
and puncture methods recorded a high recovery rate due to the aspiration and puncture considered as the applicable technique for obtaining perfect oocytes quality and quantity production, while the presence of the ovarian tissue debris in the slicing due to destruction the ova during the examination 13.

**Table (1): Effect of collection methods on recovery rate of ova**

Different superscripts showed significant difference (P<0.05).

Table (2) showed the type of collection methods on the grade of the ova recovered. Results showed that higher recovery rates were obtained from grade B in all collection methods as compared with grade (A) or grade (C). Corresponding observation was shown by 15 in goats. Wani et al 12 have made comparable observation in sheep and 18 in goats. The low quality grade oocyte recovered could be due to slaughters of low-quality does. There were statistically significant differences (P<0.05) in oocytes quality between aspiration and puncture as compared to the slicing method.

In this research, for amplification genomic DNA of in vitro produced embryos of local goat, we were used the primers for SRY gene of caprine, and the PCR products were separated on 2% agarose gels. The result showed that amplification fragment of size 116 bp, the embryos were successfully amplified and when one band dyed by red gel the embryos recorded as male embryos while the result which showed the nonappearance of such bands recorded for the produced embryos as female goat embryos (Figure 2).

The caudal spermatozoa selected from the upper layer of swim up technique, gave 71.73% male embryos and 28.26% female embryos for determination of the sex of IVF produced local goat embryos. Because X sperm has more DNA than Y sperm, the Y chromosome...
is faster than the X chromosome which results in different movement rate. Some authors described that supernatant of swim-up procedure contained more Y sperms. In this study we used accurate protocol for embryos sexing by PCR, it based on detection of the presence of SRY gene. The Y-specific target sequence amplification only was adequate to identify the gender as has been done effectively in bovine and caprine embryos sexing studies.

Table (4) shows the percentage of male and female goat embryo after IVF by spermatozoa and sexing by using PCR the result disclose that 33 (71.73%) from 46 sexed caprine embryos were male, while female embryos revealed only 13 (28.26%) with a significant difference between the two detected sex (P<0.01).

** (P<0.01).

After used swim up technique, the percentage of male embryos evaluated high compared with the results of Marco-Jiménez and Vicente using swim up technique in ovine, and that of Shnawa, (2013) who obtained 81.80 % of male embryos after swim up technique in ovine.

**Conclusion**

From these data it can conclude that it is feasible to reaping Y bearing spermatozoa from epididymis cauda of local buck by swim up technique (200×g) and use these sperms for IVF to get a high percentage of male embryos successfully.

Associations System for Breast Cancer Microarray Data

Kain R. Qasim
University of Information Technology and Communications, Iraq

Abstract
The aim of this paper is to give biologists a tool to explore reasons and impacts of the breast cancer as patients with the same stage of illness can have different treatment responses. This paper proposes a Breast Cancer Associations system (BCA) to discover and interpret the associations among the breast cancer patient’s gene expressions data. The data used in this paper is the array data of 24,483 gene expression measurements recorded for 19 breast cancer patients. BCA consists of: data preprocessing, and data mining. In the first process in BCA, the data is carried out four preprocessing steps to be suitable and enhance the second process in BCA. These four steps are data filtration, normalization, discretization, and data adaptation. The mining process stage uses a new algorithm called Row Intersection Support Starting (RISS), which traverse the row enumeration space using the user-defined mines up threshold as a starting point deploying a new data format called Row Set (RS). The last stage in the system concerns the production of the association rules based on the user defined minimum confidence threshold. Fifteen different experiments have been conducted with different parameters. The results of the experiments are recorded and compared

Keywords: Breast cancer association’s data, microarray data, data adaptation and Row Intersection Support Starting.

Introduction
Gene expression dataset provides information on the variation of gene activity across conditions. It contains numbers which characterize the expression level of a particular sample. It allows the identification of genes that are differentially expressed linked to given condition which help in understanding the response to treatments as well as provide deep insight into the nature of many diseases and lead in the development of new drugs. For example, indicates which genes will be over expressed and which will be under expressed when a breast cancer treatment is given to the cells. Since the number of samples is usually limited and the number of genes is measured in thousands, such dataset are characterized as very high dimensional ones. Association rule mining is the task of finding useful correlation between items in a dataset. They are rules of the form LHS $\leftrightarrow$ RHS, where LHS and RHS are item sets and LHS $\cap$ RHS= $\emptyset$. A brief survey for association rule mining algorithms found in. While frequent Item set are all item sets whose support is at least equal to the minus threshold, closed frequent item set is a condensed representation of frequent item sets. A frequent item set X is closed if there is no superset Y such that Y $\supseteq$ X with $\text{sup}(X) = \text{sup}(Y)$. Since the set of all frequent item sets and their exact support can be extracted from the closed frequent item set, new researches mines closed frequent item sets. The very high dimensional data like the gene expression needs special data mining techniques to discover closed frequent item sets. IRG are a set of rules that are generated from the same group of rows and meet user interestingness constrains including minus, mincing, and minimum chi-square (Minch) threshold. Mine Top-K focuses on the same problem of FARMER but generates most significant Top-K covering rule groups rather than generating IRG. Top-K covering rule groups are defined by first setting criterion for ranking and applying it to the resulted rules in the dataset. All these works performed their experiments on the same data with different minus and different row lengths. In most cases, COBBLER and FARMER outperform CARPENTER. The second category algorithms are IIMA, charm, and RERII. IIMA mines all frequent item sets separately in parallel mode and then joins the results which are returned in a compressed Set Enumeration (SE) and finally generates the rules.
BCA System

BCA is a proposed system that discovers the associations among breast cancer patients’ data. BCA consists of data preprocessing and data mining process, Fig. 1.

Data Preprocessing

a) Filtration

Data filtration task is done in two steps according to the recommendations of a domain specific specialist. The first step is removing redundancy in the data while the second step is a data domain requirement that filters data according to a threshold. Biologists specify a certain threshold to get closer to certain data values which give more insight on the disease under study. Genes expression values greater than the threshold are excluded from the mining process.

b) Normalization

The dataset is normalized using a Mat Lab Built in function called manorm. Manorm scales the values in each column by dividing it by the column mean.

C) Discretization

The dataset is discretized using the mid-range-based cutoff method. The mid-range value for each gene is the mean value for its corresponding column. Values below or equal to its mid-range are set to 0 otherwise is set to 1. Gene expressions with zero value indicate under expressed while those with value one indicates over expressed.

d) Adaptation

In this task, each gene is presented in two columns; one column is for the over expressed state of the gene and the other is for the under expressed state. This adaptation is used to produce rules that specify the state of the genes in addition to their associations. For example, the rule GI $\rightarrow$ G2 — implies that there is an association between GI and G2, when GI is over expressed, G2 becomes under expressed.

Data Mining Process

a) Closed Frequent Item sets Generation

This task produces closed frequent item sets by implementing RISS algorithm Fig.4. RISS algorithm uses the Row Set data format and the minimal bottom-up search space.

Row Set Data Format (RS)

RS is a new vertical format. Let table 1, be a discretized gene expression table of biological Samples B. \{b1, b2, .........., b6\} in rows, and genes G-{g1, g2, .........., g6} in columns. Table 1 is a triple (B, G, R), where R B*G is a relation. (bi, gj) R denotes that gene gj is over expressed or under expressed in bi. Fig.2-a shows b1 has genes g1, g2, g4, and g5 are over expressed while g3 and g6 is under expressed.

</tbody>
</table>

Figure 3. Comparison between the VTL and RS presentation of table 1.
The difference between VTL and RS is that the second uses the Tad (biological samples) instead of using the items (Genes) to build the VTL with condition that infrequent genes are deleted from the dataset. Fig.3 (a and b) shows RS and VTL of the data, in Fig.2 with mines up equals 30% of the samples.

The common genes among given samples is denoted as $G (B')$. Given a set of biological samples $B' \subseteq B$, the row support set, denoted $G (B) \subseteq G$ is defined as the maximal set of genes common to all the rows in $B'$ and the support of these genes denoted $sup(G(B'))$ is the count of Biological samples in $B'$. As an example, let $B'=\{b1, b3\}$ in Fig.2, then $G (B') = 2$.

**Minimal Bottom-up Search Strategy**

It checks row combination from the smallest to the largest to traverse the search space, Fig.3-a, for example, 1-russets, then 2-rowsets, ..., and finally n-russets. It is a modification from the traditional one (5, 6, 7, 8) as it starts the search from the items up ‘russets rather than the 1- russets. This is valid as the maximum support for the K-russets, for example if the mines up =3 the enumeration tree starts from level 3 as shown in Fig.3-b. Each node in the enumeration tree is represented by RS format. For example, the first node in Fig.3-b tree is represented by $B'=\{1, 2, 3\}$ and $G(B') = \{g2, g5\}$ as shown in Fig.3-c.

**RISS Algorithm**

RISS traverses the Minimal Bottom-up row enumeration search space using breadth first search (BPS). It has two pruning actions to eliminate unnecessary searches. RISS performs recursive generation of the Russets to present a node during traversing the row enumeration tree, Fig.4.

The first pruning action is performed in step 2 of the procedure intersection rows, it checks if the $G(B')$ is empty. This implies that there is no maximal genes common to the biological samples $B$, so no further enumeration will be required on the branch of this node.

The second pruning action is performed in step 3. It checks if the $G (B')$ exists in CFI, if it is true, current and further enumeration of this node is truncated. In other words, $G(B')$ does not discover any new closed frequent item sets. At $B'=\{1 2 3\}$, then $G (B') = \{g2, g5\}$ and results in $\{g2 g5\}$ with frequency $\{1 2 3\} \in CFI$ and no further enumeration for node $\{1 2 4\}$. At $B'=\{1 2 5\}$, then $G (B') = \{g2, g5\}$ which already exists in CFI and results in updating it to $\{g2, g5\}$ with frequency $\{1 2 3 4\} \in CFI$ and no further enumeration for node $\{1 2 4\}$. The same for $B'. \{2 3 5\}$. RISS does not need to perform the closure check among the discovered Item sets since step 1 in Intersection. Rows procedure extracts only the closed item sets. The proof is that $G (B')$ cannot be a maximal gene set that is common to all biological samples $B'$ unless it is a closed item sets 10. For example, in Fig. 2, it is not possible for the item set $\{g1 g2\}$ to be enumerated although both $\{g2\}$ and $\{g1 g2 g5\}$ are closed item sets. This is unlike the column enumeration algorithms which enumerates both $\{g1 g2\}$ and its superset $\{g1 g2 g5\}$, then checks for equal support (= 4) and same frequency ($\{b1 b3 b4 b5\}$) between them. Thus, discarding the subset $\{g1 g2\}$ and denoting the superset as a closed item set.

**b) Rule Discovery**

Rule discovery task is achieved by implementing the faster algorithm in 18. It first generates all the rules with one item in the LHS. Then, recursively use the LHS with K items of the discovered rules to generate all
possible consequents with K+1 items that can appear in the further rules. All resulted rules with the associated parameters are stored in a database to ease querying and maintenance.

**Experimental Study**

**Data**

Array data is used of 24,483 gene measurements recorded for 19 breast cancer patients. It contains: Systematic name given to each gene or sequence and a description of what is known about gene’s function. Also, it contains three values for each tumor sample profiled: Log 10 (Intensity), Log10 (ratio), and P-value. According to the biology specialists’ opinion, the P-value is used in mining process.

**Experiments**

Fifteen experiments are conducted with different filtration and minimum support thresholds. In the first step of filtration, removes the continues P-values keeping only the overall gene P-value. The second step uses three thresholds for the P-values which are 0.04, 0.05, and 0.06. Each filtered data is experimented by four mines up values (15.7%, 26.2%, 42.1%, 52.63%, and 63.15%) and mincing equals to 0.05. Experiments are performed on a PC with Core Duo 2 GHz CPU, 1GB RAM and a 120GB hard disc and the algorithm is coded in MATLAB.

**Results**

The results recorded for each experiment are shown in Table 1. For all experiments, the drawing charts exhibit decaying exponential function with different decaying parameter. Also, the drawn points collapse at higher support level for all datasets. In an attempt to carry the analysis of results one step further, a comparison for CFI and rules count is conducted. A General observation is that whenever the minus increases the common CFI and rule count among the sets increase except for one case AB in rule count at minus=8, the intersection reaches it.1 maximum then started to decrease with increasing mines up. Also, the percent of increase in intersection varies descending from AB to BC to AC.

Discussion

The proposed BCA system discovers the relationships among breast cancer patients’ gene expressions. The first set of BCA advantages exists in the different preprocessing tasks. Data filtering is an important preprocessing task since it reduces the amount of data genes under study which speeds up the mining process, and gives more insight into specific data values. The first step in the data filtration removes data redundancy existing in the continues of the genes listed in the data file. Moreover, the second filtering step reduces the amount of the data which greatly enhances the performance in terms of processing time and memory space. The second task in the preprocessing, data adaptation is a necessary one in order to indicate the state of the gene in the rules. If not applied, the discovered ‘rules specify only the over expressed associations. The discretization task converts the continuous data into binary one, thus speeds the processing cycle and reduces the memory requirement. This step did not affect the aim of the study since the interest is the differentiation between over and under expressed genes without using quantified measures.

1Assistant Professor; 2Professor; 3Lecturer, Department of Prosthodontics, College of Dentistry/ University of Baghdad, Iraq

Abstract

The aim of this study was to assess the effect of glass flakes addition on some physical and mechanical properties of a maxillofacial silicone material. Material and method: A room temperature vulcanized (RTV) maxillofacial silicone (VST-50, Factor II Inc., USA) and Micronized glass flake, surface pre-treated with silane coupling agent (GF002, Glass flake Ltd, Leeds, UK) were used in this study. Two hundred (200) specimens were prepared and divided into five main groups based on the tests conducted (tear strength, tensile strength, elongation percentage, surface hardness and surface roughness). Then, each group was further divided into four subgroups according to weight percentage of glass flakes as follow; control group (0%), other groups contain 0.5%, 1% and 1.5% of glass flake micro-particles (10 specimen from each group). Results: The collected data were analyzed with a one-way ANOVA and LSD multiple comparison test were utilized to show the differences among four studied groups. The 1% glass flakes-incorporated specimens exhibited the highest mean values of tear strength, tensile strength and elongation percentage. While, the highest mean values of hardness and roughness were obtained with 1.5% specimens.

Keywords: Glass flakes, Maxillofacial silicone material (VST-50), Tear strength, Tensile strength, elongation percentage, Hardness, Roughness.

Introduction

Prosthetic devices have been widely used to compensate for defects either from congenital or acquired origin (such as disease or trauma), the need for prosthetic rehabilitation has proportionally increased since surgical intervention may not always be possible because of the location and size of the defect 1. Various types of polymeric materials such as polyvinyl chloride, polyurethanes, poly (methyl methacrylate), chlorinated polyethylene and silicones (poly(dimethyl siloxane); PDMS) elastomers are well-known materials for the production of maxillofacial prosthesis 2. However, given their low surface-free energy (hence poor wettability), they can cause adverse reactions such as tissue irritation, abrasion and ulceration 3. The ideal mechanical and physical characteristics of the maxillofacial materials should be comparable to that of the tissue to be substituted. These materials should be non-toxic and tissue-compatible, should be colored with intrinsic and extrinsic pigments, should have easy handling and processing and should not deteriorate during clinical use 4. Regarding the vulcanizing process using heat or not, silicones are available as heat vulcanized (HTV) or room temperature vulcanized (RTV). In comparison to other materials, both HTV and RTV have high tear resistance, because the specimens do not tear but expand, as in tensile elongation and high percent elongation ranging from 422% to 445% 2. Medical grade silicone adhesives have been combined with RTV silicone based in various ratios to control the elastic properties 5. Due to hydrophobic nature, these have low adhesion to non-silicone adhesive material and suffers from limited working time 6. Surface-treated silica with small particle size fillers had increase the surface area and significantly enhance the physical and mechanical properties of
silicone elastomers. Lately, researchers have found even stronger enhancement through the use of nano silica powder, which has an even larger surface area than micrometer-size silica powder. Glass flake has been utilized as a reinforcing agent in many industrial and commercial applications, their manufacturers proved that its addition to some thermoplastics has resulted in a significant improvement in flexural properties and planar reinforcement. The efficacy of the glass flakes reinforcement is strongly based on the interfacial adhesion between the glass and the surrounding polymer matrix.

Materials and Method

Materials

In the present study, a room temperature vulcanized (RTV) maxillofacial silicone (VST-50, Factor II Inc., USA) and Micronized glass flake, surface pre-treated with silane coupling agent (GF002, Glassflake Ltd, Leeds, UK) were used. The glass flake consists of flake particles of 1.3-2.3 μm thick with a range of diameters mostly below 50μm.

Specimen grouping

A total of two hundred (200) specimens were prepared and divided into five main groups based on the tests conducted (tear strength, tensile strength, elongation percentage, surface hardness and surface roughness) with 40 specimens for each test. Then, each group was farther divided into four subgroups according to weight percentage of glass flakes as follow; control group (0%), other groups contain 0.5%, 1% and 1.5% of glass flake micro-particles (10 specimen from each group).

Specimen preparation

Four plastic mold were fabricated using laser cutting machine (JL-1612, Jinan Link Manufacture and Trading Co., Ltd., China). Each mold was fabricated into the specified dimension for each test. The thickness of the plastic sheet used for tear, tensile and percentage elongation tests was 2 mm, while the sheet used for hardness and roughness tests was 6 mm. Around 40 mm × 40 mm square test specimen was used for hardness and roughness tests in accordance with ISO 7619-1:2010 (10). Whilst, an angle test specimen without nick with dimensions in accordance with ISO 34-1:2010 was selected for tear strength test (11). While, a dumb-bell specimen was chosen for tensile strength and elongation at break test according to ISO 37:2011 (12). For each plastic mold, two sheets one on top and other glued sheet on the bottom were fabricated with the same outer dimensions of the mold to sandwich the mold between them (Figure 1).

Figure 1. Metal molds for A) Hardness and roughness tests, B) Tear strength test, C) Tensile strength and elongation tests

The mixing of RTV silicone was done according to manufacturer’s instructions. For control groups, part A (base) of silicone and part B (crosslinker) was weighed with a ratio of 10:1 and mixed by a vacuum mixer (Multivac 3, Degussa, Germany) for 5 minutes.

Testing method

Tear strength test was done by adjusting the test specimen on a universal testing machine (WDW-20, Laryee Technology Co. Ltd., China) and stretching...
it with a speed of 500 mm/min until the break. The thickness of the specimen was measured at the area of the right angle by a digital caliper before testing. The tear strength was measured by dividing the maximum force obtained from the universal testing machine by the thickness of the specimen.

For tensile strength test, the thickness and the width of the narrow portion of the specimen were measured by a digital caliper at 3 areas; at the two ends and in the middle. The average of the 3 readings was considered as the thickness and the width of the specimen. Then the specimen was fixed on a universal testing machine and stretched at a crosshead speed of 500 mm/min until it breaks. The tensile strength was calculated using the following equation: recorded for each specimen, and the transverse strength was calculated using the following equation:

$$T_S = \frac{F_m}{W_t},$$

Where $F_m$ is the maximum force in Newton, $W$ is the average width of the narrow portion of the specimen in millimeters, and $t$ is the average thickness of the specimen over the narrow portion in millimeters.

On the other hand, elongation percentage was assessed using an extensometer for each tensile specimen and percentage of elongation was calculated using the following equation:

$$E_{\%} = \frac{L_b - L_o}{L_o} \times 100$$

Where $L_o$ is the initial test length in millimeters, $L_b$ is the test length at the break in millimeters.

Statistical analysis

Statistical analyses were performed using SPSS (statistical package for social science – version 24) computer software. Descriptive statistics were made which include Means and Standard deviation. The homogeneity of variances was confirmed by Levene test and also inferential statistics includes; One-way analysis of variance (ANOVA) was used to compare means among all groups and LSD multiple comparisons test was utilized to show the significance among different groups.

Results

The results of this study agree with the hypothesis that the silica filler-treated will increase the surface area of silicone elastomers and is an important factor to enhance the physical and mechanical properties.

Concerning the results of the present in vitro study, the superior tensile strength, tear strength and elongation percentage of the micro-particles glass flakes treated groups in comparison to the non-treated control group were likely attributed to the presence of high molecular weight Polydimethylsiloxane (PDMS) chains combined with glass micro-particles. Cross-linking of a high molecular weight polymer produces a highly elastic material, thus increasing the viscosity of the resulting polymer as well increase the length of PDMS chains and produce a very elastic cross-linked network and this may considered for the high mechanical properties, thus the resulting polymer matrix is able to withstand greater deformation without rupturing or tearing. Tear strength is the most important property of maxillofacial prosthesis which indicates the thin margin integrity and durability of maxillofacial prosthesis. The results of tear strength test indicated that the tear strength was significantly increased (p > 0.005) when the glass flakes were incorporated to the silicone (Table 1). In all experimental groups, the flakes mechanically interacted with the silicone matrix and associated strongly with the polymer chains thus increasing tear strength values. Tear strength of a material depends on the ability of the polymer to scatter energy at the area of the crack as tearing propagates. Micro-sized fillers dissipate strain energy within the matrix of the polymer, thus making it more resistant to tearing and a higher applied force is needed to completely break the polymer chains. This explains the increase in tear strength, as explained by Kraus in 1978 and Sun et al. (2009). For the control group, the interaction between the –OH groups and PDMS chains is not strong enough to prevent the material from rupturing under an applied force. Generally, the tensile strength depends greatly on the crosslinking between the silicone chains. It seems that the results of tensile strength was significantly increased after incorporation of the glass flakes into the RTV silicone specimens (p > 0.000) (Table 2). The silicate groups act as multifunctional crosslinks through the generation of new bonds with silicone chains. These multifunctional crosslinks increase the overall crosslinking density of the cured silicone and make it stiffer and stronger. When the polymer is subjected to tensional forces, these crosslinks inhibit the chains from sliding over each another as well prevent the breakage, thus increasing the tensile strength. The elongation of cured silicone elastomer depend greatly on the cross-linking system. One of the reinforcement mechanisms of silica is that glass micro-particles act as multifunctional cross-links via formation of strong hydrogen bond between its surface hydroxyl group and PDMS chains; these multifunctional cross-links increase the overall cross-linking density of the polymer and make it more stiff and strong. In this study, the experimental groups revealed reduction in tear strength, tensile strength and percentage of elongation when the concentration of glass flakes was increased to 1.5% might be due to the agglomeration of flakes particles within the matrix. These agglomerates are formed when two or more filler particle aggregates bind together by weak electrostatic Van der Waals forces. These agglomerates act as stress concentration

areas within the polymer matrix. When external forces are applied to the polymer, the agglomerates break and weaken the matrix leading to crack propagation, as explained by 13.

**Conclusion**

The addition of glass micro-particle is necessary for achieving certain degree of reinforcement that leads to significant improvement of the mechanical properties. Within the limitations of this in vitro study, the following conclusions can be obtained that the addition of various concentration of glass flake to RTV silicone material considerably improved the mechanical and physical properties of the material. The 1% glass flakes-incorporated specimens revealed the highest mean values of tear strength, tensile strength and elongation percentage. While, the highest mean values of hardness and roughness were obtained with 1.5% specimens.

Investigation the Anti-Sterility Role of Ubiquinone-10 Against Procarbazine-Induced Infertility in Male Rats

Ayyed Hameed Hassan, Wafaa Kadhim Jasim

College of Veterinary Medicine, University of Kerbala, Karbala, Iraq

Abstract

Procarbazine is cytotoxic chemotherapy drug with obvious deleterious effects on male fertility. The present study aimed to investigate protective method via co-administration of Ubiquinone-10 with procarbazine to reduce harmful effects of procarbazine. Twenty-eight adult healthy male rats (3 months in age and weighing 250-300g) were randomly divided into four equal groups as following: animals of first group were received propylene glycol 20% orally and phosphate-buffered saline solution (PBS) intraperitoneally as control group while of second , third and fourth group were received procarbazine (30mg/kg), Ubiqunone-10 (10 mg/kg) and combination of Ubiqunone-10 with procarbazine respectively, all treatments were lasted for 9 weeks.

Results revealed that procarbazine induces significant increase in serum FSH and LH level while Testosterone level was significantly decreased. Similar decrease were also noticed in levels of glutathione (GSH) as well as activity of catalase (CAT) and superoxide dismutase (SOD) in testis. Moreover, procarbazine caused significant decrease in sperm count, motility and viability and significant increase in sperm abnormality. On the other hand, Co-administration of Ubiqunone-10 with procarbazine lead to ameliorate levels of hormone as well as to improve testicular catalase activity in addition to glutathione and superoxide dismutase levels.

Key words: sperm count, Ubiquinone-10, male fertility

Introduction

There are many categories of causative agents that included in male infertility, drugs related infertility, need to be investigated. Impact of anticancer agents on fertility are well-known. Antineoplastic drugs possess deleterious effects on germ and Sertoli cells in men, resulting severe oligozoospermia or azoospermia after chemotherapy courses. Spermatogonia are more affected by these drugs than that in other developing-stage due to differences in rate of cell division between them. Most alkylating chemotherapy agents (procarbazine) are toxic to spermatogenic cells and caused long lasting azoospermia due to their ability to cross-link DNA. In addition, there are patients within their reproductive age, therefore investigation a method to protect spermatogenesis and fertility is very important. It is obvious that cytotoxic drugs damaged mainly rapid dividing cells such as spermatogonia but the mechanism that govern ‘spermatogenic arrest’ to decline damage of testis is still unclear. About 30% to 80% of subfertility cases in male resultant from sperm damaging caused by oxidative stress. Susceptibility of spermatozoa to oxidative stress and reactive oxygen species (ROS) was documented by many previous studies that considered (ROS) involved in sperm damage as well as male infertility. Ubiquinone-10 is a molecule possess antioxidant ability, contribute in the respiratory chain. Light thrown on the ability of antioxidant to reduce male infertility and investigate whether antioxidant supplementation to infertile men with can enhances seminal indices. Ubiquinone-10 was one of various compound that tested due to its role in energy metabolism and antioxidant status via its function as a liposoluble chain-breaking for lipoproteins and cell membranes. Considerable amount of Ubiquinone-10 present in seminal plasma and spermatozoa to reduces oxidative stress and protect sperm viability. Seminal plasma Ubiquinone-10 concentration is significantly related with sperm number and motility. The present study aimed to assessment ability of Ubiquinone-10 to achieve recovery of procarbazine-induced infertility in a male rat.
Materials and Method

Animals and Experimental Design

Twenty-eight adult male albino rats, aged three months and their weight range 250-300 gm, were used in the present study. Rats were reared in metal cages and food and water were ad libitum. Male rats were distributed into four groups (7 rats each group), as following: Vehicle control group, rats were firstly gavaged with propylene glycol 20% then intraperitoneally injected with 0.25 ml of PBS after one hour of gavage. Ubiquinone-10 group, rats were orally administered 10 mg/kg BW of ubiquinone-10 (dissolved in propylene glycol 20%) via gavage. Procarbazine group, rats were injected intraperitoneally with 30 mg/kg BW of procarbazine (NATULAN® 50 mg, Sigma-Tau Pharmaceuticals Company, France) according to. Ubiqunone-10 plus procarbazine group, rats were gavaged with ubiquinone-10 then injected with procarbazine within one hour interval. Ubiquinone-10 (NOW Health group Inc. USA). All treatments were performed daily for 9 weeks. At the end of the experiment, blood samples were collected via cardiac puncture. Serum separated and frozen at –20°C till perform the biochemical and hormonal measurements. Animals were anesthetized by chloroform the sacrificed in order to harvest epididymis of each rat and right testis to perform epididymal sperm analysis and processed for enzymatic antioxidant assessment respectively.

Hormone Assay

Serum Testosterone, FSH and LH concentrations were measured by use commercial ELISA kits (American Laboratory Products Company (ALPCO), USA) according to the instructions of manufacture.

Antioxidant Indices Assessment

The right testis of each rat was homogenized in (1-4 v/v) of PBS (pH 7.4) thereafter, the homogenate was centrifuged (10 000×g for fifteen minutes at 4°C). The resultant supernatant used to perform enzymatic antioxidants measurement. Estimation the testicular SOD and CAT activity as well as GSH level were performed according to procedures described by Misra and Fridovich, Clairborne and Jollow et al respectively.

Epididymal Sperm Analysis

The cauda epididymis was excised and sperm suspension obtained by minicing it to release spermatoza onto a Petri dish to mixed with 2 ml of physiological saline (0.9% NaCl) at 37 °C. sperm concentration and progressive motility of sperm were performed by using methods described by Belsey et al while Sperm viability and morphological abnormalities of sperm were assayed according to Wells and Awa.

Statistical Analysis

All data were statistically analyzed by using Statistical Package for Social Sciences (SPSS, version 19). One-way analysis of variance (ANOVA) were carried out to compare between groups of study and least significant differences (LSD) used to identify significance of the differences between means and P value less than 0.05 were considered significant. Obtained results were expressed as the mean plus minus standard error.

Results and Discussion

The means of serum testosterone, luteinizing hormone (LH) and follicle-stimulating hormone (FSH) levels are present in Table 1. The LH and FSH levels were significantly (P≤0.05) increased while testosterone levels decreased in rat treated procarbazine as compared with all other groups. Procarbazine produce toxic effects on rodent spermatogenic epithelium and induces sterility in male rodents largely by killing stem spermatogonia.. Primary gonadal dysfunction is resultant from testicular damage lead to deleterious effect on spermatogenesis and/or Leydig cells dysfunction. According to above mention effect of procarbazine, the elevation of FSH in the present study may be resulted from impairment of spermatogenesis, whereas decrease of testosterone levels that associated with LH elevation may happen as a result of Leydig cell dysfunction.

The exposure to cytotoxic chemotherapy and radiotherapy causes rise in FSH levels co-incident with low sperm counts, therefore, the of suppressive effects of testosterone and analogs of gonadotrophin on spermatogonial furthermore, chemotherapy and radiotherapy are often used in combination associated with greater testicular dysfunction and germinal epithelial damage. To lead to an availability of therapy on male infertility after cancer treatment.
Qu et al., were conclude that the therapy on male infertility after chemo- and radiotherapy is an available because sever testicular dysfunction and damage of germinal epithelia resulted post cancer treatment.

Results in table 1 also revealed that ubiquinone 10 reduces the toxic effect of procarbazine represented by elevation in testosterone level and reduce in levels of FSH and LH in ubiquinone-10 plus procarbazine group although their value still less than that recorded in control group. Ubiquinone 10 also called coenzyme Q10 supplementation was found to ameliorate the reduction in testosterone induced by chemical reproductive toxicants, mainly by neutralizing the damaging effect of the generated free radicals. The mechanism by which ubiquinone 10 could counteract testicular toxicity is associated with its potent antioxidant properties and with ability to enhance transcription of steroidogenic enzymes. Therefore, the enhancement of hormone levels in the present study may resulted from reduce damage of germinal epithelia by anti-oxidant effects exerted by ubiquinone.

According testicular antioxidant status, The changes in some enzymatic antioxidants levels in testis were shown in Table 2. Significant decline in the activity of SOD, CAT, GSH levels was observed in rats treated with procarbazine as compare to other groups. Co-administration of ubiquinone 10 to procarbazine treated rats caused elevation in activity of testicular SOD, CAT, and GSH in compare to procarbazine group. However, above mentioned antioxidants exhibit non-significant differences between rats received ubicoinone 10 alone and rats of control group. Procarbazine is one of Alkylating agents that produce reactive oxygen species (ROS) causing decrease cell capability to detoxifying thiols and depletion of antioxidant enzymes.

Superoxide dismutase stimulates the radical of superoxide peroxide dismutation into plus oxygen molecule plus H2O2 ,the later converted into H2O and molecular oxygen by CAT. GSH, have an important role in cellular redox balance and participate in free radicals scavenging inside cells and considered the first guard against oxidation. In the present study, decline in levels and activity of these antioxidants due to procarbazine treatment was corroborates with result of previous studies on testis and liver which may be resultant from testicular oxidative damage.

In the present study, ubiquinone significantly emulates the redox balance in the rat’s testis which also in coordinate with previous findings in human and rats. We suppose that the improvement of antioxidant capacity and the reduction of oxidative stress caused by procarbazine due to co-admenstration of ubiquinone could be associated with the improvement of sperm indices that observed in table 3.

Results of epididymal sperm analysis in table (3) revealed that treatment with procarbazine for 9 weeks lead to a significant decrease in sperm count, studies (33,34) reported the ability of a single dose of procarbazine to cause toxic effect on spermatogenic epithelia of rodent. Moreover, Gould et al., 18 found that the procarbazine may cause most harmful effect on spermatogenic cells throughout other agents included in the MOPP chemotherapy protocol. The exact mechanism by which procarbazine can resulted the toxicity remains unknown. Conversion of procarbazine to an alkylating intermediate via bioactivation is necessary in both the anticancer activity and spermatotoxicity of the drug 35. The antioxidant properties of ubiquinone 10 make it involved in biochemistry of sperm and male infertility. Sperm number and motility are correlated with concentration of ubiquinone 10 in seminal fluid 39. However, ubiquinone 10 in the present study improve sperm count, motility and viability as well as reduces abnormal sperm percentage may be via elevation in the coenzyme Q10 level or due to improve the antioxidant status in the testis

Association of BRCA1 Epigenetic, with Breast Cancer

Rana S. Jawad¹, Rafal N. Abbas², Abdul. Ameer N Ghloub Al. Rekabi³

¹Lecturer, Biology Department, College of Science, Mustinsryah University, Baghdad, Iraq; ²Assist. Lecturer, Biology Department, College of Science, Mustinsryah University, Baghdad, Iraq; ³Prof. Dr., Biology Department, College of Science, Mustinsryah University, Baghdad, Iraq

Abstract

Breast cancer is the most frequent malignancy among Iraqi women cancer. Epigenetic alterations such as DNA methylation were involved in the earliest phases of tumorigenesis and help for early diagnoses of breast cancer.

In this study, the methylation and unmethylation BRACA1 gene have been detected of Iraqi women patients having breast cancer.

DNA extraction kit and DNA modification kits as well as polymerase chain reaction (PCR) have been used. The samples of 80 women patients’ blood with breast cancer and 20 apparently healthy individual’s blood sample are collected during the period of February 2018- April 2018 from Oncology Hospital in the Medical City - Baghdad, Iraq.

On using PCR(24) out of (80) patients having methylated BRACA1 and (56) having unmethylated BRACA1.

As discussed in this thesis, one can recommend by using BRACA1 gene as biomarker for prediction of early diagnoses.

Keywords: methylation, unmethylation, BRACA1, modification, CPG

Introduction

Epigenetic mechanisms in normal cells

Many types of human cancers and diseases are often induced by miss regulation of gene expression. Epigenetic modifications and genetic mutations are the mechanisms for this miss regulation (genetic instability) that disrupt the function of genes, including oncogenes and tumor suppressor genes, as well as other cancer-related genes ¹.

Chromatin is made of repeating units of nucleosomes, which made of ~146 base pairs of DNA wrapped around an octamer of four core histone proteins (H4, H3, H2B and H2A) ². The main epigenetic mechanisms that modify chromatin structure are: histone modifications, DNA methylation. These modifications work together to regulate the functioning of the genome by changing the local structural dynamics of chromatin, primarily regulating its accessibility and compactness. The interplay of these modifications creates an ‘epigenetic landscape’ that regulates the way the mammalian genome manifests itself in different cell types, developmental stages and disease states, including cancer (³, ⁴, ⁵).

DNA methylation

Vertebrate DNA is modified by addition of methyl residues at the 5’ position of cytosine’s residing mostly in CG (also known as CpG) dinucleotides ⁶. Not all CGs are methylated in vertebrate genomes, and the distribution of unmethylated and methylated CGs in the genome is tissue-specific, resulting in a cell specific DNA methylation pattern ⁷. The DNA methylation reaction is catalysed by DNA methyltransferases (DNMTs) ⁸, ⁹. The C-terminal catalytic domain of DNMTs transfers methyl groups onto cytosine residues within the DNA, thus methyltransferases represent the critical enzyme class responsible for hypermethylation of tumor suppressor genes. In mammals, five members of the DNMT protein
family have been discovered (Dnmt1, Dnmt2, Dnmt3a, Dnmt3b, and Dnmt3L), of which only three were shown to possess catalytic methyltransferase activity (Dnmt1, Dnmt3a, and Dnmt3b) 10.

Cancer was the first group of diseases to be related with DNA methylation alterations and to be considered for DNA methylation targeted therapeutics 15. Aberrant expression of DNMT1 and other DNMTs, hypermethylation of tumor suppressor genes, and hypomethylation of repetitive sequences and unique genes are common epigenetic features of many types of cancers (16, 17, 18).

Silencing of tumor suppressor genes by DNA methylation provides a powerful molecular mechanism by which DNA methylation can provide a rationale for therapeutics aimed at inhibition of DNA methylation trigger cancer and re-expression of silenced tumor suppressor genes 19.

The original idea driving the study of DNA methylation changes in diseased states that limited sets of candidate genes are critical for disease progression and initiation. However, unbiased approaches could potentially detect new genes and new functional gene networks that are linked with a disease, whereas candidate approaches essentially allow proof of genes that are already known to be involved. Early studies attempting to take benefit of the emerging role of methylation of promoters of tumor suppressor genes in cancer examined whether methylation of specific CGs in tumor suppressor genes associates with different breast cancer clinical states 19.

BRCA1 is directly involved in preventing cells from growing and dividing in a controlled manner and repairing damaged DNA. BRCA1 (breast cancer) gene encodes a multifunctional protein involved in DNA repair, control of cell-cycle checkpoints, protein ubiquitination and chromatin remoulding 20. It was basically detected as a gene responsible for familial breast cancer 21.

Material and Method

The study of this thesis include 20 healthy female and 80 female patients with breast cancer where their ages ranged between (30-60 years), who are suffering from breast cancer disease. The blood are collected from Medical city in Baghdad, Iraq during the period from February 2018 to April 2018.

DNA extraction kits and DNA modification kits have been used to extract and modify the DNA structural. Also nano drop techniques have been used to measure the DNA concentration before modify it. Then Polymerase chain reaction have been used with special primers designed for BRACA1 gene Table (1).

Result and Discussion

The results show that out of 80 patients with breast cancer disease 24 women’s have methylation BRCA1 gene. And the remain 56 women’s have un methylated BRCA1 gene Table (2). BRCA1 promoter methylation is associated with the early onset of breast cancer other Saudi Arabia studies also show that 13 women with breast cancer have methylation BRCA1 out of 47, and 34 out of 47 have un methylated BRCA1.
The association between BRCA1 promoter methylation and the clinicopathological features of breast tumors was assessed. A strong association ($p<0.001$) was found between BRCA1 methylation and young age ($\leq 40$ years) at diagnosis (1875% figure (1). Table (2) the proportion of methylated BRCA1 within the age of 40 and younger was 75% which confirm the important role for BRCA1 gene in the initiation and progression of breast cancer. While only 25% of the breast cancer patients aged 40 years and older have shown BRCA1 DNA methylation in from peripheral blood samples.-for more details one can see appendix (B.1) .

In Al-Moghrabi, studies show strong association between BRCA1 methylation and young age ($\leq 40$ years)

Evaluation of Hematological Parameters And DHEA-S Hormone Association with Acne In The Province Of Thi-Qar

Ayat S. Saleh1 Ali N. Salman2

1University of Thi-Qar- College of Education for Pure Sciences, Biology Department, 2University of Thi-Qar- College of Nursing

Abstract
This study was conducted in the labs of the College of Education for Pure Sciences, Al-Hussein Educational Hospital and Al-Nahrain Specialized Laboratory of the Health Department of Thi-Qar province, during the period from October 2018 to March 2019. The study included of 100 blood sample of patients with acne (39 males) and (61 females) and their age between 10-35 years. The aim of the study was to assess the level of DHEA-S hormone in acne vulgaris patients in the serum using a technique enzyme-linked immunosorbert Assay (ELISA). The study included the test of the susceptibility of phagocytic cells on phagocytosis (coefficient of phagocytosis) and measurement of hematological parameters (Red blood cell count, hemoglobin ratio, total and differential white blood cells count).

The results showed the presence elevate in the level of DHEA-S for 21 sample out of 70 patients with acne. Results showed that there was no association between disease incidence and DHEA-S when compared with the healthy control in the population of Thi-Qar province. Increase coefficient phagocytosis was significant (P≤ 0.05) in all patients with acne compared with a group of control. As for the blood parameters, the results of the present study showed no significant differences (P>0.05) in the rates of red blood cells and hemoglobin in all acne patients compared to the control group. It also showed increased rate of counting the total of WBCs and differential cell neutrophils and lymphocytes (P≤0.004), (P≤0.004), (P≤0.025), respectively in acne patients compared to healthy controls group.

Keywords: Acne vulgaris, Hematological parameters, DHEA-S.

Introduction
Acne vulgaris is the most common a chronic inflammatory disease of the pilosebaceous unit and characterized by non- inflammatory lesion (comedones with black and white heads), inflammatory lesions like (papules, pustules and nodules) (1,2). Resulting from increased sebum production, inflammatory process, androgen excess states, abnormal follicular epithelial differentiation, insulin resistance, obesity and the proliferation of Propionibacterium acnes 3.

Acne can be classified according to its severity into: mild, moderate and severe using the Global acne assessment scale 4. It occurs primarily in the oily (seborrheic) areas of the skin that involved face, neck, back and chest (5,6).

Androgen enhances sebum production and follicular keratosis plays important role in pathogenesis of acne. Therefore, testosterone, androstenedion, dehydropiandrosterone sulphat are involved in the evolution of acne 7.

The circulating androgen dehydropiandrosterone sulphat (DHEA-S) is mostly produced in the adrenal glands. DHEA-S is the highest androgen concentration in the serum in both sexes and is considered the most important regulator of sebum secretion (8,9). Elevated DHEA-S levels in male and female with acne have been repeatedly demonstrated in many studies 6. Acne is a common feature in the path of endocrine diseases distinguished by elevated levels of androgens 10.

The aim of the current study was to assessment of some blood parameters (WBCs, RBCs, HB), phagocytosis and knowledge of their relationship with acne and study of dehydropiandrosterone sulphat (DHEA-S) and its relationship with acne.
Materials and Method

Subjects :- The study groups have the following included:

This study was conducted in the labs of the College of Education for Pure Sciences, Al Hussein Educational Hospital and Al-Nahrain Specialized Laboratory of the Health Department of Thi-Qar province, during the period from October 2018 to March. The patients in this study were divided into three groups According to age :

1-First group : comprised 10 acne patients less than 20 years old.

2-Second group : comprised 10 acne patients whose ages between 21-30 years old.

3-Third group : comprised 6 acne patients whose were 31 years old and above.

In addition, the study included 30 people as a control group, with no history or clinical evidence of common acne or any other chronic disease, and have no obvious abnormalities, divided into three groups according to their age:

1-First group : comprised 10 acne patients less than 20 years old.

2-Second group : comprised 10 acne patients whose ages between 21-30 years old.

3-Third group : comprised 6 acne patients whose were 31 years old and above.

Blood sample collection: -

Blood samples were collected by venipuncture from 100 patients (39 males, 61 females) and 30 controls (five milliliters of venous blood) were drawn by disposable syringe under aseptic technique. each blood sample was divided into two parts:

a- Two milliliters were placed in a sterile tube containing EDTA for WBC deferential count and phagocytosis processes ( during 2 hour).

b- Three milliliters were put directly in a sterile Gel tube and allowed to clot , then serum was separated by centrifugation at 4000 rpm for 15 minutes. The serum was stored at -20 C˚ freezing. These sera 70 acne patients (30 male, 40 female) and 20 controls ( 10 male,10 female) were used for estimating the concentration of DHEA-S hormone.

Phagocytosis Procedure :

The procedure was carried out according 11 as follow: 0.025 ml of the collected blood was put in plane tube , then added for it 0.05 ml from Killed yeast suspension which was prepared by soluble 10 grams of Saccharomyces cerversiae yeast made in Turkish pakamaya company in 150 milliliters of normal saline and put suspension in water bathe for 60 minutes , then this suspension was filtered after cooling.

0.025 ml of HBSS were added to the mixture and incubated at 37 C˚for 30 minutes . One drop of the mixture was placed on a slid and smeared, then left to dry , fixed by methyl alcohol (99%) for min and stained for 20 min with Wright stain. then, examined under oil immersion.

No. of phagocytic cells

Phagocytosis index = × 100%

Total number of cells

Hematological assay:

The hematological tests including (total and differential WBCs counts ,RBC and Hb ) were done by using Genux Auto Hematology Analyzer in which the results read and printed automatically.

Serological assay: -

A number 1 kit was used for DHEA-S hormone, where DHEA-S hormone concentration were measured for control group (non-infected) and infected group by using the Enzyme-linked Immunosorbent Assay (ELISA) method and using the ELISA device and a measurement kit designed for this device for hormone.

Statistical Analysis

The analyses of data were expressed as mean ± SD. The comparisons between each Acne patients group with age matched healthy control were performed with T-test using computerized Minitab program. The comparisons among the three age group of Acne patients were performed with analysis of variance ( Chi – square, Odds Ratio) by using computerized Minitab 14 program. P< 0.01 was considered to be the least limit of significance . All the statistical analysis were done by
Results

Hematological parameters

RBCs, Hb count:

This doesn’t show the results of the current study in Table (1), no significant differences (p≤0.05) in blood picture of patients and healthy control group. The red blood cells (RBCs) count, hemoglobin concentration (Hb) in Acne compared with the healthy control group, where the RBCs mean are (4.89 ± 0.58) X10 cell/ml for patients and (4.98 ± 0.55) X10 cell/ml for healthy control group respectively, while the hemoglobin concentration are (13.40 ± 2.54) g/dl for patients and (13.52 ± 1.64) g/dl for healthy control group respectively, as the table (1).

Phagocytic index:

The results of the current study show significant differences (p≤0.05) in the rate of phagocytosis, as it increased the rate of phagocytosis in Acne patients to (45.89 ± 1.07) compared with the healthy control groups, and that the rate of phagocytosis (29.58 ± 1.34), as in the Table (1) and figure (1).

WBCs, Neutrophil, Lymphocytes, Monocytes, Eosinophil and Basophil count:

The results of the current study show significant differences between the two groups of patients compared with healthy controls that has been shown in Table (2). The WBCs count, Neutrophil, Lymphocytes, Monocytes, Eosinophil and Basophil in Acne vulgaris compared with the healthy control group, WBCs count that means are (9.98 ± 3.30) for patients and (8.14 ± 1.73) for healthy control group respectively, neutrophils means are (6.04 ± 2.57) for patients and (4.61 ± 1.32) for healthy control group respectively, lymphocytes means are (2.95 ± 1.08) for patients and (2.60 ± 0.60) for healthy control group respectively, while monocytes means are (3.80 ± 1.80) for patients and (3.85 ± 1.05) for healthy control group respectively, Eosinophil means are (2.05 ± 1.04) for patients and (4.65 ± 1.57) for healthy control group respectively, eventually the basophils there would have no significant difference, too and the means are(0.94 ± 0.80) for patients, and (0.78 ± 0.74) for healthy control group, as in Table (2).

Discussion

Acne vulgaris belong to a complex and multifactorial disease of pilosebaceous unit. Acne pathogenesis cannot viewed as impartial since it is etiologies influence each other. Pathogenesis of acne vulgaris recently emphasizes inflammatory process. The latest finding indicates role of P. acnes as a triggering factor of inflammatory responses which exerts an influence on severity of acne vulgaris. Pathways underlying the formation of papules, pustules, and nodulocystic acne which involve cytokines were detected. The results of the current study showed a lack of significant difference (p>0.05) in each of the concentration of RBC between the two groups of patients (4.89 ± 0.58) and healthy control group (4.98 ± 0.55), and the percentage of the hemoglobin in patients (13.40 ± 2.54) and healthy control (13.52 ± 1.64) and attribute the lack of significant differences to that the inflammation of acne doesn’t affect the effectiveness of red blood cells and its ability , as well as RBC membrane not effective and nor old and this is reflected in the level of HB ,there has been no change in rate.

Phagocytosis is considered the first line of defense against injury and carried out by Neutrophil and Macrophage and Dendritic cells, which should migrate to the places of injuries or infections in order to do its job and be the migration process in response to some of the attraction of chemical and phagocytosis one of Nonspecific immune mechanism and motivated by the entry of foreign bodies.

The current results showed significant difference in percentage of phagocytosis (P<0.05) patients with Acne (45.89 ± 1.07) and healthy control (29.58 ± 1.34). The reason of this result due to increasing the numerous of Neutrophil and Macrophage during the inflammation, and due to high levels of cytokines such IL-1α and IL-10 which belong to cellular compound inflammation that leads to the increase of phagocytosis especially in patients with acne vulgaris. This study agree with.

On the other hand there was a significant variation (p<0.05) in the WBCs count between Acne patients and the control group, the increase in WBCs may be due to the response of the immune system to face the inflammatory effects in the tissues and increase is the rise in the number of neutrophils in this study are agree with.

The results of our study showed that the proportion of hormone in males with acne (3.71 ± 1.51) compared with healthy males (1.96 ± 0.48) is higher than women where the proportion of women infected (3.31 ± 1.16) compared to healthy women (3.28 ± 1.21) Where the rise in males significantly while in females is not.
significant. The reason is probably due to the amount of DHEA-S hormone produced in the body is related to age and sex, in addition to its concentration in the blood may undergo changes during the day. As well as, the physiological role of androgens in women during adulthood is unclear. Women who suffer from hyperandro-genic disorders may develop acne, hirsutism, deepening of the voice, androgenic alopecia. This study agree with (16,17,18,19).

Evaluation of Humoral Immunological Profile in Infertile Women after IVF Failure in Baghdad City

Heba Mohammed Abed Al-Tamimi, Farhan Abood Risan

1College of Health and Medical Technology, Middle Technical University

Abstract

**Background:** An (in Vitro) Fertilization (IVF), means fertilizing an ovum with a spermatozoon outside the body in a culture dish under controlled culture conditions. And It was taken a principle option to treat infertility, which is define as a disease of the reproductive system can be diagnosis by the failure to achieve a clinical pregnancy after 12 months or more of regular unprotected sexual intercourse. The cause of infertility may be immunological or genetic. A progress was made an in vitro fertilization (IVF) techniques, However the majority of transferred embryos fail to implant. Morphology embryo scoring is the standard procedure for most IVF centers for choosing the best embryo, but remains limited since even the embryos classified as (top quality) may not implant. The initial investigation on the cause recurrent (in vitro) fertilization failure ignites the attention on the reproductive immunology. The production of antibodies is an immunomodulatory factor that causes failure of embryo implantation, and the most commonly studied antibodies in women with implantation failure after IVF procedure, include antiphospholipid (aPL), antisperm antibodies (ASA), and antinuclear antibodies (ANA).

**Objectives:** The aim of this study is to determine the immunological aspects of patients after IVF failure, such as ; antiphospholipid antibodies (aPLs), antinuclear antibodies (ANAs), and anti-sperm antibodies (ASA).

**Patients, Materials and Method:** This prospective study was undertaken on ninety infertile women undergoing in vitro fertilization (IVF) programme. Their age was from 20 years to 49 years. Blood specimens were collected from all women, on the day of egg pick up, and screened for all studied parameters by ELISA, and were statistically analyzed.

**Results:** In the present study clinical pregnancy rate was 27.8%. And the present study showed a highly significant difference (P<0.01) in aPL (IgM, IgG) between patients and control group. The data in the present study, demonstrated a highly significant difference (P<0.01) in Antinuclear antibodies (ANAs) between the studied groups. Also a highly significant difference (P<0.01) in Antisperm antibodies (ASAs) between the studied groups.

**Conclusions:** In vitro fertilization (IVF) failure, precisely failed embryo implantation, associated with produced auto-antibodies (anti-phospholipid antibodies, anti-sperm antibodies, and anti-nuclear antibodies), in the sera of the female.

**Key words:** In vitro fertilization, immunological profile and infertility.

**Introduction**

Infertility is usually defined as the disappointment of a couple to conceive after one year unprotected regular intercourse. It has been assessed that 10 –15% of couples look for medical help for fertility assessment, and the problem is obviously equally shared between male and female associates, most of the time, childlessness is some level of subfertility where 1 in 7 couples need specialist help to conceive. The infertility is divided in to; primary infertility, when never the couple have had a live birth, and secondary infertility, which means a failure to achieve live birth after having a live birth or an abortion.
The etiology of infertility is believed to be multifactorial. The realized hazard components incorporate genetic abnormalities, ovulatory disorders, tubal damage, uterine or peritoneal issues, and male factors. Unexplained infertility is characterized as absence of conception notwithstanding a year of unprotected intercourse, not clarified by anovulation, poor sperm quality, tubal pathology, or any known reason for infertility. The most applied treatments for unexplained infertility is (in vitro) fertilization, includes using standard protocols for controlled ovarian stimulation, oocyte retrieval with ultrasound management, insemination, embryo culture and trans-cervical replacement of embryos at cleavage or blastocyst-stage. Repeated (in vitro) fertilization (IVF) failure has been characterized as the lack of implantation after transfer of an embryo, which can cause physical, emotional, and financial distress for couples looking to begin family. For a significant number of ‘unexplained’ failures of IVF treatment, an immunologic basis has been suspected for a long time, and thinking about a few distinctive in vitro immune parameters, the abnormalities are related with reproductive failure in clinical cases. One of the most unexplained infertility issue in female is recurrent implantation failure (RIF). RIF is determined when transferred embryos fail to implant following several (in vitro) fertilization (IVF) treatment cycles.

There are several autoimmune factors have been associated with implantation failure result. And certain investigations concentrated on relationship between the autoimmune system and the IVF/ICSI result highlighting the role of autoantibodies during treatmen. The predominance of antiphospholipid antibodies (aPLs), and antinuclear antibodies (ANAs) was increased in unexplained infertility women. That the aPL have been described with increased frequency in women with recurrent implantation failure after (in vitro) fertilization (IVF). If aPL contained in the serum, it will have a significant impact on ovulation, fertilization and/or early embryonic development. The aPL have been presented to interact in the maternal-fetal interface causing a defective endovascular trophoblastic invasion, That aPL may induce infertility through their negative effects on implantation.

Immune or immunological infertility is identified when produced antibodies bind to the antigens spontaneously, which is occurring on either the male or female gametocytes. Antibodies bind to seminal proteins or structures present on the sperm or oocyte. So, anti-sperm antibodies (ASA) have been recognized more frequently than anti-oocyte antibodies. And the presence of ANAs is associated with immunologically estimated infertility, that the female, with high levels of ANA in their sera have also higher ANA levels in their follicular fluids, and these levels will be negatively correlated with the number of good quality embryos obtained in IVF/ICSI cycles. That ANAs could directly impact oocyte maturation and embryo development resulting in infertility. found that approximately 50% of spontaneous abortion women express ANAs, so that ANAs could be related to infertility, premature ovarian failure, and embryo transfer failure. The presence of ANAs consider a risk factor for infertile women and can be included in the mechanism, resulting in embryo implantation failure, and could impair the fertilization rate and the number of good quality embryos and thus could lead to IVF/ICSI failure.

The pathogenic mechanisms for antiphospholipid antibodies (aPL)-mediated pregnancy loss

1- aPL and intraplacental thrombotic phenomena

placental thrombosis and infarction were described. It was suggested that such an effect might be cause by the in vitro capacity of aPL, mostly anti-β2 glycoprotein I antibodies (anti-β2GP1), to induce a pro-coagulant state by disruption of annexin A5 shield on trophoblast and endothelial cell monolayers.

2- aPL and direct placental damage

Numerous evidence showed that alternative aPL, mediated pathogenic mechanisms which is directly affect placental tissue. The observation of β2GPI reactivity with trophoblast cell membranes, human stromal decidual cells, and human endometrial endothelial cells (HEECs), suggested the placental tropism of anti-β2GPI antibodies. aPL Inhibit trophoblast differentiation, which exposed via the reduced secretion of women chorionic gonadotrophin (hCG), aPL estimate trophoblast damage and apoptosis.

aPL and inflammation-mediated damage

Acute inflammatory events can be result in a negative pregnancy outcome by the activity of pro-inflammatory mediators, for example, complement, tumor necrosis factor-α [TNF-α], and chemokines that have been shown to have a role in animal models of aPL.
result in fetal loss\textsuperscript{12}

The pathogenic mechanisms for antisperm antibodies mediated pregnancy loss:

It was established that antispermatozoal antibodies impairment fertility by different mechanisms; The antispermatozoal antibodies may perhaps mask some antigens which are essential for the penetration of the spermatozoa into the ovule, Spermatozoa and antibody, can procedure complexes on uterine tissue, which triggers the excretion of histamine and makes the exclusion of the implanted embryo. It is assessed that around 5% of infertility cases are of immunological origin and related to the presence of ASAs in both women or/and men\textsuperscript{6}

The pathogenic mechanisms for antinuclear antibodies - mediated pregnancy loss

In the early stages after fertilization, the determining whether the fertilized egg would successfully develop into an embryo done by stability of nucleus, which consider the key factor in this process. In the process of mitosis, new components of the cells will be produced. Some of these components, as well as proteins, polysaccharides, and glycoproteins, may get exposed at the surface of the cells. In normal conditions, these components would not be known by the immune system. However, in an imbalanced immune system, these components may trigger the activation of autoantibodies. These autoantibodies generally associated with the components of nucleus, and ANAs have been supposed as an important immune cause of the implantation failure\textsuperscript{10}

Subjects, materials and methods

Ninety infertile couples undergoing (in vitro) fertilization (IVF) program from the Kamal Al-Samarraee IVF Center, Ministry-of Health in Baghdad-Iraq and The Institute for Infertility Diagnosis and Assisted Reproductive Technologies Al-Nahrain University in Baghdad-Iraq, enrolled in this study through the period from November / 2018 - June /2019. All couples were subjected to the basic fertility work-up of the fertility center which consists of history- taking, physical examination, ovulation detection, evaluation of tubal patency and uterine cavity, and semen analysis. The patients were divided into two groups according to success or failure IVF, into sixty five infertile women have implantation failure and didn’t get pregnant , and twenty five infertile women managed to get pregnant after where the embryos is placed in the uterine cavity in order to implant(control group). Venous blood samples were collected from all patients and healthy controls. Chemical and biological materials used in this study (to estimate to measure serum markers as ASA, aPL, and ANA) , including ; Phospholipid screen IgG/IgM ELISA, ANA Screen ELISA, and Anti-Spermatozoa Antibody (ASA) ELISA.

Results

The current study showed a highly significant difference (P<0.01) between patients ( IgM +v) and control group (aPL IgM -ve), That the mean level of of non-pregnant women and control group was (A 15.76±0.15 and B 3.5±0.31 u/ml respectively) . Also result of estimation aPL(IgG) in sera of another patients and control group show that the mean of non-pregnant women with (IgG +ve ) was (A19.7±3.22)u/ml, and for pregnant women (control IgG) was (B 0.85±0.25)u/ml. The statistical analysis shows a highly significant difference ( P<0.01) between pregnant (control group) and non-pregnant with positive result for aPL IgG (Table 1). These results were in agreement with study done by \textsuperscript{17}, that they compared with fertile control women, significant differences in the prevalences of aPLs in the IgG and IgM. All all of the IgG aPLs studied were significantly elevated over fertile control values. These results were in agreement with study done \textsuperscript{2}, who found that the results consistently showed significantly higher levels of aPL among women experiencing IVF failure.

The Socio-Psychological Variables in the Meaning of Self-Consciousness and Movement Satisfaction of Physical Education and Sport Sciences Students

Amer Saeed Jassim¹, Mustafa Jawad Mraidi², Sanna Jabbar Gatea³, Saleh Chuaied Hilaiel⁴

¹University of Babylon, College of Physical Education and Sport Sciences, Iraq, ²Ministry of education, Thi Qar Education Directorate, Iraq, ³University of Babylon, College of Physical Education and Sport Sciences, Iraq, ⁴University of Thi Qar, College Physical Education and Sport Sciences, Iraq

Abstract

This research aims at determine socio-psychological variables, self-consciousness and movement satisfaction of Physical Education and Sport Sciences students. Then, identify the relationship among the socio-psychological variable, self-consciousness and movement satisfaction of Physical Education and Sport Sciences students and predicting the socio-psychological variables in the meaning of self-consciousness and movement satisfaction of Physical Education and Sport Sciences students. In order to achieve the aims of the research, the researchers used the descriptive method by using the surveying method to recognize the variables of the research, the relationships between them and the predictions studies in order to find out how much self-consciousness and movement satisfaction contribute to the psychosocial variable. The community of the research made of Physical Education and Sport Sciences students/ University of Babylon / Fourth grade- morning classes, they were (140) students, the sample of the research made up of (15) students in order to represent the research sample by (11%), the researchers distributed the questionnaires for the research variables to the sample of the research, after analyzing and discussing the results they found out the following:

1. Physical Education and Sport Sciences students enjoy high degrees in movement satisfaction, self-consciousness and the socio-psychological variables.

2. The increasing of socio-psychological variables degrees has a relationship with the increasing of degrees in movement satisfaction, self-consciousness.

3. There is an ability of predicting the psychosocial variables, depending on the reality of movement satisfaction, self-consciousness.

Keywords: Movement Satisfaction, Self-Consciousness and the Socio-Psychological Variables.

Introduction

The Sport is considered one of the main pillars of the overall advancement of civilized societies, which explain the behavior and activates of persons in community through a set of rules and foundations, which have a direct effect in guiding the relationship among athletes in a social form that expresses the spirit of Sports and its role in creating an opportunity to race, held and work together. The Socio-Psychological variables are considered as one of the most important requirements of sport, which athlete lives in, it’s also contained things, persons and thoughts that communicated with the athlete. The Socio-Psychological variables also considered as an important factor of the psychological health of the athletes, their directions towards the team and their performance. Modern trends have confirmed that the Socio-Psychological variables in which athletes live in and a group of friends participates in it, to achieve more and better production, which makes players fell of comfortable and confidence, then it gives them the ability to adaptation and satisfaction of performance and all that is related to indications, which contains lots of Abstract factors such as feelings and emotions.
of person and team members. So, it may be say that the socio-psychological variables have a significance of player or student who face a difficult environmental situations under certain circumstances. Then, the player or the student should has a high awareness of the socio-psychological variables, because it has a great role in improving the teams’ score, because of that all athletes in the sports teams try to recognize their abilities together in order to achieve the best performance. So, athlete or student who has a motivation to achieve his maximum physical abilities, skills, knowledge and plans in order to achieve the aims of the team, which has a big role in the growth of the athlete physically, psychologically and socially. The psychological awareness is more important than all the awareness of modern life, because it studies human as the most important in the world. The self-knowledge, feeling and awareness begin from human’s observation of his/herself, with full recognition of his/her feelings as he see. Through some of starting points in which the researchers begin with, it was clear to him a clear vision in his feeling of the present research problem through the reality of the studied sample, the students of the university, the study period within the framework of the student community, in which the element of effect and effectiveness, with the varying level of awareness, culture and socialization. The university students are not immune from different circumstances and extreme life situations and conflicts and contradictions and problems that increase the requirements of life, so that there are many requirements that need to be satisfied and desires that may not be achieved, which leads them to surrender to temptations life and its charms which become urgent needs that lead the person to satisfy them in ways that may be socially unacceptable. Success in motor activity is connected with satisfaction and enjoyment, which considered as motivational elements that encourage to interesting in motor activity, the sport activities have a big and positive role to the participants in it, whether physically, mentally, socially or psychologically. Movement satisfaction is the person’s feeling of ability to achieve motor skills with his/her feeling of satisfaction and happiness as a result of performance. As Ratib mentioned “The positive previous experiences in which the player achieves success and satisfaction in any activity lead to increased willingness and desire to continue to practice the activity, which provides a better opportunity to improve the sports skills and the feeling of happiness and satisfaction as a result of achieving the aims”.

Statement of the Research Problem

One of the most important factors that contribute to the achievement of sports success is the availability of an ideal psychological and social situation for the athlete, the education is received by members of the family and society may contribute to the acquisition of many values, habits and experiences, the formulation of some rules may also contribute of behaviors that it should be directed in the light of the self-awareness of the individual and his self-building as well as the individual’s sense of motor building about the level of performance, as its measurement gives us an indication of the state of satisfaction of the learner or the athlete, so, there is no study in such a topic, thus the researchers decided to build measures for these variables to recognize the importance of the three variables and the relationship between them.

Aims of the Research

This research aims at the following:

1. Identify the changing psychosocial variables, self-awareness and motor satisfaction of students of physical education and sports science.

2. Learn about the relationship between the psychosocial variables and both self-awareness and motor satisfaction for students of physical education and sports science.

3. Predicting the psychosocial variables in the meaning of self-awareness and motor satisfaction for students of physical education and sports science.

The Research Hypothesis

The researchers hypothesized the following:

1. There is a real relationship social-psychology variables and both the self-awareness and movement satisfaction

2. There is a possibility to predict the social-psychosocial variables in the meaning of self-awareness and movement satisfaction for the students of physical education and sports science.

Limitations

1. Human limit: the students of the fourth grade in the college of physical education and sports science at
University of Babylon for the academic year 2018-2019.

3. Place limit: Classrooms of the college of Physical Education and Sports Science at the University of Babylon.

**The Basic Terms**

The social-psychosocial variable: is the qualitative aspect of interpersonal relationships, which is manifested as a sum total of psychological conditions and facilitates or hinders the productive activities and the overall development of the individual in the group, (al-Hayali: 2011, 12).

Self-awareness: identifying the individual’s feelings and vocabulary system, monitoring and deriving self-assessing results, as well as monitoring one’s own self through his/her actions and trying to influence the results of his/her actions to become more effective.

Movement satisfaction: “is the outcome of emotional feelings felt by the individual towards a particular activity, and express the extent of satisfying the appropriate needs and achieve the aims for which he/she joins this activity”.

The Methodology and Practical Procedures of the Research

The methodology of the research: the description method was used by a survey, correlation relationships and predictive studies to suit its relevance and the nature of this research.

**The Sample and Community of the Research:**

The community of the research consists of the students of college of physical education and sport science/ University of Babylon/ Fourth grade/ morning classes that made up of (140) students, the sample of the research contained (15) students to present the sample of the research with percentage of (11%).

**Tab No. (1): Shows the SD and X of the sample**

<td>10.83117</td>
<td>15</td>
</tr>
</tbody>
</table>

The previous table (1) shows that they are distinguished by a good social-psychosocial variables compared to the hypothetical mean which is (90) for having an arithmetic mean of (119,400) that means they are in a good health. This may be due to the fact that they are fourth stage students in the college of Physical Education and Sport Sciences and the positive effects of its lessons. While the degree of standard deviation, which reached (12,877), indicates a slight variation in the homogeneity of the mentioned sample of the psychiatric climate variable, movement satisfaction and self-awareness, especially if we know that the highest hypothesis of movement satisfaction and psychological variables is (150), while the highest hypothesis of self-awareness is (160) Degrees.

**Tab No. (2) Shows the value of Correlation Coefficient between Psychological variable and Movement Satisfaction**

</tr>
</tbody>
</table>
The previous table (2) shows that there is a correlation between psychological variable and movement satisfaction where the correlation coefficient reached (0.569) at the level of significance (0.01), after conducting correlations to achieve the second objective of the research, the results proved above in the table, and through the examination of the fact of correlation (Sig.) shows that the relation is strong and real, which indicates the credibility of the first hypothesis of the research, which is a real correlation between both movement satisfaction and self-awareness of the social-psychosocial variables of students of the college of Physical Education and Sports Science. This indicates that the satisfaction of the movement satisfaction a very significant contribution to the imposition of psycho-social variables, and can be explained by the results that the student who has a positive psychological variable is shown by his behavior and positive behaviors that make the student self-confidence which leads to the feeling of the student Satisfaction with his/her behavior and movements, which promotes a sense of movement satisfaction, this will achieve good results, cheers to positive self-talk, which helps the player in the formulation of goals well and work to achieve them and look at all the positive things, which makes him confident of success in his tasks and performance because of the high confidence needed, as motor satisfaction is one of the most important determinants in the development of confidence if the student’s self-image is positive, he is certainly confident and high. First in the competition.

</table>

According to Table (3), there is a strong correlation between psychological variable and self-awareness in the research sample. The correlation coefficient was (0.799). Students who have a good self-awareness helps the student to formulate aims well and work to achieve them and look at all the positive things which makes him/her confident of success in his/her tasks and performance due to the high confidence needed. Self-awareness is an important determinant in the development of confidence and enhance self-esteem. If the student’s image of himself is positive, he certainly has high confidence and good, and therefore can be said that the more self-awareness when the player positive, the higher self-esteem leading to achieve good sports results It is the top spot in the competition.

**Predicting the Psychological Variable in the Meaning of the Variables Studied**

Tests and measures may be used for the purpose of forecasting, meaning to anticipate a future outcome in the light of the results of tests and measures, and therefore use some appropriate statistical methods such as regression so that individuals who can predict their success according to a particular test can be selected.

**Array Data:**

The aim of this array is to obtain one value that reflects the psychological variables of all the sample members, as well as one value for the variable of self-awareness and the value of movement satisfaction. This measure was applied to the students in the colleges of physical education and sports sciences at the University of Babylon, which number (140) students, The data were then extracted and processed statistically by extracting the arithmetic media and standard deviations. The table below shows that.

Predicting the psychological variables in the meaning of self-awareness and movement satisfaction among students of the colleges of physical education and sports sciences:

**Array of Simple Correlations**

The main aim of this research is to predict the social-psychosocial variables in the meaning of self-awareness and movement satisfaction. This can only be achieved by knowing the simple correlations between these variables by using the Pearson equation to calculate the array of inter-correlations and Table (5) shows that.

<table>
<thead>

</tr>
</tbody>
</table>

The above table shows that there is a correlation between psychological variables, movement satisfaction and self-awareness. Social and self-awareness has reached a value of 0.799 which is also an acceptable correlation, which gives an indication that the social-psychosocial variables of the student is moving in the same direction movement satisfaction, while the relationship between the social-psychosocial variables and self-awareness has a value (0.799), which is also an acceptable correlation relationship.

The predictive value of social-psychosocial variables in the meaning of self-awareness among students of the colleges of physical education and sports sciences:

The researchers used linear regression equations and table (6) shows that.

</table>

Through Table (6), the researcher can deduce depending on the coefficients referred to, for the purpose of constructing the equation of the contribution of each of the self-awareness and movement satisfaction of the members of the research sample as follows:

Linear Regression ($y_i = \beta_0 + \beta_1 x_{i1} + \cdots + \beta_p x_{ip} + \varepsilon_i = x_i^T \beta + \varepsilon_i, \quad i = 1, \ldots, n$)

Psychological Variables = 4.420 + 0.799 X 82 (self-awareness) = 62.968

Psychological Variables = 5.004- + (0.318 X 82) + (0.408 X 101) = 62.28

**Conclusions**

Investing the present values of the studied variables in achieving the aims of physical education and sports sciences. Making attention of the social-psychosocial variables of college students through the formation of social relations between the students themselves and the teaching staff. The need to organize courses and scientific lectures for students of the college and teachers by specialists in sports psychology to promote positive values and organize the social-psychological variables when students to achieve the desired aims. The need for teachers and psychologists to hold periodic meetings with students in order to achieve the ideal social-psychosocial variables to express their feelings in a constructive manner and guide them.

Evaluation of Efficacy and Safety of Oral Cyclosporine in the Treatment of Severe Alopecia Areata

Sahar A. Majeed1, Asmaa Abdul Jaleel Swadi2, Ekhlas Sabah Hassan1

1Department of Pharmacology and Therapeutics, Faculty of Medicine, University of Kufa, Najaf, Iraq, 2Department of Pharmacology, College of Medicine, University of Al-Qadisiyah, Iraq

Abstract

Background: One of common forms of scaring hair loss is alopecia. Alopecia is an autoimmune disorder that is characterized by relapsing and remitting episodes of non scaring hair loss. Several treatment options are nowadays available to be prescribed to patients with alopecia areata including local and systemic corticosteroid therapy, immune suppressant agents and contact immunotherapy. Nonetheless, none of these agents have been 100 % effective in eradication of the disease totally and some agents are associated with intolerable side effects. Therefore, dermatologists are continuously searching for new agents and modalities in order to get better response and less sided effects.

Aim of the Study: The current study was planned and conducted to evaluate the efficacy and safety of oral cyclosporine in treating alopecia areata.

Patients and Method: This study included 35 patients with alopecia areata. The study was conducted at the dermatology unit, Al-Diwaniyah Teaching Hospital, Al-Diwaniyah Province, Mid-Euphrates Region of Iraq. The study started on June the 2nd 2018 and extended to June the 2nd 2019. The study was approved by the institutional ethical approval committee and included a verbal consent was obtained from each participant following full demonstration of the aim and procedures of the study. Every patient has received a daily dose of oral cyclosporine (3 mg/kg) for a period in the range of 2 to 12 months. Variables included in the current study were age, gender, type of alopecia areata, duration of disease, duration of treatment and treatment response. Outcome in the end of the study included clinical response and main side effects.

Results: Following treatment with oral cyclosporine, 28 patients (80 %) had satisfactory response and 7 patients (20 %) had unsatisfactory response. Treatment response was not correlated to age, gender, disease duration or type of disease (P > 0.05). There were unremarkable adverse effects in association with oral cyclosporine use.

Conclusion: oral cyclosporine is effective and safe mode of treatment in patients with alopecia areata

Key words: Cyclosporine, alopecia areata, Iraq

Introduction

In modern dermatological practice, hair loss may be broadly classified into scaring and non scaring hair loss ¹. Scarring hair loss is characterized by loss of hair follicles, whereas, non scaring hair loss is characterized by preservation of hair follicles ¹,². One of common forms of scaring hair loss is alopecia ³,⁴. Alopecia is an autoimmune disorder that is characterized by relapsing and remitting episodes of non scaring hair loss ⁵,⁶. Clinically it is classified into several forms according to the distribution of hair loss ⁷. Patchy involvement of scalp is commonly referred to as multifocal alopecia, the one which involves all scalp hair is called alopecia totalis, while the type that involves all body hair is called alopecia universalis ⁸,⁹.

The immunological basis of disease was made clear during the last 60 years owing to the discovery of several immune cells and humeral agents in close association with the disease ¹. The prevalence rate of alopecia areata has been estimated to fall between 0.1% and 0.2 %,
whereas, the lifetime incidence has been claimed to be approximately 2 % \(^1\). The data about gender variation in disease incidence are conflicting with some reports referring to a higher incidence among females \(^12\), while others have reported higher incidence rate in association with male gender \(^5\). There are no reported suggestions about ethnic predilection \(^13\). The onset of the disease can happen at any age; however, the majority of cases are seen before 40 and the mean age of onset has ranged from 25 to 36 \(^14\). The disease is often severe when being encountered in child age group \(^15\).

Familial clustering and the occurrence of disease in patients with positive family history and twins more often than general population suggest a strong genetic contribution in the causation of this dermatological disorder \(^1\). Moreover, the disease happens in association with a number of autoimmune disorders such as systemic lupus erythematosus, thyroid disorders and rheumatoid arthritis \(^14\). A physical environmental trigger has rarely been identified, but a number of psychological triggers have been linked to the onset of disease such as emotional or physical stress \(^14\).

Several treatment options are nowadays available to be prescribed to patients with alopecia areata including local and systemic corticosteroid therapy \(^16\), immune suppressant agents \(^17\) and contact immunotherapy \(^1\). Nonetheless, none of these agents have been 100 % effective in eradication of the disease totally and some agents are associated with intolerable side effects \(^17\). Therefore, dermatologists are continuously searching for new agents and modalities in order to get better response and less sided effects.

Oral cyclosporine has been regularly tested as a mode of treatment of alopecia areata by a number of researchers during the last three decades but the results were controversial \(^18-20\). Due to lack of consensus in the available published articles regarding the efficacy and safety of oral cyclosporine in treating alopecia areata and because of the rarity of national data with regard, the current study was planned and conducted in Al-Diwaniyah province, Mid-Euphrates region of Iraq to evaluate the efficacy and safety of oral cyclosporine in treating alopecia areata.

Patients and Method

This cohort study included 35 patients with alopecia areata. The study was conducted at the dermatology unit, Al-Diwaniyah Teaching Hospital, Al-Diwaniyah Province, Mid-Euphrates Region of Iraq. The study started on June the 2\(^{nd}\) 2018 and extended to June the 2\(^{nd}\) 2019. The study was approved by the institutional ethical approval committee and included a verbal consent was obtained from each participant following full demonstration of the aim and procedures of the study. Every patient has received a daily dose of oral cyclosporine (3 mg/kg) for a period in the range of 2 to 12 months. Variables included in the current study were age, gender, type of alopecia areata, duration of disease, duration of treatment and treatment response. Outcome in the end of the study included clinical response and main side effects.

Data were transferred into an SPSS (version 23) spread sheet and presented as mean, standard deviation, range, number and percentage. Mann Whitney U test was used to study difference in mean between two groups, while, Chi-square or Yates correction were carried out to assess association between any two categorical variables. The level of significance was considered at P ≤ 0.05.

Results

The currents cohort study was based on the inclusion of 35 Iraqi patients with alopecia areata. The mean age of enrolled patients was 23.69 ±10.03 years and the age range was from 10 to 40 years; most of the cases were above 15 years of age, as shown in table 1. The study included child age group cases that accounted for 10 (28.6 %), but none of patients was above 40. According to gender, the study included 24 (68.6 %) males and 11 (31.4 %) females with a male to female ratio of 1:2.18. According to type of alopecia, patients were categorized into 12 (34.3 %), 20 (57.1 %) and 3 (8.6 %) as multifocal, totalis and universalis, respectively, as shown in table 1.

Following treatment with oral cyclosporine, 28 patients (80 %) had satisfactory response and 7 patients (20 %) had unsatisfactory response. Treatment response was not correlated to age, gender, disease duration or type of disease (P > 0.05), as shown in table 2. There were unremarkable adverse effects in association with oral cyclosporine use.
Discussion

The pathophysiology of alopecia areata has been linked to immune basis a long time ago and anti-immune treatment whether local of systemic steroids or immune suppressant agents have extensively tested in treating the disease; however, complete satisfactory response has been never reached in daily dermatological practice. Therefore, there is always a need to search for new modalities in treatment approach especially if one takes into consideration the psychological trauma and poor quality of life experienced by victims who never get improved.

Cyclosporine is unusually practiced in our country when dealing with alopecia areata; however, reports from all over the world have encouraged its use in such dermatologic autoimmune disease. Nevertheless, the rate of successful remission and safety of the drug has been frequently questioned, despite the bulk of data supporting its efficient and safe use. For that reason, we in the current study included 35 patients with alopecia areata aiming at exploring the efficacy and safety of oral cyclosporine in alopecia areata and found satisfactory response in 80% of cases. Side effects were negligible especially when one takes into consideration the relatively low dose of the drug (3 mg/kg/day).

Several previous studies have found comparables results. For instance Açıkgöz et al., described significant hair growth in about 50% of enrolled cases; however, they mentioned that 3 patients have discontinued the drug because of intolerable side effects. Açıkgöz et al., have stated that they reach a dose of 6 mg/kg in some patients which is probably the cause behind intolerable side effects. Jang et al., have shown that the response of patients to oral cyclosporine was significantly better than that of oral betamethasone and that side effects were much less in association with cyclosporine use. Indeed, the findings of the latter study support the findings of the current study in that oral cyclosporine if an efficient safe treatment modality for alopecia areata. In one review it has been stated that the success rate of oral cyclosporine was in the range of 25 to 76.6% and that side effects may limit its use.

In conclusion, it is better to wait for future more research work to make clear consensus about the value
of oral cyclosporine in patients with alopecia areata; nonetheless and based on our observation and previous reports oral cyclosporine appears to be effective and safe mode of treatment in patients with alopecia areata

Removing Methods of Ultracide Residues in Imported Apple Peels in Iraqi Local Markets

Sedik A.K. Al-Hiyaly 1; Saba Riad Khudhaier 2; Jazzer, A. J. Al-Temmemi 3 and Ahmed S.A. Al-Tae 1

1 Environmental Research Center, University of Technology, Baghdad- IRAQ, 2 Department of Biology, College of Science, Mustansiriya University, Baghdad, Iraq 3 Al-Karkh University of Science, Baghdad- IRAQ

Abstract

The residues of ultracide insecticide used in controlling apple insects may have public health problems. This work was designed to find much effective method that capable of removing as much as possible of such residues from imported apple peels available in local markets. Imported apple samples were collected during winter 2018 from different local markets and divided into four subsamples as physical treatments where the first was left unwashed apple, the second was washed by tap water, the third was washed with saline solution and finally apple sample washed by tap water with acetic acid. Apple peels of all examined samples were left to dry in an oven at 85°C for 24 h and then powdered. 2.5 g from each sample was received 12.5 ml distil water to estimate the insecticide residues by using gas chromatography. It has been found that unwashed apple peels had the highest ultracide insecticide level followed by that which washed by tap water while the peels washed by saline water was obviously free from the insecticide residues.

Key words: Ultracide residues, apple peels, tap water, saline water, acidic water.

Introduction

Crop plants may severely suffer from many diseases that are induced by different kinds of organisms such as viruses, fungous, herbs, insects, rodents and other organisms. Such crop diseases would cause significant reduction and economic losses. From early ages, farmers have tried to prevent such diseases and improve crop growth by using other biological species that can control plant pathogens [1-3].

In modern agriculture, biocides in general and pesticides in particular are very efficient materials to control crop diseases and enhancing agricultural production and therefore it is used worldwide. However, such insecticides particularly those contain phosphorous and intensively used with vegetables and fruits are concerned the most toxic material that may cause severe health problems to infants and teenagers [4-6].

The randomly use of various insecticides by farmers without scientific and official surveillance in terms of trade name, type and recommended doses suggested by producing companies may lead to real public health troubles since most of these insecticides are very toxic for both the health and the environment [7,8] where such disaster related to the fungicide was occurred in Iraq during seventeenth of last century with wheat grains treated with organ mercury [9].

Organophosphorus compounds are very toxic (LD50-25) especially ultracidine pesticide which affects cholinesterase due to increasing exposure and causes reducing of the enzyme level in the blood resulting in syndromes of muscarinic, nicotinic and central nervous system damage [10,11].

The application of such compounds as agricultural insecticides being very effective in protecting various edible plant crops from different insect species [12,13] where such edible plants have large surface area capable of taking significant quantities of these insecticides [14] such as peach, apple, cherry, ground berries, grape, spinach, potato, lattice and other vegetables.

Most of these oregano phosphorene insecticides such as parathion, malathion, dipterex and ultracide may form significant public health and environmental threats where several studies have reported the inhibition of choline enzyme at higher doses [15,16].
However, handling and removing such pesticide residues was received much attention being very significant public phenomena [17-21] which needs to be investigated thoroughly and to find a proper removing method that should be accessible particularly at every home.

This work was designed to find accusable way to remove the residues of ultracide insecticide from imported apple where apple samples were collected from local markets and subjected to lab tests.

**Material and Method**

Imported apple samples were collected from local markets during winter 2018 and these samples were divided into four subsamples and subjected residues removing test where the first sample was left unwashed while the second was washed thoroughly by only tap water. The third sample was washed by diluted saline water at concentration of 1% for one minute and the forth sample was by acidic water which was tap water mixed with acetic acid at concentration of 1%. However, each treatment was replicated three times.

All apple samples after being treated as explained above were peeled and the peels placed in electric oven at 85 C° for few minutes then moved out and left to cool under room temperature. Dried peel apple samples were grinded by electric grinder and 2.5 g from each peel powder was placed in 250 volumetric flasks and received 12.5 ml distil water (1:5) and shacked for 30 min. Ultracidine pesticide residues was isolated by using chromatography/Mass Spectrometry-GC/MS following the method of previous study [22].

**Results and Discussion**

All obtained results were presented for unwashed, tap water, saline water and acetic acid water washed respectively of examined apple samples (Figures of analysis not shown).

It has been found that the residues of ultracide insecticide in apple peels of unwashed sample had highest sharp peak by the value of 87.376 among other treatments. Also, there is another peak with a value of 62.621 due to reactions of unknown materials.

The residues of organophosphorin compounds in apple peels may be accumulated in human body up to lethal dose causing severe damage of various tissues and organs and also affect cell divisions [18].

In case of apple sampled washed by tap water, it was found the ultracide insecticide residues were less than those left unwashed and had two peaks where the first peak was highest sharp peak was 12.23 while the second peak was 86.77

Again, the residues of such phosphoric compounds may be accumulated up to the lethal dose having severe effects as explained previously, the ultracide insecticide residues in apple peel after being washed by saline water.

Apparently, there was no insecticide residues in the apple samples washed by saline water but there was a small peak due to unknown material reaction. However, it seems that saline water has totally destroyed all toxic phosphorene compounds.

Finally, the ultracide insecticide residues were again totally removed from apple sample washed by acidic water (acetic acid and tap water)

The obtained results suggest that the better effective methods of removing any quantity of residues of the ultracide insecticide are washing such apples by using either saline water or acidic water that are available at all homes.

Several previous works examining similar pesticide residues removing methods were carried out worldwide. Previous work [23] has used dissolved ozone to get rid of four pesticides from vegetable which were methyl-parathion, parathion, diazinon and cypermethrin and found that low level (1.4 mg/l) of dissolved ozone was capable to oxidize up to 90% of all these pesticides except parathion within 5 minutes. Similar method (dissolved ozone) was followed by a work [24] carried on by using low concentration of dissolved ozone to remove four residues of four pesticide species and recorded a removing rate up to 99% within 30 minutes but it has reported that such removing rate was affected by temperature, concentration of applied ozone gas and preparing dissolved ozone concentration. In another study [25], five species of solutions were applied to remove blended organophosphorus pesticide residues from chines cabbage such as glycyrrhiza-mung bean, garlic juice, sods-salt, tap water and washed rice water and reported that soda-salt solution was the best removing solution while washed rice water showed very
poor effects. Another study [26] has examined the impacts of using four washing methods (tap and ozone waters, ultrasonic cleaning and boiling) on 16 pesticide residues from raw strawberries and found that within less than 5 minutes, boiling technique had the highest removing rate followed by ultrasonic cleaning and ozonized water while tap water had the lowest removing rate which were 92.9%, 91.2%, 75.1% and 68.1% respectively.

Apparently, it seems that several solutions can be used to remove pesticide residues from fresh fruits and vegetables where some of them such as ozonated, saline and acidic waters are capable of removing rate up to 90%. Nevertheless, such ability may be affected by certain variable such temperature, solution concentration and pesticide residues quantity as suggested by previous study [24]. So, the current results are supported by those of other works mentioned above but it necessary to examine other variables particularly temperature that may have significant effect on these methods used in this study.

Perception of Roles as Peer Educators in High Schools to Prevent Drug Abuse among Adolescents

Ira Nurmala¹, Elisa Dwi Pertiwi¹, Yuli Puspita Devi¹, Muthmainnah¹, Riris Diana R¹
¹Faculty of Public Health, Universitas Airlangga, Campus C Mulyorejo Surabaya 60115

Abstract

Adolescence is a transition period between childhood and adulthood, adolescent tends to have high curiosity and seek identity. Adolescent is a vulnerable group as a target for drug dealer. The objective of this study was to determine the perception of students in carrying out their duties as peer educators. This study used qualitative study approach with a case study design which intended to define the perceptions of the research subjects through in-depth interviews, observations, and also document studies. The students’ perception of their roles as peer educators such as a keeper of confidential informations, motivators, sources of information, and discussion partners. The conclusion was that the students who were selected as peer educators in their school environment had a positive perception of the application of the method to prevent drug abuse among their peers. Therefore, the application of peer educator method in high schools in North Surabaya can be used as a reference for other schools to implement peer educator method to their students.

Keywords: Student, Peer Education, Drug Abuse Prevention, School

Introduction

Adolescence is a transition period between childhood and adulthood which is characterized by changes in physical, psychological and psychosocial aspects (1). The process of independent for these adolescents are easily affected by their environment and it can lead to drug abuse (2).

Drug abuse that occurs in adolescents is caused by many factors that lead to addiction. Several factors causing drug abuse include personality, family, environment, education, and social and community, and vulnerable population factors (3).

A report from the United Nation Office on Drugs and Crime (UNODC, 2015) stated that drug abuse at 15-64 years old was as much as 3.4-6.6% of the total world population. The increase number of drug abuse also occurred in several ASEAN countries, especially Indonesia. Of the 100% narcotics transactions in the ASEAN region, 40% were in Indonesia (5).

East Java Narcotics Agency explained that in 2010 there were 2,986 cases, and then in 2011 there was an increase of 3,008 cases. The highest drug abuse occurred in adolescents between 15-19 years old with a percentage of 37.88% in 2015. Social reinforcement among students must be carried out as the basis of national development.

A research explained how to fund youth-based school programs. The article presents the rationale and content of PASS, a Danish school-based prevention program targeting cannabis-culture-related beliefs among high school students (i.e. typically 15–19 years old). The objective of the program was to prevent or delay initiation of cannabis use and limit use among students who already initiated (7).

The implementation of the peer educator was developed based on the assumption that teens will feel more open in expressing their problems to their peers. Therefore, the establishment of peer educators in the school environment is a strategy that can minimize the occurrence of drug abuse in adolescents.
The senior high schools in North Surabaya that formed peer educator method empowered their students as peer educators with the aim that students can play an active role in activities in the school environment as well as outside school activities. In carrying out the peer educator strategy, the students were required to be able to play an active and sensitive role in the social environment in their schools especially as facilitators for their friends in providing solutions and bridging the problems experienced by them. The aim of this study was to understand the students’ perception of their role as peer educators.

Material and Method

This study used qualitative study approach with a case study design which intended to define the perceptions of the research subjects. A Case Study Research was conducted to gain in depth/detail/complete information to obtain a complete picture of an event, in the sense that the data collected in the research was studied as a whole, complete and integrated.

The key informants of this study were students who appointed as peer educators. The informants were chosen to explore information according to the purpose of the study. The number of informant in this study was 10 student identified as peer-educator by the teachers.

In a qualitative case study approach, the researcher becomes the main instrument in the data collection because the aim of the research was to explore the students’ perceptions to obtain comprehensive information. Other data collection tools used to support this research were interview guidance, observations and tape recorders.

The interview guidance was prepared based on the objectives of the study, which was also guidance in the form of questions to explore the students’ perception in carrying out their roles as peer educators. The observation was done by observing the students’ access to health promotion media in the school environment such as the presence of drug abuse prevention posters. The researcher conducted an interview by using open questions. The researcher tried to create a comfortable atmosphere, so that the informants could freely convey information that the researcher wanted to obtain.

The data analysis in this study was done through some procedures, namely data reduction, data presentation and conclusion drawing. After collecting the data, the recording of the interview with each informant was transcribed and the key words related to this study was identified.

There are four forms of data analysis along with the interpretation in the case study research, namely collection of categories, direct interpretation, researcher formed pattern and found comparability between two or more categories, and later the researcher developed the result of the data obtained to infer the result of the research.

Regarding the explanation of peer educator about the program that has been running at each school, the program has varied activities. The informants explained that the existing program was considered to be less effective because of the lack of activities, so the school have to make a lot of programs that could build the students’ enthusiasm in avoiding drug abuse.

Findings

Role as a Keeper of Confidential Information

In carrying out the role as peer educators, the informants explained that their interaction with their peers was spontaneous and informal. This means that the interaction can occur anytime and anywhere (inside or outside school area). However, the principle of confidentiality should be upheld.

Seven students revealed their reason for being peer educators was because they wanted to help their peers to solve their problem. According to informants, the students tend to feel reluctant or afraid if they had to consult their problems with teachers. For example, as SK (Student 1) explained:

I want to help my friends. When they get into problems and go to the guidance counselor, they certainly will not feel comfortable. They will be less open. If they have friends to share what the feel, they will be more opened.

Although not all of the problems can be solved properly, peer educators are committed to help their peers. Peer educators also sometimes ask for help or input from the Teachers regarding problems experienced by their peers to find solutions for the problems. SK (Student 1) explained:
The problem is that there are students who tell us about their problems with their significant others, but then I cannot give them solution because I have no experience in that field. But, they said, what kind of counselor you are. That is what I experienced.

**Role as Motivators**

Based on the result of the interview, the peer educators also revealed that they have a role as motivator. They have ability to help their peers solve the problems become a motivation for them.

The peer educators encouraged their peers to solve problems without having to do negative things like drug abuse. By motivating their peers, it is hoped that this program will be able to help students to solve their problems, and motivate them to be more productive at school activities. As DH (Student 2) pointed out:

> When my friends seemed not in a good mood, I must be sensitive. I would ask them why. Maybe they are having problems or feared of something, like fear of falling into negative things. So I should motivate them.

The role of peer educators as motivators is an attitude that can be an example for other young people that as the next generation of the nation they must stay away from drug abuse by participating in positive activities at school and outside of school.

**Role as a Sources of Information**

The lack of knowledge of adolescents about the consequences of drug abuse is caused by the limited access to obtain information regarding the impact that will happen. Peer educators are students who become resources or counselors for their peer groups (11).

Peer education is a program that is implemented as a useful source of information for adolescents regarding the dangers of drug abuse so that they can avoid all kinds of drug abuse forms.

In conveying information on the dangers of drug abuse, peer educators must have good knowledge. At present, trainings are provided for the peer educators, but are still not as intensive as they once were, so the peer educators need support from the schools and the government in providing guidance and trainings for them so that they can give information to their peers optimally. The following comment was from RH (Student 3):

> [...] (The training) from the school is still minimal. Although the school gives us support but it is not maximal. There is also a funding problem.

**Role as Discussion Partners**

To achieve the goal to make students understand the danger of drug abuse, peer educators can provide peer counseling through formal and non-formal situations. Formal situation counseling can be carried out in counseling events and non-formal counseling can be done by holding a discussion (11).

The role of the peer educators as friends of discussion can also be seen from how often their friends at the school use the peer educators as facilities to exchange thoughts about information in preventing drug abuse. The following comments were from DH and KN:

> Almost every day I get questions from my friends (DH, Student 2).

Yes, (I) often (experience the same thing), it is just not as often as every day. The problem is that we are now in different classes, XII class. We often had discussion when we were still classmates. (KN, Student 5).

Students who become peer educators have the ability to understand the main tasks and roles as peer educators. However, sometimes, some cases were not well understood because the peer educators have never experienced the same things.

Actually, this can be anticipated by conducting regular joint discussion that is accompanied by teachers. The discussion can be a media to exchange views on the possibility of cases that occur in adolescents and discussion of actions to be taken so that the peer educators can carry out their role to the fullest.

**Discussion**

Perception is a process of how stimulus that influences responses is selected and interpreted the perceptions of each person towards an object is different\(^{(13)}\). Therefore, perceptions have a subjective nature. Stimulus is any physical form or verbal communication that can affect individual responses.

The previous research explained that peers are friends who can influence each other towards goodness or toward risky behavior\(^{(14)}\). In a study regarding
strategies for prevention and intervention of drug abuse among students in secondary schools in Kenya, it was showed that drug abuse was widespread among students, regardless of gender, and that there was a strong relationship between drug abuse and family members abusing drugs \(^{(15)}\).

According to the psychological abilities, adolescents, including students, have mental characteristics that are still unstable. This condition makes them vulnerable to the effects of negative interactions such as drug abuse. Students must have strong and independent attitudes and characters with the spirit to build the nation by staying away from drug abuse.

One program that has been running in several high schools in North Surabaya, is peer educator as a facility to share stories, experiences, and problems faced by students. Peer educators thought peer education to be an effective method to prevent drug abuse \(^{(16)}\). To be effective, the program is recommended to be started during middle school instead of high school, that families and local institutions should be involved in the program, and the students should be directed to participate in arts, sports, and social activities.

Goodlad (1998) explained that there are seven regulations as criteria for implementing peer educator strategy, one of which is giving trainings to students who are peer educators with assignments and explaining techniques in teaching the possibility to solve problems that are often experienced among adolescents. The Goodlad Theory provides an explanation that the school should be represented by accompanying teachers or Teachers to hold trainings so that the peer educators can carry out their duties in a good way \(^{(17)}\).

The facilities provided by the school are in the form of support to the peer educators. If there is an event outside the school that asks the peer educators to contribute, the peer educators should get a dispensation to leave the class. In addition, the guidance counselor’s room can be used as a discussion room, unless this discussion activity has not been conducted regularly.

Based on the data obtained from the peer educators and also from the teachers, there was no funding assistance from the school. The funding was intended to be developed by the peer educators in making an activity in the school environment involving the students at the school with the aim of getting to know the danger of drugs and preventing drug abuse.

From the results obtained by the informants regarding the perception of the peer educators in carrying their duties, the researcher reviewed the need to improve the support for the peer educators to be more maximal in carrying out their roles.

Peer educator prgram needs to be organized, starting from appointing a chairman of the management. The point is that it will ease the peer educators to hold meetings or discussions with other peer educators and teachers.

In addition, the guidance counselor, as a companion to the peer educators, must routinely control the development and notice obstacles faced by the peer educators. If there are problems that are difficult to solve by the peer educators, the accompanying teachers can provide input or solution.

In addition to the assistance that can be provided by the guidance counselor, the person in charge for the health unit must also routinely provide information to the peer educators. The information provided is specifically related to health impacts that will occur if adolescents commit drug abuse. Thus, in conveying the danger of drug abuse to the students, the peer educators can link it to the health problem that might occur.

The school must also involve the peer educators with activities outside the school that are collaborated with stakeholders to provide trainings for the peer educators. The activities can be in the form of counseling from the National Narcotics Agency or from the police related to the prevention of drug abuse. In addition, the school must also provide facilities to the peer educators to hold regular discussions.

**Conclusion**

The conclusions of this study are about the perceptions that arise in students who are motivated to become peer educators because they want to contribute to prevent their peers from committing drug abuse. Most students who are peer educators felt changes in themselves such as getting new friends from various classes, understanding life problems and gaining new knowledge when they were invited to the counseling. Only a few students who just felt neutral or stated that they did not feel any change in their individual self.
The constraint that was still felt by the peer educators was the lack of guidance, so that when they faced new problems that they had never experienced before, their role as peer educators could not function optimally.

Abstract

Background: Thyroid surgery has been associated with complications ranging from recurrent laryngeal nerve injury, inadvertent parathyroidectomies to death. Improvement in thyroidectomy techniques have reduced the mortality rate to minimum, while morbidity remained a significant concern. Aims: This study aims to assess a method to identify recurrent laryngeal nerve and localize the parathyroid glands during thyroid surgery by using methylene blue stain which improve outcomes following thyroidectomy.

Materials and methods: This a prospective cross-sectional study was performed on 48 adult patients of both sexes who presented to the surgical ward at Salah Al-Deen general hospital in Tikrit city between October 2017 and July 2018. Full medical history was taken and clinical examination was done to those who were suitable for surgery. After indirect larngyoscopic confirmation of normal vocal cord mobility, in addition hospital medical records were obtained including patient’s name, age, gender, residence, nature of thyroid disease, duration of thyroid disease, previous thyroid surgery, family history of thyroid disease and past medical history, relevant investigations like final histopathology; all were chosen to undergo thyroidectomy, following superior but before inferior thyroid pedicles ligation, methylene blue dye, in a concentration of 2:8 and 1:10 of Methylene Blue: Normal Saline was sprayed over the thyroid lobe and perilobar area, in the region where recurrent laryngeal nerve is predictable to be found. Recurrent laryngeal nerve and parathyroid glands were identified and safe dissection of the thyroid without injuring these structures were ensured. Results: Recurrent laryngeal nerve was not stained in all cases, in contrast to the blue stained adjacent tissue. Within three minutes parathyroid glands washed out the dye and the yellow color was regained. Conclusions: Several techniques of recurrent laryngeal nerve and parathyroid glands identification were established, our study demonstrate that visual delineation of these structures by methylene blue dye spraying during dissection of thyroid is a simple, safe and effective method for localization and injury avoidance to both recurrent laryngeal nerve and parathyroid glands during thyroid surgery.

Keywords: Recurrent Laryngeal Nerve; Parathyroid Glands; Intraoperatively; Methylene Blue Spraying Technique

Introduction

Disorders of the thyroid gland constitute the second most common endocrine disease following diabetes mellitus. The burden of thyroid disease is in an increment, therefor thyroidectomy is a very common operation, although the most frequent indications for surgery are goitre due to iodine-deficiency, other indications are: uncertainty about the nature of the thyroid mass or treatment of large goitre causing compressive symptoms, thyroid cancer and thyrotoxicosis that may or may not be refractory to medical treatment. Total thyroidectomy(TT)provides the advantages of complete removal of suspicious malignant thyroid tissue from a point and eliminating the risk of recurrence of benign conditions from another point, this resulted in increasing the number of TT.

The significant complications associated with thyroidectomy include: hemorrhage, respiratory obstruction, infection, transient or permanent
recurrent laryngeal nerve (RLN) palsy, and parathyroid insufficiency. 

A number of investigational methods for identification of RLN have been used, including visual and palpatory approach, intraoperative neuromonitoring, laryngeal nerve electromyographic activity recording, electrophysiologic nerve monitoring and staining. These techniques are accompanied with differing degrees of accuracy as well as safety to the patient and are of little help in the dissection of the tissue planes at the time of surgery, thus most surgeons nowadays prefer accurate dissection to preserve the RLN and delicate parathyroid vasculature, in order to avoid nerve injury and postoperative hypocalcaemia.

**Materials and Method**

This prospective, cross-sectional study was conducted from October 2017 to July 2018 on forty eight adult patients, belonging to both genders, with thyroid swelling who underwent thyroidectomy in Salah Al-Deen General Hospital, Iraq. The study sample involving patients with different thyroid lesions were undergoing thyroidectomy. The patients classified into 16 patients their lobar and perilobar areas stained by syringe group (A); the remaining 32 patients their lobar and perilobar areas stained by spraying pump group (B).

After positioning the patient on the operating table and induction of general anesthesia, surgical field was painted with 10% povidone iodine solution and draped. After the standard Kocher incision, total or partial thyroidectomy was performed according to the need. Following the elevation of flaps, lateral thyroid vein ligation and dissection of thyroid lobes were done. The superior pole was ligated and cut. Before ligation the inferior pedicle , the thyroid lobe rotated medially, normally at this stage the identification of RLN or the parathyroid gland is difficult ,so we spray the area with methylene blue aqueous staining solution (CDH Co. India)with the following concentrations and techniques.

In group A1: A concentration of 2:8 of (MB: NS) was sprayed over the thyroid lobe and perilobar area of 6 patients , requiring 1 min. to be stained and 2 times washing with normal saline and In group A2: A concentration of 1:10 of (MB: NS) was sprayed over the previously mentioned area in 10 patients, requiring 2 min. to be stained and rinse one time with normal saline, so In group B1:A concentration of (2:8) MB: NS was sprayed in over the lobe and perilobar area of 12 patients , the time needed for staining the tissue was 1 min. and 2 times washing for washing out the stain, In group B2:A concentration of ( 1:10 ) MB:NS respectively was sprayed over the same area in the remaining 20 patients of this group, the tissue took 2 min. to be stained without washing.

Different thyroid procedures were done for the cases of the study sample.

Statistical analysis: The Statistical Package for Social Sciences (SPSS, version 18) was used for data entry and analysis. One way ANOVA- test was used to compare mean of different factors among different groups of study sample. P value of ≤ 0.05 was regarded as statistically significant. Bar charts, and Pie graphs used to present the data.

**Finding**

The sex distribution show that 44(91.7%) of the patient were females versus 4 (8.3%) males.

The patient distribution according to the address show that 37 (77.1%) of the patient from rural versus11 (22.9%) from urban . The histopathological type was : FA 1(2.1%), HT 3(6.3%), STN 3(6.3%), MNG 26(54.2%), CG 15 (31.3%), as shown in table(1).

Intraoperatively, RLN could be identified in all the patients, as an unstained structure in the tracheoesophageal groove. The parathyroid glands washing out methylene blue stain within approximately 3 minutes and then become visible in their original yellow colour, whereas it took nearly 15 minutes for the thyroid tissue to wash out the stain in all cases. The perithyroid muscles, tendons and lipoid structures retained the blue colour for more than 30 minutes.

**Discussion**

Complications associated with thyroid surgery is comparatively reduced now a days. Standardization of the thyroidectomy technique and advances in perioperative management have led to significant decrease in the overall mortality and morbidity over the past decades (2,4,19). The most important and serious complications following thyroidectomy are RLN injury and parathyroid insufficiency (transient and permanent), when they occur, they cause catastrophic lifelong handicap (12).

Among the various risk factors that results in injury to these structures are reoperation, malignancy, retrosternal goitre, graves’ disease and surgeon inexperience (13).

Another important factor is the extent of resection i.e. TT in opposition to partial thyroidectomies. Permanent post-operative RLN palsy occurs in approximately 0.3–3% of cases and transient palsies in 3–8% of cases (Hayward 2013), while temporary hypocalcemia occurs in 50–68% of post-TT patients and permanent hypocalcemia occurs in 3% of post-TT patients (13).

The key method to protect RLN and parathyroid glands during thyroid surgery is meticulous dissection, this can be achieved by various means including capsular dissection, protection of parathyroids arterial branches and avoidance of excessive manipulation (14,15).

Several methods are used to identify the RLN intraoperatively including visual inspection first described by Lahey and Hoover in1938, laryngeal palpation, finger palpation of cricoarytenoid during nerve stimulation, intraoperative neuromonitoring (IONM), direct or fibreoptic laryngoscopy for observation of vocal cords and the use of intramuscular vocal cord electrodes (16,17).

In a current multicenter trial of 16,448 thyroidectomies, concluded that visual nerve localization, in respect to RLN, is emphasized as the “gold standard” of maintenance (18).

The technique of using dyes in identification of parathyroid glands and prevention of hypoparathyroidism, was first described by Klopper PJ and Moe RE. Initial studies were conducted using dyes like toluidine blue and tryptan blue, however, these were replaced by methylene blue as their teratogenic effects were discovered. All the studies in the literature which are associated with thyroid surgery and parathyroid staining was performed by injecting the dye via intravenous or intra-arterial route. Dudley NE applied an intravenous infusion method on 17 patients and revealed one or more parathyroid glands by this technique. Elias D et al., had
applied the similar technique over 59 cases and was able to precisely localise the parathyroid glands in 87% cases (9).

The technique above ensure the visualization of the parathyroid glands only. This is because of the rich vascularity of the glands, while RLN cannot be identified.

In our study forty eight adult patients were divided into group (A) where the spraying technique was done by a syringe in 16 patients, while in group (B) the spraying technique was achieved by a spraying pump in the remaining 32 patients.

In group A1: with the use of concentration of (2:8) MB : NS, both the concentration and the time required for staining the tissue was agree with Nofal A A ,while differ in the volume of solution needed for staining. Inasmuch we found 2ml of solution is required for adequate staining of the whole perilobar area for better identification of RLN and parathyroid glands. The number of washings required to rinse the tissue are variable with a mean 2.2 ± 0.4 while are not mentioned in any previous study.

In groups B1 and B2 the spraying technique was performed by a spraying pump with both concentrations of (2:8) and (1:10) respectively. MB: NS. We observe that the mean time for staining, number of washings and the stain volume required for staining was much less than that with a syringe insofar the staining by a pump with the concentration (1:10) did not required washing with normal saline. In addition, the resolution was better than the staining with a syringe with both concentration used. We did not find in literatures the usage of spraying pump in the staining of thyroid lobe and perilobar area for identification of both RLN and parathyroid glands.

Conclusions

- intraoperative identification of RLN and parathyroid glands by Methylene Blue Spraying is safe, cheap and readily available method which allow the surgeon especially junior one to perform safe thyroidectomy with lower level of stress.

- Both concentration of (1:10) and (2:8) mL of MB: NS by either a syringe or spraying pump helps in the identification of both RLN and parathyroid glands in all patients with disparity in resolution. The technique of spraying by a spraying pump had the superiority to that with a syringe for both concentrations ultimately for that of (1:10) mL of MB: NS in rapid and easier identification of RLN and parathyroid glands.

Evaluation of the Mexiletine Effects on Normal Cats’ Electrocardiogram

Alireza Narenjian1, Nastaran Rahimi2, Seyed Ali Shabestari Asl1

1Faculty of Veterinary Medicine, Islamic Azad University Tabriz Branch, Iran,
2Department of Pharmacy, Islamic Azad University Pharmaceutical Sciences Branch

Abstract

Mexiletine has been suggested in various studies for the treatment of ventricular arrhythmias. Extremely low toxicity of this drug has been reported in these literatures; however, there is no reasonable report on the effects and function of this drug on the cat’s heart processes in different phases of cardiac contraction. This article evaluated the effects of different dosages of mexiletine on cat’s electrocardiography.

Seven cats were used for this study and incremental dosage method with oral capsule has been used. Before starting the study, each cat were evaluated by an electrocardiogram sample, which was considered as a normal electrocardiogram (ECG). To evaluate the effects of mexiletine, doses of 4, 10, 15, 20 and 40 mg/kg were adjusted and prescribed. For each cat, the doses were prescribed sequentially every 24 hours and after prescription of the drug, the cats were examined clinically and electrocardiographically. This evaluation was done at the peak of the drug, about 2 hours after prescription. Finally, all clinical observations and ECGs were evaluated.

In the clinical study, any clinic symptoms was considered and rhythm, heart rate, and determination of heart electrical functions such as P amplitude and duration, QRS duration, R amplitude, ventricular contraction time (QT interval) and PR interval were evaluated in electrocardiographic experiments.

According to the results of this study, it can be concluded that the drug is quite safe for cats and no cardiac complication and electrophysiological disorder was observed even with the use of high doses or even incremental doses, so this indicates that the drug can be safe in terms of cardiac effects.

Key words: mexiletine, electrocardiography, cats, small animal, veterinary,

Introduction

Heart diseases are one of the most common and important diseases in human being and animals, especially dogs and cats. Among heart diseases, heart arrhythmias are assigned as a special and common group, almost (1, 2). Heart arrhythmias may generate by different origins and can produced from sino-atrial node, atrial-ventricular node and even due to electrolytes disorders. In some guidelines, treatments based on medical advices are not appropriate for animals because of a different understanding of the fundamental alterations (such as coronary heart disease versus non-coronary heart disease). Unfortunately, vet-clinicians do not know what is happening in dogs and cats with arrhythmia for various reasons and it is not possible to compare arrhythmia with different causes regardless of the outcome and the medication results (1,2).

Various classes of medications are available and used to treat cardiac arrhythmias. Antiarrhythmic drugs are mainly divided into four categories, given their potential effects on action potential. For example, selective drugs in group I, block fast sodium channels and reduce sodium inversion during the 0-depolarization step. This group is divided into 3 subgroups A, B and C with different drugs in these categories (3,4).
Due to the effects of the antiarrhythmic drug class Ib which blocks the fast sodium channel in the heart, the drug group therefore affects the zero-phase of cardiac contraction and has beneficial effects on ventricular tachy-arrhythmias. Given the performance of this class of drugs at stage zero of cardiac contraction, minimal pharmacological effects can be observed in the sinoatrial node, atrial and ventricular nodes and atrial muscles (5).

Mexiletine is one of the drugs recently proposed for veterinary use, which is an oral analogue of lidocaine. It appears to be more effective and healthier than lidocaine. Mexiletine, which belongs to group Ib, blocks fast sodium channels and has been suggested in various sources for the treatment of ventricular arrhythmias (6, 7).

Mexiletine is orally absorbed and less than 10% of this drug eliminated by the first passage of the liver. Side effects vary in dogs and include nausea, anorexia and tremor. Sinus tachycardia, imbalances, confusion and thrombocytopenia are other potential problems (1). No information is available on its use in cats (1), but in some cases it has been used to treat dogs.

For example, in a group of dogs of the Boxer breed with familial arrhythmia, mexiletine continuously tested with atenolol as one of four forms of treatment. This anti-arrhythmia treatment has been shown to decrease the frequency and degree of ventricular arrhythmia, as well as a decrease in the peak heart rate. However, the frequency of syncope has not decreased with this understanding of treatment or other methods studied. Both Mexiletine and Tocainide have synergistic properties in combination with drugs of class IA and II. These drugs are mainly used to treat ventricular arrhythmias and cardiac glycoside poisoning arrhythmias (lidocaine, Phenytoin). Tocainide is a closely related lidocaine (1, 2, 8-12).

According to the available literature and sources, no comprehensive study of the function of this drug has been evaluated in cats (2). This study, performed on 7 healthy and adult cats, studied the effects of Mexiletine on the cardiac electrophysiology of cats.

Materials and Method

Seven cats were used for this study. The cats selected were all healthy and stray. They were all short haired cats and tried to be selected from a weight class. The selected cats were also of different ages (1-3 years) and sex. All of the selected cats were clinically healthy and none showed cardiac disease at the time of examination. In addition to clinical examinations and blood tests, cardiac function was evaluated by electrocardiography to assess cardiac health in these cats.

The cats adapted to the new environment before the study and used the same commercial food during the study. The studied cats were repeatedly placed on the same examination table and trained to adapt to the environment and how to place the electrocardiogram. After adjustment with the examination table, only physical restraint was applied for electrocardiography to minimize stress at studied time.

Hexagonal electrocardiogram was obtained by Siemens single channel electrocardiography in each cat and selected as primary and control electrocardiogram.

The ECG obtained from cats at the first time (no-prescription conditions) was introduced as zero-dose (D0) and control ECG. Mexiletine is available as a 100 mg oral capsule. The drug was administered daily to 7 cats for 10 days to evaluate the drug’s effects. The doses used in this study were 4, 10, 15, 20 and 40 mg / kg. Capsules were administered orally (daily) and electrocardiograms were taken at least two hours after drug prescription in the time of drug peak effect. After 10 days of prescription of mexiletine, the cats were in rest for two weeks as drug wash out time and then, higher doses were administered to the same cats.

At the time of drug prescription, if any neurological symptoms (incoordination, ataxia, etc.) as well as gastrointestinal symptoms (vomiting and diarrhea) were observed, all cases were recorded and images and videos were obtained. Finally, in electrocardiographic examination, heart rhythm, heart rate and cardiac coordinates including P amplitude and duration, QRS duration, R amplitude, QT and PR interval were investigated. Finally, evaluation of results in this study was adjusted to mean ± SE, and the evaluation list of the results of different doses was analyzed by one-way ANOVA followed by Tukey test.

Results

All results have been evaluated for lead 2 standardization in this lead and it should be noted that no apparent abnormality was observed in any ECG and all ECGs were without arrhythmia.
In evaluating the P wave amplitude in the normal state and after administering the drug at different doses, the same results as detected in table 1 (A) were observed. According to the results, it appears that this drug has no positive or negative effect on P wave amplitude. In cats, the Pamp should not exceed 0.2 mV.

**Table 1. P wave amplitude in (mV) (A), P wave duration (B), R wave amplitude (C), QRS duration (D), PR interval (E), QT interval (F) (per second) and the number of heartbeats (in minute) in cats.**

**Figure 1.** Normal ECG of one cat (50 mm/s, 1 mv) (A), and ECG of the same cat after prescription of the drug at a dose15 mg/kg (50 mm/s, 1 mv) (B).
The same results were observed in the P duration evaluation after the administration of drugs at different doses, as shown in table 1 (B). According to the results, it seems that this drug does not have a significant effect on P wave duration. In normal cats, the normal P duration is less than 0.04 seconds.

The following results regarding the R wave amplitude obtained before and after drug administration suggest that different doses have no significant effects on the R wave amplitude. However, in some cases, some decrease in the amplitude of the R wave is observed. The amplitude of R wave varies in different references but should not be less than 0.5 mV. However, in this study, the amplitude of the R wave decreases at some doses (table 1 (C)).
There appears to be little difference in the QRS duration with different drug doses as shown in table 1 (D). It should be noted that the QRS duration should be less than 0.04 in cats.

![Figure 4. ECG of one cat before prescription of mexiletine (A), and ECG of the same cat after prescription of the mexiletine at a dose 15 mg/kg (50 mm/s, 1 mv).](image)

The PR interval time is one of the best coordinates for evaluating heart function, the results of which are measured in table 1 (E). According to our results, there is no significant difference in PR interval change. The PR interval in normal cats ranges from 0.05 to 0.09 seconds.

![Figure 5. ECG of one cat under before prescription of the drug (A), ECG of the same cat after prescription of the drug at a dose 10 mg/kg (B), and ECG of the same cat after prescription of the mexiletine with a dose 40 mg/kg in (50 mm/s, 1 mv) (C).](image)
In evaluating the ventricular contraction time (QT interval), after evaluating the ECGs obtained, the results are presented in Table 6. Due to the duration of this wave, which is typically from 0.11 to 0.18 seconds, no significant change has been achieved following the administration of different doses of this drug (table 1 (F)).

Table 1 (G) shows the heart rate in the ECG assessment of the tested cats in terms of heart rate. The results show that the heart rate varied from 111 to 333 heart beat per minutes. The heart rate appears to be highly variable both due to stress in cats and drug administration as well as the development of compensatory processes in the heart.

The results in Fig. 15 can be due to stress during ECG use or due to the heart compensatory processes due to drug administration.

In this study, a number of neurological and gastrointestinal complications have been observed due to large doses. These include temporary anorexia, tremor, obsession and incoordinance. In most cases, doses of 20 and 40 mg / kg cause symptoms of unwanted medication.

Discussion

Due to the lack of a reliable report on the effects and function of mexiletine on the electrical function of cats’ heart, the effects of this drug were evaluated in this study (2).

According to the results of this study, no increase or decrease in P wave amplitude and duration was observed and all results were normal and no significant difference was observed between different doses. So it can be concluded, this drug had no major effect on atrial function and contraction. This finding is in similar with the results of other researchers (1, 2). Therefore, it can be concluded that this drug is safe for atrial function even at very high doses.

By measuring the function of incremental doses on PR interval according to the results of this study, this drug had no adverse effects on PR interval and there was no significant difference before and after drug prescription even with the use of incremental doses (P <0.05).

According to the reports of different literatures on the absence of adverse drug effects on the dogs’ heart function (2) and also according to the findings of the present study, it was found that on R amplitude, QRS duration and ventricular contraction time (QT interval), this drug had no adverse effects on ventricular contractions (P<0.05). Therefore, mexiletine had no obvious effects on ventricular contraction strength (especially left ventricle). The evaluation of QRS duration also showed that there was no significant difference between the groups in increasing doses, so that the mexiletine had no abnormal effects on ventricular contraction time (P<0.05). But despite a slight increase
in QT interval, this increase was in normal range. Evaluation of ventricular contraction time (QTint) also revealed no significant difference between normal ECG and after different doses (P<0.05). Therefore, increasing doses of this drug did not increase the duration of ventricular contraction.

Therefore, it can be concluded that mexiletine has no adverse effects on the severity and duration of ventricular contraction even at increasing doses. It seems that mexiletine is completely safe for heart function in normal cats, indicating its safe effects on ventricular function. This seems to be the reason for choosing of mexiletine as one of the drugs of choice for the treatment of ventricular tachyarrhythmia.

Evaluation of heart rate also showed that mexiletine was able to reduce heart rate, but this change was not associated with bradycardia and there was not a significant difference in the increase or decrease of heart rate when using incremental doses (P <0.05). In only one case at doses of 20 and 40 mg / kg was observed a decrease in heart rate, which is not very abnormal at these doses.

Therefore, according to the results of this study, it can be concluded that the drug is quite beneficial and safe for cats and no cardiac complication and electrophysiological disorder was observed even with the use of high doses or even incremental doses, so this indicates that the drug can be safe in terms of cardiac effects.

Various studies have reported unwanted gastrointestinal and neurological complications while using this drug (6, 7). These studies show that the side effects are dose-related and reversible. Common complications observed in various reports include nausea, anorexia, head tilt and limb tremor, imbalance and incoordinance (2).

In this study, some of the complications mentioned in the tested cats were observed. However, these complications are individual and are usually observed at very high doses, such as 20 and 40 mg / kg. The most common complications observed in this study include temporary anorexia, tremor, obsession and imbalance. However, all of these effects were temporary and no side effects were observed when the next dose was administered or in drug wash out time. It is also suggested that the drug be used with foods to minimize the risk of drug side effects, as suggested by various studies to minimize the side effects.

However, in order to minimize drug complications in cats, a review of safe doses with a greater number of cats is needed. It seems that investigating different drug doses, as well as measuring the left ventricular ejection fraction in cats, may be helpful in adjusting the dose required in cats.

According to the results of this study, it is recommended to re-evaluate the appropriate pharmacological effects of this drug for treatment of cats with supra or ventricular tachyarrhythmia and the results to be reviewed. In addition, it is recommended to determine the necessary and safe doses for cats and it is necessary to determine the proper and therapeutic doses by HPLC.

Abstract

Introduction. Thyroid cancer is usually associated with genetic alterations. Papillary thyroid carcinoma (PTC) was found to be accompanied by point mutation occurs in a part of exon 15 in specific gene called BRAF which is a part of pathway that responsible for cell main functions such as division. The role of BRAF gene point mutation (V600E) in the occurrence of PTC was investigated in this study.

Study designs and subjects: 70 patients previously diagnosed with PTC in addition to 35 controls were recruited in this control-based study. Patients were grouped according to their ages and gender. Blood samples were collected for DNA extraction. PCR was run to detect V600E point mutation in BRAF gene.

Results: PTC incidence was found to be higher in patients aged from 40-49 years. The percentage decreased as ages increased. Females had higher PTC frequency than males, 66% to 34%, respectively. The V600E point mutation was detected in 35 patients out of 70 (50%).

Conclusion. Genetic studies have to be a part of thyroid cancer investigations. The study confirmed that PTC is usually associated with molecular defect. Other studies such as thyroid profile tests (TSH, T3 or T4) have to be done along with genetic studies for more confirmation and more understanding of this molecular defect.

Key words: PTC, BRAF, V600E and point mutation.

Introduction

Thyroid cancer is considered one of the most prevalent endocrine tumor with higher incidence rates (three-fold) in women than in men (¹). In 2008, thyroid cancer was the sixth most diagnosed cancer in women (¹,²). The frequency of thyroid cancer has increased in the recent decades due to the improvement in the diagnostic procedures and increased use of therapeutic irradiation but it still constitutes about 1% of all human malignant tumors (³). Thyroid tumors are derived primarily (90%) from thyroid follicular cells while the remainder is arising from calcitonin-producing cells or other thyroid cells (⁴). Papillary thyroid carcinoma (PTC) comprises about 90% of all thyroid cancers with incidence ages ranges from 20-50 years (⁴). Somatic mutations in BRAF gene; which is a part of signaling pathway known as RAS/MAPK pathway that responsible for controlling cell main functions such as proliferation, differentiation, migration and apoptosis, has been associated with many types of cancer including thyroid cancers (⁵). PTC is usually related to molecular defect resulted from an activating point mutation in BRAF gene (²). This point mutation is a result of thymine to adenine transversion at position 1799 (T1977A) in exon 15, leading to a replacement of valine amino acid with glutamic acid at residue 600 (V600E) which terminating with constitutive activation of BRAF kinase (²). The active kinase is believed to be produced constitutively in the presence of mutation due to the disruption in the hydrophobic interaction between the activation loop and residues in the ATP binding sites that allow the kinase to be in an inactive conformation (⁶). The mutation leads to more
interaction to be generated rendering the kinase into a catalytically competent structure (6). Mutant BRAF correspondingly exhibits higher level of kinase activity (6). The prevalence of BRAF mutation was reported by some studies in 29-83% of PTC cases as the most common detected oncogene (7-10). Poor prognosis and high aggressiveness are both related with PTCs with BRAF mutation (11). The activating point mutation in BRAF gene leads to overexpression of BRAF protein which was found in some studies to be significantly higher than that in other thyroid disorders such as multinodular goiter (MNG) (2). It is also higher in PTC with lymph nodes metastasis (LNM) than that without metastasis (2).

Keeping into mind the increased occurrence of PTC nowadays, this study was aimed to point out the frequency of BRAF point mutation (V600E) in PTC cases. The frequency of PTC among specific age groups or gender was studied as well.

**Material and Method**

**Patients and controls**

A total of 70 histologically confirmed patients with thyroid cancer admitted to Al-Sadder Teaching Hospital in Basra province/oncology unit where they prospectively considered. Patients with other types of cancer, patients undergone radiotherapy, or chemotherapy in the last three weeks; and patients with other active medical conditions such as (benign thyroid tumor, heart failure, hepatic disorder, renal failure, uncontrolled diabetes and infections) were excluded. Additional 35 persons with benign thyroid tumors were enrolled as a control group. The Ethics Committee at our institute has approved the study. The stages of PTC were classified according to the TNM staging system and related information were taken from saved patients records (12).

**Sample collection/ storage**

70 blood samples were collected from all patients in EDTA tubes for DNA extraction. PCR was run to determine the presences of BRAF (T1799A) mutation. Genomic DNA was extracted from EDTA anticoagulant peripheral blood leukocytes using Accupower® Genomic DNA extraction kit (Bioneer. Korea), and then stored at -20 C till the day of use.

**Polymerase chain reaction**

Primers used for amplification of the BRAF gene and BRAF mutant genes were designed using Primer Premier 7.0 (Bioneer. Korea ). The upstream and downstream primers; respectively, were: 5’-TCATAATGCTTGCTCTGATAGGA-3’, and 5’-GGCCAAAAATTTAATCAGTGA-3’. The amplified fragment was 224 bp in length. The reaction mix was done in 25 µl volumes including 5µl of template DNA, 12.5 µl of GoTaq®Promega Green Master Mix 2X, 2µl of primers (foreword and reverse) and 3.5µl of nuclease Free water (Applied PCR system, USA).

PCR conditions were as following: initial denaturation at 94°C for 5 min, followed by denaturation at 94°C for 30s, annealing at 60°C for 1 min and 1 min of extension at 72°C, with a final extension of 7 min at 72°C. The fragments were visualized by electrophoresis on a 1% agarose gel stained with 5% ethidium bromide. The gel was then analyzed under UV light using Cleaver Gel Documentation System (Cleaver Scientific Ltd, UK) for the presence or absence of an allele specific band.

**Statistical Analysis**

Graf pad prism 5 computer software was used to statically analyze the results. The strength of association between 2 categorical variables, such as the presence of certain grade, stage, sex and disease status, also the differences of genotype between thyroid cancer patients and control groups, the odds ratio (OR) and 95% confidence intervals (CIs) were assessed by a special χ² formula. The difference was considered significant, if \( p < 0.05 \).

**Results**

**1-Demography study**

The present study showed that maximum cases; where V600E point mutation presented, were observed in the age group (40-49 yrs) that recorded 47%, ages range between (50-59 yrs) recorded 27%, followed by 16% in (60-69 yrs) and finally 10% (70-79 yrs), Figure 1-A. The results also showed that the prevalence of mutation was higher in females ((23) 65.72%) than in males ((12) 34.28%), Figure 1-B.

2-Distribution of patients according to Staging and Grading

By returning to the saved patients’ records and as shown in table 2, the patients were classified according
to the size of tumor (T), the spread of cancer to lymph nodes (+ve for spreading and –ve for not) as well as if there is a metastasis (M1) or not (M0) were all clarified (Table 1). A significant difference (P≤0.05) was seen among different stages.

The results also showed that 14 cases (20%) were classified as grade I, while 25 cases (33.7%) and 31 cases (44.3%) were classified as grade II and III, respectively. The difference among different grades was significant (P ≤0.05).

Results of DNA sequencing

Part of exon 15 of BRAF gene was amplified using specific primers which ensures yielding a product where the length of the wild-type BRAF is 97bp while the mutant BRAF is 224bp. The results of electrophoresis of the PCR reaction products are shown in Figure 2. Nine samples were included, eight samples with PTC and one with benign thyroid tumor. The product of the eight samples were between 200 and 300 bp, while the wild-type showed a product of about 97bp. In total, BRAF V600E mutation was detected in 35 out of 70 cases (50%). No BRAF V600E mutations were detected in 35 benign thyroid cancers controls.

Discussion

Papillary thyroid cancer (PTC) is considered the most frequent malignancy that is usually associated with somatic mutations in oncogene BRAF gene \(^{(13)}\). Because of its importance in the risk prognosis and management of PTC, this gene has attracted the attention of researchers through the world in the recent years. Our study’s aim was to point out the association between the inherited BRAF variants and PTC based on a case–control study. The study showed that 35 out of 70 patients with PTC were diagnosed with V600E point mutation with a majority observed in the age group (40-49 years). The chance of having the mutation decreases gradually after the age of 50. The results also showed that gender could be a determination factor of V600E occurrence where 23 females (65.72%) were diagnosed with PTC, comparing to 12 males (34.28%). V600E has been described by many studies as the most common mutation in the BRAF which occurs in about 29%-83% of PTC cases, where classical PTC and worse patients’ outcomes can be associated. \(^{(13)}\) Importantly, research found that BRAF could play an important role in the tumor development and evolution in addition to its main role in the tumorigenesis \(^{(14)}\). Kim et al. reported that metastasis in the lymph nodes of PTC could be predicted from the BRAF V600E mutation in the primary lesion, and could be more valuable than other PTC-related factors such as age, clinical stage, and tumor size \(^{(15)}\).

Another study confirmed that BRAF gene alterations are not restricted to thyroid cancers, but they also could be seen in various cancers like malignant melanoma (27-70%), colorectal cancer (5–22%), and serous ovarian cancer (<30%) \(^{(2)}\). The progression and aggressiveness in the carcinogenesis of thyroid tissue can be indicated by the BRAF mutation and over-expression. Many other studies have focused on the association between Thyroid stimulating hormone (TSH) and PTC. A study conducted by Huang et al. found that serum TSH level below normal ranges associated with high risk of PTC among women in contrast to the risk of PTC in men where high TSH level was associated \(^{(16)}\). Boelaert et al. found high aggressiveness of malignancy in patients with solitary nodules and elevated TSH levels \(^{(17)}\). It is highly recommended that in patients at stage III or IV, the TSH level must be targeted at the undetectable level until further investigations on BRAF mutation become available \(^{(18)}\).

In conclusion, in this study we tried to point out the role of BRAF point mutation (V600E) in PTC patients especially in the ages above 40 years. Patients aged 40 to 49 years were at higher risk of having V600E mutation. As observed by many other studies, our study found that V600E is highly presented in females. The mutation was found in 50% of our study’s patients which reflect the role of this mutation in the occurrence of PTC. However, the study had many limitations such as the accessibility to only 70 patients which is considered a small sample size, and the lack of other tests results such as TSH or other thyroid hormones which could have drawn a conclusion on the relationship between any of these hormones and PTC.

Forensic and Legal Victimology Education: The Actualization of Ethical Values in Law

Djunaedi
Associate Professors, Faculty of Law, Gunung Jati Swadaya University Cirebon, Indonesia

Abstract
Ethics need to be redeveloped as an effort to build the excellent forensic and legal victimology education, and law-abiding human beings with moral value. Being ethical means, therefore the awareness of the importance of ethics must always be a basic requirement in the forensic and legal victimology education order. The relation between ethics and educations is indeed close. There are many links which make both share similarities and differences, but the difference is not meant to separate them one from another. In addition, ethics and legal norms both have the same social aims, namely humans to do deeds according to the norms of society. Without a strong ethical principle, the awareness of forensic and legal victimology education may not grow well, the education may lose its substance. Even, the forensic and legal victimology is used as a tool to merely invigorate greed and selfishness. But by sticking to ethical principles, the awareness of forensic and legal victimology might grow well, as it may deliver and elevate human standards may realize social justice in Indonesia.

Keywords: Values, Ethics, Forensic, Victimology, Law

Introduction
The awareness of legal ethics is one of the most important components in forensic education and legal victimology. Even the ethics within the said education is deemed to be more challenging to establish than building either education facilities and infrastructure or legal victimology. The awareness of legal ethics is tantamount to questioning the human characters as an object or subject of a teaching related to forensic and victimology. Therefore, the awareness of legal ethics needs to be redeveloped as an effort to build the character of students who are currently studying forensic education and legal victimology.

Forensic science reveals legal issues—specifically in criminal acts, to investigate the cause of one’s death case allegedly by poisoning in particular, the investigators will use Forensic Science and will ask for help from forensic experts. Forensics is commonly used to assist investigations in a crime case. Forensics is a field of science which is used to assist law enforcement processes through the application of science. Forensic science is applied for legal purposes by providing scientific evidence which may be used in court in solving crimes, as explained by Soekanto and Mamudji. (1)

Terminologically, according to Gosita(2) victimology means a legal study which studies the victims, the causes of victims and the consequences of victims which then become human issues as a social reality. The condition of Indonesians today shows that instead of growing further into improvement, it is evidently experiencing a setback. One of them is how the norms of decency is gradually blurred. Wiguno(3) said that there are numerous cases of rape, harassment, and crime which run rampant to other moral issues. The said norm of decency is one of the norms which applies in the society both as a barrier and reminder for each individual to not fall into such despicable act.

Legal victimology education is deemed equal as rebuilding human characters in order to learn and be more outspoken regarding existing issues, hence the
most fundamental issue in victimology is its relation to ethics.

Legal victimology issues is closely related to the existence of ethics, whereas it may be proven that when human beings are exposed to the importance of respect to others, and take care of each other’s dignity. For that reason, the actualization of ethics in human life requires such processes in a long period, in the sense of ethical education to guide human life. Ethics does not question human circumstances, yet rather on how humans should act properly, as said by Djuneaidi. (4)

It’s undeniable how humans constantly search for good things. And when humans distinguish whether something is good or not, or something should be done or not, those things happen as the humans understand those of which are deemed to be good, proper, and appropriate in order to reach the supposedly right direction, said Poespoprodjo(5) It’s the consequence of the ethics, which questions how humans act, their behavior upon their existence as human being. Basically, legal awareness will be well formed, if human individuals are aware of the importance of the ethical noble values as a guide to be expressed in various dimensions of life. Therefore, according to Keller(6) community obedience upon the existing norms might be developed by itself, which is why legal awareness is of collective awareness which needs to be supported simultaneously by individuals in order to achieve a common goal that the order of life would be more directed and run dynamically.

The legal ethics awareness issue emerges when the collective awareness of the importance of ethical values is no longer discussed in forensic education and legal victimology. Ethical values began to be fragmented of cultural influences of hedonism, pragmatism, materialism, and ego of power. So, it is crystal clear, that such influences would gradually erode the morality of forensic experts and legal victim. The impact of ethical awareness in forensic and victimology examination efforts is extremely low, the law enforcement also loses its substance if the crime is unsolved.

Method

This research used juridical normative methods and a library research about ethics and moral on the Forensic and Legal Victimology educations in Indonesia.

Findings and Discussion

In its literal meaning, the word ethics is deprived from the word ethos (singular, Greek) which then became ethics (English). Bartens(7) explained that the word ethics is rooted from ancient Greek; ethos in singular form which means customs, or good morals. The plural form of ethos is ta etha which means customs or good morals. This plural form then birthed the term of ethics which, by the Greek philosopher, Aristotle (384-322 BC) had been used to denote moral philosophy.

The word “ethics” has a number of meanings. Generally, ethics is seen as a branch of value philosophy (axiology). In this value philosophy, aside from ethics (behavior or moral philosophy). On daily basis, ethics may be interpreted as product, which then emerged the terminology of professional code of ethics, which a collection of norms which govern “the do’s and the don’ts” of a profession. Norms in a professional code of ethics are set independently (self-regulation) by those with the profession including forensic and victimology experts. It contains the vision and mission of the profession, including all traditions which involve the forensic and victimology professions. Shidarta(8) explains that the aim is nothing but to maintain the honor of the said profession.

Meanwhile, according to James J. Sphilane SJ in Muhammad(9), he considers ethics to always pay attention or consider human behavior in moral decision making. Ethics directs or connects the use of individual reason under the objectivity to determine “truth” or “mistakes” and one’s behavior toward others. While in the ethical aspects in Immanuel Kant’s view of moral values is an act which depends on the intention of the person who carries out the particular act, and such act has a moral value only if it was enacted due to obligation. This means that such act may not only have to be in accordance with what is mandated by the obligation, but it also has to be carried out in order to fulfill the obligations of the doer. According to Acton(10) an act may be considered as an obligation if it were enacted for concern of punishment or to gain advantages for others, yet said act has no moral value.

Ethics in general is to equip oneself with noble character, commendable attitude in associating and interacting with humans, or circumstances and proper approach, what might help in prevent from conducting
mistakes, or nature which may keep someone from matters which is potential to humiliation, as said by Aliyah.\textsuperscript{(11)} Hence, it can be said that the word “ethic” (manner), according to the previous Muslim writers is not indicated on the commitment to morals only, but it is also indicated on the commitment to sharia and law, the qualities that must be possessed by the authorities in power, and so forth, as mentioned by Al-Qasimi.\textsuperscript{(12)}

The Chief Justice of the United States of America, Earl Warren (1953-1969) in Asshiddiqie \textsuperscript{(13)} once said, “In civilized life, law floats in a sea of ethics”. Earl Warren called forensic science as something that can only be upheld, sailing, moving on ethics. Ethics is the foundation for the law to float on the sea. He further stated that the law could not be upheld in a fair manner if the ethical oceanic water did not flow or did not function well.

Therefore, in order for the law to be upheld and properly maintained, the development of ethical awareness in the community is very urgent. Ethics is basically very urgent. In every violation of forensic procedures and victimology provision, most of them are also a violation of ethics. Forensic officers and victimologists can let go of the criminal by changing the forensic test results or the victimology examinations if they ignore ethics.

Thus, ethical values must be explicitly stated in the law enforcement efforts that are in line with the current development. So that the education of ethical values which is the result of crystallization of human behavior must always be realized in forensics and victimology. Without ethical values, forensic science and victimology can also be controlled by crime to exploit other humans by producing false reports. For this reason, there are some basic ethical values that must be used as guidelines in building an education system of forensics and victimology to make law enforcement more authoritative, protective and giving a sense of justice.

Forensic test and victimology examination in law enforcement are vital things that must prioritize principles and ethics and must not compartmentalize humans, discredit humans, discriminate them, let alone castrate human rights. Forensic expert and legal victimologists must conduct honest examinations and in accordance with the actual fact because it is part of the ethics that must be fulfilled in the profession, said Harahap.\textsuperscript{(14)}

Thus, ethical values in the education of forensics and legal victimology are the main means that must be achieved to develop knowledge in forensics and victimology. Therefore, ethical values are the moral foundation in the development of forensic science and victimology to uphold the law in line with the empathy for humanity and the sense of justice.

According to Fernard Brundel, the current tendency for forensic experts and victimologists to betray their country and colleagues by falsifying the reports and or being half-hearted in conducting examinations, so that the mutual trust fades, the law or the institution are ineffective in maintaining order and peace, the hard work and the integrity are made into enemies, the laziness and the corruption are glorified. Ethical policies are destroyed and replaced by violence and greed.

The destroyed virtue of ethics has led to the emergence of negative connotations in the society related to the profession of forensic expert and legal victimologist such as: unethical, immoral, or uncultured. The connotations of ‘uncultured’, ‘unethical’, ‘immoral’ are people who are considered lowly civilized. This connotation is often attached to many people in the community who are considered to do the act, according to Imran.\textsuperscript{(15)}

Ethics needs to be redeveloped in an effort to build the existence of forensic expert and victimologist that are civilized and moralized. The Grand Indonesian Dictionary (KBBI-Kamus Besar Bahasa Indonesia) defines ethics as the science of what is good and what is bad, and about the obligation and rights of moral or value and the moral norm that become a guideline for a person or a group in adjusting their behavior.

Ethics and science (forensics and victimology) cannot be separated from each other, when one of them is questioned, then ethics becomes a problem. Ethics questions the problem of good and bad of human actions, ethics need to be upheld, actualized and realized in the law, with the hope to develop a legal awareness for every forensic expert and legal victimologist as a collective awareness that must be developed together in order to achieve the basic objective of the law namely justice.
Although some of these experts in the country are experiencing a moral crisis, with various unethical, immoral, and uncivilized acts, such as the misuse of authority, receiving bribes on forensic and victimology tests and other unethical actions. To realize all that, it needs to be fought by promoting ethical values as the basic rules of education that underlie it, as said by Harahap.\(^{(14)}\) Indonesia has made a policy to develop the education of forensics and legal victimology by incorporating ethical elements since 1983 to the present. Where the policy is directed toward achieving the purpose of forming forensic experts and victimologists who meet professional ethics, as mentioned by Imran.\(^{(15)}\)

Back to the ethical issue in its relation to legal awareness, in line with that, according to Franz Magnis Suseno, one of the main ethical functions is to help critically seek orientation when dealing with confusing morality. Ethics is systematic thinking, and what it produces directly is not goodness, but a more basic and critical understanding. That way, ethics can be interpreted as the attitude, the habit, the belief of a person or group with another person or group that becomes a guide for them in adjusting their behavior, said Suseno.\(^{(16)}\)

Thus, there are several main ethical functions in developing; first, ethics oriented on the behavior or the action that prioritize the values of courage, honesty and sincerity, with those values awakening the attitude and the mentality of forensic experts and victimologist to always uphold ethical values in every action and in every behavior in daily life as well as in carrying out their profession.

**Conclusion**

Education of forensics and legal victimology is not only *an sich* substantially in its field but also discusses the professional ethics, even further, because it also teaches forensic expert and legal victimologist to carry out the test based on the actual fact and present the examination result seriously and avoid all bad behavior in daily life and in carrying out the profession. Pramudya and Ananto\(^{(17)}\) said that there are many links that make the two sciences and ethics have similarities, such as both has normative nature and contain ethical norm as well as are binding.

Without a strong ethical basis, forensic experts and victimologists will not develop well, and will lose their substance, even forensic science and victimology are used as tools to strengthen greed and selfishness. However, by sticking to an ethical foundation, the awareness will develop well, because it can deliver and elevate the degree of people who work as forensic expert and victimologist, its enforcement can realize the human values that are just and civilized.

Abstract

Introduction: Stroke defined as a disease due to the trouble in the blood circulation which affected by several risk factors. It consists of fixed factors and unfixed factors. The fixed factor such as age, and gender, while unfixed factors including hypertension, blood glucose level, dyslipidemia, and job. Aims: This research aims to identify the distribution type of stroke, and risk factor which affecting the stroke patients in the RSUD Dr. Soetomo, Surabaya. Method: Research was designed as descriptive research to the stroke patient in the RSUD Dr. Soetomo, Surabaya. Various data was collected including age, gender, job, blood pressure, blood glucose level, and lipid profile when patient involved in the hospital at the first time, history of smoking, history of stroke in family. All of stroke patients in the RSUD Dr. Soetomo, Surabaya within October-December 2018 was addressed as subject in this research. Result: Result showed that ischemic stroke had the highest incidence rate in the hospital (72.6%), most of patient of stroke are male (56.2%) with age in less 65 years old (72.6%). Both hypertension 37(50.7%) respondent and smoking 29 (39.73%) respondent are the highest modified risk factor in this research. In the ischemic stroke, hypertension (62.3 %) is the highest modified risk factor. Whilst, in the hemorrhagic stroke, smoking (35 %) is the highest modified risk factor.. Moreover, the highest risk factor in all type of stroke is in age less than 65 years old (72.6%). Conclusion: Number of ischemic stroke case is higher than hemorrhagic stroke. Hypertension is defined as the highest risk factor in hemorrhagic stroke, while smoking is the highest risk factor of ischemic stroke.

Keywords: Hemorrhagic stroke, ischemic stroke, smoking, risk factor

Introduction

Non-communicable diseases (NCDs) such as heart disease, stroke, cancer, diabetes mellitus, chronic injury, and obstructive pulmonary constitute 68% (38 million) of deaths worldwide by killing 56 million people per year (1). According to the WHO, deaths of NCDs are expected to continue to increase throughout the world which the biggest increase will occur in middle and poor countries. More than two thirds or 70% of the global population will die from NCDs such as cancer, heart disease, stroke and diabetes (2). The prevalence of NCDs in Indonesia, such as strokes increased from 2007 to 2013 which was 8.3 per mile to 12.1 per mile. It increases by age. The highest stroke cases diagnosed with health workers are age 75 years and above (43.1%) and the lowest in the age group 15-24 years that is equal to (0.2%). The prevalence of stroke based on sex is more male (7.1%) compared to women (6.8%). The prevalence of stroke in cities is higher than in the villages, both based on the diagnosis of health workers (8.2 ‰) and based on the diagnosis of health care or symptoms (12.7 ‰). Prevalence is higher in people who are not working either diagnosed with health (11.4 ‰) or diagnosed with health or symptoms (18%). East Java is a province that ranks fourth and has increased from 2007 to 2013 after South Sulawesi, DI Yogyakarta and Central Sulawesi in stroke. The prevalence of stroke at the age of ≥15 years by province, East Java ranks sixth (9.1 ‰) based on health diagnosis and fourth (16.0 ‰) based on the
diagnosis of professionals or students (3). The prevalence of stroke patients in Surabaya has increased during 2007-2013. It started from 0.7% in 2007 to 16.2% in 2013 (2).

Stroke is caused by an ischemic or hemorrhagic process that is often preceded by lesions or injuries to the arteries. Of all stroke events, two-thirds are ischemic and one third are hemorrhagic. It is called ischemic stroke because of thromboembolic blood vessel blockage which results in an ischemic area under the blockage. This is different from the hemorrhagic stroke that occurs due to ruptured microaneurysm (4,5). Several factors that can cause strokes are distinguished into risk factors that cannot be changed and risk factors that can be changed. Risk factors that cannot be changed including age and male sex. Risk factors that can be changed including hypertension, diabetes mellitus, and dyslipidemia. Hypertension is defined as a condition where a person’s blood pressure exceeds the normal blood pressure limit. Hypertension is a potential risk factor for the incidence of stroke because hypertension can cause rupture of the blood vessels of the brain or cause narrowing of the blood vessels of the brain. Rupture of cerebral blood vessels will result in cerebral hemorrhage, whereas if there is a narrowing of the blood vessels of the brain it will interfere with blood flow to the brain which ultimately causes the death of brain cells. This research aims to identify the distribution type of stroke, and risk factor which affecting the stroke patients in the RSUD Dr. Soetomo, Surabaya.

Method

Research design. This research was cross-sectional design. The sample was collected by systematic random sampling method. The sample had to attain selected inclusion and exclusion criteria. The inclusion criteria were patient with Stroke diseases, willing to participate in this research, and have a complete medical history. Whilst, exclusion criteria were Stroke patients with uncompleted medical history, patients with complicated condition.

Study population and study periode. The subject in this research was inpatient and outpatient Stroke disease at RSUD Dr. Soetomo during Januari–Oktober 2018. The research sample was calculated by the formula of the cross-sectional research which included 73 respondents.

Data source and data variable. The data source in this research is primary data obtained by distributed questionnaire to Stroke patients. Whilst, secondary data obtained from medical history. Research variable in this research including dependent variable and independent variable. Dependent variable was selected as a medical history with complete information, such as age, gender, blood pressure, blood glucose level, lipid profile, Smoking history and job description. Data on age, gender and job description were obtained from primary data, whereas blood pressure, glucose level, and lipid profile were collected from secondary data. While variable of hypertension was collected from the blood test. Respondent was included into hypertension group if they have blood pressure ≥140/90 mmHg in Stroke patients without another chronic diseases and blood pressure ≥130/80 mmHg in Stroke patients with another chronic diseases. Then, variable of hypercholesterolemia was also obtained from blood test. Respondents were determined into hypercholesterolemia group if they have high density of lipoprotein ≥100 mg/dl. Meanwhile, respondents were addressed into diabetes mellitus group if they have blood glucose level of fasting about ≥110 mg/dl. Then, variable of physical activity was obtained from interview. Respondent was acknowledged into bad physical activity group if they did not have physical activity in 30 minutes for 5 times in a week.

Data analysis. Data were analyzed by univariate method. We describe all variable independent and ranked it.

Ethical Clearance. Before collecting data, This Study approved Ethical Clearance by Ethic Commision of Government Hospital Dr. Soetomo, Surabaya (Number: 0727/KEPK/X/2018). All participants were provided with written informed consent approved by the Ethics Commission of Government Hospital Dr. Soetomo, Surabaya.

Discussion

A. Characteristic of respondent. From these data, it is known that ischemic stroke types (72.60%) are higher than hemorrhagic strokes (27.39%). This result is similar to the research conducted by Mahdi Habibi-koolae (6), which also stated that ischemic stroke patients are higher than hemorrhagic stroke patients. However, it is different from the research conducted by Derrel V. Barahama (2) which exhibited more hemorrhagic stroke patients than ischemic stroke sufferers. Overall, ischemic stroke patients (66%) and hemorrhagic strokes (85%) were at most age less than 65 years old. This is similar to the research conducted by Barahama (2) which showed that more patients <65 years old who come to the hospital. More stroke patients are male in ischemic stroke and hemorrhagic stroke. In subjects with hemorrhagic strokes, 60% of the subjects were male. In subjects with ischemic stroke, 54% were male. Another study conducted by Mahdi Habibi-koolae (6) showed that male sex is more in each type of
stroke. This is supported because there is no vascular protection from endogenous estrogen in men so that it will increase the risk of stroke. In addition, lifestyle such as smoking, and drinking alcohol in men can increase the risk of hemorrhagic stroke (7).

B. Risk factor that can be change.

1. Smoking. In ischemic stroke patients (58.5%), it found that they were non-smokers. In patients with hemorrhagic strokes, 65% are non-smokers. Some study stated that smoking is a factor in determining stroke (5,8). This can happen because the majority of subjects are passive smokers. Passive smoker is a person who breathes smoke from the burning of cigarette tobacco and smoke exhaled by an active smoker (4).

2. History family of stroke. In ischemic stroke patients, only 20.8% have a history of stroke in their family members. In patients with hemorrhagic stroke, 30% of patients have a history of stroke in their family members. Some study found that there are positive associations between family history of stroke and functional status at discharge (9) lacunar stroke (10,11) atherothrombotic stroke (10,11) and the severity of early neurological deficit (12). Family history of stroke is a complex profile that includes the types of affected relatives (ie, paternal, maternal, or sibling), the ages of relatives at stroke onset (early onset versus late onset), and other characteristics. In addition, a family history of stroke may have different effects on the risk of stroke recurrence, depending on the patient’s age of stroke onset (13,14).

3. Hypertension. There are about 62.3% of patients with ischemic stroke have a history of hypertension. In patients with hemorrhagic stroke, it is only 20% who have a history of hypertension. Other study found that Blood Pressure in stroke patient are higher than in control patient without a diagnosis of stroke. Sistolic Blood Pressure on arrival significantly are higher in ischemic stroke than in controls (15). Other studies conducted by Laily and Imanda et al (5,16) also stated that there is a relationship between hypertension and ischemic stroke.

4. Diabetes Mellitus. About 22.6% of ischemic stroke patients have a history of diabetes mellitus. In hemorrhagic stroke patients, as many as 25% of patients have a history of diabetes mellitus. The prevalence of stroke with diabetes for more than 20 years in DM Type 2 patients is 7.9%, while DM Type 1 is 2.7% (17). Stroke deaths in people with DM Type 2 (13.4%) were higher than those in DM Type 2 (12.2%) (17). Diabetes mellitus is a risk factor for stroke that can be modified. In someone with diabetes mellitus, the risk of stroke increases two-fold compared with people without diabetes (18). It happens because an increase in blood sugar can increase the risk of atherosclerosis as well as other stroke risks such as hypertension, obesity, and hyperlipidemia (6). Patient with diabetes have a higher proportion of ischaemic stroke compared to haemorrhagic stroke. Microvascular disease disease dan co existence of hypertension can caused it (19–22).

C. The Rank of Risk factor

The most risk factors that are owned by ischemic stroke patients and hemorrhagic strokes are the same to those aged less than 65 years. However, second rank in ischemic strokes is a history of hypertension while ranking second in hemorrhagic stroke is male sex.

Conclusion

Based on this research, it concluded that: 1) Ischemic stroke had the highest prevalence among patients (72.6%), 2) Most of patient were 65 years old (56.2%), 3) Age of less 65 years old patient had the highest risk of any type of ischemic stroke. Moreover, the highest controlled factors among patients with ischemic stroke is hypertension history (62.3%), while among patients with hemorrhagic stroke is smoking (35%).

Data Availability

The data used to support the findings of this study are available from the corresponding author upon request and restricted by the ethics of Local Government Hospital Dr. Soetomo in order to protect subject privacy.

Conflicts of Interest: The authors confirm that there are no conflicts of interest.

Acknowledgment: We would like to thank all participants in this study including the patient as respondent. We also thank all investigators who collected and analyzed these data. It is research and publication of this article was funded by Universitas Airlangga through Faculty Public Health Research Grant in 2018.

Abstract

Diabetes Mellitus is a health disorder that is caused by an increase in insulin levels. Diabetes Mellitus, including disease, is also a risk factor for heart and blood vessel disease. Risk factors for Diabetes Mellitus itself from Abdominal/Central Obesity, Hypertension, Dyslipidemia, and smoking. This study aims to see whether there are factors associated with the place of Diabetes Mellitus in the work area of the Griya Antapani Community Health Center. The research method used is Analytical Epidemiology with a Cross-Sectional approach, Sampling many as 84 respondents. The results of study showed that there was a relationship between Abdominal/Central Obesity, Hypertension, dyslipidemia and smoking the relationship between the incidence of Diabetes Mellitus in the Working Area of the Griya Antapani Public Health Center in Bandung. Based on the results of this study, it is expected that the community will find an unhealthy lifestyle to be healthy.

Keywords: Diabetes Mellitus, Risk Factors, Elderly

Introduction

Health is a human right and one of the elements of well-being that must be realized in accordance with the ideals of the Indonesian people as referred to in the Pancasila and the 1945 Constitution of the Republic of Indonesia. Anything that causes health problems in Indonesian society will result in economic losses big for the country, and every effort to improve the degree of public health also means investment in the country’s development.1

Non-communicable diseases are one of the world’s health problems and Indonesia, which is still a concern in the world of health, non-communicable diseases are one of the causes of death.2 Non-communicable diseases, also known as chronic diseases, are not transmitted from person to person, they have a long duration and generally develop slowly.3

The Ministry of Health of the Republic of Indonesia has established a national policy to control non-communicable diseases since 2005, one of which is the “PROLANIS” or Chronic Disease Control Program implemented by the Health Social Insurance Organizing Agency.4.5

One non-communicable disease that is still a global public health problem is Diabetes Mellitus. Diabetes Mellitus is a health disorder in the form of a collection of symptoms caused by increased blood glucose levels due to deficiency or insulin resistance.6

Diabetes mellitus, besides being known as a disease, is also a risk factor (FR) for heart and blood vessel disease. Diabetes Mellitus risk factors themselves are divided into 2 (two) parts, namely: 1) Factors that cannot be modified such as Race/Ethnicity, Age, Family History, birth history > 4 kg and birth history <2.5 kg. 2) Modifiable factors such as excess body weight, central obesity, lack of physical activity, high blood pressure, cholesterol, unhealthy diet, history of impaired sugar tolerance and smoking. For this study, the researcher reviewed risk factors that could be modified or
Material and Method

This research uses a cross-sectional study. The population in this study were the elderly in the Antapani Wetan Village in the work area of Griya Antapani Health Center as many as 5938 people. So in this study the samples taken were as many as 84 people.

Discussion

Abdominal/Central Obesity

From the results of research in the field, researchers found that most of the respondents experienced Abdominal/ Central Obesity, i.e. as many as 58 respondents or 69% of the total respondents. From the results of statistical tests, the P-value is smaller than α 0.05, which means there is a relationship between Abdominal / Central Obesity and the incidence of Diabetes Mellitus.

The impact of Abdominal / Central Obesity is a higher risk to health. Abdominal /Central obesity can cause health problems such as Diabetes Mellitus and other metabolic syndromes. Metabolic syndrome is a condition in which a person experiences hypertension, Abdominal/ Central Obesity, Dyslipidemia, and insulin resistance at the same time.

A person who has Abdominal/Central Obesity (a man’s circumference> 90 cm while in a woman> 80 cm) is 5.19 times the risk of suffering from Diabetes Mellitus. It can be explained that Abdominal/Central
Obesity which is described by waist circumference can predict disorders due to insulin resistance in Diabetes Mellitus. An increase in the amount of abdominal fat has a positive correlation with hyper insulin and is negatively correlated with insulin sensitivity.\textsuperscript{10}

A person who has abdominal circumference above normal has more risk for Diabetes Mellitus. The fat stored in that part is visceral fat or visceral fat. In addition to its position in the abdominal cavity so that it covers the vital organs of the body inside it, such as the pancreas and liver, visceral fat also produces cytokine compounds and Free Fatty Acid (FFA) which is dangerous. FFA compounds cause inflammation in the body which increases the risk of developing cancer, increases the potential for coronary heart disease, and causes the body’s resistance to insulin, as the main cause of Diabetes mellitus.\textsuperscript{11,12}

**Hypertension**

From the results of the study respondents who experienced high blood pressure or hypertension as many as 52 respondents or 61.9\% of all respondents. From the results of statistical tests, p-value \( \leq \alpha 0.05 \) was obtained, which means there is a relationship between hypertension and the incidence of diabetes mellitus.

The effect of hypertension on the incidence of Diabetes Mellitus is caused by thickening of the arteries which causes the diameter of the blood vessels to narrow. This will cause the process of transporting glucose from the blood to cells to be disrupted. A person who has hypertension has 2.3 times the risk of developing Diabetes Mellitus. Increased insulin concentrations that cause hypertension occur due to increased sodium retention in the kidneys and increased sympathetic nervous system activity.\textsuperscript{13}

In addition, insulin acts like a growth hormone that can stimulate hypertrophy of the smooth muscle cells of the vessels. Insulin can also increase blood pressure by increasing intracellular calcium concentration, which will lead to increased resistance from vessels.\textsuperscript{12}

**Dyslipidemia**

From the results of the study respondents who experienced high blood cholesterol levels amounted to 58 Respondents or 51.2\% of the total Respondents. From the results of statistical tests, p-value \( \leq \alpha 0.05 \) was obtained, which means there is a relationship between Dyslipidemia and the incidence of Diabetes Mellitus.

Dyslipidemia is an abnormality of lipids (fat) in the bloodstream. These lipids include cholesterol, cholesterol esters (compounds), phospholipids and triglycerides. These materials are transported in the blood as part of a large molecule called a lipoprotein. Circulating lipoproteins that only depend on insulin and only exist in plasma glucose. Thus, the performance of the pancreas is inhibited in the spread of insulin in the body and makes blood sugar levels accumulate so that it can cause the incidence of diabetes mellitus.\textsuperscript{13}

**Smoke**

From the results of the study, a small proportion of respondents who consumed tobacco (smoking) were 13 respondents or 15.5\% of the total respondents. From the results of statistical tests, the P-value is smaller than 0.05, which means there is a relationship between smoking and the incidence of diabetes mellitus.

Nicotine in cigarettes has been shown to cause insulin receptor resistance and can reduce insulin secretion in the pancreas \( \beta \) cells. Insulin receptor resistance occurs through the nicotine process that stimulates mTOR. mTOR is responsible for cell growth, where if the activity of mTOR is excessive there will be abnormal cell growth and proliferation of insulin receptors so that the receptor does not recognize insulin anymore.\textsuperscript{14,13}

Nicotine intake can increase levels of hormones such as cortisol, which can interfere with the effects of insulin, so the risk of diabetes mellitus is higher. Respondents with active smokers are fewer in number than respondents who do not smoke (15.5\%). However, passive smokers have a higher risk of active smokers in the vicinity, which is smoking 75\% of the smoke emitted by active smokers and only smokes 25\%, so that respondents who do not smoke have a higher risk of Diabetes Mellitus.\textsuperscript{15,2,14}

**Diabetes Mellitus**

From the results of research in the field, researchers found that most of the respondents who had Diabetes Mellitus were 38 respondents or 45.2\% of the total respondents.

Diabetes Mellitus itself is defined as a disease in which the patient’s body cannot automatically control
the level of sugar (glucose) in his blood. Diabetics cannot produce insulin in sufficient quantities, resulting in excess sugar in the body. Chronic excess sugar in the blood (hyperglycemia) is toxic to the body. Diabetes Mellitus can be reduced, especially if both parents have severe diabetes, but the emergence of Diabetes Mellitus is more influenced by a bad lifestyle, even in couples who one of them is a Diabetes Mellitus sufferer, then a partner who previously did not suffer from Diabetes Mellitus, in the end, can also have it, because it follows or is influenced by their partner’s lifestyle.  

Conclusions
1. Most of the respondents experienced Abdominal/Central Obesity, high blood pressure, cholesterol Working Area of Griya Antapani Health Center, Bandung.

2. A small proportion of respondents consume tobacco (smoking) in the working area of the work area of Puskesmas Griya Antapani, Bandung.

3. Nearly some respondents have Diabetes Mellitus in the Work Area of the Griya Antapani Health Center in Bandung.

4. There is a relationship between Abdominal/Central Obesity, Hypertension, Dyslipidemia and smoking with the incidence of Diabetes Mellitus in the working area of Puskesmas Griya Antapani, Bandung.

Abstract

There are two emerging markets in Indonesia, namely traditional markets and modern markets. Traditional market reform is one of the government’s programs to improve the performance of market traders. The existence of medicine environment aspects as the development of the quality of traditional markets is important to be discussed. The greater the health and medicine environment that occur shows a reflection of the level of public welfare. its development Traditional markets are beginning to be marginalized, this is due to the quality of commodities and un health environment that are not guaranteed.

Keywords: Medicine, Environment, Traditional markets, Constitutions, Law

Introduction

In general, business competition law is the law that regulates everything related to business competition, while the terms used for this field of law, in addition to the term business competition law, namely antimonopoly law, antitrust law, as argued by Nugroho.¹ Martadisastra opines that the business competition includes all actions of business actors in the market; therefore competition law is a law that regulates the market (law regulating the market or the set of laws and regulations governing market behaviour).² Based on the above understanding, the understanding of business competition is very broad and covers all actions of business actors in the market, including unfair competition actions.

Competition law is a legal instrument that determines how competition must be conducted. Next Christopher Pass and Bryan Lowes in Hermansyah.³ Stated what is meant by competition laws are parts of legislation governing monopoly, merger and acquisition, restrictive trade agreements and anti-competitive practices. Boner dan Krueger⁴ states that competition policy includes all government policies to maintain and protect competition between buyer and seller. The aim is to improve consumer welfare by encouraging the efficient allocation of community resources, which is based on the fundamental principle that the company is competitive in conditions.

According to Boner and Krueger, quoted by Thee Kian Wie⁴ states that competition policy includes all government policies to maintain and protect competition between buyers and sellers in a free market that is relatively unconstrained. The aim is to improve consumer welfare by encouraging efficient allocation of community resources, based on the fundamental principle that in The company’s competitive conditions give consumers good prices and quality.⁶

The existence of health and medicine environment as the development of the quality of traditional markets is important to be discussed, Noor argues that the greater the volume of transactions that occur shows a stable economy and is a reflection of the level of public welfare.⁷ There are two developing markets in Indonesia, namely traditional markets and modern markets. Traditional markets are built and managed
by the Regional Government, whereas modern/central markets are sold or leased to businesses or managed by themselves to carry out trading activities of goods.\(^7\)

Modern markets provide product prices and have an health environment that is more able to answer customer demand. Compared to traditional markets that are synonymous with slums, chaos, dirty, high crime, uncomfortable, minimal facilities such as parking, toilets, trash, electricity, water, muddy and narrow streets, modern markets provide more value in the convenience of shopping. The added value offered by the modern market is what makes most customers more interested in shopping in the modern market than in the traditional market, according to Tambunan.\(^9\)

Bintoro argues that traditional markets in addition to functioning economically\(^10\) even more, important is as a place to interact with individuals in the community. Unlike the Modern Market, everything is fixed price and served by machines. this difference ultimately affects the behaviour of people’s lives, namely from a social society to an individual society. The existence of modern markets has an impact on the existence of traditional markets whose existence has decreased, it is understandable that there are striking differences between traditional markets and modern markets, especially in terms of health aspects.

This health aspect covers environmental hygiene in traditional markets. For example, not littering, packaging, cigarette butts, candy wrappings carelessly in the market environment, as well as the hygienic quality of the commodities traded. Problems arise when modern markets begin, entering the realm of traditional markets. Tambunan opines that this aggressive expansion of the establishment of a modern market shopping centre has already been granted by the Regional Government, where the process of granting permits for local authorities is not done transparently and often clashes with various personal interests therein.\(^9\)

**Findings and Discussion**

The emergence of a modern market is indeed beneficial for consumers, but a threat to the existence of traditional markets. The rapid growth of modern markets with hygienic conditions, not only influences the number of traditional markets but also greatly affects the income of traders in traditional markets. According to Boeke in Sutrisno, there is a dichotomy between modern markets and traditional markets in Indonesia\(^12\) The two economic systems are not transitional economic systems in which the nature of one is getting weaker and the other is getting stronger, but both are side by side with different systems.

The existence of markets, especially traditional markets, is one of the most tangible indicators in the economic activities of a region’s community. The government must pay attention to the existence of traditional markets as one of the public facilities that support the economic activities of the society. The development of the era makes the existence of traditional markets threatened. However, traditional markets are still able to survive and compete amid the rush of modern markets in various forms, as argued by Indrakh.\(^13\) For people who think positively will most likely behave, that “traditional markets have lost competitiveness” because infrastructure is far behind amid modern markets and poor health aspects in traditional markets.

In business, activity can be ensured that competition occurs between business actors. One important essence for the implementation of market mechanisms is the competition of market participants in meeting consumer needs. In the health aspect of the business will endeavour to create, package, and market the products that are owned by the goods or services as well and as attractive as possible so that they are in demand and are bought by consumers.

The problem of traditional market competition is a logical consequence arising from the presence of modern markets. Problems arise when modern markets begin, entering the realm of traditional markets. According to Tambunan, this aggressive expansion of the establishment of a opping centre or modern market has received permission from the relevant Regional Government where the process of issuing permits by local authorities is not done transparently and often clashes with various personal interests in it.\(^9\)

**Method**

The research method used descriptive study. This research was at the same time prescriptive research, namely research aimed at providing solutions to problems rather than theoretical testing. This research was research that connects the essence and reality of developing medicine environment in the traditional market.
Competition in business can have positive implications, on the contrary, it can become negative if it is carried out with negative behaviour and an economic system that causes it to be uncompetitive. Business competition which is carried out negatively or is often termed unfair competition, according to Hikmahanto Juwoana, according to Nugroho. Will result in a) death or reduced competition between business actors; b) the emergence of monopolistic practices, where the market is controlled only by the business actor; and c) even the tendency of business actors to exploit consumers by selling expensive goods without paying attention to adequate quality.

The increasingly unavoidable investment liberalization has made traditional markets increasingly pushed by the presence of modern markets that offer more commodity advantages, price and convenience. Conditions like this, of course, very influential on the level of growth of traditional markets. On the one hand the emergence of modern markets is indeed beneficial for consumers, but it is a threat to the existence of traditional markets, as argued by Malono.

Law No.5 of 1999 is in line with the spirit of the Pancasila and the 1945 Constitution, particularly Article 27 Paragraph (2) and Article 33. This can be seen from the sound of Article 2 and Article 3 of Law Number 5 the Year 1999 concerning the principles and objectives of establishing Law Number 5 of 1999. Article 2 states, “Business actors in Indonesia in carrying out their business activities are based on economic democracy by taking into account the balance between the interests of business actors and the public interest”. for the rapid growth of the modern market in Indonesia. Whereas Article 3 states the purpose of establishing this law is to: a) safeguard the public interest and improve national economic efficiency as an effort to improve the welfare of the people; b) create a conducive business climate through the regulation of fair business competition so as to ensure the certainty of equal business opportunities for large businesses, medium business actors, and small business actors; c) prevent monopolistic practices and or unfair business competition arising from business actors.

The market mechanism turns out to lead to a dualism of economic activities, especially trade, which in turn will also refer to dualism of other aspects such as land use distribution, environmental health, and socio-cultural conditions. In trade, the superior group usually appears that dominates the inferior group. Emerging modern markets amid the existence of traditional markets, different and adjoining economic systems, more wide open as the times. a condition where “superior” coexists with “inferior” so that there is a gap between “superior” and “inferior”.

Dualism (modern markets with traditional markets), one of the consequences in the development of trade areas The differences in zoning management and regulation are often not counted in providing spatial patterns. Planned which eventually lead to fiction and the pros and cons of his presence. This phenomenon makes us take into account the development of an area from the planning period so that the coexistence of the two situations is not opposite or antagonist, but as complementary or inter-dependency. Reformulation of business competition law as an effort to realize integration of traditional and modern markets requires various policies such as spatial planning policies, zoning regulations, development plans for the production sectors, regulation of economic infrastructure (including regulation of functions and determination of market locations), licensing, fiscal and monetary, etc. So that there is no mutual domination, modern markets cannot dominate traditional markets, otherwise traditional markets cannot dominate modern markets. So that the reformulation of business competition law as an effort to realize the integration of traditional markets and modern markets can be done through three aspects: regulatory aspects; structuring aspects and market cementation aspects.

Traditional markets that are spread both in cities and villages have distinctive features in the buying and selling process, not only as a meeting place between sellers and buyers, but also a place for very personal relations, a place of information resources, and an important means of power support the economy of cities and villages. The market is a social institution that is regulated by norms and sanctions and is formed through social interaction. This opinion confirms that the market is not just an economic space, but also as a social space. It is in this space (the market) that social capital is activated which ties social relations together and allows for lasting economic transactions.

Traditional markets have the potential that cannot be ignored both economically and socially. First, economically, the traditional market is able to support
thousands of people or is an arena to meet the needs of life or space for the empowerment of the people’s economy. Second, the traditional market as a public space is an arena to form relationships of socio-economic relations, in which the values of mutual trust, mutual respect, and feelings of empathy for each other are built. Third, naturally, in the traditional market a community of various social groups has been built, ranging from large traders, small traders, foster workers, and buyers.

There are things that traditional markets have that don’t exist in the modern market. The development of modern markets in various categories (minimarkets, supermarkets, hypermarkets, department stores) will become competitors that will be able to threaten the presence of traders in traditional markets, because of the existing reality, buyer segments for certain types of goods (nine staples) between traditional markets and modern markets are not much different (the same), this is because there is almost no significant price difference for the types of staple goods between modern markets and traditional markets, even for certain types of commodities such as sugar and cooking oil prices in Modern markets are cheaper than prices in traditional markets.

Considering the important role of traditional markets from the socio-economic aspects of society, protection of the existence of traditional markets is absolutely necessary by making efforts to synergize the strengths of modern markets with the weaknesses of traditional markets. The existence of modern markets must be able to maintain the existence of traditional markets and not vice versa. One way that can be done by the government is by issuing several laws and regulations governing the pattern of relations and structuring between traditional markets and modern markets. So, the laws in the form of laws and regulations are able to realize the protection of traditional markets. Through reformulation of regulations regarding the types of commodity commodities that can be traded in the modern market, and the types of commodity commodities for the traditional market share, there will be hormonal or synergy (mutual symbiosis) between traditional markets and modern markets. The intended integration can be in the form of physical integration, distribution channel integration, and regulation integration.

Market segmentation is an attempt to classify markets, from heterogeneous markets to market parts that have a homogeneous nature, according to Gitosudarmo. Market segmentation can also mean the division of markets into different groups of buyers who may require separate marketing or products, as argued by Kotler and Armstrong. So market segmentation is a comprehensive process where companies must pay attention to the purchase of each segment, at least the business will be more economical if the purchase units are grouped into several groups. This all can not be separated from efforts to achieve maximum profit.

The formulation of target markets in market segmentation can be done on the basis of regional criteria, regional density, population criteria such as age, gender, education, income and so on, psychiatric criteria (psychographic criteria) such as lifestyle, personality, product use behavior criteria (behavioral criteria) and various other criteria, such as the criteria for the benefits sought by consumers in selecting / consuming products (benefit segmentation). If the quality of traditional market health is improved, it will lead to an increase in consumers. The influence of the health aspects of both goods sold and the environment causes an increase in trader income. So that a positive and significant effect on the welfare of traditional market traders.

Conclusion

Reformulation of business competition law in the medicine environment is carried out to integrate traditional markets and modern markets so that one is not superior and dominates the inferior group. So that the modern market cannot dominate the traditional market otherwise the traditional market cannot dominate the modern market. Integration can be done through three aspects: regulatory aspects; structuring aspects and health aspect. Every citizen and state operator must obey the law with the principle of justice. the government must also pay attention to environmental medicine as a guarantee of the quality of traditional markets.

Triability or Observability That Influences The Youth Decision Using Mobile Application “Remaja Sehat”?

Puling Siswantara¹, Muthmainnah¹, Riris Diana R¹, Astri Meidah S¹
¹Faculty of Public Health Universitas Airlangga

Abstract

Reproductive health of adolescents in Indonesia has become an unresolved priority problem and the number of its cases keep increasing from year to year. It caused by access to information and adolescent health programs that are haven’t been distributed evenly. In fact, not all programs use the media that is in line with the current characteristics of adolescents. Media is an adolescent health promotion strategy that has to be considered in order to increase knowledge. There have been many kinds of media related to adolescent reproductive health in the form of posters, leaflets, public service announcements and so on. According to the previous research, during all this time the media tend to be patronizing and boring. The adolescents nowadays will not be far from gadgets, so researchers have developed “Remaja Sehat” application as a media for adolescent health education. The purpose of this study was to analyze the effect of media on the variables of triability and observability on the decision to use “Remaja Sehat” application.

This research was conducted to high school students in Surabaya. The method used in this research is the Quasi Experiment and uses post only design. Samples in this study were 302 conducted by using simple random sampling. The students were given a number of questions in the questionnaire after be given intervention in the form of exposure to a healthy adolescent application.

The results showed that there was a significant effect on triability (p value = 0.000) and obsevability (p value = 0.042) on the decision to use “Remaja Sehat” application. Based on this research, it can be concluded that the “Remaja Sehat” application can be used as a media for health promotion which matches the characteristics of adolescents.

Keywords: application, decision, adolescents, observability, triability

Introduction

Indonesia is one of the countries that still have problems in the field of health, especially in adolescent reproductive health. Health problems in Indonesia still become one of the things that have to be considered both in terms of the community itself as well as the health sector. Perpetrators of the community one of which must be considered are the adolescent. The adolescent is the age of transition to maturity. This age forms the identity of a person and will go through a process of instability both in psychological or feelings. The physical organ, psychological and intellectual of one’s health will be more productive and develop rapidly in adolescence because at the age of adolescence have a great curiosity and the behavior of wanting to try new things is high.

The age of adolescents according to WHO are 10-24 years old and geographically adolescents are divided into two groups, namely the 10-14 year age group and the 15-19 year age group. While the age of adolescents according to the BKKBN are 10-24 years old and unmarried. Adolescence is a transition period that has challenges of risky sexual behavior.

Adolescent sexual risk behavior can be described through one of the previous studies. Adolescents whose sexual behavior not at risk and the one who at risk were exposed through almost the same media, where adolescents whose sexual behavior not at risk using the internet as many as 25 people (32.1%). Likewise, adolescents with risky sexual behavior using the internet as many as 53 people (67.9%). The results of the bivariate analysis showed there’s no significant
relationship between electronic media and adolescent sexual risk behavior\(^2\).

Chi-square test results show there is a relationship between smartphone usage and adolescent sexual behavior in senior high school “X” Jember (p-value = 0.004; CI = 95\%). Exposure to pornography when the adolescents access the internet and social media through smartphones raises the desire of adolescents to engage in sexual behavior by their self (onani or masturbation) or with their partners (holding hands, hugging, kissing the forehead, kissing the cheeks and kissing the lips)\(^3\). It can be seen that adolescent sexual behavior can be affected by exposure to the media used so there need to be a media that can provide knowledge about adolescent reproductive health issues.

Knowledge of adolescent reproductive health is very important in the role of adolescent health. The higher knowledge of adolescents about adolescent reproductive health will cause a decrease in adolescent sexual behavior and vice versa\(^4\). One of the ways to increase knowledge is through the media as learning media. Media is all forms of intermediaries used by humans aiming to convey or spread ideas, thoughts or opinions\(^5\). The media as the means to deliver the information or messages whether it’s ideas or opinions to get thoughts, feelings, attention and to make effective and efficient communication. Media can also be a learning method in order to increase knowledge.

There are three types of exposure to mass media such as printed media (newspapers and magazines), radio, and television other than that, regarding exposure to the internet\(^6\). There are fifteen percent of women and 20 percent are not exposed to all three information media in a week. So that the three types of mass media can develop along based on their level of education. But the internet nowadays is not only for an adult age, but even adolescents can’t get far from the internet.

One of the ways to measure the effectiveness of media is by using the Diffusion of Innovations. Diffusion is one type of communication where the characteristic of the main message being communicated is new or can be called innovation. Diffusion is also an innovation communication process between citizens using a certain channel and a certain time\(^7\).

The Remaja Sehat application is one of the educational innovations regarding reproductive health knowledge that will be given to adolescents. The Android-based application will be used as an educational medium for adolescents. Adolescents are more enthusiastic about new things, including the development of information and technology. Adolescents use an android smartphone because it has excellence over other types of mobile phones. The excellence in applications and appearance is more attractive. The easiness of downloading applications through Google Play\(^8\). This application was designed based on the results of previous studies. The results showed that during all this time, adolescent health program methods still tend to be patronizing and boring so that it requires methods that are matched to the current characteristics of adolescents\(^9\).

Diffusion of Innovations has various characteristics in innovation including Triability and Observability. Triability is the possibility to be tested from an idea or innovation. While Observability is the level of results of an innovation that can be seen easily from the technical-economic advantages so it can accelerate the adoption process \(^10\). An innovation in order to reach the goals that want to be achieved it must be right on target at its usefulness. Therefore, this study will analyze the effect of triability and observability on the decision to use Remaja Sehat application.

**Material and Method**

This study uses a pre-experimental method. Researchers will provide intervention in the form of exposure to Remaja Sehat application and then will be given a questionnaire about Triability and Observability and the decision to use Remaja Sehat application. This research refers to the theory of diffusion of innovation to analyze the effect of triability and observability on the decision to use Remaja Sehat application. This study uses a post only design.

This research was conducted on senior high school students in Surabaya. The sample in this study was conducted using simple random sampling technique. There are 302 students in total as the sample. The sample was given action in the form of health education about reproductive health by using the Remaja Sehat application. The respondents study about reproductive health material and play games in the application. The respondents are given 1 week to study and operate the application. Then it will be measured according to the variables studied. The variables include adolescent
characteristics as well as triability and observability towards the decision to use Remaja Sehat application.

**Findings**

1. **Characteristic of Respondent**

   **Table 1. Characteristic of Respondent based on Age, Residence, Gender**

<table>
<thead>

There is a significant effect of triability and observability on the decision to use Remaja Sehat application. These results indicate that Remaja Sehat application is possible to be retested and the results of this application can be seen easily as good from the technical-economic advantages so it can accelerate the adoption process.

Discussion

The Effect of Triability on the Decisions to Use Remaja Sehat Application

This study uses several indicators to measure how much the triability is. These indicators are able to decide to maintain reproductive health, to feel happy to try Remaja Sehat application, and feel that Remaja Sehat application provides information that can be accessed easily.

Triability is the possibility to be tested from an innovation. According to Kurniawan, an innovation that can be tested can be adopted faster than an innovation that can’t be tested. Innovation must also show how excellence and usability match the innovation users so that innovation can be adopted faster. In this study, triability is included as good categories. In line with the results of research on the usage of android smartphones are widely used in accessing various education needed. The easiness of downloading educational applications on Google Play(8). In this study, application access has been available on Google Play as well as the easiness in operating Remaja Sehat education application.

In addition, innovation has to be maximally promoted to users to explain its usefulness, excellence until it can be tested. This can cause an increase in the user’s confidence in using an innovation. Sholahudin’s research shows there is no influence between triability and intention to adopt Solopos epaper because most of the respondents still don’t know that the innovation can’t be tested(11).

This research is also supported by research from Kurniadi. The results show that there is a significant effect of triability on Blackberry product purchase decision making(12).

The intensity of using a smartphone influences communication patterns and behavior. The results of other studies conducted have provided information that smartphone users use high duration and frequency. The content viewed is games, videos, music, social media(13). In the results of this study can be found that the adolescents use and try the application that have been made.
The effect of Observability on the Decision to Use Remaja Sehat Application

Observability is the results level of an innovation that can be seen easily as good from an economic technical advantage. The easier the user sees the results of an innovation, the greater the user will decide to adopt an innovation\(^{(5)}\). This study uses an indicator as an observability measurement tool listed in the questionnaire. These indicators are other people or friends interested in the Remaja Sehat application, friends have liked the innovation of Remaja Sehat application, feeling easy when friends or other people ask about the innovation of Remaja Sehat application.

Based on the results of the study, it shows that the more other people recommend or suggest to use Remaja Sehat application, the faster students will make decisions to use or download Remaja Sehat application. Supporting research is on Sholahudin research that showed there is a significant influence between observability on decision making to adopt innovative e-paper sloops\(^{(11)}\). In addition, on the research of Pertiiwi that showed there is an influence of observability on the decision of purchasing Blackberry products and the most influential factor is the Observability\(^{(12)}\).

Remaja Sehat application that is developed can be effective as an educational media. Remaja Sehat media application can affect the Triability and Observability, it means the adolescents can try and feel that the application can be applied easily after observing and trying the media. This is in line with the research on using Android-based games that encourage the adolescents to change healthy lifestyles, that games can improve healthy lifestyles\(^{(14)}\).

Conclusion

The effect of Triability and Observability in this study effect on the decision making on the use of Remaja Sehat application. Therefore the Remaja Sehat application can be used as an effective medium to provide education about adolescent reproductive health. The Android-based application that is developed can be obtained easily and downloaded on the Google Play application. Aside from there are educational materials about reproductive health, there are also games that relevant to increase adolescent knowledge about reproductive health. The Remaja Sehat application that can be used easily can be one of the factors of Triability and Observability variables categorized as good.

Abstract

Current research involves preparing cerium oxide nanoparticles using simple, environmental- friendly green synthesis approach via fresh green tea leaf extract (Camellia sinensis) as a capping and reducing agent, Ultraviolet-visible spectroscopy (UV-Vis.) is used to check the formation of nanoparticles by investigate the absorption peak and energy gap ($E_g$); Maximum absorption peak was around 295nm and $E_g$ was 4.2eV calculated using Planck’s equation, X-Ray diffraction (XRD) analysis of Nano powder stated that Cerium Oxide has a cubic fluorite structure with face centered cubic (FCC) structure, blood serum glucose levels, liver functions after CeO₂ Nanoparticles treatment for rats were reported in this paper. Forty eight adult male rats were used and divided randomly into six groups each group has eight rats (n=8), Results stated that blood glucose levels, liver enzymes were increased in groups that injected by dexamethasone while considerably modified in rats administered by Cerium Oxide Nanoparticles.

Keywords: green synthesis, dexamethasone, XRD, Cerium Oxide NPs, AST.

Introduction

Nanomaterials are the forms of matter at nanoscale. The “Building blocks” for nanomaterials consist of organics, semiconductors, metals and metal oxides. Nanomaterials with structural features at the nanoscale can be found in the form of clusters, thin films, multilayer and Nano-crystalline materials which are often expressed by the dimensionality of 0, 1, 2 and 3 (1)(2), The synthesis of nanomaterials is of present concern due to their huge applications in medicine and many other fields (3), commonly, most of these applications are due to the reality that the Nanometer scale has significantly different characteristics compared to the bulk state. the nanoparticles have strong surface bonds, the high surface-volume ratio in Nanoparticles is the main reason for a structural deformation that can change the physical properties of nanoparticles (4).

The most popular complications of hyperglycemia are the generation of (ROS) reactive oxygen species (5). Reactive oxygen species can cause serious harm to β-cells and insulin resistance (6). Hyperglycemia characterized by increases the percentage of metabolism and enzyme failure of elevated oxidative stress caused by beta cells failure in the pancreas (7). Using plants extract is one of the latest techniques used to synthesize nanoparticles. Many metal nanoparticles were produced this way (8), Biosynthetic pathways can provide Nanoparticles of a better defined size and morphology than some of the physicochemical preparation techniques. Plant extracts can behave both as reducing agents and as stabilizing agents in the synthesis of Nanoparticles (9).

Many researchers have defined the capacity of CeO₂ Nanoparticles to scavenge free radical species to behave as an antioxidant. Multiple scientists have indicated that cerium NPs behave as a mimetic of superoxide dismutase, the primary catalyst that reduces the production and damage caused by ROS to mammalian cells by converting superoxide into oxygen and hydrogen peroxide (10).

The objective of this research is to investigate the capacity of CeO$_2$ NPs to decrease BGL, improvement liver function using biochemical assays and histological examinations.

**Materials and Method**

8.68 grams of Ce(NO$_3$)$_3$.6H$_2$O (0.09M) was added to 200 ml of deionized water in a flask and they stirred for 5 minutes on 1,500 rpm magnetic stirrer, then gradually 20 ml of previously prepared *Camellia Sinensis* leaf extract was added to the flask. At 40°C magnetic hotplate, the mixture was constantly stirred for two hours; the solution was cooled at room temperature. Blackish brown CeO$_2$ Nanoparticles were collected by centrifugation (4,000 rpm) for 15 minutes. The NPs were washed repeatedly with deionized water and dried it with hot air oven then calcined for ~5 hours at 400°C.

**Experimental animals**

Forty eight adult male Wister albino rats weighing (175-225g) and average (10-14) weeks old, the rats were housed in polypropylene cages under controlled conditions of temperatures (25±5)°C and 12/12 hours light/dark cycles, Diet and drinking water were given *ad libitum*, the animals were reared and treated in animal house of college of science, University of Baghdad.

Laboratory animals were randomly divided into six groups, each group contained eight rats (n=8) treated for 30 days, and intended as follows: the first group (G1) was served as negative control, the second group (G2) was injected intraperitoneally with (0.5 mg/kg) dexamethasone sodium phosphate, (G3 and G4) were injected intraperitoneally with (34 and 84) mg/kg CeO$_2$ Nanoparticles and (0.5 mg/kg) of dexamethasone respectively, the fifth group (G5) was injected intraperitoneally with 34 mg/kg CeO$_2$ Nanoparticles and (G6) was injected intraperitoneal with 84 mg/kg CeO$_2$ Nanoparticles.

The experimental animals in this model was fast for 24-hours, the rats were weighed and anesthetized by their inhalation in a glass dome. Animals were injected dexamethasone sodium phosphate (0.5 mg/kg) for 30 days in a single dose daily (11). Only 30 minutes after drug administration, food and water were provided to the animals. Within 15 days of dexamethasone injection; blood glucose elevated and insulin secretion reduced these consequences of dexamethasone were agreed with Makoto Ohneda’s outcomes (12), animals have been received (34 and 84 mg/kg) Cerium dioxide nanoparticles (13).

**Biochemical analysis**

After the exposure period end, blood sample collected from animals by heart puncture, Collected blood was centrifuged at 4000 rpm for 10 min, serum was separated for assessment of various biochemical parameter such as blood glucose level (BGL) measured by commercially available kit (Biosystem, Germany), cholesterol (TC), Triglyceride (TG), High Density Lipoprotein Cholesterol (HDL-C) and Low Density Lipoprotein Cholesterol (LDL-C) were estimated using a commercially available kit (Linear kit, Spain), serum levels Aspartate Amina transferase (AST) Alanine Amino transferase (ALT), Alkaline Phosphate (ALP) and Total Bilirubin (TB) were estimated by commercially available kit (Reflotron kit, Germany).

**Histological Examinations**

Pancreatic Samples were collected from animals after organs separation and fixed in 10% buffered neutral formalin solution, dehydrated in gradual ethanol (70%), cleared in xylene, and embedded in paraffin. 5 µm thick paraffin sections were prepared and then regularly stained with Hematoxylin and Eosin (H&E) (14) and then examined microscopically.

**Statistical Analysis**

The statistical analysis was performed using analysis of one way (ANOVA) variance and t-test analysis, carried out in complete randomized design. Different between means have analyzed by Least Significant differences (LSD) at (P≤0.05) and expressed as (Mean ± SE) with letters to explain the significant using the Statistical Package for Prism 8.1.2 (Version 8.1.2, Graph Pad, San Diego, CA, USA) software.

**Results and Discussion**

Nano-powder structural characterization was registered by Pro Penalty CAL with Cu-Kα radiation (1.5406 Å). XRD models for prepared Cerium Nano-powder showed that the structure is polycrystalline; as synthesized CeO$_2$ showed no pure intense peaks Fig. (1a), which is caused by amorphous state. While eight diffraction peaks existed when calcined in 400°C. Eight diffraction peaks were recorded in tab. (1) proved the
cubic fluorite structure with face centered cubic (FCC) structure of CeO$_2$ with standard data (no: 89-8436 of JCPDS card) Fig. (1b&c). No peak of any other phase was identified the sample’s high purity. The diffraction peaks of CeO$_2$ particles are quite broad, indicating very small crystalline sizes of sample. The pure CeO$_2$ nanoparticle’s lattice parameter is 5.412Å which matches well with the bulk CeO$_2$ lattice parameter a=5.411. Using Debye-Scherrer formula, the calculated average particle size was around 14.29 nm, these findings were agreed with (15)(16).

The optical behavior recorded by VARIAN spectrophotometer (Cary 5000 Scan), Fig. (2) Shows the appearance of single peak validates the sample purity and shows a maximum absorption peak at 295 nm of green synthesized CeO$_2$ NPs. Primarily absorption peaks were formed due to the electronic transitions and excitation of electrons from valance band to conduction band between outer energy, The calculated Energy gap of CeO$_2$ NPs was 4.2 eV evaluated by following relation (17), From the obtained result, the band gap energy was blue shifted which happened by the quantum confinement effect. This effect may create by oxygen vacancies present in
the inter-granular areas. Typical UV absorption peaks were also seen in previously studies \(^{(18)}\).

![Absorption Spectrum of CeO\(_2\) nanoparticles](Image)

**Figure (2): Absorption Spectrum of CeO\(_2\) nanoparticles**

The biochemical results in tab. (2) presented a significant increase in blood glucose level (BGL) in group which treated by dexamethasone (G2) compared with control group (G1), these results similar to previous study \(^{(19)}\) they reported that dexamethasone cause tissue damage in pancreas which leads to decrease insulin secretion from Langerhans cells. After animals treating with CeO\(_2\) NPs for 30 days, there was a significant decrease (\(p\leq0.05\)) with blood glucose level for infected animals in G3 and G4 compared to G2. CeO\(_2\) nanoparticles had the ability to reduce BGL for many reasons such as delaying or inhibiting the absorption of glucose in the intestines \(^{(20)}\), Stimulate insulin secretion from pancreas cells \(^{(21)}\) or facilitate the entry of glucose into cells in fatty and muscular tissues \(^{(22)}\), G5 and G6 were found to be near the normal range of BGL.

Also; the results showed there was a significant increase in liver functions parameters such as ALT, AST and ALP in experimental animals compared with control group (G1), liver enzymes indicate the extent of liver diseases \(^{(23)}\), this study indicates increases of liver enzymes levels possibly due to hepatic damage, increases the activity of liver enzymes in experimental animals may reveal possible leakage of these cytoplasmic enzymes into the blood stream across damaged plasma membrane or increase synthesis of these enzymes in the liver \(^{(24)}\). Results of this study showed that there was a significant decreases (\(P<0.05\)) of liver enzymes in treated animals (G3 and G4), the administration of CeO\(_2\) Nanoparticles may reduce dexa-induced hepatotoxicity in rats, the effective of CeO\(_2\) Nanoparticles as an antioxidant agent by inhibiting oxidative stress formation and Reactive Oxygen Spices (ROS) due to the large surface area to volume ratio that creates reactive sites to scavenge free radicals \(^{(25)}\), increase of Bilirubin levels may be attributed to the changes in cell membrane permeability with change of effective stress of the membrane under the influence of the oxidative stress, or may be explained by the occurrence of obstruction in the gallbladder ducts \(^{(26)}\), there was a significant decrease (\(P<0.05\)) in Bilirubin levels for the treated rats, (G5 and G6) had a normal liver enzymes and Bilirubin levels.

**Histological Examination**

Histological section in (Fig. 3a) shows pancreatic lobules containing acini (*), islets of Langerhans (**) and unstained connective tissue septa (***) for control
group. Fig. (3b and c) showed damage and necrosis of endocrine cells of islet (*), Langerhans with shrinkage of islet (**), degenerated acini cells and islet of Langerhans (***) and presented different alterations of rat’s pancreas and many histological changes were detected in pancreas section of (G2) that administrated by dexamethasone, such as necrosis and damage of endocrine cells of islet Langerhans with shrinkage of islets, Dexamethasone induced necrosis is mediated by reactive oxygen species mediated lipid peroxidation which causes bursting of plasma membrane of the cell and disturbance of osmotic balance this osmotic alteration ultimately leads the cell towards necrosis.

Also the histological section show different change in pancreas of rats that administrated with dexamethasone and CeO$_2$ Nanoparticles (G3 and G4) these change increased by decreasing the dose of Nanoparticles in which cells look like normal histological structure of pancreas with dispersed necrosis cells, the healing effect of Nanoparticles from Fig. (4 a and b) photomicrograph it is observed that the empty spaces in islets created by dexamethasone induced necrosis is significantly decreased and the section showed dispersed necrosis of endocrine cells of inside the islet of Langerhans with certain reduction the contour of islets and ballooning degenerate of cytoplasm of cells; this indicates that Nanoparticles stimulates the regeneration of the damaged islets, from Fig. (4c and d) can see that Nanoparticles kept normal shape of pancreatic cells and they look like normal.

**Figure (3): Cross section of pancreas (a) Control group, (b and c) Group 2 X400 (H&E),**

**Figure (4): Cross section of pancreas (a) G3 (b) G4 (c) G5 (d) G6 X400 (H&E).**

**Conclusions**

Synthesis of biocompatible Nanoparticles was obtained by applying a novel and simple green technique using new extract of green tea (*Camellia Sinensis*) to prepare Cerium Oxide nanoparticles. It had investigated successful formation of nanoparticles by examine its structural and optical properties, nanoparticles administration provided a significant reduction against BGL after dexamethasone injection, using nanoparticles reduced serum blood glucose levels, improved Lever enzymes and Bilirubin to confirm this results the histological staining of pancreatic section have performed.

The Study of the Effect of Cognitive-Behavioral Therapy (CBT) on Reducing Methadone Consumption and Increasing Self-Esteem in Drug Addicts

Zakaria Zakariaei, Seyed Khosro Ghasempouri, Touraj Assadi, Ali Asghar Manouchehri

Clinical Toxicology Fellowship, Department of Emergency Medicine, Faculty of Medicine, Mazandaran University of Medical Sciences, Sari, Iran, Department of Emergency Medicine, Gut And Liver Research Center, Faculty of Medicine, Mazandaran University of Medical Sciences, Sari, Iran, Assistant Professor, Forensic Medicine, ShahidBeheshti Hospital, Babol University of Medical Sciences, Babol, Iran

Abstract

The purpose of this study is to determine the effectiveness of cognitive behavioral therapy (CBT) in reducing methadone consumption and increasing self-belief in addicted to substance people. This study is in terms of the objective of applied research and from the developmental branch and in terms of nature and method it is a quasi_experimental research. The study population of this study includes all clients of methadone clinic of razi hospital in qaeemshahr. The sample consisted of 30 subjects selected through targeted sampling available were divided into control and experimental groups, who referred to methadone clinic at razi hospital in Qaem-shahr during the study period. Data collection tool was a standard and researcher-made questionnaire. Franken’s Methadone Consumption Reduction Questionnaire (2002) and Self-confidence researcher-made questionnaire, which reliability was calculated to be 0.94 and 0.74 respectively, using Cronbach’s Alpha. Spss22 software was used to analysis the research hypotheses and data from the questionnaire. The data analysis method has been descriptive and inferential statistics (Kolmogorov–Smirnov, Levine, T2 and covariance test). The result of this study has been shown that cognitive behavioral therapy (CBT) is effective in reducing the consumption of methadone addicts. Cognitive behavioral therapy (CBT) increases self-belief in addicted people.

Keywords: Cognitive behavioral therapy, methadone, self-belief

Introduction

Addiction is a complex disease characterized by characteristics such as compulsive behaviors, irresistible temptations, drug-seeking behaviors, and persistent consumption even when there are many negative consequences for the individual. Continued use of substances over time and long-term toxic effects of its consumption on brain function have led to a wide range of behavioral, psychological, social and physiological abuses that prevent the behavior and normal behavior of addicts in the family, the workplace and at a wider level (1).

In society most addicts often leave the drug during adolescence, but after a while, they turn back to addiction. Addressing the psychological problems of addicts including self-esteem, self-esteem, accountability, and social and family problems is a direct link to the abandonment of addiction. Three-quarters of those who complete the course of relapse have relapsed within one year of completing the treatment. Therefore, it is essential to develop programs for treatment, reduction and prevention of it (1). It should be noted that the provision of non-medical treatments, as well as lifestyle modifications and social support, are essential for comprehensive treatment and with sustainable outcomes. Clinics working in methadone-based therapies should also provide such support. The success rate of methadone depends on the number of supplements used in various clinics and ranges from 45% to 90% (2).
The Cognitive Behavioral Therapy (CBT) approach has received high experimental support among various interventions for substance abuse treatment. The Psychiatric Association (1995) with the Public Assessment Organization (1996), although the risks of addiction to amphetamines have only been recognized in recent years.

Given the need for a thorough examination of the deficiencies of methadone treatment, which is the main treatment method currently in our country and most countries in the world, and the provision of non-pharmacological treatment is absolutely felt. These treatments and training can individually or collectively provide for the improvement of many of these problems, and, in parallel, holding private counseling sessions for the treatment and treatment of personal problems can help complete the treatment process and improve the references of the indicators. (3)

Therefore, its treatment has been very important. One of the most effective therapeutic treatments over the past years and now is the maintenance treatment program with methadone and buprenorphine. Opiate users, the dominant drug therapy, is the consumption of methadone which is currently in use in most countries of the world, and the results of studies have shown that this drug is a suitable alternative for opioids and has a beneficial effect on reducing drug intake, craving, Leak symptoms, psychiatric symptoms and dangerous behaviors of these patients during the course of treatment (4,5,6,7,8,9). The purpose of this study was to investigate the effect of cognitive-behavioral therapy (CBT) on reducing methadone consumption and increase self-esteem among addicted people.

Method

Study population, sample, measurement method

This is a descriptive study performed by collecting data on all of the clients of methadone clinic at Razi hospital in Qaem-Shahr. The sample consisted of 30 patients who referred to the methadone clinic of Razi Hospital in Qaem-Shahr during the study period. The subjects were selected through targeted sampling (15 subjects and 15 controls) and assigned to control and experimental groups.

(A) Franken’s Methadone Consumption Reduction Questionnaire (2002)

This questionnaire has 14 questions and Likert 5 options. Also, this questionnaire was designed to reduce the consumption of methadone as a motivational state by Franken (2002) and measuring the reduction of methadone consumption at the moment.

That includes 3 factors (desire and intention to use drugs, desire for consumption and negative reinforcement, pleasure and severity of lack of control). The original form of the questionnaire was designed by Lav in 1998 to measure decrease alcohol consumption, and in 2002, Francken, by adopting the alcohol consumption reduction questionnaire, has written the heroin intake reduction questionnaire. In the Iranian society this questionnaire has been used about reducing the consumption of Methamphetamine. Reliability of the components of this questionnaire in Makry, Ekhthari, Hasani Abharian and Ganjgahi (2010) survey in Consumer of the various types of opioids, including crack and heroin, are 0.89, 0.79, 0.4 respectively, and in metamphetamines Consumers was 0.25, 0.65, and 0.81 respectively.

B) Self-esteem increase questionnaire

Self-esteem increase questionnaire consists of 50 items that are used to measure self-esteem. The grading for the questionnaire is 4-point Likert spectrum, which is considered for “never,” “rarely,” “sometimes,” and “almost always,” points 1, 2, 3, and 4, respectively. The content validity of the questionnaire was confirmed in the research by Farzianpour et al. The reliability of the questionnaire with Cronbach’s alpha was more than 85%. Due to the standardization of the research questionnaires, their reliability in previous research has been proven repeatedly, but in order to ensure their reliability, 30 questionnaires before the final implementation were randomly assigned and implemented. The reliability of the questionnaires using the Cronbach’s alpha coefficient to reduce methadone consumption was 94 / 0 and for self-confidence increase was calculated 0.74.

In order to ensure the reliability of the content and formality of validity, the questionnaire was examined by several experts and supervisors and counselors and They all emphasized the validity of the questionnaires for the research.

The summary of the content of the therapeutic sessions:
First Session: introducing, Group Principles and Structure of Meetings, Motives, Objectives, and Amount of Obligations

Second session: The course of recovery and treatment, non-medical education, the problem of distrust

Third Session: Costs and benefits of consumption and Discontinue Usage, complete purity

Fourth Session: Reducing Energy, Temptation, and Starters

Fifth Session: Situations and external starters, internal factors and triggers

Sixth Session: Understanding auto Thought, Generating Negative Emotions (Depression, Anxiety, Aggression, Paranoid Thoughts, Phobia), shallow Beliefs of Negative Errors

Seventh Session: Control of Auto Thoughts, Technique A-B-C

Eighth Session: Logical Cognitive Errors, Appropriate Alternative Logical Thoughts

Ninth session: ways to change shallow thinking, to oppose with changing logic, to oppose with stimulus sentences

Tenth Session: Temptations and related beliefs, wrong ways of dealing with temptation, dealing with temptation.

Eleventh Session: Thoughts, emotions, and underlying behaviors associated with consumption, boredom, shame and sin, staying or job.

Twelfth Session: Relapse-prone activities, preventative relapses, prevention

Data analysis

Data analysis was done by descriptive and inferential methods through SPSS software. In this research, descriptive statistics have been used to calculate the mean and standard deviation of the research variables and to show the frequency and its related graphs. Inferential statistics are used to examine the research hypotheses. Before testing the hypotheses, the assumption of the normal distribution of data was done by Kolmogorov-Smirnov test. Then the homogeneity assumption of variances was assessed through Levin’s test in all variables of the two groups. To report the results, the significance of the statistical tests and the size of the independent variable was used. To analyze the inferential statistics, covariance analysis was used.

Result

According to demographic findings, 50% of the subjects formed the experimental group and 50% of the control group. Out of all patients, 63% of them were married. using the Kolmogorov-Smirnov test, we measured the normal variables.

According to the normal test table information (Table 1), the value of $p$-value in any of the variables is not significant. This indicates the normality of the research variables, which is one of the preconditions for using the covariance analysis test.

</table>

Considering that in the Levine test, the $p$-value is greater than 0.05. We can conclude that, the assumption of the equality of the variances of the two groups is confirmed, which is another test precondition for the analysis of covariance. The Levine test table is also shown in table 2.
However, in the post-test, the difference between the two groups is significant and, in fact, according to the mean value, the self-confidence of the experimental group has increased. Evaluation of self-esteem score in pre-test and post-test, has been shown in figure 2.

According to the level of \( F = 39 \), and considering that \( p \)-value is less than 0.05, with a confidence level of 95%, the hypothesis of the study is confirmed and it is concluded that the treatment of cognitive-behavioral therapy (CBT) in reducing consumption in methadone addicts is effective. Regarding the average score of drug use in the post-test (Figure 1), we find that this is a positive effect, with the intensity of its effect being very high at 0.847. In fact, cognitive-behavioral therapy (CBT) is effective in reducing the consumption of methadone addicts.

In the pretest stage, there is no significant difference between the mean score of substance use in both control and experimental groups (The value of \( p \)-value is greater than 0.05). We conclude that the subjects were divided into two groups of control and experiment equally. However, in the post-test, the difference between the two groups was significant and the test was significant, and in fact, according to the mean value, thoughts of substance use in the experimental group decreased. Evaluation on reducing drug intake in the pre-test and post-test phases, has been shown in figure 1.

Figure 1. Evaluation on reducing drug intake in the pre-test and post-test phases

In the pretest stage, there was no significant difference between the mean self-esteem score in the control and experimental groups (\( p \)-value greater than 0.05). We conclude that the subjects were divided into two groups of control and experiment equally.

**Discussion**

Hypothesis 1: Cognitive Behavioral Therapy (CBT) is effective in reducing the consumption of methadone addicts.

The results of the first hypothesis show that cognitive behavioral therapy (CBT) is effective in reducing the consumption of methadone addicts. This result is consistent with the results of research by Yaghoobi Nasrabadi (3), Keramaty (5).

In explaining this hypothesis, it can be said that in cognitive-behavioral therapy, the therapist and the patient provide a functional analysis for each case of drug intake. It identifies the thoughts, feelings and conditions of the patient before and after drug intake.

In the early stages of treatment, functional analysis helps the patient to identify determinants or risk situations that increase the likelihood of drug intake and reasons of drug intake.

This method of treatment will reduce the intake of drug in addicts, the desire to methadone and the pleasure of using methadone\(^{(10,11,12)}\).

**Hypothesis 2: Cognitive Behavioral Therapy (CBT) is effective in increasing self-esteem in addicts.**

The results of the second hypothesis show that cognitive behavioral therapy (CBT) increases self-confidence in addicted people. This result is consistent with the results of research by Jacob Nasrabadi (3), Keramati (5). In explaining this hypothesis, it can be said that cognitive-behavioral therapy is a kind of individual education program that helps abusers to abandon the old habits associated with drug abuse and to learn skills to develop healthier habits.

When the level of drug intake reaches a degree of severity that the person has to be treated. Probably the person used drugs as a way to confront a wide range of interpersonal and individual problems. Addicts usually have little self-confidence. The training of coping skills is the main core of cognitive-behavioral therapy. The
purpose of this training is helping patients to identify the most dangerous situations like high risk of drug intake and to obtain effective coping strategies to deal with those situations. The behavioral therapy helps addicted people not to be afraid of expressing thoughts and opinions and reaching their goals (13,14,15).

**Research constraints**

Obviously, the removal of research constraints will be the basis of further research and this will improve the science and research. The present research showed

A) Restrictions under the control of the researcher

1- The scope of research implementation was Qaemshahr.

2- This research was conducted in 95-94

3- This research was conducted among all patients referring to methadone clinic of Razi Hospital in Qaemshahr.

4- The tool used in this research was a questionnaire.

5- The subject of this research is the effect of cognitive-behavioral therapy (CBT) on reducing methadone consumption and self-esteem in drug addicts.

B) Restrictions beyond the control of the researcher

1. Unwillingness of some persons to answer related questions.

2. A small number of subjects

3. Lack of research done similar to the current research.

4. having problems in coordinating with addicts.

5. Subjects’ perceptual difference from the questions of questionnaire.

Future researchers are encouraged to do this research more widely in other cities. It is suggested to other researchers to investigate the role of cognitive-behavioral therapy in self-confidence and self-esteem of addicts in future research.

Study Effect of Clarithromycin drug on Cryptosporidium Parvum and Efficiency of ELISA Technique in Diagnosis Comparison with Some Traditional Methods \textit{in vitro}

Hussein A. Kadhum\textsuperscript{1}, Shaimaa A. Shlash\textsuperscript{2}

\textsuperscript{1}Assistant Lecturer in Microbiology/ Dentistry College/ Al-kafeel University, \textsuperscript{2}Assistant Prof.Ph.D in Parasitology/Pharmacy College/Kufa University

Abstract

This research aimed to study effect of Clarithromycin drug on \textit{Cryptosporidium Parvum} and efficiency of ELISA technique in diagnosis comparison with some traditional methods \textit{in vitro}. Samples collected from four different sources water were 400 liters: 100 liters tap water provider by Al-Kufa District River, 100 liters house tank water, 100 liters from sea of Al-Najaf and 100 liters stagnant water during period from October 2018 to April 2019. Examined samples by three laboratory methods: Modified Ziehl-Neelson stain, Flotation by saturated sugar solution method and ELISA to detecting from \textit{Cryptosporidium} oocysts in the water as used Clarithromycin drug effective against \textit{C.parvum} \textit{in vitro}. Capability test was implement impregnation isolated and determination cells of parasite counted when at 37\(^\circ\)C/ 48h incubated. Differ concentrations from Clarithromycin were 4, 8, 16 and 32 mg/L respectively compared with control group.

Results of the current study showed that oocysts were found in 182 from 400 liters 45.5\% as showed that height oocysts in stagnant water then followed Sea of Al-Najaf were 55\% and 45\% respectively, height percentage of oocysts were in April and March were 69.09\% and 66\% while decrease percentage of infection in October was 25\%. As showed study results presence significant differences in efficiency of ELISA technique was 83.33\% at detection from oocysts compared with Flotation by saturated sugar solution and Modified Ziehl-Neelson stain methods were 66.66\% and 61.11\% respectively. Shown results this study that Clarithromycin with 16 and 32 mg/L lead to reduction in number oocysts was 17.3±3.5 and 15.4±3.9, sporozoites counts was 17.1±3.4 and 14.9±4.0 compared with control group was 20.5±2.8. As observed significance differences \textit{P}<0.05 in the mean numbers the oocysts and sporozoites in three replicate plates after 48 h. These results proved that Clarithromycin have effectiveness in inhibition \textit{C.parvum} \textit{in vitro}.

Keywords: Cryptosporidiosis, Water, Oocysts, Sporozoites, Clarithromycin, \textit{in vitro}.

Introduction

Cryptosporidiosis is protozoan disease occurred by \textit{Cryptosporidium} \textit{spp} from phylum Apicomplexa is unicellular organisms include number of pathogenic infect human and mammals by food and contaminated water \textsuperscript{(1)}. Oocysts transmitted in arduous environment where not killed by conventional disinfectants and chlorination which causes diarrhea, massive dehydration, malnutrition and weight loss lead to abomasa cryptosporidiosis \textsuperscript{(2)}. Oocysts resisted tough environmental condition for six months where can stay alive for twelve weeks at 10\(^\circ\)C \textsuperscript{(3)}. Transmission riot by the fecal oral and involve drinking water, recreational water, person to person, animals to person and assist of sexual pursuit may locomotion through man with HIV \textsuperscript{(4)}.

\textit{C.parvum} infections diagnosed through knowledge number the infestation and non-inverting methods. The non-inverting methods, microscopic test more common \textsuperscript{(5)} or identification of these parasite is based on morphologic examination by using modified acid-fast staining method \textsuperscript{(6)}, important alternate the expansion of antigen the parasite (ELISA) showed these assay sensitive comparative with microscope examine, this lead to not request the observed of hale parasite \textsuperscript{(7)}.

Recently, observed there increase in number of infection with \textit{C.parvum} correlating with increase in number of immune-compromised patients and resistance against drugs, this disease currently endemic in 88 countries world and showed diffusion increase in immunosuppressive conditions such as HIV/AIDS \textsuperscript{(8)}. Clarithromycin known as
being semisynthetic antibiotic from macrolide derivative family (9). Also, good distribution perfect action against of parasites e.g.: *Toxoplasma gondii* (10) *Leishmania donovani* (11) and *Cryptosporidium parvum* (12) *invitro* as featuring effective, less side impacts, cheap and easy management. Clarithromycin, Azithromycin and Roxithromycin are active in inhibition *C.parvum* evolution in concentrations near those are achievable (13). The aim this research is study effect of Clarithromycin drug on oocysts and sporozoites *in vitro* and efficiency of ELISA technique in diagnosis comparison with some traditional methods.

**Materials and Method**

Water samples are collected from October 2018 to April 2019 period of Al-Najaf governate. A total amount was 400 liters: 100 liters of tap water supplies by Al-Kufa District River, 100 liters of house tank water, 100 liters sea of Al-Najaf and 100 liters of stagnant water, put in sterile bottles which delivered to the laboratory of pharmacognosy and medicinal plants in pharmacy college/ Kufa university.

**Diagnosis parasite:** 5 liters from water samples distributed in sterile test tubes placed in the centrifuged 1000g/10-15 min to get on sediment, taken 5 ml of sediment and added 15 ml of distilled water then aspirate during six layers of gauze for get rid of the suspended waste then centrifugation procedure was performed again 1000g/10 min. 10 ml add of saturated sugars solution to the sediment well mix (14). Taken drop from the upper layer of the tube by Pasteur pipette placed on glass clean slide left to dry in the air for 10 min, smear fixed by absolute methyl alcohol for 5 min and left to dry, added modified ziehl-neelson stain to the fixed smear and heating for 5 min by Bunsen burner until vapor appears and washed with tap water, the slide is immersed in 10% HCL for 10-15 sec and washed again with water then dye was stained with methylene blue for 2 min, wash the well slide with running water then air-dried, examined by microscope 40X and 100X magnification to investigate oocysts by several standard e.g form, size, color stain and surface merit (15).

**ELISA technique:** Used in these technique particular oocysts antibodies where placed these antibodies in the pits for the plate ELISA method and these antibodies have ability to interact with oocysts find in samples then plate incubated for 1 h at 21°C, wash the plate by washing solution and add the conjugation solution containing antibodies to the parasite associated with the peroxidase enzyme then incubate and wash the plate again. Add chromogen tetramethylbenzidine is solution of the reactive substance which contained bottle inside size 25 ml with ELISA diagnostic components, if the water container on oocysts, conjugation solution remains linked with the pit and the enzyme converts chromogen from colorless to blue color composite where strength this color is proportional with number of oocysts in the examined sample, stopped the enzyme reaction after addition of phosphoric acid solution then measured optical density at the wavelength of 450 nm using optical spectrum (16).

**Experiment study *invitro***: Oocysts isolated from the water by ELISA method was used throughout this study. Clarithromycin (Abbott, Ital.) dissolves in 50% Acetone and 50% Methanol to obtain 1 mg/ml of stock solution for perpetrated different concentrations where stored at −80°C in the dark. In these experiment used the methanol and acetone in alleviation of the drug not discouraged of *C. parvum* grows.

**Oocysts Preparation:** Occur by suspending portion of stock solution contain 9 portions sterile water and 1 portion 0.55% sodium hypochlorite then put in centrifuged and re-suspended during Dulbecco’s Modified Eagles Medium (DMEM) (Bio-Whittaker) then brood in Phosphate Buffered Saline (PBS) (Bio-Whittaker) contain 2000 U/mL of Penicillin G, 10 mg/L Amphotericin-B and 2000 mg/L Streptomycin busted when 37°C. Sporozoite excyst happened through oocyst incubated in buffer contain 0.75% Sodium Hypochlorite 0.25% Trypsin (Sigma-Aldrich.) at 37°C/60 min. Sporozoite liberated filtering by centrifuge 500g/10 min, re-suspended in (DMEM), counted in haemocytometer for culture (17).

**Cell Culture:** Isolated 500 cells from human stomach carcinoma preserve 25cm² tissue culture flacon. Put (DMEM) to medium with 10% Fetal bovine serum (Bio-Whittaker) in 4% L-Glutamine (Bio-Whittaker.), 1% non-essential amino acid, 100 mg/l Streptomycin and 0.5 mg/l Amphotericin-B. Lift cells from surface of the flacon by used 0.53 mM (EDTA) and 0.25% Trypsin in the (PBS). Coated 500 cells onto tissue culture glazy have 35mm in diameter of 10⁵ concentration grow able cells 5 ml overall size (18).

**Cells damage with *C. parvum***: Started by add 10⁵ sporozoite with 0.2 ml of the medium to happen connect and breakthrough of sporozoites incubate at 37°C/4 h with 5% CO2. Expel no inverting sporozoites by monolayer wash in (DMEM) also to oocysts less and epithelial cells no clinging. Cells infected are reservation in 5% CO2 during this of study (19).

**Antibiotics agent:** Clarithromycin concentrations prepared were 4, 8, 16 and 32 mg/L respectively, in
Triplicate of monolayers incubate at 37°C /48 h with 5% CO2 then washed four times in phosphate buffered saline to edit oocysts and prevent epithelial cells adhesion, well use 75% methanol for installation and Giemsa stained to estimate existence of sporozoites inwards cells to vision both intra and extracellular oocysts. Calculated the of parasite number by mean ± standard deviation are number mean of oocysts and sporozoites perceive in monolayers three for every to isolates ten to same concentration roofless of treatment, 40 field examine by 1000X magnification (20).

**Statistical analysis:** In these study association between presences of oocysts with various source of water depending to months this study and efficiency of the diagnostic methods used during the experiment by (P<0.05) (21).

**Discussion**

*Cryptosporidiosis* is great diarrheal disease happens by protozoan with health problem and poorly understood and many livestock farming industries as water consider of sources for zoonotic infections.

In the present study found oocysts 182 of 400 L from total samples 45.5% are rate varies depending to water exporter significant variation. Oocysts found about 40% in tap water provides by Al-Kufa river, as found 42% in tank houses water while oocysts appear 45%, 55% in sea of Al-Najaf and stagnant water samples respectively, this study agrees with (22) showed infection rate in the children at Al-Najaf city was 13.6% causes contamination drinking water contained on oocysts (23). As in Table1

As showed in the relation between oocysts presences and season appeared significant differences was recorded upper infection in April and March were 69.09% and 66% while decrease percentage of infection in October was 25%, this study agrees with (24) where recorded highest percentage in the spring and lowest winter, in Iraq which attributed to appropriate climatic conditions help on survival of oocysts in the environment and increased consumption of water contaminated. As in Table2

Results of the study current existence significant differences in efficiency of ELISA technique was 83.33% at detection from *Cryptosporidium* oocysts compared with Flotation by saturated sugar solution and Modified Ziehl-Neelson stain methods were 66.66% and 61.11% respectively, which may lead to examination of large number of samples, accuracy in reading results and shortening the duration of the diagnosis, this study agree with (25). As in Table3

Clarithromycin showed potent anthelmintic activity in vitro, mechanical through penetrate to larger number of the metacestode tissues in vitro, via metacestode fragment into small portions (20). In current study showed that clarithromycin when 16 and 32 mg/L lead to number decrease of oocysts was 17.3±3.5 and 15.4±3.9, sporozoites counts was 17.1±3.4 and 14.9±4.0 compared with positive control group was 20.5±2.8 respectively, lead to significance variation to mean of number the sporozoites and oocysts in three replicate plates after 48 h. As in Table4

Clarithromycin mechanism act number decline of parasite attributed to ability protein synthesis frustration by binding with transpeptidation sites for ribosomal subunits is target as *C.parvum* affect by protein synthesis frustration (26).

There are research showed that this drug is effective against protozoa such as *T. gondii*, *Cryptosporodium spp* (27) and *L. Major* in vitro action promastigotes mechanism effects through adverse binding to 50S ribosomal subunits and frustration the protein synthesis (28).

Study of Tuberculosis Related Topics in Baghdad, Iraq 2012-2016

Ali Kareem Durib¹, Ekterina Valerievna Blinova²

¹Lecturer, Medical Institute Baghdad, Middle Technical University, Baghdad, Iraq, ²Faculty Surgery Department, National Research Mordovia State University, 68 Bolshevistskaya, Saransk, Russia

Abstract

Objective(s): The present study designed to explore topics related to Tuberculosis, such as new smear positive cases, causes, treatment and new pulmonary positive cases in Baghdad City, Iraq for 2012-2016.

Method: A descriptive “retrospective” design was performed throughout the present study from the period of November 12th 2017 to February 13th 2018. All registered tuberculosis patients in Baghdad, Iraq for the period of 2012-2016. An instrument was constructed for the purpose of the study. Data were collected from the health records at the National Tuberculosis Center, State TB center, and district TB center for the period of 2012 to 2016 with the use of the study instrument. Data were analyzed through the application of descriptive statistical data analysis approach of frequency, percent, incidence rate and ratio.

Results: The study findings depicted that most of the new smear positive cases are accounted for the age group of (15-24) year old during the years of 2012-2016. Causes of Tuberculosis in the rural area were accounted for poverty (39.95%), smoking (22.39%), untreated cases (12.4%), alcoholism (11.32%), malnutrition (10.30%) and overcrowded (3.57%) respectively, and accounted for alcoholism (27.77%), overcrowded (27.16%), malnutrition (24.69%), smoking (11.93%), poverty (7.62%) and untreated cases of Tuberculosis (0.80%) respectively in the urban area.

Conclusion: The study concluded that Most of the new smear positive cases are accounted for the age group of (15-24) year old during the years of 2012-2016. Patients, in 2014, had benefited out of the Tuberculosis Program more than others based on the success rate.

Key Word: Study, Topics, Tuberculosis, Baghdad City, Iraq

Introduction

Roughly one-third of the world’s population has been infected with M. tuberculosis, and new infections occur at a rate of one per second (¹). However, not all infections with M. tuberculosis cause tuberculosis disease and many infections are asymptomatic (²). In 2007 there were an estimated 13.7 million chronic active cases, and in 2010 there were 8.8 million new cases, and 1.45 million deaths, mostly in developing countries (³,⁴). 0.35 million of these deaths occur in those co-infected with HIV. In 2015, across the world 1.8 million out of 10.4 million people affected by the disease died (⁵,⁶).

Any person who coughs and who was in contact with smear positive index case (smear positive pulmonary TB patient) should have three sputum examinations. Children aged less than 5 years: any contact aged less than 5 years who has a positive tuberculin that not previously vaccinated with BCG with signs or symptoms of TB should be treated as suffering from active TB. Those without signs or symptoms of disease should be given preventive chemotherapy (INH for 6 months) Children under one year of age with mothers who are being treated for smear positive pulmonary TB should be given Isoniazid if the tuberculin test is negative at the end of three months, INH may be stopped and BCG may be given (⁷,⁸,⁹).

Drug Resistance Tuberculosis is a man -made disease (due to non - compliance, improper drug regimen, etc.). Primary resistance is prevented by giving
the patient combination of drugs. Secondary (acquired) TB resistance is expected to be developed in (10-12):

1. A large bacillary population such as patient with cavitations.

2. Inadequate drug regimens (inappropriate drugs, insufficient dosage), drug side effects and complications.

3. Treatment of DR TB should be done by or in close consultation with an expert in the management of these cases and on hospitalization bases.

4. A single new drug should never be added to a failing regimen.

5. Treatment duration for DR TB patient may last 18 -24 months by using 4 -6 drugs (capriomycin, cyclocerin, ethionamide, levofoxacine, and PAS).

6. Second line regimens often represent the patient’s last hope for being cured inappropriate management can thus have life threatening sequences.

Based on the early stated facts, the present study ought to carry out a retrospective study to investigate related issues to detected cases of tuberculosis in Baghdad, Iraq for 2012-2016.

Method

A descriptive “retrospective” design was employed throughout the present study from the period of November 12th 2017 to February 13th 2018 in order to investigate related topics to Tuberculosis, such as new smear positive cases, causes, treatment and new pulmonary positive cases in Baghdad City, Iraq for 2012-2016. A convenient sample of (11680) registered patients with tuberculosis in Baghdad, Iraq for the period of 2012-2016. These patients were males and females and they were one year to over than 65 year of age.

An instrument was constructed for the purpose of the study. It was comprised of items that focused on patients’ characteristics of age, gender and type of Tuberculosis. A pilot study was conducted for the determination of the study instrument’s content validity, internal consistency reliability and adequacy. The study was carried out for the period of December 10th -20th 2017. Content validity of the instrument was determined through panel of (15) experts. These experts were (5) faculty members at the College of Nursing University of Baghdad, (5) Faculty members at the College of Medicine University of Baghdad and (5) epidemiologists at the Ministry of Health and Environment. They were presented with copy of the study instrument and asked to review it and provide comments for its modification to be more appropriate measure of the study. They had reviewed the instrument and presented their comments with an agreement that the instrument is content valid. Internal consistency reliability was determined for the study instrument through the use of split-half technique and measurement of Cronbach alpha correlation coefficient. The results indicated that Cronbach alpha correlation coefficient was r=0.85 which adequately reliable measure for the problem underlying the present study.

Data were collected from the health records at the National Tuberculosis Center, State TB center, and district TB center for the period of 2012 to 2016 with the use of the study instrument. Data were analyzed through the application of descriptive statistical data analysis approach of frequency, percent, incidence rate and ratio.

Results

Results out of table (1) indicate that most of the new smear positive cases are accounted for the age group of (15-24) year old during the years of 2012-2016.

Table (2) depicts that causes of Tuberculosis in the rural area are accounted for poverty (39.95%), smoking (22.39%), untreated cases (12.4%), alcoholism (11.32%), malnutrition (10.30%) and overcrowded (3.57%) respectively, and accounted for alcoholism (27.77%), overcrowded (27.16%), malnutrition (24.69%), smoking (11.93%), poverty (7.62%) and untreated cases of Tuberculosis (0.80%) respectively in the urban area. So, poverty and smoking are considered the most effective causes for patients in the rural area. In contrast, alcoholism, overcrowded and malnutrition are considered as the most effective causes for patients in the urban area.

Results of treatment out of table (3) reveal that success rate are (69%) in 2014, (61%) in 2013 and (51%) in 2012 respectively. Such rate can present evidence that patients in 2014 have benefited out of the program more than others.

Table (4) shows that age specific incidence numbers, percentage and incidence rate by gender. The percentage and the numbers in age group 15-24 years old was the highest and declined thereafter while age was increasing
for both male and female. But the incidence cases in age group 0-14 in both male and female were almost the same.

Though the incidence rate of both male and female cases the same in the age group 0-14 years old and difference was much higher as age groups increased from 15-24, 25-34, 35-44, and the highest was found among the age group 55-64 years old while the rapid decreasing was found in the age group 65+ years old.

**Conclusion**

The study concluded that Most of the new smear positive cases are accounted for the age group of (15-24) year old during the years of 2012-2016. The urban zone’s incidence rate was greater than that of the rural zone. Poverty and smoking were considered the most effective causes for patients in the rural area. In contrast, alcoholism, overcrowded and malnutrition were considered as the most effective causes for patients in the urban area. Patients in 2014 had benefited out of the Tuberculosis Program more than others based on the success rate. The incidence rate of both male and female cases the same in the age group of (0-14) years old and difference was much higher as age groups increased from (15-24), (25-34), (35-44), and the highest was found among the age group (55-64) years old while the rapid decreasing was found in the age group 65+ years old.

Forensic Examinations and Therapeutic Agreement in Indonesia

Osgar Sahim Matompo
Associate Professor, Muhammadiyah University of Palu

Abstract
This research describes the type of legal protection for doctors and patients in forensic examinations. The therapeutic agreement is an agreement between doctors and patients which gives doctors the power to give forensic examination services. In the legal aspect of the therapeutic agreement, there appears the rights and responsibilities of each party. This means that both patients and practitioners have their own rights and responsibilities. The method used in this research is the doctrinal method with deductive and inductive approaches. Meanwhile, before the forensic examinations, the doctor needs therapeutic agreements to fulfill rights and responsibilities. Without this agreement, the doctor’s work may not reach a maximum positive effect. Thus, there must be a balance. The doctors need the therapeutic agreement to fulfill their responsibilities in the forensic examinations.

Keywords: Quality, Legal Protection, Doctors, Patients, Therapeutic, Agreement

Introduction
The Constitution No. 36 year 2009 is an implementing regulation of health services. This regulation is a means to create harmony between the doctors’ rights and responsibilities and the patients’ interests to achieve success in forensic examinations. The law of health is an implementation of the health law and state’s governance apparatus. The society views doctors as legal subjects which are interrelated, which creates both medical and legal relations.1

A problem happens when someone or some institutions need forensic examinations. Anyhow, in undergoing forensic examinations, the doctors are required to have an agreement from the patient or the family, or an order from authorized institutions such as the police department or the court. This is what is called as the therapeutic agreement or therapeutic order.2

Without having the therapeutic agreement or therapeutic order, the doctors do not have the right to undergo any forensic examinations. Problems arise as the patients have limited knowledge on the forensic examination techniques and also because the information given by the doctors are not satisfying enough for the patients and the family.3 This is the main reason why the doctors need it. It is called an agreement, as the relation between the patients or family and the doctors have reached the elements of a valid agreement to undergo forensic examination as written in Article 132.4

The problem of forensic examinations has long happened. Patients (those who will be forensically examined or who will undergo visum et repertum) or the patient’s family (if the forensic examinations will be done to a body) do not understand the process. They might also feel that such procedures are against their religious beliefs. In the forensic examination of bodies, there is sometimes the need to carry out surgery or the process of cutting open some body parts. This may happen in post mortem examination, for example. According to some of the Indonesian people’s religious beliefs however, this is against the belief of honoring the dead body. The second problem is that the doctors must convince the family to understand that this is an important process, that the forensic examination is needed to find out some things such as why the victim was hurt or dead, the types of wounds or disease and other things which can only be found through the forensic examination.5 The problem happens also when the patient’s family actively inquires

or objects the authority’s decision to undergo forensic examination. The doctors may be trapped between disputes. They may also be targeted by the family in the lobby. They may even be hurt.

Forensic test efforts which are beforehand aimed to know whether the patient or their body were affected by something. The doctors need legal protection which is integrated and sustainable. Therapeutic agreement with the right mechanism is the legal agreement for the doctor rights and responsibilities in forensic test or forensic agreement.

Research Method

The method used is the doctrinal method, with interacting deductive and inductive approaches. The problem above is analyzed based on the data which become the target of a deductive-method research. Then, based on the real condition, conclusions are made regarding the legal protection of the doctors’ and patients’ rights and responsibilities in the perspective of therapeutical agreement.

Findings and Discussion

The existence of forensic examinations always involves the interests of all members of the society. The society may experience some events and become a victim. They may also be suspicious that someone has become a victim. Sometimes the people are suspicious that the one who reject is the perpetrator. The arrangement of legal protection for doctors to undergo forensic examination is said to be real when a legal subject is given rights and responsibilities. Legal protection is defined as giving guarantee or protection, provisions, licences and so that they cannot be persecuted if there are mistakes in the diagnosis of the examination results which are unintended from the authority those protected from all dangers or risks which may arise.

The therapeutic agreements or the therapeutic orders for doctors are based on the problem of legal protection for the doctors regarding forensic test service and the treatments given by doctors. Informed consent is an agreement between doctors and patients or the family to undergo forensic examination and it is known as the therapeutic agreement. From the authorized institution in the case of criminality, it is known as the therapeutic orders. In the medical world, it is called the therapeutic agreement or informed consent, which is an agreement for doctors to undergo examination or therapeutic effort a patient after the patient or family or the authority has obtained information.

Therapeutic agreement in Indonesia is a crucial thing in the forensic examination. The therapeutical agreement contains two essential elements, which are the information given by the doctor and the agreement given by the patient or the authority. The therapeutical agreement will create interacting rights and responsibilities for doctors. The therapeutic agreement gives an excellent quality of legal protection for doctor in the case of forensic examination.

The therapeutic agreement gives a trust to the doctors in giving the forensic test or forensic examinations. It can be used as a legal protection if the any wrong results were given by the doctors. It is because in the therapeutic there are provisions. It is said that if the doctors fail to perform their obligations in the forensic examinations, the patients or their family or the authority will not sue that mistake.

Even so, the patients juridically have the right to sue them if the health workers did not undergo their professional standards well. The two essential elements in the basis of the therapeutic are the information from the doctors and the approval of the patient or their families or authority. The Republic of Indonesia’s Ministry of Health Decree Article 1 No. 290/MENKES/PER/III/2008 regarding Agreement of the Medical Treatment. Regarding the forensic examinations, the doctors have the obligation to obtain the correct, clear, and honest information from their examination results.

Approval will be given for the doctor. That agreement is in the form of clear approval, which is done in a written form by patient, families and the authority. The doctors will give an explanation and medical records. The patients must obtain clear information regarding the forensic examinations which will be given by the doctor. Obtaining information is an obligation for doctors.

The Constitution of Health Article 8 states that each person has the right to obtain information regarding one’s data of health, including the treatments and the medications which have or which will be obtained from the doctors. There are the rights of the doctors as a form of legal protection which must be taken consideration of, which are the rights to obtain forensic examination service, the rightsto give information, and the rights to be protected.
The therapeutic agreement between the doctors and the patients are based on Article 1320 B.W (Burgerlijk Wetbook/Indonesians Law Codifications). It does not only create rights of patients, yet there are also consequences if the doctors purposely fake the examination results. They may be imprisoned or their licenses may be annulled.

Regarding the points above, the rights of the doctors include working according to the standard. They may refuse to carry out procedures which cannot be professionally taken responsibility of. They may also refuse undergoing forensic examinations, except through the right process.¹²

These responsibilities are binding. If the doctors do not undergo their responsibility to carry out forensic test or if they undergo maltreatments which are not according to the procedures, thus there are other responsibilities which must be taken by the doctor. The said ‘other responsibility’ is in the perspective of legal protection, where there are two kinds: legal responsibility in the aspect of civil law and that of criminal law. If the doctors do not undergo their responsibilities, thus, the authority may sue them to pay for compensation or they may be punished as written in the Civil Law (KUH Perdata) Article 1365. It is said that if there is any action which violates the law, which brings loss to others, thus the perpetrator must pay compensation or they may be jailed if they undergo crime in the forensic examination process.

Meanwhile, the elements which must be fulfilled in Article 1365 of the Civil Law (KUHPerdata) is that there are actions which violate the law. There must be wrongdoingness by perpetrators, there are losses experienced by the victim, and there is a casualty effect, which is the relation between the perpetrator’s (the doctor’s) wrongdoingness and the losses experienced by the victim.¹³

Thus, in this relation, there exists rights and responsibilities which are interrelated.¹⁴ In practicing their responsibilities in the forensic examinations, doctors may have mistakes and errors which may bring a negative impact. Such cases may grow into various things, such as: how a doctor is considered to be doing malpractice or how they fake reports, or how a doctor underwent a default.¹⁵ There are three elements of a doctor’s error which may result to imprisonment in undergoing forensic examinations, which are: (1) the doctor underwent a medical profession error, (2) such actions are done carelessly, (3) they undergo fatal actions such as faking reports, purposely undergoing errors for certain motives. Thus, the doctors who underwent professional errors may be imprisoned, and his/her practice license may be revoked by the Ministry of Health.

Thus, to protect the doctors, they need to obtain the therapeutic agreement before forensic examination. it is better if therapeutic is stated in a written form, so as to become an authentic proof if things were to happen. This may avoid the accusation of undergoing wrongdoingsness if the doctors’ forensic examination are based on the procedures, and have been explained correctly.

## Conclusion

Doctors cannot undergo forensic examination without orders from the authority in the case of forensic examination to open up criminal cases. The doctors may also undergo forensic examination based on the agreement of the patients or the family in necessary conditions, for example if someone feels that he/she is a victim and therefore needs that process. The therapeutic agreement is a mechanism which ensures that the doctors will receive legal protection after undergoing forensic examination.

The Effect of Ciprofloxacin Exposure on Ctx-M Gene Pattern of Escherichia Coli

Muhammad Amin¹, Eddy Bagus Wasito¹, Erwin Astha Triyono²

¹Department of Clinical Microbiology, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo Teaching Hospital, Surabaya 62085, Indonesia, ²Department of Internal Medicine, Faculty of Medicine, Universitas Airlangga, Surabaya 62085, Indonesia

Abstract

Background: An exposure of ciprofloxacin on Escherichia coli (E.coli) may cause cross-resistance to beta-lactam groups. The researchers obtained that ciprofloxacin, aminoglycoside, cotrimoxazole and second generation of cephalosporins were the risk factors for infection caused by Extended-Spectrum β-Lactamases (ESBL)-producing bacteria. Exposure of ciprofloxacin to E.coli causes resistance of cefotaxime and produces ESBL which is genotypically evidenced by the presence of CTX-M.

Objective: To know the effect of ciprofloxacin exposure on CTX-M gene pattern of E. coli.

Method: A total of 30 E.coli isolates were exposed to ciprofloxacin for 14 days with the Kirby-Bauer antibiotic disc diffusion method. ESBL confirmatory test and Modified Double Disk Susceptibility Test (MDDST) method was used the antibiotic disc and continued electrophoresis using Polymerase Chain Reaction (PCR). The data analysis used the chi-square statistic test with α = 0.05.

Results: In the PCR examination, 10.00% of ESBL isolates were obtained to have CTX-M-15 gene, and 33.00% of non-ESBL E.coli isolates having CTX-M-15 gene. While 10.00% of E.coli ESBL isolates and 53.30% non-ESBL did not have CTX-M-15 genes. There was no significant difference between ciprofloxacin exposure and the presence of CTX-M-15 gene (p = 0.290).

Conclusion: Most of the E.coli isolates had CTX-M-15 gene after the exposure. There was no difference in ciprofloxacin exposure to the presence of CTX-M-15 genes of E. coli.

Keywords: Ciprofloxacin, Escherichia coli, ESBL, CTX-M genes

Introduction

Ciprofloxacin is a member of the fluoroquinolone antibiotic class. The mechanism of action of fluoroquinolone class antibiotics is to interfere with the enzymes Gyrase A, B, and Topoisomerase IV, thus inhibiting deoxyribonucleic acid (DNA) replication, and further disrupt protein synthesis and bacterial cell death. Escherichia coli (E.coli) is a species of the genus Escherichia which is a member of the Enterobacteriaceae family. After the discovery and use of the fluoroquinolone, group began to emerge the fluoroquinolone-resistant Escherichia coli strain by expressing a protein that protects the active site of the gryrase enzyme targeted by fluoroquinolone antibiotics. This leads to fewer antibiotic therapy options, prolonged treatment length, high morbidity and mortality, and increased maintenance costs.

The use of ciprofloxacin as part of fluoroquinolone is alleged to be a risk factor for urinary tract infection (UTI) caused by E. coli, resulting in the enzyme extended strain beta-lactamase (ESBL). In a study conducted on E. coli isolated from cats, it was found that the CTX-M
ESBL encoding genes were also present in the same plasmid as the Plasmid-Mediated Quinolone-Resistance (qnr) gene. Research conducted in Spain shows that the ESBL enzyme in E.coli was TEM (60.00%), CTX-M (24.00%), and SHV (16.00%). ESBL CTX-M-15 enzyme obtained at E.coli at Dr. Soetomo Teaching Hospital Surabaya for 94.50% in all specimens and 84.00% in pediatric patient feces.

The abundance of ciprofloxacin and cefotaxime as an empirical therapy option in UTI should be recognized as potentially causing resistant strains to many antibiotics. This is due to cross-resistance between one antibiotic and another, in this case, ciprofloxacin and cefotaxime because of the similarity in which the gene encodes resistance to both. An exposure of ciprofloxacin to E.coli may cause resistance to cefotaxime and produce ESBL which is genotypically attested by the presence of the CTX-M gene. We aimed to know the effect of ciprofloxacin exposure on the pattern of CTX-M gene in E. coli.

**Method**

The population was a clinical isolate of inpatients Dr. Soetomo Teaching Hospital Surabaya who grew E.coli at Clinical Microbiology Installation by using the automatic diagnostic method. The sample size used the Central Limit Theorem, i.e., 30 isolates of E.coli sensitive non-ESBL ciprofloxacin from clinical specimens of inpatients in Dr. Soetomo Teaching Hospital. The inclusion criteria of E. coli were from clinical specimens of hospitalized patients, calculated colonies of E. coli ≥105 CFU/mL if derived from middle transition urine and ≥102 CFU/mL if derived from catheter urine and any amount derived from suprapubic urine, and E.coli was sensitive to ciprofloxacin based on the results of the susceptibility test of the method for diffusion. The exclusion criteria included cefotaxime, ceftazidime, aztreonam, amoxicillin, and bacterial isolates by using the Phoenix-BDCLSI M100S 2016 automatic technique, then exposure to ciprofloxacin discs for 22 hours at 37°C. The second-day isolate was suspended in a 0.9% NaCl solution to a turbidity of 0.5 McFarland. On the second day was also prepared exposure discs ciprofloxacin and cefotaxime with isolate sensitivity to cefotaxime as a screening test. If cefotaxime resistant, then it was proceeding with the confirmatory test. If the modified double disk susceptibility test (MDDST) confirmatory test results, it will be stored at room temperature for PCR test. The next step was to read the sensitivity of antibiotics using sensitivity tests. Its classified to be sensitive on ciprofloxacin if the inhibitory zone showed diameter ≥21 mm and resistant if ≤15 mm. Whereas, cefotaxime classified to be sensitive if inhibit zone was ≥26 mm and resistant if the inhibition zone was ≥22 mm. The sensitivity test for ceftazidime said to be sensitive if inhibition zone was ≥21 mm and resistant if the inhibitory zone ≤17 mm. ESBL classified to be positive if resistant to cefotaxime. ESBL confirmation test was positive if found widening of inhibition zone on the side of the disc that faces amoxicillin clavulanate. Then, prepared PCR examination with plasmid extraction using commercial kit by PureYieldTM, performed PCR examination by mixing the target DNA of extraction into a 50 μL ependorf tube inserted into a PCR machine then electrophoresis.

**Results**

Isolate Resistance to CIP and CTX by Kirby-Bauer method

The subjects obtained 5 (13.50%) E. coli isolates were resistant to cefotaxime and 3 (8.10%) isolates were resistant to ciprofloxacin sequentially after confirmation of the test by the Kirby-Bauer disc diffusion method.
(Table 1). In the post-CIP recurrence of the eighth day, 5 (16.70%) isolates were resistant to cefotaxime. Then, day 12 obtained 4 (13.30%) isolates that became resistant cefotaxime and 1 isolate become sensitive again. On day 14, 4 (13.30%) of cefotaxime resistant isolates were detected and to date, no isolates were resistant to ciprofloxacin (Table 2).

**ESBL Confirmation Test from CTX resistant E.coli**

On the day 4, there was no isolate changed to ESBL. While on day 8, was found 10.00% of the isolates into ESBL. Additional of new three ESBL isolates were obtained on day 6, 7, and 8. On day 12 the ESBL isolate did not increase with total 4 (13.30%) isolates until day 14. There were 5 isolates of E.coli exposed to CIP (1357PS, 1564US, 1590SS, 2015SS, and 2707PS) resistant to cefotaxime but after confirmation testing, there were only 4 isolates (1357PS, 1564US, 2015SS, and 2707PS) confirmed ESBL. Isolate 1590SS was not confirmed as ESBL but the next day becomes sensitive to cefotaxime. In the E.coli isolate (2056US) of the cefotaxime-exposed group that was resistant to cefotaxime but after a confirmatory test, it was not proven to be ESBL. Its becomes sensitive to cefotaxime by the next day. However, in both groups, no isolates were obtained to be resistant to ciprofloxacin (Table 3).

**PCX gene CTX-M-15 examination results in E.coli exposed to ciprofloxacin**

A total of 30 isolates of E.coli exposed to ciprofloxacin, there were 13 (43.30%) had CTX-M-15, 1 (3.30%) ESXL isolates which did not have the CTX-M-15 and 10 (33.30%) genes isolated with the gene CTX-M-15 but phenotypically were not ESBL. All of 30 clinical isolates of E.coli non-ESBL and ciprofloxacin-sensitive exposed to ciprofloxacin for 14 days, was found 4 isolates became ESBL (Table 4). All of these isolates were then examined using PCR. Statistical results showed there is no significant differences the presence of CTX-M-15 genes after exposure to ciprofloxacin (p = 0.290).

Discussion

There was no significant difference between ciprofloxacin exposure and the presence of CTX-M-15 genes. It was possible that there were other genes that encode ceftazidime (CAZ) resistance. This statement can be denied considering that in isolation E.coli was sensitive to CAZ or ESBL screening and confirmation methods were less accurate. The sensitivity of ESBL confirmation test with modified DDST method according to Clinical and Laboratory Standards Institute (CLSI) was 65.4% (21). This was because some ESBLs could not reach the concentrations that detected by the antibiotic disc diffusion test, thereby thwarting the therapy. The presence of porcine was quite instrumental in making antibiotics capable to killing bacteria. In small amounts of porins, beta-lactam antibiotics could not be able to enter the cells and phenotypically become a resistant bacteria. However, if the number of porins is large, there is an antifungal that not hydrolyzed (beta-lactamase) which is able to kill bacteria. In this condition, bacteria was sensitive to beta-lactam. This causes E. coli strains that genetically have CTX-M-15 genes but were phenotypically not ESBL. However, referring to several bands in the electrophoresis results, this was because the primers used were less specific for the CTX-M-15 gene, so bands from other genes become emerging. Each class of antibiotics has its own mechanism in inhibiting and killing bacterial cells. Such mechanisms of damaging antibiotic molecules, altering antibiotic action targets, and decreasing intracellular antibiotic concentrations. In these three mechanisms, repeated exposure to antibiotics will make bacteria remains alive. This was due to the mechanism of cross-resistance among antibiotic classes. In this study, the bacteria did not die or were outside the inhibition zone due to antibiotic concentrations.

The main mechanism of fluoroquinolone class antibiotic resistance through GyrA and GyrB gyrase encoding mutations was contained in chromosomes. In addition to the main mechanism, there was an additional mechanism, namely Plasmid-Mediated Quinolone Resistance (PMQR), in which all the genes were located in the plasmid. In certain plasmids (Inc-H, IncF, IncP) it containing the gene encoding of PMQR, there was also a CTX-M-15 gene encoding one of the ESBL enzymes. Repeated exposure of ciprofloxacin to E. coli may make it an effort to adapt by transferring plasmids Inc-H, Inc-F, and Inc-P which makes E. coli increase with ESBL-encoding genes to become dominant. The result showed that 4 isolates of E. coli exposed to ciprofloxacin were changed to ESBL while at exposure cefotaxime none became ESBL. All of E. coli ESBL was still sensitive to ciprofloxacin. PMQR was not the primary mechanism of bacterial resistance to quinolones, but the presence of an improved MIC-enhanced PMQR gene that does not always reach the limits of the resistance criterion (biological resistance). E.coli strain with PMQR were more sensitive to ciprofloxacin but not enough to kill the bacteria, or there was a non-dominant resistance strain. The number of resistant strains between 1-1.000 for each 109 bacteria.

The result of this research showed that the isolate of non-ESBL phenotype but on PCR examination was obtained CTX-M-15. There were 23.66% isolates become sensitive to ceftazidime and non-ESBL and 2.17% of K. pneumonia with CTX-M-Group IV genes are both sensitive ceftazidime of 93 E.coli isolates. CTX-M group IV refers to CTX-M-9, 13, 14, 16, 17, 18, 19, 21, and 27 as well as Toho-2. Another study stated that 38 isolates of E.coli non-ESBL (52.60%) had ESBL-encoding genes.

Conclusion

Most of the E.coli isolates (43.00%) had CTX-M-15 gene after exposure to ciprofloxacin. There was no difference between the presence of CTX-M-15 gene after ciprofloxacin exposure that caused by screening method, ESBL confirmation was less accurate, or the presence of porins. The recommendation may be that the exposure
time of ciprofloxacin is extended until proven for certain
time required by the bacteria to be resistant to cefotaxime
and ciprofloxacin and further studies are conducted to
determine the pattern of gene encoding resistance to
other antibiotics (aminoglycosides, tetracyclines, and
heavy metals) in isolates exposed to it.

**Ethical Clearance:** This research is in accordance
with ethical clearance, has not been published before
and is not being considered for publication elsewhere.

Abstract

This research aims to prove visum et repertum as an evidence of a rape crime in the trial process at Kupang District Court (PN Kupang), so as to know how the judge assembly accommodate all evidences in the court as a basis to make a verdict, regading the weight of the punishment which will be given the rape crime perpetrator. This is a juridical- empirical descriptive research, as it uses primary and secondary data in the form of the judges’ verdict at the rape crime trial which is absolute and also interviews conducted to subjects who are involved in the research. The health aspect in proving the rape case is evidenced in the visum et repertum papers and expert information from the doctors who examined the victim.

Keywords: Forensic examination, Visum et repertum, Rape crime, Judge’s verdict

Introduction

The Post-Reformation era in Indonesia is marked by the transparency of information and news. Reports show devastating information on rape crime. The data displayed in the Trauma, Violence, & Abuse journal suggest that rape victims are often children. In is said that between 8% until 13% of girls had experienced sexual violence. Meanwhile, the percentage showed 3% until 13% of boys are victims of sexual abuse. 1 The Annual National Commission of Women 2018 report said that there were 619 cases of rape in private space (families and relatives). Meanwhile, in the public/communal space, there were 669 cases. Such cases in public spaces usually happen at school, in public transportations, or even during deviating religious or spiritual rituals 2.

Anastasi Reni Widyastuti said that, “There are various possibilities which affect the high rate of reports on violence towards women. This may be because of the women’s awareness regarding their rights, their higher understanding, the law enforcement for women, or that the law is not effective enough in giving protection for women who are victims” 3. According to Reni, the various regulations which exist today only reflect the power of the patriarchic values. There are still discrimination and exploitation of justice-seekers and the common society in the enforcement of public regulations.

Results of the crime court system has brought disappointing empirical data. Harian Kompas newspaper survey showed that 72,7% of the people has not received just treatments. 45,2% of the public suggest that the judges’ verdicts are based on the consideration of money, and 30,5% of the respondents suggest that the verdicts are based on political considerations. Only 9,3% of the respondents believe that the Indonesian court verdicts are based on the consideration of law. 4

Thus, there needs to be a reformation of law and policies, especially in the law enforcement system which is just to all genders. 4 Usually, in the solving of crime cases, the law seems to emphasize the rights of the perpetrators, meanwhile the rights of the victims are ignored. 5
The judge poses a core role in the case-solving process, especially in rape crime cases. Regarding whether or not the defendant really did the action accused is the most important part in the criminal procedure law. Yet, what is not less important is the evidence given by the victim regarding the accused’s actions. There aspects of evidences: Evidences in the aspect of forensic based on Article 184 of the KUHP regulations which includes visum et repertum, expert forensic information, and DNA test for victims.

Meanwhile, the writer will use objects as an empirical study material to test the assumption regarding the verdict on the rape crime case at PN Kupang, as there is a high rate of sexual violence towards women. There are 153 cases between 2013 until 2017 which were inspected and decided upon by the PN Kupang. There are 2,573 gender-based cases which happen in East Nusa Tenggara. These numbers are accompaniment data from Kupang Women’s House or RPK from year 2000 until 2014 within the city/regency area. Meanwhile, there has been 144 cases between 2015 and 2017.

Physically, the victims experience fear, anger, disappointment, disgust to herself, and they blame themselves regarding the sexual violence they experienced. They will cry easily. Other consequences include insomnia, stress, aggressivity, social avoidance towards the family and the environment. According to Khudzifah Dimyati, there are various impacts which happens to rape victims, “Rape victim suffer losses, mental breakdown and/or suffering financially, physically, psychologically and socially, among many losses psychologically or mental, although rape victim suffers financially, physically, psychologically and socially, their position in the criminal justice system has been neglected.”

Method
This was non doctrinal research. Data were taken from State Court of Kupang, East Nusa Tenggara Indonesia, from 2013 until 2017, then analyzed descriptively. The analysis results were presented in the form of tables and narrations.

Findings and Discussion
Case Verdict of Rape Crime in PN Kupang

There are 153 numbers of cases investigated and decided upon by the PN Kupang from 2013 until 2017. If viewed from the groupings of the crimes’ maximum punishment, the punishments are very light; light (1-2 years); medium (2-4 years); severe (4-7 years); very severe (over 7 years), with further explanation as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>Case</th>
<th>Verdict Category</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Rape</td>
<td>Light</td>
</tr>
<tr>
<td></td>

<tr>
<td>2017</td>
<td>4</td>
<td>23</td>
</tr>
</tbody>
</table>

From the table above, we can see that the Defendants’ punishments, or the judges’ verdict at the PN Kupang are mostly in the categories of severe or very severe. It can also be seen that out of 55% of the sexual violence cases taken to the court, the punishment for the perpetrators usually falls under 6 years of imprisonment.
In the victims’ and the victims’ families’ point of views according Watty Bangang in a conversation with Watty Bangang as a Coordinator of the Accompaniment and Victim Division of RPK, East Nusa Tenggara, “The punishment given to the perpetrators are not equal with what they must go through after the sexual violence. The sexual violence experienced is not fully healed in a wider sense, and the healing process is not provided by the government.”

The Process of Proving Rape Crime by the PN Kupang

Munir Fuady defined the proving of law as a process in a civil court procedure, a criminal court procedure, or other courtly procedures. It uses the judge’s power procedure to consider facts and statements disputed in court to prove its truth. Then, according to M. Yahya Harahap, evidencing is also a procedure to manage evidences which are valid according to the constitution, which may be used by the judges to prove the accused’s guiltiness.

Proving is based on positive law in considering the evidences’ strength of value is based on the constitution. In this case, if a criminal action is proven based on the evidences required in the Constitutional regulation (article 184 of KUHAP), which are the forensic proof as visum et repertum or others include the expert information, the defendant’s letters, evidences, and information.”

The change of the judges’ views on rape crime is crucial. They must not perceive rape as a normal crime, but they should view it as a violation of human rights. This is parallel with Moerti Hadi Soeroso’s opinion, who said that, “The forms of rape towards women, including rape within marriage, may be categorized as gender-based violation.” Violence crime is categorized as an action which violates the women’s rights as human beings.

Other evidences, such as those from the forensic aspect, like in the form of visum et repertum, may be difficult to be proven as victims seldom report the case right after having experienced rape. This is usually because the rape victims felt scared and ashamed. They will usually clean themselves or take a bath as a manifestation of disgust towards the perpetrators’ actions and disgust towards herself. Thus, bodily evidences such as bruises, and fragments of the perpetrators’ bodies such as hair, sperm, or skin which stick to the victim’s body may not be obtained during the forensic examination. Meanwhile, if the victim is pregnant because of the perpetrator, the only way to determine the father of the fetus is through a DNA test. Yet, the DNA test is rather expensive, thus it may be hard for the victim, the family, to access.

Forensic doctors’ help to obtain legal evidences of rape cases are crucial. This is regulated in Article 133 paragraph (1) of KUHAP, which states that investigation for the sake of trial in treating victims of wounds, poisoning, or death, which are allegedly caused by criminal actions are allowed to be done based on expert information by medical experts or doctors from other expertises.

In a conversation with a pseudonym, Judge of PN Kupang on May 28th, 2018, the Judge said “The term rape is sometimes misused by the society to report the perpetrator. In this case, the society (or the victim’s parents) use the constitution to report the perpetrator, because usually the punishments of enprisonment or fine is rather high. Thus, they use this gap to obtain profit. So the visum et repertum as forensic proof was urgent” Based on the judge’s testimony above, thus the writer concludes that this visum et repertum may influence the judge’s consideration towards the victims, thus the verdict given to the perpetrator may be light, medium or severly based on forensic process.

Thus, the proposal of a visum et repertum evidence is crucial to be present in a criminal trial as it becomes the judge’s consideration in determining the severity of the criminal act’s sanctions to the rape perpetrators.

In the case No. 33 / Pid.B / 2017 / PN.KPG, the judges give consideration that the charge for the defendant is the first alternative charge, which is the violation of Article 285 KUHP, in which its principalities contain the following elements:

1. Whoever; fulfilled
2. With violence or threat of violence forces a woman who is not his wife to undergo sexual intercourse, strengthened with the evidence of Visum Et Repertum No. B/389/IX/2016/Kompartemen Dokpol Rumkit issued by dr. Chindy Tefà on the date of September 3rd, 2016 by the name of Adriana Paa, it is concluded that from the examination of the victim’s genitals, it is found that there are new tears in the hymen until the basis, with the locations in the direction of one o’clock, three
o’clock, five o’clock, seven o’clock, eleven o’clock, and reddish bruises on the labia minora in the direction of nine o’clock and three o’clock, caused by contact of a blunt object.

Judging:

States that the defendant has validly according to the visum et repertum and convincingly guilty of the crime of “rape”; and giving the verdict to the Defendant of enprisonment for 1 (one) year and 8 (eight) months;

Analysis

Regarding the case above, it seems that as always, The judges making a verdict base on the forensic process (via visum et repertum) even the judges not give severe verdict. Physical harm doesn’t become a point which makes the judge consider a severe punishment for the defendant, even though evidences has been shown through the visum et repertum report which stated that the victim experienced new wounds on the hymen on the directions of one o’clock, three o’clock, five o’clock, seven o’clock, eleven o’clock, and reddish bruises on the labia minora in the direction of nine o’clock and three o’clock, caused by contact of a blunt object. These evidences are in the form of valid and responsible medical information regarding the victim’s condition, especially that whih regards proofs of violence.

According to Susetiawan, rape in the macro vision is a form of ripping away human rights. Yet, rape in the sexual coercion vision may also be defined as ripping away rights, like the rights to be virgin, the rights to be free from suffering, the rights to be free from fear, and the rights to be free from inhumane actions. Because of the rape, the victim experienced impacts of the violation of human rights. The proving process of that case include the visum et repertum, should already be enough for the judge to give an equal punishment to the perpetrator, as it has been proven by the visum et repertum. Yet this is not accomodated.

According to the writer, in the case above, the judge assembly was not thoughtful enough in giving legal consideration as basis of the verdict, as there are some points ignored, such as: the victim’s visum et repertum examination which is written in the visum et repertum letter by the doctors, which concluded that there has been new wounds in the victim’s genitals. The forensic process via visum et repertum became evidence for the judges to made the verdict given to the Defendant by giving him a sentence in jail.

This case has fulfilled the requirements of two evidences, which are a forensic statement in the form of visum et repertum and the perpetrator’s admittance, thus these evidences may become the basis in dropping a verdict to the perpetrator which is equal to his actions, which is 12 years of enprisonment as written in Article 285 of KUHP. Based on the Police Investigation Report, in this case of rape, the crime of rape is categorized as Victim Precipita Rape which places the victim as the originator(15). This is done with the motive of coercion and threat.

Khudzaifah Dimyati says “that the judge, as an enforcer of law, must be able to discover, to read, to interpret, and to implement the legal codes rightly and correctly as part of an effort to encontent the world into what is legal and ilegal”.16 In this context, the judge must look through all evidences in the court to achieve a wholistic consideration as the basis of his/her verdict, to determine the severeness of the punishments given to the perpetrator of the rape crime, and to achieve justice, certainty, and benefit.

Conclusion

The judge assembly of a rape crime in PN Kupang, case No. 33 / Pid.B / 2017 / PN.KPG has accept the evidences in the aspect of the victim’s visum et repertum examination which is written in the visum et repertum letter by the doctors, which concluded that there has been new wounds in the victim’s genitals. The forensic process via visum et repertum became evidence for the judges to made the verdict given to the Defendant by giving him a sentence in jail.

Inhalant Abuses in India: A Review

Raghavendra Reddy¹, Tim George Jose¹, Danie Kingsley²

¹Masters in Biomedical Genetics, School of Biosciences and Technology, VIT, Vellore, 632014, ²Guide: Assistant Professor (Senior), Department of Integrated Biology, School of Biosciences and Technology, VIT, Vellore-632014

Abstract

This review article explores the studies of inhalants and inhalant misuse in India. Since much research is focused on illegal drugs not much work had concentrated on the commonly available inhalants. The abuse of inhalants is a common phenomenon in the world. In this review, we will explain why these inhalants addiction is an inalienable thing which depressed youths can’t avoid. Then we will look into various inhalants commonly used and also into various case studies available in the literature hence knowing the abuse of inhalants among youths and techniques employed by them to get a kick.

Keywords: Inhalants, abuse, volatile solvents, youth.

Introduction

People inhale vapors of toxic substances to attain an elated experience as told by Scott Silvia and L Cruz.¹ By reaching this euphoria state makes them forget their past, worries. Therefore, it was necessity to look into inhalants used by youths in India. Inhalant mishandling has been present in India since 1970s, studies done notifies us the abuse has increased. It has been on the rise within students who are among low strata of the society and those who have broken families where students are forced to live on the street, rag pickers, who are unemployed, who gets into groups of gangs. Commonly used inhalants in capital of India are the Eraz-Ex diluter and whitener, made by Kores, commonly seen all through Delhi reported in his article by Gigengack.² A typical substance abuser can be either a person with academic failure or a dropout with socio-economic factors stated by Kumar, Suresh et al ³. Leading News outlets have reported about the addiction to whitener, The Hindu⁴, The Times of India ⁵, The New Indian Express.⁶

According to report of an activist of child rights Raj Mangal believed “that closely 50,000 children of streets with no support and the lakhs of others who have some care available, a vast majority are into substance abuse”. This shows the staggering rise of the children which can be affected with inhalants. The method the youth follow is mainly by sniffing or by pouring the whitener fluid on a cloth furthering using it as an inhaler, giving them elevation of rejuvenating experience for some hours as reported by The Hindu.⁴

Inhalants

Inhalant is a substance which is intentionally inhaled and prominently volatile for the purpose of triumphing an ecstatic state which has been reported worldwide highlighted by Ballard ⁷. From past 2 decades, inhalant abuse is an alarm raising problem among children and teenagers mostly seen who live in streets (gullies) and backward villages across the world as pointed out by Praharaj, Verma, P, & Arora, M.⁸ Coping with NIDA publications dated Feb 2017 has highlighted that these substances are chemical substances which have the capability to affect central nervous system and can delay brain activity. The main reason behind inhalant abuse addiction is availability of these dangerous chemicals in numerous common products such as petrol, glue, nail-polish remover, whitener (writer correction fluid), paint strippers, dry cleaning fluids, spray paints, deodorant sprays and electronic contact cleaners and so on, as pointed out by Weir based on addiction in Canada.⁹-¹⁰ The reason behind this epidemiology of this inhalant abuse was because of their low cost, ease of availability and lack of legislative control over control.
and acquisition pointed out by Dindwiddie.\textsuperscript{11}

When it comes to the chemical nature of this inhalants, hexane which affects peripheral nervous system, toluene and nitrous oxide which cause both central and peripheral nervous system purported by Charles W. Sharp and Fred Beauvais.\textsuperscript{12( pp1-8)} Symptoms of inhalants at acute level resembles to alcohol intoxication which include excitation, agitation, drowsiness. Increasing intake of inhalants further leads to dizziness, ataxia and disorientation. At extreme level of abuse leads to hallucinations, muscle weakness, insomnia, nystagmus (eyes make repetitive movements). Charles W. Sharp and Neil L. Rosenberg have highlighted that at chronic level abuse it leads to serious complications like loss in weight, disorientation, and coordination impairment \textsuperscript{13(pp 117 -120)}.

**Modes of inhalation**

Separate studies by Weir, McGarvey, Ford found that these inhalants are taken by self-administration where chemical like fuels, solvents and adhesives like glue, acetone and butane are inhaled by nose referred as sniffing, breathing fumes from an inhalant-soaked cloth mainly nitrate canisters or gas dusters bloated in the mouth termed as huffing, breathing fumes from inhalant like paints and adhesives are placed in a plastic bag seized and forcefully inhaled by mouth termed as bagging these studies had pointed out that most of the cases were seen in other countries like Mexico, Canada, USA, South Africa, Australia, United Kingdom, Croatia and Latvia.\textsuperscript{10,14- 15}

**Typewriter correction fluid (TCF)**

As there was no significant statistical data to reveal the usage of typewriter correction fluid in India but there are some cases which has been published in recent years. Because of its low cost and ease availability without any further restriction from drug and department stores use of this type of inhalant was increasing enormously. Symptoms of using TCF depend upon the mode of exposure for example if skin is exposed then symptoms like appearance of first and second degree burns, severe rashes and erythema. If intestine is exposed then related symptoms like Nausea, Vomiting, diarrhea, agitation, euphoria, headaches, dizziness and muscle weakness. If respiratory tract is exposed signs are similar to intestinal affects and sometimes leads to coma and sudden death as explained by Pointer.\textsuperscript{16} This inhalant consist of trichloroethane, trichloroethylene at a blend of 50-60% and toluene. These chemicals at extreme levels may leads to sudden death stated by Done.\textsuperscript{17} A study examined 10 children aged 11 to 12 years and are drop out of school and working as labor. Waraich et al had told that the children were inhaling not only TCF but also petrol, nail polish remover, tobacco and alcohol\textsuperscript{18}. A study evaluated 45 homeless children aged 6 to 14 years old in Delhi who were the victims of misusing TCF covering high toluene content told by Seth et al.\textsuperscript{19} Gupta et al had pointed that two children misusing TCF and an adhesive which is used to fix punctured tires.\textsuperscript{20} A national study on 100 children living in footpaths, platforms and streets, from that 83% of children were commonly misusing products containing toluene which was TCF by Ray. Further he reported another clinical data in 2011 that more than 33% of adolescence who were school children and school dropouts are using TCF as a primary inhalant.\textsuperscript{21,22} A study conducted to examine the inhalant abuse among street children in Delhi revealed that about 96% of them were regularly inhaling volatile substances; from those volatile substances 83% of them were using TCF with toluene content by Dhawan et al.\textsuperscript{23} Another case reported that 9 children aged 10 - 17 who were school dropouts have been huffing TCF regularly and they found more than 45 children were using TCF and paint thinners as inhalants in New Delhi by Praharaj.\textsuperscript{8}

**Glue/adhesive Sniffing**

Adhesives mainly glues have been misused by children in India and many other countries. It was found that these adhesives have been misused by sniffing so the term Glue sniffing has been appeared in many blogs and previous papers. Chemicals like toluene, acetone, n-hexane, trichloroethane, trichloroethylene are existing in these adhesives. Bass and Mondal proved in separate studies that sudden sniffing death syndrome is the outcome of many chronic glue sniffing cases.\textsuperscript{24, 25} A case by Sood, where a 16-year-old boy was admitted in emergency ward, symptoms he was experiencing were severe abdominal pain, vomiting and showing irregular respiration, hypertension. Hypertension in intracranial pressure is due to possibility of toluene. Later the boy died on 7\textsuperscript{th} day of admission because of intoxication. Other was 17-year-old male admitted to hospital with severe abdominal pain and renal failure and later he confessed that he had been regularly sniffing glue for kicks.\textsuperscript{26} Another meta-analysis study by Mondal states that streets boys living in railway platforms and footpaths of West Bengal, Bhutan, Bangladesh were addicted to
glue tubes, cans and rubber cement (type of adhesive) are favorite particulars of children. They also demonstrated that sniffing or huffing of glue/adhesive enhance the genotoxic affect in epithelial cells of mucosa of these children which suggest that there might be genetic alternations that may cause mutagenic events and cause cancers. Another case illustrates a 22-year-old man covered his face with plastic bag having large amount of glue in it. This person died while he was carried to the hospital, the reason of his death was sudden sniffing death which occurred by cardiac arrhythmia (mainly ventricular arrhythmia) and there was a presence of toluene ‘was’ demonstrated in blood and liver told by Jayanth et al in his study.

**Gasoline**

Thousands of children and teenagers were inhaling a vast varieties of organic solvents in order of achieving euphoric state. Those organic solvents include highly pressurized liquids which are aerosols like dry cleaning, lighter fluids and gasoline (petrol, diesel and kerosene). Symptoms and signs include euphoria, sleeplessness, changes in psychological activity because of toxic manifestations in central nervous system, multiple manifestations and sometimes leads to encephalopathy. A case assessed and reported that 15 teenagers aged 17 were sniffing cloth soaked in petrol and these had been identified by one of the boy showed psychotic behavior because of chronic inhalation and later hallucinations, illusions, amnesia and delusions have been observed in other students stated by Mahal. Another case reported that a 13-year-old girl was addicted to fumes of petrol, later she started sniffing cloth soaked in petrol and kerosene for one year and signs of becoming violent, pleasant feeling, loss of appetite concluded that she was experiencing inhalant abuse and was later confirmed by interviewing by Pahwa. Another case by Joshi and Vankar was about a 10-year-old boy huffing and sniffing petrol from vehicles, his parents observed over activeness, hangover like behavior, dizziness, restlessness and inattention. In other study, reported by Gautam a 22-year-old boy with a history of sniffing kerosene, petrol and diesel for past eight years on daily basis and on examination revealed poor grooming, delayed speech, insomnia and increased psychotic activity. Later the boy was treated boy with Clonazepam 0.5mg.

**Conclusion**

Inhalants abuse, one may overlook due to less awareness around this topic should not be rejected as normal issues faced by the young but should be given utmost care when dealing with them.

Researchers focus highly on the illegal drugs which has greater effects, they often overlook on inhalants since it is not used as much as other prohibited drugs but these inhalants overuse can turn deadly for anyone who does not think so, studies by Charles Wm. Sharp and his colleague have proven this. Hence our focus is to get back to basic items which are available in any stationery stores e.g. whitener, glue, nail polishers etc. which have been manipulated by deceived youths who think this as a source of excitement. Also we need to look into cases of acute users and chronic users of inhalants since we have to see the results of how exposure to these volatile solvents on long term affects young people, therefore a distinction has to be made on long and short term effects of these solvents. This has been a question long before, Charles W. Sharp and his colleague had discussed about these in their early studies. But the awareness about inhalants has not reached layman due to generation gaps, therefore government agencies, NGOs and other health care groups should educate parents, teachers and adolescent ones about the growing menace of this abuse. Also in this review we had discussed about the symptoms which can be identified if a person is addicted, hence on knowledge of these symptoms any one close to the student can counsel or report to elders or authorities.

Further bills should be passed in the parliament regarding ban of certain inhalants which can be toxic when overused. Since these inhalants are freely available hence the misuse is vast. Bio-friendly chemical components should be used as the composition for these volatile solvents. Finally, extensive research has to be carried out in these fields to get the accurate data about users of these inhalants, Mahal and Pahwa in separate earlier papers had highlighted this need for data. Reasons attributing to the lack of data could be less awareness concerning volatile solvent misuse, among healthcare professionals and parents. Clinical based studies regarding addiction of these inhalants among street children, abandoned kids should be taken into consideration. If any of the youths had been found using these substances of abuse they should be placed in de-addiction centers where they should be monitored, their
progress recorded.

Evaluation of Antioxidant (GSH, Vitamin A, E, C) and MDA in Iraqi Women with Toxoplasmosis

Fayhaa M. Khaleel¹, Areej Sh. Hameed¹, Ashgan S. Dawood¹
¹Department of Chemistry, College of Science for Women, University of Baghdad/ Iraq, Baghdad

Abstract

Background: Pregnancy loss, also referred to as a miscarriage or spontaneous abortion, is generally defined as a nonviable intrauterine pregnancy up to 20 weeks gestation. Early pregnancy loss, which occurs in the first trimester, is the most common type.

Objective: The aims of the study were to assess the role of (MDA, GSH, and levels of antioxidant vitamins, C, E and IgG, IgM of Toxoplasma gondii) causes of Abortions.

Materials and Method: For this study, 45 aborted women have been selected in first – trimester, and 25 well-matched women as control group their ages range from ( 20 – 33 years).

Results: The study shows is an increasing level of Malondialdehyde (MDA) in women with toxoplasmosis. Furthermore, there is a decreasing level of antioxidant vitamins (A, C, and E), and Glutathione (GSH).

Keywords: vitamin A, E, and C, Toxoplasma gondii, GSH, MDA, Abortion women.

Introduction

Abortion is the term refers to the ending of pregnancy by loss of a fetus before it can be outside the uterus after 9 months. An abortion which occurs spontaneously is called miscarriage or may be caused purposely and is called induced abortion (¹). Infectious toxoplasmosis is a specific type of toxoplasmosis in which a fetus is infected by the placenta is associated with fetal death and abortion, and in an infant, it is associated with a defect in neurons, neurocognitive deficits, and chorioretinitis. Early pregnancy loss, which occurs in the first trimester, is the most common type. The nonspecific symptoms of vaginal bleeding and uterine cramping associated with pregnancy loss can occur in normal, ectopic, and molar pregnancies, which can be a source of frustration for patients and clinical confusion for care providers (²,³).

Toxoplasma gondii belongs to coccidia, habit the domestic cat and other fields as its definitive host and wide range of birds and mammals as intermediate hosts (⁴,⁵). T. gondii specific IgM antibody production, and low numbers of concanavalin A binding sites have been located on the surface of tachyzoites. Glycoproteins that bind specific IgG and IgM have been identified on the surface of T. gondii, and it appears that T. gondii is capable of both N. and O. glycosylation (⁵).

Glutathione is a sulfhydryl-containing compound making out of three amino acids: L-cysteine, glycine, and glutamate (⁶). play the main role in many metabolic processes polyunsaturated fatty acids (PUFAs) oxidizes by ROS in the cell membrane. This reaction will results in lipid peroxidation, that yields free radicals (⁷).

Malondialdehyde (MDA) in cells of the human body and tissue is an indicator of the oxidative stress arising from the lipid peroxidation (⁸). The Lipid peroxide is the derivative enzyme of feeble unsaturated fatty acid produced from the result of deposition of a set of complex component (⁹).

The antioxidant vitamin C, A, and E play a significant role in keeping cells and neutralizing free radicals. Cancer prevention agents are found in many plants based foods inclusive leafy vegetables. Normal doses are safe during pregnancy. Vitamin C is a fundamental supplement involved in the repair of tissue (¹⁰). Vitamin E is a fat-soluble antioxidant, it interrupts...
the propagation of reactive oxygen species (11).

**Materials and Method**

For this study, 45 aborted women have been selected in first – trimester, and 25 healthy normal group their ages range from (20 – 33 years). from the in-patients and out-patients of Kamal Al- Samarrai Hospital from the first of March 2019 till the end of May 2019. Temnlof blood was taken under aseptic technique and sent for virological and parasitological investigations including IgM and IgG antibodies detection by using enzyme-linked immunosorbent assay (ELISA) kits by abnova. com< 0.9 negative 0.9-1.1 Equivocal >1.1 positives. Glutathione (GSH) mg/dl is measured glutathione by the method (12). Malondialdehyde [MDA] has been measured level (umol/l) (13). Vitamin C,( mg/dl), vitamin E (mg / dl ), vitamin A (mg / dl ) are measured by (14-16) respectively.

**Statistical Analysis**

The analysis is carried out data utilizing the SPSS – 18 (statistical packages for social sciences – version 18 PASW statistics).

**Results**

The result shows significantly change (p<0.05) levels of Glutathione (GSH), and Malondialdehyde MDA when comparing between aborted women and the control groups, as seen in Table (1), and figure (1).

**Discussion**

Repetitive pregnancy forfeit is usually characterized as at least 3 or more miscarriages roughly 5% of couples endeavoring pregnancy have recurrent pregnancy loss. Newly, the advance has been made in understanding recurrent pregnancy loss approximately 10-15% of all first-time pregnancies bring about an unsuccessful miscarriage. In many instances, a similar miscarriage rate in subsequent pregnancies is expected (7). Jaslow (17) and Rai (18). Found there is a significant relationship between the history of miscarriage in the family and the studied group this is may be estimated to be due to the lifestyle in the family. It is well known that the most important anti-parasite influential mechanisms is produced of NO and the most important products of lipid peroxidation which is that MDA arises from fatty acids peroxidation. The products of MDA can reason...
cross-linkage of membrane elements by influencing the ion exchange from the cell membrane \(^{(19, 20)}\).

In the present study, reported the increase in MDA in toxoplasma women. It is reported the increase of MDA action in lymphocyte and erythrocyte in the dust mite positive or skin positive group which show the oxidative stress in patients with dust mite \(^{(20)}\). Another study shows an increase of MDA which refers to the increment of lipid peroxidation, due to the decreasing activity of the defense system protecting tissues from the free radical \(^{(21)}\). The Free radicals have been implicated in the pathogenesis of a variety of diseases. Thus, the large amount of lipid accumulates produced in the placenta in many diseases, involving toxoplasma infestation and must be prevented through the production of antioxidants \(^{(21)}\).

In Iraq, there is a study shows the increased level of MDA in toxoplasma seropositive patients who agree with the present study \(^{(22)}\).

The alteration of serum glutathione in patients with toxoplasmosis which shows a significant increase in serum glutathione concentration in pregnant women infected by toxoplasmosis \(^{(23)}\). This increasing of glutathione in pregnant women do not enough to decrease the detoxication capacity of the pregnant uterus. The increasing of glutathione simultaneous in response to the increase of radical and electrophilic compounds this disagreement with our study another study which shows a decrease of serum glutathione this agreement with our study \(^{(22)}\).

Antioxidant vitamins play a major role in the health of human rather than intoxication the decrease in the levels of vitamins A, E and E (nonenzymatic antioxidant) in women with toxoplasmosis may be turnover to increase for preventing oxidative damage \(^{(23, 24)}\). In a study has reported an increased vitamin E resulted in trends toward increased tissue cyst number, tissue pathology and weight loss during infection \(^{(25)}\). In Iraq, there is the first study that shows decreased the levels of antioxidant vitamins A, E and C during infection with toxoplasmosis in pregnant women which agrees with our result \(^{(26)}\).

**Conclusion**

In conclusion, there is an increasing level of Malondialdehyde and decreased levels of antioxidant vitamins (A, C, E), and Glutathione in patients with toxoplasmosis.

Prevalence of Celiac Disease among Cases of Irritable bowel Syndrome in Baghdad- Iraq

Marwan Majeed Ibrahim
CABM Internal Medicine; Tikrit University College of Medicine; Physician at Al-Yarmouk teaching Hospital

Abstract

Celiac disease is a common illness need not to be mistaken as IBS or GI motility disorders and careful evaluation of IBS patients especially those with diarrhea predominant type may need to be considered.

This study disclose that about more than 12% of patients who had been already diagnosed as IBS is discovered to have positive serology of gluten sensitivity and the diagnosis of Celiac disease had been confirmed by histopathology study.

Though and careful evaluation of presumed cases of IBS especially those with poor response to conventional therapy or those who with atypical presentations is essential in order to reach to an alternative diagnoses.

Keywords: Celiac disease, Gluten sensitivity, Irritable bowel syndrome, Anti tissue transglutaminase, Gluten free diet

Introduction

Celiac disease is a common cause of malabsorption of one or more nutrients. Recent observations have established that it is a common illness with protean manifestations, a worldwide distribution is approximately 1%.

Its incidence has been raised over the past five decades. Celiac disease has several other names, as nontropical sprue, celiac sprue, and gluten-sensitive enteropathy, the etiology of celiac disease is not completely understood, but immunologic; environmental; and genetic factors imply the major role in pathogenesis.

Celiac disease is considered an “iceberg” disease. A few number of patients have classic symptoms and manifestations linked to micronutrient malabsorption along with a varied natural history; the onset of symptoms can occur at all points of life, though the disease has two peaks of ages: the first is early in life, at approximately 2 years of age (after gluten containing diets has been introduced), or later in the second to fourth decades of life. It may first manifest after an attack of prolonged diarrhea following gastroenteritis or even after abdominal surgery.

A larger number of patients have “atypical celiac disease,” with presentations that are not obviously linked to small intestine malabsorption (e.g., anemia, infertility, osteopenia, and neurologic and psychological manifestations). Even larger figure of patients have “silent celiac disease”; they are essentially asymptomatic despite abnormal small-intestinal histopathology and positive gluten sensitivity serology.

Other symptoms of patients with celiac disease may range from significant malabsorption of multiple nutrients, with diarrhea; weight loss; steatorrhea; and the consequences of nutrient depletion (i.e., metabolic bone disease and anemia), to the total absence of gastrointestinal symptoms despite evidence of the depletion of a single nutrient (e.g., iron or folate deficiency; edema; osteomalacia from protein loss).

Both IBS and gluten sensitivity are common in the general population and both can coexist with each other independently without necessarily sharing a common pathophysiological basis.

Not all patient with IBS or IBS predominant diarrhea is candidate for screening for gluten sensitivity but testing should be considered in the following situations:

1. Patients with GI symptoms including recurrent or chronic diarrhea; weight loss; malabsorption and abdominal bloating or distension and severe lactose intolerance.
2-Patients with no alternative explanations for extraintestinal manifestations of combined nutritional deficiencies and/or anemia, persistent transaminitis, delayed puberty, short stature, females with recurrent abortions, hypofertility, recurrent aphthous ulcers, dental enamel hypoplasia, idiopathic peripheral neuropathy or cerebellar ataxia, or recurrent atypical migraine.

3-Patients with type 1 diabetes mellitus if they present with clinical manifestations of presumed celiac disease.

4-Asymptomatic first-degree relatives of patients with an established celiac disease.

These recommendations are consistent with the American College of Gastroenterology guidelines. The Rome III criteria can establish the diagnosis of IBS without further extensive testing and seeking for alternative diagnoses may be considered in cases of nocturnal diarrhea, symptoms unrelated to food or defecation. Alarm features that raise the concern of other diagnosis in presumed IBS cases are weight loss, anemia, bloody stool, positive family history of inflammatory bowel diseases, colonic cancer or celiac disease.

It is very important to remember that patients with celiac disease is at high risk of several malignancies like esophageal and intestinal adenocarcinoma, B-cell MALT lymphoma, hence increased mortality, so strict gluten free diet is essential.

Figure 1 Testing for celiac disease in cases with diagnosed IBS depending on Rome criteria, especially in cases of diarrhea predominant IBD or there is possible alternative diagnosis other than IBS.
**Diagnosis**

**SERUM ANTIBODY ASSAYS**

1. IgA endomysial antibody (IgA EMA)

2. Immunoglobulins tissue transglutaminase antibody (IgA tTGA and IgG tTGA).

3. Immunoglobulins deamidated gliadin peptide (IgA DGP and IgG DGP)

All patients with Celiac disease express the HLA-DQ2 or HLA-DQ8 allele, although only a minority of people expressing DQ2/DQ8 have celiac disease. Absence of DQ2/DQ8 excludes the diagnosis of celiac disease.

Endoscopic small bowel mucosal biopsy is the gold standard. Endoscopic biopsy is mandatory in suspected cases even if mucosa looks normal. As the histological changes can be patchy, multiple biopsies – usually, more than four biopsies from the second part of the duodenum in addition to one from the duodenal bulb – should be obtained.(7)

Histopathological feature mainly seen are villous atrophy or completely absent with a reduced villous-to-crypt ratio and crypts looks hyperplastic. There is increase in cellularity of the lamina propria with a mainly plasma cells and lymphocytes. The number of intraepithelial lymphocytes per unit length of absorptive epithelium is usually increased.(8)

- IEL/100 enterocytes, intraepithelial lymphocytes per 100 enterocytes
- Type 0: Normal; celiac disease highly unlikely.
- Type 1: Seen in patients on gluten free diet (suggesting minimal amounts of gluten or gliadin are being ingested); patients with dermatitis herpetiformis; family members of celiac disease patients, not specific, may be seen in infections.
- Type 2: Very rare, seen occasionally in dermatitis herpetiformis.
- Type 3: Spectrum of changes seen in symptomatic celiac disease.

---

**Patients and methods**

A cross sectional study conducted at Alyarmouk teaching hospital internal medicine outpatient clinic from the period of march 2018 to march 2019 involving 140 patients who had been labeled as IBS or presented with recurrent symptoms highly suggestive of IBS.

Inclusion criteria are patients had been previously diagnosed by general practitioner, physician, or gastroenterologistas having irritable bowel syndrome based on symptoms such as recurrent abdominal discomfort, colicky abdominal pain, altered bowel habits, and bloating at time of presentation.
Exclusion criteria are patients with recent infectious diarrhea, history of inflammatory bowel disease, peptic ulcer disease, gastrointestinal malignancies, previous gastrointestinal surgeries, alcoholism and patients with advanced chronic illnesses (chronic renal failure, long term diabetes mellitus, and congestive heart failure).

The patients had been re-evaluated regarding the diagnosis either due non convincing response to IBS therapy, insufficient initial work up, or new symptoms had been developed.

Screening for gluten sensitivity had been done by using anti tissue transglutaminase (tTGA) assay then the patient with positive results undergone upper endoscopy and histopathological analysis of multiple biopsy specimens from second part of duodenum to confirm the diagnosis.

All the patients who had been diagnosed as Celiac disease undergone complete evaluation for anemia and micronutrient deficiency with CBC, serum ferritin, B12, and vitamin D level.

The patient who had been confirmed to have celiac disease established on gluten free diet and set for follow up.

**Statistical Analysis**

Analysis of data was carried out by available statistical package (version 25). Statistical significance was considered at (P value ≤ 0.05).

**Findings**

This study which in cover 140 IBS cases, in which each case had been assessed for possible gluten sensitivity and the results were 17 patients of 140 (12.1%) have positive serology for gluten sensitivity, all the cases with positive serology undergone upper endoscopy which confirm the diagnosis of celiac disease.

Fourteen of 17 patient (82.4%) who were positive were females and 3 (17.6%) were males in which it carry no statistical significance. P =0.585.

Most of these cases were diarrhea predominant IBS 10 of 17 (58.8%) where as 7 (42.2%) were constipation predominant type. Table 1

Discussion

Celiac disease is one of the most readily missed illnesses in practice due to the complexity of gastrointestinal symptoms associated with this disease, such as flatulence, diarrhea or rarely constipation, abdominal cramps and fullness which may overlap with other various gastrointestinal illnesses, such as inflammatory bowel diseases, chronic infections and helminth infestation, other food allergies, lactose intolerance, motility disorders and irritable bowel syndrome.

The lack of history or features of micronutrient deficiency, mineral bone diseases and other cutaneous and neurological manifestations of celiac disease does not exclude the presence of this syndrome. So thorough evaluation for gluten sensitivity is essential in presumed cases of IBS which not respond to conventional dietary and medical approaches and carry the same importance of excluding inflammatory bowel disease or other pathologies that may simulate IBS.

Although it has to be pointed that some IBS cases with no evidence of gluten sensitivity may surprisingly get significant benefit in improvement of their symptoms after exclusion of gluten containing food from their diet.

According to this study there is significant number of those patients who had been diagnosed and managed as IBS are actually have Celiac disease, especially those with diarrhea predominant subtype.

The usual work up of patients who present with symptoms suggestive of IBS does not involve regularly screening for gluten sensitivity or any form of food allergies unless the patient has features of malabsorption of micronutrients, diarrhea, steatorrhea, weight loss or coexistence of dermatitis herpetiformis.

Still early diagnosis of Celiac disease and establishment of gluten free diet is essential to prevent long term serious complications other than vitamin and minerals malabsorption such as ulcerative jejuno-ileitis, small intestinal lymphoma and small bowel adenocarcinoma.

As compared with the study *The prevalence of celiac disease in patients with irritable bowel syndrome and its subtypes* by Danuta Domżał-Magrowska who had been published in Przegląd Gastroenterologiczny 2016 in which concomitant positive result of genetic testing and any elevated serum antibodies specific to celiac disease was found in 12.5% of IBS patients.

So this study carry a highly comparable results, Screening for anemia and micronutrient deficiency in the cases who had been confirmed to have Celiac disease reveals that anemia is present in 10 of 17 cases (58.8%) that was mainly of iron deficiency which is the most common type of nutritional anemia in Celiac disease, there is also significant number of cases with iron deficiency state to be added to cases of IDA to be a total of 12 of 17 (70.1%).

Mainly because of small size of sample there is no case with megaloblastic anemia detected but still there are 3 cases with low serum B12 level. It is also important to be referred that there is no data available about folate statues in our study because lack of availability of reliable test for red blood cell folate in our facility at time of the study and the level of serum folate does not reflect the actual folate level state.

Vitamin D deficiency is present in all cases who had been diagnosed as Celiac disease but it may reflect the high prevalence of vitamin D deficiency among Iraqi patients in general as well as the effect of Celiac disease on lipid soluble vitamins absorption.

Finally it is important to follow up all the patients who had been diagnosed as celiac disease regarding improvement in their GI symptoms following exclusion.
of gluten from their diet, if not, the coexistence of IBS or other GI pathologies still possible and careful clinical re-evaluation is warranted.

Conclusions

There is significant number of celiac disease patient had been diagnosed and managed as IBS cases (mainly diarrhea predominant type) and there may be coexistence of both illnesses in the same patient.

Psychological Empowerment and Organizational Commitment among Nurses

Rifaie Yaseen Hameed Al-Hussein
Assistant Professor, Ph.D. Community Health Nursing, Northern Technical University, Technical Institute of Mosul, Nursing Department, Nineveh, Iraq

Abstract

**Background** - Psychological empowerment plays an important role in behavioral, emotional and cognitive constructs, such as Job Satisfaction and organizational citizenship behavior. **Aim** - The study aimed to identify the relationships between Psychological Empowerment and Organizational Commitment among nurses. **Methods and Materials** - A cross-sectional, descriptive and correlational study design carried out in a period from 5th of September/2017 till 30th of May/2018 at five Public Hospitals in Mosul/Iraq. Non-probability sampling technique and accidental sampling method depended to select the sample of the study, which accounted for (317) nurse. Two instruments were used to collect data via an interview method with each subject “Psychological Empowerment Questionnaire and Organizational Commitment Questionnaire”. The findings of the study presented by mean, standard deviation, while the relationships among variables presented through stepwise regression. **Results** - Total PE and its domains had significant relations to total OC and its Affective and Normative domains.

**Keywords:** Psychological Empowerment, Organizational Commitment, Nurse.

Introduction

Psychological Empowerment is a factor affecting any work, whereas, managers need a deep understanding in order to help employees handling it, motivating, and eliminating disturbing factors appropriately\(^{(1)}\). The repository of knowledge, skills, and abilities are the employees who cannot be imitated by the competitors\(^{(2)}\). Among them are nurses who constitute the largest group of professionals, and are the cornerstone in determining and providing the quality and cost of the healthcare\(^{(3)}\). There are many factors and situations that put nurses under considerable stress, as high organizational demands, the climate of job uncertainty\(^{(4)}\), in addition to the psychological empowerment which is, in turn, having a great impact on the organizational success\(^{(5)}\).

Psychosocial empowerment can be defined as an active motivational approach to the role of the individual at work, in addition to the individual’s sense of control over work\(^{(6,7,8,9,10)}\). It is not the conditions of the work’s context, but the reactions of the employee to these conditions, that in turn, influence their organizational behavior\(^{(11)}\). It plays an important role in behavioral, emotional and cognitive constructs, such as Job Satisfaction and organizational citizenship behavior\(^{(9,12)}\). It is manifested as four-dimensional constructs of employees’ perceptions; Meaning, Competence, Self-determination, and Impact\(^{(13,14,15)}\).

In the healthcare environment, maintaining a committed workforce is a strong advantage. Committed nurses provide asset value of stable, training and developing costs, lower employee recruiting, dedicated workforce, retention of nurses with the knowledge, skills, and abilities that are critical to organizational success, improved organizational image within the community, in addition, a committed workforce influence customer loyalty\(^{(1)}\). Organizational Commitment is defined as an individual’s identification and involvement with a specific organization\(^{(16)}\). It is a reflection of individual’s psychological state, which defines the relationship between the employee and the organization, for which they work and that has deductions for their decision to
continue with the organization\textsuperscript{[17,18]}, identification with the organization and involvement in the organization\textsuperscript{[19]}, Normative commitment that means an attachment-based on perceived obligation and a sense of loyalty or duty\textsuperscript{[20]} and Continuance commitment that is an attachment-based on perceived cost and refers to an employee’s intention to leave or wish to remain a part of the organization and depends on their recognition of the availability of alternatives if they want to leave the organization\textsuperscript{[21,22]}.

The present study endeavored to identify the relationships between Psychological Empowerment and Organizational Commitment among nurses, for, they are many facets each employee can confront them in the work.

**Material and Method**

Cross-sectional, descriptive and correlational study design carried out for a period from 5\textsuperscript{th} of September/2017 till 30\textsuperscript{th} of May/2018 at five Public Hospitals in Mosul/ Iraq mentioned as A, B, C, D and E. Non-probability sampling technique and accidental sampling method depended to select the sample of the study, which accounted for (317) nurse. The inclusion criteria depended for the selection the sample were; providing bedside nursing care, having tenure in the current place ≥ 5 years, presenting at work during gathering data and didn’t engage in management or leadership position at the study period. Data gathered via an interview with each subject that lasted 20-30 minutes. Two instruments used to collect data; Psychological Empowerment questionnaire “PE” which is used to measure the level of four dimensions; (Meaning= 3 items, Competence=3 items, Self-determination=3 items and Impact=3 items), all items were of five values distributed as strongly disagree=1, disagree=2, no opinion=3, agree=4, and strongly agree=5\textsuperscript{[23]}, and Organizational Commitment questionnaire “OC” which is used to measure the level of four dimensions: (Affective Commitment “AC” =6 items, Normative Commitment”NC” =6 items and Continuance Commitment “CO” =6 items), four items of the questionnaire are reverse-keyed (labeled by “R” against each item), all items were of five-point scale ranging from strongly disagree=1, disagree=2, no opinion=3, agree=4, and strongly agree=5\textsuperscript{[24]}.

For each scale, all scores were summed and divided by the number of items to attain the means of scales. To determine the validity of the scales, content validity was measured by exposing the scales to five experts in nursing field to ascertain its consensual validity, they presented a few essential corrections that were undertaken in the final drafts, while the reliability analysis for the questionnaires yielded a Cronbach’s alpha of 0.79 for Psychological Empowerment scale and 0.87 for Organizational Commitment scale. Descriptive statistics (Mean and Standard deviation) used to review the levels of measured variables (PE, and OC), while stepwise regression analysis used to evaluate the impact of criteria variable on multiple prediction variables.

According to the administrative rules, informal permission from the participants obtained prior to starting data collection.

**Findings**

(8) Predictor (Constant)=TPE DV=CO

PE=Psychological Empowerment DV=Dependent Variable AOC=Affective Organizational Commitment NOC=Normative Organizational Commitment COC=Continuous Organizational Commitment TPE=Total Psychological Empowerment TOC=Total Organizational Commitment
Table (2) demonstrates that Psychological Empowerment as a total and its dimensions are significantly correlated with Organizational Commitment as a total and its dimensions at different levels except with Continuous Organizational Commitment.

**Discussion**

Empowerment gives a power of decision-making to employees, making employees own their work and thus increase commitment. When employees have high levels of perceived Psychological Empowerment, view their work as meaningful, acquire the skills and competencies needed, have the impact on actions in their work environment, provide a high level of autonomy, feel to influence the work outcomes, they perceive themselves as effective, see their work as important, and be more attached to their organizations(25,26). In line with many previous studies(9,27,28,29,30) and inconsistent with others(31), nurses’ Psychological Empowerment means as a total and as all dimensions in the present study are, they are higher than means of score of the scale, which indicates that nurses’ values and behaviors were, to some extent, in an accordance with the work goals and nurses’ capabilities and requirements of work, therefore, it must lead to increasing Organizational Commitment.

Organizational Commitment means in the present study were below the means of score of the scale, that means nurses were less loyal to their hospitals, also it reflects that they can leave their hospitals even they find a good offer elsewhere. A previous study found in their study that the means of Organizational commitment were less than that of the present study(32).

The results of the present study show a contradiction referring to the assumption that high Psychological empowerment must lead to high Organizational commitment for Psychological Empowerment means are higher than that the means of score of scale, whereas, the means of Organizational Commitment are below than that the means of score of scale*, in Iraqi health care agencies, may be due to the presence of hidden or unobvious factors so that the nurse possesses or enjoys the psychological empowerment without good affiliation to the healthcare agencies. These may be due to the inability of the health care agencies to meet the needs of the nurse while he/she is committed to staying in the work because of salary and wedges obtained, poor professional relationships between the nurse and other medical and paramedical colleagues, the legislation that limit the nursing role in carrying out the physicians’ orders without any nursing notes (in most settings) and any meetings corresponding the patient’s status, supremacy of physician on the health care team, cynicism from other medical and paramedical staff and verbal and physical violence and so on.

Total Psychological Empowerment indicated significant positive relationships with TOC, AOC, and NOC as 0.357, 0.353 and 0.408 respectively. The coefficient of determination ($R^2$) presents that PE predicted 12.4%, 12.2% and 16.3% of the variation in TOC, AOC, and NOC respectively. All dimensions of PE indicated significant positive relationships with TOC, AOC, and NOC at different levels, while the best was for self-determination. In line with these results were the findings of many previous studies(6,13,33,34,35).

As long as Meaning is a sense of the meaningfulness of work among employees, it must provide a suitable fit between the requirements and purposes of one’s organizational work roles and one’s personal value system, and this must lead to the creation of attachment with the work. In the present study, it is significant and positively related to AOC, NOC, and TOC as 0.156, 0.11 and 0.164 respectively, while it hadn’t any significant relation with COC. The coefficient of determination ($R^2$) presents that Meaning predicted the variation of AOC, NOC, and TOC as 2.1%, 6.2% and 2.4% respectively (Table- 2). These results are in line with the result of many previous studies(9,30, 35) for they indicated that Meaning dimension was the best significant correlation with OC. Meanwhile, another study demonstrated that Meaning was significantly influenced the AOC, and COC dimensions(13).

**Conclusions**

* Nurses possessed good Psychological empowerment.

* Nurses possessed weak organizational commitment.

* There were significant relations among all Psychological empowerment domains and two dimensions of Organizational commitment (Affective and Normative).

Abstract

Proving is the action of presenting legally valid evidences by the Rajang Lebong customary judge to inspect cases of adultery (overspel), to achieve the truth according to the forensic science. This research uses a sosiological method with a descriptive-analysis approach regarding the forensics’ expert information and the position of visum et repertum in customary trials in the case of adultery. The aim of this research is to understand the real position of forensic experts and visum et repertum in the Rejang Lebong traditional trials. This research shows that the position of the forensics’ expert information of evidences and visum et repertum are accepted as proof in overspel cases.

Keywords: medical forensics, visum et repertum, adultery (overspel) cases

Introduction

Recognition towards customary law has just been explicitly expressed in the second amendment of the 1945 Constitution article 18B paragraph (2).¹ According to Soerojo Wignjodipoero, the sustainability of customary law is maintained by the decisions of the indigenous people, particularly the ones from the authoratives who are in charge of the implementation of legal actions.²

Ethnic customary law is an indigenous law which is applied to certain communities or some particular ethnic communities. While in Islamic law, it is acceptable for customary law to be applied based on the belief of the people. Oji continued that the implementation of the legal dualism was basically influenced by the British colonial law.³ So, it other words, the image of Indonesians was formed and built from the environmental image of inigenous people.⁴

In the Rejang Lebong community, customary issues are usually resolve through a traditional institution known as the Jenang Kutei Customary Institution. Aside from issuing regulations concerning Jenang Kutei court, the Rejang Lebong district government also issued regulations regarding law enforcement from Jenang Kutei, which are the village judges and other customary officials.

This can be referred into Regent Decree No. 152 of 2009 concerning the Appointment of the Village Consultative Body/Badan Musyawarat Adat (BMA) in Rejang Lebong Regency during 2009-2012 term. Aside from appointing Indigenous People Members, the Rejang Lebong Regency Government appoints a customary Judge through the Regent Decree No. 153 of 2009 concerning the Appointment of Jenang Kutei (Village Judges) in Rejang Lebong Regency in the 2009-2012 Service Period.

Problems solved in Jenang Kutei are ranged from mild to moderate criminal cases, such as theft, fights, to adultery and cases involving other civil matters. Regarding the adultery or overspel cases, according to the custom, in its settlement at the Jenang Kutei institution, the perpetrators will usually be chastised with the purgatorial ritual.

Rape is a case which is rather confounding to prove despite the whole amount of evidences which have been
examined and collected. In order to gain legal proof that a rape has indeed been committed, Forensic Medicine holds a major role in conducting examination for the medical explanation regarding the said occurrence. This study aims to determine the management of Forensic Medicine in proving rape cases in Jenang Kutei customary trial in Rejang Lebong, Bengkulu. Based on these issues, the writer would like to examine the role of Forensic Medicine and forensic expert explanation in proving cases of sexual violence crimes in Jenang Kutei customary trial in Rejang Lebong, Bengkulu, Indonesia.

**Methods**

This research is based on legal research which is conducted with a qualitative non-doctrinal approach. The research typology which is recently known as socio-legal research. The aim of using this approach for this research is to see the relationship between legal factors and extra-legal factors related to the object under study.

**Findings and Discussion**

Orientation towards Harmony Values and processes which are abundant of Discussion Values and Kinship Values are the real representation of the local community. Karolus mentioned that for the indigenous people, they instead looked at the issue of peace as an inseparable part of the dispute resolution process (the judicial process).

The existence of Jenang Kutei as a customary institution and Kelpeak Ukum Adat Ngen Riyan Ca’o Kutei Jang as a guideline for the Rejang tribe community, repeating what Von Savigny as Volkgeist or a nationalist. Law is a reflection of Volkgeist which is a human struggle with space and time. Volkgeist is an immanent, contextual, and local concept.

As for those who are authorized to impose sanctions are Jenang Kutei (Peace Institution), which is a customary institution with special authority by indigenous people to resolve any issue of customary rules and/or customary law violation and is decided by a customary judge.

In Kelpeak Ukum Adat Ngen Riyan Ca’o Kutei, there are several “cepalo” (actions and words of someone who violates customary rules) related to overspel cases, as well as the provisions which, if violated, may be imposed for sanctions, which includes:

- **Menebo** (a guy lures a girl on a runaway without clear motive and nowhere to go, under presumption they have committed something which are prohibited by their religion and custom).

Regarding legal culture, Lawrence M. Friedman interpreted it as values, ideas, attitudes, and behaviours related to law. Because of the complexity of the matters regarding judges and the court, using merely legal sociology and legal anthropology is not sufficient for the theoretical framework, hence the forensic science involvement.

Forensic in Indonesia is related to the court and in law may be interpreted as the result of the examination required in proceedings in court. Forensic science is a science related to crime or in other words, it has roles in solving criminal cases. The sciences related to forensic include forensic medicine, forensic chemistry, forensic physics, criminology, forensic psychology, and neurology. Forensic roots from the word forum which means comprehending the main problem of the object of study and forum itself is a meeting area in the era of ancient Rome for a trial.

In the Rejang Lebong community, the solving violations of Adultery Law has relied on witnesses, particularly those who bust and capture overspel perpetrators. As the time goes by, the customary judge of Jenang Kutei has conditioned in receiving forensic elements which is a multidisciplinary science to apply biology, chemistry, psychology, medicine and criminology to verify the overspel case by examining physical evidences in overspel cases.

After being proven guilty in customary law for overspel case (NGA’EM), the convicted person will be sentenced as follows: If the victim is pregnant, the sentence will be conducted after the child is born (approximately after 40 (forty days) then KUTEI will be sanctioned). But if the overspel case is known by the community immediately, KUTEI will be instantly sanctioned upon them.

Former Chair of the RL District Customary Council/Badan Musyawarah Adat (BMA), A Rauf said, Rejang custom is a spiritual treasure which has to be preserved and developed or better known by the term “Adat Nak Beak Nioa Pinang”. Related to the technological developments, the evidence via forensic medicine, expert statements and visum et repertum are accepted in Jenang Kutei customary trial for overspel cases, rape cases, etc.
Rauf also explained that through the said evidences, if the perpetrators are proven guilty in committing serious cepalo such as an overspel, they are required to sacrifice a goat. The said punishment is known as a purgatorial ritual called Empat Petulai in order to purify the village which commences by sacrificing a goat.\(^{(13)}\)

He admitted that the forensic medicine and visum et repertum procedure fields are used as legal basis in resolving cases which occur within society is because customary law does not stand against the development of technology or the modernity. The relationship between the existence of customary law alongside with its effectiveness will make customary law acknowledge verification methods in accordance to science and technology. In other words, the effectiveness of customary law may allow the law to achieve its goal, which includes for it to be applied and functioned through the help of forensic science and expert statements\(^{(14)}\).

Regarding overspel and rape cases, judge conviction in adjudicating in customary law is based on evidences at the trial. And via visum and forensic science, evidences related to human physical conditions are also acknowledged to be present at the trial. Customary judges admit that customary law requires assistance from other scientific disciplines, especially related to injury, health and lives of people in overspel cases. And forensic doctors may prove those conditions more precisely as the evidence.

The verification with the help of forensic doctor as witness at the trial in the form of visum et repertum written statement which explains the bodily condition of the overspel (adultery) defendant, concerning semen, bodily injuries, or sexual activity traces, and based on these then the Judge of Jenang Kutei remained guided by Kelpeak Ukum Adat Ngen Riyan Cao Kutei Jang passes his sentence. If there is a man who committed adultery (overspel perpetrators), the man is subject to customary punishment/customary fines namely:

1. Mencuci Desa (cleansing the village)/menepung matahari (pulverizing the sun). This should not be carried out at night\(^{(15)}\). Menepung matahari means paying the greatest village fines which is the same as murder and adding 2. Fines from the woman according to her demands which the man affords to pay. 3. The perpetrators are flogged with sticks as many as 100 strands and flogged 10 times\(^{(16)}\).

In this research, the author took an example of the medical forensic implementation towards the case of adultery which caused extramarital pregnancy but the man didn’t take the responsibility, namely Warni binti (the daughter of) Ujang Damori from Karang Jaya village, Bermani Ulu sub-district, in the case of overspel. The examination result from the forensic expert who was asked for the statement and the examination, finally proved the pregnancy even though she wasn’t legally married so that the customary judge of Jenang Kutei sentenced her guilty for committing overspel. There was the verification of injury on the genital caused by blunt object and the semen was identical with that of the male defendant. Hence, the judge dropped the sanction in the form of a customary ceremony with the decision that cleansing-the-village ceremony must be carried out and it was required to slaughter a goat. But according to the provisions, when the goat-slaughtering ceremony was carried out, the goat’s blood must be sprinkled to 4 (four) corners of the village and the two perpetrators would be hit by sticks with as many as 100 strands.

Additional punishment imposed on overspel perpetrators who are proved committing adultery, is parading them around the village as an example. It is an extra penalty for those overspel perpetrators. The offender usually obeys the punishment imposed because the evidence is strong and social sanctions await if the decision is not obeyed. The punishment for non-compliant families in carrying out the customary sanction is that the family will be given an excommunication punishment, in which according to Kadirman, their interactions will be socially restricted.\(^{(17)}\)

Although the customary law and sanctions must still be carried out with the customary philosophy, but in this case it is known that in handling the verification it has also been received and acknowledged by other sciences, such as medical forensic. The perpetrators of adultery who have been through the procession of customary trial so that it comes to the punishment execution turn out that they also went through the forensic stages, through visum et repertum, sperm and seminal examination added with the testimony of forensic doctor. The sentencing, of course, cannot be ruled out because the evidence is strong enough and the customary trial has clear legitimacy in the community. The overspel perpetrators, of course, are underestimated and even laughed at by the people for the deeds they have done, and this will usually continue to be practiced to the newborn child later on because the child will usually necessarily be called “kampang”
The punishment given is still a punishment with a customary philosophy even though the customary law has received forensic verification. The philosophy is the belief that punishment is given so that the local residents are saved from disaster. Such disasters are for instance, they will have difficulty in earning a living, there will be a prolonged famine, the atmosphere of the community will continue to heat because many residents quarrel with each other, floods and even other unexpected disasters as a form of anger from the God Almighty.\(^{18}\)

The customary trial realizes that the customary trial procession is not merely handled by traditional aspects, but it is also handled with the new elements in proving the criminal overspel cases to make it clearer\(^{19}\). The trial process through the assistance is able to handle the verification to the end of the case by the perpetrators based on bodily conditions examined by a forensic doctor. According to General Chief of Rejang Lebong BMA, Herman Firnadi, it is undeniable, so that the perpetrators will want to admit their crime, receive their punishment and are deterrent after serving the punishments so as to set an example for others not to repeat the same thing.\(^{20}\)

After going through the process of forensic verification and sentencing, they hold the village cleansing ceremony for the overspel defendant which was carried out in the traditional institution attended by many people. The offender certainly cannot avoid admitting his actions, considering that the evidence is very strong and cannot be refuted despite the embarrassment as conveyed by Susi Damayanti:\(^{21}\)

\[\text{“We who only saw are impressed with the trial process that has become more modern so that the defendant is not possible to evade with the existence of forensic evidences and the judge pass the sentence seeing the evidences.”}\]

**Conclusion**

Medical forensic can be accepted as an evidence in handling overspel cases at the Jenang Kutei customary trial in Rejang Lebong in the form of visum et repertum examination and forensic expert’s statement as in the general trial. The perpetrators who are proved guilty with the forensic verification cannot evade because the proof is modern, logical and strong as well as acknowledged by the parties in the form of forensic expert’s statement and the result of visum et repertum examination. The trial passes the verdict based on these proofs and then sentence them in accordance with the applicable customary law.

Abstract

Helicobacter pylori (H.P) infection is an increasing concern in modern medicine due to its effect on the pathogenesis and management of peptic ulcer disease and gastritis and its possible link to gastric adeno carcinoma cases. The eradication of HP is a mandatory approach in documented cases of HP infection mainly gastric and duodenal ulcers. The treatment options is variable globally according to microbial susceptibility test and local guidelines. This study focused on two main options in the eradication of HP and found that levofloxacin based therapy is superior to clarithromycin based approach in the rate of eradication , with comparable rate of adverse events.

Keywords: Helicobacter pylori (H.P), Gastritis, Peptic ulcer, Urea breath test, Stool antigen, Clarithromycin, Levofloxacin

Introduction

In world about 50% of population , who have Helicobacter pylori (HP) that colonizing in , probably for life unless eradicated by anti-HP treatment. Colonization of HP concert main risk factor of peptic ulcer disease, also gastric mucosa associated lymphoid tissue (MALT) lymphoma gastric adenocarcinoma . Eradication of HP has revolutionized the treatment of peptic ulcer disease, and Treatment is permanent in most cases afterwards. Anti-HP therapy also represents first-line management for low-grade gastric MALT lymphoma cases. Treatment of HP is not recommended as a line of treatment of gastric adenocarcinoma, but preventing HP colonization or eradication may prevent gastric malignancy. In same time , increasing evidence suggests that lifetime HP colonization may give some protective effect against esophageal adenocarcinoma.

In most parts of the United States , prevalence of HP among adults is less than 30% , whilst in developed countries more than 80% (1).Humans are the only host of HP. Children may acquire the HP from their parents or their primary caregiver or other children essentially . Transport usually occurs either through the oral - stool or the oral-oral pathway , but HP is easily cultured from vomit us and gastroesophageal reflux fluid and to a lesser extent from stool (2,3)

Most of colonized people are healthy and asymptomatic, and only a fraction develop HP related illnesses. About 90% of patients with duodenal ulcers and 70% of gastric ulcer are infected with HP. The distribution and severity of HP–induced gastritis determine the future outcome. In most colonized patients, HP causes a mild pangastritis with little effect on stomach acidity environment and the majority develop no significant clinical outcomes.

In a minority , the infection causes an atrnal-predominant gastritis characterized by hypergastrinaemia and overt acid production by parietal cells and may end with duodenal ulceration. In a much smaller number of infected people(4), HP causes a corpus-predominant gastritis resulting in atrophy of the gastric mucosa and hypochlorhydria. The hypochlorhydria allows other bacteria to proliferate in the stomach; these other bacteria will result in chronic inflammation and produce mutagenic nitrites from dietary nitrates, predisposing to the development of gastric malignancies. The ulcer probably result as an end point of impaired mucusal defense resulting from a combination of HP infection;
smoking and NSAIDs, rather than highly acidic environment (4).

Patient and methods

This study was a single center open label randomized clinical trial to compare the efficacy of levofloxacin versus clarithromycin in the eradication of HP infection.

This study was a randomized, open-label randomized clinical trial to compare the efficacy of both clarithromycin and levofloxacin in the elimination of HP infection.

The study conducted in the outpatient internal medicine clinic at Al-Yarmouk teaching hospital during period (January 2018- January 2019) involving 130 patients. In clarithromycin group two patients was lost to follow-up and excluded and in the levofloxacin group, three patients were lost to follow-up and thus, were excluded, so the study actually covered 125 patient (52 female and 73 male), age patients from (19 to 59) years old.

Consent had been explained and obtained from the patients under supervision of ethical committee at Department of medicine at Al-Yarmouk teaching hospital.

Inclusion criteria for this study were as follows: diagnose patients have HP infection depending on history and clinical examination then confirmed by either stool antigen detection of HP or urea breath test or endoscopy and histopathology analysis.

Exclusion criteria for this study were as follows: pregnancy, previous use of clarithromycin and levofloxacin in the preceding month, consumption of alcohol or substancemisuse; advanced chronic gastrointestinal disease cirrhosis, gastric cancer, inflammatory bowel disease, cerebrovascular accidents, advance renal insufficiency, advance heart failure and severe debilitating illnesses.

Then the patient had been distributed randomly to be treated with either Clarithromycin based therapy (clarithromycin 500mg twice daily, metronidazole (500mg)twice daily and lansoprazol (30mg)twice ) or Levofloxacin based therapy (levofloxacin (500mg) twice daily, metronidazole (500mg)twice daily, and lansoprazole (30mg)twice daily) for a period between 10-14 days.

In this study we decided to replace amoxicillin; which is usually given with levofloxacin, with metronidazole in levofloxacin group for both reasons:

1- High rate of allergy to penicillins in Iraqi society.

2- Combination of metronidazole with levofloxacin is a new strategy to be evaluated for the future newer combinations in eradication of Hp.

At the end point (2) groups were compared with respect to proportion of HP eradication with either stool antigen or urea breathe test 45 days or more thereafter, then the results had been documented.

Any significant side effect of therapy had been documented and the patient followed up for any serious adverse events, discontinuation, or drug non-compliance.

Diagnosis

The current options available for diagnosis of HP infection are listed below:

- Invasive:
  1- Biopsy urease test
  2- histopathology
  3- Microbial culture

- Non Invasive:
  1- Serology
  2- Urea breath test
  3- Stool antigen testing

Breath tests or faecal antigen tests are best because of simplicity; accuracy and non-invasion (4).

Statistical Analysis

Analysis of data was carried out using the available statistical package of SPSS-25. Significance of difference of different percentages (qualitative data) were tested using Chi-square test ($\chi^2$-test) with application of Yate’s correction or Fisher Exact test whenever applicable. Statistical significance was considered whenever the P value was equal or less than 0.05.
Finding

Current regimens consist of a Proton pump inhibitors (PPI) and (2 or 3) antimicrobial agents were given for (10-14) days(Table-1). The optimal regimens vary geographically, depending on the known rates of primary antibiotic resistance in most H. pylori strains locally, therefore, guidelines on optimal regimens for HP eradication in individual countries are evolving, and physicians should select the most up-to-date local guideline.

| Table (1): Commonly Recommendation Treatment systems for H.Pylori |
|--------------------------|--------------------------|--------------------------|--------------------------|
| **Regimen (Duration in days )** | **DRUG 1** | **DRUG2** | **DRUG3** | **DRUG4** |
| Regimen 1 (10-14) | Lansoprazole (30) mg bid | Clarithromycin (500) mg bid | Metronidazole (500) mg bid | - |
| Regimen 2 (10-14) | Lansoprazole (30) mg bid | Clarithromycin (500) mg bid | Amoxicillin (1g) bid | - |
| Regimen 3 (10-14) | Lansoprazole (30) mg bid | Bismuth subsalicylate (2) tabs qid | TertracyclineHCl (500) mg qid | Metronidazole (500) mg tid |
| Regimen 4 : concomitant 14 days | Lansoprazole (30) mg bid | Amoxicillin (1)g. bid | Clarithromycin (500)mg bid | Tinidazole (500)mg bid |
| Regimen 5 :10 days | Lansoprazole (30) mg bid | Amoxicillin (1) g bid | Levofloxacin (500) mg bid | - |

Two elements as most important in successful HP eradication is the patient’s commitment to the system and the use of drugs that the patient’s HP strain has not acquired.

Increasing levels of primary HP resistance to clarithromycin, levofloxacin are of growing concern(5). In most parts of the world (the main exception being northwestern Europe), the rate of primary clarithromycin resistance is high enough that regimens containing only clarithromycin plus one antibiotic often fail; regimens with clarithromycin and two other antibiotics remain superior as the other two antibiotics are likely to eradicate HP even if the strain is resistant to clarithromycin. When a patient is known to have been exposed—even distantly—to clarithromycin or levofloxacin, these two drugs should be avoided. Resistance to amoxicillin or tetracycline is unusual, even if these antibiotics have been given previously, and metronidazole resistance is only partial; thus there is no need to avoid using these antibiotics even if they have been previously used. Assessment of antibiotic susceptibilities before treatment is not usually done because endoscopy and mucus biopsy are necessary to obtain HP culture and because most microbiological laboratories lack experience in HP culture. If initial anti HP treatment fails, the usual approach is re-treatment with another antibiotic regimen(table-1).

The third-line ideally should include endoscopy; biopsy; culture as well as treatment based on antibiotic sensitivity. However, empirical third-line therapies can be applied(6).

From the total 69 patients who had been treated with Clarithromycin based therapy only 34 patient (49%) respond and failure rate is approximately (51%) 35 patients. While those who had been treated Levofloxacin based therapy 56 patients; 40 patients (71%) had respond, while failure rate is about (29%) 16 patients (table-2).

![Figure (1): Incidence of anti HP therapy adverse effects.](image)

Incidence of minor adverse effect in both therapies is also reported; 19 cases (27.5%) in clarithromycin group and 14 cases (25%) in levofloxacine group. Diarrhea is the most documented side effect of therapy in both groups which happens in 8 cases of clarithromycin based therapy and 5 cases of levofloxacine lines, metallic taste also reported frequently but it may be due to metronidazole mainly other adverse effects had been reported in lower incidence rate but none of them resulted in discontinuation of therapy (table- 3).

Discussion

There were several findings in this study starting with comparing the efficacy of both line of management, there is significant difference in efficacy favoring levofloxacin based therapy as compared with clarithromycin which carry high failure rate exceeding 50% based line (P value 0.012). Also current study disclose that the rate of incidence of significant therapy adverse effect is almost equal in both lines; 25% for levofloxacin based therapy versus 27.5% for clarithromycin based therapy (P value 0.90).

If we compare that with the previous Iranian study regarding Comparison efficacy of both clarithromycin and levofloxacin in the eradication of Hp infection, levofloxacin-based therapy is preferable to clarithromycin-based regimen in HP eradication which achieved higher optimal rate of eradication less than 80% success rate (7), so the result of this study is almost comparable in which 71% was the success rate of levofloxacin group and 49% success rate in clarithromycin group compared with 80.4 and 57.4% for levofloxacin and clarithromycin group respectively (7).

This result may reflect the higher incidence of clarithromycin resistant strains in the population and that finding should be supported in the future by more extensive workup involving upper endoscopy and sampling for the microbiological evaluation (culture and antimicrobial sensitivity testing) or molecular based diagnostic assay for resistance detection. The incidence of adverse events with treatment had been reported in 19 cases with clarithromycin group and 14 in levofloxacin group but none of the resulted in termination of therapy but may result in discomfort and anxiety to the patient because most of these adverse events involve gastrointestinal system which is the host of HP.

We have to point that this study is a clinical trial depend mainly on the clinical response to therapy and the confirmation of eradication of HP with breath test or stool antigen, so it didn’t include microbiological antimicrobial sensitivity test so it didn’t necessarily suggest the real spectrum of bacterial resistance. Also the study is a single center study and more wide multicenter trial is needed for more clarification of the real incidence of HP clarithromycin resistance in the population.

Conclusions: Levofloxacian based therapy is superior to clarithromycin based therapy in eradication of HP infection. Both lines have comparable incidence of adverse events.

Recommendations: We recommend to depend on levofloxacian based triple therapy at least first alternative option if first line fails in eradication of HP cases in Iraq as it is effective, with accepted adverse events profile. Also we recommend against the use of clarithromycin based therapy in the management in new cases of HP infection due to high failure rate. Thorough antimicrobial sensitivity evaluation of emerging HP strains should be considered for determining local anti HP treatment guidelines.

Job Satisfaction and Relationship with Organizational Commitment among Nurses

Rifaie Yaseen Hameed Al-Hussein
Assistant Professor, Ph.D. Community Health Nursing, Northern Technical University,
Technical Institute of Mosul, Nursing Department, Nineveh, Iraq

Abstract

Background- Nurses’ job satisfaction is one of the most important factors affecting organizational commitment. Aim- The study aimed to identify the relationship between job satisfaction and Organizational Commitment among nurses. Methods and Materials- A descriptive, correlational and cross-sectional study design carried out between (5th/September/2017 till 30th of May/2018) at five hospitals in Mosul/Iraq. Depending on the convenience sampling method and Non-probability sampling technique, a sample of (317) nurses were selected. Two instruments were used to collect data via an interview method with each subject (Minnesota Job Satisfaction Questionnaire “JS” and Organizational Commitment Questionnaire “OC”). To measure the content validity of the questionnaires, they exposed to five experts in the nursing field, whereas, the reliability of them was checked by Cronbach’s alpha. The results of the study were demonstrated by descriptive statistic through (mean standard and deviation), and by inferential statistic through (stepwise regression). Findings- Total JS and its domains had significant relationships with total OC and its Affective and Normative domains, while they hadn’t any significant relationships with total OC.

Keywords: Job Satisfaction, Organizational Commitment, Nurse.

Introduction

There are many factors affecting any work, one of them is Job Satisfaction, which required deep understanding in order to handle appropriately by employees, motivating and eliminating any disturbing factor(1). Great competition and scarcer resources are confronting hospitals nowadays than ever before, in addition to the external and internal environment that are severely challenging to achieve its goals effectively and efficiently(2).

The employees consider the repository of knowledge, abilities, and skills that competitors find extreme difficulty for imitating(3). Nurses, as professionals, constitute a large group of them, who are responsible for determining and providing health care in good quality and less cost(4). They have the diverse tasks to perform, many roles to carry out, and profound experience needed to deal with many duties in many places in hospitals, so their role is very important and vital in hospitals(5). Many situations and factors make nurses stressful, as a climate of job uncertainty along with high organizational demands, in addition to the factors mentioned above which in turn have a significant impact on the organizational success(6).

Job satisfaction has a long-standing tradition in organizational research(7). It is defined as an individual’s affective reaction or cognitive attitude toward job; it is an extent to which individuals like or dislike their job(4,8,9). It can result from organizational climate together with individual’s perception and evaluation of a job, which is influenced by the individual’s unique circumstances, such as needs, values, and expectations(10,11). In addition to workload, incentives, job security and relationship with superiors, peer and organizational structure(6). Job Satisfaction is interrelated with emotions, and because of that, it affects organization as a whole productivity(12), efficiency(13), job performance, mental and physical health(14), fluctuation and absenteeism(15), also it affects the health of their personal relationships outside of work.
Later research has shown that Job Satisfaction can be arranged according to two dimensions: an Intrinsic versus an Extrinsic one. Extrinsic satisfaction refers to satisfaction with aspects that have little to do with the job tasks or content of the work itself, such as pay, working conditions, and co-workers. Intrinsic satisfaction refers to the job tasks themselves “e.g. variety, skill utilization, autonomy”(6).

Researchers have been investigating the relationship between employees and their employing organization for decades since they are aware of the importance of employees, who are the driving force of every organization(18). In the healthcare environment where nurses’ shortage is expected to increase beyond its current levels, a committed workforce must be maintained. Committed nurses provide a meaningful value of stable, professional workforce; lower employee recruiting; development and training costs; retention of nurses with knowledge; abilities and skills that are crucial to organizational success; improved organizational image within the community; in addition to that, a committed workforce and their loyalty to the organization(1).

Organizational commitment is the frame of employees’ mind to commit to facilitating the achievement of the objectives of the organization and includes levels of staff identification, participation, and loyalty. It is an emotional response driven by employee attitudes, belief, and behavior. There are three types of organizational commitment: Affective (Emotional), Continuance, and Normative. Emotional commitment (or moral obligation) occurs when employees cling to the organizational values and goals, be emotionally attached to their organization; and begin to feel responsible for the success of their organization(19). Continuance commitment occurs when the basis for staff participation with the organization is their related revenues, efforts, and costs. It describes as a kind of emotional attachment to the organization, it refers to the judgment of employees about whether spending on leaving the organization is greater than spending on continuing work(20), while feelings of the employees’ toward the organization call normative commitment(20,21).

The present study aimed to identify the relationship between job Satisfaction, and Organizational Commitment among nurses.

Material and methods

Descriptive, correlational and cross-sectional study design carried out between (5th/ September 2017 throughout 30th/ May 2018). Five hospitals in Mosul / Iraq were the setting of the study, they were pointed as A, B, C, D, and D. Depending on convenience sampling method and non-probability sampling technique, sample of (317) nurses selected based on inclusion criteria as; working at patient’s bedside, having working work ≥ 5 years, and present in the ward in the study period. An interview was depended for gathering data- each of them lasted “30-40” minutes-by using two tools; Minnesota Job Satisfaction questionnaire “JS” of two aspects; Intrinsic Job Satisfaction “IJS” (12 items) and Extrinsic Job Satisfaction “EJS” (8 items)”(22), each item had five options rated from strongly dissatisfied=1 to strongly satisfied=5, the other tool was Organizational commitment “OC” of three aspects; Affective Organizational Commitment ‘AOC’ (six items), Normative Organizational Commitment ‘NOC’ (six items), and Continuance Organizational Commitment ‘COC’ (six items)(23), each item had five options rated from strongly disagree=1 to strongly agree=5, four items of the tool were reverse-keyed (labeled by “R” against each item). The means of the scales and their aspects obtained by summation of all scores and division of their numbers. Content validity of the scales measured by opinions and comments of five nursing experts, whereas the reliability checked through test-retest on fifteen nurses outside the final sample of the study, it resulted in a Cronbach’s alpha of 0.83 for Job satisfaction and 0.87 for Organizational Commitment. The findings of the study demonstrated through mean and standard deviation as a descriptive statistic for the measured variables (PS and OC), and through stepwise regression to evaluate the impact of the prediction variables on the outcome results. Informal approvals were obtained from the participants prior to starting of collection data.
Findings

Model(7)
Table (2) depicts that Job Satisfaction as a total and its aspects were significantly correlated with Organizational Commitment and its aspects at a high level, whereas they don’t indicate any level of significance with Continuous Organizational Commitment.

**Discussion**

When work roles don’t conflict with the individual’s values and beliefs, they tend to experience Job Satisfaction because the job itself generates an inner sense of motivation, also when the employees view their work as meaningful, acquiring skills and competencies, impacting the outcomes within their organization, they can derive satisfaction to work(15). Other previous studies noted that nurses’ job satisfaction is one of the most important factors affecting organizational commitment(24,25).

Job Satisfaction means in the present study has been around the means of scores of the scale, whereas Intrinsic Job Satisfaction is best than Extrinsic Job Satisfaction (Table-1). If nurses are satisfied with intrinsic factors more than extrinsic factors, they can satisfy themselves interiorly more than the satisfaction promote from their environment and supervisors. This finding is consistent with the view of many previous studies(1,6,). This is an important issue for any organization, for, individuals who have the high level of Job Satisfaction generally have the positive attitude towards their work and vice versa(4), in another word, if employees are dissatisfied and they see a chance to work in other organization, they will leave an organization without a sense of guilt(11). Organizational Commitment means in the present study were below the mean of scores of the scale (Table-1), this means that nurses were less loyalty to their hospitals, also it reflects that they can leave their hospitals even they find a good offer elsewhere. the ignore the nurse’s role and their participation in the patient care plan. Many previous studies found that the commitment of nurses was on high levels(26,27,28), other studies found that the commitment of nurses was at a moderate level(19,29,30,31), low level among midwives(32), NOC had the lowest level(26), and COC had the highest level, highest level, and AOC had the lowest level (27).

Total Job Satisfaction (TJS) is significant and positively correlated with Total Organizational Commitment (TOC) and its dimensions AOC, NOC as 0.419, 0.386 and 0.451 respectively, while it doesn’t correlate with COC at any level of significance. The coefficient of determination (R2) presents that TJS predicted the variation of TOC, AOC, and NOC as 17.3%, 14.9%, and 20.1% respectively. From another hand, all JS dimensions present significant and positively correlated with TOC and with its aspects except COC, while IJS was best than EJS in predicting the variation of AOC, NOC and TOC as 14.9%, 23%, and 19.1% respectively (Table-4). It was revealed that Job Satisfaction was a significant predictor of Organizational Commitment and explained 36% of the variation, also Job Satisfaction was highly positively correlated with Organizational Commitment “r = .85, p < .001”(33), another study referred that Organizational Commitment explained 41% of the variance in Job Satisfaction(6).

As a total and in line with the present result, many previous studies found that Job satisfaction had a significant positive influence on Organizational Commitment(25,28,34), also it was found a significant relationship between total job satisfaction and AOC, and between extrinsic job satisfaction with Organizational
Commitment(34,35), significant relationship between job satisfaction with NOC(35).

So previous study indicated that there was no statistically significant correlation between TJS and TOC, and there was no statistically significant association between IJS and TOC domains (AOC, NOC, and COC). Also, there was no statistically significant association between EJS and TOC domains (AOC, NOC, and COC) (36).

Conclusions

* The nurses had an acceptable level of Job satisfaction.
* The nurses had an unacceptable level of Organizational Commitment.
* There were positive significant relationships among TJS and its aspects with TOC and its aspects except for COC.
