Interviews: Hospital managers interviewed for their responsibilities toward hospital safety and what is their policy program, planning to improve the hospital hygiene and the workers their training, protective measures, laws, regulations and rules governing the staff.

Reports: Reports are collected on information of health care waste management program in the hospital about reported cases of infectious diseases, regular medical examination, immunization and needle stick injury among the workers.

Observation: personal observation focused on health care waste management and the workers practice before and after the intervention.

Phase two: (intervention)

Training courses: Training courses was held for workers, two days the training courses included:

Lecture 1- Health care waste management. Lecture 2 –Health care waste hazards.

Lecture 3 –Health protection and healthy practice for workers

Audiovisual aids: Audiovisual aids e.g. Video tape and posters used during lectures of training courses
and workshop for workers to reinforcing the lectures and papers, video tap+ was used on from World Health Organization from Al Bashir hospital in Jordan.

**Phase three: (Evaluation)**

Evaluate knowledge, attitude and practice of the health workers through questionnaire and observation, to compare between pre and post questionnaire to assess effect of health education.

Revising records of intervention phases to evaluate health education activities.

**Data Analysis**

The study used frequency distribution, percentages, figures and tables, chi square test and T test to assess the effective of the intervention phase and comparison between pre and posttest and tested statistically to show the significant change, to test the correlation between two samples. The data was analyzed by computer using SPSS.

**Results**

One-day workshop which was held in the Khartoum North Teaching hospital came out with recommendations. these recommendations have to be implemented in the hospital. The first step is to designate a responsible person (public health inspector) and committee. The committee first focused on the safe practices and procedures for health care waste segregation, segregation of health care waste into three categories general waste in the black pages and hazardous waste in the yellow labeled pages and sharps in the safety boxes. Second step internal collection and storage, the committee provided a small car for collection and transportation of the health care waste from the wards to the storage area, new storage area was built.

**Interviews**

Hospital managers interviewed before the intervention, in the hospital there is no system of the health care waste management, the staff were not trained and did not use the protective cloth and no laws about medical waste management. After the intervention there were clear system of management. The law of Sudan 2009 was provided

- **Reports**

Before the intervention there were no careful records of information of health care waste management concerning, cases of infections, medical examination, immunization and needle stick injury among the workers after the intervention all of them were fully implemented due to the impact of health education.

- **Observations**

Before the intervention no segregation. After the intervention the waste were segregated into three categories general waste in black pages, hazardous waste in red pages and sharps in the safety boxes which were collected from the wards with small car to the storage area. Storage area before the intervention an open area there were uncapping syringes scat red, after the intervention the storage area was constructed away from food storage, preparation of the food, it was easy to clean with smooth finishing, good light and ventilation.

![Figure 1 Distribution of workers in the units of the hospital (N = 103).](image)
Figure 1 shows the distribution of workers in the units of the hospital. More than third of workers are illiterates (38.9%) and more than half of them are have primary education (57.4%). More than half of the workers are in the wards (55.6%). More than one third (35.2%) of the were provided with special bags before intervention. After intervention all sites (96.3%) were provided with special bags. T test = 7.968, p-value = 0.00 showing highly significant change. Before the intervention (16.7%) of the worker used to touch the contaminated cotton and linen, soiled by the patient’s fluids. After the intervention workers minimized the touching of body fluids of the patient. T test = 2.837 p. value = 0.006 showing highly significant change.

Less than half (48.1%) of the workers were exposed to needle stick injury before the intervention and after the intervention there is no new cases of injury. About (13%) of the workers were examined before intervention. After the intervention about the half (48.1%) of the worker were examined due to the impact health education test = 2.214 p value = 0.031 showing significant change. Only (11.1%) of the workers were immunized before the intervention.

Table (1) Shows the co-relation factor between education level and the knowledge of the workers about hazard of health care wastes. (N = 103), $\chi^2 = 26.491$, p- value = 0.000

<table>
<thead>
<tr>
<th>Level education</th>
<th>Knowledge</th>

This means there is co-relation between the level of education of the workers and the utilization of protective clothing showing in significant test. Because there are other factors e.g. enabling factor, availability and uncomfortable to wear in a hot climate

**Discussion**

Educational attainment of the workers, more than third of workers are illiterate 39.9% and more than half 52.4% of them are primary education which increased the difficulties of the training and explaining of the softly practices proper handling and use of protective cloth. Nazir Mirza 1996 stated that the health workers in Nerobi were over worked, poorly educated and lacking in supervision (8). and also, Shereen Eassa 2007 mention that in Zagazig Egypt the highest risk was observed among unskilled workers back (9). Mona Gamal Eldin (2000) in Egypt illustrated that the level of awareness among hospital workers especially those involved in waste handling is poor. Due to the high illiteracy rate of hospital workers handling waste and lack of supervision, changing their attitudes requires intensive planning and reorganization (8,10). Distribution of the workers in the wards, about three quarters 74.1% were employed in the hospital wards. The type of the work of the workers all of them collect waste in the bags Mamdouh H. M. Abdon (2007) mentioned that in Jeddah (Saudi Arabia) Majority of the workers are poor ignorant and work in any job regardless the hazards that may result from such work (11).

About the third 35.2% of the sites are provided with specialized bags before the intervention. After the intervention all of the sites are provided with specialized bags, showing significant change. Nasir Mirza 1996 in Narobi illustrated that disposal of the waste in an expensive exercise. The plastic bag required are costly and sometimes, simply unavailable (8). Also, Gihan et al. in 2005 in Alexandria stated that segregation in limited amounts of colored bags the remaining are mixed with domestic waste poor segregation due to lack of staff awareness (12). Also, Isam and Rana. Elkhatib (2006) in Palestinian illustrated that management practices were in adequate, there was in sufficient separation between hazardous and nonhazardous wastes (13).

Practice of touching contaminated cotton and linen with blood and other liquid of the patient and the placenta showing highly significant change which agree with, Khalid Youzif and Youzif Alameen (2018) in Sudan mention that the study population handle health care waste both in Khartoum and Bahri hospital 96%use gloves (14). Also, Ahmed and Shuwaiter (1995) in United Arab Emirates stated that biomedical waste in the hospital are primarily segregated from nonhazardous waste they are collected either in yellow bags or syringes boxes (15).
The most common form of occupational exposure experienced by health care staff and waste handlers is by pathogens in blood such as hepatitis B and C, and HIV through a needle stick injury. In Khartoum North teaching hospital, about half of workers had been picked with needle injury (48%) and there were some cases of hepatitis (13%) were reported. Musa (2014) in the Sudan stated that (58.3) of the study population have been exposed to the needle stick injury during the work in Omdurman hospital (16). Sadoh et al. mentioned that sharps injuries have become one of the most important occupational injuries and routes of contagion among health care workers (17). Also, Henry and Campbell (1995) mention that over 40% of the workers had been picked with needle while handling health care waste (18). Also, Laymer U.B (1997) in Sweden stated that needle stick injuries constitute the leading cause of job-related injuries in hospitals (19).

Abd El-Salam (2010) mention that health care workers collectors in Cairo university hospitals, it was found that HBV and HCV infected about 55% at the end of the monitoring period almost a year, also it was found that the prevalence of infection was directly related to the efficacy of the preventive measures specially vaccination and post exposure prophylaxis (20).

Regular medical examination for the workers before or during employment only 13% of the workers were examined before the intervention. After the intervention, the half of the workers were examined due to impact of health education. Henry and Campbell (1995) mention that no medical examination for workers before or during employment (18). Medical surveillance should be implemented for at risk hospital staff, particularly hospital waste collectors, special attention to be paid for hepatitis B, C viral infections. Only about 11% of the workers immunized before the intervention, after the intervention half (48%) of the workers were immunized due to the impact of health education. Ezzadin A.A. Franka (2006) in Libya stated that more than three forth (79%) of health care waste workers are not immunized against hepatitis B (21). Hassan et al. (2018) mention that majority (91.6%) of study population do not receive any vaccination services against hepatitis B (14).

Less than half 46.3% of the workers used protective clothing before the intervention, after the intervention more than three quarters used protective clothing. N Motamed and others (2006) in Iran mention that occupational safety and health regulations require both employers and employees to reduce or eliminate occupational risks protective barrier use is a major element of universal precautions. To encourage their use protective barriers must be readily available, easy to use, effective and comfortable (22,23).

After the intervention all the workers were involved in the training program. Musa (2014) mention that 71.7% of the study population do not received any training about health care waste in Omdurman teaching hospital (16). Hassan et al. (2018) stated that more than half (61.7%) of study population do not received any training in handling infectious wastes (14). And also, mention that only 20% of the study population were trained in Khartoum teaching hospital (6,16) (14).

More than half (53.7) of the workers know the hazards before the intervention, after the intervention all 98% of the workers have gained increased knowledge about hazards of health care wastes showing highly significant change. Graham Ngumi (2006) mention that population of Nairobi Kenya have failed to establish proper facilities for waste disposal and are often unaware of the danger of exposing the community at large to bio hazardous waste (24). Also, Ezzadin A.A. Franka (2006) in Libya stated that 98.7% of the worker having information about AIDS and viral hepatitis, as health risks of the health care waste (21). Ali and others recommended that mass awareness campaign needs to be planned designed and implemented to make the people aware of the consequences of infectious waste handling, storage and disposal. Appropriate communication modes need to be used for this awareness campaign (25).

**Conclusion**

The intervention undertaken achieved remarkable improvement in the knowledge, attitude and practice of the health staff as regards of health care waste management. The Study has suggested that the hazards of health care wastes which have greatly negative impact on occupational and public health. Could be reduced by improved management of hazardous health care waste, safety measures immunization, wearing protective cloth, periodic examination, hand hygiene and awareness raising through training of the health staff and health education for patient, co patient, visitors and
general public. And lastly coordination between medical departments and those involved in the management of health care waste and infection control, all of those are essential component in sustaining the operation of health care waste management system.

### Recommendations

1) To establish clear applicable policy in hospitals to supervise the health care waste management.

2) Ensuring early and proper segregation and identification of hazardous waste through proper color coding and labeling.

3) Establishment a comprehensive occupational health (safety measures, Medical surveillance, Training policy, and safety practice).

Department of Pathology and Forensic Medicine

Abstract

This study is concerned with chronic kidney disease and control group . The determine patients from (alseder hospital ) in Najaf city during the period between January 2019 to July 2019. The CKD patient and control group consisted of sixty with age mean of (±20) years. The blood samples were drawn from all patients 6 hours before and after dialysis to measurement serotonin , blood Urea, Creatinine , uric acid and hemoglobin and control group. Also the patients classified into two groups according to age . This variables measured by using assay (ELISA) technique and colorimetric methods. The higher mean value of serotonin was shown in CKD patients before dialysis ( 0.0257± 0.00224 ng /ml) compared with patients after dialysis ( 0.1894 ± 0.05189 ng/ml) compared with control group( 0.0059 ± 0.00139 ng/ml). Also the higher value of blood Urea and Creatinine reversibly in CKD patients before dialysis was (126.25± 4.869 mg/dL), (10.041± 0.3019 mg/dL) compared in blood Urea and Creatinine in CKD patients after dialysis was (48.183± 2.262 mg/dL), (3.28± 0.201 mg/dL) and control group was (28.105 ± 1.896 mg/dL), (1. 095 ± 0.0961 mg/dL).

Also the higher value of uric acid and hemoglobin reversibly in CKD patients before dialysis was (8.0623± 0.1478 mg/dL), (13.800 ± 0.16519 g/dL) compared in uric acid and hemoglobin in CKD patients after dialysis was (5.5361± 0.16055 mg/dL), (12.383 ± 0.15872 g/dL) and control group was (2.6789 ± 0.2977 mg/dL), (13.742 ± 0.18954 g/dL) , all above results there was a significant difference and correlation (p˂0.05).

Aim of study: Study the effect of serotonin, blood Urea, Creatinine , uric acid and hemoglobin 6 hours before and after dialysis on CKD patients and compared with control group .Study the effect of variables on CKD patients with different age and study the relation between CKD patients after and before dialysis.

Key words: serotonin , Before and after dialysis, hemoglobin, uric acid, creatinine

Introduction

The CKD in dialysis the has increased in the diabetes mellitus, chronic obstructive pulmonary disease [1]. Dialysis is considered a good treatment for patients . Serotonin is main neurotransmitters acting on synapses of nerve cells and found in the gastrointestinal tract . The changes serotonin are frequently observed in CKD patients [8]. Uric acid is the a final oxidation metabolite of the purine in the humans, the uric acid level is a risk factor for incident KD in the general human , that serum uric acid levels >7 mg/dl had an increased incidence of KD [8]. The kidney damage is marked by the rise in two chemical substances creatinine and urea is directly toxic and measure of the kidney function [6] . Creatinine is produced from muscles and excreted through the kidneys, creatinine concentration of the serum is maintained by the balance between its generation and excretion by the kidneys [7].
Materials and Methods

The subjects determine patients from (Al-Sadr hospital) in the city of Najaf during the period between January 2019 to July 2019. The CKD patient and control group consisted of sixty with age mean of (80 ±20) years. Also the patients classified into Patient’s age less than 40 years (n=32) and patient age more than 40 years (n=28).

- Procedure of serotonin

In the Serum the concentrations of serotonin in the Serum were determined by using ELISA assays. The ELISA kits for testing serotonin were obtained from Elabscience Biotechnology co. Ltd. The serotonin of number is Product ID is (E-EL-H2187).

- Procedure of blood Urea

In the Serum the concentrations of Urea in the Serum were determined by using colorimetric methods were obtained from abcam Biotechnology co. The Urea of number is Product ID is (ab83362) (at absorbance = 570 nm).

- Procedure of Creatinine

In the Serum the concentrations of Creatinine in the Serum were determined by using colorimetric methods were obtained from abcam Biotechnology co. The Creatinine of number is Product ID is (ab204537) (at absorbance = 490 nm).

- Procedure of uric acid

In the Serum the concentrations of Uric Acid in the Serum were determined by using colorimetric methods were obtained from abcam Biotechnology co. The uric Acid of number is Product ID is (ab65344) (at absorbance = 570 nm).

- Procedure of hemoglobin

In the Serum the concentrations of hemoglobin in the Serum were determined by using colorimetric methods were obtained from abcam Biovision co. The hemoglobin of number is Product ID is (K219-200) (at absorbance = 575 nm).

Statistical Analysis

The statistical analysis was measuring by using SPSS version 17 in which mean, stander error, t-test and ANOVA test were used for data comparison. Correlation between all variables were significant and a p value of <0.05.

Results

The purpose of this study was to evaluate the level of some variables (serotonin, blood Urea, Creatinine, uric acid and hemoglobin) associated with CKD patients 6 hours before and after dialysis and control group are shown in table (1). The higher mean value of serotonin was shown in CKD patients before dialysis (0.0257±0.00224 ng/ml) compared with patients after dialysis (0.1894 ± 0.05189 ng/ml) compared with control group(0.0059 ± 0.00139 ng/ml). Also the higher value of blood Urea and Creatinine reversibly in CKD patients before dialysis was (126.25± 4.869 mg/dL), (10.041± 0.3019 mg/dL) compared in blood Urea and Creatinine in CKD patients after dialysis was (48.183± 2.262 mg/dL), (3.28± 0.201 mg/dL) and control group was (28.105 ± 1.896 mg/dL), (1. 095 ± 0.0961 mg/dL). Also the higher value of uric acid and hemoglobin reversibly in CKD patients before dialysis was (8.0623± 0.1478 mg/dL), (13.800 ± 0.16519 g/dL) compared in uric acid and hemoglobin in CKD patients after dialysis was (5.5361± 0.16055 mg/dL), (12.383 ± 0.15872 g/dL) and control group was (2.6789 ± 0.2977 mg/dL), (13.742 ± 0.18954 g/dL), all above results there was a significant difference and correlation between the mean value in CKD patients before and after dialysis and control group (p<0.05). (Table1).

This result showed the correlation value between some variables (serotonin, blood Urea, Creatinine, uric acid and hemoglobin) in serum of 60 CKD patients before and after dialysis, the result revealed that correlation between serotonin before dialysis and serotonin after dialysis (r = 0.058 (p<0.01) . Also the high correlation between blood Urea before dialysis and blood Urea after dialysis (r = 0.694 (p<0.05) . The result showed correlation between Creatinine before dialysis and Creatinine after dialysis (r = 0.050 (p<0.05) . The result showed high correlation between uric acid before dialysis and uric acid after dialysis (r = 0.241 (p<0.05) . Also the high correlation between hemoglobin before dialysis and hemoglobin after dialysis (r = 0.276 (p<0.05) . (Table 2).
The concentrations of these variables were divided according to different age in CKD patients (Table 3). The patients were divided into two groups according to the age intervals of patients: age less than 40 years, n=32, and age more than 40 years, n=28. The all levels of these variables showed a significant difference in each age group (p < 0.001) (Table 3). This result showed the correlation between serotonin less than 40 years and serotonin more than 40 years (r = 0.268, p < 0.01). Also, the high correlation between blood Urea less than 40 years and blood Urea more than 40 years (r = 0.023, p < 0.05). The result showed correlation between Creatinine less than 40 years and Creatinine more than 40 years (r = 0.488, p < 0.05). The result showed high correlation between uric acid less than 40 years and uric acid more than 40 years (r = 0.135, p < 0.05). Also, the high correlation between hemoglobin less than 40 years and hemoglobin more than 40 years (r = -0.229, p < 0.05) (Table 4).

Discussion

In this report, we showed that the concentration of serotonin was higher in CKD patients before dialysis than CKD patients after dialysis and control groups. The concentration of serotonin in CKD was higher in less than 40 years than other different age. Until now, there are few studies about relation between serotonin and CKD. The increasing serotonin levels and serotonin receptors in patients of CKD [8]. Some factor effect on serotonin level such as depression and age is highly prevalent and is associated with poor quality of life and increased mortality among adults with CKD. Depression is well known to affect adults with end-stage KD [9]. Serotonin has been studied before and after dialysis because we believe there is a relationship between depression and kidney patients and serotonin is a trigger in depression and the risk of hospitalization due to psychiatric disturbances are higher in patients on dialysis in comparison with pre-dialysis and post-transplant patients, the neuropsychiatric manifestations in CKD patients [10]. The Serotonin mechanisms that links with CKD, our resulting shown agree with reports [11]. The creatinine and serum urea was significantly high before dialysis and reduced significantly after dialysis, both serum creatinine and serum urea are widely accepted biomarkers to assess the renal functions [12]. Generally, urea accumulation in blood serum of kidney failure patients arises from the degradation of food and tissues such as muscle [13]. The high level of urea in blood leads the body very sick unless remove it from the blood streams by kidneys. mass differences [14]. Reduction in the level of creatinine during dialysis is also used as a surrogate marker of the inadequacy of dialysis [15]. During the study it was also observed that CKD is more 40 years are more affected with CKD our result agree with [16]. Uric acid level before and after dialysis is measurement and comb with control group our result agree with [17]. It is catabolism and production of uric acid is not limited to dialysis duration and uric acid metabolism measured immediately after dialysis is indicator of uric acid accumulation in the plasma [18].

Conclusions

In CKD patients there were increasing in serotonin, blood Urea, Creatinine, uric acid and hemoglobin in before dialyses compare in after dialyses and control group. Whereas, the serotonin and hemoglobin level were increased in these patients of less than 20 years. While blood Urea, Creatinine and uric acid level showed the highest value in the group of older than 40 years.

Estimation of the Biological Activity of Some Commercial Bleaching Solutions (Hypochlorites) on Pathogenic Bacteria

Ahmed Salih Lateef¹, Ismail K. AL-Hitti¹, Atheer A. Khashan²

¹Assistant Lecturer; / Professor, Department of Medical Laboratory Techniques, AL-Ma’arif University College, Ramadi, Anbar, Iraq. ²Assistant professor, Department of Pharmacognosy, University of Anbar, College of Pharmacy, Ramadi, Anbar, Iraq

Abstract

Hypochlorites, the active ingredients in bleach, are an extremely useful chemical that have been used since the 18th century as a disinfectant. Hypochlorite solutions are in general strong oxidizing agents. The study included of five species of hypochlorite solutions widely used as commercial bleaching solutions (Shoof, Oroplus, Alwazir, Lamoa and Fas) and their concentrations were confirmed chemically by potentiometric titration methods previously and applicate their ability and efficiency against two types of bacteria (E.coli and Staphylococcus arueus) which are isolated from human infected sample in general Heat hospital /Iraq. The results revealed that all bleaching solutions have anti-bacterial influence against two species of bacteria and more successful against Staphylococcus aureus than the E.coli especially with Alwazir solution give high significant difference compared with other solutions, also the outcomes showed sensitivity of bacteria enhanced with concentrations of bleaching solutions. The study indicates the fast reduction rate in the 30S reaction showed the immediate efficiency of Hypochlorites. Finally the current study suggest and encourage to use hypochlorite solutions as antiseptics and disinfectants to killing species of bacteria which proved their efficiency during this study.

Keywords: Bleaching solutions, E.coli and Staphylococcus arueus, Antimicrobial, Microorganism, Hypochlorite’s.

Introduction

Hypochlorites are in general strong oxidizing agents. Commercially, they are used as an alternative to chlorine gas for chlorination of domestic water supplies and swimming pools ¹. They were used also in cooling towers of air conditioners and power stations to control bio fouling ². Acidified sodium chlorite was used an alternative to chlorine in reducing microbial populations to maintain food quality and safety on fresh –cut produce ³. Commercial acidified sodium chlorite and sodium hypochlorite exhibited strong efficiency on reduction of microorganisms including E.Coli ⁴.(Estrela et al) have studied the mechanism of action of sodium hypochlorite on the activity of some types of bacteria. They found that the chloramination reaction between chlorine and amino group (NH) forms chloramines that interfere in cell metabolism ⁵.

Sodium hypochlorite, the active ingredient in bleach, is an extremely useful chemical that has been used since the 18th century as a disinfectant ⁶. In the circulation, NaOCl combines with water to generate hypochlorous acid (HOCI) conferring potent anti-bacterial and antifungal properties ⁷. Some factors affecting the concentration of available chlorine in commercial sources of sodium hypochlorite were studied by (Frias et al) ⁸. The effect of storage temperature and heating on the concentration of available chlorine and pH of 2.5 % NaOCl were investigated and found that storing NaOCl at 4ºC is optimal for longer shelf life and pH of the samples did not affect the stability of NaOCl in this study ⁹. Preheating NaOCl solutions appears to improve
their necrotic pulp tissue dissolution capacity and efficacy against stationary phase of E. faecalis cells. Studies were conducted to compare the effect of sodium hypochlorite (SH) versus mono chloramine (MON) on bacterial populations, these studies indicated that (MON) is superior to SH in reducing microbial populations in poultry chiller water. Antimicrobial activity of several concentrations of sodium hypochlorite and chlorhexidine gluconate in the elimination of E. faecalis were studied, the study confirmed the antimicrobial activity of chlorhexdine and sodium hypochlorite. Other study concluded that heating the solutions have enhanced their ability to dissolve organic material.

**Materials and Methods**

**Preparation of commercial bleaching solutions**

Commercial bleaching solutions are mostly sold in the commercial market in Iraq from different companies such as: Shoof, Oroplus, Alwazir, Lamoa and Fas showed in table 1. Their concentrations were confirmed chemically by potentiometric titration methods before application them against bacteria. The percentages of each solution was converted to milligram units per milliliter. The solutions were then ready to conduct the biological activity of two pathogenic bacteria, namely: *E.Coli* and *Staph aureus*.

**Culture media:**

They were prepared in accordance with the guidance of the manufacturers and sterilized under pressure of 12-15 PSI in autoclaves for 24 hours at 37 ° C. They were then sterilized. Then used for bacteria analysis culture and diagnosis.

**Culture preparation:**

Bacteria were regenerated and kept in the incubator for 24 hours at an average temperature of 37 ° C. Then they were applied to sterilized tubes with heart infusion broth and put into the incubator at 37 ° C for 24 to 72 hours. The chances of a mild transmission were 27 percent at a wavelength of 580 nanometer and a 100 percent light transmission for the nutrient bread that was used to arrange the micro-organism. Total bacteria are counted as number predicted with the assistance of a spectrophotometer.

**Results and Discussion**

In this study, the results demonstrated that the all types of commercial bleaching solutions (hypochlorites) have anti-bacterial influence against two species of bacteria (*Staph. aureus* and *E.coli*), and the sensitivity of types bacteria were gradually increased with increasing of bleaching solutions concentrations exception of (Oroplus 50mg/ml) in E.Coli gives little sensitivity about the concentration that has before (shoof 40mg/dl)(Table.2). Previous study demonstrated that investigation in vitro the antimicrobial activity of sodium hypochlorite NaOCl at different concentrations can be used as irrigating solutions owing to their antimicrobial
properties\textsuperscript{15}.

In this research, E. coli and Staphylococcus aureus isolates displayed resistance to hypochlorite solutions\textsuperscript{16} recorded that bacteria completely isolated from contaminated disinfectant solutions and antiseptics display increased resistance to widely used antibiotics, provided that bacteria have the ability to share strong markers and, as resistance arises for one agent, cross-resistance.

The result in (fig1, 2 and table.2) explained that the hypochlorites have been more successful against Staphylococcus aureus than the E.coli confirmed with this finding\textsuperscript{17} especially with Alwazir solution as it gave the high significant efficiency compared with other solutions. The outcomes are agreement with other studies which are indicate that Gram’s negative bacteria are less sensitive to antiseptics and disinfectants. The final result was accepted\textsuperscript{18}, whereby the complicated cell layer, and their outer membrane functions as a permeability shield for restricting or blocking entry of different chemicals\textsuperscript{19}.

The fast reduction rate in the 30S reaction showed the immediate efficiency of Hypochlorites\textsuperscript{20}. The oxidizing mechanism can explain the immediate killing of bleach\textsuperscript{21}. The bleach became bactericidal for vegetative species quickly, which noticed identical tests. After five minutes of exposure to this disinfectant, the 10\% bleach concentration kills all tested bacteria. This contributes primarily to the bleach sterilization mechanism triggered by the oxidation reactions when bleach is mixed with water which lead organisms to be totally destroyed. In addition, four blanching results of the two study bacteria (E. coli and Pseudomonas aeruginosa) was (Fas 50 percent Oroplus 50 \% Shoof 40 \% Alwazuir 30\% Lamaoa 25 \% respectively) For both the two bacteria studied (E.coli and Staphylococcus arueus) the efficacy of culturing pattern was specific and from the analysis Fas 50 \% and Oroplus50 \% had the strongest efficacy against the bacteria studied following by Shoof 40 \% Alwazir 30 \% Lamaoa 25 \% had less efficacy against the bacterial measured\textsuperscript{18}. Hypochlorite concentrations (mg/ml) inhibition zone (mm) Oroplus, Shoof, Alwazir and Lamaoa concentrations indicate a high efficiency against two bacteria studied used in this research, and findings obtained have been confirmed with (Gaonkar \textit{et al.},2006)\textsuperscript{22}.

**Conclusion**

Hypochlorite solutions are strong oxidizing agents, extremely useful chemical used as a disinfectant. The study included five species of hypochlorite solutions widely used as commercial bleaching solutions (*Shoof*, *Oroplus*, *Alwazir*, *Lamo* and *Fas*) and checked their efficiency on bacteria (*E.coli* and *Staph. Aureus*). All types of commercial bleaching solutions (hypochlorites) have anti-bacterial influence against two species of bacteria and bacterial sensitivity was progressively increased with the exception of concentrations of bleaching solution in *Oroplus* 50mg/ml in *E.Coli* which gives little sensitivity about the concentration that has before, the results explained that all the bleaching solutions have been more successful against *Staphylococcus aureus* than the *E.coli*, and the outcomes enhance in agreement with other studies which are indicated that Gram’s negative bacteria are less sensitive to antiseptics and disinfectants. Finally the current study suggested and encouraged to use hypochlorite solutions as antiseptics and disinfectants for killing species of bacteria.

Detection of the Some Dominant Aerobic Microorganisms in Burn Injury and Testing their Susceptibility for Different Antibiotics in Najaf

Ahmed Zuhair Alwaeli
Instructor, Ph.D. Altoosi University College/ Department of Nursing, Najaf-Iraq

Abstract

Burn injury and wound is a pig problem that assists the pathogens to grow and cause infection. 149 burn injury swabs were taken from different site of the patients’ body ages (11-53 years old). All samples were tested to isolate the significant microorganisms that found in burn injury. Antibiotics test was performed by using disc diffusion way that stated by Kirby-Baucer. Results appeared that the most frequent pathogen in burn injury was \textit{Pseudomonas aeruginosa} 33(22.14%) and followed by \textit{E.coli} 31(20.8%), \textit{Staphylococcus aureus} 28(18.79%), \textit{Proteus vulgaris} 26(17.48%), Coagulase-negative \textit{Staphylococci} 12(8.05%), \textit{Proteus mirabilis} 10(6.71%), \textit{Klebsiella pneumonia} 5(3.35%) and \textit{Candida spp.} 4(2.68%) respectively. Antibiotic test showed that \textit{Staphylococcus aureus} was a high resistance against Gentamycin and ciprofloxacin, but it was sensitive to Vancomycin and Imipenem. Coagulase negative \textit{Staphylococci} showed a resistance to Gentamycin, Ciprofloxacin and Ceftazidime, but it was sensitive to Amikacin, Oxacillin, Cefotaxim, Vancomycin, Imipenem and Cefepime. \textit{P. aeruginosa} showed resistance against Cefotaxime, Aztreonam, Gentamcin and Ceftazidime. Whilst it showed a high sensitivity against Imipenem, Cefepime and Tobramycin. \textit{E.coli} showed a high resistance against Ceftriaxone, Ciprofloxacin and Cephalothin. whilst it showed a high sensitivity against Ticarcillin/clavulanic acid, Imipenem, Cefepime and Tobramycin. \textit{Proteus vulgaris} showed a high resistance against Ceftriaxone, Coagulase negative \textit{Staphylococci} and Cephalothin. whilst it showed a high sensitivity against Ceftriaxone, Amikacin, Cefotaxim, Ticarcillin/clavulanic acid and Ceftazidime. \textit{Proteus mirabilis} showed resistance against Amikacin, Ciprofloxacin, Ceftriaxone, Gentamcin and Cephalothin. Whilst it showed a high sensitivity against Ceftriaxone, Cefazidime, Amikacin, Cephalothin and Gentamicin. whilst it showed a high sensitivity against Cefotaxime, Aztreonam, Ticarcillin/clavulanic acid and Imipenem. \textit{Klebsiella pneumonia} showed resistance against Ciprofloxacin, Ceftazidime, Cefotaxime and Aztreonam. whilst it showed a high sensitivity against Ceftriaxone, Amikacin, Gentamicin, Cephalothin, Ticarcillin/clavulanic acid, Imipenem, Cefepime and Tobramycin. The current study was aimed to determine the most frequent pathogens in burn injury and test their antibiotics susceptibility in hospitalize patients in Najaf city.

Keywords: Burn injury, Burn infection, Antibiotics.

Introduction

Burn infection considered one of the most medical issue in the world[1], there are many reasons could lead for it, such as heat, chemical agent, electricity… etc. The big problem in burn is the infection when the skin is destroyed, many pathogens and opportunistic microbes are initiated the infection[2] and this lead to sepsis especially in the modern countries[3], and this is the cause of high morbidity and mortality in hospitalized burn patients[4,5]. Burn injury considered a harmful form of trauma so, the patients with burn injury must take essential care to prevent mortality and morbidity[6]. The term of multi-drug resistant Gram-positive bacteria and Gram-negative bacteria is used to the most microorganisms linked to injuries infection,
according to many studies, these microorganisms include *Staphylococcus aureus* which is found in 20–40% and *Pseudomonas aeruginosa* which is found in 5–15% and other microorganisms like *Escherichia coli*, *Klebsiella pneumonia* and *Acinetobacter* spp. consider as a nosocomial pathogens. Topical antibacterial reduce bacteria growth but not prevent growth other potentially invasive bacteria and fungi. These are contaminated the wound patients and their source is initiated from gastrointestinal or upper respiratory tract or the hospital environment itself. After wounds contamination and adherence, these microbes begin to penetrate the viable tissue and invasive it, invasiveness of microbes is depend on the size of local wound and who the patients’ health are, some patients have immunosuppression state. If sub-eschar tissue is colonized, disseminated infection is likely to happen, and Some microorganisms are changed with time, some of them become so aggressive and other microorganism lose it ability to cause infection and this depend on the host immunity. New microorganisms are arrived to the burn ward with new patients. These organisms live with resident flora of the burn for period of time so, they acquire new feature like antibiotics resistance. Presentation of new topical agents and systemic antibiotics influence the flora of the wound could be interested in future to prevent the mortality and morbidity by opportunistic flora.

**Materials and Methods**

**Population in study**

The current study included 149 samples (112 males and 39 females) which collected from patients with burn injury in different sites by assistance of physician or the team care in the patient’s room during the period 5 March 2020 to 12 August 2020 from the burn center in Alsadr hospital in Najaf city, Iraq. the patients in this study didn’t have any chronic diseases or any other infection, the patients ages were 11 to 53 years old. all patient were agreed to cooperate and participate in this study in order to provide service to the community.

**Sample collection**

When the samples were taken from patients under complete aseptic conditions by sterile cotton swabs with sterile normal saline, they put in to brain heart infusion broth (Himedia-India) and they stayed no longer than one hour in the broth (to prevent the growth of contaminated microorganism especially *Aspergillus* spp.), and directly transported to the medical microbiology lab in Altoosi University College and then cultured in to different media (Himedia-India) for microbiology diagnosis that was achieved according to Macfaddin, and Forbes et al.

**Identification of aerobic microorganism**

For each sample in brain heart infusion broth, three petri dishes with Nutrient agar Blood agar, Maccokey, agar mannitol salt agar and Sabouraud dextrose agar (with chloramphenicol). All agars were incubated at 37°C for 24-48h. Subculture for single colonies were achieved to obtain pure colony for each microorganism.

**Antibiotics Test**

The method of antibiotics test was performed by using disc diffusion way that stated by Kirby-Baucer. The pure colony for each bacteria was streaked like mat onto Muellur Hinton agar (Himedia-India). For gram positive bacteria, thirteen different antibiotics disc were used which provided from Oxoid-USA, these antibiotics were as follow: Amoxicillin/Clavulanic acid (20/10 μg), Gentamicin (10 μg), Amikacin (30 μg), Oxacillin (1 μg), Ciprofloxacin (1 μg), Ceftriaxone (30 μg), Ceftazidime (30μg), Cefotaxim (30μg), Cephalothin (30μg), Ticarcillin/clavulanic acid (75/10μg), Vancomycin (30μg), Imipenem (50μg) and Cefepime (10μg). While for gram negative bacteria, twelve different antibiotics disc were used which provided from Oxoid-USA, these antibiotics were as follow: Ciprofloxacin (5μg), Ceftriaxone (30μg), Ceftazidime (30μg), Amikacin (30μg), Gentamicin (10μg), Cefotaxime (30μg), Aztreonam (30μg), Cephalothin (30μg), Ticarcillin/clavulanic acid (75/10μg), Imipenem (10μg), Cefepime (10μg) and Tobramycin (10μg). The sensitivity and resistance of bacteria was determined based on the inhibition zone that form on Muellur Hinton agar after
18-24h from culture. The inhibition zone that form was compared with CLSI 2017\textsuperscript{[14]}.

**Statistical Analysis**

The percentages of the number of was achieved by SPSS version 17 windows7.

**Results**

**Identification of Microorganisms in burn injury**

The present study included 149 burn injury patients. Eight different microorganisms were isolated in this study. Forty (26.84\%) patients swabs were Gram positive bacteria (*Staphylococcus aureus* (18.79\%) and *Coagulase-negative Staphylococci* (8.05\%)), while fifty four (70.48\%) patients swabs were gram negative bacteria (*Pseudomonas aeruginosa* (22.14\%), *E.coli* (20.8\%), *Proteus vulgaris* (17.44\%), *Proteus mirabilis* (6.71\%) and *Klebsiella pneumoniae* (3.35\%). *Candida spp.* was isolated in four (2.68\%) swabs patients. **Discussion**

Burns infection death are the most notified event that occur between admitted hospitalize patients which represent over 50% of burn deaths. Although many burns centers gave specialize medical care for patients, but the nosocomial infections still the big problem for care teams[18]. In the current study, the most frequent pathogen in burn infection was *P. aeruginosa* (22.14%) in Najaf city, followed by *E.coli* (20.8%), *Staphylococcus aureus* (18.79%), *Proteus vulgaris* (17.44%), *Coagulase-negative Staphylococci* (8.05%),
Proteus mirabilis (6.71%) and Klebsiella pneumonia (3.35%). These results were in agreement with finding stated by Aljanaby et al, they found in their a three years cross-sectional study that the most frequent pathogen was P. aeruginosa (27.6%)\textsuperscript{[19]}. This could be belong to the fact that P. aeruginosa is one of the most significant microbes which is distributed in the nature. P. aeruginosa has ability to produce infection because the high rate of virulence and antimicrobial resistance\textsuperscript{[20,21]} But the current study disagree with the finding that stated by Al-Kanaany, she find the majority isolated organism in burn infection was Staphylococcus and followed by Pseudomonas. this difference is not significant because in the current study S. aureus was isolated as a third frequent pathogens in burn infection. although Both P. aeruginosa and S. aureus have high diffusion rate and consider as a nosocomial pathogens in admitted Hospitalize patients. In this study E. coli, Proteus vulgaris, Proteus mirabilis, Klebsiella pneumonia and Candida were isolated and this result are in agreement with previous studies\textsuperscript{[22,23]}. present of these bacteria may belong to environmental factor that contaminate the wounds, some patients could take these bacteria from hospital. Modern study showed that there was a relation-ship between admitted hospitalize patient for long time and the prevalence of pathogenic bacteria in burn\textsuperscript{[19]}.

Results showed the most isolated bacteria which has multi-antibiotics, resistance is P. aeruginosa and followed by S. aureus, E.coli and Proteus vulgaris. this either could belong to their ability to acquire the genes that responsible for drug resistance from other bacteria in the environment though plasmid or other vector by conjugation or any methods of gene transfer, or belong to ability of Gram negative bacteria especially P. aeruginosa to form biofilm that protect bacteria from the effect of host immunity and antibiotics\textsuperscript{[24-26]}. P. aeruginosa is one of the most important pathogens causing different infections such as bacteremia and burn infection\textsuperscript{[27]}. P. aeruginosa alone has more than 70% mortality of Burn infection\textsuperscript{[28]}.

Conclusions

From the presented study, the author conclude that the most dominant pathogens in burn infection was Pseudomonas aeruginosa and followed by Staphylococcus aureus, Proteus vulgaris, Coagulase-negative Staphylococci, Proteus mirabilis, Klebsiella pneumonia and Candida spp. We also conclude that Imipenem (10μg) is an excellent choice for burn infection as a first choice, it has 100% against all the pathogens that isolated in the current study, while Ticarcillin/ clavulanic acid (75/10μg) and Cefepime (10μg) consider the second choice.

Effect of Dentifrices with Different Abrasives on the Surface Roughness of a Nano Composite Resins materials

Ala’a Jawad Kadhim1, Linz Ali Shalan1

1Assistant Professor, Conservative and Esthetic Dentistry Department, College of Dentistry/ University of Baghdad, Iraq

Abstract

Background: to evaluate the effect of different dentifrices on the surface roughness of two composite resins (nanofilled-based and nanoceramic – based composite resins). Materials and methods: Forty specimens (diameter 12 mm and height of 2mm) prepared from different composite resin materials: Z350 (nanofilled composite, and Ceram-X (nanoceramic). they were subjected to brushing simulation equivalent to the period of 1 year. The groups assessed were a control group brushed with distilled water (G1), Opalescence whitening toothpaste (G2), Colgate sensitive pro-relief (G3) and Biomed Charcoal Toothpaste (G4). The initial and final roughness of each group was tested by surface roughness tester. The results were statistically analyzed using ANOVA and Tukey test at 0.05 significance level. Results: the surface roughness of the two tested composites brushed with the tested dentifrices was statistically higher than the roughness found in control group. Comparison among the three types of dentifrices showed that there was a statistically high significant difference in the surface roughness among all subgroups. Charcoal Toothpaste showed the highest surface roughness increase. Conclusion: Whitening dentifrices increase the surface roughness of dental composite thereby compromising its durability. Changes in composite depended on the material itself and the dentifrices used.

Key words: Abrasive, Composite resin, Dentifrices, Surfaces roughness, Whitening.

Introduction

Restorative materials have a lot of refinement in the mechanical, physical, chemical properties and esthetics since their introduction (1). The composites produced with the aid of nanotechnology became popular as they offer longevity and better esthetic (2). The recent advances in nanotechnology yielded nano-filled and nano-ceramic composite resin materials (3). Nanofill composites are composted of nanoclusters and nanosilica particles, the nanocluster fillers are collections of particles of nano-size and act as one unit to achieve higher filler strength and loading up to 80% of the resin matrix’s total weight (3, 4). The organically modified nanoceramic composite was developed by combining the nanotechnology and ormocer technology. This composite contains methacrylate-modified, silicon dioxide–containing nanofiller of 1.1–1.5 μm in size that account for 76% of total weight and resin matrix that is replaced by a matrix full of highly dispersed methacrylate-modified polystyloxane particles (2, 5).

The dental materials’ surface texture has a major influence on plaque accumulation, wear, discoloration and the aesthetic appearance of direct and indirect restorations (6). The surface roughness can wear out the opposite tooth enamel and reduce patient satisfaction and comfort (7). Tooth brushing with the aid of dentifrices decreases dental caries but might damage the surface of resin composite restorations, making it rougher, and more liable to staining and plaque accumulations (8). Different dentifrices are available in the markets to provide fast, easy and low-cost whitening effect (9).

The wear caused by tooth brushing depend mainly on tooth brushing habits, the quality of the toothbrush (hard, medium, or soft), and the dentifrice abrasive used (10). The abrasive particles are insoluble minerals designed to remove microorganisms, stains and disorganize the bacterial biofilm giving a whitened appearance (11). In dentifrices, the most widely used abrasives are hydrated silica, calcium carbonate, calcium phosphate, sodium bicarbonate and calcium pyrophosphate (12).
Other abrasives include tricalcium phosphate, hydrated alumina, calcium sulfate and sodium metaphosphate (11). Most whitening dentifrices act on extrinsic stain removal as they do not contain bleaching agents (13).

Activated charcoal dentifrices have the capacity of adsorbing pigments, chromophores and stains responsible for the color change of teeth (14). However, charcoal’s shape, composition and sizes of its particles could be abrasive and may increase the surface roughness of composite resin (15). Long-term tooth brushing with abrasive toothpastes, can compromise the esthetic appearance and hasten the degradation of the restoration (16).

This study measures the surface roughness of a nanofilled and nanoceramic composite resin after brushing with different types of dentifrices. The null hypothesis is that the dentifrices do not change the surface roughness of restorative material.

**Materials and Methods**

The composites chosen for this study (Table 1) were the following: Z350 (nanofilled composite, 3M ESPE, St. Paul, MN, USA) and The Ceram-X (nanoceramic composite, Dentsply DeTrey, Konstanz, Germany). Three brands of dentifrices containing different compositions were used: Opalescence whitening toothpaste® R, Colgate sensitive pro-relief® and Biomed Charcoal Toothpaste.

**Specimens’ preparation**

Forty specimens (disks) were made for each tested composite (2 X 12 mm). The specimens were photoactivated using a light curing device 1200Mw/cm² Blue curing light (Guilin woodpecker medical instrument, China) for 20 seconds of exposure time to both top and bottom surfaces, respectively according to the manufacturer’s instructions. Samples were polished with rubber abrasive points (Politip-P, Ivoclar Vivadent Inc., US) and stored in distilled water at 37°C for 24 hours, to stimulate clinical situation (4).

**Specimens’ Grouping**

Specimens made from tested composite were randomly divided into four groups (n = 10) as follows: G1 – brushed with distilled water (control group); G2 – brushed with Opalescence whitening toothpaste® R; G3 – brushed with Colgate sensitive pro-relief®; G4 – brushed with Biomed Charcoal Toothpaste. The composition of testing toothpastes presented in Table 2.

**Brushing**

A specially designed brushing apparatus was designed by the Department of Conservative and Aesthetic Dentistry, College of Dentistry, University of Baghdad. The brushing apparatus was set to run a horizontal course of 3.8 cm at a speed of 356 RPM, and a load of 200 g (17). For all groups, the samples were fixed and brushed with corresponding dentifrice for 60 minutes, simulating to 1 year of brushing. Toothpaste was mixed with distilled water (ratio 1:1) (1, 2, 9). After tooth brushing, to avoid interference with the results, specimens were washed with water to remove all the remnants. Similar toothbrushes (Signal, Spain) fixed to the brushing apparatus supports and adjusted so that the bristles would come into contact with the specimens.

**Surface Roughness Measurements**

A profilometer (Hand-Held Roughness Tester, TR200, Time Group Inc. China) were used to determine the initial surface roughness (prebrushing) and the post brushing surface roughness. Specimens measured by the profilometer in different three areas, then the average value registered as the mean Ra of the specimen. The mean Ra values were automatically measured by the profilometer.

Result

Descriptive statistics: Means, minimum, maximum and standard deviation of composite roughness values were listed in Table 3. According to the table there was an increase in the means of roughness values for tested composite after brushing with tested dentifrices, also the Z350 had the lowest roughness values and Ceram x had the highest value.

Inferential statistics: ANOVA test used for all groups showed that there is a high significant difference ($p<0.001$) in surface roughness values among the groups for each composite resin after brushing with distilled water or different dentifrices which show a high significant difference in surface roughness Ra values among the tested composite materials as shown in Table 3.

Table 3: Descriptive and ANOVA test among the three tested composite

For intragroup comparison, Tureky test for all groups were done which showed highly significant increases in surface roughness value Ra of the two tested composite ($p>0.001$) after brushing with distilled water and Opalescence whitening toothpaste and non-significant differences ($p<0.05$) in surface roughness value after brushing with Colgate sensitive pro-relief and Biomed Charcoal Toothpaste as shown in Table (4).

* The mean difference is significant at the 0.05 level.

Another analysis was the difference after brushing with the tested Dentifrices equation: Before-after = ∆Ra*

The data revealed that the lower surface roughness difference was with the use of distilled water, followed by Opalescence whitening toothpaste\textsuperscript{R}, Colgate sensitive pro-relief and Biomed Charcoal Toothpaste as shown in table 5.

Discussion

Direct composite resins are always exposed to chemical and mechanical challenges that can alter the material properties such as when associated with long term brushing, specially when the toothpaste contain hard abrasive particles, so the composite resin will degrade and compromise giving opposite results from what was expected from the whiting dentifrices (11, 12). Different dentifrices with different compositions have been developed to improve the affectivity of cleaning and whitening of teeth. Few of them have hydrogen peroxide (1%) in its formulation which is the active principle of bleaching products used in the dental office because it can cause irritation of the gingival tissues and lead to dentin hypersensitivity (18). Other substances used by cosmetic industries in whitening dentifrices are optical pigments such as titanium dioxide and blue covarine, which can color the enamel surface white, more than the effect in removing, stains (19).

Regardless of the addition of hydrogen peroxide or pigments to whitening dentifrice, abrasive substances are often present in their components to increase the friction during tooth brushing, which can jeopardize resin composite without contributing to whiten the teeth. So the purpose of this study was to evaluate the abrasiveness of three different dentifrices on the surface roughness of nano-manufactured composite resins after simulating one year of tooth brushing.

This study used parameters accommodated the clinical situation, such as the amount of toothpaste (ratio of 1:1), brushing load (200 gr), and brushing time (17). Brushing time was calculated by the assumption that brushing for two minutes (120 seconds) twice daily, divided on an average of 24 teeth result in 10 seconds of brushing time for every tooth per day, brushing for one year was assumed to take 3650 seconds (60 min) (20).

The results showed that, the surface roughness was significantly affected by the dentifrice factor, so rejecting the null hypothesis. This finding agrees with other studies that showed a correlation between tooth brushing with the use of abrasive dentifrice and the increase in the surface roughness of composite (11, 12, 21).

A study conducted by da Oliveira et al. (22), assessed the effect of simulated tooth brushing with different whitening dentifrices on the surface roughness of different composite resins which found a significant difference in the result for the dentifrice factor, supporting the findings of our study.

The increased Ra value may be caused by the mechanical action of the brushing and the abrasive material contained in the dentifrice (23). The mechanical factor was controlled accordingly in all groups. There was a statistical difference in the roughness values after the brushing challenge (Table 3) regardless of the toothpaste type even with brushing with distilled water (no toothpaste).

Friction causes the filler particles to fall out from the matrix, leading to increase in the surface roughness of composite resins this effect becomes even greater if accompanied by abrasive toothpaste (24) (25).

The dentifrices containing silica alone are considered to have low abrasiveness but if combined with calcium carbonate, sodium pyrophosphate, titanium oxide, and sodium phosphate, it is considered a high abrasive dentifrice (26).
Amaral et al. (27), study concluded that sodium bicarbonate is more abrasive than silica or calcium carbonate. This finding is consistent with the results of this study, in which the dentifrice Opalescence has silica as an abrasive agent only, so the surface roughness of it was the lowest. While Colgate® Snesative PRO-Relief™ whitening has calcium carbonate and sodium bicarbonate.

The highest increase in the Ra value occurred in Charcoal toothpaste which in addition to having hydrated silica and Sodium Bicarbonate contains activated charcoal which is too abrasive and can wear away tooth enamel (21).

Effect of composite

Regarding the composite assessed in this study, Z350 and Ceram X were chosen because both of them had nanoparticle fillers in their composition. Resin composites with nanofiller has good aesthetic result and good wear resistance (25). Nanoclusters has been also improved to be better wear resistance as the silane would fill the gaps and voids that observed in microhybrid composites (28).

The composition of the resin matrix, filler particle type or content, matrix/filler interface, degree of polymerization and hardness of the resin composites could affect the surface condition after tooth brushing (29, 30). Other parameters such as the polishing and light-curing method are also of fundamental parameter to the values of surface roughness. However, they were standardized and the two tested materials were submitted to the same parameters as for the polishing type / light-curing method (31). For comparative Filtek Z350, the fillers are composed of zirconia/silica, classified as a nanofilled composite, while Ceram X the fillers are silica and radiopaque barium-aluminum-silicate glass, classified as nanohybrid.

In this study Filtek Z350 presented the smoothest surfaces. Since the filler loading of the nano-filled composites is higher than that of the nano-ceramic composites, and this nanofilled materials have the ability to provide more volume of filler in homogeneous distribution, which enables it to protect organic matrix wear (11).

The nano-ceramic composite resin Ceram x demonstrated significantly greater roughness than the nano-filled composite resins Filtek Z350 Ceram; Ceram X is a nano hybrid containing organically modified ceramic nano particles comprising polysiloxane back bone. These nanoceramic particles can be best described as inorganic–organic hybrid particles where the inorganic siloxane part provides strength and the organic methacrylic part makes the particles compatible and polymerizable with the resin matrix (32). However, this modification of the matrix might cause a larger surface roughness of the Ormocer composite when compared to the conventional materials, due to the characteristic of its organic-inorganic resin matrix (30). Many studies have proposed a correlation between surface roughness and filler size, and that composites contain large filler size tend to be rougher than composites contain smaller filler size(23, 29)This finding agrees with the results of this study, as the Filtek Z350, which incorporates the smallest filler particles (from 0.2 to 1.4 µm), presented the smoothest surfaces than the Ceram X composites (from 0.4 µm up to 4.0 µm) glass filler.

The present study had some limitations, the concentration of abrasive materials in the toothpaste were not mentioned in the product which is very important in determining the abrasiveness of dentifrices, also the brushing was performed with dentifrice diluted in distilled water, but in fact this dilution occurs in saliva and the saliva properties can reduce the abrasive effects on the composite, as the saliva provides a sliding surface attenuating composite wear.

Coenzyme Q10 in the Follicular Fluid and Its Relation to Oocyte Maturity, Fertilization Rate, Embryo Grading, and Pregnancy Rate

Alaa Abdulateef Mohammed, Zainab Hassan Al-Khafajy, Ass. Prof Dr. Wasan Adnan Abdullhameed

Abstract

Background: Infertility was define as; a disease characterized by the failure to establish a clinical pregnancy after 12 months of regular unprotected sexual intercourse, or due to an impairment of a person’s capacity to reproduce, either as an individual or with his/her partner. According to the latest definition by the international glossary on infertility and fertility care, regular sexual intercourse is an important determinant for the occurrence of pregnancy.

Aim of the study: To assess the relation between Coenzyme Q10 level in the follicular fluid with oocyte maturity, fertilization rate, embryo grading, and pregnancy rate

Patients and method: A prospective cross sectional study conducted at the High Institute for Infertility Diagnosis and Assisted Reproductive Technologies / Al-Nahrain University and in fertility center at Al-Sadr general hospital during the period from December 2019 to August 2020. Sixty infertile couples were enrolled in this study; all underwent ICSI cycles

Results: Mean level of Co Q10 in Grade III and IV (0.387 ± 0.54) than that in Grade I and II (0.539 ± 0.65), CoQ10 total in pregnant were 0.79 ± 0.63 and in non-pregnant were 0.381 ± 0.2, A threshold of 0.27 of CoQ10 had a sensitivity of 80.0% and specificity of 67.0 %, PPV was (88.0%), NPV (45%) and accuracy was (74%). ROC curve of CoQ10 for pregnancy prediction

Conclusion: Significant decrease of Co Q10 between in Grade III and IV than that in Grade I and II. CoQ10 total were increase in pregnant women than non-pregnant.

Keyword: CoQ10, pregnant rate, oocyte maturity, fertilization rate, embryo grading.
and females are equally responsible for the causes of infertility, and most of the infertile couples have one of these three major causes including a male factor, ovulatory dysfunction, or tubal peritoneal disease. (3)

If the female partner is 35 year of age or older, evaluation should be initiated after 6 months of unprotected intercourse. Fecundability, or the ability to achieve pregnancy in one menstrual cycle, is a more accurate measurement to evaluate fertility potential. The fecundity rate in a normal couple who has had unprotected intercourse is approximately 20% to 25% for the first 3 months, followed by 15% during the next 9 months. (4)

Assisted Reproductive Technology (ART) is defined as a fertility treatment in which eggs and sperm are handled for the purpose of establishing a pregnancy. (5) Assisted Reproductive Technology (ART) now enables several treatment options, including ovulation induction followed by in vitro fertilization (IVF) and intracytoplasmic sperm injection (ICSI). (6)

Coenzyme Q10 (CoQ10), also known as ubiquinone or ubidecarenone, is a vitamin-like nutrient and lipid-soluble compound. As its name implies, it is ubiquitous and present in all human cells. It is primarily located in the mitochondria and also found in cell membranes and lipoproteins. The primary function of CoQ10 is its role in cellular energy production, where, along the inner mitochondrial membrane, the electron transport chain (ETC) uses CoQ10 as a component in oxidative phosphorylation converting products of metabolism (carbohydrates, fats, and proteins) into energy as ATP. (7)

**Oocyte quality and coenzyme Q10**

In in vitro fertilization cycles, the most important issue was the quality of oocyte. The main factors affecting the oocyte quality are the age of the women and the status of ovarian reserve. The inappropriately age-related decrease in oocyte quality is a main difficulty in the treatment of older patients. The main reason for this decrease was related to an accumulation of point mutations and deletions of mitochondrial deoxyribonucleic ac-id (DNA). (8,9)

**Aim of the Study**

To assess the relation between Coenzyme Q10 level in the follicular fluid with oocyte maturity, fertilization rate, embryo grading, and pregnancy rate

**Patients and Method**

A prospective cross sectional study conducted at the High Institute for Infertility Diagnosis and Assisted Reproductive Technologies / Al-Nahrain University and in fertility center at Al-Sadr general hospital during the period from December 2019 to August 2020. The study was approved by the local Medical Ethical Committee of the Arab Board council/ Obstetrics and Gynecological department. Sixty infertile couples were enrolle in this study; all underwent ICSI cycles. All selected patient was subjecte to:

- The basic fertility workup of the fertility center that consists of history- taking, physical examination, ovulation detection, evaluation of tubal patency and uterine cavity, and semen analysis.

- Assessment of follicular fluid Coenzyme Q10 level in the day of ova pick up.

**Inclusion criteria:**

- Age 18-40 years old.

- Early follicular phase FSH, LH, cycle day 2 E2, TSH and prolactin (PRL) hormonal level which was done as part of the work up must be within normal.

- Unexplained infertility or tubal function infertility

- Fresh transfer

- Informed consent

- Regular Menstrual cycle

- Normal ovulatory function

- Normal BP, not smoking, not taking any supplements

**Exclusion Criteria:**

- Age >40 years old.

- Abnormal uterine cavity due to polyp myoma, or congenital anomalies, endometriosis.

- Uncontrolled systemic disease as diabetes
mellitus, HT, or uncontrolled endocrinological disorder.

- Women with empty follicle syndrome.
- Women with no fertilized oocyte.
- Couples with semen collection failure at oocyte retrieval day
- Male factor infertility
- Diminished ovarian reserves as assessed by AFC < 5 and AMH < 1.2 ng/dl.

**Statistical Analysis**

Collected data were analyzed using SPSS version 23.0 for windows (SPSS Statistics, IBM, USA) and the results were expressed as mean ± standard deviation (SD). Differences of means within groups were examined by paired sample t-test. P values < 0.05 were considered as statistically significant

**Results**

Pregnancy were happened in 33/60 patients (55%) and 27/60 (45%) were not pregnant (fig 1)

![Fig 1: Pregnancy outcome in the studied group](image)

**Oocytes characteristics in pregnant and non-pregnant ladies**

Table 1, demonstrated the oocyte characteristics of pregnant and non-pregnant ladies. The mean total number of retrieved oocytes in pregnant ladies was 9.90 ±6.34; and that of non-pregnant women was 8.61 ± 3.88 the difference was statistically not significant (P=0.37). However, mean of number of abnormal and ruptured oocytes was significantly lower in women who succeeded to get pregnant when compared to that of women who failed to get pregnant, 1.02 ±0.51 versus 1.48 ±1.06, respectively (P=0.04). There was also no significant difference in mean germinal vesicle oocyte number between both groups, 1.18 ±1.02 versus 1.10 ±0.92, respectively (P=0.7). The difference in mean MI and MII oocyte numbers between both groups were also not significant, 1.41 ±1.34 versus 1.32±1.06 and 6.49 ±3.51 versus 6.01 ±2.38, respectively (P > 0.05). In addition, there was no significant difference in mean number of injected oocytes between pregnant and non-pregnant women, 7.22±4.43 versus 6.51±2.46 (P = 0.47).

Fertilization rate and embryo characteristics in pregnant and non-pregnant women

These characteristics were shown in Table (2). The difference in mean fertilization rate between pregnant and non-pregnant women was statistically not significant, 74.01 ± 21.38 versus 68.91 ± 15.67, respectively (p=0.2). In addition, there was significant difference in mean number of grade I and II embryos between pregnant and non-pregnant groups, 3.87 ± 1.03 versus 2.01 ± 1.09, respectively (P= <0.001). Moreover, there was significant difference in mean number of grade III and IV embryos between pregnant and non-pregnant groups, 0.85 ± 0.61 versus 1.92 ± 0.89, respectively (P= <0.001).

The area under curve (AUC) of serum levels of CoQ10 for expectation of pregnancy was (0.80) (p = 0.002, 95% confidence interval 0.63–0.91). A threshold of 0.27 of CoQ10 had a sensitivity of 80.0% and specificity of 67.0 %, PPV was (88.0%), NPV (45%) and accuracy was (74%). ROC curve of CoQ10 for pregnancy prediction is shown in Fig. 2.
Fig 2: ROC curve for serum Coenzyme Q10 for prediction of pregnancy (AUC=0.8).

Discussion

As we show in the current study, there was no significant difference in the mean dose of gonadotropin and duration of stimulation between pregnant or non-pregnant, which is in agreement with many other previous studies and these findings confirm the findings of other studies. (10-12)

However, it is not agreed with other studies that mentioned prolonged duration of gonadotropin stimulation is an independent negative predictor of ART success and obese women with BMI >30 kg/m2 required a higher dose of gonadotropin for stimulation and they face a lower likelihood of pregnancy after ICSI. (13,14)

As for oocytes characteristics in pregnant and non-pregnant ladies in the present study we found that there is a significant association were found between mean of number of abnormal and ruptured oocytes was in women who failed to get pregnant when compared to that of women who succeed to get pregnant. This is similar to the results were obtained by several other studies. (15, 16). But it is in contrast to another studies showed that the dark zona pellucida (DZP) does not affect the fertilization, embryo quality, or pregnancy rate. (17, 18)

In the present study, we found that there is significant difference in mean number of grade I and II embryos between pregnant and non-pregnant groups. Moreover, there was significant difference in mean number of grade III and IV embryos between pregnant and non-pregnant groups. which is similar to that found in may previous studies that have found better quality embryo and the number of embryos were statistically significant predictors of clinical pregnancy. (19,20)

The current study shows that the mean level of Coenzyme Q 10 in pregnant women was significantly increase than that in non-pregnant women. Turi A, et al, 2012 found that Protein levels of CoQ10/ concluded significantly in mature versus dysmorphic oocytes. Similarly, CoQ10/Cholesterol was significantly increase in grading I–II against grading III–IV embryos. (21) And total levels of CoQ10 were higher in follicular fluids related with mature oocyte and high-grade embryos, telling a possible correlation to the mechanisms of control and growth in follicular ambient. As reported in experimental in vitro cultures of myocardial cells, the CoQ10 stimulated the formation of ATP that in reproductive biology could accelerate formation of the blastocoeles cavity and consequently the hatching process (22, 23), second the existence of CoQ10 may precise ionic imbalance that happens in cultures of embryos. (24)

Gianmubilo SR et al, 2018 concluded that CoQ10 of oral supplementation might improve follicular fluid oxidative metabolism and oocyte quality, especially in over 35-year-old women. (25)

Conclusion

Significant decrease of Co Q10 between in Grade III and IV than that in Grade I and II, CoQ10 total were increased in pregnant women than non-pregnant

Abstract

Background: Vascular endothelial growth factor (VEGF) have a vital role in the molecular genetic events of angiogenesis and vasculogenesis, so it is involved in the development of cancer. Single nucleotide polymorphisms (SNP) in VEGF gene has been announced as a risk factor in colorectal cancer. Bevacizumab (BEV) is an angiogenesis inhibitor that curb the binding of VEGF to its receptors obstructing the angiogenesis process. Objective: The ideal goal of ongoing study lies in revealing the effect of rs699947 (-2578 C/A) and rs833061 (-460C/T) polymorphisms in the promoter of VEGF gene on the development of colorectal cancer and on the BEV responsiveness in a sample of Iraqi patients using High Resolution Melting Analysis (HRM) analysis. Methodology: Venous blood samples were collected from 25 colorectal cancer patients with response to BEV treatment and 25 with BEV resistant and 25 apparently healthy individuals as control group who matched with patients in age and gender. Results: AA and CA polymorphisms A allele of rs699947 (-2578 C/A) and TT and CT polymorphisms and T allele of rs833061 (-460C/T) were represent a risk factor on the occurrence of the colorectal cancer. It has been found that CC and CA polymorphism of the VEGF - 2578 C/A and CT genotype of the VEGF -460 C/T polymorphism might be a predictive factors of responsiveness to BEV chemotherapy in CRC patients. Conclusion: These outcomes confirm the essential role that VEGF polymorphisms play in the occurrence of CRC and the correlation between SNPs in VEGF promoter region and the BEV responsiveness. With this, further research and investigation of VEGF polymorphisms could allow for its use in identifying risk factors for the development of CRC and increasing its predictive value for anti-VEGF cancer therapies.

Key word: VEGF Gene, Polymorphisms, BEV Therapeutic, Colorectal Cancers, HRM – PCR.

Introduction

Angiogenesis, the growth of new blood vessels from preexisting vessels, is an important process in physiological conditions, such as wound healing and tissue regeneration, or pathological conditions, such as heart disease and tumor formation. Vascular tumor generation (angiogenesis) is an essential process play an important role in the occurrence of tumor and metastases. It is controlled by the complex and coordinated procedures of pro-angiogenic factors and their receptors that become upregulated during tumor formation. Cancer cells are characterized by their ability to secrete many defective growth factors that contribute to stimulating the formation of neoplastic vessels. Among them, the VEGF represents one of the major powerful endothelial cell generators, and one of the most important triggers for vascular formation in CRC. Vascular endothelial growth factor (VEGF) is a signaling protein that contributes to the growth of new blood vessels. VEGF plays an important role in the process of blood flow to cells and tissues when there is hypoxemia caused by poor blood circulation. Thus, VEGF have an intrinsic role in both vasculogenesis and the formation of tumor blood vessels. On the other hand, inhibiting the process of formation of neoplastic hemangiomas contributes to reducing tumor formation.
One of the angiogenesis inhibitors is Bevacizumab (BEV), which represents a humanized antibody that is used to target the VEGF gene. For this treatment is used with many types of cancer, including colorectal cancer. Many single-nucleotide polymorphisms (SNPs) were demonstrated to regulate VEGF expression. Of that, rs833061 and rs699947 are two substantial SNPs located in the VEGF promoter gene, which might affect on promoter activity.

Methods

This study was carried out on a total of 75 subjects included 50 Iraqi patients with colorectal cancer who attended Alamal National Hospital and Oncology Teaching Hospital Baghdad during the period extended from the first of November /2019 to the end of January/2020, with age ranged from 25-86, and 25 apparently healthy voluntaries matched the patients group with age and gender.

Samples collection

Amount of three ml of venous blood was withdrawn from each subject under aseptic conditions after informing them about the aim of the research and filling in the questionnaire forms by them. Two ml of blood was placed in EDTA tube (1.5 mg/ml) and kept at -20 C° to be used in molecular study.

Genomic DNA was automatedly extracted from the whole blood samples of all subjects by using Blood DNA Extraction Kit 200 (MagPurix/Taiwan). The MagPurix technology is a state of the art platform that uses magnetic beads to extract nucleic acids from samples. The platform commits a truly walk-away automation in nucleic acid purification from samples to results. The purification process contains steps of lysis, binding, washing and elution. After genomic DNA was extracted, agarose gel electrophoresis was adopted to confirm the presence and integrity of the extracted DNA.

The qRT-PCR-HRM assay with specific primers (Alpha DNA / Montreal , Canada) designed with the Prime 3 software as shown in Table 1, was used to identify SNPs rs833061 (- 460 C / T) and rs699947 (- 2578 C / A) in the promoter region of the VEGF gene to investigate effects of VEGF polymorphism on CRC occurrence and the clinical response to BEV of CRC patients, using a specific primers and positive and negative controls that ensures a high degree of specificity. The program of HRM assay shown in table 2.

Result and Discussion

In order to estimate the effects of SNPs of VEGFA gene on response to BEV therapeutic in Iraqi colorectal cancer, results of rs699947 and rs833061 SNPs were compared. The findings of this study presented that AA and CA genotypes, and A allele of VEGF rs699947 were significantly increased the risk of colorectal cancer in patients group rather than control group (O.R. = 1.766; p = 0.0001). While, CC polymorphism and C allele was elevated in control group significantly (P≤0.01) when compared with patients group, considering a protective factor for them (table 3). This result is consistent with what has been reached by Jannuzzi et al. (2015), who found that −2578A>C was altogether connected with CRC chance.

When comparing the group of patients who are response to treatment of BEV with those who were resist to this treatment, it has been found that CC and CA polymorphism of the VEGF - 2578 C/A was highly significant associated with BEV responsiveness (O.R =1.307; p= 0.0006) and C allele frequency (0.52) was significantly higher in response group, pointing to the BEV response marker in CRC patients was CC and CA genotype and C allele (table 4). This is completely consistent with the research findings of Wang et al. (2015), as he showed that CC genotype has a close relationship of the therapeutic response to BEV treatment.

An opposite results was obtained in rs833061 SNP analysis, that TT and CT genotypes increase in patients group than in control group (O.R. = 1.397; P=0.0001) and T allele was significantly higher in patients group, indicating that TT and CT genotypes and T allele were a risk marker for the occurrence of CRC, while, CC genotype and C allele was significant higher in control group to be a protective factor for them (O.R.=1.754; P = 0.0001) as illustrated in table 5. Whereas, Jannuzzi et al. (2015) pointed that the distribution of -460 C> T between patients and controls did not differ significantly.

In other hand, CT genotype of the VEGF -460 C/T polymorphism might be predictive factors of responsiveness to BEV chemotherapy in CRC patients (1.703, p= 0.0001) as shown in table 6. In addition, C allele was significantly (P= 0.015) associated with BEV responsiveness. This is in line with the Wang et al. (2015) conclusion in identifying CT genotype as a therapeutic response factor to the BEV treatment.

Blood vessels are important for tumores to get its nutrition and oxygen to be developed and grow. A major mediator of angiogenesis in cancer is VEGF, it has the powerful action to boost the angiogenesis. BEV targeted VEGF, enervate or blocks the interaction between VEGF and its receptor, In doing so, it would be discourage endothelial cell proliferation, ending in knock down the angiogenesis in tumorigenesis. Finally, suppression of angiogenesis could prohibit the growth of...
tumors and enhance the therapeutic efficiency. 14

Since CRC is one of the most malignant cancers in the large intestine, it has the highest incidence and mortality. 15

The therapeutic efficacy of the response to BEV therapy is divers in patients who receiving the same BEV therapy. This event may be determined by the individual genetic variation. According to reports published, single nucleotide polymorphisms in VEGFA gene plays a crucial role in the development of tumors and cancer, of them CRC. The therapeutic competence of BEV may influenced by the SNPs in VEGF gene. 16

The most two vastly investigated SNPs in the promoter region of VEGFA gene are rs833061 (−460C>T) and rs699947 (−2578C>A). Examinations specify that these SNPs could influence the promoter activity of the VEGFA gene, and afterward change the VEGF expression.

**Conclusion**

As a goal of BEV treatment, abnormal VAGFA accumulate may lead to angiogenesis, leading to therapeutic disappointments. Although VEGF has been targeted by BEV, the polymorphisms at the promoter region of VAGFA gene may cause accumulation of its product and lead to angiogenesis and subsequently may fundamentally impact the helpful adequacy of BEV chemotherapy. 17,18

Abstract

\textbf{Aim:} To develop a reference manual for the management of drug overdose and poisoning.

\textbf{Methods:} A prospective developmental study was performed for a span of six months at a tertiary care hospital in Erode. Information on the management of cases of drug overdose and poisoning was provided based on queries received at the Drug Information Center and the poisoning cases identified in the respective hospital over the past three years. Further attention was paid to detecting local poisons. Such information was collected on the basis of literature reviews, magazines and newspapers. In addition to drug and poison monographs; android applications, toxicological databases and links, standard reference books and articles on drug overdose and poisoning were included. Locally reported cases have been given more focus.

\textbf{Results:} A formulary was prepared which includes the management information for 100 drugs and 57 toxic substances that were identified after extensive research. The signs and symptoms of the various poisoning cases were graded as mild, moderate and severe based on poison severity scale (PSS) and respective antidotes were mentioned.

\textbf{Conclusion:} As per our knowledge, this is the first formulary that focus on local poisons. The implementation of the formulary may have a significant impact on healthcare professionals to improve the quality of life of patients. This provides important information of localized poisoning and drug overdose in a nutshell and therefore offers as a quick data to the enquirer.

\textbf{Key words:} Drug overdose, Formulary, Monograph, Poisoning

Introduction

Poisoning and drug overdose are important health problems in developing countries.\textsuperscript{1} The WHO reports annually that 0.3 million people are killed by specific poisoning agents. Acute pesticide poisoning is one of the most common causes of intentional death worldwide.\textsuperscript{2} High doses of analgesics, tranquilizers and antidepressants are widely used for intentional poisoning in industrialized countries and agricultural pesticides are used in Asia for self-poisoning, especially in rural areas with a fatality range of 10-20 percent.\textsuperscript{3,4}

Almost a million people die each year as a result of suicide, and chemicals account for a significant number of these deaths. An estimated 370,000 deaths each year are caused by deliberate ingestion of pesticides.\textsuperscript{5} On average, because of an accidental drug overdose, India loses at least two people every day. According to the latest data released by the Ministry of Health and Family Welfare, in three years from January 2014 to January 2016, 2381 people died from drug overdose, with 5 states responsible for 53% of all cases. Tamil Nadu peaks at 20%, followed by Punjab with 15%.

In India, especially in southern India, the incidence of drug overdose poisoning, organophosphates, and plant poisoning is growing. Tamil Nadu is topping deaths because of a drug overdose, according to the National Crime Records Bureau.\textsuperscript{6,7}
To save the patient’s life, providing timely information about poison and drug toxicity is very important. Poison information centers are a ready source of help in handling poisoning cases as they can provide reliable first aid information and guidance and emergencies related to chemical exposure. For developing nations, the number of poison and drug information centers is limited relative to developed nations. The number of poison centers that operate 24x7 for our country, particularly in southern India, is very minimal. In addition to the poison information centers, hospital formularies play an important role in the management of drug overdose and poisoning.

In developed nations, hospitals have own formularies that include local and regional poison management information. A hospital formulary on the treatment for drug overdose and poisoning is very limited in our region. In order to provide reliable and timely information, a quick reference manual is essential. Hence the objective of the study was to prepare a quick reference manual for drug overdose and poisoning treatment in the tertiary care hospital. As per our knowledge, this is the first poison management formulary in our region.

**Materials and Methods**

A prospective developmental study was performed for a span of six months at a tertiary care hospital in Erode. The endorsement of the study was obtained from the institutional ethics committee (JKNCP/ETHICS PRACTICE/019PDS07). Information regarding the management of drug overdose and management of poison cases were included based on queries received at the Drug Information and the poisoning cases reported at the respective hospital over the past three years. More attention has been paid to the detection of local poisons. Such information was collected on the basis of literature reviews, magazines and newspapers. Locally reported cases have been given more focus.

Monograph on all drugs and poisons in the formulary were prepared from primary, secondary and tertiary drug information resources. In addition to drug and poison monographs; android applications, toxicological databases and links, standard reference books and articles on drug overdose and poisoning were included. Depending on the ratings and reviews in the play store, android applications were selected.

**Results and Discussion**

Nearly 13 drug overdose and poisoning queries were collected from Drug Information Centre (DIC), out of which 2 were herbal related, 5 drugs and 2 insecticides queries as shown in Table 1. In addition, an extensive literature search was performed and categorized to local, South Indian and Indian poisons and it was found that in South India during a period of 2013-2018, there were 8 categories of herbal poisoning followed by 7 drugs and 4 insecticides queries. And in India during a period of 2013-2017, there were 25 categories of drug poisoning followed by 8 herbal, 6 others and 4 insecticides. Simultaneously, drug details of all the drugs that were available in the hospital were collected to suggest an antidote, in case of overdose. Along with this poison information scale or poison severity scale, a list of toxicological databases and links, lists of standard reference books regarding poisoning and toxicity monitoring, lists of android applications regarding poisoning and drug overdose, Journals regarding primary poison information and Poison Information Centers in India were included in the formulary.

Monograph content: While considering the Drug section, the particular drug comprises the following details: Name, Functional Class, Mechanism of Action, Uses, Unlabeled Uses, Contraindications, Precautions, Dosage and Routes, Adverse Effects, Signs and Symptoms of Toxicity and Treatment overview. The Monograph of the particular poison contains the following details: Name, Synonym, Description, Clinical effects, Treatment overview. Signs and symptoms of toxicity are classified into mild, moderate and severe by using Poison Severity Scale (PSS).

Poison Information Scale or Poison severity scale: A standardized poison rating scale allows for qualitative assessment of morbidity caused by poisoning, better detection of real risks and comparability of results. The PSS has been published externally. PSS helps in the initial diagnosis and assessment of drug overdose and poisoning.

Toxicological Databases and Links: For further references, toxicological databases and their respective links are provided for easy access to detailed information.

Journals Regarding Poison Information: 19 international poison information standard journals issued by different medical associations are included.

Standard Reference books regarding poisoning and toxicity monitoring: Details of Standard reference books on Toxicology, Pediatric toxicology diagnosis and management, Poisoning and drug overdose, Pharmacopoeias, Formularies, Manuals of toxicologic emergencies are included.

Android Applications: Easily access able android applications detailing poisoning and drug overdose are included in the formulary. These applications were selected based on the user’s reviews and ratings. These applications are innovative, online triage tools and guide users faced with poison emergency through a series of simple questions to denote the toxicity provides a quick guide on poisoning and antidotes.

Poisoning is reported to be a major global public health issue. A developed country may have its own information services for its unique needs, but the Poison Information Center where it exists may be the only source of information accessible 24 hours a day on toxic chemicals in a developing country. The reality that there are fewer poison knowledge centers in India is appalling to notice. Due to the lack of information on poisoning cases in India, the introduction of new guidelines and the updating of existing protocols requires knowledge.
of demographics and the management of poisoning cases. It is necessary to understand the interventions needed in the management of poisoning and to define the role of health professional studies. Knowledge of the general pattern of poisoning in a particular region can help reduce mortality and morbidity rates in the early diagnosis and treatment of cases.

Conclusion

Drug overdose and poisoning is a serious problem that arises whether deliberately or accidentally. An overdose can be mild, moderate, or extreme. Symptoms, treatment, and recovery depend on the specific drug involved. Medical professionals are implementing new approaches for diagnosis and treatment due to the alarming rate of a drug overdose and poisoning, especially in developing countries. The introduction of new guidelines and the updating of existing protocols requires knowledge of demographics and the management of poisoning cases due to the lack of information on poisoning cases in India. The strategies needed to manage to poison need to be identified and the role of health professional studies established. This formulary provides the important details of localized poisoning and drug overdose into a nutshell which is easy to access and thereby provides the enquirer with quick information. The formulary is handyuser-friendly, and saves the precious time of busy physicians. It may also promote the safe and effective use of medicines thereby minimizing drug-related problems in the population.

Abstract

Background and aim: Hyperbilirubinemia is an elevation of the bilirubin levels in blood of newborn babies that presented as jaundice. This study aimed to evaluate the levels of important of immunological system proteins (IgG, IgM, IgA, C3 and C4) in both newborn babies with severe hyperbilirubinemia and healthy controls.

Methods: Thirty (30) full-term neonates with severe hyperbilirubinemia (serum bilirubin >20 mg/dl) and twenty five (25) healthy control full-term neonates were included in the study. Blood samples taken and Hb, total serum bilirubin, total protein measured immediately by spectrophotometer. IgG, IgM, IgA, C3 and C4 measured by immune-nephelometric method.

Results: In hyperbilirubinemia group (Male/ Female percentages) were (63% / 37%), (IgG 373.4±218 mg/dl), (IgM 20.5 ± 24.03 mg/dl), and (C3 209.4±17.81 mg/dl) values were significantly lower than control group ( 588.2±298.5 mg/dl IgG, 26.44 ± 2.92 mg/dl IgM and 627.5±221.1 mg/dl for C3). Correlation analysis revealed that in control group IgG, IgM, and C3 shown to be significantly (P value <0.05) and positively correlated (r-value >3) with both age and weight.

Conclusions: jaundice is a risk factor for sepsis that could be due to lower levels of immunoglobulins and complements components. The normal development of immune system that observed with increasing age and weight was impaired in patients with neonatal hyperbilirubinemia.

Key words: Neonatal hyperbilirubinemia, Complement components, Immunoglobulins and Total serum bilirubin.

Introduction

Hyperbilirubinemia is one of the commonest clinical conditions in newborn babies that presented as jaundice (1). It affects both full-term and premature neonates in about 60% and 80% respectively (2, 3). However, most of the cases are physiological jaundice that is a safe and do not involve any clinical complications, but excessive elevation of unconjugated bilirubin has a potential development of neurotoxicity and kernicterus. A variable risk factors have been proposed for neonatal hyperbilirubinemia that includes; genetic, maternal, prenatal, neonatal and other factors (4).

Physiologically, bilirubin is produced and elevated in neonatal life as a results of excessive distraction of fetal red blood cells (5). These resultant molecules are not merely bi products of a heam metabolism rather than its potential cytoprotective role and has an antioxidant activity such as that observed of serum uric acid (6, 7). Newborn baby is continuously produced free radicals even in the absence of any pathology , during this period the body is at great vulnerability of oxidative stress (8). Indeed, at this period different body antioxidant mechanisms are not fully matured and thus bilirubin at
physiological level is suggested as a defense mechanism against the harmfully generated reactive oxygen species (9). The other side it showed that exceeding limited level of bilirubin in neonatal period has an adverse effect on baby defense mechanisms. Studies had shown that a strong associations were observed between hyperbilirubinemia and risk of infection and septicemia (10, 11). Furthermore, accumulative evidences have demonstrated that, severe hyperbilirubinemia was associated with modulation of different components of immune response. Haga, Tempero (12) showed that intracellular bilirubin precipitation causes an inhibitory effect on T helper-1 cell and their inflammatory response. Neonates with hyperbilirubinemia showed an impairment of immunological response (decrease immunoglobulins production) to routine vaccination series against measles, diphtheria and tetanus (13). Neonates with hyperbilirubinemia showed a reduced Lymphocytes proliferation (14).

Both adaptive and innate immune responses are still immature during neonatal period (15). B lymphocytes, the origin of immunoglobulins, produced in late 1st trimester in fetal life but remain unable to produce antibodies or immunoglobulin class switching during early neonatal periods (16). Indeed, active IgG production starts around the third month of life but during neonatal period serum IgG represents maternal IgG transported via placenta to fetal blood. IgA in neonatal serum supplied via early breast feeding (17). Furthermore, studies observed that the components of complement system are under-developed in newborns as well (18).

Hyperbilirubinemia causes reduction of antibodies production, total, IgM and IgA levels (14). In addition, a strong inverse association was observed between elevated serum bilirubin and the development and maturation of complement cascade (19).

This study was set to evaluate the influence of severe hyperbilirubinemia in neonates, regardless its cause, on immunological markers represented by IgG, IgA, IgM and complement components C3 and C4.

**Patients and Methods**

The current cross-sectional study approved and conducted in Chemistry and Biochemistry Department/College of Medicine / Mustansiriyah University in 2019-2020. Thirty(30) full-term neonates were selected as cases with severe hyperbilirubinemia (serum bilirubin >20 mg/dl) in neonatal word during their preparation for phototherapy or exchange transfusion in the Central Child Teaching Hospital in Baghdad over the period from April - November 2019. Twenty-five (25) healthy control full-term neonates been chosen from an outpatient clinic of the same hospital for any presentation and shown not have jaundice as confirmed by total serum bilirubin (TSB) measures. For both groups, age, sex, gestational age and mother age recorded and body weight measured. Five (5 ml) of venous blood were with drowning of each individual and allowed to clot, or with drowning in heparin tubes or EDTA tubes. Hb, total serum bilirubin (TSB) and total serum protein measured immediately. Serum and plasma were stored at -20°C or tested immediately after collection and separation for total immunoglobulin (IgG, IgM, IgA, C3 and C4) measurements.

IgG, IgM, IgA and complement components C3 and C4 measurements:

Immunoglobulins and complement C3 and C4 measurements performed using nephelometric method; the device used for the assay was Beckman IMMAGE® Immunochemistry Systems using provided commercially available kits by Beckman Coulte, USA. The test performed according to the manufacturer’s protocol under controlled laboratory conditions. Note; no interference was observed between serum bilirubin and parameters measured.

Statistical Analysis

Analysis of data carried out using the available statistical package of Graph Pad Prism (California) software. Data were presented in simple measures of frequency, percentage, mean, standard deviation, and range (minimum-maximum values). The significance of difference of different means (quantitative data) was tested using Students-t-test for difference between two independent means or ANOVA test for difference among more than two independent means. The significance of difference of different percentages (qualitative data) was tested using Pearson Chi-square test ($\chi^2$-test). Statistical significance was considered whenever the P value was equal or less than 0.05.
Results

Hyperbilirubinemia affects male (63%) baby more than female (37%). The mean age jaundiced baby was (4.07±1.31) days and their TSB was (23.63±2.30 mg/dl) while (0.9± 0.24 md/dl) in control group, as shown in (Table 1). The mean levels of IgG in control group (588.2±298.5 mg/dl) was significantly higher (P value <0.01) than that found in hyperbilirubinemic babies (373.4±218 mg/dl), the rest of immunoglobulins and complement proteins results were showed in (Table 2) and (Figure 1). IgG, IgM, and C3 shown to be significantly (P value <0.05) and positively correlated (r-value > 3) with both age and weight of healthy control neonates as shown in (Figures, 2 and 3) where graphs representative of correlation analysis of neonatal age and weight with IgG, IgM and C3 in both controls and hyperbilirubinemic group.

Figure 1: Immunoglobulins and complement C3 and C4 for study subjects.
Figure 2: Graph representative of correlation analysis of neonatal age in days with IgG, IgM and C3 in both control and hyperbilirubinemic groups.
Discussion

This study aimed to compare the levels of immunoglobulins and complement components C3 and C4 in neonates with severe jaundice, regardless its cause, with aged matched healthy controls.

The main findings of this study were predicted that; in hyperbilirubinemia group, there were lower body weight and lower total protein level when compared to controls. In addition, low levels of IgG, C3 and C4, while high IgA levels were found in jaundiced neonates compared to controls. No significant differences were demonstrated of level of IgM between the two groups. Furthermore, the strong positive correlation that observed in control group between body weight and age with each of IgG, IgM and C3 was disturbed in babies with hyperbilirubinemia.

Hyperbilirubinemia in newborn babies is usually due to elevation of unconjugated (indirect) bilirubin that accrued as results of increased bilirubin production over conjugation and hepatic clearance of bilirubin (20). The clinical classification of significant hyperbilirubinemia could categorize according to bilirubin level as;
Significant hyperbilirubinemia (TSB ≥12) mg/dL, Severe hyperbilirubinemia (TSB ≥20) mg/dL. Extreme hyperbilirubinemia typically (TSB ≥25) mg/dL and hazardous or critical hyperbilirubinemia (TSB ≥30) mg/dL (1). In the current study the hyperbilirubinaemic neonates group was either severe or extreme class, TSB (23.63±2.30) mg/dl, the range of TSB readings was (20-29) mg/dl, those admitted to neonatal word for either phototherapy or exchange transfusion treatment.

Results of the current study showed that, neonatal hyperbilirubinemia affects male more than female, more than 60% of hyperbilirubin group were male and they tend to have higher serum bilirubin level (24.1±2.4) mg/dl than female (22.8±2.0) mg/dl however this was statistically not significant. These results come in agreements with many studies including, Al-Banna, Riad (21) and Greco, Arnolda (22). The exact causes for this gender differences are unknown but different mechanisms been suggested. Tioseco, Aly (23) attributes the sex difference due to that dysfunction of placenta, which is more common during pregnancy in male fetus which could contribute to higher risk of early life jaundice. Furthermore, during fetal life, male fetus has higher metabolic rate than female which could contribute to the elevated turnover of bilirubin in male newborn baby (24).

Both Immunoglobulins and complements components are proteins that were detected in the plasma and body fluids and the play a significant role in protection from infections. and the knowledge of these components of immune system in neonates is vital in detection of immunological as well as infectious disease (25).

In control group, the level of IgG and IgM were comparable with study conducted by Kardar, Oraei (26). They found that mean IgG was (507.6 mg/dl, IgM 26 mg/dl, IgA 5.6 mg/dl, C3 690 and C4 was 167 mg/dl), which was so close to present results. The current study values were (588.2±298.5 mg/dl for IgG, 26.44 ± 2.92 mg/dl for IgM, IgA was 6.5±5.5 mg/dl, C3 627.5±221.1 mg/dl and C4 186±71 mg/dl). Another important study conducted in Turkey published in 2015 by Alkan Ozdemir, Ozer (27) also confirmed what this study found. Their finding regarding IgG, IgM and their correlation with body weight and gestational age. IgG was 791.5±234.9 mg/dl and IgM 10.6±6.7 mg/dl that seem to be slightly higher to the findings of our study. Strong positive correlation observed between body weight and age with these parameters. The correlation measures of the current study was similar and found that IgG, IgM and C3 protein level were strongly and positively correlated with age and weight with P value <0.05.

To our knowledge, this is the first study conducted in Iraq comparing immunoglobulins and complement factors in hyperbilirubinaemic neonates. No recent published data for the last ten years world widely covered this subject even thorough exploration to the scientific database.

Low level of serum Bilirubin in early fetal life has a strong beneficial effect and it acts as antioxidant, but evolving evidences have observed that at severe hyperbilirubinemia could act as risk factors for disease and injury (28, 29). Furthermore, Old observation documented in Větvička, Šíma (30) and Jangi, Otterbein (14) showed that low levels of immunoglobulins and complement components were observed in neonates and adults with hyperbilirubinemia and affects their immunological status. The results of present study come in accordance with these findings. An attractive finding of the current study, the positive correlation that observed between age and weight of normal neonates with immune protein factors been lost in high bilirubin level group.

In conclusion, neonatal hyperbilirubinemia associated with an increasing risk of infection and injury that could be due to lower levels of immunoglobulins and complements components in affected neonates. Additionally, the elevation of immune related proteins with age and body weight of jaundiced baby was disturbed.

Aetiology and Findings of Recurrent Chronic Rhino Sinusitis with Nasal Polyposis after Functional Endoscopic Sinus Surgery

Ali Aziz Abed¹, Ragheed Turky Miteab², Ali Majid²

¹Surgeon (F.I.C.M.S), Division of Otolaryngology, Department of Surgery, Al-Karama Teaching Hospital, Al-Karkh Health Department, Baghdad-Iraq. ²Surgeon (F.I.C.M.S), Division of Otolaryngology, Department of Surgery, Martyr Ghazi Al-Hariri Hospital for surgical specialties, Medical City, Baghdad-Iraq.

Abstract

Background: Nasal polyps are the edematous sinonasal mucosa prolapsing into the nasal cavity. Allergy, asthma, aspirin intolerance and fungal rhinosinusitis have been implicated in various studies. Recurrence of nasal polyposis after functional endoscopic sinus surgery is prevalent but there are no specific causes for recurrence. Intensity of relapse varies depending on multiple factors that implicated in showing characters and findings of the recurrence.

Objective: To evaluate causes of nasal polyposis recurrence after FESS.

Patients and method: 30 adult patients age between 18 and 60 years (with recurrent nasal polyposis after FESS) were studied in the period between March 2017 and September 2018. Assessment done for all patients by taking Medical history, documented data from the primary surgery, rhinoscopy with CT-scan examination.

Results: In this study, most of nasal polyp recurrence occur in 1-3 years after primary surgery, patients using post-operative steroid showed delay in recurrence, post-operative antibiotic showed no effect on time of recurrence, patients with (asthma, allergy, aspirin sensitivity and allergic fungal rhinosinusitis) showed high Lund-kennedy and Lund-mackay scores and some patients had anatomical findings mainly (40% incomplete anterior ethoidectomy).

Conclusions: Recurrence of nasal polyposis could occur at any age mainly in middle age group and male gender showed higher prevalence. Asthma, aspirin sensitivity (Samter’s tried) and allergic fungal sinusitis were the most important associated diseases. CT-scan showed some anatomical variations like incomplete anterior and posterior ethmoidectomy which occupying the highest percentages. Post-operative steroid showed delay in time of recurrence.

Keywords: nasal polyp recurrence, functional endoscopic sinus surgery, nasal polyp associated with asthma, aspirin sensitivity and allergic fungal rhino sinusitis.

Introduction

Nasal polyps are edematous grapelike protrusions most often originating in the upper part of the nose around the osteomeatal complex on the lateral wall. The surface epithelium tends to be smooth and consists of pale translucent tissue which distinguishes them from the more vascular mucosa of the nasal cavity.

Polyps can vary widely in size and should be considered a bilateral condition. Rare cases of unilateral polyps should only be diagnosed once all other more likely pathologies have been reliably excluded (1)

Surgical management is considered for patients who have failed to respond to maximal medical treatment and for those with complications. Functional endoscopic sinus surgery (FESS) aims to improve sinus ventilation
and drainage as well as removing polyps

Embryology of the nose and PNS

Developmentally nose and paranasal sinuses are interlinked. They are always considered together developmentally. The various sinuses may follow different calendars but their origin is the same.

Nose and paranasal sinuses always considered together developmentally

Relevant anatomy

Nasal endoscopy of patients with nasal polyposis and anatomic examination of specimens have shown that nasal polyps are situated in the middle meatus and that they originate from the mucousa of paranasal sinuses outlets. This area, so critical for sinus pathology, and referred to as the ostiomeatal complex.

Nasal polyposis

Nasal polyps are the oedematous sino-nasal mucosa protruding into the nasal cavity. Simple nasal polyps are part of the spectrum of chronic rhinosinusitis and are formed by the sino-nasal lining becoming progressively more inflamed and thicker and then pedunculating into the nasal cavity.

Site of polyp formation:

Polyps usually arise from the lateral nasal wall in the middle meatus or sphenoid recess. Those polyps that originate lateral to the middle turbinate usually take their origin from the frontal, anterior ethmoid, or maxillary sinuses. Polyps medial to the middle turbinate are usually arising from the posterior ethmoid or sphenoid sinuses. In rare cases, polyps may originate on the nasal septum or from the olfactory cleft.

Diagnosis and staging

Rhinoscopy

Large polyps can be identified by simple anterior rhinoscopy. In contrast to a hyperplastic turbinate, a polyp can be made to move by touching with a probe, mainly senseless and not bleed in touch. Endoscopic examination with a rigid scope is the preferred examination, as it can diagnose even small polyps in the middle meatus and give a good assessment of the extent of the disease and of anatomical abnormalities.

Endoscopy is useful, not only for the diagnosis, but also for follow-up examination after medical and surgical treatment, and for staging of the disease.

Imaging

CT scan of the nose and paranasal sinuses gives a demonstration of the anatomy and even pathology. It is indicated when there is a suspicion of malignancy or meningocele, and also in all cases before endoscopic surgery. In addition, it is used for staging of the disease.

TREATMENT

Intranasal and systemic steroids are the most common treatments for the management of nasal polyps. Endoscopic surgery is reserved for severe nasal obstruction resistant to maximal medical therapy. Nasal polyps tend to be more severe and refractory to medical and surgical treatment, especially in the subset of aspirin-sensitive asthmatics.

Endoscopic polypectomy

For large nasal polyps or patients that fail medical treatment, endoscopic polypectomy with the microdebrider is performed.

Nasal polyposis recurrence

The recurrence of NP after the sinonasal surgery is prevalent but the frequency and intensity of relapse vary based on multiple factors: Medical factors, environmental factor like smoking and iatrogenic factors.
Fig. (1): (A) coronal CT scan of patient with Samter’s triad showing recurrence of polyps after FESS (7) (B) Sagittal CT scan of polyps recurrence (7)

Patients and Methods

All 30 patients in this study had previously undergone bilateral primary FESS procedure for CRSwNP. Independent variables which were assessed included patients name, age, gender, history of nasal obstruction, purulent nasal discharge, post nasal drip, facial pain, anosmia, headache, History of asthma and aspirin sensitivity and allergic fungal sinusitis.

Patients information were collected from outpatient, inpatient notes and primary FESS reports.

Nasal endoscopy using 0,70 degree Hopkins rod nasal endoscope for assessment of the nasal polyp by using Lund and Kennedy score for presence of polyps, edema, scarring, crusting and discharge.

Each side was graded separately, and the scores for each side were collected to determine the overall endoscopy score.

Fig. (2): Endoscopic examination of Rt. Nasal cavity by 0° endoscope.

Prior to revision surgery, prescription of maximal medical therapy for each patient included:

Ø Systemic oral steroid (0.5 mg/kg/d) for 5-10 days in case of massive polyposis.

Ø Local corticosteroid (budesonide) spray.

Ø Antihistamines for patients with history of allergy.
Ø Macrolide antibiotics (azithromycin tab. 500 mg. once daily for 3 days).

Ø Saline irrigations.

Medical treatment was given for 3-6 weeks before undergoing a preoperative CT scan and another endoscopy were done.

Revision ESS considered after one month of medical treatment failed.

All patients had preoperative computed tomography (CT) scans of the nose and paranasal sinuses (coronal, axial, and sagittal) and scoring done according to Lund McKay scoring system.

For each finding the incidence is identified in all patients included in the study.
Surgical procedure:

In reverse trendelenberg position, head elevation up to 30 degree, bilateral otrivin packs was inserted for about 10 minutes as to decrease congestion.

We used 0 degree nasal rigid endoscopes and endoscopic nasal suction tip, to remove polyps from the nasal cavity by using microdebrider and Blakesely weil cupped forceps, multiple pieces taken as biopsy.

After identification of remaining landmarks, we started removal of polyp and access all involved sinuses and remove the polyp as can as possible.

Correction of any anatomical abnormality if present like (septal deviation, middle turbinate lateralization, residual uncinate process, and other anatomical findings. then irrigation of the nasal cavity with normal saline and suction.

This follow up was done by examination of the nasal cavity endoscopically using 0, 70 degree angles, bilateral three passes nasal endoscopic examination done to identify edema, discharge, synechiae, crust and recurrence of nasal polyposis.

Result

Gender:

male to female ratio was 1.5:1.

Symptoms (chief complaint)

There were no dominant symptoms.

Asthma, aspirin sensitivity and AFRS

some patients associated with asthma, aspirin sensitivity and allergic fungal rhinosinusitis as shown in Fig.(21)

![Graph](image)

Fig.(4) patients numbers according to associated diseases.(asthma, aspirin sensitivity and AFRS).
Date of primary surgery

Our patients did the primary surgery in different times. The oldest one in 2010 and the newest one in 2016 so we divided the patients into 3 groups according to the year of primary surgery.

We found that the largest number of the patients in our study did the primary surgery in the years between 2014 and 2016, that means NP recurrence occurs mainly (1-3 years) after surgery.

Effect of post-operative steroid

We found that patients those received steroid (local or systemic) after primary surgery showed delay in polyp recurrence.

Anatomical findings

In some patients we found anatomical variations in CT scan and intra-operatively.

Incomplete anterior and post. ethmoidectomy had the largest percentage.

Discussion

Gender and age distribution

In our results male to female ratio was 1.5:1 just like what found by Manpreet Singh Nanda et al. when most patients were within the middle age group and M: F ratio of 1.6:1 (8) but not goes with Shabbir Akhtar et al. that showed the recurrences in 36 patients from 192 patients, and no association between polyp recurrence age, gender (9)

Symptoms:

In our result there were no dominant symptoms just like Studies done by Shabbir Akhtar et al. showed recurrences developed in 36 patients. No association of recurrence with sinonasal symptoms (9)

Also Adam S. DeConde et al. studied the factors may related to nasal polyp recurrence and addressed
nasal symptom among these factors and found that there was no clinical risk factors for that (10).

Asthma, aspirin sensitivity with ct-scan and endoscopic finding

Wynn et al. in study patients with severe polyposis, they found (50%) patients had asthma (11) and this goes with our results.

In the study done by Fereshteh Esmatinia and Mahdi Bakhshaei, 80% of patients with asthma who had been underwent the ESS revealed the Sino-nasal polyposis recurrence (12) And this goes with but higher than our results.

AFRS: Study done by Younis RT, Ahmed J. found that patients with polyps in AFRS had high Lund-Mackay score and had higher revision rates. This does with our result (13)

Study done by Laila M. Telmesani showed there was a significant direct relationship between the CT grading of nasal polyps and polyp recurrence in nasal polyposis with and without AFRS (14) this goes with our results.

Figen Aslan et al. found the mean Lund–MacKay CT score and the mean Lund–Kennedy endoscopic score were significantly higher in patients with AFRS (15) And this consistent with our results

Date of primary surgery and recurrence

We found that the largest number of the patients in our study did the primary surgery 1-3 years after primary surgery. (The most recent period).

In study done by DeConde AS et al. Polyp recurrence is common after ESS, and the high recurrence rate (60%-70%) occurred just post-operative up to 18 month (10) and this goes with our result. In Yaniv Eitan et al. from 148 patients underwent FESS, polyp recurrence occurred in 74 patients in the first 2 years after surgery and an additional 17 in the next 3-4 years. During the following years, the recurrence rate was lower (16) and this also goes with our result.

Pär Stjärne et al. found the recurrence occur mainly about one year after primary surgery and this result consistent with our result (17)

Effect of post-operative steroid on polyp recurrence rate

Esmatinia et al. only 46% of patients consumed beclomethasone dipropionate, revealed the NP regrowth which was lower than the 87% of patients in placebo group that revealed recurrence of NP (12)

Fandiño C. et al. they found using of intranasal corticosteroid showed significant improvement in polyp score (18)

Anatomical findings

During examination of our patient by endoscopy and using of CT scan and intraoperative we found that some patients had anatomical variations contribute in failure of primary surgery and we documented that as an incidence in bilateral assessed sides and found:Incomplete anterior ethmoidectomy in 40%, Incomplete posterior ethmoidectomy in 36%, MMA stenosis in 30 %, Middle turbinate lateralization in 22%, Residual uncinate process in 20%, Septal deviation in 17%.

Khalil et al. They found residual anterior and posterior ethmoid cells in 97% and 92% of patients, respectively (96% and 92% of sides, respectively) (19)

Ramadan et al. reported a series of 52 patients prepared for revision FESS, among these, he observed (residual uncinate) in 15% (20)

Adam S. DeConde et al. mentioned that the examination of the association between surgical extent and polyp recurrence in a previous single institution cohort study found that more extensive surgery was protective against polyp recurrence (10) and this goes with our result.

Conclusion

ü Most of nasal polyposis recurrence occurs in (1-3 years) after FESS.

ü Asthma, aspirin sensitivity (Samter’s tried) and allergic fungal sinusitis were the most important associated diseases.

ü CT-scan of patient with recurrent nasal polyposis showed some anatomical variations from the primary surgery, incomplete anterior and posterior
ethmoidectomy showed the highest percentages.

ü According to the date of primary surgery, patients who received post-operative steroid showed delay in time of recurrence unlike other patients who did not receive steroid so recurrence appeared earlier.

ü Medical treatment post-operative is mandatory by nasal wash, local steroid and close follow up to decrease the rate of recurrence.

**Recommendations**

ü Meticulous dissection during surgery and wide surgical exposure of nasal sinuses and removal of polypoidal mucosa are the most important points for successful surgical removal and decrease of polyp recurrence.

ü Post-operative regular and frequent follow-up is important to assess operative field for any infection, edema, crust and polyp recurrence.

ü We recommend use of post-operative steroid which showed to be so important to decrease the chance of nasal polyposis recurrence or even delay the recurrence.

ü Further study of large number of patients and long time is needed to show other etiological factors and possible ways to prevent or decrease polyp recurrence.

Abstract

Cancer, which is the most important health problem, develops the ability to resistant traditional medications this leads to increase efforts to develop new cancer medication protocols. In this review, the chemotherapy resistance could be due to several mechanisms. These mechanisms involve either inactivation by two important phases, phase I which involve oxidation, reduction and hydrolysis or phase II which involve conjugation wi, alteration of the target site which decrease either activation of anticancer prodrug and/or decrease its influx to cancer cells. Other mechanisms for chemotherapy resistance return to the repairing of cancer cell DNA, modulation of efflux for drug, inactivation of apoptosis, besides how the role of heterogeneity of tumor cells in drug resistance. All of these strategies obligated the oncologist to use a combination of chemotherapy medication to overcome or avoid resistances to treatments.

Keywords: cancer, resistance, inactivation, apoptosis, DNA damage

Introduction

Cancer research provides important information about its biological characteristics, this information is updated every day. As a disease, cancer is characterized by many features such as the uncontrolled proliferation of abnormal cells and dynamic changes in the genetic materials (¹). The progression of malignant cells overwhelms normal cell divisions. This overwhelming is achieved by the invasion of normal tissues nearby and metastasize to distant tissues (²). Conventional cancer treatments such as surgery for removing cancer mass, ionic radiation therapy, chemotherapy therapy, combination therapy, and laser therapy show improvement for several cases but with high tendencies for side effects, the selective therapies which depend on the other origin like genetically targeting in the tumor progression used for the promising treatments with fewer side effects (³). Chemotherapy has been using for decays with an acceptable degree of success, this success sometimes flips into a failure due to cancer cell resistance, 90% of chemotherapy treatment in advance cases of cancer disease have been failed due to this resistance. According to these facts, the resistance situation considered as a serious condition should be deal with it (⁴). The scientists reach to advance level of the invention of the new anticancer drug in which its target specific gene or interfere with RNA by forming (RNAi), these studies have been expanded (⁵).

These therapies include

1. Target kinase enzyme responsible for cell proliferation
2. Interfere with the immune system by making it more efficient against cancer cells.
3. Specializing the medications.
4. Using different techniques for targeting like drug delivery
5. Minimizing the side effects of anticancer drugs, etc (⁶).

There are different mechanisms involving in inactivation of the drug (⁷), these mechanisms include:

- Multi-drug resistance
· Inhibiting program cell death (suppression of apoptosis)
· Alteration in drug metabolism
· Epigenetic modification
· Changes in drug targets
· Enhance DNA repair
· Gene amplification that causes the resistance to the chemotherapy (Figure 1).

**Figure (1): mechanisms of anticancer resistance (7)**

**Intrinsic and Extrinsic Factors in Chemotherapy Resistance**

- Tumor Heterogeneity

Cancer cell differs from the normal cell in that cancer cell is highly proliferative cell as compared to normal cells. These dynamic conditions of cancer cells generate many heterogeneous. As a result of this heterogeneity, the response to the chemotherapy becomes varied either increase or decrease (8).

Gene instability induces a high degree of heterogeneity within cancer cells in intercellular genetic materials. miRNA, transcriptomic and proteomic heterogeneity are epigenetic factors, these factors occur due to primary genotypic variations, but may also represent different stages of the cell cycle, hierarchical cell organization, and stochastic cell alteration according to the stem cell theory of cancer (9). All of these collectively recognized alterations as intrinsic factors contribute to tumor heterogeneity while Extrinsic factors include other parameters, such as pH, hypoxia, and paracrine signaling interactions with stromal and other tumor cells (10). These factors are not constant, but products that directly and/or indirectly involved in the generation of drug resistance and poor prognosis may be reduced, modified, or increased.

**Tumor Microenvironment**

The tumor microenvironment plays a significant role in drug resistance, being the key explanation for multiple cancers’ relapse and incurability (11). Signals for tumor cell growth and survival are given by factors such as growth factor (GF), tumor cell-produced cytokines, which are called a tumor microenvironment (12).
Environment factors that mediated drug resistance (EM-DR) could be other factors involved in many soluble factors that mediated drug resistance products, these factors like vascular endothelial growth factor, basic fibroblast growth factor, stromal cell-derived factor-1 etc. (13).

Multi-Drug Resistance (MDR)

Significant problems of resistance to cancer chemotherapy due to multidrug resistance (MDR) in which the cancer cells have acquired the capacity to survive against a wide variety of anti-cancer drugs. MDR mechanism can be established by the outflow of chemotherapy drugs in addition to improvements in the absorption of drugs in these cells (14).

Increasing the release of drugs outside the cell

Drug efflux is mediated by a transporter family dependent on ATP so it’s called ATP-based transporters, this transporter involves in the transportation of several macromolecules including nutrients and other molecules across the cell membrane.

ATP-biding cassette transporters are very important transporter involve in drug resistance. ABC Family divided into three types, including

1. P-glycoprotein
2. Multi-drug Resistance-associated Protein-1

P-Glycoprotein (P-GP), the most critical form of the transporter. This transporter responsible for much medication resistance involves chemotherapy medication. Generally, its mechanism involves transfers chloride ion out of the cell. Sometimes these transporters bind to specific medication instead of chloride and move it outside the cell. If the cancer cell gains the ability to synthesis a huge amount of P-GP transporter it gains the ability of resistance toward specific types of an anticancer drug like doxorubicin, vinblastine. As a result, the cell releases the chemotherapy agent to the outside (17).

Reducing the Absorption of the drugs

Absorption of medication is a process of transfer medication from the site of administration to the bloodstream and from the bloodstream to the cells. Absorption is achieved either by simple diffusion or facilitated diffusion. If the cancer cell decreases its ability to absorb chemotherapy medication, this leads to chemotherapy resistance (18). The entry of chemotherapy into cancer cells occurs either with or against concentration gradients, the entry with concentration gradient mostly occurs with simple diffusion meanwhile the against concentration gradients is occur with active transporting (19). Another type of transporter that participates in chemotherapy resistance is called solute carrier family (SLE). Two important strategies adopted by cancer cells to gain resistance to chemotherapy, one of them either decreases the total number of this type of transporter and/or alteration in binding between anticancer drug and transporter (20, 21).

Inhibition of the Cell Death (Apoptosis Pathway Blocking)

The three critical events are regulated by programmed cell death (apoptosis). Necrosis, apoptosis or autophagy, of these cases. However, in their biological characteristics, these processes vary from each other (22). All these promote the death of the cell. Apoptosis happens, both internally and externally.
The metabolisms of chemotherapeutic agents can occur via different types of enzymes. This enzyme activity determines the concentration of the agent in both the inner and outer cells. The metabolism process achieves by specialized groups of enzymes mainly CYP-450. The metabolism process is divided into two phases first one called phase I which involves oxidation, reduction, and hydrolysis, and the second phase is called phase II which involves the conjugation of a metabolite with specific molecules such as glucuronide. Both phases plat an important role in the decrease of toxicity of many medications or loss its activity (23).

These reactions in phase I and phase II decrease the drug resistance in cancer cells by two means including

1. Reduce pro-drug activation (reducing the activity of certain enzymes)
2. Boost inactivation of the drug (increased activity of certain enzymes).

One of the essential examples in Phase I cell-managed reactions is the enzyme detoxification called cytochrome P450 (24). Resistance to chemotherapy in breast cancer occurs when cytochrome P450 activity increases, and the activation of cytochrome P450 contributes to the inactivation of docetaxel (25). Similarly, a better response to the treatment was observed along with the inhibition of the activity of this enzyme. The conjugation phase or what is commonly named phase II is achieved by the addition of especial molecules like glutathione, this phase causes an increase in the polarity of molecules and sometimes decreases its activity (26). The overproduction of glutathione and the detoxification resulting from glutathione transferases play a significant role in the resistance to many chemotherapy drugs such as alkylating agents and platinum-based anticancer drugs such as cisplatin and doxorubicin (27).

Changing the Chemotherapeutic Agents Targets

The effect of chemotherapeutic agents may have been based on modifications (modification), such as the mutations and changes in their target site’s expression levels. These types of modifications will eventually lead to drug resistance and the loss of their activity in the agent targets (28). One of the most important examples of changing the target site is the involved topoisomerase II enzyme. This enzyme is responsible for unwinding the DNA doubles helix. Topoisomerase II enzyme is targeted by doxorubicin which inhibited its activity, if cancer cells change the structure of topoisomerase II enzyme doxorubicin loss its ability to bind and inhibit enzyme activity (29).
Enhancing the DNA Repair

DNA repair was considered one of the most advanced drug-resistance mechanisms in the cancer region. The chemotherapeutic agents act to damage the cancer cells’ DNA directly or/and indirectly, so there are many pathways in these cancer cells that can repair the DNA damage. E.g. cisplatin that causes damage to DNA those results in the activation of programmed tumor cell death (apoptosis)\(^{(30)}\). Resistance to such agents occurs in cancer cells by enhancing the genetic material repair systems, such as the nucleotide excision repair system (NER) and homologous recombination repair mechanisms (RRM). Sometimes the success of chemotherapy treatment is depending on the repair system of cancer cells\(^{(31)}\). If the repair systems of cancer cell are very efficient and active and anticancer drug work by destroying its DNA structure, this lead to a loss of anticancer activity and resistance was seen\(^{(32)}\). Suppression of DNA repair systems in cancer cells may be one of the therapeutic objectives that can be accomplished in these systems by mutations and epigenetic silencing. Resistance to doxorubicin (alkylating agent) is also caused by enhancing DNA repair and alkyltransferase activity\(^{(33)}\).

Gene Amplification

Gene amplification is another drug resistance mechanism, considered to be 10% of cancer resistance, especially in leukemia. Increasing the number of target genes via the method of gene amplification induces the drug resistance as shown in leukemia while resisting methotrexate\(^{(34)}\). The cancer cells obtain chemotherapy resistance by making numerous copies of the Dihydrofolate reductase gene (which is methotrexate target enzyme). The amplification of the genes rises the copying of oncogenes per cell to several hundred folds\(^{(35)}\).

MicroRNA in Cancer Drug Resistance

MicroRNAs (miRNAs) are small nucleotide RNAs that are derived from hairpin structures with RNA. MicroRNAs are not protein synthesis code but play an important role in controlling the expression of genes. MicroRNAs regulate most protein-coding genes, including essential cancer genes, and in particular the generation of drug resistance to cancer\(^{(36)}\). There are three mechanisms involved in gene silencing with the miRNA process:

1. Breakdown of the mRNA strand into two pieces.
2. Destabilization of the mRNA through shortening of its poly (A) tail of mRNA.
3. Decrease the efficiency in the translation of the mRNA into proteins by ribosomes\(^{(37)}\).

miRNA plays an important role in all of the mechanisms of drug resistance listed above. miRNA involve in resistance mechanisms of cancer cells against chemotherapy. These mechanisms could be summarized as either enhancing sensitivity or preventing resistance toward chemotherapy\(^{(38)}\).

Conclusion

The overdose and/or unregulated antibiotic uses contribute to drug resistance against the bacteria. And the rapidly dividing cells and undergoing high mutation rates cause these bacteria’s resistant strains and thrive in the presence of such antibiotics. Human cancer cells with a high frequency of proliferation were considered genetically abnormal; hence the drug resistance may be similar. Interestingly, the studies accepted the intelligent cancer cells and cell stress tolerance of different forms. Drug tolerance to cancer is called a complex phenomenon. The combination therapy is the best option for drug resisted type of cancers.

Efficacy of Hyaluronic Acid in Patients with Osteoarthritis of The Knee

Ali Hasanain Alhamadani
Lecturer, Instructor at Nursing College / Al-Muthanna University, Iraq

Abstract

Osteoarthritis (OA) of the knee is the most common chronic degenerative joint disease characterized by pain, stiffness, swelling and progressive functional limitation in elderly. Non-surgical management modalities like physical therapy, lifestyle modification and oral non-steroidal anti-inflammatory drugs, are often ineffective or do not alleviate symptoms adequately. Intra-articular corticosteroid (CS) and hyaluronic acid (HA) injections have been used for long to alleviate the symptoms of knee OA. viscosupplementation has been used as a therapeutic modality for the management of knee OA. The principle of viscosupplementation is based on the physiological properties of the hyaluronic acid (HA) in the synovial joint which helps tissue lubricate, cushion and reduce pain in the joint.

Study diagnosed forty patient of knee Osteoarthritis for both gender with age (45-70 years) and observed change and effectiveness to pre-and post of HA injection, All patients diagnosed by Orthopedists and Rheumatologists whose used X-rays were graded as stage I, II and III according to Kellgren and Lawrence scale.

All the measurements were used at the time of enrollment in the study before any injection and then measured again at the end of three months by using Western Ontario and McMaster University Osteoarthritis Index (WOMAC). All the patients before therapy were having minimum score of 72.4 & 9.045 for Mean and Standard Deviation respectively while after the therapy there score reduced to 36.2 & 4.783.

The results show improvement significant during four month under study and the effect peaks at around 8–12 weeks following administration, This supports the potential use of intra-articular HA as an effective long therapeutic option for patients with OA of the knee.

Keywords: Osteoarthritis, hyaluronic acid, hyaluronate physiochemical functions, extracellular matrix, glycosaminoglycan, Knee Intra-articular injection.

Introduction

Osteoarthritis of the knee is the most common slowly progressive chronic degenerative joint disease, characterized by varying degrees of loss of joint cartilage with local inflammation, usually affecting the elderly population. There is cartilage damage combined with a significant reduction in the viscoelastic properties of the synovial fluid and the molecular weight and concentration of the naturally occurring hyaluronic acid in synovial fluid decreases. This loss of viscoelasticity decreases the lubrication between joint surfaces and erodes the articular surfaces and is the mechanism of origin of pain in osteoarthritis. The patient presents with pain, swelling, stiffness, deformity, decreased range of motion and disability, which significantly affect the quality of life. The knee is the most common joint that is affected in the population with OA and plays an important role in weight bearing and mobility.
Treatment is aimed at reducing symptoms like reducing pain and inflammation and maintaining performance and normal movement of the joints and slowing the progression of the disease. It includes holistic therapeutic modalities including non-pharmacological measures like patient education, physical therapy with exercises to maintain range of motion and strength, lifestyle modifications such as dieting and weight reduction. The aim of this study was to assess the efficacy of HA intra-articular injections in managing osteoarthritic knee pain.

Characteristics of Hyaluronic Acid (HA)

HA is a glycosaminoglycan constituent of synovial fluid and cartilage matrix in normal joints. The properties of the synovial fluid are dependent on the concentration of HA and its molecular weight (MW); in OA, the concentration and MW of HA are decreased. The exogenous HA available for IA viscosupplementation is formulated as different MW preparations: low (range: 500,000–730,000 Da), intermediate (800,000–2,000,000 Da), and high MW (average: 6,000,000 Da) including cross-linked formulations of HA.

Its physiological properties include shock absorption, traumatic energy dissipation, protective coating of the articular cartilage surface and lubrication. In vitro, it is shown to have anti-inflammatory effects on cells and it may slow chondrocyte apoptosis in OA by binding CD44 and ICAM-1 receptors, and regulating in this way the process of cartilage matrix degradation. The concentration and the molecular weight of HA in the synovial fluid of patients with knee OA are shown to be reduced.

Study population

A total of 40 subjects were enrolled in this study in accordance to various criteria. These included gender (15 man and 25 woman), age (45–70 years) and Grade of disease by Kellgren-Lawrence (K-L) severity grade I, II and III OA of the knee. All subject collects of different city and diagnoses by specialists Doctors.

Materials and Methods

This prospective randomized study was diagnoses 40 patients (53 knees) with knee osteoarthritis who were treated with a single intra-articular injection of HA by 88mg/4ml lightly cross-linking HA (Monovisc®, Anika Therapeutics, Inc).

All patients who were diagnosed with knee OA by Orthopedists and Rheumatologists whose used X-rays were graded as stage I, II and III according to Kellgren and Lawrence scale. The injection was given at a site near the superolateral pole of patella in the suprapatellar pouch under aseptic conditions, with knee kept in 15–20 degree flexion and the patient was advised to take 1 day of rest after injection and apply ice to the area if there were any signs of inflammation.

All the measurements were used at the time of enrollment in the study before any injection and then measured again at the end of 3 months by using Western Ontario and McMaster University Osteoarthritis Index (WOMAC) was used as a self-administered test to compared as regards pain and functional improvement pre and post used the HA injection, with the using of WOMAC (Appendix 1), a lower score represented a better outcome.

WOMAC

The WOMAC is a self-administered questionnaire that is composed of 24 questions categorized into three subscales (pain, stiffness, and physical function). In the current study, we used 5-point Likert scale format: none (0), mild (1), moderate (2), severe (3), and extreme (4). Scores for each subscale were determined by summing the component item scores for each subscale—possible score range: pain (0–20), stiffness (0–8), and physical function (0–68). The final total scores (possible score range, 0–96) were determined by summing the scores for each subscale. WOMAC-total score in the range of 0 (best score) to 96 (worst score).

Results

Forty patients enrolled in our study suffered from osteoarthritis, who were treated with HA intra-articular injections, Pain and stiffness and physical function on Knee patients were estimated pre and post treatment by used WOMAC index.

The subjective scoring with WOMAC score done after 4 months showed gradual decrease in WOMAC score which suggests that the patients have observed
relief in pain, stiffness and physical has improved due to importance of hyaluronic acid (HA) and its physiological and biochemical functions at cellular level (Table 1). All the patients before therapy were having minimum score of 72.4 & 9.045 for Mean and Standard Deviation respectively while Significant improvement (p<0.05) were obtained After the therapy there score reduced to 36.2 & 4.783 (Figure1).

And based on individual results for each patient, it was observed that best effectiveness of the HA intra-articular injections was for patients suffering from primary knee OA with Kellgren and Lawrence (KL) Grade I and II, while in patients suffering advanced OA in last grade III of Kellgren-Lawrence, it was observed that were less effective.

Table 1. WOMAC Index Pre and Post treatment.

Figure 1. Comparison of Mean WOMAC values in Study Group Pre and Post treatment by HA injection.
**Discussion**

Primary treatment goals in knee OA include pain reduction and improvement of joint mobility and function. The secondary goal is to decrease the progression of disease. Vissco-supplementation with hyaluronic acid is a non-operative intervention.

WOMAC Scores showed improvement in all the parameters post-intervention after 4 months, there is due to it keeps the space between your bones well lubricated and viscoelasticity of the synovial fluid. When the joints are lubricated, the bones are less likely to grind against each other and cause reduce pain.

Moreover hyaluronic acid supplements are very helpful for people suffering from osteoarthritis, a type of degenerative joint disease caused by wear and tear on the joints over time. whereas high-impact movements that generate compressive forces on a healthy joint benefit from the shock absorption properties of HA. Furthermore, with inflammation, HA may offer protective properties to the joint tissue by scavenging free radicals and reducing oxidative damage.

Injected HA’s main functions stem from its antinociceptive properties, ability to improve the viscoelastic properties of synovial fluid, and indirect lubrication of the joint through stimulated endogenous HA synthesis. Other potential anecdotal benefits of HA injections that have been proposed include chondroprotection and potential function as a disease-modifying agent for OA. More specifically, Type II collagen degradation products appear to be a marker of cartilage degradation and OA disease activity.\(^{15}\)

The improvement was more significant in Hyaluronic acid at the end of 4 months providing a good cue to compare the clinical efficacy before and after intervention over four months.

**Conclusion**

According to results, the intra-articular HA injection was very effective in pain relief and improvement of knee function beginning from three months.

There is good evidence for the efficacy of HA injection in reducing pain and increasing function in knee OA. this supports the potential use of intra-articular HA as an effective long therapeutic option for patients with OA of the knee and we recommends that use of HA injection in knee OA patients with mild to moderate disease to get best result.

Changes in Interleukins and Follicle Stimulating Hormone in Toxoplasmosis Male Patients

Alia Salim Altemeemi1, Noor Kareem Kadhim2, Ghufran Saad Nsaif3
1Research Scholar, College of Farabi, Department of Medical Laboratory Technology, Iraq, 2Research Scholar, Corresponding author, College of Farabi, Department of medical laboratory, Iraq technology, 3Research Scholar, College of Farabi, Department of medical laboratory technology, Iraq

Abstract

In several countries there are endemic of parasitic diseases, specifically in developing countries, several studies investigated that toxoplasmosis is related with sterility of male. Aims of study are assessment of anti-Toxoplasma IgG antibodies in patient’s serum and their relation with interleukins and FSH hormone. IL-6 stimulates antibody production and extend effect of proinflammatory by stimulating the production of acute phase proteins. IL-10 and IL-12 control the immune response type. Cytokine synthesis is inhibits by the former and by blocking the IL-6 and TNF-α production, the response with involvement of Th2 and activation of B cells has an advantage. Detection for the toxoplasmosis which is based on toxo IgG , interleukins and FSH used the classic ELISA technique that based on immunoassay system using fluorescence technology and antigen antibody interaction. They were found in 1 (3.03%) of azoospermic patients and 4(12.12%) of oligozoospermic patients, while the negative results found in 32(96.97%) of azoospermic patients and 29(87.88%) of oligozoospermic patients. The control group had 34(100%) negative results in toxoplasmosis. The mean serum levels of IL-6 and IL-17 (pg / ml) increased significantly in patients with Toxoplasma gondii compared to the control group (237.97±9.09 pg / ml 285.52±12.45and pg / ml, respectively; p<0.0001) . In this study, it has been concluded that infection with T. gondii can effect on the level of the interleukins and FSH in infertile couples.

Keyword: Toxoplasma gondii, Interluekin, FSH hormone , Cytokine , Immune Response

Introduction

Toxoplasmosis is caused by parasite Toxoplasma gondii, then might be cause impaired folliculogenesis , endometritis, uterine and ovarian atrophy, vasculitis ,adrenal hypertrophy and decrease in semen quality, concentration, and motility in male (1). Through ingestion of parasite cysts present in infected foods, undercooked or through swallowing oocysts contained in polluted water and vegetables it is highly transmitted. So, human infections from T. Gondii are normal but are minimally symptomatic or asymptomatic in most cases of immunocompetent humans and their effects may remain unnoticed (2) . It was confirmed that in this case, T. Gondii infection is slightly higher in infertile couples relative to fertile couples. Another researchs found that the amount of anti-sperm antibody in toxoplasma infected pairs was higher than in non-infected pairs (3) . For most cases of adults infection with T. Gondii doesn’t cause severe illness, but during pregnancy may have implications for the deformities of developing fetus (4). It was later reported that after the T. gondii infection there was a reduced fertility in the rats. along with lower epidididymis weight, and increased irregular morphology of the sperm. In addition, the association between increased apoptosis of sperm and toxoplasmosis, especially of diploid spermatozoa (5).

Cytokines are significant mediators during the whole pregnancy in the bidirectional association between the reproductive system and the maternal immune system (6) . IL-17 is a pro-inflammatory cytokine created by several tissues induced by several factors, inclusive viruses and different cytokines, whose effect is directed cellular targets either to myeloid or non-myeloid (7) . Various cytokines (IL-4, IL-5, IL-6, IL-10, IL-13, and IL-14)
synthesize by Th2 lymphocytes, which play an important part in pathogenesis of parasites. IL-6 stimulates the synthesis of antibodies and extend proinflammatory action by stimulating acute phase protein development (8). Both IL-10 and IL-12 regulate the form of immune response. Cytokine synthesis is inhibits by the former and by blocking the IL-6 and TNF-α production, the response with involvement of Th2 and activation of B cells has an advantage, reaction with Th2 involvement and B cell activation has an advantage (9).

Materials and Methods

This study was conducted on 130 samples (100 Patients , and 30 control group ) their age ranged from (19-55years). Blood samples were collected from High institute of infertility diagnosis during the period from December to March 2020. About 5 ml fasting venous blood specimens were gathered from both patients and control groups , and transferred into anticoagulant gel tube for centrifugation. After that, serum was separated which then used for assess biochemical parameters.

Follicle-stimulating hormone (FSH) was evaluated by (1-chromaTM FSH), and IgG was assessed from serum samples by enzyme-linked immunosorbent assay (ELISA) using Human IgG anti Toxoplasma gondii ELISA Kit (Human company).

The levels of interleukins were assessed in blood serum using ELISA method for IL-6, and IL-17 by (MyBioSource, USA, Cat No. MBS261259, and Cat No MBS764076) respectively.

Results

Table (1) show the presence of anti-toxoplasma gondii IgG antibodies (ELISA test) in 100 men. They were found in 1 (3.03%) of azoospermic patients and 4(12.12%) of oligozoospermic patients, while the negative results found in 32(96.97%) of azoospermic patients and 29(87.88%) of oligozoospermic patients. The control group had 34(100%) negative results in toxoplasmosis.

Discussion

The one of most usual disease consider to have adverse effect on the human reproduction is toxoplasmosis; previous studies of parasite infections in the male genital tract proved the possibility of *T. gondii* infection increase the defects of testicular during secondary hypogonadism via hypothalamic-hypophyseal axis changes and found that toxoplasmosis can change all spermatic parameters include concentration, morphology and motility that lead to the production of significantly decreased sperm cells but without sterility (10).

This study proved that the infection with *T. gondii* in infertile male is intensity higher than fertile male, four patients of oligozoospermic patients and one patient of azoospermic patients have toxoplasmosis infection.

The patients of *T. Gondii* had significantly higher the IL-6 and IL-17 levels compared to the control group, which indicate an inflammatory condition. The key role of IL-6 is immune response involvement by lymphocyte intervention B. It is a mediator in charge of the development of acute phase protein and the cytotoxic activity of NK cells will be increased, though unspecific, inflammatory marker which states this study agreement with Matowicka’s study found *T. Gondii* patients had double the IL-6 levels compared with control group (11).

The study conducted by Satti showed the mean serum level of IL-17 in patients a highly significant increase when compared with control group (12) this agreement with our study. In the present study, the early increase in IL-17 serum level matches the results of different researchers (13), investigated that an early rise in IL-17 was identified in the early stages of infection. IL-17 was also presented to be included in the early recruitment and development of neutrophils, which are necessary for parasite clearance during initial stages of infection (14).

Previous studies correlated the decrease in the concentration of sperms with toxoplasmosis infection that *Toxoplasma* parasites lead to elevate the level of cell apoptosis that is stimulated by a decreased in
gonadotropin level. As well as, decrease in the levels of LH, FSH and testosterone and these results effect the spermatogenesis process that lead to decrease proliferation of sperms and spermatocytes which predict to be the most sensitive stage (15). Marathe’s research showed that, in addition to testosterone and FSH, selective immunoneutralization of LH triggers the apoptotic cell death of meiotic and post-meiotic germ cells in testes that have been shown to regulate the survival of germ cells, the cellular apoptosis in the testis result from exposure to decrease of hormones which related with the lower numbers of sperms in toxoplasmosis infected patients. Also more previous findings indicated that Toxoplasma has the effect on the efficiency of immune system and induction of IL-1b which triggered the modification of hypothalamic GnRH release and may be manufacture is interposed by increased release of the dopamine and norepinephrine from neurons in the brain stem as well as, hypothalamus that are suppressor to gonadotropin releasing hormone (16). Another studies indicated that cytokines have more effects in deficiency the release of anterior pituitary hormones. Also, cytokines are show to depress the HPG axis, directly or indirectly via increased corticotrophin-releasing hormone (CRH) and/or cortisol. indicating it or not changed CRH and/or cortisol participate in part to HPG axis selectively suppress serum FSH concentrations (17).

**Conclusion**

Toxoplasmosis infection leads to decrease in sperm concentration. As well as, significantly increased the levels of interleukin in contrast, decrease in the level of FSH of infected patients affect the spermatogenesis process that lead to decrease proliferation of sperms and spermatocytes in toxoplasmosis patients.

Evaluation of the Acute Flaccid Paralysis Surveillance System of Polio Free in East Java, Indonesia, 2019

Alya Hanifa Rasyidi, Anik Suroiyah, Laura Navika Yamani

1Student, Department of Epidemiology, Faculty of Public Health Universitas Airlangga, Indonesia, 2Health officer, Surveillance and Immunization Section, Disease Prevention and Control Sector, East Java Provincial Health Office, Indonesia, 3Associate Professor, Department of Epidemiology, Faculty of Public Health Universitas Airlangga, Indonesia

Abstract

Background: Proving that the wild polio virus no longer exists in Indonesia, the symptoms must be found that resemble polio. These symptoms are found in patients with AFP (Acute Flaccid Paralysis). AFP surveillance is an observation made of all cases of acute paralysis or AFP in children aged <15 years who are vulnerable to polio. The priority problem that is still found in the East Java Provincial Health Office regarding AFP surveillance is the reduction in the discovery of non-polio AFP cases and adequate specimens.

Aims: The purpose of this study was to analyze the implementation of AFP surveillance activities in the East Java Province Health Office in 2019.

Methods: Data collection was carried out by primary and secondary to study the AFP surveillance overview. Primary data were obtained from in depth interviews with AFP surveillance program holders in East Java Provincial Health Office. Secondary data is processed using Microsoft Office Excel, Epi Info and Quantum GIS.

Results: The result is in 2019 the rate of non-polio AFP and the percentage of adequate specimens in East Java Province has under the target. In 2019 there was a decrease compared to the previous year, the non-polio AFP rate was 1.64 and the percentage of adequate specimens was 56.2%. Only as many as six districts / cities in East Java Province had pass these two indicators.

Conclusion: The lack of visits and reports from both the hospital and the community is one of causative factor. Intensive and routine AFP surveillance is needed to monitor the emergence of polio cases

Keywords: Keywords: AFP, surveillance, polio, adequate specimens.

Introduction

Poliomyelitis is an infectious disease caused by the poliovirus. Polio virus predilection can cause paralysis, muscle atrophy and even irreversible paralysis to death in children. Since this disease causes paralysis, polio is one of the important diseases to be eradicated globally(1). The polio eradication program was launched by the World Health Organization (WHO), known as the Global Polio Eradication Initiative (GPEI). GPEI in Indonesia is known as ‘Eradikasi Polio’ (Erapo) or Polio Eradication which aims to break the chain of transmission of the polio virus globally through coordinated efforts nationally and internationally. The program is based on evidence that humans are the only reservoir of the polio virus(2). Poliomyelitis cases are mostly non-paralytic or not accompanied by clear clinical manifestations. A small portion (1%) of cases of poliomyelitis that causes paralysis (Paralytic Poliomyelitis) requires observations focused on cases of poliomyelitis through AFP surveillance (Acute Flaccid Paralysis)(3).

AFP (Acute Flaccid Paralysis) surveillance is an observation made of all cases of acute paralyzed paralysis or AFP (Acute Flaccid Paralysis) in children aged <15 years who are vulnerable to polio. In 2005 there was an
outbreak of polio which resulted in an increase in public awareness of all the paralysis that occurred, so that the discovery of AFP cases instead of polio increased by more than 2/100,000 even though the specimen was adequately less than 80%. The discovery of this case shows a minimum estimate of non-polio AFP cases in Indonesia. Based on this, since 2006 non-polio AFP rate was set 2/100.000 children aged less than 15 years(3).

The problems that are still found in the East Java Provincial Health Office regarding AFP surveillance are:

a. The reduced discovery of the non-polio AFP case

b. Decreased percentage of adequate specimens (Target ≥80%)

c. 60 days return visits is under the target

d. The percentage of completeness of the AFP report is still low

Based on four problems above, the East Java Provincial Health Office determines two issues that are priority and important to study in order to obtain an evaluation in assessing the performance of AFP surveillance in East Java Province. The decrease in finding of non-polio AFP cases and adequate specimens are a priority issue in AFP surveillance.

**Material and Methods**

This study was sourced from the East Java Provincial Health Office. Secondary data collection was obtained from AFP surveillance performance reports that have been processed by the East Java Provincial Health Office. All data is processed using Microsoft Office Excel and Epi Info to determine the distribution of cases based on time, place, and person. In addition, secondary data processing is used to determine the percentage of AFP surveillance performance that pass the target or under the target. Distribution of non-polio AFP cases by place in all districts/cities of East Java Province is described using the Quantum GIS application. Quantum GIS is an open source software that can be used for spatial data processing and geographic information system application development, so that the data used is data that has coordinates or location instructions internationally namely longitude and latitude(4). Primary data collection to study the surveillance overview and evaluation was obtained from in-depth interviews with AFP surveillance program holders and surveillance coordinators in the East Java Provincial Health Office. In addition, a study of Minister of Health Decree document No. 483 of 2007 was conducted.

**Results**

**Overview of AFP Surveillance Recording and Reporting System**

1. Collecting Data

The earliest implementing units in the AFP case finding were Puskesmas (Primary Health Care) and Hospitals in the sub-district, district/city areas. Primary health care and local hospitals reported cases as sources of AFP surveillance reports. Reporting no later than the 10th of every month. The AFP case is cumulative and will be identified based on AFP surveillance performance. The District/City Health Office also sends the FP1 form (AFP Case Tracking Form) to the East Java Provincial Health Office.

2. Data Processing

Data obtained from the District/City Health Office is collected and processed using Ms. Office Excel and Epi Info by the East Java Provincial Health Office. The purpose of the grouping is to facilitate data analysis according to epidemiological variables, namely people, place, and time.

3. Data Analysis

The East Java Provincial Health Office conducted an analysis of AFP case data using the Ms Office Excel and Epi Info applications. These results are also presented in the form of AFP surveillance performance. A spatial analysis was also made about the distribution of non-polio AFP cases and adequate specimens and classified according to good, moderate, poor and very poor categories.

4. Data Dissemination

The East Java Provincial Health Office follows up or give feeds back to the District/City Health Office every three months by sending back AFP case data, weekly report attendance, and AFP surveillance performance analysis. It is aims to make District Health Office to check the data and immediately report if it has been not
Benefits of AFP surveillance

The benefit of AFP surveillance is the data collected can detect at least 1 (one) AFP case among 100,000 children aged <15 years. A very strong AFP surveillance system is very important to detect early wild poliovirus as the ultimate goal of eradicating polio(5).

Analysis Results

Secondary data obtained will be processed to determine the distribution of cases based on time, people, and place variables.

a. The distribution of non-polio AFP cases by age group in East Java in 2016-2019 is as follows:

Figure 1 shows the distribution of non-polio AFP cases by age group. Age of children is grouped into five categories, namely the age group <1 year, age 1-4 years, age 5-9 years, age 10-14 years, and age ≥15 years. The case of non-polio AFP in East Java Province throughout 2016-2019 tends to attack the 1-4 years and 5-9 years age groups.

b. The distribution of non-polio AFP rates in 2014-2019 are as follows:

The target of non-polio AFP rate for people aged <15 years is ≥ 2/100,000. The non-polio AFP rate from 2014 to 2019 tends to fluctuate.

c. The percentage distribution of adequate specimens for 2014-2019 is as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>Adequate Specimens Percentage (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2014</td>
<td>84.3%</td>
</tr>
<tr>
<td>2015</td>
<td>90.5%</td>
</tr>
<tr>
<td>2016</td>
<td>88.3%</td>
</tr>
<tr>
<td>2017</td>
<td>94.3%</td>
</tr>
<tr>
<td>2018</td>
<td>56.3%</td>
</tr>
<tr>
<td>2019</td>
<td>56.2%</td>
</tr>
</tbody>
</table>

The target specimen examination results received from the laboratory within ≤ 14 days is ≥ 80%. From 2014 to 2017 the percentage of adequate specimens passed the target of ≥80%. But in 2018 and 2019 the percentage of adequate specimens has under the target, the percentage <80%.

d. Distribution of non-polio AFP rates based on districts/cities in East Java Province in 2019:

Districts/cities with case finding rates ≥2/100.00 are depicted with a map of the area in green and have been categorized well. Districts/cities with case finding rates <2/100,000 are depicted on a red map and are categorized as poor.
e. The percentages distribution of adequate specimens by districts/cities in East Java Province in 2019:

**MAP DISTRIBUTION OF ADEQUATE SPECIMENS PERCENTAGE BASED ON AFP SURVEILLANCE PERFORMANCE IN EAST JAVA 2019**

![Map showing distribution of adequate specimens percentage in East Java Province in 2019](image)

Figure 5 shows the percentage of good adequate specimens ≥80% on the map above marked with a green zone. A total of 15 districts/cities are categorized well in the percentage of adequate specimens. As many as 23 districts/cities still lack adequate specimens.

**Discussion**

**AFP and Non-Polio Cases of East Java Provincial Health Office**

a. Distribution of Non-Polio AFP Cases by Age Group in 2016-2019

Figure 1 shows the distribution of non-polio AFP cases by age group in the East Java Provincial Health Office in 2016 to 2019. The results show that the distribution of cases most occurred in the 1-4 year age group and 5-9 year age group. These results are consistent with research by Soltani et al that most AFP cases occur in the 0-5 years group(6). Research conducted by Momen and Shakurnia (2016) in Iran also shows that more than half of non-polio AFP cases occur in the age group under five years(7).

b. Distribution of adequate specimen percentage for 2014-2019

Specimens sent to the laboratory and arrive at the laboratory are in eligible conditions with a target of ≥80%. Adequate specimen examination which includes examination of stool can contain poliovirus. The polio virus in feces is not only found in children who have just been immunized but in children who are not immunized but are infected with the polio virus through the oral faecal of immunized children(9). Figure 3 shows that the percentage of adequate specimens in 2014 to 2017 has been more than 80%. But in 2018 and 2019 the percentage of adequate specimens is less than 80%.

c. Distribution of Non-Polio AFP Rate by Districts/Cities in East Java Province in 2019

Based on AFP surveillance data from the East Java Provincial Health Office, the distribution of non-polio AFP rates exceeded the target (≥2/100,000) occurred in 2014, 2017 and 2018. In 2019 the non-polio AFP rate has under the target. Research conducted by Dhiman et al in India shows that the rate of AFP not polio in 2004 to 2017 greatly exceeded the target (≥2/100,000)(8).
Figure 4 shows the distribution of non-polio AFP rates per district/city in the East Java Provincial Health Office. A total of 25 districts/cities were declared bad in the non-polio AFP rate in 2019. 13 regencies/cities were declared good in the non-polio AFP rate, which pass the target of ≥2/100,000.

e. Distribution of Adequate Specimens by Districts/Cities in East Java Province in 2019

Specimens from the AFP case were categorized as good if at least two stool specimens were obtained within 24 hours apart within 14 days after the discovery. The specimen is then sent to a WHO accredited laboratory, and the specimen must be in good condition(10). The quality of AFP surveillance is conventionally evaluated, one of which is collecting adequate faecal specimens. Collection of specimens in a number of areas requires collection of kits. If it is not available it becomes very difficult to assess the presence of a virus(11).

Distribution of AFP cases by Districts/cities based on the performance of AFP Surveillance in 2019

East Java Provincial Health Office classifies districts/cities in several categories. The category is good if the Non-polio AFP rate is ≥2 and the specimen is adequate ≥80%. The category is moderate if the Non-polio AFP rate is ≥2 and the specimen is adequate <80%. The category is less if the Non-polio AFP rate <2 and the specimen is adequate ≥80%. The category is very less if the Non-polio AFP rate <2 and adequate specimens <80%.

MAP DISTRIBUTION OF AFP CASES BASED ON AFP SURVEILLANCE PERFORMANCE IN EAST JAVA 2019

Legend

\[
\begin{array}{c}
\text{Good, non AFP rate} \geq 2 \text{ and adequate specimens} \geq 80 \\
\text{Less, Non-polio AFP rate} < 2 \text{ and adequate specimens} \geq 80\% \\
\text{Very less, Non-polio AFP rate} < 2 \text{ and adequate specimens} < 80\% \\
\text{Moderate, Non-polio AFP rate is} \geq 2 \text{ and adequate specimens} < 80\%
\end{array}
\]

Figure 6. Map Distribution of AFP Cases Based on AFP Surveillance Performance in East Java 2019.

Source: AFP Surveillance Report on East Java Provincial Health Office, 2019

Figure 6 shows that 16 districts are still very lacking, marked by a red zone with a non-Polio AFP rate <2 and an adequate specimen <80%. A total of eight districts are categorized moderate with non-polio AFP rate ≥2 and adequate specimens <80%. A total of six districts/cities have been declared good, with marked green zones, non AFP rate ≥2 and adequate specimens ≥80. Districts that have been declared good are Sumenep, Surabaya, Madiun, Pacitan, Blitar, and Tulungagung.

The AFP non-polio AFP rate and the percentage of adequate specimens that exceed the target is very important in assessing AFP surveillance performance. The non-polio AFP rate has been proven in administering doses of polio vaccine. This can be causatively related to OPV vaccination(8).
Factors Causing the Reduction in AFP Case Discovery and Adequate Specimens

Weaknesses found in the conduct of AFP surveillance in the East Java Provincial Health Office include the lack of socialization, training and development for AFP surveillance officers in primary health care, hospitals, and district/city health offices. The one of effectiveness in AFP surveillance depends on the community reporting a disease. The lack of socialization about the AFP case to the communities also becomes a weakness in conducting AFP surveillance.

Conclusion

To prove that the wild polio virus no longer exists in Indonesia, symptoms must be found that resembles polio. These symptoms are found in patients with AFP. The non-polio AFP rate in East Java Province in 2019 is 1.64 (target ≥2/100,000). All specimens for virus isolation must be collected as soon as possible after symptoms appearance. In 2019, most districts/cities have adequate specimen which is not reaching 80%.

The East Java Provincial Health Office classified districts/cities into several categories based on non-polio AFP indicator and the percentage of adequate specimens. The results showed that 16 districts are still said to be very lacking. A total of eight districts have been said to be moderate, and six districts/cities have been declared good. AFP surveillance must be carried out intensively and routinely to produce good surveillance performance in finding AFP cases as indicators of polio eradication.

Acknowledgements:

a. Improved implementation of HRR (Hospital Record Review) by the East Java Provincial Health Office optimally by increasing coordination with stakeholders.

b. Supervision by the East Java Provincial Health Office can be carried out routinely and optimally to evaluate the achievement of performance indicators for each District/City Health Office. Implementation of supervision can also improve coordination between relevant parties.

c. Increased collaboration with local governments, hospitals, health centers, in an effort to strengthen commitment and support for the implementation of AFP Surveillance.

E-Cigarette Vaping and Periodontium: A Systematic Review

Ameer A. Altabatabaie1, Ahmed A. Alquzweeni2, Hussein A. Alnajar3, Raya Ali Dalol4
1Research Scholar, Department of Conservative Dentistry, Faculty of Dentistry, University of Kufa, 2Research Scholar, Department of Conservative Dentistry, Faculty of Dentistry, University of Kufa, 3Research Scholar, Department of Orthodontics, Faculty of Dentistry, University of Kufa, 4Research Scholar, Periodontics Department, Nassir Almoussawy Specialized Dental Center

Abstract

Conventional cigarettes have shown severe toxicity on immune cells and wound healing in the periodontium, but little is known about the comparative effects of vaping or electronic cigarettes. If current conventional cigarette users are to transition to a less detrimental alternative, the evidence must demonstrate if electronic nicotine delivery systems can be deemed safer than conventional options. The intent of this literature is to summarize the evidences on the effect of E-cigarette on the periodontal health.

The main sources of evidence for this report included: a comprehensive report from National Academies of Sciences, Engineering, and Medicine, reviews published in the past 10 years.

As a conclusion, further investigation and studies are needed to evidence the effect of new smoking methods on the oral health of newly users and on the shifted persons who was previously tobacco smokers.

Keywords : E-cigarettes, Vaping, Periodontium, Nicotine, Aerosols

Introduction

In recent years, electronic e-cigarettes have been gaining popularity. The main purpose of invention of e-cigarettes was to replace the conventional cigarette for helping in smoking cessation (1). E-cigarettes are the electronic devices that produce aerosol. Aerosol is a mixture of fine particles/liquid droplets suspended in a gaseous medium (2).

Several authors have shown that tobacco smoking, was a risk factor in periodontal disease progression, and can also impair the effectiveness of periodontal treatment. Over the past years, a new mode of nicotine delivery has been introduced, claiming less harm to the consumer when compared to conventional smoking (3). Electronic-cigarettes (e-cigs) represent a significant and increasing proportion of tobacco product consumption, which may pose an oral health concern. Different level evidence including systematic reviews of randomized control trials (RCTs) on the effect of E-cigs on the periodontium is currently lacking and the available data worldwide is necessary to allow further knowledge on this subject (3).

E-Cigarettes

E-cigarettes or Electronic nicotine delivery systems (ENDS) are battery-operated devices that electronically heat a solution to create an inhalable aerosol. This solution, also known as ‘e-liquid’ or ‘e-juice’, is commonly made up of propylene glycol or glycerin, water, flavorings and nicotine (although many liquids do not contain nicotine) (4). E-cigs are battery operated devices, which consist of a metal heating element in a stainless steel shell, a cartridge, an atomizer and a battery. The heating element vaporizes a solution containing a mixture of chemicals including nicotine and other additives/humectants, such as base/carrying agent’s propylene glycol, glycerin/glycerol, and flavoring agents including fruit and...
candy flavors. Apart from inhaled nicotine, variable levels of aldehydes and carbonyls are detected in e-cig aerosols during vaporizations (5,6). E-cigarettes are also commonly referred to as ‘vape pens’, ‘hookah pens’ or ‘e-hookah’ among youth (7,8).

**History of evolution**

Electronic smoking devices are not a new phenomenon, with a patent being recorded in 1965 in the USA (9). The modern rise of e-cigarettes is attributed to Hon Lik, a Chinese inventor, who filed a US patent in 2005 for an ‘electronic atomization cigarette that contains nicotine without tar’ (10). E-cigarette devices firstly introduced in the early 2000s (11). Over the years, e-cigarettes have evolved to more complex devices that come in different shapes and sizes, also involved changes in device configuration and components (12).

Newer versions of e-cigarettes, such as JUUL pods, incorporate nicotine salts in a novel product design. These more recently available products have a higher nicotine content, have become immensely popular with users, particularly among youth, and account for a major portion of the e-cigarette market share in the US at this time (13).

**Types of E-Cigarettes**

**First generation**: Also known as ciga-likes/minis. It is low cost and disposable. 200-300 puffs per cartridge which is equivalent to 1 pack of 20 cigarettes. It has limited battery life. The nicotine delivery is poor.

**Second generation**: Also known as ‘tanks’. It resembles a pen. It contains a tank which is refillable. It has larger batteries and is rechargeable.

**Third generation**: Also known as ‘mods’. It has advanced features like adjustable voltage systems and is digitalized (14).

**Content of fluid and vapor**

Most studies have used conventional cigarettes as reference and investigated presence or concentrations of substances that are known to be harmful in conventional cigarettes. Some of the studies performed in vitro experiments with cells exposed to fluid or vapour, for example to test for cytotoxicity or viral defense (15). These studies are also mentioned in this section. Many studies found that the product labels did not show the ingredients (e.g. flavours, solvent, nicotine) or that the declaration did not correspond with the concentrations found (e.g. of nicotine) (15). The following ingredients may be found:

1. **Glycols.**
2. **Nicotine.**
3. **Particles.** One study found that e-cigarette liquids generate many nanoparticles, up to 3000 times more than found in ambient air (16).
4. **Metals.** Such as lead and chromium, nickel, tin, silver and aluminum (17).
5. **Tobacco-specific nitrosamines.**
6. **Carbonyls.**
7. **Volatile organic compounds.**
8. **Hydrocarbons and polycyclic aromatic hydrocarbons.**
9. **Phenols** (15).

**Effects of smoking on periodontal diseases**

Epidemiological studies have demonstrated that tobacco use is a significant risk factor for the development of periodontal diseases (14). Disease severity increases with the frequency of smoking (18). Smokers accumulate markedly more dental calculus than do non-smokers, and the quantity of calculus is correlated with the frequency of smoking (14). Smoking is also associated with an increased risk of periodontal attachment loss and formation of periodontal pockets, as well as alveolar bone loss.

The adverse effects of smoking on the periodontium correlates well with both the quantity of daily consumption and the duration (19). Approximately half of the cases of periodontitis in the United States have been attributed to smoking (20). Smokers were recorded to have a 2.5 to 3.5 times greater risk of severe periodontal attachment loss (14).

**Mechanism of the effect of tobacco on the periodontal tissue**:
The main property of nicotine is the vasoconstrictive effect at the end-arterial vasculature of the gingivae and other tobacco components can also induce tissue necrosis and ulceration seen in the disease. Smokeless tobacco users known to possess a painless loss of gingival tissues and alveolar bone destruction in the area of chronic tobacco contact, as a result of collagen breakdown due to increased release of collagenase (22). Nicotine inhibits the growth of gingival fibroblasts and their production of fibronectin and collagen (23). Furthermore, oral leukocytes, especially neutrophils, may exhibit diminished ability to migrate and phagocytose, and they contribute to the inactivation of tissue protease inhibitors (23). Tobacco smoking may exert a masking effect on gingival symptoms of inflammation, which might give smoking patients a false sense of assurance of gingival health (22). Interleukin-1 genotype positive smokers are more susceptible to severe adult periodontitis (24).

**Effect of e-cigarette on periodontal tissue**

Since e-cigarettes became available in the markets, their safety and use as a substitute for tobacco smoking have been surrounded by medical and public controversy. However, a recent report by the Royal College of Physicians concluded that e-cigarettes are likely to be much safer than smoking (25).

The effect of e-cigarette use on the gingival condition and inflammatory biomarkers has not yet been investigated (26). E-cigarette users also have been known to develop lacy white patches on the gums, tongue or insides of the cheeks, a condition called an oral lichenoid reaction. Oral thrush also can develop in vapers, caused by an overgrowth of Candida yeast in the mouth (27).

It could cause a pretty significant burn, where you lose at least the top layer of skin, if not more. Device explosions also have caused people to lose teeth, the findings showed. For example, an estimated 2,035 people with electronic cigarette burn injuries were treated in U.S. emergency rooms between 2015 and 2017, more than 40 times the number of vaping burns reported between 2009 and 2015, researchers found (28).

**Nicotine and periodontal health**

Nicotine is vasoconstrictor. It constricts the arteries and reduces the amount of oxygenated blood flow and nutrients to the gums thereby reducing the wbc’s that provide anti-inflammatory action against harmful foreign substances. Three types of bacteria thrive in a deoxygenated environment which are porphyromonas gingivalis, aggregatibacter actinomyctem comitans, prevotella intermedia (29). These bacteria are found in plaque, tartar and pocket depth of up to 3mm. This leads to the destruction of PDL and alveolar bone. Without sufficient blood gingival and periodontal tissues cannot be healthy. Also nicotine is a muscle stimulant which causes bruxism due to hyperactivity of the muscles (30).

Cigarette smoke induces epidermal growth factor receptor-dependent redistribution of apical Mucin 1 and junctional beta-catenin in polarized human airway epithelial cells (31). Desmoglein 3 and keratin 10 expressions are reduced by chronic exposure to cigarette smoke in human keratinized oral mucosa explants (32).

**Aerosols and periodontal health:**

E-cigarettes produce aerosol. Aerosol can cause carbonyl inflammatory action. Also heat produced from the vapor leads to xerostomia . Saliva contains lysozymes that kill the bacteria. Therefore, xerostomia leads to formation of harbor for the bacteria to pool in. Especially in the advanced featured cigarettes the voltage is regulated at high temperature for more effect which causes xerostomia. When e-cigarettes are heated to high temperature it produces carbonyls like formaldehyde, acetaldehyde. Researchers have noted that Propylene based e-liquids produced more carbonyls. There were multiple user questionnaires/surveys that repeatedly detailed ‘mouth and throat dryness and irritation’ as one of the most common reported side effects of e-cigarette use (31,33).

An in vitro study on periodontal ligament fibroblasts demonstrated decreased fibroblast proliferation rates with menthol additives (31). The topical effects of nicotine are worthy of specific consideration. The nicotine in the aerosol is primarily absorbed in the buccal and pharyngeal mucosa, rather than the alveoli, demonstrating the potential to have effects on the oral tissues (34).
Conclusion

Numerous studies over the past several years have made stronger correlations to the effects of conventional cigarette smoking on the periodontium. A systematic review has linked smoking to increased risk of tooth loss, periodontal attachment loss, deeper periodontal pockets, and more expansive alveolar bone loss. E-cigarette vapor and conventional cigarettes, especially with flavoring chemicals, have been shown to contribute to the pathogenesis of periodontal disease as well as dysregulated repair responses. The damage done to myofibroblasts can affect the patient’s ability to heal properly due to the decrease in wound contraction (34).

The research explored in this review shows an association between E-cigarette and detrimental effects on the periodontal tissues as well as the inflammatory immune response. However, further studies should be performed to establish a stronger association between vaporized metals and chemicals found in E-cigarette and the effects on the periodontium.

Relationship Between Spermatid Specific Thioredoxin-3 Protein and Antisperm Antibody in Patients with Varicocele Compared with a Control Group

Ameer Ali Imarah1, Waleed A.H.2
1Research Scholar, Corresponding Author; Biology Department, Faculty of Science/ University of Kufa, Iraq, 2Research Scholar; Biology Department, Faculty of Science/ University of Kufa, Iraq

Abstract

The spermatogenesis process are very complex and involves many process to lead to give normal sperm, these sperms a very important to fertility in the men). Protein in the male fertility that is very important which give the significant job in fertilization. The infertile varicocele patient grade 1, 2 and 3 (n= 25 , 25 and 25 respectively) compare with control patient (n=15). The present study Shown spermatid – specific thioredoxin 3 level a significant increase in varicocele patient grade 1,2 and 3 compare with control group (mean± Std. Error 17.97± 0.8 & 22.92±0.75 Respectively ). Also in Antisperm antibody a significant increase in varicocele patient grade 1,2 and 3 compare with control group (mean± Std. Error 73.85±2.71 & 45.6±1.44 Respectively ). Consecutive (r= -0.840, r = -0.745 and r = -0.475). Also theirs a negative correlation between Antisperm antibody level and the sperms concentration, Sperm Progressive motility percent and sperm normal morphology present in varicocele patient grade 1,2 and 3 Consecutive (r= -0.443 , r = -0.370 and r = -0.384 ) .

The result show a positive correlation was found between Spermatid specific thioredoxin-3 protein level and antisperm antibody level in varicocele patients .(The present study conclude that a negative function of Spermatid specific thioredoxin-3 protein and antisperm antibody which that appears on sperm function and sperm parameters , The study showed that spermatid specific thioredoxin-3 protein and antisperm antibody has a harmful effect with the time).

Keywords - Spermatid Specific Thioredoxin-3 Protein (SPTRX3), ASAs, Varicocele

Introduction

The most successful fertility in pets. Also, fertility is a success against sperm DNA damage (1). Thioredoxin family proteins It participates in an antioxidant system and is one of various groups, as it has a role in cellular functions, There are three thioredoxins It is especially expressed in male mammals (2,3). A group of proteins has been discovered in sperm, including Spermatid specific thioredoxin-3 SPTRX3 in the pro-acrosomic granule of round spermatids, which leads to a belief in its role in synthesis (4). There are a number of mechanisms that stimulate autoimmunity and antisperm antibodies including the peripheral acceleration of cells Immuno-type-1, accelerate the secretion of pro-inflammatory cytokines and Tissue necrosis factor (5). Decrease anti-inflammatory cytokines (IL-10, TGF-B) tissue growth factor and/or major (histocompatibility complex, associated molecules for the expression of co-stimulatory molecules expression, and/or the descending complexity of the process of corrosion by immune cells (6). TGF-β is A group of peptides of a special nature, as they control the spread, differentiation and many functions of cells(7). TGF-β acts with TGFA Together, they make a difference as a negative autocrine growth factor , Dysregulation of TGF-β It works to activate and produce signals in apoptosis (8). Many cells synthesize TGF-β There are receptors on all cells that form this peptide , TGF-β1, TGF-β2, and TGF-β3 It has systems and shares the same indicators (9). TGF-β1 It was first discovered in the last century in platelets and its role in recovery (10). Finally it is described as a group
of the safe acids that produce this protein \(^{(11)}\). There are a number of mechanisms that stimulate autoimmune and antisperm antibodies including the peripheral acceleration of cells Immuno-type-1, accelerate the secretion of pro-inflammatory cytokines and Tissue necrosis factor (TNF-a) \(^{(12)}\). Decrease anti-inflammatory cytokines (IL-10, TGF-B) tissue growth factor and/or major histocompatibility complex, associated molecules for the expression of co-stimulatory molecules expression, and/or the descending complexity of the process of corrosion by immune cells \(^{(13,14)}\).

**Materials and Methods**

Samples were collected from semen and serum from infertile patients include (grade 1, 2 and 3) as well as the control group from the infertility center of Al-Sadr Teaching Hospital. As the average age of the patients was \((36.87\pm74)\) years, Years, collected 90 samples and 88 eyes were examined.) A biochemical test was performed on (88) samples had been measured between Spermatid specific thioredoxin-3 protein by immunological method (Enzyme-Linked-Imuno-Sorbent- Assay) by using ELISA reader (Huma Germany origin). Before using the samples, they were placed at room temperature, as well as the reagents. All fluids were used with great care to prevent any errors as the checks were done step by step, All examinations were carried out by the apparatus of the College of Science, Kufa University. Used ELISA kits as follows from the global company (between Spermatid specific thioredoxin-3 protein) (MBS9319574) and ASAs (MBS702581) MYBIOSOURCE USA in Origin).

**Results**

The result show a significant spermatid specific thioredoxin-3 protein level was increase in varicocele patient grade 2 and 3 (mean± Std. Error 17.97± 0.8 & 22.92±0.75 consecutive) also significant ASAs level was increase in varicocele patient grade 2 and 3 (mean± Std. Error 73.85±2.71 & 45.6±1.44 consecutive as in table 1), while the result show negative correlation between(spermatid specific thioredoxin-3 and the sperms concentration); sperm progressive motility percent and sperm normal morphology present in varicocele patient grade 1, 2 and 3 consecutive \((r = -0.443, r = -0.370 \text{ and } r = -0.384 \text{ as in table 3})\).

The result show a positive correlation was found between spermatid specific thioredoxin-3 protein level and antisperm antibody level in varicocele patients).

Discussion

The current study showed a significant decrease (p<0.05) of Spermatid specific thioredoxin3 protein level in infertile men grade 1, 2 and grade 3 male infertility compared with control group and show a negative correlation between Spermatid specific thioredoxin3 protein level and sperm concentration , sperm progressive motility in addition to sperm normal morphology these SPTRX3, In biological generation it has an important role to play in the structures of sperm and its dissolution in the semen, They also have many functions In various cellular activities, including DNA synthesis, they also act as antioxidants, regulators of apoptosis h, as well as immune response. These resulted may be effected in these SPTRX3, have a function during the biogenesis of sperm accessory structures but then are degraded within the spermatid cytoplasmic , They also have many functions in Various cellular activities, where it is involved in the defense of sperm, from influences that act as antioxidants that prevent DNA damage and regulate apoptosis and immune response. The protein synthesis is affected by accompanying with increase free radicals (15-17). The study by Moughelinejad et. al., (2018) that showed a negative correlation between Spermatid specific thioredoxin3 protein with sperm parameter when showeda negative correlation between sperms count, sperm progressive motile and sperm normal morphology in Asthenozoospermia and also these study found the elevation of the SPTRX3 level in Asthenozoospermia compare with control.expressed in testis and localized to the Golgi apparatus of mammalian spermatocytes and spermatids. Interestingly, SPTRX-3 is more abundant in defective spermatozoa from infertile male (18).

The current study showed a significant increase (p<0.05) of antisperm antibody level in grade 2, 3 and non-significant increase of grade 1 male infertility compared with control group, while there was significant increase (p<0.05) between grade 1 and grade 2, 3 showmen, and show a negative correlation between antisperm antibody level and sperm concentration , sperm progressive motility in addition to sperm normal morphology , this result may be caused by the disruption of blood-testis barrier and this result is abnormal spermatogenesis (19). Our results agreed with the study that including 238 cases of ASA positive infertility male and 929 ASA negative controls, and show in patient with ASA positive infertility male that have reducing in sperm parameter while the patient with ASA negative controls that have normal sperm parameter and also this study illustrates the effect of ASA on semen liquefaction (20).

Another study that agreement with our result these study including azoospermia (n=22), oligozoospermia (n=9) and control group (n=2), and show in a patient with azoospermia and oligozoospermia elevate of ASA concentration compare with the control group and show the effected of ASA on sperm parameter (21).

Conclusions

Spermatid specific thioredoxin-3 protein and Antisperm Antibody have a negative effective on sperm function when that lead to infertility .

Abstract

Tuberculosis Arthritis of the knee joint is rare. A 25-year old female patient presented with pain and swelling of her left knee. The symptoms first appeared two months earlier; she was given glucocorticoid after diagnosed with Rheumatoid Arthritis. The patient did not improve with the treatment. The patient was diagnosed with tuberculosis arthritis according to biopsy and PCR TB result. Biopsy excision of the left knee found granulomatous appearance, which is consistent with tuberculosis, PCR TB examination also found a positive effect. Antituberculosis treatment was started and will be continued for nine months. Tuberculosis arthritis frequently mimics more common etiologies and can be difficult to diagnose. Tuberculosis arthritis may be suspected in a chronic case of joint pain, usually monoarticular, although pulmonary TB may absent.

Keyword: Tuberculosis, arthritis, knee, pain

Introduction

World Health Organization (WHO) declared tuberculosis (TB) as a global emergency since 1993. In 2002, WHO stated that the incidence of TB was 144 in 100,000 people per year with a world population of 6.08 billion people [1]. About 80% of pulmonary TB cases occur in 22 countries, mainly in Southeast Asia, sub-Saharan Africa, and Eastern Europe. In addition to pulmonary TB, there has been a surge in the prevalence of extrapulmonary TB with or without lung involvement in the past 10 years, where 10 to 11% of these extrapulmonary TB cases involve joints and 1 to 3% of these cases involve bones [2,3].

TB arthritis is often presented with several manifestations of subacute or chronic monoarthritis of the weight-bearing joints such as hips, knees, or ankles. This disease has been underdiagnosed for years. The risk factors of TB arthritis are similar to pulmonary TB coupled with the presence of local factors such as pre-existing joint disease including inflammatory arthropathy, crystal arthropathy, joint injury, and surgery. Early diagnosis is required to prevent any delay in the initiation of anti-tuberculosis drugs, thereby reducing morbidity and disability. TB diagnosis requires standard microbiological or histopathological confirmation. Acid-fast bacilli examination of synovial fluid can confirm the diagnosis in only 20-40% cases. Therefore, a synovial biopsy (or other affected tissue) is the gold standard for diagnosing TB arthritis. TB multidrug therapy is not recommended without confirmation. A total of 9 months of treatment for joint and bone TB is supported by some centers [4,5].

Case Description

A 25-year-old woman presented with complaints of worsening pain in the left knee since three months before hospital admission, accompanied by swelling and movement difficulties (Figure 1).

Additionally, in the following two months, the patient also complained of a fluid-filled lump in the chest. The fluid-filled bump was ruptured, producing...
yellowish fluid and pus. The patient denied any respiratory complaint (coughing, hemoptysis, shortness of breath, and chest pain), night sweat, fever, decreased appetite, and weight loss. The patient sought treatment to an internist since the complaint arose and received 8 mg methylprednisolone twice a day, 500 mg calcium carbonate daily, and a capsule of drug combination daily. The patient worked as a salesperson at a souvenir shopping center in Bali. She was a passive smoker. Physical examination revealed swelling and pain during movement on the left knee. Left knee X-Ray showed an impression of joint effusion, soft tissue swelling, and localized osteopenia on the tibial lateral condyle (figure 2).

Chest x-ray examination showed no abnormality. Laboratory tests revealed leukocytosis, increased C-Reactive Protein, and increased erythrocyte sedimentation rate, with negative Rheumatoid Factors (Qualitative RF). Ultrasonography examination found complex joint effusion in the medial compartment of the left knee and left suprapatellar recess with possible synovitis and internal hematoma as well as mild left medial meniscus extrusion. Magnetic Resonance Imaging suggested osteomyelitis in the proximal tibia and distal femur accompanied by Brodie abscess in the medial tibial condyle and septic arthritis. Magnetic Resonance Imaging suggested osteomyelitis in the proximal tibia and distal femur accompanied by Brodie abscess in the medial tibial condyle and septic arthritis. Enhanced chest CT supported mediastinitis appearance on the right superior mediastinum. Excisional biopsy on the left knee showed granulomatous presence, which is consistent with tuberculosis, while synovial fluid was positive on PCR TB. The patient was treated with first line antituberculosis drugs for nine months and followed up clinically.

Figure 1. Patient’s clinical appearance showed swelling and asymmetry on the left knee seen from anterior posterior (A) and lateral (B).

Figure 2. X-Ray (A) anterior posterior and (B) lateral view of the left knee showed an impression of joint effusion, soft tissue swelling, and localized osteopenia on the tibial lateral condyle.
Discussion

Lungs are the central location for TB infection, while skin, digestive tract, tonsil, and placenta are other less common sites for primary TB. Regarding TB arthritis, most infections are due to secondary hematogenous spread via vessels from the primary site. In peripheral diarthrodial TB arthritis, disease originates from adjacent TB osteomyelitis which erodes into the joint space or from direct range to the synovium through the bloodstream resulting in inflammation with edema, muscle spasms, and limited movements. Granulation tissue may cause effusion and pannus formation, which ultimately causes damage to the cartilage. It starts from the edge of the joint eroding into the subchondral cancellous bone, interfering nutrient intake, and loosening the attachment of cartilage to the underlying bone [6]. Severe bone damage can occur following demineralization and necrosis. Cartilage erosion triggers severe muscle spasms with limited joint movement. Imaging in advanced stage shows reduced joint space which is often known as TB arthritis or TB osteoarthritis [4,5,7]. Following this stage, spontaneous para-articular abscesses and external fistula formation occur. The course of tuberculosis synovitis is very typical, and the development of joint damage in TB is much slower than pyogenic infection because mycobacteria do not produce collagenase.

Some conditions have been associated with TB as high-risk factors such as certain socioeconomic classes, immunocompromised hosts, and disturbances in local joints and bone tissue factors. People who use corticosteroid therapy can also be considered as immunocompromised [8]. Other elements of local joints and bone tissue also contribute to the occurrence of TB arthritis. These factors include surgical trauma, intravenous drug usage, and pre-existing joint or bone disease [9]. The patient, in this case, had prolonged use of corticosteroid (methylprednisolone) therapy and osteomyelitis infection (based on MRI) so that the patient became an immunocompromised host, making her more susceptible to TB arthritis. Hips and knees are the most common sites of TB arthritis. Poly/oligoarticular presentation is rare. However, these types should be considered in immunocompromised patients, patients in close contact with TB patients, elder, patients using corticosteroids, or post trauma patients. The early presentations of TB joint are swelling (20%), stiffness (10%), and weakness or limitation of movement. The bones are usually warm and sometimes characterized by thigh muscle atrophy. Synovial hypertrophy and effusion occur in most patients. Muscle cramps and synovial effusion can cause flexion deformity. As the disease progresses, articular cartilage damage occurs coupled with decreased joint space that can lead to its narrowing and irregularity of the cartilage surface. Worsening left knee pain along with swelling and movement difficulties in this patient mimic the symptoms of rheumatoid arthritis, leading to corticosteroid therapy.

Histopathology and microbiology technique remain the gold standards for the diagnosis of TB arthritis and osteomyelitis. Tissue biopsy of representative lesions is the fastest method, one of which is synovial biopsy with more than 90% accuracy. In contrary, synovial fluid smear for TB is positive in only 20-40% cases, while culture can produce positive results in up to 80% cases. Analysis of synovial fluid shows unspecific findings of inflammation, even deficient glucose levels support the diagnosis [10]. Typical radiographic images of TB arthritis are called Phemister triads, characterized by juxta-articular osteoporosis, osseous erosion located at the edges, and gradual narrowing of the joint space. This is different from rheumatoid arthritis and pyogenic arthritis, where joint space narrowing occurs at the beginning of the disease.

The multidrug administration is mandatory because TB bacilli quickly develop into drug-resistant bacilli with different growth patterns between TB bacilli in the same TB location. It is complicated for the TB bacilli to become resistant if two or more drugs are used in combination. The challenge of initial drug resistance can be ignored in TB arthritis due to its small number of microorganisms (10^5-10^6). The optimal duration of therapy for extrapulmonary TB, including TB arthritis, remains unclear. The latest recommendation is nine months of treatment to prevent disability. Second-line drugs are only used for the treatment of TB that is resistant to first-line drugs. TB arthritis treatment outcome is evaluated only by the clinical method. This patient was given first-line drug treatment in the form of 3 fixed-drug combinations (FDC) daily for two months in the intensive phase according to the patient’s body weight and was planned to be continued with an
awkward stage for seven months (total of at least nine months). This regimen was by recommendations for joints and bones TB.

Occasionally, surgical intervention is needed with clear indications, such as diagnostic interventions (synovial biopsy or lesions), inadequate response to drug therapy, adequate joint lavage or arthroscopic drainage, bone debridement, aspiration or even drainage (in case of abscess) [6]. As a common rule, multidrug therapy is required for four weeks to stabilize the general condition of the patient before the surgery is performed. At the beginning of the treatment, immobilization can be helpful to eliminate pain and prevent any deformities.

Conclusions

TB arthritis can occur primarily as subacute or chronic monoarthritis of the weight-bearing joints such as hips, knees, or ankles. Back pain with ‘spooky’ clinical features is another general presentation. The diagnosis of TB arthritis requires standard microbiological or histopathological confirmation. Synovial biopsy (or other affected tissue) remains as the gold standard for TB arthritis diagnosis. TB multidrug treatment is not recommended without a confirmed TB diagnosis.

Peritoneal Tuberculosis as a Final Result of Diagnostic Conundrum: A Case Report

Ananda Febriani Aulia1, Azizman Saad2, Zarfiardy Aksa Fauzi2, Ari Hidayat3, Yenni Oktavia4, Wiwit Ade Fidiawati5

1Resident, 2Assistant Professor, Department of Pulmonology and Respiratory Medicine, Faculty of Medicine, University of Riau - Arifin Achmad General Hospital, Pekanbaru 28133, Indonesia, 3Assistant Professor, Department of Obstetrics and Gynecology, Arifin Achmad General Hospital, Pekanbaru 28156, Indonesia, 4Lecturer, Department of Radiology, Arifin Achmad General Hospital, Pekanbaru 28156, Indonesia, 5Lecturer, Department of Anatomical Pathology, Arifin Achmad General Hospital, Pekanbaru 28156, Indonesia

Abstract
Peritoneal tuberculosis is a disease which can mimic malignancy especially in women present with ascites and elevated CA125 levels. It always should be considered in the differential diagnosis. Peritoneal tuberculosis with ambiguous patient symptoms and diagnostic difficulties still poses a great challenge in clinical practice. A 33 years old woman was admitted to hospital with complaints of abdominal pain and shortness of breath. Initially, elevated serum antigen CA-125, ascites, pleural effusion, and multiple suspicious nodules in the lungs and abdominal cavity on CT were found, thus, diagnosing advance stage ovarian cancer. Biopsy laparotomy was performed, and post-operative histological examination was peritoneal tuberculosis. The patient was treated with first-line antituberculosis agents and discharged home. Almost in all other cases, peritoneal tuberculosis is diagnosed only after surgical intervention.

Keywords: ascites, pleural effusion, ovarian cancer, peritoneal tuberculosis, CA125

Introduction
Diagnosis of extrapulmonary tuberculosis is difficult. Tuberculous peritonitis, accounting for 1%-2% of all tuberculosis cases, is caused by abdominal or pelvic tuberculosis that involves the peritoneum (1). The postulated mechanism is tubercular bacilli reaching the peritoneal cavity via the bloodstream or by direct spread from the contiguous infected small intestine, lymph nodes, and fallopian tubes (2). Patients usually have nonspecific symptoms and signs, such as abdominal pain, abdominal distension, and poor appetite. The serum cancer antigen (CA)-125 can be elevated in both ovarian cancer and peritoneal tuberculosis. Similar clinical and image findings lead to diagnostic difficulty and the challenge of distinguishing these two disease entities.

Case Report
A 33-year-old nulliparous woman was admitted to hospital with a two-month history of tenderness in the abdomen who referred from another center to us with reported ascites in ultrasonography and elevated CA-125. She had fevers, chills, or night sweats and weight loss. The significant patients past medical history were only abortion five months ago. Her positive physical findings were limited to her abdomen, which was grossly distended, and although no masses were palpable, ascites was present. On pelvic examination, the cervix and vaginal walls were without gross lesions, and the adnexa and uterus were not palpable secondary to the ascites. Primary ovarian malignancy was suspected, and the patient was referred to the gyne-oncology clinic.
Laboratory showed a normal white cell count, a haemoglobin of 12.02 g/dL and elevated CA-125 to 460.78 U/mL (normal range, <35 U/mL), CEA level 0.39 (normal range: 0–3.0 ng/mL), B-HCG level < 2 (normal range 0-5). Abdominal sonography revealed ascites, and no mass were found. Abdominopelvic CT revealed ascites, subdiaphragmatic nodules, enlarged parailiaca lymph nodes, and adnexa mass (figure 1). The liver, spleen, and kidneys appeared within normal limits. A few days later she developed left pleural effusion, and a chest tube was inserted (figure 2). Pleural fluid was negative for AFB and malignancy. Chest CT showed multiple subcentimeter nodules as well as a ‘tree in bud’ appearance throughout the lung parenchyma. Sputum analysis did not reveal any mycobacteria. The ascitic volume decreased but became denser. The patient then agreed to diagnostic laparoscopy. At laparoscopy, the peritoneal cavity was difficult to enter with thick adhesions and miliary seedlings (figure 3).

No intraabdominal mass was seen. Frozen section facilities were not available; however, biopsies were taken for tissue diagnosis, leaving the uterus and ovaries intact. Histology revealed caseating granulomas with epithelioid and Langhan’s type of giant cells (figure 4). The final diagnosis from the biopsy was peritoneal tuberculosis. Symptoms resolved, and the CA125 levels normalized after two months of antituberculosis therapy. She is to continue her treatment for a total of 6 months.

Figure 1. CT Abdominopelvic showed ascites, subdiaphragmatic nodules, enlarged parailiaca lymph nodes and adnexa mass at anterior posterior (A); lateral (B).
Figure 2. Chest CT showed pleural effusion and multiple subcentimeter nodules as well as a ‘tree in bud’ appearance throughout the lung parenchyma (A & B).

Figure 3. Intraoperative findings Miliary seedlings on peritoneum and serosal surface of bowel with dense adhesions.
Figure 4. Histopathology showed granulomatous inflammation - caseating granulomas with epithelioid and Langhan’s type giant cells.

Discussion

The diagnosis of any extrapulmonary forms of TB is especially difficult, particularly for the peritoneal type as the symptoms and physical findings of the disease do not substantiate the diagnosis. Diagnostic delays and delayed initiation of treatment can lead to high morbidity and mortality rates (3). The signs and symptoms typically associated with advanced ovarian carcinoma include abdominal distension, ascites, and pelvic or adnexal masses (4). Many of these women go on to have radical surgery due to the difficulty of definitive preoperative diagnosis of ovarian cancer and the low negative predictive value of ascitic fluid cytology (5).

Abdominal tuberculosis can present with a similar clinical scenario, with most cases diagnosed incidentally at laparotomy. This has often led to unnecessary extensive surgery, frequently in women of reproductive age (5, 6). CA125 lacks specificity, elevated in many conditions, including tuberculosis (7). One study showed that CA125 titers higher than 1,000 U/ml correlated with malignancy (8). However there was a reported case of peritoneal tuberculosis with a CA125 level of 1,081 U/ml (9). This means that absolute CA125 levels are not definitive in determining malignant versus nonmalignant causes. Although CA125 levels are useful in monitoring response to therapy in ovarian carcinoma, there has been no report of CA125 levels declining without treatment in malignant conditions (10). Chest radiographs can be normal in patients with peritoneal tuberculosis, approximately 40% of the time (11).

Abdominal CT in tuberculous peritonitis typically shows smooth, strongly enhancing peritoneal thickening and a dirty omentum. Peritoneal carcinomatosis, however, commonly shows nodular peritoneal thickening and a nodular or caked omentum. Other findings that suggest a diagnosis of tuberculosis include dense ascites, caseous nodes and soft-tissue mesenteric and omental infiltration (12). There are high false negative rates for tuberculosis skin tests and AFB detection in pleural and peritoneal fluid (13). For preoperative detection of tuberculosis, ascitic fluid adenosine deaminase (ADA) and PCR
analyses have proven to be useful. However, these tests may not be available in all settings (14).

The determination of ADA in peritoneal fluid is also helpful for TB diagnosis. This enzyme involves the conversion of adenosine to inosine in the catabolism of purines, and its levels are elevated in peritoneal TB due to stimulation of T-lymphocytes by the immune response to antigens of mycobacterial cells. The estimation of ADA levels in ascitic fluid have 98% specificity, 96% sensitivity, 88% negative predictive value, and a high positive predictive value of 95% (15). Levels more than 40 units per liter are indicative of tuberculosis (16). Ultrasound-guided trucut biopsy has also been shown to be a valuable first-line approach. All investigations for diagnosing peritoneal tuberculosis have proven to be inconclusive only histopathologic investigation is confirmatory. Diagnostic laparoscopy or laparotomy is usually necessary however, for definitive diagnosis, where intraoperative frozen sections can aid in avoiding unnecessary extensive surgery.

**Conclusion**

By the information given in this case report, one can understand that peritoneal tuberculosis can often mimic advanced ovarian cancer and peritoneal carcinomatosis. It should always be considered in the differential diagnosis, but the diagnosis is rarely easy for clinicians. True diagnosis and then correct and careful follow-up can save the patient’s life, and doctors should start the treatment as soon as possible.

The Relation between Exercise Duration and Intensity on Phosphocreatine (PCr) Level: an Article Review

Aprilia Durotun Nasikhah¹, Roy Januardi Irawan², Trias Mahmudiono³

¹Bachelor of Nutrition, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, ²Doctoral of Public Health, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, ³Health Nutrition Department, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

Abstract

Exercise is a physical activity that planned, structured, and sustainable. Exercise has 4 criteria, that is frequency, intensity, type, and duration. During exercise, phosphocreatine (PCr) depletion increases, and early intracellular acidosis has occurred. These changes contribute to a decrease in training capacity in terms of training duration. This literature review aimed to determine the relationship between the intensity and duration of exercise with the concentration of PCr and recovery factors. The literature study has carried out by selecting an Experiment research design. The results of the review showed that PCr was the largest energy contributor in the first 10 seconds of exercise in the heavy-intensity exercise where phosphocreatine triggers energy without oxygen or anaerobic. The recovery of PCr influenced by a person’s health condition and age. The concentration of PCr in children was higher than in adults because of the relatively high rate of oxidative ATP formation. It proved that there was a significant relationship between PCr and the duration and intensity of exercise.

Keywords: Exercise duration, Exercise intensity, PCr, Phosphocreatine

Introduction

Health is considerable for humans. Everyone must be healthy to maintain physical fitness so that they can carry out daily activities. According to the Indonesian Law No. 23 of 1992 concerning health states that health is a state of well-being of body, soul, and society which enables everyone to live productively socially and economically(1). Health can be pursued in various ways, one of which is by exercising.

Exercise is a physical activity that has planned, structured, and continuous by involving regular and repeated body movements to improve physical fitness and achievement(2). Exercise is useful for maintaining and increasing mobility and independence to move in human bio-psycho-sociologic life(3). Exercise has four criteria, that is frequency, intensity, type, and duration(4).

Exercise can stimulate the disruption of homeostasis and change the physical and chemical environment of cells. Exercise can cause body temperature to increase, increase blood acidity, decrease oxygen in fluids, and increase CO2. Environmental changes in the body start at the receptors, namely body cells that will stimulate complex response pathways. This pathway causes changes in nerve activity (nerve pathways), hormonal changes (hormonal pathways), and exchanges in specific pathways (intrinsic pathways). Also, chemical, mechanical and thermal stimuli affect changes in metabolic, cardiovascular, and ventilator functions to meet increased demand(5).

Exercises of longer duration (2-3 minutes) that rely primarily on oxidative metabolisms, such as swimming and long-distance running, are classified as aerobic activities. Many sports activities require a combination of anaerobic and aerobic metabolism. In stop and go sports, about 60% -70% of energy comes from ATP storage from phosphocreatine (PCr) and anaerobic glycolysis, the remaining 30% from oxidative processes(6).

Phosphocreatine (PCr) is a high-energy compound that has a high-energy phosphate bond that can be hydrolyzed into energy and can resist ATP. In physical activity or strenuous exercise such as sprinting, PCr in the skeletal muscles makes a big contribution for the first 10 seconds. The storage of PCr will quickly run out but, in the first few seconds of exercise, PCr provides a significant buffer before other aspects of metabolism are activated\(^7\).

During exercise, physical activity, or exercise, PCr depletion increases, and early intracellular acidosis has occurred. These changes contribute to a decrease in training capacity related to exercise duration\(^8\).

**Material and Method**

This study used a literature review method. The article search strategy has carried out by using international or national journal articles that were searched through Google Scholar and PubMed. Through the keywords searched were exercise duration, exercise intensity, phosphocreatine, and PCr, from Google Scholar website founded 31 articles of search results and on the PubMed website as many as 13 articles. Then, screening has carried out by selecting articles that were relevant to the topic, namely the effect of exercise duration on phosphocreatine (PCr) levels. The articles selected were articles with inclusion criteria using Experiment research methods. The exclusion criteria in this literature review were articles that were not related to the topic of the effect of exercise duration and intensity on phosphocreatine levels.

**Results and Discussion**

Various types of sports can be an option to maintain body fitness. However, it is considerable to note in planning exercise activities that at least four criteria are met, namely the frequency of exercise, intensity/weight of exercise, type of sports activity, and length of time exercising\(^4\). In sports, various kinds of metabolism will produce different types of waste products, one of which is creatinine.

Creatinine is a chemical waste molecule that results from muscle metabolism. Creatinine has produced from creatine, a molecule that is essential for energy production in muscles. About 2% of keratin in the body is converted to creatinine every day. Creatinine
is transported through the bloodstream to the kidneys. Creatinine levels are determined by the amount of muscle mass (protein catabolism rate), in addition to how our body’s metabolic activity, for example, increases when we are sick (heat/infection). Creatinine is produced during skeletal muscle contraction through the breakdown of creatinine phosphate\(^9\).

Muscles use phosphocreatine during the first few seconds of intense muscle contraction, such as during weight lifting or sprinting. Unlike aerobic contraction, which utilizes oxygen to produce energy, phosphocreatine triggers energy without oxygen or is anaerobic\(^10\).

Bogdanis et al. stated that aerobic metabolism provides a significant part (~ 49%) of energy during the second sprint, whereas PCr availability is important for high power output during the initial 10 s\(^11\). This is supported by the statement of Hall and Trojan that creatine monohydrate can improve muscle performance in a short duration, and high-intensity resistance training will rely on the transport of phosphocreatine to become adenosine triphosphate so that an increase in the level of total creatine in cells will allow for the faster synthesis of phosphocreatine\(^10\). Increasing the creatine level in the body can delay fatigue because creatine can be re-synthesized and sent back to the site of ATP use more quickly\(^12\). Fatigue during short-term high-intensity exercise is related to the availability of PCr because PCr can regenerate ATP at very high rates, and its concentration in muscle is limited\(^13\).

The energy at the start of a workout or exercise that uses very high-intensity muscle work (85% -100% of maximum capacity) and has a short duration (up to 10 seconds) has determined from the small amounts of ATP and PCr stored in muscle cells \(^5,11\). The total energy available in the stored ATP-PCr is sufficient for short duration exercises, such as lifting weights, high jumps, or 10-second sprints\(^14\).

The amount of energy generated from the PCr has limited because of the intramuscular pathway. The high anaerobic demands on the muscles can decrease muscle PCr concentration. At the same time, in a short period of maximum exercise, the anaerobic utilization of muscle PCr and glycogen will trigger muscle contraction\(^15\). Short-term contractions are associated with metabolic changes in the muscle so as decreased muscle phosphocreatine\(^16\).

According to Haseler, Hogan, and Richardson, in skeletal muscle, PCr recovery from submaximal exercise is a measure of muscle-oxidative capacity. PCr recovery was significantly altered by FIO2 and after submaximal exercise, in normoxic conditions, PCr recovery was limited by O2 availability\(^17\). Also, The PCr recovery time constant is prolonged in patients with the symptomatic peripheral arterial disease (PAD), whether differences in PCr recovery time result entirely from changes in tissue blood flow, alterations in skeletal muscle at a cellular level, or a combination of both deserves further investigation\(^18\).

In patients with PAD symptoms, the PCr recovery time constant is longer than that of ordinary people, so it is recommended for PAD sufferers to do sports with a long duration of intensity\(^19\). Also, there is the notion that phosphate regulation and muscle O2 utilization is fully mature in peri-pubertal children, which may be due to the comparable capacity for mitochondrial oxidative phosphorylation in child and adult muscles\(^19\). The relatively higher rate of oxidative ATP build-up in children’s muscles to mask the ATP demand from high-intensity intermittent exercise compared to adults, allows children to start each exercise interval with a much higher concentration of PCr and lead to more muscle acidification. Low overall\(^20\).

**Conclusion**

From the review above, it can conclude that PCr has a significant relationship with exercise duration and intensity. PCr is the largest energy contributor in the first 10 seconds of exercise in a heavy-intensity exercise where phosphocreatine triggers energy without oxygen or anaerobic, so with an increase in creatine phosphate capacity, very high-intensity exercise performance can be improved. PCr concentration is not only influenced by the duration and intensity of exercise, but also by health conditions and age.

Abstract

To analyze the effect of mixed liquor administration on the Johnsen’s score and the number of Sertoli cells and Leydig cells on the Wistar strain white rats (*Rattus norvegicus*). A total of 28 rats were divided into 4 groups: C, P1, P2, and P3. Rats were given mixed liquor with different dose, namely P1 (1 ml), P2 (2 ml), and P3 (4 ml) each day for 14 days, then compared to C group which was given 4 ml of distilled water using an oral gavage. Mixed liquor consists of 20% ethanol and 4% methanol. The histopathological features were evaluated by the Johnsen’s score, the number of Sertoli cells, and Leydig cells in cross-sectional preparation of rat testicular tissue with 400× magnification. Data were analyzed using the Kruskal-Wallis test and One-Way ANOVA test with a confidence level of \( p < 0.05 \). The P3 group had the lowest Johnsen’s score and the number of Sertoli cells, 6.442±0.293 and 5.942±0.674, respectively. A significant decrease in increased dose occurred in the Sertoli cell count but not in the Johnsen’s score. Group P2 had the lowest number of Leydig cells, 6.421±0.360. The administration of mixed liquor caused a decrease in Johnsen’s score and the number of Sertoli cells and Leydig cells on the Wistar strain white rat (*Rattus norvegicus*).

Keywords: mixed liquor, spermatogenic cells, Sertoli cells, Leydig cells.

Introduction

Alcoholic drinks or liquor are drinks that contain ethyl alcohol or ethanol (C\(_2\)H\(_5\)OH) which are known to cause addiction.[1] Addiction that is satisfied continuously will cause a tolerance effect, that is a desire to increase the dose in order to get the same effect. [1,2] This type of mixed alcoholic drink is often called mixed liquor or *miras oplosan* in Indonesian. Ethanol, which is commonly consumed has negative effect on the male reproductive organs and is associated with several incidence of infertility. [3,4] A study by Fauziah proves that *arak bali*, Balinese wine can reduce the number of spermatogenic cells and the size of the seminiferous tubules of mice. [5] In another study by Antari, *arak bali* also had an impact on lowering the quality of spermatozoa and testosterone levels. [6]

Methanol is one of the substances that is often added because it is effective to increase the effect of drunk. [7] Mixed liquor containing methanol is also reported to cause some death in several areas in Indonesia.[8,9] Ethanol is known to have an effect on male infertility, so the addition of methanol to mixed liquor may have more impact on male reproductive organs. [3,4,10]

Apart from the substance themselves, cell damage is also caused by metabolites of these substances. [11-14] The transformation of ethanol into acetaldehyde and free radicals is known to occur directly in the testes. [15,16] Cell damage by ethanol and methanol occurs due to increased levels of ROS, decreased GSH levels, and
decreased ATP synthesis.\textsuperscript{11-13} Therefore, this study aims to analyze the effect of mixed liquor administration on the Johnsen’s score and the number of Sertoli cells and Leydig cells on the Wistar strain white rats (\textit{Rattus norvegicus}).

\section*{Materials and Methods}

This study is an experimental laboratory study with post-test only control group design. This study used 28 male Wistar rats (\textit{Rattus norvegicus}) which were divided into four groups. The treatment given was administration of mixed liquor with an oral gavage for 14 days to determine its effect on the histopathological features of rats’ testes.

Mixed liquor was given at different doses in each group, namely 1 ml (P1), 2 ml (P2), and 4 ml (P3). The composition of mixed liquor was 20\% ethanol and 4\% methanol. The composition was determined based on the results of gas chromatography tests of mixed liquor samples.\textsuperscript{17} This study used 28 rats in each group, so the total volume of mixed liquor to be prepared for 14 days was $14 \times [7 (1 + 2 + 4)] = 686$ ml. 1000 ml of mixed liquor was made to simplify calculations and anticipate spills. The mixed liquor was made by mixing 208.3 ml of 96\% ethanol, 40.81 ml of 98\% methanol, and 750.89 ml of distilled water. Assessment of the histopathological features was carried out by identifying spermatogenic cells, Sertoli cells, and Leydig cells referring to Pintus et al.\textsuperscript{18} The data was analyzed by statistical software product and service solution 20 for Windows (SPSS 20).

\section*{Results and Discussion}

The samples of this study were 28 adult male rats with 7 rats in each group. Observation of spermatogenic cells, Sertoli cells, and Leydig cells were made on both testes, so that each rat produced two data which were then averaged. The analysis was performed on 28 datas. The data of Johnnsen’s score was an ordinal data, so non-parametric test (Kruskal-Wallis) was chosen. The result showed that the data of Johnnsen’s score had significant difference ($p = 0.000$). Therefore, the analysis was continued with Mann-Whitney test.

*p <0.05, significantly different by statistic

The Mann-Whitney test showed that the Johnsen’s score of the control group (C) was significantly higher than
the group receiving mixed liquor with different doses: 1 ml (P1), 2 ml (P2), and 4 ml (P3) with the value of $p=0.002$ on each compared group. So, all of the treatment groups (P1, P2, and P3) had significant reduction in Johnsen’s score compared to the control group. Besides, the significant reduction was also found in the increasing dose from P1 group to P3 group (7.550 vs 6.442; 0.002); and from P2 group to P3 group (7.478 vs 6.442; 0.002), but there was no significant reduction from the P1 group to P2 group (7.550 vs 7.478; 0.301).

The data normality of the number of Sertoli cells was tested by Shapiro-Wilk test; the result showed that each group was normally distributed ($p>0.05$). The analysis was continued by the One-Way ANOVA test and showed a significant difference in the number of Sertoli cells ($p=0.000$). The homogeneity test was also conducted to determine the selection of the post-hoc test method; the result showed that the data was homogeneous. Therefore, the analysis was continued with the post-hoc test.

The post-hoc test showed that the number of Sertoli cells of the control group (C) was significantly higher than the group receiving mixed liquor with different doses with the value of $p=0.000$ on each compared group. So, all of the treatment groups (P1, P2, and P3) had significant reduction in the number of Sertoli cells compared to the control group (C). Besides, the significant reduction was also found in the increasing dose from P1 group to P2 group (9.657 vs 7.557; 0.000); from P1 group to P3 group (9.657 vs 5.942; 0.000); and from P2 group to P3 group (7.557 vs 5.942; 0.000).

The data normality of the number of Leydig cells was tested by Shapiro-Wilk test; the result showed that the control group (C) was not normally distributed ($p=0.006$) and the remaining groups were normally distributed ($p>0.05$). The analysis was continued by the non-parametric test (Kruskal-Wallis) and showed a significant difference in the number of Leydig cells ($p<0.05$). Therefore, the analysis was continued with the Mann-Whitney test.

The Mann-Whitney test showed that the number of Leydig cells of the control group (C) was significantly higher than the group receiving mixed liquor with different doses with the value of $p=0.002$ on each compared group. So, all of the treatment groups (P1, P2, and P3) had significant reduction in the number of Leydig cells compared to the control group (C). But, there were no significant difference in the increasing dose between P1 group and P2 group (6.907 vs 6.421; 0.083); and between P1 group and P3 group (6.907 vs 7.150; 0.442). There was significant difference between P2 group and P3 group (6.421 vs 7.150; 0.025) but P3 group was higher than P2 group and also P1 group.
The study showed that there was a significant decrease of the Johnsen’s score in the treatment group (P1, P2, and P3) compared to the control group (C) \((p < 0.05)\). It means that mixed liquor administration can reduce spermatogenesis activity and the number of spermatogenic cells, as evidenced by a decrease in the Johnsen’s score at the increasing doses.\(^{[19]}\) Increasing dose of mixed liquor can increase the testicular damage of rats.\(^{[20]}\) This study found that there was no significant decrease in the Johnsen’s score from the P1 to P2 group. In addition, the spermatogenic cells were still not protected by antioxidants from the toxic effects of ethanol.\(^{[21]}\)

The decrease in the number of Sertoli cells per tubule in the increasing of dose was found to be significant \((p < 0.05)\). These result is in line with a study by Figueiro et al. that there was a significant decrease in the number of Sertoli cells in all treatment groups of mice that were given ethanol.\(^{[22]}\) The Sertoli cells are part of the testicular blood barrier (BTB), which separate the basal compartment and the adluminal compartment.\(^{[23]}\) BTB is a collection of protein structures consisting of several types of cellular junctions.\(^{[23]}\) The testes are organs that are susceptible to alcohol because alcohol can penetrate the BTB.\(^{[24]}\) This can occur because the structural proteins that make up the tight junction are interfered due to alcohol.\(^{[25]}\)

This study found a significant decrease in the number of Leydig cells on the treatment group (P1, P2, and P3) against the control group (C) \((p < 0.05)\), while there was no significant decrease \((p > 0.05)\) between treatment groups (P1, P2, and P3) as the dose increased. Several studies showed that there was a decrease in testosterone levels in the ethanol-treated group.\(^{[20,21]}\) A decrease in testosterone levels was followed by an increase in LH levels after ethanol administration for 4 weeks as a compensatory feedback.\(^{[21,26]}\) In this study, there was a decrease in the number of Leydig cells from P1 to P2 group. Moreover, the P3 group had a higher number of Leydig cells than the P1 group. It might be due to increase in LH level that stimulates Leydig cell progenitor proliferation.\(^{[27]}\)
Conclusion

The administration of mixed liquor caused a decrease in Johnsen’s score and the number of Sertoli cells and Leydig cells of the Wistar strain white rat (Rattus norvegicus).

Conflict of Interest: The authors declare that they have no conflict of interest.

Abstract
Indonesia has abundant medicinal plants, which have been historically used by the population in treating diseases for generations. Traditional Indonesian medicine and the medicinal plants used could lead to the discovery of novel drugs. The mangosteen or Garcinia mangostana L. is a well-known medicinal plant that has been used to treat various diseases worldwide. The pharmacological activities and phytochemical composition of the whole plant of mangosteen have been investigated and identified by scientists in recent decades. Therefore, this study aims to generate the prediction of the biological activity of phytocomponents in mangosteen. In this study, we extracted 18 phytocomponents of mangosteen from PubChem, an open chemistry database at the National Institutes of Health (NIH), USA. Then, we predicted the pharmacokinetic properties and druglike nature of the phytocomponents using the SwissADME web server, Swiss Institute of Bioinformatics, Swiss. Furthermore, PASS (Prediction of Activity Spectra for Substances) web resource has been employed as a strong potential tool to predict the biological activity. In summary, we revealed the biological activity of 18 phytocomponents of the mangosteen. However, further trials, such as in vitro and in vivo evaluation, are needed to prove the validity of these findings.

Keywords: Biological activity, Garcinia mangostana L., in silico.

Introduction
Indonesia has rich sources of natural medicines and traditional medicine preparations that have been used by most of the population for generations[1,2,3]. A direct advantage of traditional medicine formulations to the community is the ease of obtaining them[4]. The demand for plants used as traditional medicine formulations by the community is also increasing because plant-derived medicines have proven to be healthier and do not cause as many side effects as those derived from chemicals. However, a problem with traditional medicine formulations is the lack of adequate knowledge and information about the various types of plants commonly used as ingredients and their methods of use[5,6].

Garcinia mangostana L. or mangosteen appertain to the family of Clusiaceae and genus Garcinia[7]. Garcinia is a large genus that consists of around 400 species originated from Malay Peninsula, East India, and Southeast Asia, including Indonesia. Moreover, based on the morphological and cytological studies, it can be suggested that the mangosteen is originated from Southeast Asia[8]. As a matter of fact, mangosteen is a plant as traditional medicine for hundreds of years worldwide[9].

Furthermore, mangosteen contains bioactive compounds such as xanthones, terpenes, anthocyanins, tannins, phenols, and some vitamins[10,11]. In fact, mangosteen’s pericarp has many important benefits for health[12,13,14]. The main compounds in the content of mangosteen’s pericarp are xanthones[15], such as alpha-mangostin[16], gamma-mangostin[3,17], 8-deoxygartanin, garcinone E, mangostanol[18], beta-mangostin[19], tovophyllin A and B[20],

mangostenin\textsuperscript{[21]}, and mangostenones C, D, and E\textsuperscript{[22]}. The main xanthone derivative is alpha-mangostin, this compound has a variety of pharmacological activities such as antidiabetic\textsuperscript{[23,24]}, antioxidants, and anti-inflammatory\textsuperscript{[12,13,14,25]}. Therefore, this study aims to generate the prediction of the biological activity of phytocomponents in mangosteen.

**Materials and Methods**

**Data retrieval**

We extracted 18 phytocomponents of mangosteen from PubChem, an open chemistry database at the National Institutes of Health (NIH), USA (Table 1). We revealed the Canonical SMILES of the 18 phytocomponents and submitted them to the SwissADME web server for further analysis.

**Pharmacokinetics and drug-likeness predictions**
In the present study, we predicted the pharmacokinetic properties and druglike nature of the phytocomponents using the SwissADME web server, Swiss Institute of Bioinformatics, Swiss. We identified gastrointestinal absorption prediction for the oral drug probability according to the white of the BOILED-Egg\textsuperscript{[26]} and Lipinski parameter for the drug-likeness prediction implemented from Lipinski \textit{et al.} (2001)\textsuperscript{[27]}.

\textbf{Biological activity prediction}

We employed PASS (Prediction of Activity Spectra for Substances) web resource as a strong potential tool to predict the biological activity. This web resource estimates the predicted activity spectrum of a compound as probable activity (Pa) and probable inactivity (Pi) as described by Goel \textit{et al.} (2011)\textsuperscript{[28]} and we used Pa>0.3.

\section*{Results and Discussion}

We successfully revealed pharmacokinetics, drug-likeness, biological activity predictions of the various phytocomponents from \textit{Garcinia mangostana} L. All phytocomponents predicted as high in pharmacokinetics prediction (gastrointestinal absorption), except Garcinone E. In addition, all phytocomponents predicted fulfill all Lipinski rule-of-five. Furthermore, 18 phytocomponents of \textit{Garcinia mangostana} L. predicted as antioxidant, anti-inflammatory, and antineoplastic activity.

In addition, phytochemical screening, based on ethnomedicinal data, is considered as an effective approach for the discovery of new therapeutic agents. The major bioactive secondary metabolites of mangosteen are xanthone derivatives\textsuperscript{[1,4]}. The major constituents from the xanthone fraction in mangosteen were found to be α-mangostin and γ-mangostin\textsuperscript{[4,14]}. More than 60 other xanthones are isolated from its different plant parts of including 3-isomangostin, β-mangostin, gartatin, mangostabin, 1-isomangostin, garcinone B, 9-hydroxycalabaxanthone, mangostanol, mangostinone demethylcalabaxanthone, 8-deoxygartanin, and garcinone D\textsuperscript{[1]}. The majority of investigations are focused on the extraction and structure elucidation of xanthones from the pericarp of mangosteen\textsuperscript{[14]}. Recently, the presence of these compounds in the stem, seed, and heartwood was reported by many authors\textsuperscript{[9,11,19,20,23,24,25]}.

On the other hand, bioinformatics provides more efficient target discovery and validation approaches, thus help to ensure that more drug candidates are successful during the approval process and making it more cost-effective\textsuperscript{[26]}. Notably, the work of Lipinski \textit{et al.} analyzed orally active constituents to describe physicochemical ranges for high probability opportunities to be an oral drug. This called rule-of-five delineated the relationship between pharmacokinetics and physicochemical parameters. Lipinski rule-of-five helps in distinguishing between drug-like and non-drug like molecules. It predicts a high probability of success or failure due to drug-likeness for molecules complying with 2 or more of the following rules, such as molecular mass less than 500 Dalton, high lipophilicity, less than 5 hydrogen bond donors, less than 10 hydrogen bond acceptors, molar refraction should be between 40-130\textsuperscript{[27]}.

In this study, an attempt has been made to investigate a more extensive pharmacological appearance of phytoconstituents by application of PASS web resources. The proposed in silico method extends further to generate novel bioactivities of selected phytochemical leads, related side-effects, and their mechanisms. In addition, the recent version of PASS predicts approximately 3750 pharmacological activities, specific toxicities, biochemical mechanisms of action, and metabolic terms on the basis of the structural formula of drug-like substances with average fidelity ~95%. This might be further validated in vitro as well as in vivo trials\textsuperscript{[28]}. In line with this, the present study revealed the use of PASS for exploring the hidden pharmacological potential of the various phytocomponents from the mangosteen.

\section*{Conclusion}

In summary, we revealed the biological activity of 18 phytocomponents of the mangosteen. However, further trials, such as \textit{in vitro} and \textit{in vivo} evaluation, are needed to prove the validity of these findings.

A Mini-Review of the Medicinal Properties of Okra (Abelmoschus esculentus L.) and Potential Benefit against SARS-CoV-2

Arif Nur Muhammad Ansori
Doctoral Student, Doctoral Program in Veterinary Science, Faculty of Veterinary Medicine, Universitas Airlangga, Surabaya, Indonesia.

Abstract

Indonesia is rich in medicinal plants, where its population has traditionally used them for generations to cure diseases. Traditional medicine and medicinal plants from Indonesia may lead to the discovery of novel drugs. Abelmoschus esculentus L. or okra is well known as a cure for several diseases and is included in various folk medicinal stockpiles. In recent decades, scientists have discovered the phytochemical composition in the whole okra plant, as well as its pharmacological activities. These studies established the therapeutic potential of okra for drug discovery. Therefore, the present review provides a sneak peek of okra’s pharmacology and phytochemistry, also the potential benefit against SARS-CoV-2.

Keywords: Abelmoschus esculentus L., medicinal properties, SARS-CoV-2.

Introduction

Indonesia is encompassed by many vegetations, including tropical rain forests. Additionally, Indonesia is one of the top five countries in the world that has a high plant diversity, including approximately 6,000 medicinal plants. Consequently, Indonesia is rich in medicinal plants that is used by its population to cure many diseases. One of the medicinal plants in Indonesia is Abelmoschus esculentus L. or okra. Okra is also called qiu kui, bendi, lady’s finger, gumbo, dharos, kacang, and bamieh. It is usually cultivated in warm temperate and tropical regions worldwide and belongs to the Malvaceae family.

Okra is a medicinal plant due to the multiple benefits of its seeds, buds, stems, flowers, leaves, and pods in traditional and contemporary medicine. Okra fruits traditionally have been used as aphrodisiac, appetite-stimulant, cooling, and astringent agents. Other uses of okra include treatment of gonorrhea, bladder blockage, urinary discharges, diarrhea, and chronic dysentery. Okra seeds have also been used as fungicide agents, anti-tumor, and anti-cancer. The pharmacological properties of okra, such as antioxidant, anti-inflammatory, immunomodulatory, gastroprotective, neuroprotective, lipid-lowering, anti-cancer, and anti-bacterial properties (Figure 1). Therefore, the present review provides a sneak peek view into okra’s pharmacology and phytochemistry against SARS-CoV-2.

Okra Distribution

The okra plant grows annually up to 1 m. The plant prefers light (sandy), requires clay soils and well-drained moist soil. The plant prefers basic (alkaline), neutral, acidic soils, and it can grow in very alkaline soil. This plant cannot grow in the shade. The flowers are pollinated by bees and insects and are hermaphrodite (with both male and female organs). The flowers of the okra plant bloom approximately from June to October.

Chemical Composition

The main components of okra bast fiber are lignin, hemicellulose, α-cellulose, and the rest are minor in...
The chemical contexture of okra bast fibers, such as 2.7% aqueous extract, 3.9% fatty and waxy matter, 3.4% pectin matter, 7.1% lignin, 15.4% hemicellulose, and 67.5% α-cellulose.

Nutritional Potential of Okra

Ca, Mg, Na, and K are the important elements in okra pods, which contain approximately 17% seeds; the presence of Ni, Mn, Zn, and Fe has also been reported. A fresh okra pods are low in calories, no fat, high in fiber, and many precious nutrients, including approximately 10-20% folate (46-88 g), about 5% of vitamin A, approximately 30% of the recommended levels of vitamin C (16-29 mg), and both okra mesocarp and seeds are good sources of zinc (80 g/g). Flavonol derivatives (3.4 mg/g of seeds) and oligomeric catechins (2.5 mg/g of seeds) are importantly composed of okra seeds. On the other hand, the mesocarp is structured of quercetin derivatives and hydroxycinnamic acid, 0.3 and 0.2 mg/g of skins, respectively. Seeds and pods are composed in phenolic compounds with notable biological properties such as hydroxycinnamic derivatives, catechin oligomers, and quercetin derivatives. These components, along with the high content of glycoproteins, proteins, carbohydrates, and other dietary elements, enhance the importance in the human diet.

Okra’s Benefits for Human Health

Okra is useful for minimizing blood sugar levels, and therefore beneficial in diabetes, owing to the fiber content, along with other nutritional components. Okra contains high fiber and helps to stabilize blood sugar levels by regulating the rate at which sugar is absorbed. Previous studies have reported that okra polysaccharide possesses hypoglycemic activity and anti-complementary in normal mice. Additionally, okra can be used in kidney disease prevention.

The okra pods are high in beta-carotene and vitamin A, which are important for healthy skin and sustaining eyesight. Okra is used to rectify eyesight. Additionally, these types of nutrients also assist in inhibiting skin related problems and eye-associated diseases.

The soluble fiber within okra helps to reduce serum cholesterol. Okra is also loaded with pectin, which can help in reducing high blood cholesterol. Consuming okra is an efficient method for managing the body’s cholesterol level. Okra used to improve heart health.

Okra is a good vegetable for those exhausted and feeling weak. Okra is also used in asthma, irritable bowel lung inflammation, ulcers, and sore throat.

Okra used to treat many digestive system problems. Okra is used to support colon health. The polysaccharides present in okra pods suggested that they help to erase the adhesive between stomach tissue and bacteria, preventing bacteremia. Okra’s polysaccharides are effective at inhibiting the adhesion of Helicobacter pylori. Therefore, okra can create an environment that prevents destructive cultures from flourishing and cleanse our stomach. Okra smoothly moves down the colon, excess water in its path and absorbing toxins.

Mucilage are very rich in okra roots and have a sturdily demulcent action. This mucilage can be used as a plasma replacement. The roots infusion is used in the medication of syphilis. In Nepal, the juice of the roots is used to treat boils, wounds, and cuts. In addition, the leaves furnish an emollient poultice. Then, a decoction of the immature capsules is used as diuretic, emollient, and demulcent. It is used in the medication of dysuria, gonorrhea, and catarrhal infections. The seeds of okra have stimulant properties and anti-spasmodic. On the other hand, infusion of the okra roasted seeds also has specific properties. Based on these numerous beneficial properties, okra may be a viable candidate against the SARS-CoV-2, but we need many confirmatory studies such as in silico, in vitro, and in vivo (Figure 1).
Medicinal plants for a forthcoming cannot bring any cognizance for any antagonistic effects from the utilize of plants. In addition, always seek recommendation from professionals before using a plant medicinally for any of its properties including vulnerary, stimulant, emollient, diuretic, diaphoretic, demulcent, and antispasmodic properties.

**Conclusion**

In summary, prior potency and scientific reports of the medicinal properties of okra identify it as a valuable plant and establish it as a candidate for future development of drugs against SARS-CoV-2.

Identify Population Attitude Towards Osteoporosis and Pharmacists Involvement in Community Education in Makkah, Saudi Arabia: A Cross-Sectional Study

Arwa Fairaq1, Byader Sulimani2, Ghada AlAhmadi2, Nouf Adnan Hijii2, Rahma AlEssa2, Sara AlHarthi2 and Yosra Alhindi1

1Assistant Professor, 2Pharm. D graduate, Department of Clinical Pharmacy, Faculty of Pharmacy, University of Umm Al-Qura, Makkah, Saudi Arabia

Abstract

Introduction: Fracture is the most severe clinical consequence of osteoporosis. Unfortunately, most patients are unaware that they have fragile bones until they fracture the hip, spine, pelvis, or wrist. Thus, increase disability, hospitalization, and so on total health care costs. In Saudi Arabia, many middle-aged and older women were unaware of osteoporosis risk factors with a high prevalence of osteoporosis reported in Saudi Arabia.

Aim: This study’s main objective is to evaluate population awareness about osteoporosis and pharmacist’s involvement in patient education to minimize the risk of osteoporosis in the Makkah region.

Methods: A cross-sectional study was performed using an online survey. A total of 1390 participants completed the questionnaire from 15 February to 15 March 2019.

Results: Only 1.4% of participants had a risk for osteoporosis and got the advice from pharmacists. Significantly, 53.7% had a chance but didn’t get any advice from either physicians or pharmacists.

Conclusion: The results show a low self-awareness level in Makkah’s general population with insufficient involvement of pharmacists in patient education.

Keywords: osteoporosis, pharmacists, fracture, vitamin D deficiency, and calcium

Introduction

Several definitions of osteoporosis have been offered to describe fragility fractures; the process is characterized by low bone mass and microarchitectural deterioration of bone tissue, leading to enhanced bone fragility and increased fracture risk. Fracture is the most severe clinical consequence of osteoporosis. Unfortunately, most patients are unaware that they have fragile bones until they fracture the hip, spine, pelvis, or wrist. Thus increase disability, hospitalization, and so on total health care costs. The diagnosis of osteoporosis can be determined by measuring bone mineral density (BMD). According to The World Health Organization, osteoporosis is diagnosed with a T-score of < -2.5. Non-modifiable risk factors for osteoporosis include female gender and old age. In contrast, modifiable risk factors for osteoporosis have calcium intake, vitamin D deficiency, smoking, alcohol intake, exercise, underlying disease conditions such as rheumatoid arthritis, and systemic lupus erythematosus. Some medications have been reported to increase osteoporosis, such as glucocorticoid treatment, levothyroxine, proton pump inhibitors, and warfarin.

Osteoporosis treatment medications include bisphosphonates, receptor activator of nuclear
factor kappa-B ligand inhibitors, estrogen agonists/antagonists, parathyroid hormone analogs, calcitonin, Bisphosphonate, and Ca and Vit D supplement.\(^\text{6, 14}\).

Available treatment does not always solve the problems as several studies indicated the link between the long-term use of bisphosphonates and the risk of fracture of the femur.\(^\text{15, 16}\)

Osteoporosis is estimated to affect 200 million people worldwide.\(^\text{17}\) However, many studies reported that incidence is varied among populations.\(^\text{18-21}\) It affects 30% of all postmenopausal women in the United States and at least 40% in Europe.\(^\text{22}\) It affects men, as well.\(^\text{23-25}\) In Saudi Arabia, osteoporosis reported prevalence ranges from 30% to 48% in women,\(^\text{26-32}\), and 21% of Saudi men older than 50\(^\text{33}\). Importantly, conducted studies in Riyadh showed a low level of awareness about the disease among Saudis men and women.\(^\text{34, 35}\) Osteoporosis is considered as one of the most important causes of morbidity and mortality in aging women.\(^\text{36}\)

Prevention is better than cure, and awareness about this disease can help in its prevention.\(^\text{37}\) Many studies related to osteoporosis have been conducted in different regions worldwide and pointed out different awareness levels with poor knowledge about this disease in some countries such as UAE, India, and the USA.\(^\text{34, 38-43}\)

Until our knowledge, no previous study has been conducted to assess pharmacists’ involvement in patient education about osteoporosis. Thus, we aim to evaluate population awareness about osteoporosis and pharmacists’ involvement in patients’ education to minimize the risk of osteoporosis in Makkah region.

Methodology

Study design

This is a cross-sectional study with a total of 1390 participants who completed the questionnaire from February 15 to March 25, 2019 within Makkah, Saudi Arabia.

Data collection

The online survey was anonymous, prepared in Arabic-language format. Consent of participants was considered by their submission. The questionnaire had four sections; demographic characteristics and risk factors of osteoporosis, daily food intake habits of participant in relation to bone health, participant attitude towards disease management and involvement of physicians and pharmacist in patient education.

Statistical Analysis

All the variables were analyzed using SPSS Var 23.0 software 2015. Descriptive analyses such as percentages and graphs were used to describe the findings of this study.

Results

Participants included in this study were predominantly female (74%, n=1028). Overall 58% of participants had moderate diet contain dairy products and other calcium sources. Beside 31% had low diet containing dairy products and other calcium sources. However, only 11.9% had high diet contain dairy products and other calcium sources (Figure.1. A). Among our participants, 5% of participants are taking calcium supplements (Figure. 1. B). While 13% are taking vitamin D supplements (Figure. 1. C).

Regarding participants attitude towards osteoporosis and its risk factors, around 87.1% of participants never had check for osteoporosis or monitor level of calcium supplements (Figure. 2. A). Despite 66% had at least one of diseases or medications that may increase the risk of osteoporosis (Figure. 2. B). Specifically, 52.7% of participant had a risk for osteoporosis but didn’t check for diagnosis. Additionally, 7.3% didn’t remember if they ever checked for osteoporosis or not even though they have risk factor (Table. 1).

Finally, only 1.4% of participants had risk for osteoporosis and got the advice from pharmacists. Furthermore, 7.5% listen to advice from a doctor and 2.9% listen from both. Importantly, 53.7% had a risk but didn’t get any advice from either physicians or pharmacist (Table. 2).

Discussion

This questionnaire-based study helps to evaluate the patient attitude towards osteoporosis and pharmacists involvement in patients education to minimizing risk of osteoporosis in Makkah region. Current study indicates
that lifestyle patterns of most participants could increase their risk of osteoporosis. Most of participants 89% had low or intermediate calcium intake compared 60% in previous study conducted in Riyadh. It is very important to maximize calcium daily intake in order to increase bone mass, thereby minimize the risk of fracture and osteoporosis in the future. Furthermore, our data indicate many peoples may suffer from osteoporosis but they didn’t know, as their risk factors suspect potential of osteoporosis disease. Previous study conducted by Al-sharhrani focused on awareness of postmenopausal women.(35) However, this study is more generalized since we included younger women too.

For the first time, this study found low level of pharmacist involvement in patient education about osteoporosis even in patients with some risk factors. Health authorities and pharmacists should have better involvement in patient education about osteoporosis. Efforts should be applied to improve the awareness about the disease and the importance of early follow up and therefore minimize risk factors and cost of osteoporosis management.

Future studies including another research questionnaire that includes pharmacists to take their opinion, may be helpful. As the pharmacist may have good counselling and communication skills but the patient’s response is poor. In that case, increase the awareness of population about the role of pharmacists in community is needed.

**Conclusion**

The results show low self-awareness level in general population in Makkah with poor involvement of pharmacist in patient education.

The Possible Relation between Pityriasis Alba and Intestinal Parasitic Infestation Among Children in Tikrit City, A Case Control Study

Asaf Kamal Asaad Taha¹, Mazin Hamid Ayyash²

¹Scholar Researcher, M.B.Ch.B, Salahuldin General Hospital, Iraq, ²FICMS, Higher Diploma in Laser, Assistant Professor in Dermatoveneriology, Tikrit University College of Medicine, Iraq

Abstract

Background: There is a solid belief stated that the appearance of hypopigmented patches on children face is a sign of their helminthic or parasitic intestinal infestation despite the constant health education about the absence of such relation. Pityriasis Alba (PA) is common benign skin lesion characterized by fine scaly hypopigmented patches (HP) or macules¹ mostly in the face and upper body parts.²⁻⁴ PA may be atopic dermatitis related or endemic PA. PA occurs mostly in 3-16 years old children and accounts of 5% of pediatric population worldwide. Prevalence rate in Iraq is high (38.2%). No specific cause of PA has been identified. Diagnosis of PA depends on the clinical picture and treatment may implicate sunscreen and topical corticosteroids despite its self-limiting privilege. Helminthiasis (worm infestation) is the hosting of parasitic worms after invading humans and other animals necessarily to complete their lifecycle. *Enterobius vermicularis* is the most common helminthic intestinal infestation among children in Iraq. The main complaint of helminthiasis is the perianal itching, especially at bed time. The study aims to determine the relation of intestinal helminths with PA. Study Design: This prospective and a case-control study had consisted of 43 males (53.5%) and females (46.5%) children of 5-15 years of age presented with HP. Results and Discussion: 4 (9.3%) cases presented with *Enterobius vermicularis* given antihelminthic drugs and had their infestation eradicated completely after a week. 39 (90.7%) children presented with no infestation, regarded as control group, and so given placebo treatment. Number and size of HP varied after the 6 weeks of treatment. Although cases shown more numerous (6.0 ± 2.9) HP and larger size (120.0 ± 72.2) than control group (4.9 ± 3.6 and 90.0 ± 58.3 respectively), but the difference was not significant for both groups (cases and control) and between them for both HP number and sizes (p>0.6). Conclusion: There is no enough prove of the relationship between children intestinal parasitic infestation and the appearance of hypopigmented patches.

Keywords: pityriasis alba, erythema streptogenes, pityriasis streptogenes, impetigo furfuracea, pityriasis simplex, parasites, *Enterobius vermicularis*, pinworm, threadworm, seat worm, nematode, roundworm.

Introduction

Pityriasis Alba (PA) is common benign skin lesion or dermatological disorder characterized by the appearance of fine scaly hypopigmented patches (HP) or macules¹ that are most commonly seen in the face, neck, shoulders, trunk,² and to a lesser extent, in extremities²⁻⁴. There are two main (typical) types of pityriasis alba and two atypical types:

1. Atopic Dermatitis Related PA, is mostly related with postinflammatory hypopigmentation. Most of the patients were cases or have a history of atopy, and PA in this case regarded as an atopic dermatitis minor manifestation.

2. Endemic PA, Endemic PA is usually occurring among infants to children of low socioeconomic condition.⁶

3. Pigmented Pityriasis Alba, mostly described as a central darker patch surrounded by a lighter
colored scaly zone of PA. Pigmented PA lesion have a bluish hue in the center that is surrounded by a halo of hypopigmentation.

4. Extensive PA (Progressive Macular Hypomelanosis). The lower part of the trunk is the most common site of involvement symmetrically and usually in a relapsing attitude. Extensive PA patches are widespread and have more persistent course. Lesions aren’t favoring the face. Females are more often affected than males. (7-8)

There is no gender difference for the disease. There is a global distribution of PA, though its prevalence may differ among different countries. The most prevalent countries were Iraq (38.2%), India (31%), Mali (20%), and Egypt (18%); while lower prevalence was in developed countries like United states (5%) and Hong Kong (1%). PA occurs more predominantly in children between the ages of 3-16 years. PA is noninfectious and there is no identified peculiar etiology. Many cases with PA are presented with iron and copper deficiency. Possible triggering factors that may cause PA are deficiency of vitamins & calcium, temperature variations, humidity, excessive sunlight exposure, frequent bathing, usage of harsh detergents and soaps, dry and itching skin, hypopigmentation, worms and parasites, stress, deficiency of copper and atopic diseases and/or a family history of eczema (2-3).

The diagnosis in most cases of pityriasis alba is straightforward and depending on the clinical picture (3). PA most frequently seen as 2 or 3 macules or patches in different stages. Vargas et al described 3 stages of PA:

1. The early stage, also called papular erythematous stage, begins as faint pink to red elevated bordered round to oval macule or patch that may last for weeks. In most cases this erythematous stage may run unnoticed.

2. The next intermediate stage, papular hypochromic stage, or follicular pityriasis alba. The patch is converted into a smooth scaly layer.

3. The final stage, the smooth hypochromic stage presented as a visible, round and hypopigmented macule with mostly well-defined borders. In this stage, the patient usually or his/her parents will seek medical assistance (10).

Telling the patients and/or their parents about the PA benign nature and self-limited course is mandatory. They should be informed about its slow resolution that may exceed a one year (1). Patients can be informed to follow some lifestyle modification with support use of sunscreens, skin moisturizers, and skin hygiene. Topical steroids (low-potency) appear to be more widely prescribed.

**Intestinal Parasites:**

According to the given hypothesis, this study emphasizes on helminthic infestation. Among the most common modes of transmitting these organisms is through contaminated water, food, soil, as well as contact. Helminthiasis (worm infestation) is the hosting of parasitic worms after invading humans and other animals necessarily to complete their lifecycle and either causing clinical manifestation or hide as an asymptomatic carrier status. In third world countries, including Iraq, the majority of helminths infections are associated with poor sanitary facilities, indiscriminate disposal of human waste, inadequacy and lack of quality drinking water. It is also potentiated by poverty and low socioeconomic status. *Enterobius vermicularis* or the so-called pinworm, threadworm, or seatworm, is a nematode (roundworm) that is common in human children transmitted by feco-oral route. It hosts humans only (11).

Night perianal itching grew the suspicion of the worm infestation. Eggs can be recovered using the “Scotch Tape” technique in the morning before a bowel movement. Transparent Scotch Tape is applied directly to the perianal area, and then placed on a microscope slide for examination. Eggs are football shaped and have an outer shell. Infectious larvae are often visible inside the egg. The small adult worms may be seen in a stool test (ova and parasites). Because the eggs are lightweight and highly infectious, it is important for bed linens, towels, and clothing to be washed in hot water to prevent reinfection (5).

**Patients and Methods**

This was a prospective and a case-control study conducted in the department of dermatology of Salahuldin-General Hospital in Tikrit city, Salahuldin province, Iraq. The study was conducted during the
period from Nov 2019 to May 2020. The study targeted children aged between 5 and 15 years. A total of 43 children were enrolled in the study. The intestinal parasite infested attendant children presented with skin hypopigmented patches were regarded as the case group. The non-infested children with PA were the control group. All participants passed a medical examination by a dermatologist and consolidated by taking opinions of two or more dermatologists. Three separated (2-days apart) stool samples were taken for parasitological examination from all the participants. Additionally, stool samples and sticker tapes were taken from PA children with parasitic infestation a week after treatment completion to confirm parasite elimination. No local drug applications, sunblock, or soothing agents were given for HP. Therapy was given to PA patients infected with Enterobius vermicularis with mebendazole (a single 100 mg chew tablet that can be repeated 3 weeks later if infestation had not been eradicated)\(^{(12)}\), while parasite free PA children were given placebo made of starch pills of the same size and shape of the mebendazole tablet, and given to the control group in the same amount and frequency. Both treatment and placebo were well tolerated, and no side effects were complained. All patients were examined for the pityriasis alba at the first visit. After a one week another contact with the patient to evaluate the state of helminthic eradication. After 6 week patients were contacted to observe the changes in skin hypopigmentation. Clinical efficiency of parasite elimination was evaluated one week after the completion of antiparasitic therapy. A positive clinical response included: complete HP disappearance and reduction of intensity, size and/or hue of HP. A negative clinical response included: the absence of visual changes of HP or enlargement of size and hue of HP\(^{(13)}\).

**Results**

The forty-three studied children ages were ranged from 5 to 15 years. Their mean age was 9.2 years (Table 1). It was consisted of 23 (53.5%) males and 20 (46.5%) females. Twenty-eight of them were living in urban districts (65.1%) whereas 15 were living in rural areas (34.9%). The HP presented in different numbers, sizes, and various body regions (Table 2). Four (9.3%) children were shown to have parasitic intestinal infestation, while 39 (90.7%) children with HP were free of infestation. All infesting parasites were the helminths *Enterobius vermicularis* that were symptomatic and had been isolated and observed microscopically (Figure 1).

HP: hypopigmented patch, SD: Standard Deviation, p: probability (p>0.05: not significant), mm: millimeter.

**Discussion**

In Iraq, there is a common belief among society regarding the presence of white patches in the face of the child as a sign of intestinal infestation. Lower than a tenth (9.3%) of children with hypopigmented patch complaining of intestinal parasitic infestation is not enough evidence as a causation for the majority (90.7%) of HP incorporated in the study were found to be free infestation. A near finding was obtained by Vinod et al (2012) whom microscopic examination of the stool shown ova presented in 15.5% of the sample, and concluded no significant relationship between intestinal parasitic infestation and HP (14). Unlike, Osipova (2017) founded 43.4% out of 30 children with HP had helminthic intestinal infestation and concluded a positive significant relationship between infestation and HP (15). Three out of the four infested children in this study were living in rural area. This may be due to the lower hygiene, lower sanitation, habitual longer contact with soil, or eating unclean vegetables or fruits.

Similar to what found by Vinod et al (14) and Toychiev et al (16), the majority of children in this study had HP in the head especially in cheeks (93%), forehead (70%), and in the neck (67%) (14, 16). The study shown those children with intestinal infestation had slightly more numerous HP compared with control group (mean = 6.0 and 4.9 respectively) (Table 4). This difference was not statistically significant (p=0.7642); nor significant was the difference between the number of HP observed after 6 weeks of taking antihelminthic vs placebo treatment (p=0.7718). This was agreeing with Vinod et al (14) whom found a similar non-significant relation; but disagreeing with both Toychiev et al and Osipova. This study shown no significant change in number of HP after 6 weeks of the treatment or placebo for both intestinally infested children (p=1) and control group (p=0.976). This was disagreeing with what was found by Toychiev et al whom declared that 33.3% of children with enterobiasis had complete disappearance of their HP after 6 weeks of treatment and had their parasitic infestation eliminated. It is also disagreeing with Osipova whom founded 69.2%
of cases underwent complete disappearance of their HP after 6 weeks of antihelminthic treatment (compared to 0% in this study (Table 3).

In this study, children with intestinal helminthic infestation shown larger HP size (measured by mean of the summation of diameters of patches for each child) compared with control group (120 and 90 mm respectively) (Table 4). This difference was not statistically significant (p=0.61). Similar insignificant difference was found between case vs control after treatment and placebo (p=0.7566). Although there was some decline in the HP size of the group of cases after treatment (averaged 8.8 mm reduction), it was also statistically not significant (p=0.9044). A lesser (3.2mm) (but also insignificant p=0.9522) decline in the average of HP size of control group after 6 weeks of placebo intake. This decline was observed in 21 (48.84%) (i.e. nearly a half) of the total 43 observations. These finding were disagreeing with Toychiev et al whom founded 20.3% of patients had reduced HP size significantly.

Conclusions

1. Despite the familiarity of the relation between intestinal helminthic infestation and HP among the society, there is no significant relationship between the two.

2. Despite the frequently observed cases of intestinal infestation attending pediatrics consultation as well as children with HP attending dermatology’s one; there is no prove stating the former as an aetiology of the latter.

Abstract

Background/ aim: The kidney excretes waste materials and regulates important metabolic functions, and renal disorders constitute a significant medical problem and can result in fatalities. In the present study, mesenchymal stem cells derived from canine adipose tissue were isolated and evaluated for their ability to improve renal function in a canine model of ischemic renal failure. Materials and Methods: The canine ischemic renal failure model was developed by a traumatic occlusion of the renal artery in 10 dogs. ASCs were administered directly into the renal artery following ischemic renal failure induction. Blood analysis and histological parameters were analyzed. Results: The group treated with ASCs had decreased blood urea nitrogen and creatinine levels, and showed an improving histological manifestation. ASCs were detected around the tubules of these kidneys at the histological level. Conclusion: our findings suggest that ASCs could be an alternative therapeutic agent for canine ischemic renal failure.

Key words: dog, ischemic renal failure, autologous adipose-derived stem cells

Introduction

Acute renal failure (ARF) is a type of kidney disorder where epithelial cells of the renal proximal tubule in the nephron undergo necrosis as a result of ischemia or toxic damage. This leads to sudden decrease in glomerular filtration rate (GFR), which is caused by loss of auto-regulation, tubular obstruction, and increased renal vasoconstriction (¹). In kidney failure, the therapeutic strategies of renal replacement are still more sufficient than those of current hemodialysis (²). The adipose tissue has recently been shown to be involved in the pathophysiology of renal disease and kidney failure (³). The main cause of renal failure in dogs is renal ischemia. Usually renal failure caused by renal nephrotoxic substances, infection, renal ischemia, inflammation, shock or hypovolaemia and obstruction of urinary tract by calculi, strictures or tumors (⁴,⁵). Adipose-derived stem cells (ASCs) are confirmed as a source of multipotent stem cells that can be differentiated into osteogenic, chondrogenic, myogenic, and adipogenic cells in the presence of lineage-specific induction factors in vitro (⁶). The major cause is tubular necrosis as a consequence of ischemic renal injury after episodes of hypotension or surgical vascular clamping (⁷). The pathogenic incidents in ischemia/reperfusion damage include apoptosis and acute tubular necrosis, glomerular damage, and inflammation. Healing of inflammatory and ischemic renal injury include mesangial, epithelial and endothelial, regeneration (⁸). Mesenchymal stem cells have the ability to divide, generate and differentiate, which at last is part of either an adult or embryonic tissue (⁹). It has tremendous
potential for the evolution of therapies at the future (10). Mesenchymal stem cells can secrete growth factors and cytokines such as vascular endothelial growth factor (VEGF), insulin like growth factor-1 (IGF-1), hepatocyte growth factor (HGF) and anti-apoptotic cytokines which have capability to diminish the fibrosis of tissues through regeneration and play a role in tissue repair (11, 12). MSCs have capability to differentiate into three types of cells such as chondrocyte, osteocytes, and adipocytes. Mesenchymal stem cells are immunosuppressive and non-immunogenic, and have the capability to migrate to sites of damaged tissue and inflammation to share in tissue healing (10, 13).

Adipose tissue is a more eligible source because of its plenty and rapid expansion rate in culture. Subcutaneous adipose tissue usually composed of mature adipocytes and a heterogeneous stromal vascular fraction which involve fibroblasts, pre-adipocytes, endothelial cells, vascular smooth muscle cells, monocytes, lymphocytes and adipose stem cells. Adipose stem cells are promising candidates for cellular therapy in regenerative medicine due to its properties such as anti-inflammatory, anti-apoptotic, proangiogenic, anti-scarring and immunomodulatory effects (14). Angiogenesis based on the pathology of ischemic diseases, it is reasonable to believe that angiogenesis and vasculogenesis are the indispensable premises for tissue regeneration (15). The purpose of the study reported here was to investigate the effects of autologous adipose stem cells on renal function and renal structural changes, in dogs.

Materials and Methods

Ten healthy dogs age range, 1 to 1.5 years; weight ranges, 15 to 18 kg were used in the study. It divided into two equal groups. Prior to the experiment, all dogs were acclimated for at least two weeks and screened for underlying diseases on the basis of results of a complete blood count CBC and serum biochemical analysis. During the experiment, dogs were housed separately in cages and fed dry food and water.

Evaluation of renal function: Renal function was evaluated based on blood urea and creatinine levels. Blood samples were collected from cephalic vein from each dog three days before surgery, three days after surgery and same period after treatment with ASCs to determine the serum chemistry profile. The reference range of serum BUN was 8-30 mg/dl and that of serum creatinine was 0.5-1.5 mg/dl, Serum BUN and creatinine levels above the reference range were considered abnormal.

Collection adipose tissues: Briefly, adipose tissue was obtained from subcutaneous, inguinal fat depots of dogs, using standard surgical procedures. At obtaining, adipose tissue was placed into a sterile 50 mL conical tube containing 15 mL of phosphate-buffered saline (PBS) and brought quickly to stem cells laboratory.

Cell culture and characterization:

Collected adipose tissue was washed three times with phosphate-buffered saline containing 100 IU/mL penicillin and 100 g/mL streptomycin, then chopping sample with scalp knife size 15 and surgical forceps and digested for 1 hr. at 37 ºC with collagenase type IA. The enzymatic activity was inhibited with (DMEM) Dulbecco’s Modified Eagle’s Medium containing 10% (FBS) fetal bovine serum. Following centrifugation at 1200 x g for 5 min, the pellet was filtered through a 70 µm falcon cell strainer to remove debris, then incubated in DMEM containing 10% FBS at 37˚C in a humidified atmosphere of 5% CO₂ after 48 hrs. cultures were washed with PBS to remove non-adherent cells and incubated with fresh medium, which was changed every 48hrs. until cells reached 70% to 80% confluence. The cells were then repeatedly subculture under standard conditions (4). Cells were brought to a final volume of 2mL with PBS and loaded into a sterile syringe for injection.

Induction of unilateral renal ischemia reperfusion (I/R):

After standard surgical preparation performing, Dogs were anesthetized by intramuscular injection mixture of ketamine HCL (15 mg/kg) and 2% xylazine (5 mg/kg). A midline abdominal incision was made to expose the left kidney. Blood supply to the kidney was interrupted by clamping the left renal artery using an artery clamp for 1 hour. After 1 hour the clamp was removed and reperfusion was confirmed visually. Then the catheter was inserted into the renal artery, while its proximal end inserted through a tunnel created in the dorsal wall of the abdominal cavity and fixed to the skin out the body with silk stitch suture and closed.
its opening permanently. The wound layers were then closed routinely and the animals were allowed to recover with free access to food and water (16).

**Intra-arterial ASCs infusion:**

At day 3, after inducing ischemic renal failure, all dogs placed under general anesthesia, and ASCs were injected directly into the left renal artery via a catheterization approach. A total of \(10^6\) ASCs suspended in \(2\) ml phosphate-buffered saline was slowly infused through the arterial catheter into the kidney over \(1–2\) minutes in treated group while control group injected with normal saline.

**Histopathological examination:**

At day 10 of ischemic renal failure induction (day 7 of treatment with normal saline and ASCs infusion), the kidneys were harvested and fixed with \(10\%\) buffered formalin. The fixed tissues were embedded in paraffin wax and \(4-\mu\)m sections were stained with hematoxylin and eosin (H&E) by standard procedures for histological examination.

**Statistical analysis:** Renal function analyzed using SPSS Statistics. Statistical analysis of serum BUN and creatinine was performed by one way ANOVA for comparisons among groups. P values of \(p < 0.05\) were considered to record statistical significance. All data were expressed as means ± standard error (SE).

**Results**

**Evaluation of renal function:**

The results showed that the levels of serum blood urea nitrogen (22.70 ± 0.54 and 14.40 ± 1.67) and creatinine (0.93 ± 0.10 and 0.77 ± 0.10) in both groups at 3 days before induction ischemic renal failure was with in normal reference range. At 3 days after induction ischemic renal failure the results showed increase significant differences (\(P< 0.05\)) in the levels of BUN (36.80 ± 0.63 and 33.90 ± 1.27 in control and treated groups respectively) and creatinine (2.70 ± 0.10 and 2.71 ± 0.03 in control and treated groups respectively) compared with the levels at 3 days before surgery. While the levels of BUN and creatinine at 7 days after treatment showed continuous increasing in the group which treated with normal saline, but significantly decreased in the ASCs treated group. (Tab.1, Tab.2)

**Histopathological examination:**

Control group at day 7 of treatment with normal saline infusion showed, atrophied glomeruli as well to periglomerular necrosis of renal tubules, in addition to marked dilation of some renal tubules. Hyperplasia of mesengial cells, as well to vacuolation of mesengial cells of the glomerulus, in addition to necrosis of peri-glomerular renal tubules with infiltration of inflammatory cells (Fig.1).

Treated group at day 7 of treatment with ASCs, revealed infiltration of polymorphic stem cells in the surrounding area of the renal arteriole, also there was an elongated fibroblast-like cells deposition in the necrotic renal tubules (Fig. 2) and in the peri-glomerular region (Fig. 3) as a replacement state.

Marked fibrin deposition in the peri-renal tubules area, and there was a marked area of fibroblasts proliferation in the renal parenchyma (Fig. 4).

![Figure (1): Control group at day 7 of treatment with normal saline infusion showed, hyperplasia of mesengial cells (A), as well to vacuolation of mesengial cells of glomerulus (B), in addition to necrosis of peri-](image-url)
glomerular renal tubules with infiltration of inflammatory cells (C). H&E. Stain. 40X

Figure (2): Histopathological section of kidney of treated group at day 7 of treatment with ASC₅ showed infiltration of polymorphic stem cells in the surrounding area of renal arteriole (A), also there are an elongated fibroblast like cells deposition in the necrotic renal tubules as a replacement state (B). Figure (3): Histopathological section of kidney of treated group at day 7 of treatment with ASC₅ showed elongated fibroblast like cells deposition in the peri-glomerular region as a replacement state (A). H&E. Stain 40X.
Discussion

Artificial ischemic renal failure is induced by mechanical or medical method (4). In our research we used mechanical procedure and the induction time was 60 minutes. Monitoring serum BUN and creatinine levels alone are quite an accurate measure of renal function and a meaningful method in a clinical setting (17). Creatinine is a muscular metabolic product. As a more precise indicator of renal function than BUN, creatinine is a significant criterion of the severity of renal failure (18). Recently, the potential for renal repair by using stem cells has been clarified for various renal diseases. Among several sources of stem cells, adipose stem cells have attracted attention because of its ease of access (19). Effects of adipose stem cells on the damaged organs occur through mesenchymal stem cells fusion with existing host cells rather than via true differentiation (20). In our study, creatinine and blood urea nitrogen serum levels of the ASCs-treated ischemic group decreased after ASCs infusion compared with those observed in the ischemic renal failure injected with normal saline group this findings agreement with other workers (4). Treating animals with mesenchymal stem cells will result in a reduction of creatinine and urea plasma (8). MSCs may not only secrete cytokines within the injured kidney but also participate in endothelial cell proliferation or angiogenesis to facilitate renal regeneration (21).

To evaluate the therapeutic effects of ASCs in the ischemic renal failure group, we performed histopathological analysis which revealed infiltration of polymorphic stem cells in the surrounding area of the renal arteriole, also there was an elongated fibroblast-like cells deposition in the necrotic renal tubules and peri-glomerular region as a replacement state, in addition to marked fibrin deposition in the peri-renal tubules area, and there was a marked area of fibroblasts proliferation in the renal parenchyma, these finding reduce the damage in ASCs group. Many studies have revealed that after local damage to the tissue, MSCs replace their damaged counterparts in the bone, fat, liver, heart, brain, heart and skeletal muscle (22), MSCs therapy is effective, safe and reduced the rate of renal damage for patients with acute renal failure (20) and hastens the regenerative process (23).

The route of MSCs administration is more significant; in the other reports, intra carotid, jugular vein; cephalic vein, femoral artery and lateral caudal veins injection was used (22, 24, and 25). Many reports have shown that systematically administered MSCs move through the blood circulation and are ultimately retained at the liver, lungs or spleen (24, 26). Whereas we directly injected ASCs into target organ (kidney), as it could also
hold the cells. Migration of injected ASCs to damaged tissues can accelerate renal healing. Local vasculature procedure in cell therapy is an attractive approach in which select cells can be introduced into an aimed area and that will result in achieving cell localization with infusion little number of stem cells as well as it could minimize superfluous adverse effects and this considered an advantage in stem cells therapy as reported recently.

Conclusions

The administration of ASCs trans catheterization lead to improve renal excretory function, which was verified by the levels of serum BUN and creatinine in the canine ischemic renal failure model also play important role in renal tissue reconstitution there for, our findings suggest that ASCs could be an alternative therapeutic agent for canine ischemic renal failure.

Abstract

Background: Prostate cancer (PC) is the largest and most unusual site of robust neoplasm in Europe, accounting for 22.8% of all newly diagnosed cancers in men. An increase in the prevalence of pentachloro anisole has been observed in most countries. This may be explained by the massive use of prostate unique antigen (PSA) in the early detection of PCa in the early stages. Objective: Detection of PTEN loss by IHC and FISH technique and compare between the two methods and correlate with Gleason grading system. Patients and method: A retrospective sample study was performed. From January 2014 - Joe. 2019. This study included 120 cases of prostate cancer from Baghdad and Duhok, with different age groups. Fixed formalin paraffin biopsy for prostatectomy in cases obtained from the Archives of Pathology Laboratories in Baghdad” (Shahid Ghazi Hariri Training Hospital and Laboratories). 

Results: PTEN (FISH) detected the gene in 29 case and confirmed by PTEN (IHC) expression results, underestimation occurred in five case detected by PTEN (IHC). Concerning PTEN (IHC), it detected the gene in 34 case. Percentage of cases showing negative staining for PTEN protein in high grade was higher than cases showing positive protein expression (good correlation with new grading group). IHC to detect PTEN protein levels is an interesting alternative to knowledge of the FISH PTEN gene loss and as a prognostic biomarker. There was significant association between PTEN gene expression and age. PTEN (IHC) showed negative results in 65.3% of case; while loss was shown in 58.2% of s by PTEN (FISH). 

Conclusion: The important result in this study was a substantial agreement between the expression results of PTEN (FISH) and PTEN (IHC). 

Keyword: PTEN (FISH), PTEN (IHC), Prostate adenocarcinoma, immunohistochemistry

Introduction

Prostate cancer (PCa) is the largest and most unusual site of solid neoplasm in Europe, accounting for 22.8% of all newly diagnosed cancers in men. An increase in the prevalence of PCa has been observed in most countries. This may be explained by the massive use of prostate unique antigen (PSA) for detection of PCa in early stages. In Iraq, prostate cancers represent the seventh most common malignancy in Iraq Registry for 2012. 

(4) Most prostate cancers are detected by virtual rectal exam (DRE), and transurethral ultrasound, however, ultrasound misses almost 30% of isoechoic carcinomas, or PSA improvement (both above 4ng / dL and growing over time). Nowadays, needle biopsy identifies several prostate cancers. Less often – its miles recognized by transurethral resection samples. Prostate cancers can be classified into:

(1) Adenocarcinomas (“secondary”) of peripheral ducts and acini ,

(2) large (“primary”) ductal carcinomas.

Roughly speaking, a lump can be hard to look, but it can usually be diagnosed as a poorly defined gray or
yellow area, poorly delineated or corporation area.

Early detection tasks can detect minor tumors. (5)

**Microscopically:** The four basic structures of cellular architecture patterns are the medium sized glands, little glands, diffuse single infiltration of cells and the cribriform form.

It is accompanied by a cytological incongruity in the nuclear enlargement, contour irregularity, hyperpigmentation and most importantly notable nucleoli (“macro-nucleoli” ,Calibration > 1 μm in diameter). Nucleoli are typically numerous and more likely to be emarginated. Mitosis also important, however, it is rare in a well-differentiated tumor. (5)

The types of prostate cancer that form glands are usually lined with a single cell layer, but rarely contain stratified epithelial tissue that mimics PIN (6) and have many benign mimics (7)

**Materials and Methods**

During the period from January, 2014 to June 2019, a retrospective selective study was performed included 120 cases of prostate cancer with different age groups from Baghdad and Duhok.

Fixed formalin paraffin biopsy for prostatectomy obtained from the Archives of Pathology Laboratories in Baghdad” (Shahid Ghazi Hariri Teaching Hospital and Laboratories, Duhok Central Health laboratory and Vajeen specialist laboratory & certain private clinical laboratories.

Additionally, normal prostate in the form of paraffin blocks is a positive control (PTEN), and kidneys with RCC is a positive control (AMACR).

Patients’ clinical data, including age and provisional clinical diagnosis, were obtained from archival histological reports.

Each H&E stained slide was reviewed for pathological evaluation and diagnostic evaluation to confirm the diagnosis of prostate cancer. Cases are scored and graded in accordance with new grading.

Immunohistochemical technique and molecular work of the study were performed in Duhok (Vajeen specialist laboratory).

**Inclusion Criteria**

Various types of prostate specimens were included in this study, including transurethral resection of the prostate, needle biopsy, and resection of the prostate.

**Exclusion criteria:**

Insufficient biopsies, poorly preserved prostate specimens, and biopsies with acute inflammation and necrosis were excluded.

Tissue Microarray Technology (TMA):

A new technique used in this study which is Tissue-Microarray

The procedure involves using a hollow needle to cut core of tissue just 2 mm in diameter from the areas of interest (previously detected prostate tumor areas in stained glass (H&E slides) into paraffin embedded tissue.

Sections of the Microarray blocks are excised by a microtome, equine on a single microscope slide, then evaluated by staining with H and E, then another 4 μm section is made for the immunohisto-chemical stain for PTEN and one section for the FISH probe.

**Immunohistochemical technique:** Agilent Company ®.

A. The following equipment was used during the study For IHC:

- Microtome
- Water bath
- Glass slides.
- Microwave oven.
- Humidity champer
- Optical microscope.
- FLEX IHC microscope slides (code K8020)
- Silanized chip (code S3003)
- Buffer solution - phosphate saline (PBS).
xylene.  
- Envision™ FLEX Hematoxylin (counter stain) Link (code K8008).  
- Distilled water.  
- Ethanol  
- Aqueous mounting medium  
- Permanent mounting medium  
- Dako Autostainer / Autostainer Plus and Dako PT Link Tools.  

B. PTEN Primary Antibody:  
- monoclonal mouse against human clone PTEN 6H2.1, catalog number M3627; Made in Dako, USA.

**Immunohistochemical method:**

Immunohistochemical work in this study was performed with an automatic Link 48 autostainer. Micron sections were obtained from formalin-fixed and paraffin-embedded tissue blocks, a section utilizing Dako PT 3-in-1 specimen preparation procedure. Follow the pre-treatment procedures posted in the EnVisionTM FLEX Target retrieval Solutions. Height of PH (10x) and PH 9 (code S2388) for PTEN.

Post staining the sections, they were dried, cleaned and impregnated with a permanent fixing medium.

**Fluorescence in Situ (FISH) technique:**

A. Equipment and materials required to study FISH in this research:

Zytolight FISH Tissue Incorporation Kit (serial number Z-2028-5 / -20.  
Positive and negative control specimens  
Positively charged slides  
Water bath (37 °C - 98 °C)  
Hybridization / hotplate  
Hybridization or humidity chamber in the hybridization oven

- Adjustable pipettes (10 ml, 25 ml)  
- Staining: cans or baths  
- Timers  
- Calibrated thermometer  
- Xylene  
- Distilled or Deionized water  
- Cover-slips (22 mm x 24 mm x 60 mm)  
- Rubber glue, such as B. fixogum cement-based rubber.  
- Fluorescence microscope (400-1000X)  
- Certified immersion oil for fluorescence microscopy  
- Appropriate filter sets

**Reagent provided:**

The Zytolight SPEC PTEN / CEN 10 dial probe consists of:

ZyGreen-labeled polynucleotide (excitation 503 nm / irradiance 528) (10 ng / mL, target sequence mapping in 10q23.2-q23.31 * (chr 10: 89,440,649-89,755,790) contains a region of PTEN gene

ZyOrang-labeled (547 nm excitation / 572 nm irradiance) polynucleotide (1.5 ng / mL) targeting the sequences shown in the 10p11.1-q11.1 of the alpha satellite central region of the D10Z1 chromosome 10.

Hybridized Buffer based on formameda.

**Counter –stain vial:**300 μl per vial (30 tests). The counterstain is DAPI antifade (ES: 0.125 μg / ml DAPI (4,6-Diamidino-2-phenylindole)).

Cytocell comp. manufactured a pre-treatment kit and a removal kit.

B. Fluorescence in the in situ hybridization method:

Preparation of solutions used in FISH workings:

Sodium chloride sodium citrate (SSC solutions):
- Sample preparation:
  - A section of tissue placed on a charged slide, then preserved in the oven at 55 °C overnight to remove paraffin
  - Then dehydrated in the next day

Pretreatment of tissue samples:

It consists of two stages:

1. Heat pre-treatment
2. Enzymes-Digestion

The samples then dried at room temperature in a 75%, 85% and 100% series of ethanol for 2 minutes at each concentration. Keep the slide for air drying and proceed to predenaturation, denaturation and hybridization.

FISH signaling analysis:

A fluorescent microscope should be available. Use the DAPI / FITC / Texas Red triple-band filter for optimal green, red, and DAPI fluorescent imaging.

Normal state: In interphases of normal cells or cells while not a deletion involving the PTEN gene region, two green and 2 orange signals appear.

Aberrant situation: In a cell with deletion affecting the PTEN gene region, a reduced number of green signals will be detected. Deletion affecting only parts of the PTEN gene region might result in normal signal pattern with green signals of reduced size

statistical analysis:

All statistical procedures, data management and analyses were performed with the aid of the SPSS,IBM,US, version 25, The Kappa Cohen value was used to assess the degree of consistency and agreement of PTEN expression results FISH and PTEN(IHC). All analyses done under the assumption that p. value was two tailed and ≤ 0.05 to be considered significant

Results

A total of cases 98 cases with proved diagnosed adenocarcinomas were enrolled in this study.

Age Distribution

As it shown in figure 1, age distribution of the cases revealed that a mean age of the studied group was 70.15 ± 8.8 (range: 50-95) years. Higher proportion of cases aged 70 years or older accounted for (60.2%) of cases.

Figure 1: Age distribution of the studied group

PTEN (IHC and FISH)

Results of PTEN test using immunohistochemistry and FISH are shown in table 1. PTEN (IHC) showed negative results in 65.3% of cases; while the loss was detected at 58.2% by PTEN (FISH).

Figure 2  negative staining PTEN immunohistochemistry  prostatic adenocarcinoma score 9 (4+5) Grade 5

Figure 3  negative staining PTEN immunohistochemistry with internal positive control of PTEN benign prostatic hyperplasia
PTEN (FISH) detected the gene in 29 cases and confirmed by PTEN (IHC) expression results, underestimation occurred in five cases detected by PTEN (IHC). Concerning PTEN (IHC), it detected the gene in 34 cases. Percentage of cases showing negative staining for PTEN protein in high grade was higher than cases showing positive protein expression (good correlation with new grading group). IHC to detect PTEN protein levels is an interesting alternative to knowledge of the FISH PTEN gene loss and as a prognostic biomarker. There was significant association between PTEN gene expression and age.

Relationship between PTEN expression (IHC) and PTEN gene expression by (FISH).

PTEN (FISH) detected the gene in 29 cases and was confirmed by the results of PTEN (IHC) expression. Underestimation occurred in five cases (detected by PTEN (IHC). As for PTEN (IHC), the gene was detected in 34 cases.

During tissue sections, a part of the cell and the nucleus can be cut, resulting in a “truncation effect” in which loss of the PTEN signal from the nucleus can be erroneously estimated as deletion of the gene. Therefore, it is very important that false positive results, which were probably the result of truncation, were determined by comparison with normal nuclei in all FISH deletion tests. (8)

Another explanation for the false negative result is a technical error in the FISH procedure due to air bubbles while the cap is slipping. This prevents the probe from reaching the desired area.

Twelve cases showed presence of a gene by FISH procedure, which is not confirmed by immunochemotherapy, in fact there were two explanations for this finding, the first cause may be exposure to microRNA (miR-4534 directly represses the tumor inhibitor PTEN gene). The second is due to a point mutation in 10q23.3. (9).

An important outcome in this study was the significant substantial agreement between PTEN (FISH) and PTEN (IHC) expression results, and this agreement was statistically significant (kappa = 0.635, P = 0.001).

The PTEN (IHC) sensitivity was 70.7%, specificity 91.2%, and accuracy 82.7%.

In the same direction with this study, another study found that low PTEN expression was significantly associated with PTEN genomic removal which indicated that erasure is the main procedure erasures as the main method causing reduced PTEN protein expression.

In 28/39 cases (72%), a similarity was observed between deletion state of PTEN and lower expression of PTEN protein. Moreover, in eight cases out of eleven disagreement cases, grade I (declined) or grade
0 (absent) expression of PTEN protein were detected, these 8 cases were negative for PTEN deletion. While normal expression of PTEN was reported in the other 3 cases. (10)

The possibility that PTEN FISH might not recognize some cases of prostate cancer with PTEN inactivated greatly supports the need for replacement analysis to characterize PTEN loss.

IHC for detection of PTEN protein levels is a clear alternative for detecting PTEN FISH gene loss. Four previous studies assessed the usefulness of PTEN-IHC in prostate cancer as predictor of loss of PTEN. (11-14)

some of which are currently in clinical trials for prostate cancer. PTEN loss could also be a biomarker of resistance to hormone therapy in advanced prostate cancer. (15) The opportunity that PTEN FISH may fail to distinguish some cases of cancer of the prostate with PTEN deactivation powerfully maintains for the need for a

The PTEN protein expression by IHC is a simple analysis that is easier and cheaper to perform than FISH. As it is compared to FISH, this test is easier to be performed by needle biopsy-sampling and may indicates PTEN protein absence among additional cases. Therefore, when there PTEN protein is lack or absent on needle-biopsy specimens it could be a promising predictive biomarker that is useful in screening patients with low risk prostate cancer who are likely to progress, where there will be a need to treatment and intervention. (15)

Moreover, loss of PTEN as a biopredictive marker may help select appropriate patients for treatment with Novel-PI 3-kinase pathway therapies, nonetheless, currently these therapies are under investigations by different clinical trials for treatment of prostate cancer. From other point of view, in advanced cases of prostate cancer, loss of PTEN can be used as an indicator-biomarker to predict resistance to hormonal therapy. (16)

Conclusion

The important result in this study was a substantial agreement between the expression results of PTEN (FISH) and PTEN (IHC).

Impact of Diastasis Recti Abdominis and Low Back Pain on Quality of Life in Post-Partum Female

Bhavna Gandhi¹, Shalaka Dhankar²

¹Final year B.P.T., Ravi Nair Physiotherapy College, DMIMS(DU) Wardha, Maharashtra, ²Assistant Professor, Department of Community Health Sciences, Ravi Nair Physiotherapy College, DMIMS(DU) Wardha Maharashtra

Abstract

Introduction: The separation of the two rectus abdominis muscle along with linea alba is called diastasis recti abdominis. Diastasis recti is common in Post-partum females. In Post-partum period Low back Pain is very common which lead to daily activity limitation. Post-Partum women complaint regarding there usual activities, mobility, pain, which affect the quality of life in individual.

Aim: To study the” Impact of diastasis recti and low back pain on quality of life in post-partum females”

Method: This study will be carried out in Physiotherapy OPD, Ravi Nair Physiotherapy College and AVBRH, Sawangi (Meghe), Wardha. Diastasis recti will be evaluated in Post-partum females. Impact of Diastasis recti and Low back pain on Quality of Life in post-partum female. Low back pain is going to asses with the help of Modified Owestry low back pain disability questionnaire .And quality of Life with the help of Maternal postpartum questionnaire

Results: Study yet to be commenced.

Conclusion: Conclusion will be published after the result are analysed.

Keywords: Diastasis recti, Post-Partum female, Low back Pain, Quality Of Life.

Introduction

Diastasis recti abdominis is defined as the separation of the two rectus Abdominis muscle along the linea alba¹. Mechanical effect of pregnancy on the Abdominal musculature is mediated hormonally in diastasis rectus abdominis¹. Diastasis recti abdominis occur due to weakening of anterior abdominal wall due to mechanical strain¹. The space form in diastasis recti abdominis due to Separation of linea alba is Inter-recti abdominis¹. Measurement of diastasis recti done with the help of dial caliper⁸. In postpartum period diastasis recti Abdominis is more common¹. 4th Stage of Labor is sometimes referred to as postpartum⁵. Post-partum extend up to 6 month after giving birth⁵. Risk factor mainly occur in post-partum women generally include physical health risk⁵. Diastasis recti is seen 68% immediately after post-partum³. At the 8 week of Post-partum the inter-recti distance resolve gradually with the time and with Individual validity¹. At 12-14 week of post-partum and 6 month of postpartum mota et al asses inter-recti abdominis¹. The universal health problem for all age group is low back pain, of these Postpartum low back pain is the more common and which lead to daily activity limitation⁶. More than 6 month of postpartum more prone to diastasis recti. It may change posture and give more back strain, which lead to reduce strength and function that lead to occur of low back pain⁷. With in half a year after delivery 4 out of 10 women report of persistent low back pain and 20% of women with back pain report persistent symptom

Corresponding Author:
Dr. Shalaka Dhankar,
Assistant Professor, Department of Community Health Sciences, Ravi Nair Physiotherapy College, DMIMS(DU) Wardha Maharashtra. Shalakad92@gmail.com Orcid ID: https://orcid.org/0000-0003-4588-8536

DOI Number: 10.37506/ijfmt.v15i1.13528
at the 3 year of postpartum. Lumbopelvic pain occur in pregnant women which may persist or arise after delivery. Women with diastasis recti often experienced back pain. To provide the proper support to the trunk and spine our body require strong and intact abdominal muscles. During activity more demand gets place on the spine because of improper support from the abdominal muscle so pain begin at the spine. Post-partum women report complaint regarding mobility, Self-care, usual Activities, pain or discomfort which affect quality of life in individual. At the end of 1st month there is limited problem in the women and can perform usual activities.

Rationale:
Various studies have been undertaken which concluded that diastasis recti is one of the cause for prevalence of low back pain in postpartum women even after 1 year of delivery resulting in persistence of symptom of low back pain that affecting the functional activity of female which can hamper quality of life therefore need was felt to carry out the current study to find the effect of Diastasis Recti on Quality of Life in Postpartum women with Low back pain.

Objectives:
1. To Evaluate of width of diastasis recti
2. To Evaluate of low back pain
3. To Assess quality of life using
4. To find association of diastasis recti with low back pain
5. To correlate diastasis recti with QOL.
6. To correlate low back pain with quality of life.

Methods
Study design: Observational study

Study setting: AVBRH Hospital and Physiotherapy OPD.

Participants:

Inclusion Criteria:
1. Females with diastasis recti
2. Upto 6 months post-partum females
3. Post – partum Females having low back pain
4. Age 20 to 35 years

Exclusion Criteria:
1. Females with lower limb radiculopathy
2. Females with PIVD or Stenosis

Variable:
1. Width of diastasis recti
2. Severity of Low back pain
3. Quality of life score

DATA SOURCE / MEASUREMENT:

For diastasis recti – width of gap between the two bellies of Rectus Abdominis will be measured using digital caliper

For severity of Low back pain – score of Modified Oswestry low back pain disability questionnaire will be measured

For Quality of life – Score of Maternal postpartum questionnaire will be measured

Bias: Subjects not fulfilling the selection criteria will be excluded from the study to prevent bias

Study size: 175

Statistical method: Simple random sampling

Result: Upon completion of the study results, statistical analysis will be estimated.

Discussion

The current study is carried out to find the impact of diastasis recti and low back pain on Quality of life in postpartum females. Various studies carried out have
reported back pain can affect the quality of life. The weak abdominal result in imbalance of muscle support to the truck and can over stress the back muscle causing back pain, in postpartum females due to pregnancy the abdominal muscles are stretched causing weakness and even separation of rectus muscle if this persists support to the trunk may be compromised causing back pain and this may prevent female from carrying out various activities even taking care of her newborn and may affect her Quality of life. Thus, current study aims to find out effect of diastasis recti and low back pain on quality of life in postpartum females.

**Key results:** Diastasis recti, Post-Partum female, Low back Pain, Quality Of Life.

**Limitation:** It might be difficult to convince patient for being a part of this study.

**Generalizability:** Study not done yet.

**Conflict of Interest:** There is no conflict of interest.

**Source of funding:** No funding needed

**Ethical Clearance:** Being an observational study institutional ethical committee permission was taken.

The Influence of Interpersonal Communication on the Prevention Action of Dengue Hemorrhagic Fever (DHF) in Meo-Meo Public Health Center of Baubau City

Budi Utama1, Andi Zulkifli2, Hasnawati Amqam3, Wahiduddin2, A. Arsunan Arsin2, Lalu Muhammad Saleh4

1Master Student Program, Department of Epidemiology, Faculty of Public Health, Universitas Hasanuddin, 2Lecturer, Department of Epidemiology, Faculty of Public Health, Universitas Hasanuddin, 3Lecturer Department of Environmental Health, Faculty of Public Health, Universitas Hasanuddin, 4Lecturer, Department of Occupational Health and Safety, Faculty of Public Health, Universitas Hasanuddin

Abstract

Dengue infection is a global health problem. One of the city in Indonesia that has a high incident of DHF is Baubau City, especially the area of Meo-Meo Public Health Center in 2016 to 2018 ranked first of the incident of DHF respectively for three years among 10 Public Health Center on the coastal area and third among 17 Public Health Center in Baubau City. DHF cases are not only caused by mosquitoes, but also by human behavior that does not carry out healthy and indifferent lifestyles in the environment where mosquitoes nest. Such behavior includes leaving the hanging used clothes, does not drain the tub, leaving puddle around the residence. This study involved 39 people in the intervention group and also in the control group who met the criteria including the age of 17-65 years old, can read, write, and communicate well, and willing to participate in this study. The result indicates a significant from the intervention groups to the control group (p< 0.05), is action (p=0.001), and the difference in the percentage of action in both groups. So, it can concluded that interpersonal communication is more influential than counseling on increasing DHF prevention action.

Keywords: interpersonal communication, counseling, action, prevention, Dengue Hemorrhagic Fever (DHF)

Introduction

According to WHO, dengue infection is a global health problem with an estimated incidence of around 390 million people each year. Asia is headed for the dengue epidemic in 2019. Several countries including Australia, Cambodia, Laos, Malaysia, the Philippines, Singapore, and Vietnam have been facing a surge in dengue cases in the past six months1. DHF cases until the beginning of February 2019 reached 16,692 cases with 169 people dead. This number increased compared to the previous month, which was 13,683 cases with 133 people died. This number increased compared to the previous month, which was 13,683 cases with 133 people died. Most cases of DHF in Indonesia are in the regions of East Java, Central Java, NTT and Kupang2.

Cases of dengue in Southeast Sulawesi in 2018 amounted to 624 cases, with the number of deaths of 4 people. This figure decreased from 2017, which was 817 cases, and while the number of deaths was as many as 12 people. DHF Incidence Rate (IR) in 2018 decreased compared to 2017, which is from 31.39 to 23.51 per 100,000 population. The increase in case fatality rate (CFR) from the previous year was 0.26% in 2017, to 0.64% in 20183. In Baubau City, in 2018 the number of DHF patients was 98 which was decreased from 116 cases in 2017, but increased again to 157 cases in 20194.

budiutam3012@gmail.com
DHF cases in the area of the Meo-Meo Public Health Center in Batupoaro Sub-District, Baubau City were 11 in 2015, 20 in 2016, 17 in 2017, 10 in 2018, and 10 in 2019. Meo-Meo Public Health Center in 2016 – 2018 ranked first in the incidence of DHF cases respectively for three years among 10 Public Health Center on the the coastal area and third among 17 Public Health Center in Baubau City. In 2019 there were still 10 cases of DHF.

DHF cases are not only caused by mosquitoes, but also by human behavior that does not carry out healthy and indifferent lifestyles in the environment where mosquitoes nest. Such behavior as includes leaving the hanging used clothes, does not drain the tub, leaving puddle around the residence.

Shidiq’s research found that counseling was effective against increasing knowledge, attitudes, and actions but not effective against the existence of larvae. Research by Ikhlasari showed that there was a significant relationship between education, income, and knowledge in the control group. There is a relationship between the control group and the treatment group on the aspects of knowledge and attitudes that indicated that the administration of DHF prevention interventions is related to knowledge and attitude.

Hutapea’s research stated that interpersonal communication conducted by parents was seen as effective and successful in preventing dependence on others in the feelings and abuse of drugs in adolescents. Interpersonal communication is communication between a communicator and a communicant. Interpersonal communication is also known as the communication of people by face-to-face that allows each participant to capture the reactions of others directly, both verbally and nonverbally.

Interpersonal communication is verbal and non-verbal interaction between two or sometimes more than two people who are interdependent with each other. Interpersonal communication aims to learn, build relationships with others, influence others, and help others. Interpersonal communication is carried out through face to face where the source of the message can see who the recipient of the message is. Then, there is immediate feedback without having to use an intermediary. Therefore, communication participants can also easily and immediately receive feedback from other communication participants at that time.

To overcome the DHF cases, various efforts have been carried out including larvae monitoring by the DHF Team of Baubau City Health Office where the target is the Public Health Center area where DHF cases are found, cross-program and cross-sector meetings, fogging in areas where DHF cases occur, giving abate powder by Public Health Center staff in each of the houses of the Health Center working area, counseling the Mosquito Eradication Movement (PSN) movement in all walks of life.

The health promotion efforts that have been done were not able to cultivate the community partisipan in PSN. The effort to break the chain of infection of dengue fever with the PSN movement will not be meaningful without the awareness of the community itself. So the purpose of this study was to determine the effect of interpersonal communication on DHF prevention measures.

**Material and Method**

This research was an experimental study through Quasi-Experiment with a non-randomized pre-test – post-test control group design. The intervention group and the control group presented a pretest to find out the primary state then the intervention group was given interpersonal communication and the control group was did counseling. After the treatment, both groups performed a post-test with the same questionnaire. The distance between the pre-test and post-test for approximately 2-3 weeks or a maximum of 4-5 weeks.

The following is the method scheme:

Table 2 shows that the mean score of pre-test (6.77) and post-test (10.00) increased in the intervention group. The statistical test results obtained $p = 0.000$ ($p < 0.05$) shows that there were significant differences in the mean score of the pre-test and post-test scores on the increase in prevention of DHF.

The increase in the mean score of actions also occurred in the control group at pre-test (8.56) and post-test (9.85). Statistical test results obtained $p-value = 0.000$ ($p < 0.05$) showing that there was a significant difference in the score of the pre-test and post-test actions to increase the prevention of DHF.

Table 3 shows the results of the statistical test on the pre-test score of the action between the intervention group and the control group which was not significant, with the value of $p = 0.079$ ($p < 0.05$). Furthermore, the results of significant in which, the value of $p = 0.001$ ($p > 0.05$). The post-test score of the intervention group was 7.67 which was higher than the control group of 1.50, in which the difference score is 6.17.

**Discussion**

The selection of research sites was based on the consideration that Lanto Village had the highest cases of
Dengue Hemorrhagic Fever (DHF) for the last 3 (three) years. Likewise, Wameo Village had the lowest cases of DHF for 3 (three) years. Most recently in the area of Meo-Meo Public Health Center. This was based on the results of an initial survey through interviews with DBD programmers of Baubau City Health Office and the health profile data of Baubau City in 2019.

Statistical test results in the interpersonal communication intervention group obtained $p = 0.000$ ($p < 0.05$) showing that there were significant differences in the scores of pretest and posttest actions to increase the prevention of DHF prevention measures. The results of the statistical test in the counseling control group obtained a value of $p = 0.000$ ($p < 0.05$) showing that there were significant differences in the mean score of the pretest and posttest scores on the increase in the prevention of DHF.

Based on the statistical tests of the two groups, both are significant. However, there was a difference in the percentage of the attitude of the intervention group which was 47.7% higher than the control group of 15% with a difference of 35.3%, as well as a higher score in the intervention group by 0.15. So, it can be concluded that interpersonal communication was more influential than counseling on increasing the prevention of DHF.

This is in line with research conducted by Aysha et al, that there was a relationship between the eradication of mosquito breeding and DBD events. Furthermore, research by Ayudyah et al shows a relationship between knowledge, attitudes and preventive measures for DHF disease vectors. The prevention action of DHF can be done with several appropriate methods, one of which is controlling the mosquito vector by draining the bathtub, burying used cans, etc.

The results of this study are also in line with research carried out by Weningtyas et al. that interpersonal communication influenced customer satisfaction and service quality to customer satisfaction. Research by Patriana also showed that interpersonal communication between social counselors and the families of criminal offenders runs effectively because it fulfilled elements such as trust, openess, mutual support, and empathy.

This is reinforced by the Hutapea’s study that interpersonal communication was most effectively used by parents in preventing drug abuse in adolescents. Maharja also stated that good interactions tend to lead to good behaviors.

Interpersonal communication is communication carried out in an interpersonal relationship between two or more people, both verbally and nonverbally, to achieve the same meaning of communicating with others in the context of interpersonal communication, it is not only about communicate verbally, but also nonverbally. Nonverbal communication in the interpersonal communication process serves to complement verbal communication.

Giving interventions in the form of interpersonal communication present to the intervention group and counseling to the control group facilitates the delivery of information so that both groups can receive the message delivered and directly influence the pretest and posttest scores in both groups.

**Conclusion**

Based on research, it can concluded that there is an increase in actions before and after counseling on the prevention of DHF in the area of Meo-Meo Public Health Center in Baubau City. Furthermore, it finds that interpersonal communication is more influential than counseling on increasing DHF prevention behavior in the working area of Meo-Meo Public Health Center in Baubau City.

The Coronal Pulp Cavity Index an aid in age determination - A Cone Beam Computed Tomography Study

Ceena Denny E1, Bastian TS2, Srikant Natarajan3, Nithin Thilak4, Almas Binnal5
1Associate Professor, 2Professor and Head, 3Professor and Head, 4Post Graduate, Associate Professor, Department of Oral and Maxillofacial Pathology, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, Manipal, Karnataka, India

Abstract

Background: The objective of the present study was to assess the accuracy of age estimation from TCI of mandibular molars (except wisdom teeth) of both sides using CBCT images of known age and sex, so that we can apply this method to estimate age in both living individuals and skeletal material of unknown age.

Methods: A cross sectional retrospective study was conducted on a total of 100 CBCT images of subjects who were referred to the department for varied diagnostic purposes of known age and gender. All CBCT images with a fully visible pulp cavity were selected. Two measurements were taken at two different levels. Height of the crown (CH) and height of the coronal pulp cavity (CPCH). Then tooth – coronal index (TCI) for each tooth was calculated as follows: TCI = CPCH X 100 / CH.

Results: Comparison of TCI value between male and female showed no significant difference between the gender. Among the four mandibular molars (lower left and right 1st and 2nd molars) 46 and 47 TCI correlates well with age. TCI of 46 has significant prediction of age in female with an R value of 0.426. Inter observer measurements showed a moderate to good agreement of the measures.

Conclusions: TCI method of mandibular teeth was found to be a reliable method for age estimation and not gender determination. CBCT can be used in age determination for forensic purposes as it is non-invasive and also makes it possible to reconstruct the images in different planes showing the anatomical and imaged structures at different planes.

Key words: Coronal Pulp Cavity Index, Age Estimation, Cone Beam Computed Tomography, Forensic Odontology.

Introduction

Saunders, in 1837 was the first to publish an article ‘Teeth A Test of Age’ implying the importance of teeth in age estimation. In forensic dentistry, age determination using teeth plays a vital role in identification of the victim during mass disaster, criminal cases or social issues. Teeth being the hardest structure also is least resistant to decomposition. Various age estimation methods require extracted tooth by sectioning which is not feasible in a living individual.

The size of the canal and the pulp chamber is inversely proportional to human age. The various age related changes seen associated are odontoblastic vacuolization, reticular atrophy, fibrosis of pulp, hyaline and mucoid degeneration and diffuse calcification. Reparative dentine formation also results in decrease of the pulpal volume due to wasting disease, trauma and restoration.

Age estimation using Tooth coronal index (TCI) has been done using 2 dimensional (2D) radiographs like intra oral periapical (IOPA) using the paralleling technique and orthopantomograph (OPG). It was found to be simple and cost effective than histological methods and could be used in both living and un identified dead for age estimation. Even though, conventional radiographs have been widely as a non-destructive method in the measurement of the pulp chamber. The
disadvantages of these 2D radiographs is that it could have projection errors and the tooth could not be assessed in all directions from a single radiograph. Cone Beam Computed Tomography (CBCT) scans has overcome these disadvantages of 2D imaging modalities as it is also non-invasive. A 3 dimensional (3D) reconstructed image can be obtained which allows us to visualise the morphology of a tooth from all angles without any image distortion.

The present study was done to assess the accuracy of age estimation from TCI of mandibular molars (except wisdom teeth) of both sides using CBCT images of known age and sex, so that we can apply this method to estimate age in both living individuals and skeletal material of unknown age.

**Method**

A cross sectional retrospective study was conducted on a total of 100 CBCT images of subjects who were referred to the department of Oral Medicine and Radiology for varied diagnostic purposes of known age and gender. The study protocol was approved by the Institutional Ethics committee. The inclusion criteria for selecting the images were those images of patients with healthy teeth without any periapical or periodontal pathologies. The second requirement was that the scanned images were of good diagnostic quality without any artefacts. The images excluded were of those patients with history of trauma or pathology to the teeth and in which the pulp that could not be identified. Images of patients with syndromes or any congenital disorders were excluded. The study images were taken using Promax 3D, Mid version (Planmeca Oy., Helsinki, Finland) CBCT unit. CBCT images were chosen over panoramic images as the measurements were more accurate in terms of magnification and better individual detail could be obtained as there were no superimposition of other structures.

The study images were of 200 subjects (56 females and 44 males). Four mandibular molars (lower left and right, 1st and 2nd molars) excluding the 3rd molars were assessed. The individual tooth was assessed in the axial section and was aligned in the coronal section so that the long axis of the tooth was perpendicular to the lower border of mandible. The measurements were taken in the sagittal section after proper alignment in the axial and coronal section. All CBCT images which with a fully visible pulp cavity were selected. Two measurements were taken at two different levels. Height of the crown (CH) and height of the coronal pulp cavity (CPCH). Then tooth – coronal index (TCI) for each tooth was calculated as follows: TCI = CPCH X 100 / CH.

All measurements were taken using the same machine. To ensure the accuracy of the technique used for measuring TCI detailed reference points were used: Cervical line that connect two landmarks to be measured; the mesial and distal cemento-enamel junction points; and divides the tooth into crown and root. Crown height is the maximum perpendicular distance from the cervical line to the tip of the highest cusp of teeth. While pulp height is the distance from cervical line to the coronal tip of the pulp chamber as shown in Figure 1.

After the procedures of image acquisition and measurement of the height of the crown and the pulp cavity as described above, the volume of pulp chamber was calculated using the region growing tool using the Romexis software as shown in Figure 2.

The measurements were taken using the software–based calibrated measurement tool. All measurements were carried out twice by two observers and the mean was recorded to minimize intra and inter-observer errors.

**Statistical Analysis**

The statistical analysis of data was done by using excel program for figures and SPSS (SPSS, Inc, Chicago, IL) program statistical package for social science version 20. Independent t-test was used for comparison of gender. Linear regression analysis was used for prediction of age using TCI of 36, 37, 46 and 47. Interclass correlation coefficient for interobserver variability between 2 observers for the calculated parameters of TCI.

**Results**

Interobserver variability was carried out using Interclass correlation coefficient test. The ICC values were 0.730, 0.592, 0.679 for male, female and total population respectively for measurement of TCI (P value of <0.001) which indicated moderate to good agreement of measures.
Independent students t test was used to compare TCI value between male and female and showed no significant difference between the gender (Table 1).

Linear regression analysis was performed to predict the age of the individual using the TCI of the first and second molars. Significant association was seen with the TCI values of the tooth 46. Among the four molar teeth 46 and 47 TCI correlates well with age (AGE =13.808+0.131(TCI 46), SEE of 4.25 years and AGE =14.912+0.124(TCI 47), SEE of 4.374 years). TCI of 46 has significant prediction of age in female with an R value of 0.426 and standard estimate of error (SEE) of 3.71 years (AGE =13.651+0.14(TCI 46)). This was the best predictor equation. The other two significant equations were total population equation of 46 and 47. TCI values, with an R value of 0.333 and 0.241 respectively.

Independent t test was done to compare the volume of the pulp among both the sexes and it showed a statistical significant difference between the gender in the mandibular left 1st molar and both molars on the right side with p value of <0.001.

Pulp volume did not show any significant changes among the different age groups. Linear regression analysis shows that the equation Age= 21.243 + 1.127 x ln (pulp volume36) +10.654 x ln (pulp volume 37)-10.721x ln(pulp volume 46) +0.163 x ln(pulp volume 47) has an R value of 0.427 and SEE of 6.27 years for prediction of age which was statistically insignificant.

Discussion

Tooth coronal index aids in age estimation in people whose age is unknown for a variety of reasons like, minor children are made to work for various reasons, among people who migrate for various reasons, in natural disasters and also from archaeological specimens.

Secondary dentine is formed due to wasting diseases (erosion, abrasions and attrition), ageing, caries etc. which gradually results in the decrease in the pulp volume. Secondary dentine is considered as an age predictor. As age advances the pulpal volume decreases due to apposition of secondary dentine along the dentinal walls. The second reason being that it can withstand damages caused due environmental factors in human remains as it is encased in a harder tissue. This deposition of secondary dentine is not uniform and can vary in different parts in the pulp chamber.

Pulp cavity size decrease as age advances due to secondary dentine getting deposited along the roof and floor thereby reducing the height rather than the width. Pulpal changes were also seen after orthodontic treatment. This decrease in pulpal height acts as a biomarker in age estimation. Sectioning of tooth and radiographs can be used for measuring secondary dentine deposition.

CBCT, a three dimensional imaging modality has advantages over 2 D imaging as it provides images of tooth without magnification, distortion, no superimpositions and images can be viewed in multiple sections at multiple levels. Due to the spatial resolution of CBCT, it can be used to visualise the pulp chamber and anatomic variations. Radiation dose is relatively less when compared to other 3 D imaging modalities.

In our study we measured both coronal and pulp height in sagittal section as it was the ideal section for measuring the maximal height of both tooth and pulp chamber when compared to other sections.

Comparing the TCI value between the genders showed no significant results which was similar to the study done by Drusini AG; Khattab et al.2017 and Nawaya and Burhan 2016; but was not in accordance with the studies done by Igbigbi P and Nyirenda SK 2005, they found that gender had significance influence on age using TCI. Few studies support this theory explaining that it could be due to the influence of estrogen in secondary dentine deposition.

In our study using images taken in CBCT we found that the mandibular right molars (46,47) the TCI values corelated well with age and it was found that the lower right first molar (46) showed a significant prediction of age in females. This was the best predictor in the equation, which was in accordance to a study by Agematsu H & El Morsi DA 2015. As R value is positive it shows a positive correlation indicating that...
as age increases the index increases and also it was more in females when compared to the males which was similar to the study done by EL Morsi DA 2015 which could be related to the hormonal influence, which could lead to increase in the sequential obliteration of the pulp with growth.

Pulp volume measurement was not statistically significant; it could be because the measurements were taken from images of patients with an age range of 15-30 years. But in our study there was a significant change in the volume of pulp when compared among both sexes. The volume of the pulp chamber was stronger for the males in the present study which was in accordance to a study done by Agematsu H et al. 14.

**Conclusion**

CBCT plays an important in age as it gives a more accurate picture regarding the dimensions in all planes without with less radiation dose. CBCT could prove useful in forensic odontology as important diagnostic tool in age and sex determination in living and also aid in diagnosing the age and gender of victims in mass disasters. In present study TCI was useful in in age estimation this method was not useful in gender determination.

A Cross-sectional Radiological Study of Ossification at Lower End of Ulna and Tip of Olecranon among Children and Adolescents coming to Forensic Medicine Department, Medical College, Kolkata, for Age Estimation

Chandan Bandyopadhyay¹, Anamica Chakraborty²
¹Associate Professor, Dept. of FSM, MCH, Kolkata, ²PGT, Dept. of FSM, MCH, Kolkata

Abstract

Objectives: To study radiologically the ossification status of lower end of ulna and tip of olecranon and compare with Galstaun chart and other standard charts.

Material and Methods: A record based cross sectional study was performed in the department of Forensic and State Medicine, Medical College Kolkata for one month, on children and adolescent coming to the department for age estimation over a span of past one year. Their chronological age was noted from birth certificates. The X-Ray plates was looked for appearance and fusion of lower end of ulna and tip of olecranon and compared with Galstaun chart and other standard charts.

Results: The records of 199 subjects (Male-142, Female-57) were examined, who belong to the age group of 7 yrs to 19 yrs. After observing the appearance and fusion from X-Ray plates and comparing them with Galstaun chart it was seen that maximum deviation from mean age occurred in appearance of lower end of ulna. Appearance of tip of olecranon also had a wide deviation. Males were found to have more variations than females.

Keywords: Age estimation, Radiological study, ossification, children, adolescent.

Introduction

Age estimation is one of the regular assignments in clinical forensic medicine. As illiteracy is a major drawback in India, many citizens are unaware of the importance of registration of birth and death. Even if there is registration, there is often lack of maintenance of records. That’s why forensic age estimation becomes important in certain civil and criminal issues. Though there are many methods of age estimation, namely physical (general development), dental (eruption of teeth and root calcification sometimes aided by Gustafson’s method) etc., radiological estimation by observation of time related appearance and fusion of different secondary ossification centers, is the commonest method used. It is reliable upto 22-25 years of age only, as mentioned by most of the authors.¹ Age, for the appearance of ossification centers, is relatively constant with minor variations. There are many factors which influence the appearance and fusion of bony centers like climatic, economic, hereditary, dietetic, geographical and some other unknown factors.¹

The Indian population differs from the western population in different anthropological traits. Studies done on this subject in India are inadequate. Galstaun in 1930 and 1937 has done a study on Bengali population. The Galstaun chart is the most widely used chart of its kind for comparison, in most parts of West Bengal. According to this chart the age of appearance of ossification centre for lower end of ulna in male is 10 to 11 yrs and in females is 8 to 10 yrs; and the age of fusion for the same in males is 18 yrs and in females is 17 yrs respectively. Similarly the age of appearance of ossification centre for tip of olecranon in males is 11 to 13 yrs and for females is 9 to 12 yrs and age of fusion for males is 17 yrs and for females is 15 yrs respectively.³
Likewise Bajaj studied on Delhi population in 1967, Pilai in Madras in 1936, Basu & Basu on Bengalis in 1938, Agarwal & Pathak on Punjabis in 1957 etc. [2] Most of the data for those studies were collected using traditional X-Ray. The present study focuses on observation of status of ossification of secondary ossification centers using digital x-ray and applying traditional comparison method. Determination of the age of an individual from the observation of appearance and fusion of the secondary ossification centers is legally and medico-legally accepted in India. The present study was carried out by observing the epiphyseal appearance and union at the lower end of ulna and tip of olecranon. This study was carried out in subjects (children and adolescents) who attended forensic medicine department of Medical College, Kolkata for estimation of age in civil matters (recruitment in age-category sports).

**Aims and Objectives**

1. To study the radiological appearance and fusion of secondary ossification centers in lower end of ulna and tip of olecranon

2. To assess whether there is any significant difference between the radiological bone age of today’s population with that of standard charts (Galstaun)

3. To find out the gender wise disparity if any

4. To compare the results with other studies done in India

**Material and Methods**

Study type (Design) – Record based cross-sectional study (Descriptive)

Study period – 1 month (15th December 2019 to 15th January 2020)

Study population- All the children and adolescent from native Bengali population who came to the Upgraded Department of Forensic and State Medicine of Medical College, Kolkata for determination of age.

Place of study – Upgraded Department of Forensic and State Medicine, Medical College, Kolkata

Sample size – 199; Male-142, Female-57

**Inclusion criteria-**

1. All the children and adolescent from native Bengali population residing at sub-urban areas of Kolkata, who came to the forensic and state medicine department of Medical College Kolkata for age determination for the purpose of recruitment in age category sports

2. Sex- all inclusive

3. Age – all inclusive

4. Must have age proof in the form of birth certificate and mothers hospital discharge certificate

5. Must have residential proof in the form of residential certificate

**Exclusion criteria –**

1. Individuals having skeletal or craniofacial deformity.

2. Individuals suffering from hormonal disorders affecting growth and development.

3. Individuals suffering from malnutrition and other nutritional disorders affecting growth and development

**Study tools :**

1. Digital skiagram showing antero-posterior view of wrist joint and antero-posterior and lateral view of elbow joint of non-dominant hand.

2. View box

3. Standard charts (of radiological appearance and ossification of secondary ossification centers)

4. Technical features of digital X-ray machine-generator of 80 KW (kilowatt) power, collimator with focal spot size of 0.6mm, anode heat capacity of 300 KHU (Kilo Heat Unit where 1 Joule =1.4 HU), ceiling suspended tube with movements in all direction, x-ray table having a weight bearing capacity of 200 kg, digital detector with a spatial resolution of 2.5 lines pair/millimeter, high speed processor of 32 bit and an image storage disc of 70 gigabyte.

**Study technique :**

All cases recorded during the last one year from the study period were considered for study after observing the inclusion and exclusion criteria. Digital
x-ray of wrist and elbow joint of non dominant side were taken for observation. Records of preliminary physical examination were looked for to exclude any apparent growth retardation, malnutrition and other exclusion criteria. The x-ray plates were examined for the appearance and fusion of secondary centers of ossification in respect to lower end of ulna and tip of olecranon and compared with the Galstaun chart for known chronological age. The age was estimated using the conventional comparison method. As a convention and regular practice in the department of Forensic and State Medicine, Medical College Kolkata each and every x-ray plate was interpreted by a team of four members comprising of one senior faculty, one junior faculty and two residents. This method was applied to minimize interobserver variation as collective decision (consensus) of the team was taken into account for interpretation. So the data in the record was actually an interpretation by a team of forensic experts. Moreover, each and every plate was re-examined by the authors. However no statistical analysis was done to measure the interobserver variation and this is mentioned in the limitation of study. For appearance, “just appeared” was also taken into account and for fusion, “complete fusion” was taken into consideration. The results were then statistically evaluated after tabulating the collected data in excel-sheet.

Consent for the study:

As it is a record based study on subjects coming for age estimation in relation to qualification in age category sports, no separate consent was taken, as consent was given during medical examination for using the data for academic purposes in the future.

Review of Literature

There appears to be limited number of studies in India related to age estimation using routine x-rays and quite fewer in West Bengal. Age estimation, being an important aid in legal matters, demands accuracy and so it becomes pertinent to follow the latest data related to a particular population. But unfortunately in most of the set ups age old data chart is still in use.

In one of the studies which was carried out on 104 subjects, 54 males and 50 females, in the age group of 15-21 yrs, in B.J Medical College, Ahmedabad in 2009, using x-rays of lower end of radius and ulna, it was seen that completion of epiphyseal fusion in lower end of ulna of both hands in males is 19 to 20 yrs and for females is 18 to 19 yrs.

Another study done in the department of forensic medicine of Surat Medical College, using x-rays of lower end of radius and ulna, among 218 cases of age group of 14 to 21 yrs, was of the conclusion that fusion of lower end of ulna started at 14 to 15 yrs and completed at 19 yrs in female and 21 yrs in male.

In a study on epiphyseal union at elbow and wrist joints in the radiology department of King George Hospital, Lucknow among Indian females of age group 10 to 18 yrs, showed that the results were about at least 2 years ahead of the figures given in most of the textbooks.

Department of Anatomy of Government Medical College, Nagpur carried out a study on ages of epiphyseal union around wrist joint among 80 subjects (44 girls and 36 boys) of age group of 13 to 23 years; lower end of ulna was found to be completely fused at 19 to 20 years in both males and females.

A radiological study of epiphyseal union of distal end of radius and ulna in subjects of age group 16 to 22 yrs was carried out on 100 healthy medical students (50 males &50 females) of Dr. S.N. Medical College, Jodhpur (Rajasthan). In the same study average age for complete epiphyseal fusion of lower end of ulna for males is 19 to 20 years and for females is 18 to 19 yrs.

In a prospective cross sectional hospital based study, conducted in Sudan, with data collected from 5 hospitals; Khartoum, Khartoum North, Omdurman, Police, and Um badda, 57 (Fifty seven) AP and Lateral plane elbow x- rays were taken for healthy Sudanese children (40 Males and 17 Females), aged 13 to 23 years. In this study, the films of the 1st group (at average of 14 years) only 20% of them showed closed olecanon process. In the 2nd group (at average of 17 years) 66.7% showed closed olecranon process. All children above 19 yrs (3rd group) had closed physeal. The female physeal fusion precedes the male in one of all the 6 centers.

The discrepancies in so many studies have heightened the need for a digital skiagram based study
to focus on the need of a region based data for age estimation using x-ray plates.

**Results**

Out of 250 recorded subjects, 199 were included keeping in mind the inclusion criteria, in which 142 were males and 57 females. There are variations in appearance of lower end of Ulna in both males (Table I) (Fig. 2) and females (Table II) where there are frequencies of appearances below the given age range by standard charts. Similarly the fusion for lower end of Ulna occurred before the stipulated age range of standard charts in males (Table III). But in all females the fusion of lower end of ulna occurred by 17 yrs.

Frequency of tip of olecranon appearance in males (Table IV) and females (Table V) (Fig.1) also showed variations from Galstaun chart. Similarly the secondary centers for tip of olecranon showed earlier fusion than the standard age according to Galstaun in both males (Table VI) and females (Table VII). The comparison of radiological bone age of this study with that of Galstaun chart (Table VIII) for both the secondary centers of ossification clearly depicts the variations. The percentage for conformation in appearance of the ossification centers in both males and females (Table IX) with Galstaun chart showed that the female age ranges have less variations than males, however, the percentage for conformation in fusion with the Galstaun chart showed a mixed variation. A comparison with other charts followed in India (Table X) heightens the need for updating the standard charts.

Discussion

There are limited number of studies in India related to age estimation using routine x-rays and quite fewer in West Bengal. As Age estimation is an important aid in legal matters, it becomes pertinent to follow the latest data related to a particular population. But unfortunately in most of the set ups age old data chart is still in use.

In the present study, total number of subjects taken into consideration from the records were 199 (n= 199), out of which 142 were males and 57 were females. The results for appearance of lower end of ulna in males showed that for 26.1% of male subjects the appearance occurred before 10 years whereas in Galstaun chart, which is followed in West Bengal the age for appearance of secondary ossification centre of lower end of ulna is 10 to 11 years[3]. But in females, 3.5% of the subjects showed appearance before 8 years, the age of appearance of lower end of Ulna according to Galstaun being 8 to 10 years. The fusion of lower end of Ulna in males in 99.3% of cases occurred at 18 years which is in accordance with the Galstaun’s age range and in females all showed fusion by 17 years of age which is at par with the Galstaun chart.

The age of appearance of tip of olecranon in 19.7% of males occurred below 11 years of age and in the rest it appeared at 11 to 13 years of age which is the age range mentioned in Galstaun chart and in 7.0% of females the appearance occurred below 9 years, the age according to the galstaun chart being 9-12 years. In 5.6% of males, the tip of olecranon was found to have fused below 17 years and in the rest 94.4% it fused at 17 years in accordance with Galstaun chart and in 12.3% of females the fusion occurred below 15 years and in the rest 87.7 % the fusion was at par with the Galstaun chart that is at 15 years of age.

Hepworth et al. in his study found the age for lower end of ulna fusion in males and females to be 16-17 years which is similar with the results of study by Basu & Basu, which is almost consistent with the results of our study. However Pillai stated that the age for fusion of lower end of ulna in both males and females is 18 years.[2]

In results of the studies which were carried out in BJ Medical College, Ahmedabad (2009), Department of forensic medicine of Surat Medical College, Department of Anatomy of Government Medical College, Nagpur, Radiology department of King George Hospital, Lucknow and Dr. S.N. Medical College, Jodhpur (Rajasthan), are inconsistent with our study results. The discrepancies in so many studies demands the need for a digital skiagram based study to focus on the need of a region based data for age estimation using X-Ray plates.

Conclusion

The appearance of lower end of ulna and tip of olecranon in both males and females vary significantly from GALSTAUN CHART as well as from other studies. The fusion of the lower end of ulna and tip of olecranon in both males and females is almost in accordance with other studies. The variation can be due to the factors affecting the ossification like geographical, environmental, hereditary factors etc. The uniqueness of the finding of the study lies in the fact that it is one of the very few studies to include tip of olecranon on native Bengali population and in our study fusion was less variable than the appearance, which is quite contrary to the general rule.

Limitations:

1. The other factors affecting bone age were not taken into consideration like geographical, genetic, nutritional factors etc.

2. Larger sample size is preferable in further studies

3. A certain amount of children from a locality might not represent the whole population of said age group of that community.

4. There might be considerable interobserver variation in the interpretation of x-rays in such type of observational studies. Every effort was made to minimize interobserver variation while designing the study, through the process of collective observation (i.e. consensus) by a group of forensic experts and re-examination by the authors. However, the interobserver variation was not measurable. Still some amount of interobserver variations cannot be ruled out.

5. Further study regarding different stages of fusion is preferable
Recommendations:

- To formulate separate standards of ossification for geographically distinct regions
- To carry out further studies on a larger sample size
- To update the age old standard charts

Conflict of Interest: Nil

Source of Funding: The study was conducted within the set-up of a state government medical college with the help of self funding when and where required.

Ethical Clearance: Ethical clearance and approval taken from the Institutional Ethics Committee of Medical College, Kolkata.

Abstract
Indonesian Tuberculosis (Tb) case is the highest third rank in the world. It is caused by disobedience in therapy. Three factors affect medication compliance include predisposing, reinforcing and enabling factors. This research aims to analyzed factors that affects medication compliance in Indonesian Tb patients. The study was analytical research. The population were 119 Tb patients in Surabaya Health care center, Indonesia. Simple random sampling technique was used to take sample, consist of 93 respondents. The variables of this study were predisposing factors, reinforcing factors and enabling factors. The data was collected with questionnaires and analyzed with chi square test. The study showed that all factors related to incompliance medication people with Tb, namely predisposing factors: knowledge, attitude, belief (p=0.000), trust (p=0.013, and values (p=0.001); reinforcing factors: family support (p=0.034) and healthcare personnel support (p=0.022); and enabling factors: healthcare facility (p=0.000) and physical environment (p=.000). The determinants of incompliance medication people with Tb include predisposing factors (knowledge, attitudes, beliefs, trust and values); reinforcing factors (family and healthcare personnel support); and enabling factors (healthcare facility and environment). Tackling incompliance medication on Tb should involve private sector, family sector, society/healthcare sector and government sector.

Keywords: Tuberculosis, predisposing, reinforcing, enabling

Introduction
The WHO reports there are three issues related to tuberculosis. The first issue is high pain and mortality figures due to Tb. Tb became the second largest disease killer infection. The second issue is that almost three million Tb cases are not detected by the health system, both undiagnosed and diagnosed but not checked. The third issue is the increase of MDR-TB case[1]. Indonesia has a free TB program in 2035, with efforts among others: ensuring that 95% of TB cases get treatment and increased 90% of treatment success[2].

The Millennium Development Goal targets for 2015 of reducing TB prevalence and deaths by half globally has made some impact on the burden of targeted diseases, including TB. The number of TB cases in Indonesia is in the ranks of three worlds after India and China[3]. On the national scale, the number of TB cases in East Java was at the rank of two after West Java. Based on the results of a survey in Healthcare Surabaya in September 2018 was obtained the number of TB sufferers of 121 people, this number is included from the number of patients with lung tuberculosis both children and adults. Based on the observation data obtained by 10% sufferers are reminded by PMO (supervision of drug swallowing), then by 15% sufferers experience a drug drop out, and as high as 3% died due to TB.

Factors affecting one’s adherents as discussed in Precede and proceed theories by Lawrence Green include predisposition factors, supporting factors and reinforcing factors[4]. The predisposition factor is a factor that exists in a person, among them the knowledge, attitudes, beliefs, and values that a person believes strongly affects
how the person’s behavior is to obey in taking medicine. Determining the success of tuberculosis therapy is one of the patient’s compliance with therapy. Compliance is a behavior that complies with the order to comply with the regulations. In achieving the objective of compliance with TB drugs need to be used to become a living norm and culture of TB sufferers so conscious and self-reliant for healthy living. However, growing an awareness of compliance with TB drug, need an action that can motivate correctly and consistently.

Therefore, it is important for people with TB to complete the therapeutic program well. In other words, adherence to the sufferer for the cure of TB disease is useful to improve patient’s compliance in taking medicine, it is necessary information addressed to the sufferer on how important it is to take medication, give confidence in healing, and provide consultation for the sufferer and family.

**Materials and Methods**

This Design research is an analytical study using the cross-sectional approach. The population in this study is the patient with lung tuberculosis who came to medicine at the Perak East Surabaya Health Center for 119 people. A large sample is 93 respondents were taken using probability sampling techniques with simple random sampling. Independent variables in this study are predisposing factors (knowledge, attitudes, beliefs and values); Enabling factor (health facilities, environment); Factor reinforcing (living support and healthcare personnel support) and dependent variables are adherence to taking medication. Data collection instruments using questionnaires with a check list. Data analyzed using Chi square test.

Factor predisposing

Predisposing factors are defined as personal characteristics or populations that motivate individuals in adopting certain health behaviors; This includes knowledge, values, and attitudes that may explain individual behavior[4].

Knowledge is one of the domains of behavior formation in the treatment of tuberculosis[5]. Patient knowledge needs to be improved, especially knowledge about treatment procedures (how to take medication, drug side effects and taking the drug until complete is not interrupted)[5,6,7].

Patients’ lack of comprehensive information about Tb and its treatment at the start of treatment make incomplete treatment[8]. The more information received can increase the knowledge of TB sufferers and the more obedient to take medication. Compliance is a person’s obedience to a commandment, self-awareness is increasingly open with only the information obtained. The increase in knowledge is not absolutely obtained in formal education, but also can be obtained in non-formal education such as, counseling, health seminars, and health counseling[9].

Attitude has not been an action (open reaction) or activity, but it is a predisposition of behavior (action), or a closed reaction is not a readiness to react to objects in a particular environment as an action to the object. Attitudes have a significant influence on the obedience of a person in taking medicine. Attitudes are an underlying form to be willing and submissive in this respect in taking the medicine. Exposure that is often given to a person affects the individual in decision-making and acting. The compliance attitude of taking medication and having a diet has the opportunity to heal very large. While disobedience can extend the pain and increase the severity of the disease[9].

Belief is one’s willingness to rely on others where he has faith in him. Trust is a mental condition based on a person’s situation in the social context. Healthy lifestyle is the choice that one has for his life for those who believe that the disease comes from a wrong lifestyle will always keep his lifestyle to be healthy. In line with the health theory belief models that trust can affect health.

Tb was curable. This belief needs to be matched to the patient, so that the patient has the motivation to heal by undergoing complete treatment[10].

Values are freely selected, containing beliefs or behaviors about the meaning of a person, object, idea, or action. Value is crucial because it affects decisions and actions. The linked value of compliance in taking the drug will increase the value of the device to a priority. Berman (2014) mentioned that the device value is a small group of values embraced by individuals. Individuals regulate their value devices along the continuum, ranging from the most important to the least important, forming a value system. The value system is the foundation of the path of life, gives direction in life, and forms the basis of behavior, especially behaviors based on decisions or choices[11]. TB sufferers who are undergoing treatment have moderate stress due to taking the drug for a long period[12].

Factor reinforcing

Family support is one of the factors affecting medication compliance. Family support includes instrumental, informational, appraisal, emotional support. The family plays a role as a supervisor to take medication and reduce stigma in family and society[5,13]. Family support includes the patient’s motivation to undergo treatment, to be a medical supervisor and provide support in accessing health care to obtain anti-TB medications. Caring for TB sufferers is a stressor for TB caregiver at home. Caregiver TB not only acts as a drug-taking supervisor. Caregiver TB should be able to manage stress while caring for TB sufferers to avoid contracting easily[14]. Stress condition if not immediately resolved will increase cortisol levels to suppress immune system caregiver TB and easy to get displaced[14,15].

The support of healthcare officers (physicians and nurses) is an important factor in treatment of tuberculosis. Activities undertaken by the health Officer include Health promotion (counseling related to prevention of infection), curative (treatment process, side effects of the drug, and taking medication until complete)[7,16]. The challenge for health workers is how patients and families will undergo complete treatment, including attitudes (friendliness, empathy, and attention).
Factor enabling

Enabling factors, such as access to services or support, which can facilitate the adoption of a particular behavior\[5\], type of facility, type of providers at first visit, number of visits, number of providers consulted before reaching a TB diagnosis and expenses plus travel time were assessed\[17\]. Health facilities that are available in Puskesmas Surabaya is very adequate, among others, the availability of drug flow, health promotion brochure, comfortable waiting room, and a clean toilet. It is also a factor that affects patients to come remediation\[18\]. As a form of support to the TB program, the government of Indonesia has secured all TB patient financing through the Social Security Administering Agency (BPJS) since 2014\[19,20\].

Conclusion

In conclusion, the determinants of incompliance medication people with Tb include predisposing factors (knowledge, attitudes, beliefs, trust and values); reinforcing factors (family and healthcare personnel support); and enabling factors (healthcare facility and environment). Tackling incompliance medication on Tb should involve private sector, family sector, society/healthcare sector and government sector.

Conflict of Interest: The authors declare that they have no conflict of interest.

REVIEW ARTICLE
COVID-19 – Current Status and Trends: A Comprehensive Review

Cinosh Mathew1, Jayesh Rawal2, Nishant Saxena3, Ashish Sharma3, Rahul Jain3
1 Associate Professor, 2 Professor and HOD, 3 DM Cardiology Senior Resident, Department of Cardiology, Smt. B. K. Shah Medical Institute and Research Centre, Sumandeep Vidyapeeth Deemed to be University, Vadodara, Gujarat

Abstract
The current global pandemic of COVID-19 is caused by a virus of corona family named SARS-CoV-2. Cardiovascular manifestations of COVID-19 are varied and complex and include myocarditis, acute coronary syndrome, heart failure, pericarditis and pericardial effusion. Those with cardiac comorbidities are at higher risk of severe infection and death. SARS-CoV-2 may infiltrate and injury the heart directly or may cause Myocardial infarction, LV dysfunction secondary to myocarditis, congestive cardiac failure, rhythm abnormalities and pulmonary and other vascular embolisms. The medications used to treat COVID-19 may also have serious cardiac side effects. A through understanding of the cardiac involvement of COVID-19 and its varied presentation is needed for management of COVID-19 infection and its complications.

Keywords COVID-19, myocarditis, myocardial injury

Introduction
Coronavirus disease 2019 (COVID-19) is a disease syndrome caused by the novel coronavirus, Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2), a single stranded positive sense RNA virus belonging to the family Coronaviridae[1, 2]. The current pandemic of COVID-19 is one of the greatest threats faced by humanity in the 21st century. This disease, identified by Dr Zhang Jixian from Hubei Provincial Hospital had started initially in Wuhan, China in December 2019[1] but has then spread rapidly and on March 11 was declared a pandemic. As of October 1st, 2020 the virus has spread to countries with 33 million cases and one million deaths of COVID-19 have now been reported globally.[3] COVID-19 is extremely contagious and if precautions not taken can infect 60-80% of the population.[4]

COVID-19 can have variable presentation ranging from asymptomatic infection, Mild sore throat to severe pneumonia with Acute Respiratory Distress Syndrome, Multi Organ Dysfunction to death.[5] The lungs have been the main involvement seen in COVID-19 infection, however in 27-40% cases, cardiac involvement is also seen and has a worse prognosis in them.[6-8] Earlier studies have shown cardiac involvement in previous influenza and coronavirus epidemics, including myocarditis, acute myocardial infarction, and worsening of heart failure leading to significant morbidity and mortality.[9] COVID related myocarditis has been described with varied electrocardiographic changes, rise in troponin and echocardiographic evidence of systolic dysfunction. Patients with pre-existing comorbidities are thought to be at an increased risk of infection with SARS-CoV2 and also tend to have worse clinical outcomes[8]. Myocardial injury is associated with cardiac dysfunction and arrhythmias and death compared to those without cardiac injury.[10]

In this article we have reviewed available literature to describe cardiac involvement in COVID-19 with respect to the risk factors, comorbidities, pathophysiology
and complications associated with the infection. This review aims for physicians and cardiologists to update the knowledge of the pandemic and assist them in management of the same.

CARDIOVASCULAR INVOLVEMENT IN COVID-19

Epidemiology

Age

The severity of COVID infection and complications increase with age.[11]. In the elderly age group of 75 to 84 years the rate of admission to ICU was 11 to 31% while in less than 20 years of age the risk of hospitalization was 2 to 3%[12]. Increasing age was also associated with increased mortality with death rate up to 27.3% in the elderly age group and 0.1 to 0.2% in the younger age group[13]. There have also been reports of increased incidence of Kawasaki disease noticed in children with COVID-19 infection.[14]

Sex

Higher Hospitalization rates, more complications and mortality was noted in males compared to females[11]. Studies have shown male preponderance ranging from 52.9% to 60% of the hospitalized patients[11, 15]. The mortality rate in men was higher than women for every age group. The pathophysiology and significance of male predominance of COVID-19 disease is uncertain.

Comorbidities

Patients with pre-existing co-morbidities are at an increased risk of infection with SARS-CoV2 and tend to have worse clinical outcomes[16]. In a study by Wang et al it was reported that in patients with severe disease 25% had cardiovascular diseases, 44% had arrhythmia, and 58% had hypertension.[17] Notably a high complication rate with mortality rate of 10.5% was reported in cardiac patients while hypertensive patients had 6.0% death rates and diabetic patients had 7.3% death rates.[6] In a review of 1590 patients by Zhou et al, those with comorbidities of hypertension, diabetes, heart disease had severe COVID-19 disease requiring ICU care and increased mortality.[18] Recent studies have suggested that obesity may also be a risk factor for severe COVID-19 disease.[15, 19]

Virology and entry into human host cell

Coronaviridae (CoV) are so called because of their crown like appearance. The COVID-19 pathogen belongs to the β-CoV group. CoV has four major structural proteins: the nucleocapsid (N) protein, envelope (E) protein, the membrane (M) protein, and the spike (S) protein which allows attachment and fusion with the host receptor.[20] The animal reservoir of COVID-19 is presently uncertain, but the viral genome was found to be approximately 88% similar to Bat coronavirus and distant to the previously known SARS and Middle East respiratory syndrome viruses.[2] The entry of virus into the human cell followed by the pathophysiology of COVID infection is demonstrated in figure 1.

Mechanism of cardiovascular Involvement

SARS-CoV-2 can bind to the angiotensin-converting enzyme 2 (ACE2) receptor and enter the host cell.[21] These receptors are highly expressed in the heart and lungs, and they have been confirmed to be the functional receptors for the novel coronavirus.[22] Hence The virus infiltrates the human cells through angiotensin-converting enzyme 2 (ACE2) receptors which leads to ARDS, myocarditis and cardiac failure.[23] This receptor may be upregulated in people taking ACE inhibitors and ARBs, thus theoretically providing more targets for the virus’ spike protein, which binds to the ACE-2 receptor. Due to this pathway there has been a lot of discussion on use of ACE inhibitors for hypertension whether they make patients susceptible to SARS-CoV-2 infection. However, there is no clear evidence that ACEIs or ARBs may increase the odds of virus entry into host cells. Hence updates from the American heart association, European Society of Cardiology and European Society of Hypertension suggest that ACE inhibitors should be maintained or initiated as per need in patients with myocardial infections, heart failure, or hypertension.[24]

COVID-19 and myocarditis

Acute myocarditis is a known complication of any acute viral infection. Cardiac muscle autopsy specimens have shown signs of myocarditis such as mononuclear cell infiltrates and myocardial necrosis.[25, 26] Acute myocardial injury is the most common cardiovascular complication inCOVID-19 manifested by elevation of high-sensitivity cardiac troponin I and the incidence of
acute myocardial injury has been reported to be around 8% to 12%. These studies suggest that fulminant myocarditis is an important cause of the acute cardiac injury in COVID-19 patients. The symptoms may vary from angina, breathlessness on exertion, tiredness to cardiac failure, shock, rhythm disturbance and sudden cardiac death. Varied arrhythmias ranging from AV blocks to atrial and ventricular tachyarrhythmias. Transient ECG changes are common and may even mimic a ST Elevation MI but coronary angiogram is usually not showing any obstructive lesion. Up to two to three times elevation of cardiac troponin levels is suggestive of previous cardiac conditions or mild cardiac injury cardiac condition and/or acute injury related to COVID-19 whereas more than five times elevations is suggestive of myocarditis, myocardial infarction secondary to plaque rupture and systemic thrombosis. Serum high-sensitivity troponin, High BNP/NT-proBNP and Hs CRP levels correlate with the extent of ventricular stress and also the severity of illness. Elevations of DDimer have been associated with poor outcome. The rise in Tn-I does not occur in isolation but alongside the rise of other inflammatory markers, such as ferritin, c-reactive protein, interleukin-6 [IL-6], interferon-γ, tumor necrosis factor-α, and lactate dehydrogenase possibly representing a cytokine storm syndrome. Echocardiography may help to assess for global and regional wall motion abnormalities and also demonstrating thickened interventricular septum with associated enlarged left ventricular diastolic diameter, decreased left ventricular ejection fraction, and increased pulmonary arterial pressure. MRI may confirm acute myocarditis and myocardial injury. Endomyocardial biopsy (EMB), long considered the gold standard diagnostic test, can directly demonstrate myocyte necrosis and mononuclear cell infiltrates. EMB will detect evidence of a viral cause in some cases, though in others an immunologically autoimmune-mediated cause of the myocarditis is suspected. However EMB and MRI may be cumbersome and not practical during the current situation but can be considered for research purpose in an appropriate setting.

The various distinct mechanisms for non-ischemic myocardial injuries that have been published in the literature are – [i] inflammation and cytokine storm mediated through pathologic T-cells and monocytes leading to myocarditis and documented by significantly raised inflammatory markers [ii] secondary to hemophagocytic lymphohistiocytosis, [iii] viral myocarditis with reports of progression to fulminant myocarditis, [iv] stress cardiomyopathy, [v] hypercoagulability and development of coronary microvascular thrombosis [vi] respiratory failure and hypoxemia

induced cardiac myocyte apoptosis. COVID-19 induced cardiac injury leads to activation of the innate immune response with release of proinflammatory cytokines. Proteins released through cell lysis like Myosin heavy chain, a cardiac sarcomere protein, appears to be a prime example of ‘molecular mimicry’. Myocarditis appears in COVID-19 patients after a prolonged period (up to 10–15 days) after the onset of infection. Together, the data suggest that a delay in myocardial inflammation is consistent with at least two pathogenic mechanisms: first, that the ‘cytokine storm’ unleashes a subclinical autoimmune myocarditis, and secondly that myocardial damage and/or molecular mimicry initiate a de novo autoimmune reaction.

There is no specific treatment option for myocarditis and need to be managed by supportive therapy like antivirals and early application of interferon, corticosteroids, tocilizumab, anakinra, intravenous immunoglobulin, statin, and active mechanical life support.

Arrhythmias

Viral infections are associated with myocardial inflammation, metabolic imbalances and activation of the sympathetic nervous system, all of which predispose to cardiac arrhythmia. The incidence of arrhythmias has been reported in COVID-19 patients up to 16.7%. The commonest rhythm abnormality noted is tachycardia, uncommonly bradycardia has been noted in some patients. Arrhythmias were observed in 7% of patients without ICU care as compared to 44% of patients admitted to an ICU. A 5.9% incidence of malignant arrhythmias, with a significantly greater incidence in those with elevated troponin level was found (17.3% vs 1.5%, p<0.001). Other arrhythmias seen include atrial fibrillation, conduction block, ventricular tachycardia, and ventricular fibrillation. Others causative factors include dyselectrolytemia, medications affecting QT interval with potential to cause torsades de pointes and fever which may predispose to Brugada syndrome.
and long QT syndrome.\cite{6} Even after hospital discharge, we should consider that myocardial injury might result in atrial or ventricular fibrosis and scarring which may form the substrate for subsequent cardiac arrhythmias. The extent of myocardial scar, as assessed with cardiac magnetic resonance, helps to stratify the arrhythmic risk in patients recovered from COVID-19.\cite{36}

**Acute coronary syndrome**

Acute ST elevation Myocardial Infarction due to plaque rupture or coronary thrombosis due to hyperinflammation may be seen in patients of COVID-19. Patients with risk factors or existing CV disease have a heightened risk of developing an acute coronary syndrome (ACS) during acute infections, including viral illnesses and other acute inflammatory conditions.\cite{32} However the number of patients presenting with Acute MI in Emergency room has been significantly reduced and this has been attributed to the reluctance of patients to go to a hospital during the COVID-19 outbreak, delays in evaluating patients with STEMI after hospital arrival due to precautions such as detailed travel and contact history, symptomatology, and chest X-ray. SCAI and other Expert groups recommend to consider fibrinolytic therapy in select patients with ‘low risk’ ST-elevation MI (STEMI).\cite{37} Additional precautions taken in catheterization laboratory such as time needed to wear protective gear may further delay intervention.\cite{38}

**Heart Failure**

Although data on incidence of left ventricular systolic dysfunction, acute left ventricular failure, and cardiogenic shock is less but available studies have shown heart failure as a complication of COVID-19. ACE2 expression is up-regulated in failing human hearts, which may lead to a higher infectivity of virus and a higher mortality in patients with heart failure. Underlying mechanisms of acute HF in COVID-19 may include acute myocardial ischemia, infarction or inflammation (myocarditis), ARDS, acute kidney injury and hypervolemia, stress-induced cardiomyopathy, myocarditis and tachyarrhythmia. Heart failure has been seen in 23% of COVID patients in a study by Zhen et al. The incidence of significant heart failure in 52% of the non survivors and up to 12% patients who recovered.\cite{18} Also as with any critically ill patients in ICU, they may develop reversible sepsis-related cardiomyopathy with left ventricular dilatation and impaired systolic function. COVID-19 infection can cause decompensation of underlying heart failure and may lead to mixed shock syndrome (combination of septic shock and cardiogenic shock). Significantly elevated BNP/NT-proBNP levels also suggest acute HF.\cite{3} If heart failure is suspected, a limited TTE or focused ECHO can be performed. Invasive hemodynamic monitoring and supportive measures like inotropes and diuresis can be used to treat cardiogenic shock and fluid overload in such cases.

**Venous and Arterial Thromboembolism**

COVID-19 disease causes a prothrombotic state leading to venous and arterial thrombosis. Prolonged immobilization leads to venous stasis and hypercoagulability due to use of glucocorticoid, immunoglobulins as well as vascular endothelial damage due to central venous catheterization and/or ECMO, hypoxia often are a contributing factor for occurrence of VTE. The Exact incidence of thromboembolism is unknown but few case reports have mentioned the occurrence of pulmonary embolism in these patients. Report of occurrence of acute pulmonary embolism in two patients aged 57 and 70 years with elevated D-dimer and multiple filling defects on CT pulmonary angiogram.\cite{39} Multiple studies from China have reported higher D-dimer levels in COVID-19 patients with adverse outcomes.\cite{18} D-dimer levels were significantly higher in non survivors than survivors (2.12 μg/ml vs 0.61 μg/ml; p<0.001) thus reflecting a worse prognosis.\cite{40} Multiple reasons can be postulated for activation of coagulation cascade in critically ill-patients which include i) pro-inflammatory cytokines lead to activation of coagulation cascade; ii) during inflammatory conditions, the alveolar hemostatic balance is tilted more towards a prothrombotic state; iii) proinflammatory cytokines may itself lead to endothelial injury and activation of coagulation cascade. In such a scenario, levels of D-dimer which serves as marker of fibrinolytic activity is elevated along with other inflammatory cytokines. Critically ill patients with COVID-19 are at an increased risk for venous thrombosis and hence the need for anticoagulation in these patients. A recent study showed that in COVID-19 positive patients with sepsis-induced coagulopathy score <4, administration of heparin led to a reduced 28-day mortality. Anticoagulation with heparin has been recommended for patients with raised D Dimer.\cite{40}
**Long term sequel of COVID-19 infection**

Since COVID-19 infection is a new disease it is too early to understand the long-term cardiovascular outcome for patients who have recovered from COVID-19. Patients recovered from previous SARS infections and followed over 12 years showed that 40% had cardiovascular abnormalities, 60% with abnormal glucose metabolism and 68% with hyperlipidemia. [38] Patients recovered from pneumonia followed on long term show cardiovascular abnormalities like myocardial infarction, stroke, and fatal coronary artery disease. These are secondary to increased systemic inflammatory and procoagulant state seen in these patients. The hyperlipidemia may be attributed to the high dose methylprednisolone therapy. In addition, these patients had significantly higher lipid levels as compared to controls which had been attributed to the high-dose pulses of methylprednisolone [41].

**Social effects and consequences on health care**

COVID-19 will lead to a huge burden on developing countries. In a resource limited setup already burdened with existing disease COVID-19 can potentially crash the healthcare system. The focus on COVID-19 treatment has lead to Cardiac diseases taking a back seat. Patients with CVD are not only more susceptible to have COVID-19, the neglect in the care of their primary disease will lead to disastrous consequences. Although control measures like lockdown and curfews are needed due to these restrictions and also fear of contracting disease patients with acute MI delay in coming to hospitals and increasing patients with sequel like LV dysfunction and heart failure are now seen [42]. Hence, strict control measures such as social distancing, lockdown and curfews are the need of the hour to prevent the disease spread. Also, routine follow up and compliance to medications especially in patients from rural areas would be hampered. More emphasis on telemedicine to maintain consultation and follow up with patients and to minimize contact should be encouraged.

**Interventions and cardiac implications**

There are various medications (new and established ones which are repurposed) that are currently being tested in various ongoing studies. Chloroquine and hydroxychloroquine shown promise in some trials when used early in the disease [43]. However clinicians need to be watchful for some rare cardiac arrhythmias associated with these drugs like polymorphic VT (Torsade de Pointes) as they have potential to prolong the QT interval [44]. Convalescent plasma and tocilizumab (a monoclonal antibody against interleukin-6) are other therapies that have shown some promise in reducing severity of illness [45].

Although, ACEi might facilitate viral entry into respiratory cells leading to viral mediated cell damage, these same medications might upregulate ACE2 and reduce the acute lung injury caused by COVID-19. As for now, guidelines recommend that patients on ACEi and ARBs should continue taking their medications as usual and should not discontinue them with COVID-19 disease. Some statins like pitavastatin have shown some effect against COVID but further studies are needed in this regard. [46] NSAIDS have been shown to increase the expression of ACE2 on the cellular membranes and could theoretically increase viral entry into respiratory cells. More studies will be needed on this, but given this concern, many European countries have suggested that in patients with respiratory tract infections, acetaminophen should be used in preference to NSAIDs for control of pain and fever [47].

Remdesivir an antiviral repurposed from previous used for Ebola has shown to be effective in trials to reduce time to clinical improvement and mortality in patients on oxygen [48] but needs larger studies for efficacy and tolerability. Tocilizumab has shown to cause dyslipidemia in patients treated for rheumatoid arthritis. Following tocilizumab, LDL-C, and HDL-C were increased, while cardiac risk markers like phospholipase A2 and Lpa were decreased. [49]
Conclusion

SARS-CoV-2 with its varied presentation and rapid infectivity has emerged to be the biggest challenge faced by mankind in this century. Cardiac patients are at increased risk of severe COVID-19 infection and it is associated with worse prognosis. COVID-19 infection leads to fulminant myocarditis, acute coronary syndromes, heart failure, arrhythmias (Atrial Fibrillation, Ventricular Tachycardia and Fibrillation) etc. all of which are life threatening. Cardiac complications usually appear 10 days after onset of fever and can be detected early using biomarkers. Hence there is need for close monitoring of patients to detect and manage these cardiac complications especially in those with comorbid conditions. Several potential areas of research include pathogenesis and therapeutics; along with randomized control trials are urgently needed which will help in managing this global pandemic.

Tubo-ovarian Abscess and Uterine Leiomyoma in a 35-year-old woman with 8 years of infertility: A Case Report

Cipta Pramana1, Kartika Budi Peranawengrum1, Jennifer Nanda Dewi1, Charity Harlim1, Victor Sepriyadi Wohangara1, Dina Nihayati2

1Medicine Faculty of Tarumanagara University Jakarta, Indonesia, 2Medicine Faculty of Sultan Agung Islamic University Semarang, Indonesia

Abstract

Infertility can be influenced by several factors, including the presence of leiomyomas and tubal abnormalities like a tubal abscess or tubo-ovarian abscess which can cause adhesions of the tubes and surrounding tissues or obstruction of the tubes. A 35-year-old woman is diagnosed with primary infertility of 8 years with intramural uterine leiomyoma, right tubo-ovarian abscess, and left tubal abscess with tubal obstruction. Laparotomy myomectomy and salpingostomy surgery were carried out. There were no complications during or after the surgery. The management of infertile patients with leiomyoma and tubo-ovarian abscess who wish to preserve reproductive function requires special attention.

Keywords: Laparotomy, Intramural leiomyoma, Tubo-ovarian abscess, Infertility

Introduction

Infertility is one of the major problems affecting 13-15% of couples worldwide. The causes of infertility in women can be due to ovarian, tubal, peritubal and uterine abnormalities.1 Uterine leiomyoma is the most common benign uterine tumor found in the lower abdomen and affects women in reproductive age. Leiomyomas can be found in 30-40% of all women between the ages of 30 - 40 and are often seen in African women compared to women of other ethnicities.2 Although its association with infertility is still controversial, it is still a major concern for physicians and patients themselves.3 A tubo-ovarian abscess (TOA) is a serious complication of untreated pelvic inflammatory disease (PID). TOA is often found in women of reproductive age and nearly 60% of nulliparous women. Long-term complications of TOA include infertility, increased risk of ectopic pregnancy, and chronic pelvic pain. Since most of these patients are of reproductive age, fertility preservation should be considered when deciding on the optimal treatment strategy.4

Case Report

A 35-year-old P0A0 woman self-referred to the Gynecology clinic in KRMT Wongsonegoro General Hospital Semarang, Indonesia with lower abdominal pain. The pain was most significantly felt during the beginning of her menstruation period for 2-3 days. The patient also felt a mass that has been growing since a year ago. A history of white, odorous vaginal discharge was recognized by the patient since 2 years ago, and only appears a few days before menstruation. Every menstrual period the patient feels abdominal and back pain. The patient admitted that she had never sought medical attention for her complaints before. The patient has been married for 8 years with no children. Currently, the patient is sexually active and does not use any contraceptives.

Assessment of the general condition shows no abnormality. Vital signs were measured: her blood pressure was 123/78 mmHg, heart rate 92 beats/minute, respiratory rate 20 breaths/minute, and 36.9°C body temperature. The patient weighs 61 kg with 155 cm height and BMI 25.3 kg/m², which puts the patient’s
nutritional status in level 1 obesity.

On abdominal physical examination, a mass with the size of a baby’s head was palpated at the umbilical area, mobile, and has a firm consistency. On gynecological examination, toucher vaginal revealed the size of the corpus uteri was as big as an adult fist. Based on ultrasound examination, an intramural uterine leiomyoma was found with a size of 9.4×8.5×6.4 cm and adnexal mass measuring 8.2×9.5×10.2 cm. The abdominal CT scan demonstrated a 9.51×8.46×9.85 cm leiomyoma, as well as multiple cystic lesions with lobulated septa and regular edges at the right adnexa measuring 7.61×9.91×7.9 cm and oval cystic lesions with regular edges margin at the left adnexa measuring 4.27×3.79×3.25 cm. [Fig 1]. Complete blood count showed hemoglobin 13.1 g/dL, leukocytosis (15.5×10^3/µL) and increased neutrophils (75.4%). The remainder of her laboratory results were within physiological parameters.

The patient was diagnosed with intramural leiomyoma, unilateral tubo-ovarian abscess and 8 years of primary infertility. An exploratory laparotomy was performed with an incision on the uterine wall with cautery, an intramural leiomyoma mass with a size of 8×8×7 cm was found, then myomectomy was performed [Fig.3., Fig. 4]. On the right adnexa, the tube was enlarged with the size as large as an adult fist, adhesions to the surrounding tissue were released, and the ruptured tube secreted pus [Fig.2] which gave the impression of a tubo-ovarian abscess, then the abscess was drained salpingostomy was performed. The left adnexal was also enlarged and the ovary tube was widened with tubal obstruction. A salpingostomy was performed. The pelvic and abdominal cavity was washed with normal saline. The operation was completed in 1 hour 8 minutes. The estimated total blood loss was 50 cc. The collected mass was sent for histopathologic examination. There were no complications during and after the surgery. The patient was given a 2 × 1 gr cefotaxime injection afterward. The patient was discharged on the third day in good and healthy condition.
Discussion

The effects of a uterine leiomyoma on fertility are still controversial. The exact mechanism by which leiomyoma affects infertility is uncertain, but the hypothesized mechanisms are as follows (i) blockage of the fallopian tubes; (ii) changes in tubal motility and prevention of fertilization; (iii) prevention of sperm migration through the cervical canal; (iv) dyspareunia; (v) thin and vascular endometrium; and (vi) abnormal uterine movements.

El Mahdi explained that the location and size of the leiomyoma influence on infertility. Intramural leiomyoma and submucosal leiomyoma with intracavity distortion were associated with lower pregnancy rates, implantation, and live birth rates compared with women without leiomyomas. In previous studies, leiomyomas with a size of 2-6 cm did not affect infertility, however, recent studies have shown that intramural leiomyomas > 4 cm in size affect fertility.

Apart from uterine leiomyomas, TOA that occurs in this patient can be one of the factors that cause infertility. TOA is an abscess that involves the fallopian tubes, ovaries, and surrounding pelvic organs. TOA is common in women of reproductive age and is usually a complication of untreated PID or with inadequate treatment. Tubal obstruction due to TOA can inhibit the reproductive process especially the fertilization stage.

Management of TOA and uterine leiomyoma includes exploratory laparotomy, myomectomy, salpingostomy and adhesiolysis. If the patient wishes to preserve her reproductive functions and fertility, myomectomy is the treatment of choice. Pregnancy rates are as high as 50-60% after myomectomy, with favorable obstetric results but postoperative adhesions are of particular concern, as it may harm future fertility.

There are various surgical intervention options for TOA, namely laparoscopic or laparotomy abscess drainage, unilateral or bilateral salpingo-oophorectomy or pelvic clearance. Factors influencing the treatment of choice include previous surgical history, fertility preservation, and the size of the abscess.

In TOA, drainage of the pelvic abscess by irrigation in the abdominal cavity can be considered if fertility is to be maintained. In women with children, salpingooophorectomy can be considered to reduce the chance of recurrence and the need for further surgery. Given that the patient has no children after 8 years of marriage, we did not perform salpingo-oophorectomy and chose salpingostomy to maintain the tube.
Conclusion

A 35-year-old woman with 8 years of infertility was diagnosed with intramural leiomyoma and right tubo-ovarian abscess and left tubal abscess, which is treated successfully with laparotomy, myomectomy and salpingostomy. There were no complications during or after the surgery. The patient was discharged three days after the surgery in good health.

Abstract

The consumption of drugs of abuse among females in the Health Services is a frequent problem, but often it is not diagnosed. Aims: We have analyzed the variations in the clinical profile of female patients came to obstetric emergency department in a period of sex months and made screening for various drugs to assess the percentage of addicted females in this period of life. Secondly, we have assessed also the accuracy of the presumptive method of detection compared to the confirmatory method. Method: Urine samples were taken from pregnant females came to obstetric emergency department, Beni Suef University hospital and was screened to detect the drugs of abuse that taken by these females by immunoassay and GC- mass and clinical assessment of the babies were done. Results: from 300 females there were 20 cases Tramadol positive by immunoassay but all of them were false positive when GC-mass was used. There was a questioned cross reactivity between Ranitidine and tramadol by Immunoassay needing for more researches. 62.3% of the female were no educated 42% of the female’s husbands were SHISHA smokers. Intra uterine growth retardation was the most common fetal complication

Conclusions: scientific survey which done to detect drug abuse among group of people should never depend on immunoassay methods. The belief that women are more biologically complicated than men and that they were too busy caring for their children to participate in studies should be changed. Women should be included in clinical researches.

Keywords: drug abuse, ante partum female, immunoassay, cross reactivity, GC-mass, Beni Suef

Introduction

The problem of drug abuse is not in the individual alone but its general impact on the family and society. The impact of addiction is catastrophic for the family as a whole; Relationships suffer, financial sources get depleted, health costs increase. Also, the consequences of addictive devastating sexual relations and the resulting sexual transmitted diseases and epidemics which is difficult and sometimes impossible to cure them.

Addiction is also strongly associated with domestic violence, which increases the physical and emotional distress of the family. Having an addicted woman in the family is a catastrophe as women are the backbone of the family, the mother and the wife, and women are also the most suffering from men as a result of addiction. Therefore alternative strategies to identify women with problems related to drug abuse should be used.¹
Scientists have discovered that the problem of addiction in women has to do with hormonal changes such as menstruation, pregnancy, childbirth, breastfeeding and menopause. Also, women themselves describe unique reasons completely different from men for using drugs, including get rid of excess weight, fighting exhaustion, coping with pain, and attempts to self-treat mental health problems.\(^2\)

Immunoassays dominate urine drug screens (UDSs) because they are simple to use, easy to automate and provide rapid results. Unfortunately, they are subject to cross-reactivity with structurally related and unrelated compounds potentially yielding false-positive results.\(^3\)

Because many Technicians have limited knowledge of immunoassay cross-reactivity data, patients with false-positive results may be inappropriately terminated from employment or suffer from medical staff bias because of lack of trust and also contribute in giving false survey on the accurate number of drug abuse and gives a false bad impression about a particular sector of population. As a result, programs are put in place to combat addiction in the wrong unsuitable places.

Opiates belong to a large class of compounds characterized by their ability to interact with endogenous opiate receptors. Synthetic opioids as Tramadol that bind to opiate receptors generally require separate immunoassays for screening purposes.\(^4\)

The current study was done on 300 pregnant female in Beni Suef City. Samples were collected from obstetric emergency department, Beni Suef University hospital in a period of 6 months (January to June) in the year of 2019. Every one filled a complete written consent and a questionnaire before collection of samples. Confidentiality of records was kept. The screened drugs were cannabis, benzodiazepine, morphine, tramadol and Amphetamine.

**Samples collection**

Urine samples (usually 10-50 ml from each driver) were collected from drivers in plastic containers, transferred to lab in ice boxes and free zed in \((-20^\circ C)\) until analysis. The samples were collected in front of guardian to avoid dilution of the samples. Each sample took a serial number in view of the females.

**Samples analysis**

**Screening:** All samples were screened by dip stick to detect studied types of drugs at forensic lab at Beni Suef University.

**Confirmatory:** positive samples were confirmed by G.C at forensic lab at Beni Suef University.

**(1) Dip stick**

**Principle of use of dip stick to examine urine sample before extraction:**

It is an immunoassay based on the principle of competitive binding. Drug which present in the urine specimen compete against their respective drug conjugate for binding sites on their specific antibody. During testing, a urine specimen migrates upward by capillary action.
Results

**Negative:** - A colored line in the control line region (C) and a colored line in the test line region (T) for a specific drug indicate a negative result. This indicates that the drug concentration in the urine specimen is below the designated cut-off level for that specific drug. The shade of color in the test region (T) may vary, but it should be considered negative whenever there is even a faint colored line.

**Positive:** - A colored line in the control line region (C) but no line in the test line region (T) for a specific drug indicates a positive result. This indicates that the drug concentration in the urine specimen exceeds the designated cut-off for that specific drug.

**Invalid:** - Control line fails to appear due to insufficient volume or incorrect procedural techniques. These is the most likely reasons for line failure.

(3) **Gas chromatography:**

Instrument: Thermo scientific Trace1300 Gas chromatography

Type of column: Thermo scientific .TG-SQC. Length: 30 m, I.D:0.25mm.

Carrier gas: Helium

Flow rate: 1 ml/ min

Injection volume: 1 micro

Detector: Thermo scientific Trace, ISQ.QD. Single Quadrupole Mass Detector.

Retention time: time of standard peak start from time of injection to time of appearance of peak.

**Method of extraction**

2 ml urine + 5 ml dichloromethane then vortex for 10 minutes then centrifuge. Aqueous part is discarded and solvent is evaporated then reconstitution with 50 micro methanol. Reagents used are G.C grade.

Questionnaire were answered by pregnant female including age, Educational level, Medicinal history, Maternal complication, Premature labor, Fetal complication, Drug intake by Husband.

**Ethical Considerations:** Written consent was taken for all participant pregnant female in line with the Ethics protocol of medical research.

**Results**

About 62% of the participated females were non-educated. Ranitidine was the most common drug (4.7%) which had taken during pregnancy while about 91% of the participated females were not on any drug during pregnancy. 12% of the ante-partum females have pre-eclampsia followed by Diabetes Miletus 3.3% as a maternal complication during pregnancy. 42% of their husband were Shisha smoker, 6.7% were cigarette smoker. Fetal complications were variable as IUGR, macrosomia and congenital anomalies. IUGR came as the major fetal complication by 22%. 15.3% of fetus entered in the incubators because of many complications. From 300 females there were 20 cases Tramadol positive by immunoassay but when GC-mass was used all of them were discovered to be false positive. So in our survey there were no cases of drug abuse among 300 ante partum females came to Obstetric Department, Beni Suef University Hospital.

**Discussion**

Immunoassays were developed for general screening. Urine drug testing is now done for any occupations (i.e., truck drivers and train engineers, any positional governmental employers and also in proposal for many private works). Interpretation of drug test results should be performed by a medical trained and certified technician, who can make result interpretation to understand the pitfalls in interpreting urine drug screen results.\(^7\)

According to the manufacturer reports there are some agents known to cross-react with each class. This list should not be considered the only substances that making the cross react which mean that there are many unlisted substances could make the same cross react. The sensitivity and specificity of the various components of the immunoassays are variable between manufactures.\(^7\)

There are many factors affecting drug detections in urine as UDS’ cutoff or detection level of specified urine metabolite above which the test will be positive, substance’ dose, elimination half-life, urine pH, urine dilution, frequency of use, and time of last use.\(^9\) Thus, health care providers should be aware of all these factors during making their research.

GC/MS is both more sensitive and specific than immunoassay but more expensive, slower, and not readily available for acute management.\(^8\)

Most urine drug screens are designed to detect opiates (namely morphine) and drugs metabolized to morphine by the human body (i.e., heroin) and often “miss” the majority of semi-synthetic and synthetic opioids; although, cross-reactivity does occur and is assay dependent. False positive opiate tests have reportedly been caused by dextromethorphan, diphenhydramine, quinine, quinolones, rifampin, verapamil, and poppy seeds. In the hopes of testing for medical adherence, some urine drug screens specifically include methadone. Of note, false positive methadone screens have been reported to be caused by quetiapine, doxylamine, olanzapine, diphenhydramine, and verapamil.\(^10\)

Many studies reported that, positive screens should be confirmed by GC/MS and / or quantitative levels of the specific drug of abuse in question should be sent in these types of cases.\(^7\)

Immunoassays give to some extent helpful information, but should be treated as ‘presumptive positive’ results which should be confirmed by other an independent procedure such as GC–MS or liquid chromatography–tandem mass spectrometry as we done in our study.

In a study that done on youths and young adults, they suggest that gender may play a role in the patterns of drug use, abuse, and dependence. They found that overall rates of substance use were significantly higher for males than for females.\(^5\) figure 1 highlights country-level variations in the drug use gender gap in Europe.\(^12\) Another data indicate marked differences in the male to female gender ratio in Georgia and Albania.\(^13\)

In our study there was no case of drug abuse among 300 ante partum females while It was estimated that nearly 30 000 pregnant women use opioids in Europe in a survey done in 2009.\(^14\) Also other studies which done in Canada showed that percentage of drug abuse between females and males resemble approximately 1:2.\(^16\)

Our explanation for these results is that Pregnancy and motherhood can be a strong motivator in a woman’s pathway to stop any drug addiction and also sense of guilt and fear of having abnormal children.

Also ethnic, cultural and religious diversity needs to be considered when working with this group of women.\(^15\)

Federal agencies, including the National Institutes of Health (NIH), have been instrumental in pushing for women to be included in clinical research. These efforts have ensured that broader public health issues related to sex and gender are studied.\(^11\)

**Conclusion**

Understanding the reasons for differences between males and females In drug abuse and between females themselves in different countries and continuing to evaluate these patterns over time could help in the development of targeted and more effective prevention and treatment interventions. Scientific survey which done to detect drug abuse among group of people should never depend on immunoassay methods. The belief that women are more biologically complicated than men and that they were too busy caring for their children to participate in studies should be changed. Women should
be included in clinical researches.

**Recommendations**

Because of the poor sensitivity and specificity of immunoassays the clinician usually make definitive confirmation by other methods as GC/MS but it is done in cases with forensic or legal ramifications but this confirmations should be done also in survey studies to give accurate data that can deal correctly through these results. More surveys should be done on bigger sectors of females to detect cases of drug abuse between them.

**Conflict of Interest:** Nil

**Funding:** This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Overview of the Content of Bisphenol A in the Amniotic Fluid of Pregnant Women And Its Adverse Health Outcomes

Dardan Dreshaj 1, Flaka Pasha2

1Researcher, University of Prishtina “Hasan Prishtina”, Kosovo, 2Researcher, Department of Pharmacology and Toxicology and Clinical Pharmacology, University of Prishtina “Hasan Prishtina”, Kosovo

Abstract

Background: This review represents a critical and constructive analysis of literature in the content of Bisphenol A in amniotic fluid of pregnant women and its adverse health outcomes. The review is generated through summary, classification, analysis and comparison of already existing material and researches on field.

Methods: Databases as Scopus, PubMed, Medline, Web of Science, Global Health, were used to extract data for the review. Search terms like “Bisphenol A”, “pregnancy”, “amniotic fluid”, “endocrine disruptors” were used. Out of 200 research articles screened, 70 most relevant studies are included in this review.

Conclusions: This review highlights the correlation between Bisphenol A and its endocrine disrupting potential, impacting especially fragile categories as pregnant women and their fetuses through its toxicokinetic features and its metabolites. Thus, BPA distorts important physiological processes necessary for fetal development and disease progression later in life.

We can conclude that human exposure to BPA, as one of the leading environmental contaminants, represents a major global issue and its adverse health outcomes can be debilitating for human health. Further research on field considering BPA distribution, varying exposure rates, racial disparities, inter-species differences and EDCs cumulative effects, should be conducted. Finding safer alternatives for replacing BPA in market must remain a priority.

Keywords: amniotic fluid; Bisphenol A, pregnancy; adverse health outcomes;

Introduction

Bisphenol A (BPA), 2,2-bis(4-hydroxyphenyl) propane (CAS No. 80-05-7), is a synthetic chemical excessively produced worldwide.1 BPA commercial production began in the United States in 1957, followed by Europe one year later. Its global production grows consistently, varying between 0% and 5% annually, with the strongest growth occurring in China.2 A yearly increase of 4.6% in production of BPA is envisioned to happen from 2013 to 2019.3

Bisphenol A is used to manufacture polycarbonate plastics and epoxy resins.4 Out of the total production of BPA, 65% is dedicated to polycarbonate synthesis, 25% for epoxy resins and the rest 10% for our daily use products such as food storage containers, food antioxidants, metal food cans, baby bottles, thermal papers, dental seals, medical devices, personal care products, safety helmets, sunglasses, lenses, cosmetics, infant incubators, CD/DVDs, hair dryers, fridges, computers and smartphones.5

Bisphenol A is synthetized by the condensation of phenol with acetone in the presence of a catalyst, a strongly acidic ion-exchange resin. BPA consists of a central tetrahedral carbon atom with two methyl and two phenol groups. BPA is relatively water-soluble (120-
300 mg/L),\textsuperscript{6} dissociates in alkaline environment, has a moderate bioaccumulation rate, low vapor pressure, high melting point, and low half-life in air (0.2 days).\textsuperscript{7,8} BPA leaches into environment and impacts human health during its production, processing or waste disposal.\textsuperscript{9} BPA leaching also occurs when polycarbonate and epoxy resin-containing products are exposed to heat, are re-used or their pH changes.\textsuperscript{10} BPA products in contact with heat, acidic or basic conditions accelerate the hydrolysis of the ester bonds between BPA molecules, thus exposing humans to its harmful metabolites. This happens when people heat cans to sterilize food, place acidic or basic food in cans or polycarbonate plastic, and keep heating or washing these products.\textsuperscript{11,12} Even though ingestion of contaminated food is the most common way how human get exposed to BPA, inhalation and skin absorption are considered to be of great importance too.\textsuperscript{13,14} Also, moderate levels of active unconjugated BPA have been detected in human serum, adipose tissue, breast milk, placenta, maternal and fetal plasma, indicating that BPA can accumulate in human body.\textsuperscript{15,16,17}

The United States Environmental Protection Agency (EPA) reported that more than 400,000 kilograms of BPA leach into environment every year,\textsuperscript{18} alarming us on the great burden of exposure, BPA’s cumulative effects and life-long disadvantageous health impact.

**Bisphenol A mechanisms of action and its disrupting potential**

BPA is qualified as a xeno-estrogen that disturbs synthesis, transport, activity and metabolism of endogenous estrogens, consequently affecting the development, growth and reproduction of organisms.\textsuperscript{19,20} BPA can mimic or antagonize endogenous hormones, subsequently perturbing endocrine function, by binding weakly to several steroid receptors including the estrogen receptors (ER $\alpha$ and $\beta$) and thyroid hormone receptor.\textsuperscript{21,22,23} As well BPA strongly binds to transmembrane endoplasmic reticulum, G protein-coupled receptor 30 (GPR30) and estrogen-related receptor gamma (ERR$\gamma$).\textsuperscript{24,25} BPA can also activate peroxisome X receptor (PXR) and the aryl hydrocarbon receptor (AhR), often involved in cross-talk with steroid receptors.\textsuperscript{26,27}

Many of these receptors play an important role in gene regulation, suggesting that BPA may influence normal differentiation and maturation processes especially during embryonic and fetal development.

The United States Environmental Protection Agency established a reference dose (RfD) for humans of 50 $\mu$g BPA/kg body weight (BW) day$^{-1}$, based on a thousand-fold reduction of the lowest observed adverse effect level (LOAEL) of 50 mg kg$^{-1}$ BW day$^{-1}$.\textsuperscript{28,29} Studies indicate that daily human intake of BPA is less than 1 $\mu$g kg$^{-1}$ BW day$^{-1}$, rendering the reference dose to be considered safe to humans.\textsuperscript{30}

However, other studies have shown that administration of low-dose BPA as 0.2 $\mu$g kg$^{-1}$ BW day$^{-1}$ can reduce fertility and sperm production in male animals.\textsuperscript{31,32} At doses of 0.23–23 ng kg$^{-1}$ BPA, the number of ERK-positive cerebellar cells increases and calcium ion signaling in pancreatic cells can be suppressed leading to diabetes mellitus.\textsuperscript{33,34,35}

To add, BPA is thought to elicit aneugenic effects by interfering with microtubule assembly, spindle apparatus function, chromosome segregation during mitosis,\textsuperscript{36,37} and disturbing DNA damage signaling pathways,\textsuperscript{38} thus affecting DNA stability, leading to potential carcinogenesis.

The content of Bisphenol A in amniotic fluid of pregnant women

Human pharmacokinetic data support rapid metabolism of free BPA to its BPA glucuronide (BPAG) and BPA sulfate (BPAS) metabolites, through UDP-glucuronyltransferase (UGT2B15) and sulfotransferase (SULT1A1) enzymes, resulting in faster urinary excretion of BPA in adults.\textsuperscript{39,40}

In comparison to adults, human fetuses and neonates have reduced capacity for chemical detoxification.\textsuperscript{41,42} Studies report that mammalian placenta presents with $\beta$-glucuronidase (GUSB) and steroid sulfatase (STS), breaking down inactive BPA metabolites to free BPA.\textsuperscript{43,44}

Performing liquid chromatography coupled with mass spectrometry (LC/MS) to compare levels of
conjugated and free BPA, in second and third trimester amniotic fluids, detected free BPA levels to comprise of 83% and 91% of total BPA, highlighting the role placental β-glucuronidase has on deconjugating BPA, thus exposing fetuses to even higher amount of free BPA and potentiating its adverse effects.45

A considerate number of studies measured BPA in fetal cord blood 46,47, fetal liver 48,49,50, and amniotic fluids 51,52, on concentrations varying from 0.14 to 9.2, 1.3 to 50.5, and 0.36 to 5.62 ng/g, respectively. Potential correlations between maternal and fetal blood in pregnant women, and between peripheral blood and peritoneal fluid in non-pregnant women, unveiled BPA levels ranging from non-detectable to 4.46 ng/ml for maternal serum (MS) and from non-detectable to 4.60 ng/ml in fetal serum (FS) of pregnant women. In the other hand, BPA levels in non-pregnant woman ranged from 1.30 to 8.17 ng/ml in peripheral blood and from 0.19 to 13.45 ng/ml in peritoneal fluid. Thus, positive correlation between maternal and fetal serum was found, highlighting a continuous distribution of BPA between the mother and fetus. Further, differing BPA concentration levels between pregnant and non-pregnant women reveal the role pregnancy has in underestimating the actual levels of BPA in blood.53

A more complex study, using novel enzyme-linked immunosorbent assay (ELISA), compared BPA concentration on blood samples obtained from healthy premenopausal women, women with early and full-term pregnancy, ovarian follicular fluid, amniotic fluid and umbilical cord blood at full-term delivery.

Surprisingly, results reviled there was 5-fold higher concentration of BPA in amniotic fluid in comparison to other fluids, ranging between 8.3 +/- 8.7 ng/ml at 15-18 weeks of gestation. Findings suggest significant exposure during the prenatal period and accumulation of BPA in fetuses, which must be cautiously considered in evaluating the potential human exposure to endocrine-disrupting chemicals.54

Differently, measuring BPA concentration levels in pregnant Korean women resulted in slightly higher BPA concentrations, ranging from non-detectable to 66.48 microg/L in mother serum, and from non-detectable to 8.86 microg/L in umbilical cords.55 These higher BPA rates in Korean pregnant women may be attributed to different geographical exposure rates to BPA, having in mind that BPA market in Asia raised 13% annually from 2000 to 2006.56 So, different geographical exposure rates, should be considered when interpreting BPA concentration levels.

Moreover, a nested cross-sectional study revealed significant racial disparities in maternal and fetal BPA concentrations. African-Americans had 10-fold higher maternal serum BPA concentrations than Caucasians (30.13 vs 3.14 ng/ml(-1); P=0.038), Hispanics had intermediate concentrations with a trend towards higher concentrations compared with Caucasians (24.46 vs 3.14 ng/ml(-1); P=0.051) and Hispanics had higher fetal BPA concentrations than non-Hispanics (2.05 vs 0.35 ng/ml(-1); P=0.025). These findings potentiate the immediate need to determine if such differences come from different levels of BPA exposure, fetal-placental transfer and its metabolism, or racial genetic variations.57

It is crucial to know that measuring BPA as the end analyte might lead to inaccurate estimates, considering potential interferences from background sources during sample collection and analysis. Aglycone BPA and its primary conjugates as BPAG, BPAS, represent better candidates for biomarkers of BPA exposure, since they are not prone to external contamination and require in vivo metabolism.58 To 2016 only ten studies reported analytical methods to measure BPA metabolites instead of just BPA. Research was limited by either lack of commercial or custom-synthesized BPA conjugates, or lack of labeled internal standards.59,60,61,62,63,64,65,66

In order to achieve even more accurate and comprehensive representation of human exposure to endocrine disrupting chemicals, such as BPA, it is crucial for the future studies to consider cumulative effect of EDCs, knowing that humans are not exposed separately to just one EDC at a point of time.57,68,69

BPA adverse health effects in fetuses and disease progression later in life

Exposure of rodent fetuses to Bisphenol A, at doses similar to environmental exposure, is found to cause postnatal estrogenic effects, as alteration of mammary gland morphology, detrimental long term effects in vagina and faster growth and puberty in females. As
well, reduced sperm production in males, increased prostate weight, and disruption of sexual differentiation in the brain was noticed.\textsuperscript{70,71,72,73,74,75,76}

Short time exposure to so considered “safe levels” of BPA, proved to have direct adverse effect on remodeling uterine spiral arteries, thus limiting blood supply to fetus \textsuperscript{77}, resulting to implantation failure, spontaneous abortion, recurrent miscarriages, or even leading to an increased risk of pre-eclampsia.\textsuperscript{78,79,80,81}

Studies support that women with detectable bisphenol A (BPA) concentrations have significantly higher risk of being infertile. La Rocca et al. \textsuperscript{82} found that the mean concentration of BPA was twice as high in infertile than fertile women (10.6 vs. 4.8 ng ml\(^{-1}\)). Among infertile women, estrogen receptor alpha (ER\(\alpha\)) and beta (ER\(\beta\)), androgen receptor (AR) and pregnane X receptor (PXR) were significantly expressed higher than in fertile patients, highlighting the distorting effect BPA has on these receptors.\textsuperscript{83}

Increased BPA concentrations are also reported to raise the occurrence of polycystic ovary syndrome (PCOS) \textsuperscript{84}, and are related to abnormalities in uterus morphology and endometriosis \textsuperscript{85}. Some other studies prove that BPA may cause atopic hyperplasia, uterine polyps or even cervical sarcoma and nipple adenoma.\textsuperscript{86,87,88}

![Figure 1: Effect of BPA on women reproductive processes. BPA, bisphenol A \textsuperscript{89}](image)

In addition, BPA-treated testes contain mostly spermatogonia and spermatocytes with markedly less round spermatids, indicating signs of meiotic arrest. Neonatal BPA exposure disrupts meiosis during the first phase of spermatogenesis, due to inhibition of BOULE (conserved key regulator for spermatogenesis expression and up-regulation of ER\(\alpha/\beta\) expression in BPA-exposed developing testis) \textsuperscript{90}. This situation leads to increased presence of apoptotic cells in seminiferous tubules, sperm cells DNA damage and decreased sperm counts.\textsuperscript{91}.
Rather than just having disruptive effects in reproductive tract, high BPA concentrations correlate with increased incidence of obesity and earlier puberty in females, altered physical and mental development in children, modified childhood behavior, cardiovascular disease and immune system dysfunction.92,93,94,95

A ten year study, comparing BPA levels in amniotic fluid between pregnant mothers with normal and abnormal karyotype fetuses, highlighted that mothers with abnormal karyotype fetuses had higher levels of BPA concentrations in amniotic fluid, in comparison to pregnant women with normal karyotype fetuses. Therefore, these findings highlight the distorting potential BPA has in DNA stability and carcinogenesis induction.96

Studies aiming to evaluate the role of BPA in carcinogenesis97,98 have indicated that exposure to BPA may increase the incidence of multiple cancers, as breast cancer 99,100,101, ovarian cancer 102,103, uterine cancer 104, prostate cancer 105,106, testicular cancer 107, and liver cancer.108

**Conclusions and Perspectives**

Governmental restriction on BPA and general public concern regarding bisphenols adverse health effects, increased manufacturers interests on developing BPA substitutes such as Bisphenol S (BPS) and Bisphenol F (BPF).109 Due to their stability in sunlight and high temperature, they were initially thought to be safer alternatives.110 In contrast, in vitro studies found that BPS and BPF can elicit even greater estrogenic activities than BPA111, can decrease cell viability, increase DNA damage and induce reproductive and neural toxicity.112,113,114,115,116

In addition, having in mind BPA’s accumulation potential, its distribution to fetal-placental unit, interspecies placental differences117, high BPA exposure in early weeks of gestations, racial disparities, varying geographical exposure rates, and BPA’s cumulative effects with other EDCs, no endocrine disruptor dose should be assumed to be safe in pregnancy.118,119

Therefore, increasing population’s awareness around BPA adverse health effects through health education, and avoiding exposure to products containing BPA, remains the fastest and easiest way to limit BPA long life term adverse health outcomes.

Study of Students’ Perception Regarding Open Book Assessment and Closed Book Exams

Dayananda R1, Mahantesh Patil2, Manjunath S N3, Rajapur Parshuram4, Vijay Kautilya5

1Associate Professor, Department of Forensic Medicine, 2Associate Professor, Department of Biochemistry, 3Associate Professor, Department of Community Medicine, 4Associate Professor, Department of Anatomy, Mysore Medical College & Research Institute, Mysuru, 5Professor & HOD, Shri Sathya Sai Medical College and Research Institute, Chennai

Abstract

Background - An “open book examination” is one in which students are allowed to refer to their notes, textbooks, and other approved material while answering questions. This practice is mostly unheard of. It is ideally suited to professional courses like MBBS which especially aim at developing the skills of critical and creative thinking.

Materials and Methods – After a lecture on chapter Medical Law and ethics 100 students selected through simple random sampling after obtaining informed consent were given Pre test. Then they were divided into 2 groups. The topic Medical Law and Ethics was divided into 2 Parts. The students of Group 1 undertook open book exams for Part A and Self study exams for Part B and for students of Group 2 it was reversed. Post test was done with the validated pretest questions. To check the retention another open book exam was performed after a month. The students also answered a questionnaire on their perception of open book exams and the reason for their preferences and it was analyzed.

Conclusion – A total of 100 students participated in the study. In that 60 were medium achievers and 40 were high achievers. Both medium achievers and high achievers obtained high scores in open book exams. Most of the students felt that Open book exam is less time-consuming for preparation, less stressful and increased their Self-directed learning. Open book exams is better to the closed book exams and inculcates the habit of life-long learners.

Introduction

The present time is accepted as the era of advancing knowledge, rapidly changing science and information technology. Consequently there have been many changes in the life styles of people. In yester years the student use to go to the place of Guru, reside there and learn. The test conducted by the “Guru Dronacharya” and the contemporary three hours written test of closed book type have wide difference.1

As per cognitive psychological research, examination or test enhances the retention of knowledge and known as testing effect.2-4 A closed book examination is probably the most common method of student assessment used in all levels of the education system in India.

The continued use of closed book examinations may encourage our students to live in the past rather than the future. Closed book examinations emphasize heavily on low-level skills such as memorization, instead of testing high-level skills such as the abilities to reason, conceptualize and solve problems

The MCI has also changed its curriculum from knowledge based to Competency based curriculum. Students must now move away from passive reading

MMCRI, Mysore E mail – dr_mgpatil@yahoo.co.in, Mobile no – 09738514199.
of prescribed texts to the process of acquiring skills for lifelong learning. Hence medical educationalists are inspired for the innovation in assessment too. Here is one such attempt to compare the Open Book Exam with traditional Closed Book Exam.

**Materials and Methods**

The present study was conducted at Mysore Medical College and Research Institute, Mysore after obtaining ethical clearance from the Institutional Ethics committee. 100 students were selected through convenient sampling. A written informed consent was obtained from the students.

Didactic lectures will be conducted on the topic “Medical Law and Ethics”. After the lecture a validated Pre test of 200 multiple choice questions was administered to the students.

The second year students were divided into two groups by stratified randomization based on their previous internal assessment score. The students who had scored were divided into high achievers (Group 1) and medium achievers (Group 2) with 60 percentage of marks as the cut off. The topic Medical Law and Ethics was also divided into Part A and Part B.

The students were given a month time. The students undertook an exam in the form of short answers. Group 1 students were administered Open book exam for Part A and Closed book exam for Part B and the order was reversed for Group 2 students.

A post test was done with the same set of 200 Multiple choice questions containing 100 MCQs from Part A and Part B respectively. The gain in the score of open book exam was compared with that of the closed book exam. To assess the retention of the open book exams delayed post test was administered to the students after a month. Feedback was taken from the students on the open book exam through a validated questionnaire in the Likert scale Type (Type 1 – Type 5, Strongly agree to strongly disagree respectively)

**Results**

A total of 100 students were included in the study among them 40 were medium achievers and 60 were high achievers. Perception of MBBS students about the open book exam is depicted in the Table 1. Majority of the students opined that the open book exam was less stressful, less time consuming because of less memorization hence not boring. The majority of students felt that the open book exam assessed their ability to apply knowledge and also inculcated the habit of self directed learning.

Table 2 depicts the comparison of gain in score between open book, closed book and repeat open book test. The high and medium achievers had higher score in open book exam as compared to the closed book exams. In the repeat test too both high and medium achievers showed higher gain scores.

### Table 1 - Perception of students about the open book test.

Discussion

Since assessment is not unique to any of the specific academic discipline. The closed-book exam is a well-established approach to assessment in higher-education. It is both widely accepted by educators and frequently used, it basically tests how well a student uses the knowledge they can recall with no additional material available for use on the exam. On the other hand, open-book exams allow students to consult textbooks, notes, and other course-related material during the exam. Some educators may consider open-book tests less conventional, but they have gained popularity.

Open book exam is believed to be able to enhance deeper learning among the learners. There is also sufficient evidence to show that open book exam could have a significant contribution to learning at higher taxonomical level. Specifically, students liked the idea of open-book exams, but not necessarily for the reasons educators might think. Anecdotally, students indicated they learned more through the open-book testing approach than they do through the conventional closed-book approach regardless of their grades in the assessments, because they were able to focus on mastering concepts rather than memorizing aspects they could look up in the textbook. Further, they also indicated they did not have a false sense of security going into the open-book exams, as they knew they would have to be able to apply concepts rather than simply report facts from the textbook.

In the present study gain in scores was higher and the retention of the learning was more in both medium and higher achievers. Most of our findings are in agreement with the study done by Pragnesh Parmar except in their study retention for repeat exams was lesser in medium achievers.

In the present study it was observed that the students had appeared for open book exams with all the relevant material necessary. They were even aware as to which topic is better described in which book, they could identify the topic in those books within a few minutes, which was similar to the study conducted by Pragnesh Parmar and Chen at al.

Conclusion

In our study we found a partial support that open-book exams would significantly increase students’ learning, we believe our study was successful in demonstrating usefulness of this type of assessment and further research in this regard.

Mandibulectomy in Desmoblastic Ameloblastoma: Physiotherapeutic Approach in a Sporadic Oral Surgery Case

Deepali Patil¹, Waqar M. Naqvi², Pratik Phansopkar³

¹Associate Professor, Department of Musculoskeletal Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India, ²Professor and HOD, Department of Community Health Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India. ³Assistant Professor, Department of Musculoskeletal Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India

Abstract

Introduction: Ameloblastomas are slow-growing lesion with local infiltrative and odontogenic tumors of epithelial origin. Desmoblastic ameloblastoma is traditionally considered to be a subtype of SMA. The purpose of this case report is to describe the physiotherapy rehabilitation in mandibulectomy of the right side. A patient chief complaint was inability to open mouth, inability to eat food, impaired cognitive and social behavior. The primary goals of mandibular reconstruction are feature restoration and an appropriate cosmetic outcome. The diagnosis of desmoblastic ameloblastoma was confirmed by bone biopsy. Mandibulectomy of right side done due to desmoblastic ameloblastoma. Physiotherapy treatment is found to be best to resolve patient’s chief complaints.

Results: The case report demonstrated that patients with Mandibulectomy with minimal mouth opening regain near-normal range and improvement in social skills.

Conclusion: The patient was able to do essential activities of daily living like eating and talking without pain and regain near-normal face appearance due to physiotherapy intervention.

Key words: Ameoblastoma, Mandibulectomy, Physiotherapy, Rocabado mobilisation, Quality of life.

Introduction

The origin of Ameloblastoma is from the odontogenic epithelium and it is the second most common tumor, only next to odontoma. The tumor is considered benign even with its locally invasive nature (1). Ameloblastomas signify 1 to 3 percent of all oral and maxillomandibular cysts and tumors. The most common type of multicyctic/solid ameloblastoma is 91 percent of all ameloblastoma.

There are several options available for restoring the defects after surgery. The primary goals of mandibular reconstruction are feature restoration and an appropriate cosmetic outcome. Many options like vascularized or non-vascularized bone grafts, bone morphogenic protein, and osteogenesis disturbance (OD) are choices. Desmoblastic Ameloblastoma case mandibulectomy is the surgical option though it is noncarcinogenic (2).

To avoid arbitrary conclusions, a reasonable exercise planning must be proposed by scientific research society (3,4).

Patient information

A case of 51-year-old female severely affected by cystic lesion over the right mandibular body region is presented in the study, wherein the final diagnosis was desmoplastic ameloblastoma of the right mandibular region.
body region (figure 1). The patient complains of painful swelling over the lower right back region of the jaw which was initially small in size and gradually increased to present size 7×4 cm approximately. No history of regression in size of the swelling. History of associated pain which was gradual in onset, dull aching, intermittent, and localized in nature. Pain aggravated on mastication and relieves on its own over a time. There was no history of associated trauma or burning sensation on the consumption of hot and spicy food. Positive history of change in consistency of saliva from normal to thick and ropy since 1 month approximately. Reduced in salivation for 1 month. Composite resection of lesion, segmental mandibulectomy from 41 to angle of mandible of the right side, and reconstruction with peak implant was done (figure 2). Then from next day physiotherapy treatment was started.

Assessment

The patient in this study had difficulty in opening mouth, swelling over the right cheek, difficulty in eating, and talking. The patient was disturbed due to the pain and appearance of the face. Neck movement was normal. Further assessment was taken by FONSECA questionnaire.

Physiotherapy intervention

The patient received physiotherapy for 1 week on a regular basis in the oral surgery ward by a skilled Musculophysiotherapist. Facial muscle exercises and mouth opening actively within the pain limit done by the patient.

The treatment was started with the goal to reduce pain and increase mobility. Further training was carried out when the patient came to the physiotherapy department on a regular basis. Proper mobilization and exercise were given to patient. Joint mobilization can be performed in various directions to improve the joint play at TMJ, such as distraction, distraction given with anterior glide, distraction given with anterior glide, and lateral glide right/left and lateral glide without distraction. And Rocabado’s 6X6 exercise program has various exercises that had to be performed 6 times a day with 6 repetitions of each exercise and it includes rest position of the tongue, shoulder posture correction, stabilization of head flexion, axial extension of the neck and controlled TMJ rotation.
Result

Improvement in range of mouth opening and reduction in pain. Due to early exercise reduction of swelling over face and eating was easier to patient. The patient was depressed by facial appearance and difficulty in talking. After physiotherapy sessions, pain and swelling were reduced so the patient could talk properly and evenness in facial muscles nearly same.

Discussion

Ameloblastomas (odontogenic tumors) of epithelial source and are sluggish rising lesion with home-grown infiltrative development possible (5). Ameloblastomas, excluding odontomas, are the most common odontogenic tumors. Desmoplastic ameloblastoma varies from other predictable ameloblastomas meticulously, in the clinical sense, and X-ray prediction (6). OPG (Orthopantomogram) and FNAC (Fine Needle Aspiration Cytology) were done in the above patient to confirm the diagnosis.

In this case, the patient represented with painful swelling over the lower right back region of the jaw and gradual increase in swelling. After Composite resection of the lesion, segmental mandibulectomy from 41 to angle of mandible of right side and reconstruction with peak implant was done referring to physiotherapy, patient complains of pain and swelling on the operated side. A successful plan of care was made following a clinical evaluation. Goals for rehabilitation were set, starting from mild exercises to strengthening and manipulations to the temporomandibular joint. All the exercises were performed with each one six times a day 6 types of exercises and 6 sets; ice packs were applied around the patient’s right TM joint and cheek to reduce the exercise caused discomfort during the therapy session. There are works of literature that show the effects of temporomandibular joint dysfunction recovery for patients, but research on surgical cases like mandibulectomy with minimal mouth opening regain near-normal range. The patient was able to do essential activities of daily living like eating and talking without pain and regain near-normal face appearance due to physiotherapy intervention.

Conflict of Interest – The authors declare that they have no conflict of interest.

Informed Consent – Written and Oral informed consent was obtained from the participant included in the study. Additional informed consent was obtained from all individual participants for whom identifying information is included in this manuscript.

Funding Support – No funding support.

\textsuperscript{1}Senior Resident, \textsuperscript{2}Assistant Professor, \textsuperscript{3}Professor, Department of Forensic Medicine and Toxicology, Cooch Behar Government Medical College and Hospital

Abstract

Homicidal deaths are a significant public health problem and affect every society around the world. The incidence of homicide has seen a worldwide upsurge with varying trends across geographical locations. Detailed information on the characteristics of victims of homicide from the Cooch Behar region is limited. This article explores recent trends of homicide in the Cooch Behar region. The study was conducted between June 2019 to May 2020 at the Department of Forensic Medicine and Toxicology, Cooch Behar Government Medical College and Hospital, Cooch Behar. 1133 autopsies were conducted over the time-period with 70 homicidal deaths. Most of the victims were males (70\%) with a male to female ratio of 2.33:1. 34.3\% of victims were between the ages of 21 – 30 years. Most of the victims were laborers (18.6\%) while Hinduism was the most common religion (65.7\%). 06:00 pm to 12:00 midnight was the time when the majority of the incidents took place and 68.5\% of victims were brought dead. Injuries by hard blunt weapons and sharp cutting weapons were responsible for maximum deaths, constituting 21 (30\%) and 15 (21.4\%) cases respectively. Multiple regions of the body were involved in 35.7\% cases followed by head and face region with 34.3\% cases. This study is significant as it aims to identify the profile of risk factors of victims of homicide and suggest new lines of research that would help to reduce the number of homicides.

Keywords: Homicide, Victims, Pattern of injuries, Weapon, Survival period.

Introduction

Homicide is the most nefarious and atrocious crime known to mankind having a grave impact on the psycho-social, political and socio-economic aspects of a country.\textsuperscript{1} The word homicide has originated from two Greek words “homos” which means human beings and “cidos” which means destruction.\textsuperscript{2} It is the intentional act of taking another person’s life and is one of the leading causes of unnatural deaths.\textsuperscript{3} The United Nations Office on Drugs and Crime (UNODC) has declared that homicide is a powerful indicator for determining a country’s level of violence and safety.\textsuperscript{4} In recent years, the incidence of homicide has seen an upsurge throughout the world due to various factors like population explosion, changing lifestyle and exposure to negative experiences in society, cosmopolitanism of urban areas and the psychological burden it brings along. This has been compounded by the improvised and easily obtainable weapons of violence as well as the negative impact of mass media.

According to the National Crime Records Bureau, the total number of murders in India in the year of 2018 was 29,017; and it showed an increase of 1.3\% over 2017 when 28,653 cases were reported.\textsuperscript{5} While the highest numbers of murders among all the states were noted in the state of Uttar Pradesh (4018), 1933 cases were reported from West Bengal.\textsuperscript{5}

The trends of homicide, the profiles of people committing the crime as well as their victims and the methods adopted by the assailants vary in different parts of the world and different parts of the same country. Cooch Behar is an agriculture-based region in the northern parts of West Bengal which shares international
borders with Bangladesh. With the advent of the 21st century, the area has witnessed radical changes along with rapid developments in segments like industries, real estates and IT firms which has led to a change in its demographic profile. And this transition has also changed the crime profile of the area.

There has been no study on the trends and patterns of homicidal deaths in this area till date. Hence the present study was undertaken to analyze the incidence and trends of homicides occurring in the region of Cooch Behar. The insights procured from this study will help to increase the efficiency of criminal investigations and improve the management of human resources and materials besides looking for avenues to curb this menace. We also aim to identify the profile of risk factors of victims of homicide, which may help to prevent and safeguard those at increased risk in the entire society.

**Materials and Methods**

This observational, descriptive, and analytical study was conducted at the Department of Forensic Medicine and Toxicology, Cooch Behar Government Medical College and Hospital. The period of study was from the 1st of June 2019 to 31st of May 2020. All the cases brought to the department for medico-legal autopsy during the specified time-period which were either confirmed by investigating officers before autopsies as homicidal or found to be homicidal at autopsies or declared as homicide during the investigation were taken into account. The unknown and decomposed bodies were excluded from the study.

A detailed history of the cases was initially noted from the inquest reports, bed head tickets, injury report and other relevant documents provided. Other associated information was gathered from the deceased’s close relatives, friends, police and other available persons who were present at the time of the incident and those accompanying the victims, with special reference to General information like Name, Age, Sex Religion and occupation. The suspected patterns of homicide and affected body parts were preliminary noted from the investigating report submitted by the police i.e., the inquest paper. These were further corroborated with the autopsy findings. Details of the crime scene are obtained from crime scene visits or photographs of the crime scenes.

The data collected in a predetermined format during this study was analyzed in tabular form along with its representation in form of diagrams and charts like bar diagram and pie charts etc.

**Results and Analysis**

In the present study carried out at Cooch Behar Government Medical College & Hospital over a period of 12 months, 1133 autopsies were conducted. Out of these, 70 cases (6.17%) were of homicidal deaths.

The study demonstrates a preponderance of male victims 49 (70%) over female victims 21 (30%), with a male to female ratio of 2.33:1. The majority of the victims belonged to the age group of 21 – 30 years, with 24 (34.3%) cases, which was followed by the age group of 31- 40 years, with 12 (17.1%) cases. The least number of cases was observed in the 1st decade as well as the 6th decade with 5.7% cases each. No victim aged more than 70 years was registered. (Table -1).

Most of the victims were Hindu 46 (65.7%), followed by Muslims 17 (24.3%). (Figure -1).

Regarding the occupation of the victims, maximum victims were laborers (18.6%), followed by farmers (17.1%) and businessmen (14.3%). Of the 70 victims, 18.6% were housewives while 8.6% were preschool children and students. (Table -2).

The maximum number of homicides took place in the dark of the night between 06:00 pm to 12:00 midnight with 19 (27.1%) cases. 25.7% of cases were recorded from 12:00 midnight to 06:00 am while another 24.3% of cases between 12:00 noon to 06:00 pm. This suggests that cases of homicide are more prevalent during the night hours when committing the crime and escaping the scene becomes easier. (Table -3).

Out of the 70 cases, 48 (68.5%) were spot dead/brought deaths. 28 cases were hospitalized before death, of them, 14 (20%) died within 24 hours of hospitalization, 6 (8.6%) survived for a week while the rest 2.9% victims died after atleast a week of treatment. (Table -4).

When infliction of fatal injuries in respect to body regions was considered, in most cases the injuries involved more than one body region and due to the extensive combinations, they were grouped into multiple
regions. 35.7% of cases had involvement of multiple body regions closely followed by head and face region alone with 34.3% cases. The neck region was targeted in 12.8% cases while no incidence was recorded where the fatal injury was inflicted over the limbs exclusively. (Table -5).

It was observed that hard and blunt weapon was most commonly used to inflict injuries 21 (30%) cases, followed by sharp cutting weapons 15 (21.4%) cases. In 12.9% of cases both hard and blunt as well as sharp cutting weapons were used. Incidence of firearm use was observed in 8 (11.4%) cases. Asphyxial deaths were seen in 10 (14.3%) cases, with 5.7% of cases of ligature strangulation and 4.3% cases of throttling. In another 5.7% cases the pattern of homicide was due to infliction of fatal burn injuries. (Table -6).

Discussion

Incidence:

The incidence of homicide in the Cooch Behar region over the time-period of the study was 6.17%. This is in accordance with studies by Gupta et al\textsuperscript{6} - 5.9% at Delhi, Mohanty et al\textsuperscript{7} - 6.9% at Behrampur city and Patowary\textsuperscript{8} - 7.36 at Guwahati region. However, the findings are in contrast with studies by Jhaveri et al\textsuperscript{9} - 2.31% in the city of Surat and Parmar et al\textsuperscript{10} - 2.4% in Bhavanagar city. This difference in the incidence of homicide may be due to the geographical variations and the divergent demographic profile of the regions in which the studies were conducted.

Age and Sex Distribution of cases:

Our study reveals that the maximum number of victims of homicide were in the age group of 21 – 30 years (34.3%) followed by 31 – 40 years (17.1%). These findings are in unison with previous works done by fellow Indian researchers Gupta et al\textsuperscript{6}, Patowary\textsuperscript{8}, Jhaveri et al\textsuperscript{9} and Parmar et al\textsuperscript{10}. This is also concurrent with foreign studies by Hilal et al\textsuperscript{11} and Al-Azad MAS et al\textsuperscript{12} who have also reported that the maximum numbers of victims of homicide are in the 3rd decade of life. But it differs from the studies made by Kominato et al\textsuperscript{13} and by Saint Martin P et al\textsuperscript{14} where those in the 5th and 6th decade of life are more vulnerable. This might be explained by the social structure in their setup. The high incidence of cases in the age group of 21 – 30 years may be since this is the time when the responsibilities of earning and stabilizing in life start growing in the Indian individuals as they escape from the parental society. This added responsibilities, failures in some cases and ever-growing frustration in the fast-paced life lead to frustrations, intake of alcohol and bad accomplices and thereby making the youth susceptible to violence. Also, people in this age group are more combative and less humane, leading to altercations and brawls and ultimately ending in homicides.

Among the female victims, most cases were seen in the age group of 21 – 30 years followed by 11 – 20 years. The prevalence of incidence of homicide among females in this age group is owing to marital and romantic discords. Also, newly married females belonging to this age group are more likely to become victims of dowry death.

Males predominate in all the age groups except in the age group of 11 – 20 years where the ratio was 1:1. The overall ratio of all age groups was 2.33:1. This is in accordance with studies by Buchade et al\textsuperscript{15} (2.23:1), Parmar et al\textsuperscript{10} (2.47:1) and Hugar et al\textsuperscript{16} (2.56:1). The male: female ratio was found to be significantly higher in studies by Patowary\textsuperscript{8} (8:1), Jhaveri et al\textsuperscript{9} (6.57:1) and Shah et al\textsuperscript{17} (3.71:1). A predominance of males victims was also seen in studies abroad as reported by Hilal et al\textsuperscript{11}, Al-Azad MAS et al\textsuperscript{12} and Saint Martin P et al\textsuperscript{14} while Kominato et al\textsuperscript{13} noted a male to female ratio of 1:1. The male predominance may be because they are significantly involved in outdoor activities and are generally more aggressive by nature which makes them more vulnerable to be involved in violent crimes. On the other hand, the low incidence among females may be credited to the social norms, traditions and predilection to stay indoors.

Religion of victims:

The present study revealed that the maximum number of victims belonged to the Hindu community which was in accordance with the findings of other studies from various regions of India.\textsuperscript{7} The reason behind this is the Hindu dominant population in the Cooch Behar region.

Occupation of victims:

Our study finds that most of the victims were laborers (18.6%) and farmers (17.1%) besides 18.6% housewives among females. In a study by Shah et al, maximum victims were laborers (20%) followed by businessman (15%); cultivators or farmers (14%) and housewives (14%).\textsuperscript{17} Similarly, Mohanty et al concluded that most victims were laborers or farmers.\textsuperscript{7} This trend is even seen in a study at Malaysia which revealed that about 72% of the victims were semiskilled and unskilled workers.\textsuperscript{18}

Time of Incidence:

In our study, it was observed that 27.1% cases of homicide took place in the evening hours (06:00 pm – 12 midnight) while another 25.7% cases took place in the late-night (12 midnight – 06:00 am). It was concluded that cases of homicide are more common during the night hours. This may be because a chance of being
recognized reduces in the dark of the night due to lack of public presence, besides the abuse of alcohol and other substances increases considerably at night. This finding is in accordance with studies by Gupta et al, Mohanty et al and Shah et al. But the findings were not consistent with those of Bhupinder et al and Vougiouklakis T. both of whom have concluded that the maximum number of incidences occurred during the day time.

Period of Survival:

Most of the cases were reported as brought dead (68.5%) while 20% of cases died within 24 hours of admission. Even with advancements in life support systems, a mere 2.9% of the cases survived for more than a week. This signifies the use of improvised and lethal weapons, multiple injuries to the vital organs of the body or involvement of more than one assailant in some cases. Our findings are concurrent with Kohli et al who revealed that 60.4% of the victims were brought dead and Shah et al (74% spot/brought dead). Hugar et al, Jhaveri et al and Bhupinder et al all revealed that more than 80% of cases were brought dead which are much higher than our numbers suggest.

Distribution of Injuries with respect to body region:

From our study, it was revealed that the majority of the fatal injuries were over multiple regions of the body (35.7%) closely followed by head and face injuries (34.3%). Injuries to the thoracic region were relatively less at 7.2% which is in contrast to studies by Kohli et al and Marri et al. Marri et al suggested that chest was the primarily targeted area of the body as almost 86% of the cases were due to firearm injuries. Our study is in unison with studies by Mohanty et al and Jhaveri et al both of whom have suggested maximum involvement of multiple regions of the body. Parmar et al and Buchade et al have however concluded that head and neck are the most commonly involved regions of the body. This involvement of multiple body regions may be due to the assailant wanting to ensure that the victim will not recover from the trauma in any way possible or may be due to over-kill or involvement of multiple assailants. Homicidal burn and charring injuries also lead to the involvement of multiple body regions.

Method and Weapon used to inflict fatal injuries:

Most of the victims had mechanical injuries over their bodies leading to death. And most of these injuries were caused by hard blunt weapons (30%), followed by sharp-edged weapons (21.4%). This finding is in accordance with studies by Buchade et al and Singh et al. Similar findings were revealed by Kominato et al at Japan and Bhupinder et al at Malaysia. On the other hand Parmar et al, Hugar et al and Shah et al suggested sharp cutting weapons to be the commonest type of weapons used in the homicide. Cooch Behar is basically an agricultural area with forests in and around. This socio-cultural aspect of the population and the geographical location can be the reason for more use of hard blunt weapons as homicidal weapons. Also use of only hard blunt weapons is a sign of spontaneous and unplanned explosive behavior of the assailant. However, quite contradictory to this, Hilal et al, Saint Martin P et al and Marri et al observed firearms as the most commonly used weapons in homicide. The greater accessibility of licensed and country-made firearms in their respective study areas can be an explanation for such a finding. Overall, the weapon of homicide depends on the socio-economic status of the population as well as the political scenario of that study area.

Our study revealed asphyxia was reported in 14.3% cases with 5.7% cases of ligature strangulation and 4.3% throttling. Shah et al found 4% cases of ligature strangulation and throttling each while Hugar et al revealed 7.0% cases of ligature strangulation and 1.8% cases of throttling. On the contrary Jhaveri et al reported 19.81% of cases of asphyxial deaths which were higher than our number. In our 80% of the victims of asphyxial deaths were either females or children. This is because they offer less resistance to the acts of throttling or strangulation. Buchade et al in their study also concluded that most of the victims of asphyxial deaths are females and children.

Conclusion

Homicide is a complex criminal phenomenon with varying trends over geographical locations. Our analysis of autopsied victims of alleged homicide is an attempt to understand certain aspects of victimology. This understanding is crucial during criminal investigations, since these socio-demographic characteristics offer
information on potential victims, help understand the probable modus operandi of the perpetrators and suggest new lines of research that would help reduce the number of homicides. The facts that have surfaced from our study suggest that to curb this peril the Government should take measures to reduce the unemployment rate and address the issues of marital disputes by enhancing an individual’s social and emotional skills along with psychological counseling. Strict laws on possession of dangerous weapons and firearms should be enforced. Further well designed and large scale multivariate studies need to be carried out to get a clear insight into the psychopathology of the assailants and formulate strategies that can thwart such unlawful human killings.

Evaluation of Posture and Quality of Life in Females Undergone Modified Radical Mastectomy: A Research Protocol

Aachal Birelliwar¹, Shalaka Dhankar²

¹Aachal Birelliwar 4th BPT student, Ravi Nair Physiotherapy College, Sawangi(M), Wardha, ²Assistant Professor, Department of Community Health Sciences, Ravi Nair Physiotherapy College, Sawangi (Meghe),

Abstract

Modified radical mastectomy performed for CA breast is a life modifying surgery for most women. It creates a profound impact on the quality of life enjoyed by the women. Body image in patients with breast cancer differs from all other cancers. The assessment of quality of life after modified radical mastectomy for early breast cancer patients using the World Health Organization Quality of Life-Brief Questionnaire (WHOQOL-BREF).

Women suffers from day to day activities. Postures become impaired. Postural changes, such as increase in thoracic kyphosis, scoliosis leads to poor postural habits. There is also decrease in shoulder range of motion, scapular muscles weakness. Contractures may develop in axilla after surgery. Breast cancer survivors have muscle weakness of upper limb are Pectoralis major, serratus anterior, upper trapezius, rhomboid muscles, latissimus dorsi.

Spine alignment also may effect due to poor posture. Women with Modified Radical mastectomy may have some social phobia. Anxiety, stress level may increase. Women may have fear of recurrence. Because of this factors, there is impaired Quality of Life in Women.

Conclusion: Breast cancer is a serious disease that reduces the quality of life, particularly in physical domain and in the emotional area. Oncological disease is becoming a disease for a lifetime. It connected with the constant fear of cancer recurrence and the consequences of treatment.

Key Words - Posture, Quality of Life, Modified Radical Mastectomy.

Introduction

¹In India breast cancer is most commonly diagnosed as cancer. ²Among women it is most common neoplasm. ³Modified Radical Mastectomy is very common operation in women which causes different changes in the body. ⁴It’s stres ful event in women’s lives. ⁵The life expectancy of breast cancer is longest in categories cancer, the Quality Of Life in patients is most relevant factor to be considered for women undergone MRM.

Problems following surgery. – which may affect female’s working capacity, also her family life and her social involvement. ²After MRM there are various factors like tightness in pectoral region, post surgery contractures in axilla, weakness of scapular muscles and restricted ROM of shoulder will affect body posture. Muscle contractures in the cervical and easy fatiguability scapular region are evident observed. Women suffer difficulty in performing daily activities because of impaired the upper extremity function and some bposture disorders. Postural defects like scoliosis, kyphosis due to trunk asymmetry can lead to poor postural habits.

⁶Improper body posture may cause somatic abnormalities. In Mastectomy, patient’s both physical and psychological aspects should be considered. Complications associated with post mastectomy are changes in body posture caused by disorders in static and dynamic postural changes affecting the appearance thus affecting the ability to function in an ideal way.
restricting women from participating in various activities and thus affecting her QOL. 7 After treatment, women experiences some changes like limitation in movement and postural asymmetry. 8 This is associated with lot of changes in musculoskeletal functions. Because they are abnormal in the development of anteroposterior curve, their position may be incorrect due to functional changes.

9 Recent article suggested that breast cancer surgery can affect posture, spine alignment and increase thoracic kyphosis and decrease shoulder range of motion. Women with modified radical mastectomy constantly fear recurrence of disease. 4 This anxiety in breast cancer patients affects their way of living and further postural changes and difficulty in functioning according to desired patterns may contribute towards reduced quality of life. 10 Quality of Life in women is highly impaired after diagnosis because of the effects of physical, social and psychological factors.

Materials and Methods
Study Setting: Physiotherapy OPD and AVBRH
Study design: Observational Study
Selection criteria:
Inclusion criteria:
1. Females upto 6 months post modified radical mastectomy surgery.
2. Age between 40-70 years.
3. Subjects willing to participate voluntarily.
Exclusion criteria:
1. Females upto 6 months post modified radical mastectomy surgery.
2. Age between 40-70 years.
3. Subjects willing to participate voluntarily.
Data Source :
For Quality of life – self reported questionnaire score will be measured and analysed.
For Posture – Deviation in posture will be measured using Kinect Azure.
Bias : Subjects that does not match the selection criteria will be excluded to prevent bias
Study size: 35 sample size
Quantitative Variables: Score of Quality Of Life.
Statistical Methods: This will be done by using descriptive and inferencive statistics using chi square test students unpaired t test. Software used in the analysis will be SPSS 24.0 version, praphpad prism 7.0 version and p <0.005 is considered as level of significance (p>0.005m)

Findings
After successful completion of the study it will provide evidence on Posture and Quality of life in Females undergone Modified Radical Mastectomy.

Discussion
6,9 The current study is carried out to find out association of postural with Quality of life in females undergone Modified Radical Mastectomy various studies conducted have shown postural deviation in females with breast cancer also that their Quality of life is altered resulting in various difficulties. 4 Current study will be carried to find out whether there is any correlation between posture and Quality of life because changes in posture and spine may affect the working of women whether it may be at work or in household activities because of muscle tightness or other musculoskeletal changes causing restriction at joint decreasing ROM and pain preventing the female to carry out various activities efficiently which may ultimately affect Quality of life. Thus current study aims to find out association between posture and Quality of life.

Limitation : Only Evaluation of posture is done and its effect on Quality Of Life is assessed but not on the treatment outcomes of Modified Radical Mastectomy.

Conclusion
Conclusion will be discussed once study is completed.

Conflict of Interest: There is no conflict of interest.
Source of Funding – No funding needed.

Ethical Clearance: Being a observational study institutional ethical committee permission was taken.

Retraction in Orthodontics – A Short Review

R. Vighnesh¹, Ashith M.V², Siddarth Shetty³, Supriya Nambiar⁴, Nidhin Philip Jose⁵, Shravan Shetty⁶, Asavari Desai⁷

¹Post graduate Student, ²Associate Professor, ³Professor, ⁴Head of the Department and Professor, ⁵Associate Professor, ⁶Assistant Professor, ⁷Associate Professor, Department of Orthodontics, Manipal College of Dental Science, Mangalore, Affiliated to Manipal Academy of Higher Education

Abstract

Aim- The aim of this review is to discuss about the retraction mechanism in orthodontics and to discuss in detail regarding the mechanism of action and their application in orthodontics.

Objective- To list out the difference types of retraction mechanics used and their merits and demerits

Background- The basic principle of retraction mechanism can be used in orthodontic space closure involving retracing the canine initially followed by remaining anterior teeth or entire anterior teeth can be retracted at once using intra or extra oral anchorage. They are broadly classified into friction and frictionless mechanism. Once the extraction of the teeth has been done, the orthodontist must choose the procedure to retract the teeth based on the demand of the case. This article provides the basic information of both the mechanics and their application in orthodontics.

Reason- This review mainly done for better assessment and benefits of retraction mechanics and its appliances

Keywords- Two step retraction, loop mechanics, enmass retraction, space closure

Introduction

The different methods to close spaces, reduce procumbency, overjet, and eliminate extraction sites by antero-posterior therapy is generally categorized as Retraction mechanics. Whether retracting the anterior or protracting the posterior or a combination of both principles of retraction mechanics apply for space closure remains the same.

As extraction was done in late 19th century finger springs or other methods were employed for simple pushing back of canine teeth. This often resulted in tipping and elongation of teeth. Tweed used the molars as anchorage by tying back the arch and using a coil spring arch to retract the cuspids back with the help of 0.016 round archwire. In 1980, rickets employed closed coil springs to obtain sectional cuspid retraction. Several studies have been made on the amount of force required for specific tooth movements. Storey and Smith’ reported that 150 to 200 grams is the optimum force range for retraction of the lower canine tooth. Reitan’ has reported that the maximum force needed for continuous bodily movement of canine teeth is 250 grams. Burstone and Groves found the optimum force for the retraction of anterior teeth to be 50 to 75 grams. Lee in 1966 showed optimal force for distal movement of maxillary canine with tipping was 15 to 260 cm. Burstone in 1982 developed composite TMA spring for canine retraction. Poul gjessing in 1985 developed a sectional arch technique that produces optimal force system for controlled canine retraction.

Determining the anchorage value while retracting the teeth is of major concern no matter the technique used.

Maximum anchorage is indicated when only anterior teeth are retracted. Minimum anchorage is used if only posterior teeth is protracted and when combination of both is used moderate anchorage is used.

Retraction is the most frequently used technique in space closure. The strategy used in retraction mechanics must be based on a careful diagnosis and treatment plan made according to the specific needs of the individual. Two step retraction and en mass retraction are two most used mechanics in anterior retraction. In two step retraction retraction of canine teeth is done followed by retraction of all four incisors and en mass retraction involves retraction of all six teeth. Two step retraction involves retraction of canine teeth in one step later retracting followed by retracting the remaining teeth in next step. This will reduce the tendency of anchorage loss by incorporating more teeth in the anchorage unit. However, this will take longer time to complete the treatment. In addition when the entire anterior unit is retracted compared to canine retraction they tend to tip and rotate less, thus requiring less time and effort when compared to canine retraction. En mass retraction occurs when incisors and canines are retracted together. In clinical situation it is difficult to maintain anchorage in clinical situation. Anchorage can be derived from segment of the teeth or the entire arch. In some difficult situations the requirement for extra oral anchorage such as headgear, face mask, intermaxillary elastics and mini implants is needed.

The principles for retraction currently used can be explained as either frictional system in which teeth is allowed to slide distally and it’s guided by continuous arch wire or a non-frictional system with couples and force built into the loops of an arch section.

Mechanics of Tooth Movement

Every free body or an object can be perfectly balanced on one point which is known as centre of gravity. The relationship between line of action of force to the center of the body determines the movement of the free body. In a tooth which is a restrained body, a point similar to the centre of gravity is used which is known as centre of resistance.

If the force passes through the center of resistance an object undergoes translation. The centre of resistance is on the long axis of the tooth for single rooted tooth and probably between one third and one half of the root length apical to alveolar crest for a multirooted teeth.

A body appears to rotate around its center of rotation. The more translational the moment of the tooth the farther apically the centre of rotation would be placed. Moment is defined as tendency to rotate. If the line of action of force does not pass through centre of resistance it will produce some rotation which can be calculated as force multiplied by perpendicular distance from centre of resistance to point of application of force. When two forces of equal magnitude act in opposite direction it will produce a couple. This will produce pure rotation, spinning the object around its centre of resistance. The way an object is rotates while its being moved can be changed by different combination of force and couple.

The ratio between magnitude of couple and the amount of force applied at the bracket determines the type of tooth movement exhibited by the tooth. A single force produces a uncontrolled tipping so in order to produce a controlled tipping or translation a single force is insufficient, a rotational tendency (moment) must also be applied at the bracket.

A force of 100 grams produced at a distance of 10mm from the centre of resistance produces a clockwise moment of 1000gm-mm which will cause tipping of the tooth. we must generate counter balancing moment of 1000 grams-mm so that bodily moment can be achieved since the tipping is undesirable. This can be done by twisting the anterior segment of rectangular wire and fitting it into a rectangular slot. After the wire is engaged in a bracket slot it generates an inherent moment of couple which is a couple produced within the wire itself and now it will result in bodily movement of the teeth.

RETRACTION MECHANICS IN EDGewise

Once the extraction of the teeth is done orthodontist have to plan how to close the space. There are two schools of thoughts of retraction mechanism:

i. Two step canine retraction (Friction or frictionless mechanics)

ii. En-mass retraction (Friction or frictionless mechanics)
FRICITION MECHANICS

A tooth can be moved bodily only when force is applied such that it can pass through center of resistance. When a bracket is placed on a tooth and the force is applied at it, both force and moment is experienced by the tooth. The tooth moves in two planes due to this moment of force. The canine moves mesial out as force is applied buccal to center of resistance due to one moment. The second moment produces distal tipping of tooth is caused because force is applied occlusal to centre of resistance. A moment in opposite direction is produced due to interaction between the bracket and wire which counteracts this moment. When the tooth tips in distally it glides along the archwire till binding occur between the archwire and the bracket. This produces a couple at the bracket which results in distal root moment and hence uprighting of the tooth. As it uprights the moment decreases until the wire can no longer bind. Then the canine retracts along the archwire till distal crown tipping again causes binding. Until the force gets depleted this continuous to take place which is known as walking of canine because of initial tipping of crown followed by root uprighting. The major advantage of friction mechanism is it provides comfort to the patients and less time consuming as complicated wire bending is not required.

V – BEND SLIDING MECHANICS

This was developed by Thomas F Mulligan, this approach is used for closing space by moving each teeth (canine retraction or molar protraction). He gave the concept of differential torque as a means of effective intraoral anchorage. It is obtained by applying unequal alpha and beta moments. An off center V- bend is used in a wire to create unequal moments with higher moment applied to the anchorage teeth. The closer the bend is to the bracket shorter the wire and shorter wire has a higher bending moment than a longer wire. Therefore, a higher moment acts on the bracket which is closer to the V bend than the more distant bracket.

In case of canine retraction using the V-bent mechanics the tooth located closure to the bend is the anchor side and the opposite is the non-anchor side. As the cuspids continue to move distally, the bend is centered and the differential torque begins to gradually disappear. Root parallelism begins to effect as the bend approaches the center.

METHODS OF CANINE RETRACTION IN SLIDING MECHANICS:

1. Elastic module with ligature
2. Elastomeric chain or power chain
3. Intra or inter maxillary elastics to kobayashi ligature
4. Coil springs (stainless steel or NiTi)
5. J-hook head gear
6. Sliding jig and traction
7. Mulligans v bend sliding mechanics

ELASTIC MODULE WITH LIGATURE

This method of retraction has been popularised by Bennett and McLaughlin (Fig A). A single elastic module is used to secure the arch wires to brackets which is attached to canine by a ligature wire extending from the molar. These elastic tie backs are activated 2-3 mm or to twice then original size to generate approximately 100 – 150 grams.

Figure A: Elastic modules

ELASTOMERIC CHAIN OR POWER CHAIN

E chain were introduced into the dental profession in 1960 for canine retraction, diastema closure, rotation correction and arch constriction. (Fig B) They are available in configuration of closed loop, short filament, and long filament chains. It has many advantages such as being inexpensive, relatively hygienic and can be easily applied without arch wire removal and do not depend on patient cooperation. Most of elastomeric chains lose 50% - 70% of their initial force during the 1st day of force application and at three weeks retain only 30% -
40% of their original force. Elastomeric chains should be changed every 4 – 6 weeks 10.

It can be used for distal movement of canines without causing loss of posterior anchorage. It involves the use of headgear with j hooks where the hooks attach along a continuous arch wire mesial to the canines and exert a force over them so that they will slide along the arch wire. Since it incorporated extra oral anchorage in canine retraction, it should be effective in maximum anchorage cases 11.

SLIDING JIG AND TRACTION

0.022 round wire or 0.017 x 0.022 rectangular wires are used in making this jig and it is slide on to the arch wire in addition to a short piece of open coil spring of about 4mm in length. The coil spring lies in contact with mesial end of canine bracket and circle of jig lies on mesial end of coil spring. The traction can be applied to the jig either intra or inter maxillary elastics or by extra oral traction.

MULLIGANS V BEND SLIDING MECHANICS

It was introduced by mulligan 1970’s. The basic principle was to apply differential moments to the teeth via bends in the continuous arch wire while force for retraction was applied by auxiliaries like E chain, coil springs etc. during cupid retraction 12. The 45 degrees v bend are added to the wire and 200 grams of force are applied without removing the archwire using calibrated optic pliers.

The v bend helps in differential medio distal movements on the canines and molars. If the bend is placed off center it creates a short and a long segment. The shorter segment is more rigid and hence applies greater moments. So, if maximal canine retraction is required the bend is placed very close to molar and bicuspid. This causes a strong distal crown moment on the molar which counteracts the auxiliary force tending to move the molar crown forward.

EN-MASS RETRACTION

It literally means retracting group of teeth together as a single unit. The anterior teeth are intruded and retracted simultaneously and also maintaining the torque control however, demand on the anchorage should be evaluated carefully 13. It can be effectively employed in moderate and minimum anchorage cases. In frictionless mechanics retraction is done with a continuous wire with
one closing loop each side distal to cupid. Various loop design are available for retraction and all are having pre-determined vertical heights ranging from 7-10 mm in vertical direction to keep it closer to centre of resistance of tooth.

In 1990s, a method of controlled space closure was described using sliding mechanics. Rectangular archwire 0.019 x 0.025 wires are recommended with the 0.022 slot. This wire size had good overbite control while allowing free sliding through the buccal segment. Thicker wires sometimes restrict free sliding of molars and premolars and thinner wires have less control. Thinner wires along with the heavy forces of E-chain can give rise to roller coaster kind of effect.

Soldered hooks of 0.7 brass hooks can be used and alternatively soft stainless steel (SS) 0.6 soldered hooks can also be used. The most common hook length are 36 – 38 mm in upper and 26 mm in the lower arch.

Active tiebacks refer to use of stainless-steel ligatures threaded through an elastic module that goes directly from the terminal molar to the canine bracket. They are stretched to their original size during activation, without pre stretching the force levels range between 200-300 grams. If large spaces are to be closed Niti coil spring are used instead of elastomeric module. The force decay in the Niti coil spring is very much less as compared to elastomeric modules.

FRICTION ISSUE IN SLIDING MECHANICS

Using the friction mechanism has few disadvantages during retraction because of mainly two components friction and binding, due to which applied force should be higher than the required optimum force because of decay in force. When E chain is used for retraction if excessively stretched leads to breakdown of internal bond leading to permanent deformation. It also absorbs water and saliva when exposed to oral environment causing degradation of force by 50%-70% by 1st day. Due to these drawbacks in friction or sliding mechanism, frictionless mechanism is in better position for retraction, as monitoring of optimum force can be done effectively, and it is active for longer duration of time.

FRICTIONLESS MECHANICS

In frictionless mechanism retraction is accompanied with loops or springs which offer more controlled tooth movement than sliding mechanism. In frictionless mechanism when the loops are activated, they distort from their original shape as the tooth moves and then it gradually returns to its undistorted (preactivated) position, delivering the energy stored at the time of activation. It is activated by by pulling the arms of the loop away and cinching them back at the molar tubes. Thus, this approach is friction free, so can be used to move group of teeth more accurately with more precise anchorage control to achieve treatment goals more readily than methods in which friction plays a role.

The Gable bend and Neutral Position

A simple loop when activated is unable to generate adequate counter moment required to achieve the desired tooth movement so preactivation bends also known as gable bends are given which increases the M/F ratio. To maintain the neutral position of the loop which has been altered by the introduction of gable bends, appropriate magnitude and occlusogingival location of the gable bends are vital. Because of the gable bends, the closing loop functions as V- bend in the arch wire. Practically, this means that during canine retraction with the vertical loop placed closed to a canine, a higher ratio M/F ratio would be present on the canine which could better control the apex. The undesirable effect is extrusion of the canine.

Preactivation bends or gable bends can be placed within the archwire or where loop meets the archwire which are placed to increase M/F ratio. For anterior retraction loops should be placed closer to the canine than to the molar and a gable bend should be added near the molar. A gable bend that is larger in the posterior dimension will produce a larger beta moment thus increasing posterior anchorage. For both retraction of anterior and protraction of anterior segment the loop should be placed midway between posterior and anterior segments. A gable bend of equal dimension should be used so that alpha and beta moments are equal and reciprocal space closure occurs. When only posterior protraction is desired, the loop should be located closer to the posterior segment and anterior gable bend should be placed with a greater alpha moment than beta moment, making the anterior teeth the anchorage segment.

METHODS OF CANINE RETRACTION IN
FRICIONLESS MECHANICS

1. Ricketts retraction spring
2. Poul gjessing spring
3. Burstone T loop retraction and attraction spring
4. Marcotte spring
5. Drum spring
6. Opus loop
7. Kalkra simultaneous intrusion retraction spring
8. Wave spring
9. A statistically determined retraction system
10. Niti canine retraction spring

RICKETTS RETRACTION SPRING

Maxillary cuspid retractor is a combination of a double vertical closed helix and an extended crossed T closing loops spring which contains 70mm of wire. (Fig D) It produces 50 grams per mm of activation. The additional wire in its design helps in activation of the spring by contracting the loops and 3 – 4 mm of activation for upper cuspid is sufficient for retraction. Mandibular cuspid spring is a compound spring with a double vertical helical closing loop. It contains 60 mm of wire and produces approximately 75 grams of force per mm of activation. Activation of 2 – 3 mm is required to produce the desired force.

POUL GJESSING SPRING

The Poul Gjessing maxillary canine retraction spring was described by Poul Gjessing in 1985. Essentially the spring consist of a double ovoid helix with a smaller occlusally places helix and is in the preformed version is available commercially constructed in 0.016 x0.022 inch stainless steel wire. The spring is activated by pulling distal to molar tube until the two loops separate (Fig E). The amount of activation produces the recommended initial load of 100 grams. It is critical to avoid over activation of the spring because a few mm of over activation can result in anchor loss. Since the average distance from the centres of the brackets to the CR are identical for the upper and lower canines, the PG retraction spring works equally well for canine retraction in either arch.

BURSTONE T LOOP RETRACTION AND ATTRACTION SPRING

The burstone composite ‘T’ loop retraction spring is made from 0.017 x 0,025-inch TMA wire. T loop retraction spring can be used in group A arches. The attraction springs are used in group B and group C arches. The difference lies in rotational control of the canine, which is achieved with a non-sliding mechanism. Antirotational bends are placed in the retraction assemblies to prevent the canine from rotation as it retracts. It is also possible to use an arch wire to prevent rotation. It is engaged into auxiliary tube of first molar and the vertical tube on the burstone canine bracket. Initially after preactivation controlled tipping occurs (M/F 8:1), as space closes and spring deactivates, the force level decreases so translation occurs (10:1), further deactivation leads to root movements (12:1).

MARCOTTE SPRING

This is a type of minor cuspid retraction spring and is small, light 0.016 closing loop. This spring extends from the auxiliary tube of 1st molar brackets to the bracket on the cuspid and it is activated by being pulled through the auxiliary tube and cinched. The buccal segment feels, then a protractive force and a positive moment, while
the tooth being “walked back” on the wire. Hence are used in group B and group C arches. Activation should be limited to 1-2 mm.

**OPUS LOOP**

This new design can be fabricated from 16 x 22 or 18 x 25 or 17 x 25 TMA wire. The loop is positioned off center about 1.5mm from the mesial canine bracket. It is activated by tightening it distally behind the molar tube and can be adjusted to produce maximum, moderate, or minimum incisor retraction. It also delivers a nonvarying target M/F within the range of 8.0 – 9.1 mm inherently, without adding residual moments by twist or bends anywhere in the archwire or the loop.

**KALRA SIMULTANEOUS INTRUSION RETRACTION SPRING (K – SIR)**

It is made up of continuous 019 x 025 TMA arch wire with closed 7 mm x 2mm U – loops at the extraction site for en masse retraction. The u loop has a 90 degree bend to create equal and opposite moments. A 60 degree V – bend is also located posterior to the center of interbracket distance producing an increased clockwise moment on the first molar.

**A STATICALLY DETERMINATE RETRACTION SYSTEM**

This novel system consisted of a single – force cantilever arm of 017 x 025 TMA for active retraction and a passive rigid stabilizing unit. A turn of helix is placed in front of auxiliary tube for the molar and ended with a hook on its anterior end. A 90 bend is placed in middle of spring. The spring is activated 90 at the helix as well.

**THE WAVE SPRING**

This spring can be used where a closed coil would be appropriate for retraction. It is made up of superplastic nickel titanium alloy delivering large amount of activation about 90g of force from extremely a compact spring only 6mm long in its resting state.

**NITI CANINE RETRACTION SPRING**

The spring is available in 016 x 022 NiTi wire with antitip and antirotational incorporated. It has an ability to deliver continuous force and moments over a broad range on activation.

**RAPID CANINE RETRACTION THROUGH DISTRACTION OF PERIODONTAL LIGAMENT**

Liou and huang in 1998 proposed a concept in which first premolar of the patient is extracted then the interseptal bone distal to canine is undermined by a bone bur. After debridement of that area tooth born custom made distraction device is placed which helps in retraction of canine within three weeks into the extraction space. No complications were also observed during or after the treatment.

**CANINE RETRACTION WITH RARE EARTH MAGNETS**

In a study conducted by John daskalogiannaskisa and Kenneth roy in 1996 they hypothesised that a prolonged constant force provides more effective tooth movement than a impulsive force of a short duration arylene coated neodymium-iron-boron block magnets were used in the experiment. The appliance provided a constant force, and this method was two times faster than the conventional methods of retraction as they use interruptive force which degrade after some time.

**CANINE RETRACTION WITH REMOVABLE APPLIANCES**

Canine retractors are the springs which are used to move the canine in distal direction.

**THE VARIOUS TYPES OF CANINE RETRACTORS ARE AS FOLLOWS:**

Palatal Canine Retractor: The distal movement of the canine teeth can be brought about by a palatal canine retractor if the canine is palatably placed which is made out of 0.6mm stainless steel wire with a coil of 3mm diameter, an active arm and a guide arm. The helix is placed along the long axis of the canine. Activation is done by opening the helix 2mm at a time.

The ‘U’ Loop Canine Retractor: Mechanically it is least effective and used when only minimum retraction of 1-2mm is required. It is made of 0.6mm stainless steel wire. It consists of a U loop, an active arm and a retentive arm which is distal. The base of the U loop is 3mm below the cervical margin. It is activated by closing the U loop. The advantages of this retractor are
its simplicity of fabrication and lesser bulk.

Reverse Loop Buccal or Helical Canine Retractor: It is used when the sulcus is shallow, as in the lower arch. Its flexibility depends on the height of the vertical loop and should be as high as possible. It is made of 0.7mm stainless steel wire. Activation is done by cutting off 1mm of wire from the free end and re-forming it to engage the mesial surface of canine.

Buccal Canine Retractor: The buccal canine retractor is used when the tooth must be moved palatally and distally. It is made of 0.7mm stainless steel wire to provide sufficient strength. It should not be activated by more than 1mm because it is stiff and force decays rapidly as the tooth moves which results in difficulty to maintain continuous tooth movement.

Supported Buccal Retractor: It is made of 0.5mm stainless steel wire supported in a tubing of 0.5mm internal diameter. It is more than twice as flexible as the standard canine retractor, the tubing imparts excellent stability.

RETRACTION IN BEGGS TECHNIQUE
The beggs technique advocates a two-stage retraction. The first stage involves distal tipping of the anterior crowns with elastomers and/or interarch elastics. Begg brackets permit only a point contact between bracket and archwire, so no moment is produces by wire bracket interaction. As a result, uncontrolled tipping of the anterior teeth occurs during the first stage of retraction. The second stage involve lingual torqueing of the anterior roots, usually by means of torquing auxiliary. A moment to force ratio of about 12:1 is required, and such a high ratio is technically difficult to achieve. For this reason, two-stage retraction with initial uncontrolled tipping is not the most efficient retraction method.

Conclusion
Depending upon the condition and severity of malocclusion and treatment techniques employed, a number of methods are used for the retraction of canine either by fixed or removable orthodontic appliances. Every situation requires different technique because of its own limitations. Thus the individual clinician must choose the method he prefers to treat malocclusion which requires tipping or bodily movement or rotation of teeth with minimal time, to produce an aesthetic and functional and near ideal occlusion as much as possible.

Abstract

Background: Traumatic amputations may be devastating and can result in irreversible functional and psychological problems in individuals who sustain them. With developmental advances in microvascular surgery, amputated body parts are now routinely attached in many centres across the world. Successful replantation of amputated digits may allow better appearance, better functional outcome and minimal pain to the patient.

Materials and Methods: This is Prospective observational descriptive study comprising of 20 cases with traumatic amputation of extremities and its parts treated with replantation and revascularization of part from October 2014 to February 2017. Nature of injury was classified by Yamano classification of amputation based on mechanism and severity of injury. Patients were evaluated by Chen & Quick DASH score.

Results: The viability of replanted part is guaranteed by a successful vessel anastomosis, while the quality of bone, tendon, nerve and skin repair will determine the overall functional success of replanted parts. Revascularisation procedures had overall better survival than replantation due to less complexity of procedure.

Keywords: Replantation, Revascularization, digit amputation, Microvascular anastomosis.

Introduction

The term replantation is defined as, the reattachment of a body part that has been totally severed from the body without any attachments. Revascularization is the repair or reattachment of a body part which is incompletely amputated from the body and requires vascular (arterial and/or venous) repair. (1)

Traumatic amputations may be devastating and can result in irreversible functional and psychological problems in individuals who sustain them. They occur in all age groups from the children to elderly. So it is imperative that the surgeon be both knowledgeable and meticulous in order to afford the best possible outcome. (2)

When an extremity or part has been severed, it is common desire of both the patient and the surgeon to achieve survival and functional use of replanted extremity.

With developmental advances in microvascular surgery, amputated body parts are now routinely attached.

The ultimate goal of replantation is to restore normal hand or finger function. Successful replantation of amputated digits may allow better appearance, better functional outcome and minimal pain. (3) The surgeon should guide the patient in making the decision by

explaining the risks involved and likely outcome, secondary procedures and prolonged rehabilitation after the procedure.

**Materials and Methods**

This research is Prospective observational descriptive study conducted in Department of Plastic Surgery, Government Medical College and Sir Sayaji General Hospital, Vadodara. It comprises of 20 cases with traumatic amputation of extremities and its parts treated with replantation and revascularization of part in Department of Plastic Surgery, Medical College Baroda and S.S.G. Hospital, from October 2014 to February 2017.

- Nature of injury was classified by Yamano classification of amputation based on mechanism and severity of injury.\(^{(4)}\)
- Care of amputated part:-
  1) Optimal – Part is wrapped in moist saline gauze and placed in waterproof plastic bag. Plastic bag is placed in ice.
  2) Suboptimal – not following above mentioned standard care of amputated part.

Detailed clinical history and relevant clinical information were recorded and patients have been followed up regularly at 1 week, 1 month and 3 months.

**Inclusion Criteria:**
- Patients with traumatic injuries causing devascularization or amputation of limb and its parts presenting to S.S.G. hospital, vadodara.
  - Patient who are medically fit for surgery

**Exclusion Criteria:**
- Patients with concomitant life threatening injuries.
- Severe crushing or avulsion injury of tissues.
- Multiple segmental injuries in amputated parts.
- Prolonged warm ischemia time (>9hrs).
- Patient who are medically unfit for surgery.
- Mentally unstable patients.

**Surgical Technique:**

Amputated part if not preserved in optimal condition, was wrapped in moist saline gauze and preserved in plastic bag and bag inserted in ice slurry. All partial and near total amputations were assessed for devascularizing injuries. Temporary splintage was given for all associated fractures while patient was transported to operating room. After ruling out all major injuries, if patient is stable for surgery was shifted to operating room.

Feasibility of replantation was judged by examining the amputated part under microscope. Debridement of unhealthy tissue was done and arteries, veins and nerves were identified and tagged with 8-0 nylon. Mid axial incisions were taken on volar and dorsal skin to explore the vessels.

![Figure 1(a) Volar aspect (For vessel exposure)](image)

![Figure 1(b) Dorsal aspect (For vessel exposure)](image)
part and other on extremity simultaneously. Exploration and preparation of extremity was done under operating microscope (TAKAGI OM-10).

**Figure 2- Preparation of amputed extremity**

Depending on amount of soft tissue loss and condition of proximal and distal vessels amount of bone shortening was planned followed by bone fixation, tendon repair, vascular anastomosis and skin closure.

Bone fixation was done with vertical K-wire in all cases of distal amputations while in forearm amputation radius and ulna were fixed with plate and screws. Tendon repair was done with nylon 4-0 with modified Kessler’s sutures and peripheral sutures with nylon 6-0. In zone 2 injuries only flexor digitorum profundus tendon was repaired.

Proximal artery was cut till pulsatile bleeding was seen.

Vascular anastomosis was done with nylon 10-0 round body micropoint needle using 3V S&T clamps for radial and ulnar arteries, 2V S&T clamps for common digital and digital vessels till middle phalanx level and 1V S&T clamps for digital vessels at distal phalanx level. Vessels were anastomosed end to end with simple sutures.(Fig. 3)

**Figure 3- Showing end to end anastomosis between digital vessels**

Heparin injection 1ml (5000IU) bolus followed by heparin drip (5000IU in 500 ml D5 @ 40ml/hr) was started before release of microvascular clamps.

If after proper debridement gap precludes primary repair then interposition vein grafts were used for anastomosis, which were harvested from volar aspect of forearm.(5)

Venous anastomosis was done after arterial anastomosis was found functional and bleeding seen from distal veins. Nerve repair was done with perineural repair technique with nylon 10-0. Skin closure was achieved with primary suturing with or without skin graft. Loose dressings were done with paraffin gauze. Cotton wool dressing was done over the limb. Cast was applied over the dressing, till above elbow maintaining elbow in 90 degree flexion. Limb elevation was given post operatively and adequate hydration was maintained. Heparin drip was continued postoperatively for 5 days. Complete bed rest was given for 5 days.

Smokers and tobacco chewers were advised to stop the habit in post operative period. Patients were monitored and complications such as bleeding, infection, wound dehiscence at surgical site, skin blackening and necrosis (complete or partial), if any, were noted. Post operatively change of dressing was done on day 5 in most of the patients. No case was re-explored. In case of complete necrosis of part, it was managed by shortening closure, debridement and dressings, skin grafting or flap closure.

On follow up, subjective patient evaluation (Quick DASH Score) and functional outcomes (Chen’s criteria for functional outcome) were assessed at 3 months post operatively. Percentage total active motion of survived part was accessed as total active motion in fingers/limb compared to opposite normal finger/limb. Following moments of thumb were noted: flexion and adduction at 1st MCP joint and opposition with little finger, and were described as percentage of movement compared with normal opposite side. Sensory recovery was assessed subjectively and classified in complete, near complete, partial and no recovery, based on patient’s response. (6),(7).
Results

Total 20 patients were taken in study from age 5 to 65 years out of which 4 were females and 16 were males. Commonest mode of injury was machine injury followed by injury by sharp object followed by road traffic accidents. Replantation was done in 9 (43%) patients and revasularization in 12 (75%) patients. One patient had two amputations (middle and ring finger) who underwent revascularization procedure for both amputations.

Out of 12 procedures of revascularization 7 (58.3%) had near total amputation of part of which 1 (14.3%) procedure had complete survival. Among 3 partial amputations 1 (33.3%) had complete survival and 2 (66.7%) had partial survival. Among two patients with deep incised wound with vascular compromise both patients had complete survival of distal part. In replantation procedures one patient had complete survival of distal part and rest were failure.

Mean warm ischemia time in cases of complete survival was 4.8 hours and in cases of failure was 3.9 hours.

Optimal care of amputated part during transportation was taken in only 3 (33%) cases.

In our study 9 (45%) patients were smokers out of which 6 (66.7%) had failure of surgery and 3 (33.3%) had complete survival of distal part. In non-smokers 7 (63.6%) had failure of surgery. Although percentage of failure was high in smokers, it was not statistically significant. (p value of 0.350).

Out of 20 patients 11 (55%) had Yamano type 3 (crush avulsion injury), 7 (35%) had Yamano type 2 (crush cut injury) and 2 (10%) had Yamano type 1 (clean cut injury). Of 13 patients who had failure 9 (69.2%) patients had crush avulsion injury. While only 2 (15.4%) patients of crush avulsion injury had complete survival of part. One patient of clean cut injury had failure.

All patients had single amputation except one who had partial amputation of ring and middle fingers. Amputations were more common on right side of body and on upper limb. 16 (80%) patients had injury on right upper limb of body while only 3 (15%) patients on left upper limb. There was only one case of lower limb amputation at first metatarsophalangeal joint level. Out of 21 total amputations, thumb and little finger were equally affected 5 (23.8%) cases each while only one (4.7%) patient had devascularizing injury over middle finger and one had over palm/dorsum of hand.

Of 21 amputations, most common level of injury was at proximal phalanx with 8 (38%) cases. Out of 8 cases, 1 (12.5%) had complete survival and 2 (25%) had partial survival. 17 (81%) cases were distal to metacarpophalangeal joint level, 1 (4%) case was at metatarsophalangeal joint level and remaining 3 (14.28%) cases had injury proximal to metacarpophalangeal joint. 2 (9.5%) patients had major injuries proximal to wrist joint.

Mean time duration of surgery in failure cases was 7.08 hours while in cases of complete survival was 5.4 hours and 4.5 hours in cases of partial survival.

Thrombosis was most common complication in 16 (76%) patients. Out of 16 patients 9 (56%) had arterial thrombosis and 7 (44%) had venous thrombosis. Of these patients 2 (12.5%) had partial survival of part and rest were failure.

Out of 13 (61.9%) procedures complicated with wound infection 9 (69.2%) had failure, 2 (15.4%) had complete survival and 2 (15.4%) had partial survival. Haemorrhage was seen after 2 (9.5%) procedures. 1 (5%) patient who underwent revascularization of right ring finger had pulp atrophy of the digit.

Salvage procedures—Shortening and closure was most common procedure for defect closure done in 9 (42.8%) procedures. 4 (19%) distant flaps were done (2 groin and 2 abdominal flaps). Groin flaps were done for thumb reconstruction after failed procedure. Debridement and dressing and skin grafting were done in 2 (9.5%) cases each.

Functional recovery (Range of motion):

Functional evaluation of finger motion was done by percentage of total active motion. 4 (80%) patients had percentage TAM more than 70%. One patient (20%) of middle finger revascularization who had partial necrosis of distal part had total active motion of 55%. Patient with successful revascularization at forearm had near
normal (90%) TAM.

Three patients with failed procedure for thumb replantation received reconstruction for thumb. Movements of thumb were measured in four patients of thumb amputation. All patients had adduction more than 70% while three patients had flexion restricted to 50-55% and one patient with thumb tip amputation (Tamai zone 2) had flexion of 95%. All the patients were able to oppose thumb with little finger. Chens grade was measured for functional evaluation in 7 patients with part survival and two patients with thumb reconstruction with groin flap. Of 9 patients 3 (33%) were in grade 1, 5 (56%) patients in grade 3 and 1(11%) in grade 2. No patient had non functional limb (grade 4).

Discussion

Age: Youngest patient in our study was 5 years old female with complete amputation at metatarsophalangeal joint of right great toe while eldest patient was 65 years old who sustained near total amputation of right thumb due to assault. Maximum numbers of cases (33%) were present in age group of 21 to 30 years.

In H. Venkatramini et al(9) series similar age distribution of cases was seen with maximum number of cases (33.34%) in age group of 21-30 years.

Sex: In our study there were 16 (80%) male patients and 4 (20%) female patients. In study done by Nadezhda Gavrilova(7) et al 86% cases were males and 14% females. In Mahajan(10) series only 6% cases were females.

It is because males are more outgoing and more prone to machine injury at work and road traffic accidents which are commonest causes of such amputations.

Mode of injury: Injury while working on machine was most common cause of injury in our study which was seen in 6 (30%) patients while road traffic accident
in 4(10%) cases. Assault with sharp object was in only 1 (5%) patient who sustained right thumb amputation.

Two most common injury mechanisms were similar in Njoku Isaac Omoke et al (11) series. Road traffic injuries were higher in their series. There were 30 (56%) road traffic accidents and 7 (13.2%) machine injury cases. Other modes of injury in their series were gunshot, explosives and collapsed building, 3 (5.7%) patients each. The difference may be because their series included all patients of traumatic amputations presented in their hospital, while we included only those cases that met our inclusion criteria for operative procedure.

In study done by Nadezhda Gavrilova et al (3) industrial machinery injury was most common mode of injury seen in 46% cases which is similar to our study.

Lack of awareness and safety measures may be the reason for more cases of machine injuries seen in our study.

**Ischemia time:** All patients presented to us early with mean warm ischemia time was 4.8 hours in 5 complete survival cases while it was 3.46 hours in 13 failure cases. Mean cold ischemia time was 2.3 hours. One patient who presented to hospital after 7 hours of ischemia time had partial survival after revascularization.

**Site of injury:** In our study thumb and index finger were most commonly amputated digits (53.8%), devascularizing injury at the level of metacarpal was seen only in 1 (4.7%) patient and major injuries were seen in 2 (9.5%) patients.

In study done by J.Q.L. Neto et al (12) also, thumb is the most commonly amputated digit. This may be because the thumb is the most important digit for pinch function and rarely the replantation/revascularization of thumb is contraindicated.

**Effect of tobacco and smoking:** In our study of although percentage of failure was high (66.7%) in smokers but result was not statistically significant. There was no statistically significant correlation between tobacco chewing and failure of procedure.

Similar findings were obtained by Ji-Yin He et al. (13) in their study of 149 replants. The study showed that use of cigarettes / tobacco did not affect the replantation outcome.

**Vein graft:** We did not find any significance between use of vein graft and survival of distal part, however study done by Jing Li et al. (14) found statistical significance between use of vein graft and success of procedure.

**Type of amputation and procedure done:** We divided devascularizing injuries of limbs into 4 classes. Complete amputation (part completely separated from limb), near total amputation (part is attached to limb by a small skin tag), partial amputation (part is attached to limb with structures other than skin, with or without skin attachment) and deep incised wound.

Of complete amputations only 1 (11.1%) replantation of little finger at middle phalanx level was successful. Among near total amputations 1 (14.3%) patient with amputation at distal phalanx level was successful. There was no failure case in partial amputation and deep incised wound.

In study by N. Waterhouse (15), success rate was 61% in total amputations and 75% in subtotal amputations.

In our study 85% patients had severe crush injury and 55% patients had avulsion component. Replantation and revascularization was attempted in all cases presented and criteria for selection was not rigid.

81% cases in our study were distal to metacarpophalangeal joint involving digital arteries which are technically more demanding.

In 67% cases care of amputated part was suboptimal.

Mean time duration of surgery in failure cases was 7.08 hours which increased intraoperative ischemia time.

Replantation and revascularization procedures are technically demanding and there is longer learning curve.

**Complications:** In our study thrombosis occurred in 16 digits of which 9 (56%) had arterial thrombosis and 7 (44%) had venous thrombosis. Wound infection was seen in 13 (62%) patients. Two patients had reactionary haemorrhage, probably because of slippage of ligature, these patients were managed conservatively. One patient developed pulp atrophy in follow up. Skin grafting was
done as salvage procedure in 2 (9.5%) patients. Distant flaps (groin and abdominal) were done in 4 (19%) failed procedures, for thumb reconstruction. Shortening and closure was done in 9 (42.8%) procedures.

In N Waterhouse (15) series thrombosis was seen in 13 digits (31%) of which 11 (85%) had arterial thrombosis and 2 (15%) had venous thrombosis. local flaps (cross finger flap) were done in 2 (4.7%) digits. 2 (4.7%) digits had infection along track of k-wire. All patients had some degree of atrophy in fingers.

In N Waterhouse study, all cases of thrombosis were explored and they could salvage 2 cases from 13 cases of thrombosis. In our study we did not re-explore any case of thrombosis due to lack of patient willingness and motivation and it was difficult to manage re-exploration with limited human resources. (15)

Raja Sabapathy S et. al. (16) in their study of ring avulsion amputations found raw areas at wound margins in 6 (75%) patients who required split skin grafting. One patient had partial necrosis of volar skin managed by cross finger flap.

**Total Active motion:**

In 4 (80%) survived fingers, range of motion was >70% while only 1 (20%) patient had range of motion in 50-70%.

In Mahajan et al (10) study range of motion was >70% for 2(14.28%) cases and 50% in 4(28.67%) cases.

The reason for difference being we studied all devascularizing injuries i.e. both replantation and revascularization and in Mahajan et al study only replanted hand at wrist were studied.

We studied thumb function as flexion, adduction and opposition. All patients in our study had adduction >70%. One patient in our study having thumb tip amputation had flexion >70%. All patients were able to oppose thumb with little finger. In Mahajan et al (10) study opposition was >70% in 3 (21.42%) patients. Reason for difference may be because of preservation of 1st metacarpophalangeal joint in all patients of our study.

In our study we included both major as well as minor amputations. Chen grade (8) was measured for both. No patient in our study had cold intolerance. Out of 9 patients three were treated by distant flaps, two with groin flaps for thumb reconstruction and 1 with abdominal flap for thumb tip reconstruction. Although %TAM and power was more but there were no sensations in the flap area and so were grouped in grade 3. Three (33%) patients had grade 1 function (excellent outcome), while no patient had non functional limb, grade 4 (poor outcome).

B. Yaffe et al series and Sabapathy SR series considered only major upper limb replant.

In B Yaffe et al series 2(33.3%) patients had excellent outcome and 1(16.67%) had poor outcome.

In Sabapathy SR series majority, 9(45%) patients had grade 2 (good outcome), while 2(10%) had non functional limb.

**Quick DASH:**
Quick DASH compares the postoperative result with the patient’s functional competence in day to day activities.

Quick DASH score was calculated in 17 patients out of 20 as one patient was lost to follow up, in one patient 3 months follow up is still awaited and one patient had amputation of great toe.

In our study mean quick DASH score in cases of complete survival was 9.65, for failure cases it was 18.39, and in partial survival cases it was 26.1.

In study done by J. Dabernig et al (18) after successful replantation DASH Score achieved was 12.3. while in Hass F et al (19) Quick DASH score was 11.3. Findings were similar to our results. Quick DASH score of partial survival cases were high because it took longer time for wound to heal following partial necrosis of skin which delayed physiotherapy.

**Conclusion:**

Traumatic amputations were more common in young, working and economically productive age group, so successful replantation and revascularization procedures helps to reduce the financial burden on them.

First responders should be adequately educated regarding optimal care of amputated parts.

There are multiple factors to be considered for replantation and revascularization procedures. Preoperative selection includes ischemia time, contamination and care for preservation of part, avulsion and crushing injuries. Intraoperative management includes number of arteries, veins and nerve repaired, use of vein graft, bone shortening, anticoagulation and postoperative rehabilitation including physiotherapy, which independently influence the overall outcome of replantation and revascularization cases.

The viability of replanted part is guaranteed by a successful vessel anastomosis, while the quality of bone, tendon, nerve and skin repair will determine the overall functional success of replanted parts.

For thumb amputations, replantation and revascularisation is best option for thumb reconstruction and should be attempted in all cases.

Revascularisation procedures had overall better survival than replantation due to less complexity of procedure.

These procedures require specialized microsurgical skills and appropriate use of microvascular techniques, ultra-modern microscope, pneumatic drills and fine instruments for providing better results.

Well-developed replantation centre and multiple skilled replantation teams is need of modern time for assurance of good success rate.

**Conflict of Interest:** None

**Funding:** None

**Ethical Approval:** Ethical clearance for study was taken from ethical committee of Baroda Medical College, Vadodara before conducting this study.

Abstract

In this study, we evaluated the RBC indices in differentiating β-thalassemia minor and iron deficiency anemia in a healthcare center. This was an observational analytic study with a cross-sectional design using blood specimens of children aged 3 years to 17 years with microcytic hypochromic anemia based on the results of complete blood counts and evaluation of peripheral blood smears. Calculation of the RBC indices was performed as an initial screening to differentiate β-thalassemia minor and iron deficiency anemia. Iron profile examination and hemoglobin electrophoresis were performed to confirm the diagnosis of β-thalassemia minor and iron deficiency anemia. The results of the independent samples t-test showed significant differences in Hb, MCV, MCH, and MCHC between β-thalassemia minor and iron deficiency anemia (p <0.05). The results of the Mann Whitney test showed a significant difference in the Mentzer Index to distinguish between β-thalassemia minor and iron deficiency anemia (p <0.05). Also, the results of the independent samples t-test showed significant differences in the Green & King formula, Sirdah et al. formula, and the Maltos and Carvalho Index (p <0.05). The Green and King formula has a diagnostic sensitivity of 78.6% and a specificity of 76.6% and an accuracy of 78.03%. Various formulas based on the results of complete blood count parameters have been developed to detect β-thalassemia minor in areas with a high prevalence of β-thalassemia with different sensitivity and specificity. In this study, it showed that the Green and King formula has a diagnostic sensitivity of 78.6% and a specificity of 76.6%, and an accuracy of 78.03%. Green and King’s formula can be applied as an initial screening to differentiate β-thalassemia minor and iron deficiency anemia.

Keywords: RBC indices, β-thalassemia minor, iron deficiency anemia.

Introduction

WHO study shows that as many as 800 million children and women have anemia, which the population with the highest prevalence of anemia and the lowest hemoglobin concentration being in the Southeast Asian, Eastern Mediterranean, and African regions. Approximately 50% of cases of anemia are considered to be due to iron deficiency, other causes are inherited or acquired disorders that affect hemoglobin synthesis, red blood cell production, or red blood cell survival.[¹]

The results of Basic Health Research from the Ministry of Health of the Republic of Indonesia (2013) have shown that 21.7% of the age of population ≥1 year, 28.1% of toddlers aged 12-59 months, and 37.1% of pregnant women are the proportion of anemia in Indonesia.[²] Differential diagnosis of microcytic hypochromic anemia is very important to be considered because the interpretation of its peripheral blood smear...
can be found in iron deficiency anemia and β-thalassemia trait.[3,4] Iron deficiency and β-thalassemia minor are best differentiated using serum ferritin level, serum iron level, total iron-binding capacity, transferrin saturation, and Hb A₂ level, along with a complete blood count (CBC) and examination of a peripheral blood film.[3] Carriers of β-thalassemia are usually clinically asymptomatic. However, they have characteristics of the CBCs with mean corpuscular volume (MCV) less than 80 fL and mean corpuscular hemoglobin (MCH) less than 27 pg.[5]

The ability and experience of a doctor in discriminating between β-thalassemia minor and iron deficiency anemia (IDA) clinically is very important because there are still difficulties in distinguishing between these two diseases. There are differences in the prognosis and management of those diseases, so the exclusion of iron deficiency anemia could be achieved mathematically using the red blood cell (RBC) parameters.[4,5] Various formulas using a complete blood count have been developed to detect β-thalassemia carriers in areas where the prevalence of thalassemia major is high; however, specificity and sensitivity vary across regions.[4,6]

In an attempt to simplify the differential diagnosis between IDA and β-thalassemia minor, several indices using blood cell count parameters have been suggested.[4] According to many studies, the formula developed by Green and King \[\frac{\left((MCV^2 \times RDW)\right)}{Hb \times 100}\], Sirdah et al. Formula \[(MCV – RBC – 3 \times Hb)\], Matos and Carvalho Index \[(1.91 \times RBC) + (0.44 \times MCHC)\], and Mentzer Index \[MCV/RBC\] have a good performance.[4,5,7] Capillary zone electrophoresis (CE) was able to detect the most common variants but differed concerning measurement HbA. The CE was able to measure HbA₂ in the presence of HbE. This is important to diagnose thalassemia and hemoglobinopathies.[8] Few data are available about the evaluation of the diagnostic reliability of different RBC indices and formulas to differentiate of the β-thalassemia minor and iron deficiency anemia (IDA) in Surabaya, Indonesia. In population or mass-screening programs especially in developing countries, these hematology indices could be applied where resources are limited.[7] Therefore, this study aimed to evaluate the sensitivity and specificity of different RBC indices and formulas in the differentiation of the β-thalassemia minor and iron deficiency anemia.

### Materials and Methods

#### Study Subjects and Sample Collection

This was an observational study with a cross-sectional approach performed in all blood specimens in patients aged 3 years until 17 years with hypochromic (MCH <27 pg) microcytic (MCV <80 µl) anemia based on the results of a complete blood count (CBC) and evaluation of peripheral blood smears. A total of 223 subjects (124 males, 99 females) were studied in Dr. Soetomo General Academic Hospital, Surabaya, Indonesia between January 2019 and August 2019. The hematological index calculation (Mentzer Index, Green and King Formula, Sirdah et al. Formula, and Matos and Carvalho Index) was performed as initial screening in distinguishing iron deficiency anemia and β-thalassemia minor. Examination of iron profiles (serum iron, total iron-binding capacity, and serum ferritin), and hemoglobin electrophoresis was carried out subsequently as confirmation of the diagnosis of iron deficiency anemia and β-thalassemia minor.

Inclusion criteria for iron deficiency anemia (IDA) subjects were microcytic hypochromic anemia with serum iron level <50 µg/dl, TIBC level >390 µg/dl, transferrin saturation <15%, and serum ferritin level <15 µg/L.[9] In addition, inclusion criteria for the β-thalassemia minor (BTMi) subjects were children with microcytic hypochromic anemia, had a family history (parents or siblings) of β-thalassemia. Their CBCs show hemoglobin (Hb) less than 13.5 g/dl, MCV less than 80 µl, and MCH less than 27 pg. Subjects with severe sepsis were not included in this study and none of the subjects had a combined case of β-thalassemia minor and iron deficiency anemia. Then, β-thalassemia minor is confirmed by quantitation of HbA₂, in which HbA₂ >3.5% indicates β-thalassemia minor.[3] The following indices and formulas were calculated and compared:

Green and King formula \[(\frac{\left((MCV^2 \times RDW)\right)}{Hb \times 100})\].[10]  
Sirdah et al. Formula \[(MCV – RBC – 3 \times Hb)\].[7]  
Matos and Carvalho Index \[(1.91 \times RBC) + (0.44 \times MCHC)\].[4]  
Mentzer Index \[MCV/RBC\].[11]
Sensitivity [true positives/(true positives + false negatives)], specificity [true negatives/(true negatives + false positives)], positive predictive value [true positives/(true positives + false positives)], negative predictive value [true negatives/(true negatives + false negatives)], and accuracy [(true positives + true negatives)/total subjects] were calculated for each index and formula at wide-range of cut-off values.

Sample Preparation, Hematological and Clinical Chemistry Evaluations

Peripheral blood (3 mL) was collected in tubes containing K3EDTA (ethylenediaminetetraacetic acid) with a final concentration of 1.5 mg/mL. Complete blood count was examined using an automated hematology analyzer (CELL-DYN Ruby, Abbott® and Sysmex® XN-1000) in the laboratory unit of clinical pathology, Dr. Soetomo General Academic Hospital.

Hemoglobin electrophoresis tests were performed using a capillary electrophoresis system (MINICAP Sebia®) which able to measure HbA₂ in the presence of HbE. The capillary electrophoresis system does not require daily calibration, but normal HbA and HbA₂ migration controls are analyzed through each capillary daily before running QC materials or patient samples to ensure proper charge and function of the capillaries.[12] Normal HbA₂ control (Sebia®, France) for QC materials were also run daily.

Another sample of the peripheral blood (2 mL) was collected with BD Vacutainer® SST™ blood collection tubes contain spray-coated silica to aid in clotting and a polymer gel for serum separation to evaluate serum iron, total iron-binding capacity, and serum ferritin values.

Statistical Analysis

Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy were calculated for each measurement of the formulas. Descriptive statistics such as the mean, the median, and the standard deviation (SD) were calculated for hematological parameters (RBC, hematocrit, RDW-CV) and also age variable. The differences between the two groups parameter (β-thalassemia minor and iron deficiency anemia) were compared using the Mann-Whitney U test, because of the distribution of these parameters were non-normal. The independent samples t-test was used to compare the differences for hematological parameters (Hb, MCV, MCH, and MCHC) between these groups. The normality of data was evaluated using the Kolmogorov-Smirnov test.

Results

The Hb value in the BTMi group was 8.53±1.62 compared to the IDA group was 10.96±2.13 (p <0.001). MCV values of 71.95±6.76 and MCHC 30.96±1.86 in the BTMi group were lower than in the IDA group (76.48±4.85 and 32.20±1.45 with p <0.001). RDW-CV in the BTMi group was 20.15±4.77, significantly higher than the IDA group (14.6±3.28 with p <0.001). Erythrocyte count (RBC) was higher in the IDA group of 4.46±8.86 than in the BTMi group (3.86±0.81 with p <0.001) (Table 1).

</table>

The data from the present study (Table 2) showed the Green and King formula has the highest sensitivity (78.6%) and specificity (76.6%) in the differentiation of BTMi and IDA. The highest PPV value was found in the Green and King formula (89.3%) and the lowest was in the Martos and Carvalho index (47.8%). The highest NPV value was found in the Green and King formula (59%) and the lowest was in the Martos and Carvalho index (12.2%). There were none of the differentiation indices with high sensitivity and specificity (100%) in differentiating BTMi and IDA, but the overall index was significant in differentiating BTMi and IDA (\( p < 0.05 \)) against the gold standard examination of hemoglobin electrophoresis (HbA2).

Discussion

The ability and experience of a doctor in distinguishing between BTMi and IDA is very important because it has clinical implications where the two diseases have different aspects of etiology, prognosis, and management.\[^{13}\] The most common causes of anemia are iron deficiency anemia (IDA) and thalassemia trait (TT).\[^{1}\] In infants, the incidence of IDA is estimated to be between 20-25%. The results of the Basic Health Research of the Ministry of Health of the Republic of Indonesia (2013) showed that the proportion of anemia in toddlers aged 12-59 months is 28.1%.\[^{2,14}\] Many investigators still have used hematological index calculations based on complete blood parameters as the initial screening to differentiate BTMi and IDA.

A capillary electrophoresis system for the examination of hemoglobin electrophoresis costs more than a routine CBC, and if we can routinely include an automatic alert signal in any routine CBC analyzed by the hematology analyzer, the referring physicians can get an indication of whether they need to perform further studies.\[^{15}\]

The data from the present study (Table 1) showed significant differences in hematologic parameters between the BTMi and IDA groups. The higher RBC increase in the IDA group compared to the BTMi group was probably related to the administration of iron therapy in children with IDA. Vehapoglu et al. (2014) observed that the RBC increased in patients with IDA at the time of initiation of iron therapy and a decreased of the RBC at the end of iron therapy.\[^{13}\] This is consistent with the study of Aslan and Altay (2003) that 36 out of 140 (26%) children aged 6 months to 48 months with nutritional IDA without bleeding, experienced a
significant increase in RBC accompanied by an increase in Hb and Het, as well as a decrease in MCV values. A continuous increased in RBC occurred in patients with higher RBC (high-RBC patients) up to 4 weeks of iron therapy compared with those with lower RBC (low-RBC patients).[16]

Evaluation of the hematological indices in this study showed the Green and King formula had the highest sensitivity (78.6%) and specificity (76.6%) in differentiating BTMi and IDA, followed by the Mentzer index (66% and 62.5%), the Sirdah et al. formula (64.2% and 64.1%), and the Martos and Carvalho index (27.7% and 25%). These results were in accordance with the study of Urrechaga et al. (2011) who showed that the Green and King formula had high sensitivity (91%), specificity (99.1%), Youden index (90.1%), and area under the curve (AUC) in differentiating BTMi and IDA.[17]

This study had several limitations such as no mutational analysis data was carried out in the study. The platelet parameters were not included in this study which are available in the CBCs result that may be helpful as discriminating guide for BTMi and IDA.

**Conclusion**

In summary, it was concluded that none of the differentiation indices or formulas provided 100% sensitivity and specificity for the discrimination of BTMi and IDA. For the population of children in Surabaya, Indonesia, applying the Green and King formula might be useful in the early or initial screening stages of children with the hypochromic microcytic anemia.

The Effect of Interleukin-10 and Its Relationship with The Level of White Blood Cells in Women Spontaneous Miscarriage Undergoing Intracytoplasmic Sperm Injection (ICSI) Technique

Dhirgam F. Hassan Al-Shimerty¹, Alaauddeen S. M. AL-Sallami²

¹Research Scholar, Faculty of Pharmacy/ University of Kufa; ²Professor, Biology Department/ Faculty of Science/ University of Kufa, Iraq

Abstract

This study was conducted on 84 samples of women subject to the ICSI program. Blood sample was taken to measure WBC count, Interleukin-10 and β-hCG levels. Groups were divided based on the β-hCG level to two groups (Pregnant Women Group - Pregnancy Failure Group) and the total of pregnant women divided into (Pregnancy Group and spontaneous miscarriage).

The results of the current research showed a significant increase in the level β-hCG and that the increase in the level of this hormone is evidence of the presence of high success rates for pregnancy in women who performed operations IVF, where the success rate at the beginning of the matter reached 61.9%, after which it decreased to 33.3% after the first three months due to the occurrence of spontaneous miscarriage of pregnant women due to various immunological and physiological reasons, as well as a positive correlation between the level of β-hCG and other parameters within the study (Interleukin-10 -WBC).

The results of the current research also showed a significant difference between the group (pregnancy failure) and the group (spontaneous miscarriage) compared with the control group (continued pregnancy) in relation to the level of Interleukin-10, Also, The results of the current research showed a significant difference between the group (pregnancy failure) and the group (spontaneous miscarriage) compared with the control group (continuation of pregnancy) in relation to the level of WBC, and the present study found a positive relationship between the level of Interleukin-10 and WBC.

Keywords: miscarriage, ICSI technique, Interleukin-10, white blood cells.

Introduction

Infertility is a widespread disease worldwide and it means “the inability of the spouses to achieve pregnancy within one year of marriage” and the estimated rate of infertility in the world is around 15-20% (¹).

In vitro fertilization, intracytoplasmic sperm injection (ICSI), and intrauterine insemination (IUI) be are the main methods of assisted reproductive technology (ART). Found several Various studies in recent years have indicated that occur risk factor for implantation failure of women after In vitro fertilization - ICSI which may be immunological parameters or biochemical parameters may be affected on In vitro fertilization intracytoplasmic sperm injection results (¹⁵).

White blood cells (WBCs) They are considered an important part of the immune system in the body. It should be noted that the increase in the number of white
blood cells or their lack of a normal limit indicates the presence of a health problem that afflicts the patient, hence cause of white blood cells rise for a number of reasons, the most important of which are summarized below. For pregnancy and childbirth or spontaneous miscarriage because increase Infection in Urinary tract with or immune system problem (2,16).

Interleukin -10 has several effects and has many roles in regulating the body’s immunity as well as affecting inflammation and is involved in stimulating phagocytic cells as well as has a role in the survival of B cells and building antibodies. There are many studies that have demonstrated that interleukin-10 inhibits fatty polysaccharide and is also stimulated by the bacterial product of pro-inflammatory (3).

Materials and Methods

This study was conducted in the laboratories of the Department of Biology, College of Science, University of Kufa, and in the Laboratory of the Fertility Center in Sadr City Medical City in Najaf Governorate / Najaf Health Directorate / Ministry of Health / Iraq.

Taked about five milliliters of intravenous blood samples were drawn in the morning from women which undergoing intracytoplasmic sperm injection (ICSI) technique during three parts, the first part after 14 day from injection, the second part after trimester spontaneous miscarriage while the third part for women which be continuous pregnant and using a needle and syringes which is used for one time from each patient and control. Four milliliters of the blood then it was left in a gel tube at room temperature for 10 minutes to complete the blood clotting, then centrifuged at 3000 rpm for 5 minutes, then the serum was separated for measurements of β-hCG level and Interleukin-10 level by ELISA method and one milliliter of the blood was put in EDTA-Na2 treated collection tubes for measurements of number of white blood cells count by Genex Hematology Analyzer.

Statistical Analysis

The popular statistical system (Graph Pad prism ver. 5) was adopted, and a one-way analysis of variance - Anova method (by Tukey’s multi-comparative test) was used to compare the groups divided into the measured parameters. The results are expressed as (Mean ± Standard Error). Correlation coefficients were calculated to estimate the correlation between tags and parameters. Descriptive statistics and correlation coefficients were performed using mega stat (V10.12 version) for excel 2010 (4).

Results

In this test showed found significant difference (p<0.05) between pregnant women which was 52 (4.24±0.25) and non-pregnant women (Implantation Failure) (2.56 ±0.10) which was 32 from women which undergoing intracytoplasmic sperm injection technique as shown in table (1).

Discussion

The results of the current research showed a significant increase in the level of significance (p<0.05) in the level of the β- Human chorionic gonadotropin hormone, and the reason for this is that this hormone is evidence of the presence of pregnancy in women who underwent ICSI operations may be because it is excreted mainly from the placenta during the formation of the fetus and this study is consistent with what reached by some authors in this regard and that the increase in the level of this hormone is evidence of high success rates of pregnancy for women who conducted ICSI operations, where the success rate initially reached 61.9%, after which it decreased to 33.3% after the first three months due to the occurrence of spontaneous abortions for women. Pregnant women for various immunological and physiological reasons, as this study indicated, and these results are consistent with what was reached.
The results of the current research showed a significant increase at the level of significance (p<0.05) between the group (pregnancy failure) and the group (spontaneous miscarriage) compared with the control group (continued pregnancy) in the concentration of interleukin-10 in When the differences were not significant between the group (pregnancy failure) and the group (spontaneous miscarriage may be because the pregnant women have a low white blood cells level compared to aborted women because white blood cells is evidence of infections in the genital and urinary tract as a result of the spontaneous miscarriage process and Interleukin-10 is one of the cytokines that stimulates the occurrence of infections and is responsible for the start of the inflammatory process and is called the inflammatory station The fourth of the cells devoured and through the diagnosis of the concentration of interleukins, the reaction of the immune system can be known as normal, high or low, and it is consistent with its findings (9,10).

As it was explained by increasing the level of interleukin-10 in aborted women, it is an indication of the role of interleukins whose function is the communication between immune cells, whose action is directed at defending the body.

The results of the current research showed a significant increase at the level of significance (p<0.05) between the group (pregnancy failure) and the group (spontaneous miscarriage) compared with the control group (continued pregnancy) with respect to white blood cells count while The differences were significant between the (pregnancy failure) group and the (spontaneous miscarriage) group, and this study is consistent with the findings of (11,12) and this result may be explained that the reason for this is that pregnant women have a low white blood cells count level compared to aborted women This may be because white blood cells count is evidence of the presence of infections in the genital and urinary tract as a result of the abortion process, where these results are consistent with what was reached (11,14) where he explained the presence of a significant increase in white blood cells women abortifacients and pregnancy after a period when the failure of vaccination compared to non-spontaneous miscarriage women.

The current study also showed a positive correlation between the level of interleukin-10 and WBC and perhaps the reason for this is that the increase in the level of white blood cells during pregnancy or spontaneous miscarriage in women, which is often accompanied by an increase in urinary and genital tract infections which leads to an increase in the level of interleukin - 10 (15,16).

Conclusions

The level of interleukin - 10, and increase in the level of significance (p<0.05) in the level of the β- Human chorionic gonadotropin hormone and The results of the current research showed a significant increase at the level of significance (p<0.05) between the group (pregnancy failure) and the group (spontaneous miscarriage) compared with the control group (continued pregnancy) with respect to white blood cells count.

Constitutional Right to Vote for People with Mental Disorders (PMWD) with Case Study in Yogyakarta, Indonesia

Diastama Anggita Ramadhan
Lecturer at Faculty of Law, Diponegoro University, Semarang, Indonesia

Abstract
The right to vote as one of the constitutional rights is certainly in favor of all Indonesian citizens, including those who suffer mental disorders. The Constitutional Court through the Constitutional Court Verdict Number 135/PUU-XIII/2015 has stated people with mental disorders, as long as their condition is not permanent, they can vote. However, this verdict has the potential to violate the constitutional rights of the citizen. This research location will be carried out in the Special Region of Yogyakarta where it is one of the provinces with the largest mental disorder communities in Indonesia. This research uses a normative juridical method and focusing on literature studies as its main sources. This research will conclude about the method used by people with mental disorders to access their right to vote. Furthermore, it will also explain the extent to which the Constitutional Court’s decision has an impact on patients with psychiatric disorders in the Special Province of Yogyakarta.

Keyword: constitutional rights; right to vote; people with mental disorder

Introduction
Political rights contain the nature of universality and equality, which means that everyone has the same opportunity in the electoral process, arranges political access that is not limited by anything, and channels references that are owned by each person through voting mechanism. This is in line with what has been mandated in Law Number 18 of 2014 concerning Mental Health, which in Article 2 letter h states that one of the principles implemented in the Law is the principle of non-discrimination. Article 3 of the same law also guarantees the rights of a citizen suffering from mental disorders. This article then aims to find out how persons with disabilities, especially persons with disabilities with the category of mental retardation, channel their right to vote through general elections. Especially considering that political rights (to vote and be elected) are under gable rights for everyone and without discrimination.

Thus, it can be seen that every Indonesian citizen has the right to vote regardless of the condition of each person. In general, Indonesia’s General Election Commission (KPU) has established special regulations that provide opportunities for persons with disabilities to be able to exercise their rights. The KPU has basically provided a means for persons with this type of mental retardation to be able to channel their constitutional rights. This is then an elaboration of the Constitutional Court Decision Number 135/PUU-XIII/2015 which in its decision states that as long as a person does not have a mental illness that can permanently affect a person’s choice, then that person still has his constitutional right to vote. The problem here is that the Constitutional Court decision has the potential to injure the constitutional rights of citizens, especially someone suffering from mental disorders. The Court’s decision has great potential to injure the constitutional rights of citizens, especially someone suffering from mental disorders. The Court’s decision has great potential to injure the constitutional rights of a person with a mental health disorder, especially their right to vote. It is possible for people with mental disorders to recover, although it requires strict assistance and a long process. Yogyakarta Province based on Basic Health Research (Riskesdas) is choose as research location as it has the number of people with psychiatric disorders that
has increased from a number of 2.8% in 2013 increased quite high to 10% in 2018. This makes Yogyakarta Province occupy the 2nd position with the largest number of people suffering from psychiatric disorders. This explains that there are 10 people with psychiatric disorders every 1000 people in Yogyakarta Province. This illustrates the legal conditions that occur in the field that there are a number of people in Yogyakarta Province who have the potential to be impaired by their right to vote, which is a citizen’s constitutional right as a result of the Constitutional Court Decision.

Research Methods

This research is a conceptual research with normative juridical research. Normative legal research is legal research that puts down the principles, values and legal norms that are contained in statutory regulations, as well as court decisions. The approach used in this paper is a statutory approach. The technique of collecting legal materials in this study was carried out by using literature study techniques. This research uses the deductive legal material analysis method, in which the legal materials that have been collected are classified and then conclusions are drawn from general matters into specific matters.

Urgency of Inclusive Elections for Patients with Psychiatric Disorders

The implementation of inclusive elections is very relevant to be implemented in Indonesia, considering that the right to vote is not only owned by normal people, but also for those with disabilities. The inclusiveness of an election can be said to be successful when everyone who has the right to vote can participate in the electoral process by selecting the party who is most deemed capable of solving their problem. One indicator that an election can be said to be of quality is the large level of community participation from all groups in an overall electoral process. Including those with psychiatric disorders, the implementation of inclusive elections in Indonesia itself is far from being feasible. The “human side” of state administrators has not yet grown to provide all the needs of voters with this special category, making it very difficult for them to be able to exercise their rights.

Realizing inclusiveness in the general election process itself is not as easy as turning your hand. Reflecting on the electoral process that was carried out by the Bolivian state in 2002, the participation of both parties is very strong to be able to realize inclusiveness in general elections. Apart from the participation of the parties, inclusiveness also needs to be achieved in several ways, including: fundamental changes in the electoral system, understanding of the ideal conception of elections (through an appropriate electoral education process), and social consolidation of those who wish to be included in the concept. Inclusiveness of elections that are being formed. The failure of the process of inclusiveness can be the beginning of a disaster that general elections, where elections are only held as a formal process to maintain power from a group of people who easily gain power.

Participation of People with Mental Disorders in Yogyakarta in the General Election

According to research conducted by the Provincial Health Office of Yogyakarta in 1999, of the 3.5 million residents of the Province of Yogyakarta, 12,322 of them were sufferers of psychiatric disorders. The results of the 2017 Yogyakarta regional head election show that the turnout rate for voters with disabilities has increased compared to the results of the last election in 2014. The results of the 2017 Yogyakarta regional elections were 350 out of it. 494 persons with disabilities registered in the Permanent Voters List (DPT) who exercised their voting rights. This means that the percentage of persons with disabilities recorded in the DPT who exercised their voting rights in the 2017 Yogyakarta city elections reached 70.9%.

Seeing the position of the participation of persons with mental disorders in the general election can be examined from 2 points of view, philosophical and sociological. Philosophically, the revision of Law Number 8 of 2015 refers to the consideration that all basic human rights must be fulfilled, without exception. Despite experiencing conditions of limited mental illness, every Indonesian citizen has rights directly guaranteed by the Constitution. Sociologically, the role of the state is very important to create political justice for every level of society. Efforts made by the government for people with mental disorders began to
be implemented in the 2019 general election. This is the start of a change in perspective that not all people with mental disorders cannot participate in the general election. Efforts to change this point of view are based on 4 things that are always stigmatized in people with mental disorders, including equation of mental disorders with crazy people; concern about acts of vandalism that may be committed by people with mental disorders on voting day; concern that voices made by people with mental disorders can be manipulated and misused; and doubts about the capabilities of the mentally impaired at the time of voting.

In the eyes of the law, people with psychiatric disorders have the same rights as citizens who are not affected. Giving special treatment for sufferers of mental disorders is the maximum effort for respecting, advancing and fulfilling human rights for them. Contrary to this, the opinion that developed in the community later said that people with mental disorders are considered not to have the capability to make legal decisions, and it is even considered dangerous if a person with mental disorders continues to make legal decisions.

Based on data collected by the Ministry of Health, it is stated that the number of people with mental disorders in Indonesia reaches 7% of the total population of Indonesia as a whole. In the 2019 general election alone, the number of people with mental disorders who are counted in the DPT is 3,500 people. In accordance with the principle of the presumption of liberty which generally applies within the scope of human rights, it is the state that is burdened with the responsibility of being able to guarantee that every law that is enacted can accommodate all citizens and does not limit their movement. The state must be able to provide guarantees for people with mental disorders, in this case non-permanent mental disorders, to continue to have access to their constitutional rights.

Sufferers of psychiatric disorders are proven to have sufficient knowledge, a sense of responsibility for their actions, and the majority of them have positive feelings about the implementation of general elections. This explains that in the concept of democracy and rule of law, every vote that comes from a citizen cannot be reduced in any way. This is in line with the main pillars of the establishment of a rule of law, one of the pillars in order to create a strong rule of law requires guarantees of equal treatment before the law, protection of human rights, and social control.

Looking at the categorization of people with psychiatric disorders, there are several differences between someone who is said to be legally competent and someone who is psychiatrically unhealthy. The word refers to the legal situation faced by each sufferer. This in turn causes the person to be considered legally competent. Law focuses on the thoughts and mindset of a person who commits legal action, not looking at the organs that cause interference to a person who commits legal action. If a person is said to be legally competent in taking a legal action, then that person is still legally able to take legal action.

The Commission has directed that persons with mental disabilities to be included in the DPT. The KPU noted that there were 43,769 people with mental disabilities who had the right to vote in the 2019 elections. This number is expected to increase because data collection is still ongoing. In the 2014 election, there were only 8,717 voters with mental disabilities, while in the 2019 election it reached 43,769 people.

**Conclusion**

The implementation of inclusive elections is a very important part if the state wants to protect the right to vote for people with psychiatric disorders to participate actively in elections. Inclusive elections not only provide opportunities for persons with disabilities in general, but also pay attention to the needs of those who are also Indonesian citizens. Providing access to people with mental disorders will open up access for them in the policy making process, so that it will be possible for them to form policies that are more inclusive and friendly. Election inclusiveness can be the first step to improve the overall level of life of persons with disabilities. The right to vote for people with mental disorders is a right inherent in them. In general, the right to vote protected by laws and regulations applies to all Indonesian citizens. This then brings a consequence that people with mental disorders are one of the legal subjects whose voting rights must be protected.

Purified Pyocyanin from Clinical Isolates of Pseudomonas aeruginosa Enhances Antibiotic Sensitivity Against Some Pathogenic Bacteria

Duaa Ghazi¹, Hasan Faisal Kahya²
¹Research scholar; ²Lecturer, Department of Biology/College of Education for Pure Sciences/University of Mosul/ Mosul/Iraq

Abstract

Pseudomonas aeruginosa is one of the most life-threatening pathogen. It is considered nosocomial opportunistic microbe that cause wide range of infections including wound and burn infections, respiratory infections, and Otitis media. Despite the efficiency of antibiotics against infectious diseases, P. aeruginosa still causes complicated infections with antibiotic resistance in many clinical strains. The pigments produced by P. aeruginosa exhibits antibacterial properties. Thus, we have examined its ability to enhance antibiotics effect against some pathogenic microbes. 286 samples were collected from patients with different infections who visited Mosul hospitals. 76 samples were positive to P. aeruginosa. Among them, 38 (13.28%) of isolates were isolated from surgical infection, whereas, 12 (4.19%), 11(3.84%), and 7(2.447%) were isolated from Otitis media, Urinary tract infection, and pus, respectively. The pyocyanin in low concentrations showed synergistic effect with some antibiotics against Staphylococcus aureus and Escherichia coli. E. coli became sensitive to ciprofloxacin and nalidixic acid when mixed with 100 mg/ml pyocyanin. However, cloxacillin did not show any activity against Staph.aureus when mixed with 1 mg/ml and 6.25 mg/ml pyocyanin. Staph aureus became sensitive to nalidixic acid when mixed with 1 mg/ml pyocyanin.

Key word: Pseudomonas aeruginosa, pyocyanin, Antibiotics, Synergistic effect.

Introduction

Pseudomonas aeruginosa is widely spread in the environment. It is a gram negative, aerobic microbe in rod shape belongs to Pseudomonadaceae family. In this family, there are 12 other genus as well as P. aeruginosa. Although P. aeruginosa can be found in soil and water, it is considered the most opportunistic pathogen in hospitals ¹⁹. It is also one of the nosocomial pathogens with antibiotic resistance strains ¹³ P. aeruginosa composed of virulence factors including polysaccharide layer, exotoxins, pilli and biofilm formation ability. The key factor of pseudomonal infections is bacterial attachment to the host epithelial layer that keeps the microbe away from the host immune defense ²¹.

P. aeruginosa produces many pigments, including pyocyanin (bluish green), pyoverdin (fluorescent yellow-green) and pyorubin (brownish red) ²⁸. These pigments contribute to pseudomonal infections. Many studies suggest that pseudomonal pigments can be a virulence factor in the lungs of patients with cystic fibrosis. They also may interfere host cell respiration. The mechanism of the pigment pathology is still unknown ²⁴.

The produced pyocyanin has antibacterial properties. It has been proved that pyocyanin prevents other bacterial growth is the site of infection ¹. This characteristic provides a persistence growth for P. aeruginosa. Many studies examined the possible activity of pyocyanin against other pathogens.

Multi-resistant strains of P. aeruginosa as nosocomial pathogen has spread in hospitals leading scientists to dig out other efficient drugs. In this study, we hypothesized that pyocyanin is a drug nominate and
whether can be used to enhance antibiotic efficiency by examining the synergistic effect of pyocyanin and antibiotics with less effect. We isolated and diagnosed clinical isolations from patients with different infections including otitis media, wound infection, surgical infection, urinary tract infection and upper respiratory infection. The synergistic effect of pyocyanin with antibiotics was examined.

**Materials and Methods**

**Samples collection and identification:**

286 samples were collected from different infection sites including wounds, otitis media, burns, surgical infections, urea and sputum, from patients who visited Mosul hospitals. Identification process were initially based on bacterial colony appearance on blood agar as well as the smell of culture. The haemolysis of blood on blood agar were reported as well as pigment production. Other standard diagnostic methods were performed according to. Molecular diagnosis of isolates were performed using 16S rRNA sequencing method. The genomic DNA were extracted using the extraction kit supplied from Geneaid. The genomic DNA were then visualized on agarose gel electrophoresis. The PCR reaction was carried out using the primers 16S RNA-F: AGAGTTTGATCCTGGCTCAG, and 16S RNA-R: AAGGAGGTGATCCAGCCGCA. The reaction was prepared by mixing 50 ng of DNA template with 10 pmol of primer mixture and 10 µl of hot start taq polymerase. The reaction was then topped up to 20 µl. The tubes were then put into the thermocycler and the program was run. The reaction condition was performed as 1 cycle of: initial denaturation at 95°C for 6 minutes, and 35 cycles of: denaturation at 95°C for 45 seconds, annealing at 58°C for 1 minute, and extension at 72°C for 1 minute, and 1 cycle of: final extension at 72°C for 5 minutes. The amplicons were then visualized on agarose gel electrophoresis. The amplicons were then purified from agarose gel and extracted using DNA extraction kit. The purified PCR products were sent for sequencing using 16S RNA-F and 16S RNA-R. The sequence process was performed at Hitachi Company (Japan). The sequencer 3130 provided from Macrogen Biotechnology Company were used for gene sequencing. The sequence results were then blasted with DNA database using National Center for Biotechnology Information (NCBI) website (https://blast.ncbi.nlm.nih.gov/Blast.cgi).

**Pyocyanin extraction and purification:**

*P. aeruginosa* isolates were grown on King A media to confirm the pigment production and they were then grown on alanine minimal agar glycerol medium to enhance the pigment production. The cultures were incubated at 37° C for 48 hours. The culture were then exposed to light source with incubation at (25° C)°. The extraction of pyocyanin were performed according to the method described by Watson et al., 1986 with some modifications.

**Antibiotic susceptibility test:**

The sensitivity test was performed according to Clinical and Laboratory Standards Institutes (CLSI). Fresh bacterial culture were spread finely on Muller Hinton agar and left to dry. The antibiotic discs were put on the inoculated plates and incubated at 37 ° C for 24 hours. The antibiotics used in this study were penicillin, Cefixime, peperacillin, nalidixic acid, gentamycin, azithromycin, amikacin, ciprofloxacin, doxycycline, cloxacillin, erythromycin, chloramphenicol, amoxicillin, novobiocin, and tetracycline.

**Synergetic effect of pyocyanin with some antibiotics:**

The synergistic effect of pyocyanin with some antibiotics was performed according to the method described in with some modifications. The disc diffusion assay was used in this study. The optimal and minimal concentration of pyocyanin and antibiotics were reported against *Staph. aureus* and *E. coli*. The minimal concentrations of the pigment and antibiotics were then mixed to examine the synergistic effect of pseudomonal pyocyanin with antibiotics.

**Statistical Analysis**

Graphpad Prism software (Graphpad, California, USA) was used for statistical analysis. Means and standard error of means (SEM) were used to analyze the results. Significant difference was assessed at *p* values: * p<0.05, ** p<0.01.

**Results and Discussions**

Collecting of sample:
Among 286 samples collected from patients visited Mosul hospitals, we have isolated 76 positive samples of *P. aeruginosa*. The positive samples were confirmed using biochemical tests as well as molecular identification using 16S RNA gene sequencing. All samples tested for 16S RNA showed conserved sequence of the gene confirming that the gene is present in all *P. aeruginosa* isolates. The Figure 1 shows agarose gel electrophoresis of *P. aeruginosa* genomic DNA. This shows the purity and integrity of genomic DNA as the key factor of PCR process success is the purity of DNA used\(^{27}\). The Figure 2 shows agarose gel electrophoresis of PCR amplicons showing the exact size of gene of interest using the specific primers (16S RNA-F and 16S RNA-R). The amplicons were then purified from the gel and sent for sequencing. The results of sequence were then blasted and aligned with universal gene bank (NCBI). The molecular identification of microorganisms has been extensively used to confirm the bacterial identification. The gene polymorphism analysis is based on conserved sequences present in some housekeeping genes such as 16S RNA\(^3\). Although it is widely known that *P. aeruginosa* belongs to genetically diverse group of bacteria, 16S RNA gene is highly conserved in most of species with minor modifications\(^{30}\).

![Figure 1: Aggarose gel electrophoresis of *P. aeruginosa* genomic DNA.](image1)

![Figure 2: Aggarose gel electrophoresis of 16S RNA amplicons with expected size of 650bp DNA. 16S RNA-F and 16S RNA-R primers used to amplify the gene of interest. Lane 1: 100bp DNA ladder, lanes 2-9: DNA amplicons of gene of interest.](image2)
Table 1 shows the samples taken and the site of infection as well as the proportion of infections. As can be seen from the Table 1, the highest percentage of infection was 13.28% from surgery infections, whereas the lowest percentage was 0.699% from patients with burns. Surprisingly, *P. aeruginosa* isolated from the respiratory tract infections was relatively low (2.09%) compared to other site of infections. Although many studies have founded that *P. aeruginosa* is a main cause of burn infections with multidrug resistance \(^{16,21}\), we found that the burn infections was the lowest. This might be because of the extent of the hospital’s concerns with the cleanliness of the hallways and medical equipment as well as the type of detergents and disinfectants that used in hospitals \(^{15}\). It has also been reported that *P. aeruginosa* favors the moist and aerobic conditions to cause infections \(^{23}\). This explains the reason of the variation of *P. aeruginosa* infections might be affected by the site of infection and environment conditions.

**Synergistic effect of pyocyanin and antibiotics:**

In order to examine the activity of pyocyanin with antibiotics, the optimal concentration of antibiotics that did not show activity against *Staph. aureus* and *E. coli*. Antibiotic resistance test showed diverse activity of antibiotics used in this study. The Table 2 shows antibiotic activity on *Staph. aureus* and *E. coli*. As can be seen from the Table 2, the *Staph. aureus* showed resistance against most antibiotics used. Therefore, we have chosen cloxacillin and novobiocin that showed either intermediate or resistance. Regarding *E. coli*, the results also showed that the microbe was resistant to most antibiotics (Table 2). The antibiotics have chosen for synergistic activity for *E. coli* were ciprofloxacinc and nalidixic acid.

Pyocyanin was extracted and purified from the culture to examine its activity against the pathogens used in this study. Different concentrations of pyocyanin used against Staph. aureus and E. coli to choose the concentrations that have either intermediate or no activity. The reason for choosing these concentrations to find out whether pyocyanin could enhance antibiotics activity. The results showed that P. aeruginosa produced pyocyanin in different concentrations (Table 3). The production of pyocyanin is influenced by many factors including environmental and genetic factors. It has also been reported that the site of infection might affect the amount of pyocyanin produced by P. aeruginosa. The production of the pigment might also be affected by other pathogens at the same site of infection. It is proved that P. aeruginosa produces high concentrations of pyocyanin to compete other pathogens as the pigment has antibacterial properties. Although all strains of P. aeruginosa have genes that encode to pyocyanin, the expression level of these genes might be influenced by environmental conditions and whether the pathogen requires the pigment during the infection.

Synergistic activity showed that *E. coli* became more sensitive to antibiotics when mixed with pyocyanin. *Staph aureus* showed intermediate resistance when antibiotics mixed with pyocyanin. The Figures 3 and 4 shows synergistic activity of pyocyanin with antibiotics against *E. coli* and *Staph. aureus*. As can be seen from the Figure 3, although *E. coli* was intermediate resistant to ciprofloxacin and resistant to nalidixic acid, it became sensitive to the antibiotics when mixed with 100 mg/ml pyocyanin (Table 4). However, ciprofloxacin did not show any activity against *E. coli* when mixed with 10 mg/ml pyocyanin (Figure 3, Table 4). This might be because pyocyanin activity is concentration dependent manner when mixed with antibiotics. Regarding *Staph. aureus*, the results showed that the pathogen became sensitive to novobiocin when mixed with 1 mg/ml pyocyanin (Figure 4, Table 4). It is possible that pyocyanin enhanced the activity of novobiocin in terms of DNA gyrase inhibition. Other explanation might be that pyocyanin might interact with bacterial DNA causing mutations that in favor to novobiocin activity 12, 29. However, Cloxacillin did not show any activity when mixed with 1 mg/ml and 6.25 mg/ml pyocyanin, respectively (Figure 4). The limit activity of antibiotics with *P. aeruginosa* pigment reflects the fact that Gram positive bacteria might exhibit resistance strategies against antibiotics, and thus, pyocyanin could not enhance the activity 9.

It is reported that the ability of inhibition of pyocyanin is increased over the years as a result of the ability of bacteria to adapt to the environment and produce more efficient virulence factors. This might be due to the development of their genes that encode to pyocyanin more efficiently 25. The synergistic activity of pyocyanin with antibiotics might be affected by the cell wall composition. It is clear that peptidoglycan and lipopolysaccharides layer could prevent the penetration of antibiotics as well as pyocyanin 7,30,31. This explains why *Staph. aureus* is less affected by pyocyanin and antibiotics as the thickness peptidoglycan layer reduces the penetration. On the other hand, *E.coli* showed less sensitivity against pyocyanin and antibiotics. The peptidoglycan layer in Gram negative pathogens is not thick compared to Gram positive bacteria 8,20. Cloxacillin belongs to penicillin antibiotic family that can be broken down by staphylococcal beta-lactamase enzymes 11. These enzymes might affect the synergistic activity of cloxacillin with pyocyanin, and thus, did not show any activity.

It is widely known that pyocyanin stimulates the formation of free radicals (-O₂ and H₂O₂). This leads to increase the oxidative stress in bacterial cells and makes them more affected by antibiotics 26. It is also reported that generation of active oxygen compounds (ROS) due to the exposure to pyocyanin stops all NADPH pathways by excluding electron 12. The gene expression is also affected by ROS and this might be beneficial for antibiotics to stop protein synthesis of bacterial cells 4. Therefore, pyocyanin activity against pathogens could be beneficial to test whether can be used in antibiotics structure to boost their activity.

Table (4): Synergistic effects of pyocyanin with antibiotics. The concentration of pyocyanin were chosen as they have shown no effect on *Staph. aureus* and *E. coli*. Antibiotics used in this test were chosen because they did not show activity against pathogens.

Efficacy of Plyometric Training on the Agility in Police Cadets

Dushyant Bawiskar¹, Pratik Phansopkar²

¹Final year B.P.T, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Sawangi(M), Wardha, Maharashtra, India ²Assistant Professor, Department of Musculoskeletal Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Sawangi(M), Wardha, Maharashtra, India

Abstract

Background: Plyometric training is a hybrid between strength and endurance training. This allows muscles to exert maximum force in short intervals of time, with the goal of increasing power (speed-strength) which ensures better agility in police cadets. Agility has been defined by the capacity to retain or determine the location of body by shifting its direction rapidly in a sequence of movements. Agility, speed and explosive power are qualifying components of physical fitness and desirable athletic performance, and play a key role in most sports. Agility can enhance the coordination and regulation of locations of the body throughout movement.

Objective: To study the efficacy of the 6-weeks and 12-weeks Plyometric training on the agility in police cadets.

Method: 40 Cadets aged above 18 years were grouped into two. A group continued their regular activities while rest underwent 2 sessions of plyometric training every week for 6 weeks, along with their daily activities. Analysis was then carried out with assessment of T-test Agility test, Illinois Agility Test, Edgren Side Step Test. Study duration is 6 months and intervention duration is 12-weeks, hence participants will be enrolled during first 3-months of study so 12 week intervention will be completed successfully. Assessment will be done on 1st day of visit then at the end of 6th week and again at the end of 12th week. Participants would have to perform 2 session of Plyometric Training per week in other group.

Result: Data will be analyzed using paired T-test.

Conclusion: Will be published after the results are analyzed.

Key words: Plyometric training, Agility, Agility Test.

Introduction

For the physical preparation of the job, tactical sportsmen, such as military, firefighters, or police officers require speed, strength, agility and stamina training.

While research has shown that the role of a police officer is shockingly often sedentary, it is recognized that physical fitness is an important component of being able to perform unusual and often vital tasks, such as chasing running people, managing arrest and handcuffs and even managing crowds. A police officer’s capacity to perform these various physical tasks will decide his professional performance. The tactical athlete literature tends to be a void with a strong emphasis on the physical qualifications of the Police Cadet and the outcomes of training within the academy.¹ Police officers are expected to perform a range of physical activities, including housekeeping and checking the identity of a suspect to chasing suspects on foot over different distances.
Plyometrics are conditioning methods that athletes use to boost strength and quickness in all kinds of sports. Plyometrics is composed of a rapid muscle lengthening followed right away by shortening movement of the muscle and tissue which are connective. Greater strength is generated than the concentrated action itself by the collected elastic energy inside the muscle.

Researchers have explained about plyometric exercises which can lead to changes in efficiency in jumping vertically, agility, strength of leg and that of muscles, improved perception of articulation of bones and muscular sense in whole with the use of a periodic strength training plan. Plyometric drills usually involve the explosive stop, start, and change of direction. All such movements are elements that can help the agility to develop.

Plyometric exercises — jump, striding, and hop movements which use the stretch muscle unit to alter the process. — It has repeatedly been shown to boost muscular strength and power generation. It is used to improve maximum strength, movement speed and explosive power increase. Dynamic in nature, these exercises comply with the basic training concepts of precision, practice with movements of a similar nature and pace to the skills or activities for which one is trained.

In fact, the rapid force efficiency of the training muscle is increasing, combined with smaller rises in isometric force level. Such physiological improvements have allowed higher vertical jump heights and reduced sprint and acceleration times. Agility has been defined by the capacity to retain or determine the location of body by shifting its direction rapidly in a sequence of movements. Agility helped in motor learning via neuromuscular stimulation and adaptation of neural spindle, golgi organs of tendon, and proprioceptors present in joint. Theoretically, agility can enhance the coordination and regulation of locations of the body throughout movement.

Agility, speed and explosiveness are the characteristics of physical fitness and play a important role in most sports. Agility components includes speed, balance, strength and coordination; necessary for technical, competitive sports and “tactical” players in order to change position quickly for sport or work on all planes. Upgraded agility benefits involve improved body flexibility throughout rapid movement, improved intramuscular mobility and reduced risk of injury or re-injury. Agility skills will require a strong mix of dynamics. The balance system will have to be calibrated and modified because the fast code would move the centre of gravity out of the base of support again and again and challenge balance or metastability.

Michael G. Miller et.al determined that plyometric training course of 6 weeks influences the agility and inferred that it has encouraging effect and benefits in increasing the agility in athletes.

Kevin Thomas and team determined results of 2-plyometric conditioning technique over strength of muscle in young soccer players and results determine both Counter Movement Jump and Depth Jump. Plyometric Training are useful in training exercises to develop strength and agility among young soccer players.

Issam Makhlouf et.al explained that strength and plyometric training together has equal fitness advantage with the combination of endurance and plyometric training of soccer players of younger age group and the result are significant improvements in agility in both training group of soccer players.

Although it has been shown that plyometric training enhances performance variables, i.e. agility training targets for visual orientation, retain a good position yet little empirical evidence is present to establish whether the plyometric training actually increases agility.

Objectives
1. To determine the effect of 6-week plyometric training program on agility of the cadet.
2. To determine the effect of 12-week plyometric training program on agility of the cadet.

Methods
This study will be carried out at training camps which are in the vicinity of Wardha District, Wardha, Maharashtra, India only after approval by the Datta Meghe Institute of Medical Sciences Institutional Ethics Committee, Deemed University.
Study design: Experimental Study

Study duration: 6 months.

Inclusion Criteria: -
1. Participants over 18 years of age.
2. Free from lower extremity injuries.
3. At the time of the analysis, they did not engage in any form of plyometric training.

Exclusion Criteria: -
1. History of injuries to the lower limb in recent times.
2. Fractures in the lower limb in near past.
4. Non-cooperative participants.

VARIABLES

Outcome measures:
1. T-test Agility test
2. Illinois Agility Test
3. Edgren Side Step Test

DATA SOURCE MEASUREMENT

1. T-test Agility test - Agility is measured with r=0.98, p<0.05.\(^7\) that designates the reliability and validity of the T-test.

2. Illinois Agility Test – It is a reliable and valid velocity change tool with r=0.77, p<0.001.\(^8\)

3. Edgren Side Step Test- Another valid as well as reliable tool for changing in duration and speed with r=-0.640, p = 0.046.\(^9\)

STUDY SIZE –

Group A: 20 participants will continue their regular activities.

Group B: 20 participants must undergo 2 sessions of plyometric training every week for 6 weeks, along with their daily activities.

Procedure

The institutional ethics committee clearance will be obtained before the start of the study. The permission will be obtained from the head of institute for cadets and after meeting the criteria for inclusion and exclusion, the informed consent must be received from the participants. Participants are classified into two categories, i.e. Plyometric Training Group and Control Group. Several tests were developed in order to measure agility, but few were defined for young adult males as effective or legitimate measures and no connection between the tests was established.\(^5\) Demonstration of agility tests would be given to both groups. And plyometric training would be demonstration only to experimental group.

During the time period of training, all participants will be told not to alter their current physical activities. The participants in plyometric training group will receive plyometric training for 6 week which consists of range of plyometric exercise designed for the lower extremity, whereas no plyometric exercises will be performed by the control group. The plyometric exercise is Squat jump, tuck jump, lateral jump, lunge jump etc. During the 12\(^{th}\) -week’s duration, all subjects will continue normal daily living activities. The Plyometric training program consists of 2 training programs in a week. The training depends on intensity as well as volume, using similar exercises, sets, and replays.\(^2\)

Pre and Post 6\(^{th}\) week and 12\(^{th}\) week-training assessments will be used to analysis the agility results. The T-test gives the measure of the speed of variation in direction. The Illinois agility test assesses the preparedness to increase, decrease, rotate in various directions and move in various angles.

T-Test Procedure

Describe the participant regarding test procedures. Conduct health risk screening and gain informed consent. Prepare forms and record basic details such as age, height, weight, gender, test conditions. Measure and classify the test area. Carry out a good warm-up. Five meters apart three cones are placed in a straight line. 10 meters from the middle cone another cone is positioned and a ‘T’ shape is formed. Start point of cadets is the base of the ‘T’. Go signal is given by the examiner and the period starts as the cadets crosses the mark point.
Cadet heads to the centre cone and hits it. Cadet runs 5 metres towards cone at the right and hits it. Cadet’s hand moves 10 meters to the far cone and touches that one. Cadet’s hand moves back to the middle cone for 5 meters and hits it. Cadet moves 10m backwards and touches the cone at the ‘T’ base. When the participant reaches the mark point, the time is stopped and duration is measured.

Illinois Agility Test procedures

Describe the participant regarding test procedures. Conduct health risk screening and gain informed consent. Prepare forms and record basic details such as age, height, weight, gender, test conditions. Measure and classify the test area. Carry out a good warm-up. The test has agility region (10 metres length and 5 meters breadth) that is formed by four cones. Point A cone marks the start point. The turning point is marked by Cone B&C. The end point is shown by Cone D. At the centre of the test area, four cones are positioned 3.3 meters apart. Starts with the person lying down and facing the ground and hands on his side. “Go” button signals the cadet to begin and as the start marker point is crossed, the time starts. The cadet is asked to get up and run in the course of the direction chosen (left to right / right to left) by him. At the turn points B and C, cones are supposed to be touched by hands. As the cadet reaches the finish line and no cones are knocked over and duration is assessed which completes the trial.

Edgren Side Step Test

Describe the participant regarding test procedures. Conduct health risk screening and gain informed consent. Prepare forms and record basic details such as age, height, weight, gender, test conditions. Measure and classify the test area. Carry out a good warm-up. The course is 4 m long and has four intervals of 1 m. The beginning position is at the centre of the circle, facing forward, with the legs straddling the centre line. With the ‘go’ signal, the person moves in right direction before the right foot crosses the outer cone. The participant then moves in the left direction before his left foot hits the left outer cone. The person runs in backward and forward direction to the outer cones as quickly in duration of 10 seconds. A score of 0 is given to the cadet, if he had not kept the trunk and legs pointing forward in the test period, legs crossed, or failed to successfully complete the course.

After recording the results of the agility test at the beginning of the plyometric group training, the plyometric training process will be clarified and again the agility test results will be reported after the 6th week of training and the 12th week of training for both classes.

Expected Results

After completion of the study result will be calculated by statistical analysis using paired T-test and will be presented in the form of research paper.

Discussion

To our knowledge, this will be the first study to evaluate the effects of plyometric training on the aspect of agility in the Indian population of police cadets. This is important as good reporting of how agility training is going to impact the agility specific outcomes. Also the process of involving agility training into the regular strength training programs of these cadets would change the focus of just strength training in their routines. More over this study will employ well established and widely used methods with appropriate reliability and validity to assess the agility parameters. Post the sessions at the end of 6th week assessments will provide a immediate effect of the agility training and another timeline of assessments after total 12 weeks will provide the differences to have better understanding about the improvements sustained. The potential lack of keeping a track on the cadet’s activities between sixth to twelfth weeks may represent a limitation of the study. Although we assume that the cadets would have a better understanding towards agility-based training in regular routines.

Abstract

Background: Candida sp. is the most common opportunistic pathogen found during the development of Human immunodeficiency virus (HIV) & Acquired immune deficiency syndrome (AIDS) disease. The clinical severity of oral candidiasis and the prevalence profile of Candida species reflect immunological changes in HIV / AIDS patients. Objective: Evaluating the relationship between CD4 T lymphocyte cells counts and the number of Candida species. Methods: A cross-sectional analytical study was carried out at Dr. Soetomo, Surabaya, Indonesia. For identification of Candida species, culture was carried out on Chromagar media followed by culture with vitek 2. Results: There were 114 study subjects who were divided into three groups based on the number of CD4 T lymphocyte cells, with 158 isolates of Candida species growing in culture. The highest number of Candida species was Candida albicans with a total of 107 isolates (67.7%). Candida non-albicans were 51 isolates (32.3%). Statistical test results showed a significant correlation between the number of CD4 T lymphocyte cells and the number of Candida species (p <0.001). Conclusion: The decrease in CD4 lymphocyte cell counts is influenced by various types of Candida sp. in oral candidiasis patients.

Keywords: Candida sp, CD4 T lymphocytes, HIV / AIDS, oral candidiasis

Introduction

In the human oral cavity, there are various kinds of microorganisms which composition, metabolism activities and pathogenicity are influenced by external and internal factors. Among all fungi, Candida is a genus of yeast that is considered to be the most fungal species found in the oral cavity. Candida species are the main cause of mucocutaneous infections which are usually classified as oral, oesophageal and vulvovaginal candidiasis (1, 2).

Oral candidiasis (OC) is the most common mucocutaneous candidiasis found in patients with infection of Human Immunodeficiency Virus (HIV) / Acquired Immune Deficiency Syndrome (AIDS) worldwide. OC is an infection of the mucosa caused by Candida species. Nearly 90% of patients with HIV / AIDS have experienced OC in the course of their illness. High viral load and low CD4 T lymphocyte counts are found in OC patients (1, 2). Although oral candidiasis is caused by various genera of Candida, Candida albicans is the most common cause as stated by previous studies, but several studies found an increase in the cause of oral candidiasis due to Candida non-albicans (3, 4). This study aimed to analyse the relationship between CD4 cell counts and Candida species in oral candidiasis patients with HIV / AIDS.
Methods

Participants

Participants in this study were HIV / AIDS patients at Dr. Soetomo General Hospital Surabaya, Indonesia. Participant inclusion criteria included patients diagnosed with HIV / AIDS using a rapid test / HIV 3 \(^5, 6\), having a positive candidiasis diagnosis using 10-20% KOH \(^7, 8\), and aged >18 years. Participant exclusion criteria included subjects taking anti-fungal drugs within 2 weeks before the study took place and no growth of colonies was found on culture examination. Participants in this study first filled out the consent form, in which the patient had received an explanation regarding the benefits and objectives of the study.

Design

This research was conducted at Dr. Soetomo General Academic Hospital, Surabaya, Indonesia, from May to September 2019. It was a cross-sectional study with consecutive admission sampling method. There were 114 participants, which were divided into 3 groups (38 participants in each group; Figure 1). This study was ethically approved by the ethics committee of Dr. Soetomo General Hospital (1125 / KEPK / IV / 2019). The research procedure consisted of identifying the type and amount of \textit{Candida} fungus in the participant’s oral cavity and calculating the participant’s CD4 count.

Measurement of \textit{Candida} Species

Participants were first told not to do oral hygiene before checking the type and amount of colonisation of \textit{Candida} sp. Participants gargled using 25 ml of sterile water. The water was then put into sterile bottles that had been prepared. Water from the mouth rinse was immediately sent to Dr. Soetomo General Academic Hospital, Surabaya, Indonesia. The water was shaken gently, and took ± 5 - 10 ml and put in 15 ml sterile centrifuge tubes and rotate 2,500 revolutions per minute (rpm) for 5 minutes. Discard the supernatant and take the pellet using a sterile pipette, place it in an object glass and drop 10-20% KOH. \textit{Candida} positive was planted on Sabouraud dextrose agar (SDA) at 37ºC for 48 hours \(^9\). The SDA media used was CHROMagar Candida (CHROMagar Candida, France). Growing \textit{Candida} specimens were identified using cornmeal agar and tween 80 incubated at 42-45ºC \(^{10, 11}\).

CD4 Measurement

The researchers took venous blood samples and put into K3EDTA-countaining tubes, stored at room temperature, immunophenotyping for 6 hours. CD4 count calculations used flow cytometry (BD FACSCounttm System; San Jose, CA). Participants were divided into three groups: group I (participant with a CD4 level of \(\leq 100 / \mu \text{L}\)), group II (participant with a CD4 level of 101 - 200 / \(\mu \text{L}\)), and group III (participant with a CD4 level of > 200 / \(\mu \text{L}\)).

Lesion Area

The area of participant’s candidiasis oral lesions was assessed using a score of 0 = no lesions, 1 = partial lesions, and 2 = all / all lesions. The locations assessed included the tongue, mucous membrane, and palate with a minimum score of 1 and a maximum score of 6. Calculation of the area of the lesion by adding up the three locations of the assessed lesion.

Statistical Analysis

The results of the study were presented in the form of mean ± standard deviation (SD) or median (minimum - maximum) and percentage (%). Statistic analysis used IBM SPSS Statistics software version 23.0 (IBM Corp., Armonk, NY, USA). Analysis of the measurement data used the Chi Square test, Fisher exact test, the Spearman correlation test, or the Anova test with a significance level of \(p <0.05\).

Results

The study showed that 114 oral candidiasis patients with HIV / AIDS met the inclusion criteria as research subjects. The age characteristics of the study subjects had a standard deviation of 36.41 ± 9.825 years, with an age range of 18 years to 59 years (Table 1). Most research subjects worked as private employees (58.8%). As many as 48.2% of research subjects had a high school equivalent education level (Table 2).
The clinical condition of oral candidiasis in this study showed the main complaint in form of white patches in the oral cavity that was found in 100 subjects (87.7%). Most locations were found on the tongue in 54 people (47.4%). Most participants were not accompanied by swallowing pain (64 participants; 56.1%). The most common clinical condition of OC was pseudomembranous type found in 103 patients (90.4%), followed by acute cheilitis (10 participants; 8.8%) and acute atrophic (1 participant; 0.9%) (Table 2).

The identification of species from 114 patients found 158 isolates of *Candida* sp., consisting of *Candida albicans* (107 isolates; 67.7%) and 51 non-albicans isolates (32.3%). The highest number of *Candida non-albicans* species were *Candida krusei* (26; 16.5%), *Candida glabrata* (13; 0.8%) and *Candida tropicalis* (7; 0.4%). This study also found rare *Candida* isolates, namely *Candida parapsilosis, Candida dubliniensis,* and *Candida lypolitica* (Figure 2). Spearman test obtained a significant relationship between the number of CD4 T lymphocyte cells with the number of species (p < 0.001), and a significant relationship between the number of species with lesion area (p = 0.004). However, the relationship was not significant between the number of species with duration of sickness (p = 0.081). Fisher Exact test showed no significant relationship between the number of CD4 T lymphocyte cells with clinical condition (p = 0.016), and a non-significant relationship between the number of species and clinical condition (p = 0.284; Table 3).

Discussions

Based on gender, the distribution of subject was dominated by male patients (83; 72.8%) compared to female (31; 27.2%). This finding is consistent with data from the Indonesian Report of HIV Development Situation published by the Ministry of Health of the Republic of Indonesia in 2017, in which the pattern of HIV patients was more prevalent in male than female group (5). In general, there is no difference in terms of disease occurrence based on gender because unlike vulvovaginal candidiasis, oral candidiasis is not influenced by hormonal factors. Characteristic of subject’s age in this study had a standard deviation of 36.41 ± 9.82 years, with an age range of 17 years to 59 years. This age range is considered as productive age and sexually active, so that many may perform unprotected sexual behavior that is at risk of HIV transmission (4). In terms of distribution of educational levels, there were still research subjects who did not complete elementary school (1; 0.9%), and 20 subjects (17.5%) had elementary school education. In this study, there were still HIV/AIDS patients with low educational background, so that they had lack of oral health knowledge and a very poor ability to maintain oral hygiene. Poor oral cleaning is one of the factors that could increase the incidence of oral diseases, including oral candidiasis (5, 13). The distribution of occupational backgrounds showed that 41 (36%) patients did not work. Patients with HIV/AIDS in the course of their illness will experience opportunistic infectious diseases that will affect the quality of life, one of which is occupation (2, 4, 13).

The description of the main complaints from OC patients with HIV/AIDS in this study had more than one type. The most common complaint was white patches found in the oral cavity (100 subjects; 87.7%), followed by white and red patches in the oral cavity (4 subjects; 3.5%). Complaints of red patches, patches or sores on the corners of the lips were found in 7 subjects (6.1%), while white patches on the oral cavity, patches and sores on the corners of the lips were found in 3 subjects (2.6%). Complaints of white patches in the oral cavity were found in the pseudomembranous OC (38.3%) and plaque hyperplasia (9.6%). The subjects were mostly not accompanied by complaints of swallowing pain (64; 56.1%). Patients with complaints of swallowing are clinical signs of lesions attacking the pharynx and esophagus (14, 15).

Infection of Candida sp. is always associated with OC in HIV/AIDS. Candida sp. is a commensal microorganism that develops into pathogens due to a decrease in the secretion of immunoglobulin A (sIgA) and a decrease in the number of T lymphocyte cells (8). The pathogenesis of OC in HIV is closely related to proteins produced at the beginning of HIV virus replication cycle. Trans-Activating Transduction or Transcriptional Activator (TAT) is one of the proteins that regulates HIV virus replication. This protein can resemble the workings of extracellular matrix proteins (Integrin-like) in the regulation of cell life activities through activation of signal transduction pathways. The cell wall of C. albicans is thought to have receptors that resemble extracellular matrix (Integrin-like) which can bind to TAT. Interaction between HIV TAT protein with C. albicans cell wall allows the occurrence of specific gene transduction in candidiasis in HIV/AIDS with CD4 T cell lymphocyte counts <200 cells / mm (16, 17).

In this study, identification of Candida species conducted on 114 subjects found 158 isolates of Candida species with different species variants. Candida albicans was found in 107 isolates (67.7%), whereas Candida non-albicans was found in 51 isolates (32.3%). The highest number of Candida non-albicans species were Candida krusei (26; 16.5%), Candida glabrata (13; 0.8%) and Candida tropicalis (7; 0.4%). This study also found rare Candida isolates, namely Candida parapsilosis, Candida dubliniensis, and Candida lypolitica. This proves that in OC with HIV/AIDS, there has been a change in the spectrum of the causative species (12). In addition, the high detection rate of Candida non-albicans in this study is due previously incorrect identification of species due to the similarity of the phenotype to C. albicans and is now increasingly recognized. The proportion of Candida infections caused by C. albicans in HIV/AIDS patients has shifted to Candida non-albicans species, corresponding to previous studies comparing Candida species causing OC in HIV-seropositive patients and HIV-seronegative patients. The study showed that colonies of Candida albicans species in HIV-seropositive was less than in HIV-seronegative. In HIV-seropositive patients, Candida species are also rarely found in immunocompetent patients, namely Candida dubliniensis, Candida glabrata, Candida
A meta-analysis and study conducted in Sub-Saharan Africa in 2005-2015 showed a prevalence of *Candida non-albicans* species as much as 33.5% in general, with dominant species namely *Candida glabrata*, *Candida krusei*, and *Candida tropicalis* (19). The results of this study also showed a mixed infection between *Candida albicans* and *Candida non-albicans*. Out of 114 subjects in this study, there were 31 subjects (27.2%) with more than one *Candida* species isolate, and 83 subjects (72.8%) with one type of *Candida* species isolate. A meta-analysis study conducted in Sub-Saharan Africa for 10 years also showed the incidence of mixed infections of *Candida albicans* and *Candida non-albicans* by 85.2% (19, 20).

Oral candidiasis in HIV / AIDS patients is often of longer duration, repeated, and has more severe clinical symptoms. In HIV / AIDS patients, viral replication has the potential to trigger OC, which directly increases the progressive rate of HIV / AIDS infection. The Long Repeat Terminal (TLR) at the end of the provirus has two sites that function as transcription factors that bind the host, NFkB and SP1. Infected T cells are activated and release cytokines such as Interleukine-2 (IL-2) and Tumor Necrosis Factor (TNF). IL-2 and TNF will induce HIV provirus to end the latent period and start replicating. T cells will facilitate the replication of the HIV / AIDS virus, so that CD4 T lymphocyte cell levels will continue to decrease (21, 22). This is supported by research on a strong correlation between the occurrence of OC in the number of CD4 T lymphocytes <200 cells / mm3 on arising clinical manifestations, including the number of species and lesion area (23, 24). Consistent results illustrated in this study were a significant correlation between the number of CD4 T lymphocyte cells with the number of species and lesion area (6-8).

**Conclusions**

Participants with low levels of CD4 T lymphocytes allow the number of *Candida* species growing in the oral cavity to be more diverse with lesions found in the oral cavity. The reverse condition is also possible if the CD4 T lymphocyte levels are high then the possibility of the number of *Candida sp.* growing in the oral cavity and lesion area are getting smaller.

Abstract

Background: Oral Candidiasis (OC) still mainly opportunistic infection problem in HIV/AIDS Patients. Due to increasing report of fluconazole resistant as common antifungal drugs nowadays, there have been many studies focusing on natural substances and its antifungal properties. In this study, a form of green tea extract, named Epigallocatechingallate (EGCG) 1,25% were examined for their in vitro antifungal activity against Candida sp in comparison to fluconazole (2 mg/ml) as standard antifungal agents. Objective: To evaluate the antifungal activity of EGCG in compare with fluconazole against Candida isolates taken from HIV / AIDS patients with OC. Methods: Fourty Candida sp. isolates taken from HIV / AIDS patients with OC in the Outpatient Unit and Inpatient Installation of the Infectious Disease Intermediate Care Unit (UPIPI) Dr. Soetomo, Surabaya. Antifungal activity were evaluated by using microdilution tests. Results: The microdilution test revealed the MIC of EGCG for all Candida sp. was 0.625%, while the MIC of fluconazole was 100% for all Candida sp. There was significant difference (p <0.05) between the MIC values for Candida sp. by fluconazole and EGCG. The MFC values of EGCG was 50%, while value of fluconazole MFC was 100%. Conclusion: Antifungal activity of EGCG with fungistatic and fungicidal effect is better than fluconazole.

Keywords: Antifungal activity, Candida albicans, Candida non-albicans, EGCG, Fluconazole, HIV/AIDS, Oral candidiasis

Introduction

Oral candidiasis (OC) develops in 80%–95% of the patients with Human Immunodeficiency Virus (HIV)/Acquired Immunodeficiency Syndrome (AIDS). It is described as an opportunistic infection, often involved in the alteration of oral microflora, systemic diseases and reduced immunity of the host. Opportunistic infectious diseases in HIV/AIDS patients can decrease the quality of life in these patients (1, 2).

Candida albicans is the most prevalent and pathogenic species, but other Candida species, such as C. tropicalis, C. krusei, C. glabrata, C. dubliniensis, C. guilliermondii, C. parapsilosis, C. kefyr, and C. pelliculosa, has become a significant cause of infection in patients with HIV/AIDS (3, 4). Majority of the clinically used antifungals suffer from various drawbacks in terms of toxicity, drug-drug interactions, and lack of fungicidal efficacy, and emergence of resistant strains resulting from frequent usage. For example, fluconazole limited because of the high rate of primary and secondary resistance (5). To identify substances that might be alternatives to traditional medicines, studies were conducted on the antimicrobial activity essential oils for the control of OC (6).
Research on alternative therapies using natural ingredients is currently on the rise. The use of natural extracts to treat Candida is becoming popular, one of which is green tea (Camellia sinensis) extract, which is found to have beneficial effects on health, due to its high antioxidant and immunomodulatory effects. Research conducted by Rahayu and colleagues in 2018 on the immunomodulatory effect of green tea extract in immunocompromised mice with Candida using polyphenols and EGCG. After evaluation, it was found that EGCG 1.25% had an immunomodulating effect against C. albicans infection in immunocompromised mice by increasing the expression of IL-8, IL-17A and HBD-2. It was also found that the minimum inhibitor concentration of green tea extract on the growth of Candida albicans was 12.5% and the minimum bactericidal concentration was 25%. Therefore, administering EGCG can provide an immunomodulating effect against oral candidiasis in immunocompromised patients. Therefore, this study wanted to test the sensitivity of green tea extract and nystatin in oral candidiasis patients with HIV. The use of Epigallocatechingallate (EGCG) is expected to have a better sensitivity than fluconazole.

**Methods**

**Strains and Growth Conditions**

This research used 40 isolates divided in two groups 20 isolates of Candida albicans and 20 isolates Candida non-albicans, were obtained from forty patients Candidiasis oral with HIV/AIDS infection. Candida non-albicans species included in this study consisted of 7 species of Candida krusei, 6 species of Candida glabrata, 2 species of Candida dubliniensis, 2 species of Candida parapsilosis, 1 species of Candida tropicalis, 1 species of Candida norvegensis and 1 species of Candida lypoitica. All of the strains were grown on Sabouraud dextrose Agar under aerobic conditions at 37°C for 24 h before the antifungal assays. The yeast (107 cells/mL) suspensions used in the assays were prepared in sterile phosphate-buffered saline (PBS) at pH 7.2.

**Antifungal Tests**

The minimum inhibitory concentrations (MIC) were obtained using the serial microdilution method in culture of 96-well cell plates based on the Clinical and Laboratory Standards Institute (CLSI). Prepare a 96 well microtiter plate that has been filled with Mueller Hinton Broth (MHB) and fluconazole with 10 levels of concentration using a multilevel dilution technique, which is 100%; 50%; 2.5%; 1.25%; 0.0625%; 0.312%; 0.156%; 0.078%; 0.0039%; and 0.0195%. Then enter the EGCG with the highest concentration of 100% in the first row and then do the multilevel dilution along the Y axis to the lowest concentration of 0.19%. Candida species were inoculated into the plate by leaving row one as a negative control. MIC observations are determined by observing at what concentration in the well begins to clear and there is no sediment that indicates the growth of Candida is inhibited. Minimal Fungicidal Concentration (MFC) is tested by taking 10 µL from the well with a predetermined MIC each well is inoculated on a Petri dish containing Sabouraud dextrose agar and incubated at 37 °C for five days. MFC is defined as the lowest concentration without growth that is seen to be used as the end point for the fungicidal effect.

**Statistical Analysis**

The statistical differences were evaluated using SPSS 17 version. The data for microdilution methods were analyzed by chi square on normal data distribution and MannWhitney on abnormal data distribution in statistic. Statistical significance was determined at \( p < 0.05 \).

**Results**

Fourty isolates taken from HIV / AIDS patients with OC. The male patients were 31 patients (77.5%) and female patients were 9 patients (22.5%). The age of patients from isolates in this study varied between the age group 17-25 years to 56-65 years. The most age range is 20 subjects (50%) in the 26-36 years old group. The isolates most were taken from HIV / AIDS patients with OC who had an absolute CD4 count <100 cells/L for 28 patients (70%).

Table 1 shows the results of microdilution, there is a statistically significant difference with the chi square test method at a concentration of 50% between fluconazole and EGCG \( p <0.05 \). At a concentration of 25% there was no significant difference \( p> 0.05 \) and the rest could not be analyzed because all the results were still visible turbidity. MIC was produced by EGCG statistically through chi square test for Candida albicans species.
at a concentration of 50%, while MIC fluconazole at a concentration of 100%.

Table 2 shows with the results of microdilution, there is a statistically significant difference with the chi square test method at a concentration of 50% between fluconazole and EGCG (p < 0.05). From the concentration of 25% until 0.38% concentration there were no significant differences between fluconazole and EGCG (p > 0.05). The MIC produced by EGCG was statistically through the chi square test for Candida non-albicans species at concentrations of 50% while MIC fluconazole at 100% concentration.

Shapiro Wilk test confirmed that the data were not normally distributed (p < 0.05); therefore, nonparametric statistical tests, the Mann Whitney test, was performed. Based on data from Table 3 shows the results of microdilution method research, the MFC values EGCG statistically through the Mann Whitney test is 50%, with this concentration can kill the Candida albicans and Candida non-albicans. The value of fluconazole MFC was 100%. Mann Whitney test results showed there were significant differences between MFC fluconazole with EGCG on the growth of Candida albicans and Candida non-albicans (p < 0.05).

**Discussions**

Basic data of this study showing isolates mostly taken from male than female (77.5% and 22.5%). The most age group is productive age groups in the age range of 26-35 years with 20 subjects (50%). In 2017 report of the Directorate General of Disease Control and Environmental Health, Ministry of Health Republic of Indonesia, found HIV/AIDS patients more male than women, and related more common in young adult which makes it more likely to engage in unsafe sexual behavior that is at risk of HIV transmission (8). The domicile of HIV / AIDS patients with OC mostly came from Surabaya (90%). This is because most patients have to seek help from the nearest health center with most patients from within the city. The isolates most were taken from HIV / AIDS patients with OC who had an absolute CD4 count <100 cells / L for 28 patients (70%). This data is supported by a 2015 Indian study by Kumar that showed 71.4% of patients with a CD4 cell count <200 cells / µL obtained by the fungus growth of Candida species from OC lesions (9).

The evaluation of the antifungal activity of EGCG against all strains of Candida isolates, showed MIC values ranging from 50%-100% and MIC values fluconazole were varying. MFC produced by EGCG for Candida sp. through the Mann Whitney test is 50%, in which concentration is able to kill the Candida albicans and Candida non-albicans. The value of fluconazole MFC was 100%, which was higher than EGCG. Previous study also found that EGCG perform better antifungal activity based on its MIC and MFC in compare to azole drugs (ketoconazole and fluconazole). EGCG showed a significant inhibitory effect in the growth of Candida sp especially through its ability to destroy the Candida biofilm and inhibit mature biofilm maintenance on its MIC. In an in vitro studies, it was shown that EGCG, EGC and ECG caused metabolic instability of *C. albicans* cultures even at the physiological polyphenol.
concentrations found in green tea. Of the three catechins, EGCG was found to be the strongest in slowing down the formation and maintenance of Candida biofilms and interfering with the formation of biofilms. EGCG was also found to be able to bind strongly with ergosterol. This activity might result in pores creation on fungal cell membranes which eventually leading to fungal cells death. It was also shown that higher EGCG concentrations inhibited the chymotrypsin-like activity of C. albicans in vivo which suggests that the impaired proteasol activity contributes to the metabolic and cellular structural disorders of this fungus (10, 11).

Another study with murine model of oral candidiasis showed that EGCG increased the neutrophil count and decreased the amount of infected cells by C. albicans. The increasing concentration of EGCG leads to the increase of neutrophil count. This might be due to immunomodulatory effect performed by EGCG itself which also beneficial for oral candidiasis therapy, especially in immunocompromised patient as in HIV/AIDS patient (12).

 EGCG also produced synergistic effect when used together with fluconazole or ketoconazole resulting in higher fungicidal activity. The results in 4 species with EGCG (MFC) alone resulted in a reduction of 95.13%, while in synergistic combination resulted in a decrease of 92.27% for fluconazole and 97.51% for ketoconazole, compared to controls. The MIC value of fluconazole/EGCG or ketoconazole/EGCG decreased 3 to 4-fold in compare to the inhibitory effect of those drugs alone. Another study also found that the mechanisms of EGCG inhibitory effect on C. albicans is obtained via key enzymes in the biosynthesis of purines, pyrimidines and some amino acids, and independent of pH (10, 11).

Conclusions

These results highlight the potential of EGCG as an antifungal drug candidate. Based on the data showed antifungal activity with fungistatic and fungicidal effect better than fluconazole. We acknowledge the need to determinate the active compounds that inhibit germ tube formation and their mechanisms of action. However, if these substance is planned to be used in medicinal purposes, issues of safety and toxicity will need to be addressed in the next research.

Ethical Approval: All procedures performed in studies involving human participants were in accordance with the ethical standards of the Ethics Committee in Dr. Soetomo General Academic Hospital, Surabaya, Indonesia.

Conflict of Interest: The authors declare that they have no conflict of interest.

**Abstract**

**Background:** Oral Candidiasis (OC) still mainly opportunistic infection problem in HIV/AIDS Patients. Due to increasing report of fluconazole resistant as common antifungal drugs nowadays, there have been many studies focusing on natural substances and its antifungal properties. In this study, a form of green tea extract, named Epigallocathecingallate (EGCG) 1.25% were examined for their in vitro antifungal activity against Candida sp in comparison to fluconazole (2 mg/ml) as standard antifungal agents.

**Objective:** To evaluate the antifungal activity of EGCG in compare with fluconazole against Candida isolates taken from HIV / AIDS patients with OC.

**Methods:** Forty Candida sp. isolates taken from HIV / AIDS patients with OC in the Outpatient Unit and Inpatient Installation of the Infectious Disease Intermediate Care Unit (UPIPI) Dr. Soetomo, Surabaya. Antifungal activity were evaluated by using microdilution tests.

**Results:** The microdilution test revealed the MIC of EGCG for all Candida sp. was 0.625%, while the MIC of fluconazole was 100% for all Candida sp. There was significant difference (p <0.05) between the MIC values for Candida sp. by fluconazole and EGCG. The MFC values of EGCG was 50%, while value of fluconazole MFC was 100%.

**Conclusion:** Antifungal activity of EGCG with fungistatic and fungicidal effect is better than fluconazole.

**Introduction**

Oral candidiasis (OC) develops in 80%-95% of the patients with Human Immunodeficiency Virus (HIV)/ Acquired Immunodeficiency Syndrome (AIDS). It is described as an opportunistic infection, often involved in the alteration of oral microflora, systemic diseases and reduced immunity of the host. Opportunistic infectious diseases in HIV/AIDS patients can decrease the quality of life in these patients (1,2).

Candida albicans is the most prevalent and pathogenic species, but other Candida species, such as C. tropicalis, C. krusei, C. glabrata, C. dubliniensis, C. guilliermondii, C. parapsilosis, C. kefyr, and C. pelliculosa, has become a significant cause of infection in patients with HIV/AIDS (3,4). Majority of the clinically used antifungals suffer from various drawbacks in terms of toxicity, drug-drug interactions, and lack of fungicidal efficacy, and emergence of resistant strains resulting from frequent usage. For example, fluconazole limited because of the high rate of primary and secondary resistance (5). To identify substances that might be alternatives to traditional medicines, studies were conducted on the antimicrobial activity essential oils for the control of OC (6).

Research on alternative therapies using natural ingredients is currently on the rise. The use of natural extracts to treat Candida is becoming popular, one of which is green tea (Camellia sinensis) extract, which is found to have beneficial effects on health, due to its high its low toxicity with antioxidant and immunomodulatory effects. Research conducted by Rahayu and colleagues in 2018 on the immunomodulatory effect of green tea extract in immunocompromised mice with Candida using polyphenols and EGCG. After evaluation, it was found that EGCG 1.25% had an immunomodulating effect against C. albicans infection in immunocompromised mice by increasing the expression of IL-8, IL-17A and HBD-2. It was also found that the minimum inhibitor concentration of green tea extract on the growth of Candida albicans was 12.5% and the minimum bactericidal concentration was 25%. Therefore, administering EGCG can provide an immunomodulating effect against oral candidiasis in immunocompromised patients (7). Therefore, this study wanted to test the sensitivity of green tea extract and nystatin in oral candidiasis patients with HIV. The use of Epigallocatechingallate (EGCG) is expected to have a better sensitivity than fluconazole.

**Methods**

**Strains and Growth Conditions**

This research used 40 isolates divided in two groups 20 isolates of Candida albicans and 20 isolates Candida non-albicans, were obtained from forty patients Candidiasis oral with HIV/AIDS infection. Candida non-albicans species included in this study consisted of 7 species of Candida krusei, 6 species of Candida glabrata, 2 species of Candida dubliniensis, 2 species of Candida parapsilosis, 1 species of Candida tropicalis, 1 species of Candida norvegensis and 1 species of Candida lypotica. All of the strains were grown on Sabouraud dextrose Agar under aerobic conditions at 37°C for 24 h before the antifungal assays. The yeast (107 cells/mL) suspensions used in the assays were prepared in sterile phosphate-buffered saline (PBS) at pH 7.2.
Antifungal Tests

The minimum inhibitory concentrations (MIC) were obtained using the serial microdilution method in culture of 96-well cell plates based on the Clinical and Laboratory Standards Institute (CLSI). Prepare a 96 well microtiter plate that has been filled with Mueller Hinton Broth (MHB) and fluconazole with 10 levels of concentration using a multilevel dilution technique, which is 100%; 50%; 2.5%; 1.25%; 0.625%; 0.312%; 0.156%; 0.078%; 0.039%; and 0.0195%. Then enter the EGCG with the highest concentration of 100% in the first row and then do the multilevel dilution along the Y axis to the lowest concentration of 0.19%. *Candida* species were inoculated into the plate by leaving row one as a negative control. MIC observations are determined by observing at what concentration in the well begins to clear and there is no sediment that indicates the growth of *Candida* is inhibited. Minimal Fungicidal Concentration (MFC) is tested by taking 10 µL from the well with a predetermined MIC each well is inoculated on a Petri dish containing Sabouraud dextrose agar and incubated at 37 °C for five days. MFC is defined as the lowest concentration without growth that is seen to be used as the end point for the fungicidal effect.

Statistical Analysis

The statistical differences were evaluated using SPSS 17 version. The data for the microdilution methods were analyzed by *Chi square* on normal data distribution and *Mann Whitney* on abnormal data distribution in statistic. Statistical significance was determined at $p < 0.05$.

Results

Forty isolates taken from HIV / AIDS patients with OC. The male patients were 31 patients (77.5%) and female patients were 9 patients (22.5%). The age of patients from isolates in this study varied between the age group 17-25 years to 56-65 years. The age range is 20 subjects (50%) in the 26-36 years old group. The isolates most were taken from HIV / AIDS patients with OC who had an absolute CD4 count <100 cells/L for 28 patients (70%).

Table 1 shows the results of microdilution, there is a statistically significant difference with the chi square test method at a concentration of 50% between fluconazole and EGCG ($p <0.05$). At a concentration of 25% there was no significant difference ($p >0.05$ and the rest could not be analyzed because all the results were still visible turbidity. MIC was produced by EGCG statistically through *chi square* test for *Candida albicans* species at a concentration of 50%, while MIC fluconazole at a concentration of 100%.

Table 2 shows with the results of microdilution, there is a statistically significant difference with the chi square test method at a concentration of 50% between fluconazole and EGCG ($p <0.05$). From the concentration of 25% until 0.38% concentration there were no significant differences between fluconazole and EGCG ($p >0.05$). The MIC produced by EGCG was statistically through the chi square test for *Candida non-albicans* species at concentrations of 50% while MIC fluconazole at 100% concentration.

Shapiro Wilk test confirmed that the data were not normally distributed ($p <0.05$); therefore, nonparametric statistical tests, the Mann Whitney test, was performed. Based on data from Table 3 shows the results of microdilution method research, the MFC values EGCG statistically through the Mann Whitney test is 50%, with this concentration can kill the *Candida albicans* and *Candida non-albicans*. The value of fluconazole MFC was 100%. Mann Whitney test results showed there were significant differences between MFC fluconazole with EGCG on the growth of *Candida albicans* and *Candida non-albicans* ($p <0.05$).

Discussions

Basic data of this study showing isolates mostly taken from male than female (77.5% and 22.5%). The most age group is productive age groups in the age range of 26-35 years with 20 subjects (50%). In 2017 report of the Directorate General of Disease Control and Environmental Health, Ministry of Health Republic of Indonesia, found HIV/AIDS patients more male than women, and related more common in young adult which makes it more likely to engage in unsafe sexual behavior that is at risk of HIV transmission (9). The domicile of HIV / AIDS patients with OC mostly came from Surabaya (90%). This is because most patients have to seek help from the nearest health center with most patients from within the city. The isolates most were taken from HIV / AIDS patients with OC who had an absolute CD4 count <100 cells / L for 28 patients (70%). This data is supported by a 2015 Indian study by Kumar that showed 71.4% of patients with a CD4 cell count <200 cells / µL obtained by the fungus growth of Candida species from OC lesions (9).

The evaluation of the antifungal activity of EGCG against all strains of Candida isolates, showed MIC values ranging from 50%-100% and MIC values fluconazole were varying. MFC produced by EGCG for Candida sp. through the Mann Whitney test is 50%, in which concentration is able to kill the Candida albicans and Candida non-albicans. The value of fluconazole MFC was 100%, which was higher than EGCG. Previous study also found that EGCG perform better antifungal activity based on its MIC and MFC in compare to azole drugs (ketocanazole and fluconazole). EGCG showed a significant inhibitory effect in the growth of Candida sp especially through its ability to destroy the Candida biofilm and inhibit mature biofilm maintenance on its MIC. In an in vitro studies, it was shown that EGCG, EGC and ECG caused metabolic instability of C. albicans cultures even at the physiological polyphenol concentrations found in green tea. Of the three catechins, EGCG was found to be the strongest in slowing down the formation and maintenance of Candida biofilms and interfering with the formation of biofilms. EGCG was also found to be able to bind strongly with ergosterol. This activity might result in pore creation on fungal cell membranes which eventually lead to fungal cell death. It was also shown that higher EGCG concentrations inhibited the chymotrypsin-like activity of C. albicans in vivo which suggests that the impaired proteinase activity contributes to the metabolic and cellular structural disorders of this fungus (10,11).

Another study with murine model of oral candidiasis showed that EGCG increased the neutrophil count and decreased the amount of infected cells by C. albicans. The increasing concentration of EGCG leads to the the increase of neutrophil count. This might be due to immunomodulatory effect performed by EGCG itself which also beneficial for oral candidiasis therapy, especially in immunocompromised patient as in HIV/AIDS patient (12).

EGCG also produced synergistic effect when used together with fluconazole or ketoconazole resulting in higher fungicidal activity. The results in 4 species with EGCG (MFC) alone resulted in a decrease of 92.27% for fluconazole and 97.51% for ketoconazole, compared to controls. The MIC value of fluconazole/EGCG or ketoconazole resulting in higher fungicidal activity. The results in 4 species purposes, issues of safety and toxicity will need to be addressed in the next research.

Conclusions: These results highlight the potential of EGCG as an antifungal drug candidate. Based on the data showed antifungal activity with fungistatic and fungicial effect better than fluconazole. We acknowledge the need to determine the active compounds that inhibit germ tube formation and their mechanisms of action. However, if these substance is planned to be used in medicinal purposes, issues of safety and toxicity will need to be addressed in the next research.

Ethical Approval: All procedures performed in studies involving human participants were in accordance with the ethical standards of the Ethics Committee in Dr. Soetomo General Academic Hospital, Surabaya, Indonesia.

Conflict of Interest: The authors declare that they have no conflict of interest.

Funding: None

Abstract

Introduction: Oral candidiasis is a common symptom in HIV/AIDS patients and in some cases have low CD4 levels. Objectives: Analyzing the correlation of CD4 counts with Candida colonization in oral candidiasis patients with HIV/AIDS. Methods: The research procedure consisted of identifying the type and number of Candida species grown in the participant’s oral cavity, and calculating the CD4 count. The statistical tests used Chi Square, Fisher exact, Spearman correlation test, or Anova test (95% CI; p <0.05). Results: Candida colonization found in group I was 1 – 10 (71.05%), group II was 11-100 (60.53%), and group III was >100 (50.00%; p <0.001). The patient’s lesion area in group I was 3-4 (47.37%), group II was 3-4 (65.79%), and group III was 1-2 (94.74%; p <0.001). Most patients had acute pseudomembranous type, consisting of 81.58% (group I), 92.10% (group II), and 97.37% (group III; p <0.001). Conclusion: This study found a significant correlation between CD4 counts and Candida colonization in oral candidiasis patients with HIV/AIDS. The lower the CD4 counts, the higher the number of Candida colonization in the oral cavity.

Keywords: CD4 count, HIV/AIDS, candida species, oral candidiasis

Introduction

Human Immunodeficiency Virus (HIV) and Acquired Immunodeficiency Syndrome (AIDS) infections are still major problems throughout the world and most of the clinical manifestations are oral candidiasis. Candida can spread widely, directly from the oral cavity throughout the body depending on the target organ experiencing immune deficiency. In general, HIV/AIDS patients likely have immune deficiency, and cause individual vulnerability to be detected. CD4 counts in peripheral blood are important when evaluating immune status.1, 2

Common oral candidiasis is estimatedly found in 4.2% of HIV patients and 11.6% of AIDS patients. Some literature stated that CD4 counts <200 per mm³ are found in HIV/AIDS patients.3 The pathogenesis of HIV infection is largely due to a decrease in the number of T-cells (certain types of lymphocytes) that contain CD4 cell surface receptors. The immune status of HIV/AIDS patients can be assessed by measuring the absolute number (per mm³) or percentage of CD4 cells. This is considered a way to assess the severity of immunodeficiency associated with HIV/AIDS. The decreasing number of T cells (CD4) progressively marks the prognosis of HIV/AIDS decreases and increases the chance of other infections. HIV will infect and eliminate Th17 cells, resulting in a reduction in IL-17 secretion which then results in a reduction in b-defensin induction, a downregulation of CXC chemokine expression, a decrease in the production of antifungal cytokines, and the result is a shape transition. Candida albicans forms a hyphae which is pathogenic. This causes Candida, which was initially commensal to turn pathogenic and

causes a fungal infection in the oral cavity mucosa, so it is called oral candidiasis.4,5

Dr. Soetomo General Hospital, Surabaya, Indonesia, is the highest referral hospital in East Java, Indonesia. The number of HIV/AIDS patients has increased every year. In 2017, 1891 patients were reported for treatment, 1997 patients in 2018, and 1671 patients in September 2019. The number of oral candidiasis patients with HIV/AIDS in 2017 was 30%, 32% in 2018, and 33% by September 2019. Based on the description above, researchers were interested in conducting research aimed at analyzing the correlation of CD4 counts with Candida colonization in oral candidiasis patients with HIV/AIDS.

**Methods and Material**

**Participants**

Participants in this study were HIV/AIDS patients at Dr. Soetomo General Hospital Surabaya, Indonesia. Participant inclusion criteria included patients diagnosed with HIV/AIDS using a rapid test/HIV 3 6,7, having a positive candidiasis diagnosis using 10-20% KOH 8,9, and aged>18 years. Participant exclusion criteria included subjects taking antifungal drugs within 2 weeks before the study and no colonies found on culture examination. Participants in this study first filled out the consent form, in which the patient had received an explanation regarding the benefits and objectives of the study.

**Design**

The study was conducted at Dr. Soetomo General Hospital, Surabaya, Indonesia from May 2019 to September 2019. This research was a cross-sectional study with consecutive admission sampling method. The number of participants was 114 participants, which were divided into 3 groups (each group = 38; Figure 1). We have conducted an ethics test at the ethics committee Dr. Soetomo General Hospital (1125 / KEPK / IV / 2019). The research procedure consisted of identifying the type and number of candida fungi in the participant’s oral cavity and calculating the participant’s CD4 count. The patient will take anamnesis, physical examination, laboratory examination, namely KOH and culture with material from the patient’s mouth rinse water, and blood as much as 3 cc for CD4 examination.

**Figure 1. Flowchart Diagram of Participant Candida Spesies Measurement**

Before checking the type and amount of Candida colonization, patients were told not to do oral hygiene. Participants gargled using 25 ml of sterile water, then the water was put into a sterile bottle. Water from the mouth rinse was immediately sent to Dr. Soetomo General Hospital, Surabaya, Indonesia. The water was shaken slowly, then taken ±5-10 ml and put in 15 ml sterile centrifuge tubes and rotated 2,500 revolutios per minute (rpm) for 5 minutes. Eliminate the supernatant and took the pellet using a sterile pipette, placed it in a glass object and added 10-20% KOH. Candida positive was planted on Sabouraud dextrose agar (SDA) at 37°C for 48 hours.10 The SDA media used was CHROMagar Candida (CHROMagar Candida, France). Candida specimens were also carbohydrate tested to identify Candida species.11 Candida specimens that grew later were counted by specialists in the Department of Microbiology, Dr. Soetomo General Hospital, Surabaya,
Indonesia in a colony forming unit (CFU).

**CD4 Measurement**

Patient’s venous blood samples were taken, then put into K3EDTA-countaining tubes, stored at room temperature, and followed by immunophenotyping for 6 hours. CD4 count calculations used flow cytometry (BD FACSCounttm System; San Jose, CA). Participants were divided into three groups: group I (participant with a CD4 level of \(\leq 100/\mu L\)), group II (participant with a CD4 level of 101 - 200/\(\mu L\)), and group III (participant with a CD4 level of > 200/\(\mu L\)).

**Lesion Area**

The area of participant’s candidiasis oral lesions was assessed using a score of 0 = no lesions, 1 = partial lesions, and 2 = all/all lesions. The locations assessed included the tongue, mucous membrane, and palate with a minimum score of 1 and a maximum score of 6. Calculation of the area of the lesion by adding up the three locations of the assessed lesion.

**Statistical Analysis**

The results of the study were presented in the form of mean ± standard deviation (SD) or median (minimum - maximum) and percentage (%). Static analysis used IBM SPSS Statistic software version 23.0 (IBM Corp., Armonk, NY, USA). Analysis of measurement data used Chi Square test, Fisher exact test, Spearman correlation test, or Anova test with 95% CI and significance level of p <0.05.

**Results**

**Characteristics of Participant**

There were 114 patients who were divided into 3 groups based on CD4 count, with each group consisting of 38 participants. The average age of participants in group I was 43.15 ± 3.67 years, group II was 40.02 ± 10.23 years, and group III was 51.02 ± 3.28 years (p = 0.812). They were divided into several age groups, where most participants were in the age range of 36-45 years (37 participants; 32.46%), followed by the age group of 46 - 55 years (28 participants; 24.56%), and the age group of 26 - 35 years (26 participants; 21.05%). Most participants attended senior high school (55 participants; 48.24%), consisting of 42.10% in group I, 52.63% in group II, and 50.00% in group III (p = 0.015). Most participants were Madurese (60 participants; 52.63%) and followed by Javanese (41 participants; 35.96%). Most of the participants in group I were Madurese (63.16%) and most in groups II and III are Madurese too (47.37%; p = 0.002). Most of the participants were private employees (67 participants; 58.77%), consisting of 52.63% in group I, 76.31% group II, and 47.37% in group III (p = 0.025; table 1).

Patient’s Clinical Description

Most participants complained about the appearance of white patches on the oral cavity (100 participants; 87.72%), followed by participants who complained of red patches and sores on the oral cavity and/or the corners of the lips (7 participants; 6.14%), participants with complained of white and red patches on the cavity mouth (4 participants; 3.51%), and patients with white patches and sores in the oral cavity and/or the corners of the lips (3 participants; 2.63%). Most participants had no pain complaint (64 patients; 56.14%), while the rest (50 patients) complained of pain with an average pain scale of 4.13 ± 0.62. The pain included swallowing pain or accompanied by a burning sensation in the throat. Most patients had lesion location on the tongue (54 participants; 47.37%), followed by lesions on the tongue and mucous membrane (38 participants; 33.33%), and on the tongue, mucous membrane, and lips (11 participants; 9.65%), palate (6 participants; 5.26%), tongue and palate (2 participants; 1.75%), tongue, mucous membrane, and palate (2 participants; 1.75%), and mucous membrane (1 participant; 0.88%). The patient’s physical condition can
Candida Species

Culture results from 114 participants found 149 isolates, where 1 participant was able to produce >1 isolate or >1 species of Candida species. Most of the Candida species grew were Candida albicans as much as 98 species (65.77%), while the rest were 51 non-albicans species (34.23%), including Candida glabrata, Candida tropicalis, Candida krusei, Candida dublinensis, Candida lypolitica and Candida parapsilosis (Figure 3).

Correlation between CD4 Count and Candida Species Colonization

Most participants in group I had >100 Candida species colonization (71.05%), while most patients in group II had the colonization of Candida species of 11-100 (60.53%). On the other hand, the number of Candida species colonization of 1 - 10 and 11 – 100 found in group III were similar (50.00% each; p <0.001). Most participants in group I and II had lesion area in the range of 3 – 4. Meanwhile, most patients in group III had lesion area in the range of 1 – 2 (p <0.001). Most participants in all groups had oral candidiasis of acute pseudomembrane type as much as 81.58% (group I), 92.10% (group II) and 97.37% (group III) (p <0.001).

Discussion

Candida albicans is the most commonly found species in isolates, but non-albican species can also develop into pathogens with various susceptibility to antifungal agents. Various studies have shown that Candida species are found in 61-100% of people infected with HIV/AIDS with oral candidiasis. Candida albicans is one of the most common fungi found in HIV/AIDS patients. CD4 count is a sign of immunosuppression to determine the prognosis of HIV/AIDS. The results of this study showed a significant correlation between CD4 counts and Candida colonization. The lower the CD4 cell count, the more Candida colonization. The condition showed that the decreasing immunity of HIV/AIDS patients indicates normal amount of Candida species, which is the normal flora of the body that can become parasitic colonization to the body.

Factors affecting oral Candida colonization in patients with HIV/AIDS and low CD4 counts are important contributors to increasing the likelihood of
oral Candida colonization. A CD4 cell count <200 cells/mm$^3$ is considered a predisposing factor for oral candidiasis. Positive HIV/AIDS patients without antiretrovirals have a high risk of decreasing CD4 counts. Candida species, especially Candida albicans, normally exists in the oral cavity, but when a person experiences decreasing CD4 counts, the colonization becomes uncontrolled.$^{14,15}$

This study showed that correlation of CD4 with lesion area has a significant relationship, in which the lower the colony, the greater the lesion area. Oral candidiasis is probably the earliest prognosticator of HIV infection. The degree of immune suppression affects the risk, severity and anatomic location of the disease. Oral candidiasis is very common when CD4 counts are less than 300/mm$^3$ and esophagitis counts are less than <100/mm$^3$.4,14,15

White patches in the oral cavity mostly found in pseudomembranous oral candidiasis and plaque hyperplasia are common types of oral candidiasis. Participants with complaints of swallowing pain and burning sensation in the throat are clinical signs of lesions attacking the pharynx and esophagus. Recurrence in oral candidiasis can occur in individuals who have low immune status and/or do not receive appropriate and adequate antifungal therapy.$^8$

Candida infections in immunocompromised patients are often severe, progressively fast, and difficult to treat, and such patients have a definite risk of developing oral candidiasis, which is an important oral manifestation in patients with HIV/AIDS. Age and sex do not have a significant significance in this Candida infection. Individual immunological status has a definite impact on the severity of the disease as reflected by a high colony relationship with a low CD4 count. Given the changing patterns of Candida species, isolation and identification are very important and can help in a better treatment strategy, and thus, get good control of the disease.$^4$

In addition, oropharyngeal candidiasis is considered to be an HIV/AIDS-defining condition where oral clinical features of candidiasis and oropharyngeal candidiasis consisting of white plaque, mouth sores and swelling pain can also be observed. Although Candida albicans is the most species isolated from oral opportunistic infections, an increase in the frequency of infections in the oral cavity caused by non-albicans species, such as Candida tropicalis, Candida parapsilosis, Candida glabrata, Candida krusei and Candida dubliniensis, have been observed in the last decade.$^7,16$

The main target of HIV virus is a subset of lymphocytes derived from the thymus, the helper/inducer cell. The surface of this cell has a glycoprotein molecule called CD4, which is known to bind to the HIV virus glycoprotein envelope. CD4 damage in lymphocytes is one of the causes of the occurrence of immunosuppressive effects by viruses. At present, it has been found that CD4 also exists in other cells, although in lower densities, such as monocytes and macrophages as well as those in tissues such as Langerhans cells in the skin and dendritic cells in the blood and lymph nodes. These cells are also cells that have an important role to start the immune response so that this function is also disrupted by the presence of bonds with the HIV virus.$^2,4,5$

CD4 or similar molecules are also detected in the brain, although it is not clear which cells express the CD4. HIV that has entered into CD4 lymphocyte cells will carry out multiplication by hitching a ride in the process of growth of its host cell. In CD4 lymphocyte cells, HIV replicates and damages these cells, and when they are mature new viruses emerge and then enter other CD4 lymphocyte cells, multiplying and subsequently damaging these cells. A low CD4 T lymphocyte count is said to be the biggest risk factor for current oral candidiasis. An increased risk of oral candidiasis is inversely proportional to the number of CD4 T lymphocytes. The decreasing CD4 T lymphocytes to under 200 cells/μL is a significant risk factor for a more growing colonies in the oral cavity. There is a significant relationship between low CD4 cell count (<200 cells/ml) and oral candidiasis due to immune suppression caused by HIV infection.$^{17,18}$

**Conclusion**

Oral candidiasis patients with HIV/AIDS who have low CD4 levels tend to have a large Candida colonization in the oral cavity, and lesions in the oral cavity are expanding. Patients who are not treated immediately will likely have a broader oral candidiasis, higher number of colonies, wider area of lesion, and lower CD4 T lymphocyte level. This condition represents
a circle that worsens each other’s condition.

Abstract

Background and Objective: Cadmium chloride (Cd cl$_2$) is a highly toxic heavy metal that causes severe degenerative effects to different body organs. Bone marrow mesenchymal stem cells (BMMSCs) may have a protective effect upon CdCl$_2$ induced structural and functional changes in the rat’s organs. This systematic review aimed to test the regenerative effects of bone marrow‐derived mesenchymal stem cells on different body organs of albino rats exposed to cadmium chloride toxicity.

Methods: Experimental animal studies were identified by the following electronic databases: PubMed, Scopus, Ovid Medline, KoreaMed, Google Scholar, Latin American and Caribbean Health Sciences Literature (LILACS) and Central Cochrane Library. The literature search was done from January 2010 to 2020.

Conclusion: From the selected articles, using stem cell therapy enhances the regeneration process in CdCl$_2$ toxicity of different body organs.

Keywords: Cadmium chloride; bone marrow stem cells; rats; systematic review.

Introduction

Civilization advances and increased environmental pollution exaggerate the effects of different xenobiotics as heavy metals on the function of the living organism [1-3]. Heavy metals are defined as trace naturally occurring metallic elements that found throughout the crust of the earth and have high density when compared to water [4]. Human exposure to these metals has been increased dramatically due to their excessive use in industry, agriculture and technological applications [5]. Cadmium is one of the most abundant and toxic heavy metals. It is the 17$^{th}$ most toxic metal and its concentration in earth crust reach about 0.1 mg/kg. It accumulates in body throughout the life. Human exposed to Cd by inhalation and ingestion from plants leading to acute and chronic intoxications. Cd remains in soils and sediments for many years. Plants take up this metal which gets accumulated in them and concentrates along the food chain, reaching the human body [6, 7]. Once absorbed, Cd is rapidly cleared from the blood and concentrates in various tissues. Chronic exposure to inorganic Cd results in accumulation of the metal mainly in the liver and kidneys, as well as in other tissues and organs causing many metabolic and histological changes, membrane damage, altered gene expression and apoptosis [8]. Mesenchymal stem cells are excellent option for cell therapy because they are easily accessible, cells can expand to clinical scales in a relatively short time and...
can be preserved with minimal loss of potency [9]. The regenerative potential of MSCs has been widely studied as it includes in treating tissue lesions caused by ionizing radiation and clinical radiotherapy. Animal studies and early clinical experiences suggested a role for MSCs in the regeneration of these tissue injuries by differentiating into functional parenchymal cells and creating a nurturing microenvironment for other cells [10]. According to PICO, the research question for this systematic review was that ‘dose BMSCs reduce cadmium toxicity in rat’s different body organs. The population was rats; the intervention was use of stem cells to treat cadmium induced toxicity; the comparator was control positive groups that receive cadmium without stem cell treatment; the outcome was the therapeutic effects of stem cells on toxicity induced by Cd in different body organs.

Methods

Protocol development and eligibility criteria: The question was formulated using the PICO format for the research question construction. The methodology of this SR was designed on the basis of the guidelines of the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) [11].

Inclusion criteria: All the studies involved in this SR should have the following criteria: (1) Experimental animals exposed to Cd were only rats, (2) The toxicity was induced by cadmium chloride only, (3) Treatment option was BMSCs, (4) Affected structures were different body organs, (5) All included studies must contain control group that receive cadmium chloride with no treatment, (6) The main evaluation is based on the histopathological and/or laboratory evaluation tests and (7) The outcomes were degenerative changes of Cd toxicity in different body organs and regenerative effects of BMSCs.

Exclusion criteria were (1) Animals other than rats, (2) Therapeutic modalities other than BMSCs, (3) Toxicity induced by heavy metals other than Cd toxicity, (4) Studies with no control group, (5) Reviews, (6) Book and book chapter, (7) Case reports, (8) Clinical studies, (9) Studies on human and (10) In vitro studies.

Information sources and search strategy: The PROSPERO and the Cochrane Database of SRs were searched in 10 August 2020 and no existing reviews were found dealing with the effect of BMSCs on Cd-induced toxicity in different body organs. To obtain eligible studies related to our criteria, comprehensive search of peer reviewed literature, published up to 2020, was performed of the electronic databases PubMed, Scopus, Ovid Medline, koreaMed, Google Scholar, Latin American and Caribbean Health Sciences Literature (LILACS) and Central Cochrane Library. The literature search was done from 2010 to 2020. The population was rats; the intervention was use of stem cells to treat cadmium induced toxicity; the comparator was control positive groups that receive cadmium without stem cell treatment; the outcome was the therapeutic effects of stem cells on toxicity induced by Cd in different body organs. As mentioned before, the research question for this systematic review was that ‘dose BMSCs reduce cadmium toxicity in rat’s different body organs. All searches were performed independently by two authors (EH and ME) to identify published articles related to the focused question.

Searching keywords: Search word/term was performed as following: stem cells and cadmium toxicity or bone marrow stem cells and cadmium chloride and rats or stem cells and cadmium and salivary glands and rats or “cadmium chloride” toxicity and bone marrow stem cells in rats.

Study selection and data collection: Two authors (EH&MM) screened all the titles and abstracts, unrelated studies at this stage were excluded. All the potentially related studies were evaluated independently and the relevant studies were extracted by each author. Disagreements between the two authors about study inclusion or exclusion criteria were solved by third author (MEH). The data of interest from the selected studies was tabulated and the following data were obtained: authors and their country, journal (publication year), number of study groups, number of rats used in the study, gender and weight, type of stem cells and their concentration, duration of the study and outcomes. Fields for which information not found in a publication were entered as “unknown.

Assessment of risk of bias (ROB) in included studies: To assess the quality of the articles, two authors (EH&MEG) independently used the SYRCLE’s risk
of bias (RoB) tool [17]. They assessed selection bias (sequence generation, baseline characteristics, allocation concealment), performance bias (random housing, blinding of the operators), detection bias (random outcome assessment, blinding of outcome assessor), attrition bias (incomplete outcome data, selective outcome reporting) and other sources of bias. Each item was assessed to be low, high, or unclear RoB. “Unclear” means either lack of information or uncertainty over the possibility of bias. Table 1: Any disagreements in the assessment were also resolved by discussion with a third author (MA).

**Statistical analysis:** Degree of chance – adjusted agreement (kappa coefficient value) was used to determine the inter-reviewer reliability.

**Results**

The total articles identified from the search through PubMed, Scopus, Ovid Medline, koreamed, Google Scholar, LILACS and Central Cochrane Library were 1967 articles. After filtering, 1259 were excluded, in addition to 43 duplicates were removed. After the eligibility criteria were applied on the remaining 665 articles, five unduplicated studies were included in this review. A flow chart for the selection process is presented in figure1

**Study characteristics:** According to the publication date, the included five studies were divided into one performed in Saudi Arabia at 2015 [16], one in China at 2017 [14], two in Egypt at 2018 [12, 13, 15]. All studies used cadmium chloride to induce toxicity with different concentrations ranging from 0.4-5 mg/kg body weight. One study induce cadmium toxicity by intraperiotonial (IP) injection of 0.4mg/kg body weight five times per week for five weeks [14], two studies used single IP dose of 2 mg/kg body weight [12, 13], one study inject cadmium IP with the dose of 1 ml/kg saline (solvent of Cd) for 3 days 2020 [15] and the remaining study used Cd orally with the dose of 5 mg/kg body wt/day) for 30 days [16]. All studies concentrated on testis as an organ of interest [13-16] except one study had taken liver, kidney and testis as organs for the study [12]. According to the treatment used, BMMSCs used in all studies with concentration ranged from $1 \times 10^6$ in three studies [12,15,16], $1 \times 10^7$ cells in one study [14] and $2 \times 10^6$ in one study [13]. Four
studies injected BMMSCs intravenously (via retro-orbital, penile vein, portal vein and via tail vein)\(^{12,13,14,15}\) and one study via intratesticular injection\(^{16}\).

**Results of risk of bias within the study:** The overall RoB for the included studies was low risk in one study\(^{14}\) and high risk in four studies\(^{12,13,15,16}\) due to the lack of random allocation concealment of the rats in the study groups, unmentioned blindness of investigator and assessor in most of the studies, in addition to unmentioned information about random housing of animals, if there have the same housing conditions or not. In addition, the reporting of the outcome for the most of studies was not mentioned, if there were any damaged or missing samples or not.

**Study of low risk of bias:** Wang et al\(^{14}\) used CdCl\(_2\) to induce damage in testis of rats with dose of 0.4 mg/kg body weight by intraperitoneal injection 5 times per week for five weeks. Five weeks following Cd exposure; 5×10\(^6\) BMMSCs were transplanted into rats by retro-orbital injections on two consecutive days (1×10\(^7\) BMSCs in total) and sacrificing 2 weeks after cell transplantation. H&E stain showed that testes appeared to have varying degrees of injury as atrophy, endothelial cell swelling and reduced layers of mature cells. The apoptosis rate markedly decreased, body weights were higher in stem cell group than Cd group and greater Cd accumulation was detected when compared with the control group. Histologically, there was a significant improvement in the pathological changes caused by Cd in model group including more cell layers and regularly arranged spermatogenic cells layers. The status of rats improved significantly compared with the model rats.

**Studies of high risk of bias:** Elbaghdady et al\(^{12}\) used CdCl\(_2\) to induce testicular toxicity; each rat received 2 mg/kg IP Cd dissolved in normal saline. Sperms collection, counting and viability were assessed. A lesser weight gain was recorded in Cd-group as compared to the controls. Histologically; necrosis, marked interstitial fibrosis and infiltration of mononuclear inflammatory cells are the main obvious changes. Testis showed an overall atrophy thus; the study supposed that Cd impairs the reproductive capacity caused by the severe testicular damage. BMMSCs used to treat Cd-induced toxicity in testis. Each rat received 2 mg/kg intra-peritoneal Cdcl\(_2\) dissolved in normal saline then the first dose of 1×10\(^6\) stem cells in 0.2 ml DMEM injected intravenously via penile vein. After one week, the second dose of 1×10\(^6\) SCs was given. Results showed that there was an overall reduction in the severity of Cdcl\(_2\)-induced pathological damage after BMMSCs treatment. Higher body weight gain and higher sperm count and sperm were recorded in comparison with the Cd-group. Elbaghdady et al\(^{13}\) also used Cd to induce hepato-renal and testicular toxicity. 2 mg/kg Cdcl\(_2\) dissolved in normal saline was injected IP for each rat. When compared to the control group, the rats treated with Cdcl\(_2\) showed a great decrease in the total number, motility and viability of sperm. There were high levels of abnormal sperm morphology. Lipid peroxidation and oxidative stress were associated with the increase in testicular necrosis and lowered sperm count and viability. Significant abnormalities in all measured biochemical analyses were documented. Rats showed marked decrease in total protein levels and significant increases in serum uric acid and creatinine levels and this may be due to kidney damage caused by CdCl\(_2\) exposure. After Cd treatment, the rats received two successive doses of MSCs separated by one week, each dose of 1×10\(^6\) cells/ rat suspended in 0.2 ml DMEM via intravenous injection into the portal veins. Results showed a statistically significant increase in sperm total count, viability and motility in comparison with the controls. Improvement in all biochemical measures were recorded to the extent that they reached the normal values. The microscopic examination of liver sections of stem cells treated animals showed marked reduction in the hepatic vacuolation, mild leukocytic infiltration and significant decrease in cell degeneration. Abdel Latif et al\(^{15}\) used CdCl\(_2\) to induce toxicity in their study. CdCl\(_2\) was dissolved in normal saline and injected intraperitoneally, each rat received1 mg/ kg for consecutive three days. Rats were received BMMSCs injection once via tail vein, at a dose of 1×10\(^6\) cells/ rat suspended in 0.2 ml PBS after Cd treatment for 3 days and remained for 4 weeks. Sections of the stem cell-treated group showed normal architecture of tubules, minimal fluid exudates and vacuoles. Serum levels of testosterone showed marked increase (137%) while MDA and NO levels were decreased as related to non-treated group. Moreover, there were 154% significant increases in the mean values SOD and 138% significant increments in the mean values of GSH in relation to that of non-treated group. BAX level recorded significant decrease, however Bcl-2 levels
were decreased. Hussein et al\textsuperscript{16} induced toxicity to rats using Cd at the dose of 5 mg/kg body weight dissolved in water daily via oral administration for 30 days then blood samples were collected from retro-orbital plexus and used for detection of sex hormones using ELISA, liver and kidney functions and total antioxidant capacity. Oxidative stress parameters (MDA and NO) contents and antioxidant parameters \{reduced glutathione (GSH), Superoxide dismutase (SOD) activity and CAT activity\} were estimated. Results revealed that there was marked decrease in the body weight after 4 weeks of Cd ingestion with gradual and sustained significant decrease in the weights of left and right testis. There was a significant decrease in serum levels of testosterone and LH and marked elevation in FSH, prolactin serum levels, MDA, NO, CAT, ALT, AST, ALP, creatinin and urea levels in relation to control values, while total protein and albumin were not affected. Decrease in sperm count and sperm motility was recorded. BMMSCs were used to regenerate damaging effects of Cd. 24 hours after the last dose of cdcl\textsubscript{2}, animals were received a single intratesticular injection of rat BMMSCs containing \(1 \times 10^6\) cells then left for 30 days. Results revealed that treatment of cd-exposed rats with stem cells caused body weight gain, reversed or fixed all injuries caused by cdcl\textsubscript{2} and retained to control levels. Significant improvement in the sperm count and motility so, they indicated that BMMSCs may play an important role in recovering the testicular function of adult rats.

\textbf{Discussion}

This systematic review aimed to assess the therapeutic and protective effects of BMMSCs as a treatment option for Cd induced toxicity, so the experimental animal chosen for this review was the albino rats, as they provide an appropriate model to study naturally or experimental occurring cadmium toxicity to different body organs. All the included studies were published in the last 10 years. Heavy metals are metallic elements that have high density compared to water \textsuperscript{18}. There is an increasing ecological and global public health concerns related to environmental contamination by these metals and exposure of human has increased as a result of their frequent use in many industrial, technological and agricultural applications \textsuperscript{5}. Industrial progress has brought human into close contact with several injurious chemicals, including heavy metals such as cadmium, lead and mercury. Cd is a highly toxic metal with widespread exposure to human causing tissue damage that lack effective treatment\textsuperscript{14}. It presents at low levels but human activity as tobacco smoking has greatly increased its level. Exposure to this metal can occurs in the workplace and in the environment as it is utilized in a number of industrial practices and is considered as a contaminant of the environment and dietary products \textsuperscript{19}. Cadmium accumulation occurs mainly in the soft tissues as the liver, kidney and testes \textsuperscript{20, 21}. This metal acts as a catalyst so its toxicity associated with oxidative tissue damage. Cd increases the production of ROS as a result of its inhibitory effects on mitochondrial electron transport \textsuperscript{22}. The present review aimed to investigate the effect of injected BMSCs to decrease the hazardous effects of Cdc\textsubscript{2} which induced changes in some biochemical and histological parameters in different body organs of rats. It was concluded that BMMSCs have the ability to improve and recover the cellular damage induced by Cd exposure in testis, liver and kidney of rats. It was not possible to perform a direct comparison between the selected studies due to different variations between them in number of stem cells implanted, concentration of Cd, route of toxicity induction, period of the experiment and the organs of interest, so quantitative meta-analysis of the data could not be carried out. Irrespective of all of that difference, the majority of the studies demonstrated a statistically significant improvement in the outcome measures between the groups used stem cells as a treatment for Cd induced toxicity. After all of that, the present review has some limitations. Firstly, studies selected should be written in English, but this under represents the studies written by any language other than English. Secondly, the finding of most of the included studies don’t based on follow up periods even short follow up periods as long follow up period will be difficult to be done in animal studies. Thirdly, the toxicity induction in these studies has different concentrations, periods and organs of concern. Also stem cells used of different numbers and routes of administration that may affect the regeneration.

\textbf{Conclusion}

The finding from this systematic review demonstrates that Cd induces great injury to different body organs. Using stem cell therapy enhances and improves the regeneration process in Cd toxicity of
different body organs so they can be used as a therapeutic potential to overcome harmful effects of such toxicity.

Diagnostic Accuracy of Recto-Sigmoid Index Evaluation on Barium Enema in Hirchsprung’s Disease

Emma Ratna Fury\textsuperscript{1}, Andy Darma\textsuperscript{2}, Alpha Fardah Athiyyah\textsuperscript{3}
\textsuperscript{1}Resident, \textsuperscript{2}Lecturer and Consultant, \textsuperscript{3}Lecturer and Consultant in Paediatric Hepatology Division, Department of Child Health, Faculty of Medicine, Universitas Airlangga/Dr. Soetomo General Hospital, Surabaya, Indonesia

Abstract

Background: Hirschsprung’s disease is a congenital disorder caused by the absence of ganglion cells in the bowel wall, which results in functional obstruction of the aganglionic segment due to failure of relaxation during peristalsis. The recto-sigmoid index on barium enema may constitute in the diagnosis of Hirschsprung’s disease.

Aim: To evaluate the sensitivity, specificity, positive predictive value, and negative predictive value of recto-sigmoid index for the diagnosis of Hirschsprung’s disease in patients who underwent barium enema examination.

Methods: This retrospective study was conducted in Dr Soetomo Hospital. Medical records of patients suspected of Hirscsprung’s disease who underwent both barium enema examination and diagnostic full thickness biopsy were evaluated. Moreover, the sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of recto-sigmoid index was calculated.

Results: A total of 37 patients were examined; 21 of them were male. The average age was 24.5 (SD 17.34, range 1 month-72 month). Biopsy revealed the absence of ganglion cells in 32 (91.8%) patients. The recto-sigmoid index agreed with the histopathologic diagnosis in 30 (81%) patients. The sensitivity, specificity, PPV, and NPV were 87.5%, 40%, 90.5% and 33% respectively.

Conclusion: Recto-sigmoid index evaluation in barium enema for the diagnosis of Hirscsprung’s disease has poor diagnostic accuracy.

Keywords Hirschsprung’s disease; aganglionic; recto-sigmoid index; barium enema

Background

Hirschsprung’s disease (HD) is a congenital disorder in the form of parasympathetic aganglionic segments in the submucosa or Auerbach’s plexus of the colon, from the internal anal sphincter to the proximal with varying lengths. The clinical symptoms are functional bowel disorders. This disease is caused by the cessation of the craniocaudal migration of the neural crest cells in the distal colon in the fifth week to the twelfth week of pregnancy that functions to form the intestinal nerve system.\textsuperscript{1}

HD occurs in 1 out of 5,000 births and it is the most common cause of neonatal lower gastrointestinal obstruction.\textsuperscript{2} This disease shows a predominance of men over women with a ratio of 4:1. The incidence of HD increases in familial cases to an average of about 6% (ranged between 2% and 18%).\textsuperscript{3}
Specimen examination using full thickness biopsy is the gold standard in enforcing the HD method. This examination must be carried out immediately on fresh specimens, so it is often difficult to carry out due to technical difficulties and a shortage of experts. In addition, this examination is invasive, requiring general anesthesia and sutures at the biopsy site.

The border area between the ganglion and aganglionic segments is called the transition zone, which is usually found in the recto-sigmoid region. This zone can be detected using a radiological examination, namely barium enema. In barium enema examinations, the recto-sigmoid index (RSI), which is the ratio of the widest diameter of the rectum to the widest diameter of the sigmoid colon, is calculated. However, the RSI often gives many false negative results in a certain age group, particularly under 1 month of age.

This research aims to determine the accuracy of RSI in the diagnosis of Hirschsprung’s disease using barium enema by calculating the sensitivity, specificity, positive predictive value, negative predictive value, and likelihood ratio of RSI.

Methods and Materials

This research is a diagnostic test that applied the cross-sectional method. It was conducted from February 2017 to May 2017 at Dr. Soetomo General Hospital Surabaya. The research samples are infants and children suspected of Hirschsprung’s disease who were treated in the neonatal ward, pediatric ward, and operating room of the hospital and underwent barium enema and histopathological examinations. Those whose medical records contain incomplete patient characteristics were excluded. The data used in this research are secondary data collected from the medical records of inpatients with gastrointestinal conditions in the neonatal and paediatric wards of the hospital from February 2017 to May 2017.

The diagnostic accuracy of RSI was obtained by comparing it with the results of full thickness biopsy with calretinin staining, which was used as the gold standard. The RSI was calculated by a radiologist at Dr Soetomo Hospital. If the RSI is greater than 1, it does not support HD, but if the RSI smaller than 1, it supports HD. Unprepared barium enema examination was carried out using a tool from Canon manufactured in 2000. The accuracy is good if the sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and likelihood ratio (LH) have a high value.

Meanwhile, full thickness biopsy was performed by a pediatric surgeon at Dr Soetomo Hospital. The result is positive if ganglia and nerve fibers are not found in the submucosa and muscular layers and negative if ganglia and nerve fibers are found in those layers.

Results

36 subjects between the age of 1 and 72 months with medical records containing a biopsy and barium enema evaluation met the inclusion criteria. Based on their sex, 20 subjects were male and 16 were female. 31 subjects were born at term, the mothers of 2 subjects experienced preeclampsia and eclampsia, and malnourishment was found in 21 subjects. The characteristics of the subjects are presented in Table 1.

Table 2 shows the clinical illustration of the research subjects. Abdominal distension, which occurred to 33 research subjects, was the most frequent complaint. It was followed by delayed meconium passage or delayed first defecation that occurred to 32 patients; constipation, which was experienced by 30 patients; and another congenital disorder, which was down syndrome that occurred to 2 patients.

32 (82%) subjects had positive biopsy results. If highlight is found on ganglia with or without nerve fibers, Hirschsprung’s disease is excluded. Conversely, if highlight is not found on ganglia in the microscope slide, it can be inferred that the patient suffers Hirschsprung’s disease. Table 5.3 shows the results of S100 staining on the full thickness biopsy specimen. The biopsy resulted in 32 positive and 3 negative cases.

The diagnostic values of RSI evaluation can be seen in Table 6. The sensitivity and specificity were 87.5% and 40% respectively. The positive predictive value of anti-*H. pylori* IgG in urine was 90% and the negative predictive value was 33%. The negative and positive likelihood ratio of anti-*H. pylori* IgG was 0.32 and 1.45 respectively.

**Discussion**

The research subjects were dominantly male, which constituted 55.27% (20 patients), whereas the female patients were 44.73% (16 patients). 32 (88%) patients were born at term and only 4 patients (12%) were born preterm with gestational age under 37 weeks. Abdominal distension was experienced by 33 (91%) patients, delayed meconium passage by 30 (88%) patients, and chronic constipation by 30 (90%) patients. These characteristics are in line with the results of previous research, which revealed that most HD patients are male,8,9,10,11,12,13 were born at term,14,15 as well as experienced abdominal distension (Chirdan, 2000; Nasir et al, 2007), delayed meconium passage,16 and chronic constipation that usually persists despite therapy using laxatives.17

Down syndrome was included in the research subject characteristics because the syndrome is a genetic disorder that often accompanies HD.18 Out of 36
patients, 2 (13%) of them have Down syndrome. This is in accordance with the previous research, which found that the prevalence of Down syndrome in HD patients ranges from 10% to 13%.19,20

In this research, four samples that were examined using full thickness biopsy with calretinin staining showed a positive imaging, indicated with blackish-brown color on the ganglia in the submucosa, muscularis propria, and/or lamina propria with or without nerve fibers. Calretinin reagent makes cells or tissues containing calretinin protein into brown, including tissues of the brain, heart, intestines, etc. The colored cells are not only ganglion and neuron cells, but also the morphology unique to ganglia and fibers that are easily recognized in specimens stained with calretinin.21

A diagnostic test has a high value if the sensitivity and specificity is ≥ 90%.22 The sensitivity, specificity, PPV, and NPV were 87.5%, 40%, 90%, and 42% respectively. Other results of anti-\textit{H. pylori} IgG in urine in other countries can be found in Table 7.

The sensitivity of the RSI in this research was 87.5%, which is considered adequate for the initial screening of a disorder or a disease. In general, previous research that assessed the accuracy of RSI resulted in adequate sensitivity, but some argued that the sensitivity is better as the patient ages because the older the patient, the more visible the transition zone. The research based on age groups conducted by Garcia et al.7 showed that the highest sensitivity value was found in the group of above 1-month old patients. However, transition zones that indicate HD are not always present in HD cases. Rosenfield et al.23 discovered that the transition zone is not found in the radiology imaging in HD-positive cases, RSI shows positive results in 32 of 42 patients (72%), and positive cases are more frequently found in children than neonatal subjects.

This research has low specificity, which was only 40%. It suggests that the RSI in the barium enema examination is not good enough to be used to diagnose HD, which may lead to inaccurate management and unwanted outcome, such as discomfort and disappointment of patients, the need of further tests, and the use of unnecessary resources and additional costs.24

The PPV and NPV in the RSI evaluation were 90% and 33% respectively. It means that the subject has 90% probability to suffer from \textit{H. pylori} infection if the test result is positive. Conversely, the subject has 33% probability to not suffer from the disease if the test result is negative.

Likelihood ratio is also a determining value of a diagnostic test. The higher the LR (positive), the more accurate the test in diagnosing which subject is ill and which is not.22 This research resulted in the LR (positive) value of 1.45. Although it is greater than 1, the LR value is insignificant. LR value is significant if the difference is 10 or higher.22

The evaluation of RSI in barium enema examinations can show false negative and false positive results. False negative results in this research may have been caused by the failure to visualize the transition zone in the barium enema examinations due to various factors, such as the inaccurate procedure during rectal washout and inaccuracy in reading or interpreting the imaging results. In certain cases, the causes can be the unclear visualization of the total aganglionic and long HD segments, as well as transition zones. In fact, transition zones are not found at all. Some research emphasized that the transition zone is more visible as the patient ages. In infants under 1-month old with delayed meconium passage of over 24 hours and several cases, the transition zone does not appear (Garcia et al., 2013).

On the other hand, false positive results in this research may have been caused by other factors that resulted in the imaging of transition zones in the reading of barium enema examination. Some of them are meconium plug, microcolon, and colonic atresia and stenosis.25

**Conclusion**

It can be concluded that the evaluation of RSI in the barium enema examinations had adequate sensitivity, but it had low specificity, so it cannot be used as the sole diagnostic tool in the diagnosis of HD. The high positive predictive value indicates that if the test result is positive, it can be used as the basis of a more specific examination, namely rectal biopsy. Further prospective research involving more subjects of certain age groups is necessary to obtain results with good accuracy.

Edible Oils Consumption and the Fatty Acids Profile of the Most Common Consumed Brands in Shiraz, Iran

Erfaneh Aalipanah1, 2, Enayat Berizi1, Anoush Khamoushi1, 2, Morteza Zare1, Zahra Sohrabi1

1Student Research Committee, Shiraz University of Medical Sciences, Shiraz, Iran, 2Nutrition Research Center, School of Nutrition and Food Sciences, Shiraz University of Medical Sciences, Shiraz, Iran

Abstract

Aim: This study aimed to measure edible oils consumption, the most preferred brands and their fatty acid profile compared with standard values in Shiraz, Iran.

Methods: In this cross-sectional study 384 households were assessed. Edible oil types (frying, sunflower, corn, canola, rapeseed, mixed, solid, olive, grapeseed, sesame, and animal), brands, volume of consumed, attention to the label, and changes in the volume of oil consumption compared to the last year were measured. Resistance, fatty acid patterns, total trans fatty acid, smoke point, and saturated fatty acids of the three most frequently consumed edible oils were compared to the standard recommended values.

Findings: The mean of households oil consumption was 40.34 ± 32.88 kg per year. Frying (78.6%), sunflower (60.7%), and olive (37.5%) oils were the most common consumed oil. 57.6% of participants read the labels. 28.9% could not understand the labels information. Compare to the last year, 53.8%, 46.8%, and 55.5% of studied households reported decrease in the liquid, solid and frying oils consumption. Fatty acid profile in majority of studied brands were in the standard range. Myristic acid level in the three major brands of solid oil was out of the standard range. The level of C16:1, C18:1, C18:2, C18:3 in the third common olive oil, C14:0 and saturated fatty acid in the third common frying oil were out of the standard range. The resistance level in the third common corn oil, the first common and the third common frying oil was out of the standard range.

Conclusion: Liquid, solid and frying oils consumption among studied population decrease than the last year, which can be helpful to reduce the risk of chronic diseases. The fatty acids profiles of the most common consumed brands were in the standard range.

Key words: Edible oils consumption; Fatty acid profile; Saturated fatty acids

Introduction

Noncommunicable diseases are one of the main public health challenges in the 21st century. Globally, these diseases are the leading cause of death with unacceptably high burden(1). In 2016, 71% of the world’s deaths were related to noncommunicable diseases. 78% of all noncommunicable diseases deaths occurred in low- and middle- income countries(2). Cardiovascular diseases, cancers, chronic respiratory diseases, and diabetes are the major noncommunicable diseases responsible for these deaths(3). Global Noncommunicable Diseases Action Plan focused on reducing risk factors prevalence as the main effort to prevent and control these diseases(4).

Unhealthy diet is among risk factors for noncommunicable diseases. It is known that the dietary factors have an important role in the development and prevention of these diseases(1). Obesity, as one of the main risk factors for many noncommunicable diseases,
is directly related to unhealthy diet and less physical activity\(^5\). Dietary habits with high trans fats, saturated fats, sugar and salt are associated with increased risk of cardiovascular diseases, diabetes, and hypertension\(^6\). Also, it is shown that the risk of cardiovascular disease and diabetes are influenced by oils fatty acid profile. The risk of cardiovascular events increased following dietary content of high saturated fatty acids. And the higher risk of both cardiovascular disease and diabetes was associated with high intake of trans fat\(^7\-\(^8\). So, fatty acid reduction policies were considered. The World Health Organization, in 1994, recommended that less than 4% of the total fat as trans should be found in oil consumed\(^9\).

Edible oil intake, as one of the important sources of fatty acids, plays key roles in human health. Edible oils are used by consumers in the preparation of everyday meals\(^10\). The type of oil consumed can be relate to risk factors associated with noncommunicable diseases. In the human body, low-density lipoprotein can be raised following excessive consumption of saturated fats and cholesterol\(^11\-\(^12\). Some oils with possible high levels of fatty acids like erucic acid or trans isomers of linolenic acid can be harmful for human health\(^13\). In the other hand some fatty acids that cannot be synthesized by human body are essential and need to be solely supplied through the diet\(^14\). Some oils that are unsaturated or contain omega-3 fatty acids or gamma linoleic acid are healthful\(^15\-\(^16\). So, it is important to examine the composition of edible oils in dietary intake across the world.

Iran as a developing country with a population more the 80 million fasses with burden of noncommunicable diseases. The changing dietary patterns is one of attributed factors to the rise in disease burden in Iran as the same as in the world\(^17\). The commonly used variety of cooking oils in Iran are solid and liquid oils, vegetable oils and animal oils\(^18\). The per capita consumption of edible oils among Iranian population has been increased remarkably\(^19\). Evaluation of household’s patterns of the consumption of oils and fats, and brand preference of consumers for edible oils can be useful for policy makers. Little data is available regarding the status of edible oils consumption in Iran. So, the present study was designed to evaluate oils consumption, the most preferred brands in a sample of Iran population. Also, the fatty acid profile and physicochemical characteristics of frequently consumed edible oils were assayed and compared with reference value recommended by the Iranian Standards Organization.

**Materials and Methods**

This cross-sectional study was carried out on different edible oils consumed by urban households in Shiraz, Iran between July to September 2019. Participants included 384 individuals who willing to participate in the study. Those of the participants who did not response half of the questions were excluded. The protocol of the study was approved by the Ethics Review Board of the Shiraz University of Medical Sciences.

The participants were selected using random cluster procedure. Five of eleven municipal zones (as clusters) were randomly selected. Individuals in each area were randomly selected from the malls and supermarkets consumers in a simple random manner based on the population ratio of that area. Selected consumers (preferably the mother of the household) invited to participate in a face-to-face interview by trained interviewer. A questionnaire included questions about sociodemographic characteristics and brand preferences and consumption pattern of edible oils was used for data collection. Sociodemographic data included age, family size, marital status, job, education, family income, and presence of chronic diseases in the family. Data about the participants’ pattern of oil consumption included edible oil types (frying, sunflower, corn, canola, rapeseed, mixed, solid, olive, grapeseed, sesame, and animal), edible oil brand, volume of used edible oils during the last week, consumers’ attention to the oil label, and changes in the volume of oil consumption compared to the last year (as decreased, no change, increased). Eleven brands reported by participants are coded in alphabetical order from A to K.

The three most frequently consumed edible oils, based on participants’ responses, were selected to analyses the oils physicochemical profiles by comparison to reference standards. For each type, three frequently consumed brans were purchased and sampled in coded packages (as A, B and C). The coded samples were sent to a unique laboratory. Resistance to heat, fatty acid patterns, total trans fatty acid, smoke point, and saturated fatty acids of the oils were measured by standard methods.
High-performance liquid chromatography method\(^{(20)}\) was used to measured fatty acids including Lauric acid (C12:0), Myristic acid (C14:0), Palmitic acid (C16:0), Palmitoleic (C16:1), Margaric acid (C17:0), Stearic acid (C18:0), Oleic acid (C18:1), Linoleic acid (C18:2), Linolenic acid (C18:3), Arachidonic acid (C20:0), Eicosenoic acid (C20:1), C20:2, Behenic acid (C22:0), Erucic acid (C22:1), C22:2, Lignoceric acid (C24:0), and Elaidic C18:1T. The Rancimat technique was used to measure the oils resistance\(^{(21)}\). Measured values were compared to the standard values recommended by the Iranian Standards Organization and reported in three categories including in standard range, not in standard range and not measured (if the measuring was not necessary).

All statistical analyses were done using SPSS software for Windows (SPSS, Inc., Chicago, IL, USA, version 24). Findings reported as mean ± SD, number (%) or median [IQR] as appropriate. Multivariate logistic regression analysis was used to assessed factors associated with the use of each consumption oils. Odd Ratio with 95% confidence interval (CI) are reported for each factor and the statistical significance of the relationship was inferred from the CI.

### Findings

384 individuals participated in this study. The characteristics of the study participants are presented in table 1. The mean of age was 39.4 years and 90.1% were married. Most of the subjects (69.8%) were housekeeper and 45.6% were overweight or obese. Hypertension (19.8%), hyperlipidemia (16.1%), and type 2 diabetes (15.4%) were the most common comorbidities in the studied participants according to their self-reports.

The mean of households\(^{\square}\) oil consumption was 40.34 ± 32.88 kg per year (110.5 grams per day). Of studied households, 66.4% (255 participants) reported that they reuse the consumed oil. 39.8% (153 participants) reported that they use the oil in low flame heat, 56.1% (198 participants) use the oil in moderate flame heat and 8.6% (33 participants) high use flame heat during oil consumption. 246 participants (64.5%) reported that they keep the oil in low flame heat, 32.3% (124 participants) keep the oil outside the cabinet and 36% (14 participants) reported that they keep the oil inside the refrigerator. Table 2 and 3 presented the oil consumption and brand preference of the studied participants for different types of oils. Households consume more frying (78.6%), sunflower (60.7), and olive (37.5%) oils than the other oils. The annual consumption of oil among households who consume sunflower oil (24 kg), solid oil (20 kg), frying oil (18 kg) and corn oil (18 kg) was more than the other oils. For frying oil, B (41.1%), G (13.9%) and C (12.6%) were the most brand preference of the households. For sunflower oil, B (40.3%), C (23.2%) and A (11.2%); For solid oil, C (44.6%), J (10.9), and E (6.9%) were the most popular brand of the households (Table 2). Also, for olive oil, A (16.7%), Imported edible oils (16.0%), and Home-made oils (11.8%) were the most brand preference of the households (Table 3).

Multivariate logistic regression was used to find factors associated with the type of oil consumption in studied participants (Table 4). Factors significantly associated with the use of cooking oil were age (OR, 1.04), academic education (OR, 3.26), income between 30-50 million Rials (OR, 2.54) and stroke (OR, 3.88). Older participant’s age was significantly associated with lower use of sunflower oil (OR, 0.96). Participants who had a diploma (OR, 0.37) or academic education (OR, 0.27), preferred lower solid oil than those who were under diploma. Higher number of family size (OR, 1.53) and the family presence of hypertension (OR, 2.71) were significantly associated with increasing use of frying oil. Older age (OR, 1.03), having diploma (OR, 2.01), academic education (OR, 2.65), and the family presence of hyperlipidemia (OR, 1.83) were significantly associated with increasing use of other oils.

Of the study participants, 57.6% (n=221) reported to read the labels on the oil container and 28.9% (n=111) reported that they could not understand the labels information. Of 331 participants who consumed liquid oil, 53.8% reported decrease in the oil consumption than the last year. Of 109 subjects who consumed solid oil, 46.8% reported decrease in the oil consumption, and 55.5% of 308 subjects who consumed frying oil reported decrease in the oil consumption than the last year.

Fatty acid patterns and resistance in the major brands of oils according to the Iranian national reference standard are presented in Table 5. Fatty acid patterns and resistance to heat in the three major brands of sunflower oil were in the standard range. Myristic acid level in the
three major brands of solid oil was out of the standard range. The level of C16:1, C18:1, C18:2, C18:3 in the third common olive oil (C) were out of the standard range. Fatty acids including C16:0, C18:0, C18:3, C20:0 in the second common corn oil (B) were out of the standard range. Fatty acids including C18:3 and C20:0 in the first common sesame oil (A) and C18:0, C18:2, C18:3, C20:0 in the third common sesame oil (C) were out of the standard range. C14:0 and saturated fatty acid in the third common frying oil (C) were out of the standard range. Also, the resistance level in the third common (C) corn oil, and the first common (A) and the third common (C) frying oil was out of the standard range.

Data are expressed as Odd’s Ratio (95% CI). Cooking oils including corn, canola, rapeseed and mixed oils; Other oils including olive, sesame, animal and grapeseed oil.
Discussion

In the present study the profile of edible oils in a sample of Iran population in Shiraz was assessed. Our findings show that the daily households’ oil consumption was 110.5 grams. Frying (78.6%), sunflower (60.7%), and olive (37.5%) were the most frequent oils consumed by our studied households. Age, income, family presence of chronic disease, education, and family size were among factors associated with the type of oil consumption. 57.6% participants read the oil container labels, 28.9% do not understand label information. The level of fatty acids and resistance to heat in the most frequent brands of different types of assessed oils were in the standard range.

We find that daily use of oil consumption in our study population was 110.5 grams. This finding is lower than that reported for other study. Salehzadeh et al. studied 460 households in Sanandaj city, Iran, and reported that the mean oil consumption per household was 149.2925 grams(22). The difference between findings can be explained by different characteristics of studied population. Our study population were older and had higher education level than Salehzadeh et al. studied population. It is previously show that age and education are associated with edible-oil intake behavior(23). Salehzadeh et al. identified that consumed amount of oil was associated with higher education levels, however, they found that the households with higher education used sesame and olive oils significantly more than those households with low education levels consumed amount of oil was higher education levels(22).

Frying oil was the most frequent consumed oils in our study. Frying oil which is the most common consumed oil in Iran is vegetable and animal oil that is used to fry food at high temperatures. In our study all fatty acid profile of most of common consumed frying oil are in the standard range. The third common brand of frying oil which used by 12.6% of consumers contain myristic acid and SFA out of standard range. In a study by Abedi et al. (24), fatty acids of frequently consumed edible oils and fats marketed in Iran were assessed and they found that the highest and contents of SFA was seen in frying oils. Evidence show that myristic acid and SFA is associated with coronary heart disease. Where the replacement of...
myristic acid and SFA were associated with reduction of coronary heart disease risk\(^\text{(25)}\). Sunflower oil was the second most frequent consumed oils in our study. Also, all fatty acid profile of the most of common consumed sunflower oil are in the standard rang. Similarly, other studies reported that sunflower is the most consumed oils for cooking in India and Turkey\(^\text{(26-27)}\). Compare with the other oils, refined sunflower oil is one of the healthiest and cheapest oils. This oil is suitable for frying due to good thermal stability and high smoke point. In addition, because of ability to keep viscosity and consistency at lower temperature it can good to making salad. In the other hand sunflower oil is containing high proportion of polyunsaturated fatty acids\(^\text{(28)}\). Linoleic is one of the acids that is high in this oil. It is shown that presence of linoleic has hypocholesterolemia effect and can reduce the risk of cardiovascular disease. Also, this oil contains vitamins and natural antioxidants\(^\text{(29)}\). Olive oil was the third most frequent consumed oils in our study. The fatty acid profile of the two most of common consumed olive oil were in the standard rang. Home-made olive oil which used by 11.8% of consumers contains palmitoleic, oelic, linoleic, linolenic acids and SFA out of standard range. Similarly, olive oil reported to be the second most consumed oil in Turkey\(^\text{(26)}\). Olive oil contains high amount of triolein which is beneficial for health and has aging retarding effect\(^\text{(29)}\). In addition, olive oil known to be effective in the prevention of cardiovascular, hypertension, cancer, digestive system and nervous system diseases\(^\text{(29-30)}\).

Our results showed 57.6% of consumers read labels before making a purchase but 42.4% do not read the labels. Similarly, one study reported that 53.4% of the consumers read and 46.6% do not read the labels before purchasing\(^\text{(31)}\). Another study, show that 27% of consumers have never or rarely read food labels before purchasing\(^\text{(32)}\).

This study has some strengths and limitations to highlight. Strengths were as follow; a comprehensive assessment of the various common brands of oils was done. Other than participants oil consumption assessment, their attention to labels and their literacy in this regard were also evaluated. Also, for better precision, all questionnaires were completed by face- to-face interview by the main investigator. Our limitations were as follow; first, data collected for this survey is self-reported households’ consumption and used brands of edible oils in their daily diets. This can lead to an under/overestimation of consumption data and information regarding the used brands. Second, sample size may be not enough to generalize our results to all regions of Iran. Third, this study is limited to the one city, therefore because of the different cultural and economic characteristics, the results cannot be generalized to the other cities in Iran. So, multicenter studies with larger sample size must be down to more clarify households’ consumption and used brands of edible oils.

**Conclusion**

In summary, the present study revealed that frying, sunflower, and olive oils were the most frequent oils consume reported by studied households. We found that oils consumption among studied population decrease compare than the last year, these can be helpful to reduce the risk of chronic diseases as one of the main causes of overweight or obesity. The level of fatty acids and resistance heat in the most frequent brands of different types of assessed oils were in the standard range. These finding show that Iran policies targeting to control the fatty profile of the most of the edible oils were effectiveness, although, monitoring and updating information on the fatty profile of edible oils based on new evidence should be considered by policy makers. In addition, our other finding identifies that 42.4% of studied households do not read the oil container labels before making a purchase. These finding shows the need for learning programs to increase the households’ knowledge and awareness about the appropriate use of edible oil container labels.

2. Global Health Estimates 2016: Deaths by Cause,

Mitigation of the Biofilm Using Nanoparticles By Enhanced by D-alanine and D-proline

Fakhri Alajeeli
Lecture in Al-HIKMA University College –Department of medical laboratory-Baghdad –Iraq.

Abstract

The present study was undertaken to investigate the susceptibility patterns as antifungal and growth of certain D-amino acids inhibitory effects, includes D-alanine (D-ala) and D-proline (D-pro). The obtained results indicated that D-proline acid is potent mostly as antifungal, among tested D-amino acids, then followed by D-ala. The study aim was evaluating the of D-amino acids and nanoparticles against Candida albicans adhered cells and bio-films. Results showed that D-ala MIC value was 25 μg/ml, while in methods of TCP, (D-pro) MIC 50 μg/ml value. Nanoparticles (lithium and silver) and amino acids (D-pro and D-ala) effect in preventing cells adhesion on polystyrene surface and mature bio-film inhibition was studied. Highest inhibition was obtained at D-pro concentration 50 μg /ml, while the lowest at concentration D-ala 25 μg /ml against mature bio-film and cell adhesion.

Keyword: D-aminoacids, D-alanine, D-proline, bio-film, nanoparticles

Introduction

Candida considered as part of human body normal flora that colonize different anatomical sites i.e. digestive tract, oral cavity, skin and vagina 1. Candidacies are the cases where local change in the environment or debilitation of host take place and encourage overgrowth of Candida resulting in candida infection 2. Candida species pathogenicity is reasoned to certain factors being virulence, i.e. adherence, evades host defenses ability, bio-film formation (on medical devices and on host tissue 3. Candida species ability for forming bio-films drug-resistant is significant factor in their human disease contribution. Drug resistance progression within Candida bio-films correlated with a parallel elevation in process of maturation4. Resistant strains increase necessitates new targets search for new agent as antifungal 5.

In all life kingdoms, amino acids are basically found in L-enantiomeric form. Nevertheless, D-amino acids significant amounts are bacteria produced; as major D-amino acids producer at ecosystem 6. In peptidoglycan cross-linking 7. In recent years, D-amino acids are releasing via various species of bacteria in the growth stationary phase and behave as agents controlling modification and assembly of cell wall 8.

Nanoparticles for many years have been known for its importance as antimicrobial broad-spectrum activity against bacteria of G+ and G-, protozoa, certain viruses, and fungi 9, including antibiotic-resistant strains 10. Ag, as agent being antimicrobial, is utilized in burn treatments, creams, wound dressings, and as coatings on various devices in medicine 11.

Material & Method

The Candida isolate from different sources were isolated and identified. All samples were cultured on agar of Sabouraud Dextrose then were aerobically incubated for 24-48 h at 37 ºC 12. Isolated of Candida were identified based on features of morphology on culture media, formation of germ tube, formation of Chlamydospore, CHRO Magar 13 and along Vitek 2 compact system utilizing 14. Bio-film formation by Candida spp. isolates 15.

Nanoparticles preparation

Nanoparticles in de-ionized water were insoluble based on producer 16.

Amino acids (D-ala and D-pro) Minimum
Inhibitory Concentrations Determination

Preparation of D-ala and D-pro was done for determining planktonic cells MIC. Solution of 1 M as stock for every amino acid was prepared in D.W. These solutions were filter-sterilized via membranes passage through of 0.45 µm (Billerica, MA. USA). Such were prepared to obtain various molarities for every amino acid, beginning with 100 µg/ml and following dilution series were preformed with the media till concentrations point ending. Tests of MIC were preformed in ninety six plate’s flat bottom micro-titer (TPP, switerland). With hundred ml broth of Mueller-Hinton, every test well was filling. Addition of 100 µl of solution as stock to 1st test well and mixing, then dilutions series was applied across the plate after that ten µl of microorganism liquid of (Candida albicans isolate) was applied for inoculating every plate well of micro-titer to reach a final size of inoculums $1.5 \times 10^8$ CFU/ml well with culture overnight. Fungi inoculums along broth of Mueller-Hinton but with no a.a. treatment were considered as positive controls growth, while D-amino acid without inoculums considered as negative controls. Under same conditions of experiment, all wells as control were prepared and incubated where plates incubated at 37°C for 48 hr. Wells were tested via naked eye for growth of microbes. MIC values were described as the lowest concentration of D -amino acid inhibiting microbial growth of 80%, comparing to positive and negative controls, and growth of microbes in wells as turbid was detected. Determination of MIC in triplicate was done.

Effect of combination of (D-ala and D-pro) and Nanoparticles(Ag and LiO₂) on the adherent cells and mature biofilm as treatment.

Bio-film assays formation were done utilizing 96 micro-titer well plate, according to protocols of with minor modifications. Briefly C. albicans isolate were cultured overnight in SD Broth and dilution preformed to the resulting culture as 1:100 (SDB + 1% w/v glucose). Suspensions of cells (two hundreds µL) were poured in every well and incubation at 37°C for 48 h was preformed, after bio-film formation for 48 h. Every well of plate micro-titer was filled with hundred ml of media and hundred µl of D-pro fifty µg/ml and D-ala twenty five µg/ml, whereas well of control no amino acids were added. Every concentration for each tested amino acid was triplicate assayed. Incubation for plates was preformed for 24 h at 37 °C. The fungi as planktonic were taken away via dish shaking over tray of waste loaded by sterile D.W. Solution (crystal violet) of 0.1% v/v subsequently was added to every well where plates were stand for staining at room temperature for 10 min. Solution (crystal violet) was taken away through plate submerging in tray of water. Inverting to plates was done and on paper towels was topped to take away liquid as excess and left for air drying. Ethanol of 95% v/v applied to wells stained at room temperature for 10 min for dye solubility. Suspension of fungi in every well was well mixed and its OD was read at 490 nm at micro-plate reader. Also the effect of mixing 25 µg/ml of D-ala with twenty five µg/ml of Lio2, fifty µg/ml silver and fifty µg/ml D-pro with twenty five µg/ml of Lio2, fifty µg/ml silver were prepared by loaded 50 µl of each amino acid and nanoparticle with 100 µl of medium after biofilm formation for 48 h and the other steps were the same.

Statistical Analysis

The experiments in the current study was designed as factorial experiments (2×6), every combination treatment was replicated 3 times. By SPSS 2010 program, Duncan Multiple test and ANOVA were applied to show differences among means at (p < 0.05).

Result and Discussions

D-ala and D-pro Minimum Inhibitory Concentrations (MIC) Determination

Table (1) expresses values of MIC for D-amino acids in respect to isolate of C. albicans. D-proline MIC was 50 µg/ml. The MICs for D-alanine was 50 µg/ml

Table (1): (D-ala and D-pro) MIC means against isolate of C. albicans.

values of MIC for D-lysine and D-alanine were 18 and 39 µg/mL\(^{-1}\)\(^{20}\). In other study,\(^{21}\) recorded D-isomers antifungal activities, L-isomers with no detectable activity against species under test (MIC more than two hundreds µg/µL). D-lys as one among D-amino acids tested revealed activity as highest against *Candida albicans* with a 6 µg/µL value of MIC. Least species susceptibility was *Candida glabrata* of treatment to mostly D-amino acids. Growth of *Candida krusie* was extensively mostly inhibited via D-lys then by D-ala, while considerable D-ser higher concentration was required for growth inhibiting all species tested of *Candida*. It is obvious, D-pro exhibit no significant activity as anticandidal against tested species.

Antimicrobial peptides affect dendrites’ cells recruitment and inflammation, thus immune response modulating\(^{22-23}\); some AMPs can induce apoptosis\(^{24}\). Limited studies were reported regarding ultra-structural level of D-amino acids effect with fungal cells. It was proposed that *C.albicans* exposure to D-amino acids yield membrane changes significant, cell surface pits formation and ultimately poress formation and death of cell\(^{25}\).

**Effect of combination of (D-ala and D-pro) and Nanoparticles(Ag and LiO\(_2\)) on the adherent cells and mature biofilm as treatment.**

Highest mature bio-film and adherent cells were (70.714 and 52.848)% in D-Pro(conA) acid of 50 µg/ml with high differences of significant comparing to other concentrations which of no significant against mature bio-film and planktonic cells. Although the lower percentage value (52.509) of mature bio-film and adherent cells, inhibition was noticed for isolate of *C.albicans* at combination D-amino acids (Ag50+AL25) µg/ml of sub-MIC and sub-MIC of nanoparticles(Ag), respectively, Tabel(2),fig(1)

Observed report showed that in assay of bio-film, both L- and D- Asp, Glu, and Cys enantiomers with 40 mM concentration inhibit significantly formation of *S. mutans* bio-film, where other A.A. not. Asp and Cys anti-bio-film activity were higher than of Glu. At 20 mM concentration, Glu significantly did not prevent formation of bio-film. The reported that D-aspartic acid inhibit biofilm formation on tissue culture plates similar to, which observed that the high concentration above (10mM) inhibited the growth of *staphylococcus aureus* planktonic cells. In recent years, D-amino acids proved to have significant roles in regulating disassembly and bacterial bio-films formation, and might express bio-film prevention general strategy. Hassan et al. (2013) stated that results obtained revealed the Ag-NPs MIC50, Grisofulvin and Itraconazole on *T. mentagrophytes* and *C. albicans* which were (8±0.18) µg/ml, (4±0.25) µg/ml and (2±0.10) µg/ml respectively, on *C. albicans*. Such result confirms requiring investigation agents as alternative or drugs combinations, i.e. SN use with drugs as antifungal. Combinations use along lower concentrations drug able to elevate efficacy of drug and minimize drugs adverse effects. Based on SN effect yeast cells via membranes attacking, hence membrane disruption potential. Such authors noticed, via microscopy as transmission electron, pits formation on the *C. albicans* membrane surfaces and ultimately pores formation and subsequent death of cell.

Detection the Serogroups of Escherichia coli isolates from Urine sample of UTI patients

Fakhri S.Ahmed Ph.D
Lecture in Department of medical laboratory technology, Al-Hikma University college

Aims: Determining of E.coli serogroups which isolation from UTI patients

Patients and Methods: the study was conducted between September 2019 to April 2020 and they was collected 40 sample from patient how are diagnosis with UTI during this study .

Results: From the UTI patients individuals, 40 strains were identified in which O serogroups showed 8(30%) and 2 (20%), respectively, of occurrence in those strains. Moreover, the enterohemorrhagic E. coli (O157 H7) and the enteroaggregative E. coli (O44 H7) were detected in two strains of the UTI-based urine samples only. For the antibiotic resistance properties of the biofilm positive producers isolated from the UTI urine samples, multidrug resistance was revealed in 60% of those isolates; however, only 20% of the biofilm negative producers from the UTI urine samples showed the MDR characteristics. Biofilm was identified in 75% of the UTI urine. For the antibiotic sensitivity test, the results demonstrated that the sensitivity rates to Imipenem, Amikaci, gentamicin, and tobramycin were 90%, 100%, 65%, and 40%, respectively, in the UTI strains.

Conclusion: The herein study provides thorough data about the Escherichia coli based biofilm,

Keywords: Biofilm, E. coli, UTIs, Resistance of antibiotics, uro-pathogenic Escherichia coli.

Introduction

Escherichia coli is a well-known resident of the human and animal gastrointestinal system. E. Coli establishes a significant symbiotic connection together with its habitat, performs a significant act in encouraging the stabilization and maintenance of ordinary gastrointestinal homeostasis of the macrobiotic. For the commensal property, E. coli is contained in the gastrointestinal tract causing illnesses only in occasion cases. However, even E. coli of non-pathogenic-commensal natures can induce illnesses in immunosuppressed or in the GIT-barrier-based defected patients 1 Virulence factors are acquired by these strains playing very important roles in providing these bacteria with specific properties to perform intestinal-niche-based adaptation and generate illnesses. These properties are obtained by the bacteria via genetic materials transferring for other bacteria or environment such plasmids, horizontal gene transfer, and/or bacteriophages. E. coli can generally be categorized into enteric/diarrhegenic E. coli or extra intestinal E. coli . More specifically, E. coli can be classified into six “pathotypes” of enterohemorrhagic E. coli (EHEC), enteropathogenic E. coli (EPEC), entero aggregative E. coli (EAEC), enterotoxigenic E. coli (ETEC), diffusely adherent E.Coli (DAEC), and enteroinvasive E. coli (EIEC) 2

One of the more often recognized infections in humans caused by uropathogenic Escherichia coli (UPEC) are urinary tract infections (UTI) that include pyelonephritis and cystitis. The UTIs can rely on various factors such as host immune responses, anatomical properties, and the bacterial virulence. For the E. coli to induce an infection, the bacterium has to have the abilities performing host-cell-related adhesion, tissue bacterial colonization, intracellular invasion (in some bacteria), bacterial proliferation, and blood-dependent dissemination to different body systems. Bacteria can be present in the urine as a result to colonization generating no symptoms as it is named asymptomatic bacteriuria 3. Asymptomatic bacteriuria based illnesses may not require medical attention, in fact, it can provide the immune system with proper defense mechanisms
against other strains of *E. coli*[^4]. UTI treatment with antibiotics can be successful; however, the problem of resistance by the bacteria to antibiotics is increasing leading to recurrent occurrence of the UTIs especially in the presence of biofilm formation and virulence factors[^5].

The aim of this study is determination of serogroups of *E. coli* which are isolated from UTI patient.

### Patients and collecting samples

There were 150 urine samples were collected from patients with the symptoms of urinary tract infection who had been admitted at Al-Yarmouk teaching hospital in Sept 2019 tell April 2020. To confirm infection with *E. coli*, the samples were cultured in the EMB Agar and Blood Agar and were identified by the Gram stain, Indole test, and Citrate and MR-VP tests. The laboratory criteria of acute urinary tract infection with *E. coli* included one positive culture of colonies with a minimum number of 105 colonies per 1 ml of urine collected in the urology department of Al Yarmouk teaching hospital in Baghdad between September 2019 tell April 2020.

### Serotyping

According to Liu et al., 2015. The test included O and H antigenic based identification using an antibody (polyvalent and monovalent)-detected agglutination test. The test was performed using methods concluded from.[^6]

### Antibiotic sensitivity test

The antibiotic sensitivity test depended on Kirby Bauer disc diffusion method.

### Biofilm formation

According to Nourbakhsh et al., 2016 the ability of *E. coli* isolates to produce biofilms, biofilm test was performed in laboratory based on the Micro titer Plates Assay as follow as:

The micro titer plate method was used for evaluating the formation of UPEC biofilm. The Micro titer Plates Assay method, such as ELISA, the color-producing chromogenic in this technique is fuchsine, whose color intensity is directly related to the concentration of biofilm.[^7]

### Statistics

BM SPSS software v20.0. (Armonk, NY: IBM Corp) was used to process the observed data. Chi-square and Fisher’s exact tests were performed. Data, sometimes, were displayed as numbers and percentages (%). The null hypothesis was not followed when *p* is less than 5%.

### Results

#### Serotyping

From the UTI patients and healthy individuals, 40 and 20 strains, respectively, were identified in which O serogroups showed 7 (35%) and 3 (15%), respectively, of occurrence in those strains. Moreover, the enterohemorrhagic *E. coli* (O157 H7) and the enteroaggregative *E. coli* (O44 H7) were detected in two strains of the UTI-based urine samples only, figure 1

Figure 1: Total of serotype percentages of *E. coli* isolation from UTI patient
Antibiotic sensitivity test

For the antibiotic resistance properties of the biofilm positive producers (BPPs) isolated from the UTI urine samples, multidrug resistance (MDR) was revealed in 60% of those isolates; however, only 20% of the biofilm negative producers (BNPs) from the UTI urine samples showed the MDR characteristics. For the antibiotic sensitivity test, the results demonstrated that the sensitivity rates to imipenem, amikacin, gentamicin, and tobramycin were 90%, 100%, 65%, and 40%, respectively, in the UTI strains, figure 2

Discussion

UTIs are well-known cases of illnesses with high incidence rates in humans, and UPEC plays an important role in the etiology of these infections. For those bacteria, a wide range of virulence factors are considered as critical components of the UPEC providing those strains with different capabilities such as adherence to the host cells enhanced by some factors; for example: adhesins that play huge roles in bacterial attachment to epithelial cells of the urinary system.

For the O serogroup, UPEC-associated O-serogroups were detected in high rates, 60%. The current work revealed that 2 (10%) of the strains isolated from the urine samples were not placed in a certain serogroup. This agrees with who found that in their results about (28%) of their strains were unidentifiable in a certain serogroup. have also found that 25.5% of their recognized strains were from unknown serogroups. Moreover, Gilbert NM, Lewis AL, observed the same rate, 25%, of the unidentifiable strains.

Moreover, the enterohemorrhagic E. coli (O157 H7) and the enteroaggregative E. coli (O44 H7) were detected in two strains of the UTI-based urine samples only. This was also reported by who found that strains of UPEC from UTIs but not the stool were able to produce UTIs in murine.

For biofilm formation, this bacterial mechanism is considered as a defense strategy to defeat body boundaries and escape body immune system components. The biofilm was recognized in human infections in a rate of 60%.

Management of Non-Vital Teeth Discoloration with the Internal Bleaching: A Case Report

Dewi Fitria Anugrahati¹, Rizky Ernawati¹, Windi Irsya¹, Yulianti Kartini Sumur¹, Sukaton², Kun Ismiyatin²

¹Resident of Conservative Dentistry Department, Faculty of Dental Medicine, Universitas Airlangga, Surabaya, Indonesia, ²Staff of Conservative Dentistry Department, Faculty of Dental Medicine, Universitas Airlangga, Indonesia

Abstract

Tooth discoloration due to intra coronal bleeding after trauma can cause aesthetic disturbances and appearance. Internal bleaching is a non-invasive method to restore tooth color which is performed after endodontic treatment by placing a strong oxidizing agent in the pulp chamber. Aim of this study was to report the success of internal bleaching procedure to restore discolored teeth due to trauma. A 44-year-old female came to Conservative Dentistry Universitas Airlangga with chief complaint of the upper right insisor tooth looks darker than the adjacent teeth. The patient had fallen 10 years ago from her motorcycle and her tooth had been painful and then the pain disappeared. In intra oral clinical examination, it showed that tooth 11 had discoloured, vitality test of tooth 11 showed no response to electric pulp test. Radiographic view showed that radiolucen in periapical area and no fracture was found. At the first visit, treatment of single visit root canal using rotary instrument and gave dressing calcium hydroxide. A week later on the second visit, internal bleaching with hydrogen peroxide 35% was done. After bleaching, calcium hydroxide was applied to neutralize the oxidizing agent and then re-evaluated for the color. At the third visit, it showed that the tooth colour was obtain as desire from C3 to A3 (Vitapan Classical). The internal bleaching procedure on the traumatized tooth was the best option to restore the function and aesthetics according to the original tooth colour and also provided benefits in terms of saving time, lower price, and maximum results.

Keywords: non-vital teeth, internal bleaching, discoloration

Introduction

Discoloration of teeth can be caused by intrinsic, extrinsic or a combination of both. The occurrence of discoloration is caused by the incorporation of intrinsic chromatogenic materials into dentine and enamel during odontogenesis or after the eruption of teeth¹. The intrinsic cause of discoloration in pre-erupted teeth is the provision of tetracycline or high number of fluoride exposure. In addition, it also can be caused by hereditary diseases such as amelogenesis imperfecta and dentinogenesis imperfecta². After the eruption of teeth, the main cause of discoloration is the pulp necrosis, the deposition of the blood component to the dentine tubules after trauma or pulpectomy, and secondary dentine deposition due to aging or iatrogenic²,³. Foods and beverages such as coffee, tea, red wine, carrots, oranges, and tobacco are primarily responsible for extrinsic stains³.

Teeth whitening offers a conservative and aesthetic solution and is an option because it is not invasive, such as crowns or porcelain veneer. The non-vital teeth whitening technique puts the oxidizing agent inside the pulp chamber in direct contact with dentine. Chemicals which are often used as bleach are hydrogen peroxide 35%⁴. Walking bleach technique is a bleaching method...
by placing the active ingredient in the pulp chamber, followed by closing the tooth cavities. The results obtained depends on the etiology of discoloration and for a satisfactory result bleaching can be carried out for two to four times the application\textsuperscript{4}. The case report aims to demonstrate the success of non-vital teeth whitening that has discoloration after the endodontic treatment performed using a walking bleach technique with a good prognosis and without side effects.

**Case Report**

A 44-year-old female came to Conservative Dentistry and Endodontics Clinic Airlangga University with chief complaint of the upper right incisor tooth looks darker than the adjacent teeth. Patient had fallen 10 years ago from her motorcycle and her tooth had been painful and then the pain disappeared. The patient wants her tooth colour same as the adjacent teeth. Patient does not has a history of systemic diseases.

Extra oral examination shows symmetrical face, no abnormalities of the lips, the left and right mandibular glands are unaffected and painless. Intra-oral examination showed that crown of tooth 11 is darker in colour than the adjacent teeth. Hygiene of the oral cavity is good, it shows an overview of radiolucency on periapical area. Examination of negative percussion test, negative bite test and negative palpation.

Radiographic view after endodontic treatment shows the radiopaque depiction of the crown to the apex which means that it fills the hermetic root canal. There is widening of lamina dura, alveolar bone resorption and radiolucen in periapical area which are smaller than before endodontic treatment.

On the first visit, the patient was given an explanation of the procedure to be performed. The cost of treatment, side effects can occured, possible outcome to be achieved, failures and complications about the use of bleaching material understood by the patient and then carried out the signing of informed consent. The next step was to do single visit root canal treatment using rotary instrument and given dressing calcium hydroxide.

A week later on the second visit, internal bleaching with hydrogen peroxide 35% was carried out for 7 days. Previously, it was carried out tooth colour recording before treatment and intra oral photographs. Previously, the tooth was cleaned using a rotary brush and pumice powder to obtain the actual colour. The tooth colour was matched using Vitapan classical shade guide. In this case, the initial colour was C3 and the colour which want to achieve was A3 colour.

The working area was isolated with rubber dam and coronal access was carried out by reopening the temporary patch using a rounded diamond bur. The root canal filler material was ejected to a depth of 2 mm below the CEJ by using a hot plugger that has been given a stopper to provide a place for cervical seal material. The depth of filler intake was confirmed again using periodontal probe. Tooth 11 cavity was irrigated with sterile aquadest until clean and dried. The cervical seal was made by applying 2 mm thick glass ionomer cement following the cervical stripe outline. The resultant shape from a facial view is the “bobsled tunnel” outline.

The outline from the proximal view resembles a “ski-slope” (Figure 1, 2).\textsuperscript{5} After the cervical seal dried, the bleaching material in the form of hydrogen peroxide gel 35% (Opalescence Endo, Ultradent Product Inc., USA) was applied to the labial part, then the pulp chamber was given with cotton pellet and covered with glass ionomer cement. The patient was instructed to control 1 week later.

On the third visit, a subjective examination was conducted, it was no complaints from the patient. Objective examination showed that tooth discoloration from C3 to A3 (Vitapan Classical). Two weeks later, the tooth was restorated by composite materials which in accordance with the tooth colour.

On the third visit, a subjective examination was conducted, it was no complaints from the patient. Objective examination showed that tooth discoloration from C3 to A3 (Vitapan Classical). Two weeks later, the deposition was carried out by composite materials which in accordance with the tooth colour.
Tooth staining especially in the anterior teeth can interfere with a person’s appearance. In addition to invasive treatment, such as the making of crowns or veneer, tooth whitening or bleaching can be an alternative treatment. Contrary to the making of crowns or veneer, tooth bleaching is a relatively non-invasive treatment. The tooth bleaching which has been carried out before root canal treatment can be done with internal bleaching treatment. In this case, the tooth discoloration in the tooth 11 is caused by intrinsic factors.

Necrosis in the tooth 11 is caused by trauma that occurred about 10 years ago. Trauma to the tooth causes intra pulpa bleeding and erythrocytes lysis. Blood or blood components that bathe the pulp chamber will enter the dentinal tubules diffusely, resulting in a discoloration of the tooth crown. The discoloration which occurs relates to how long the pulp has become necrosis, the longer the colored compounds are in the pulp, the greater the degree of discoloration.

Bleaching is a more conservative alternative
treatment than making of the crown and labial veneer in the stained teeth. The chemical process in bleaching occurs when the whitening material is applied to the teeth, usually using oxidizing materials such as hydrogen peroxide, chlorine or sodium hypochlorite. Although the bleaching process is a complex chemical process, the basic principle of the majority of bleaching processes is the step-by-step oxidation of the dye with decomposition. Bleaching material is oxidizing, reacting to the organic structure of a hard tooth tissue, pigments which have long chains slowly degraded into simple molecules such as carbon dioxide, oxygen and water which have a brighter colour, inorganic molecules are not broken down, the reduction-oxidation reaction which occurs in the bleaching process is known as redox reaction. In general, unstable peroxide becomes unstable free radicals. These free radicals oxidize other molecules.

Hydrogen peroxide is a strong oxidizing agent. The use of high concentration of hydrogen peroxide must be careful because it is unstable thermodynamically and can explode, because it must be placed in the refrigerator and stored on a dark container. Bleaching materials can be applied using the plastic and plugger instruments and must be replaced every 3-7 days. Usually it takes 2-4 sessions depending on the intensity of discoloration. The patient must be reminded to pay attention to her teeth everyday so as not to overbleach. When this material is in contact with teeth, hydrogen peroxide will lose and penetrate into the surface of enamel and dentine due to the relatively low molecular weight of peroxide (30 g/mol). These reactive molecules attack dark chromophore molecules and long chains and break down these molecules into smaller, more colourless, and more diffuse molecules.

The success of the intracoronal bleaching in endodontically treated teeth depends on the etiology, the precise diagnosis, and the selection of appropriate bleaching techniques. Walking bleach technique is chosen because it takes a shorter time, safer and more comfortable for the patient. Internal bleaching indications on the teeth that have been treated endodontically are: discoloration in the pulp chamber, dentine discoloration, discoloration which can not be lost with extracoronal bleaching. Internal bleaching contraindications: superficial discoloration, enamel formation with defects, severe dentine loss. The cervical seal/barrier used is the glassionomer to cover endodontic obturation. The coronal height closes the dentinal tubules and corresponds to the external epithelial attachment. The barrier thickness is approximately 2 mm, and is located 1 mm below the cemento-enamel junction.

This protection is carried out to prevent the occurrence of internal bleaching side effects in the form of external root resorption. Resorption occurs because of chemicals diffused through the dentine tubules and cementum defects. The leakage which occur can cause cementum necrosis, inflammation of the periodontal ligament so that eventually root resorption occurs. The application of bleaching material leads to denaturation of dentine protein with oxidizing agents and pH acid which induces foreign body reaction. A low pH of bleaching material can damage tissues due to the optimal acidic environment for osteoclas activity results in the root resorption.

In this case, restoration after internal bleaching using a composite resin. The remaining peroxide of the bleaching material, especially hydrogen peroxide can affect the strength of composite bonding, so it is advisable to wait several days after bleaching before the composite restoration is performed. The placement of calcium hydroxide in the pulp chamber for several days is useful for buffering acidity caused by bleaching material.

**Conclusion**

Internal bleaching procedures for traumatized teeth was the best option to restore the function and aesthetics according to the original tooth color.

Abstract

Background of the study: One type of assisted reproductive technique is intracytoplasmic sperm injection (ICSI) Despite use ofintracytoplasmic sperm injectionICSI it remain has low birth rate rate due to failure there are many markers associated with poor predict the outcome one of these factor effect outcome intracytoplasmic sperm injection ICSI presence of antithyroid antibody ineuthyroid patient

Aim of study: To examine the effect of antithyroid antibody on pregnancy results following the in vitro fertilization and fetus transmit

Methods and patients: Cross section study conducted at AL-Sader infertility center a total of eighty one Iraqi women were enrolled in this study of them 22 positive antithyroid antibody, 59 negative antithyroid antibody were undergone intra-cytoplasmic sperm injection ICSI in Al-Sader infertility center. The group of the study involved only euthyroid women outwardly any clinically showed autoimmune illness.

Result: there was higher significant difference p value<0.004 in fertilization rate number of available embryos p value<0.003 and number of transfer embryos p value< 0.001 among study group which was higher in group of women with antithyroid negative followed by group with antithyroid positive in infertile euthyroid women Conclusion: patients with antithyroid antibody associated with poor pregnancy outcome in infertile euthyroid women undergoing intracytoplasmic sperm injection ICSI

Keywords: antithyroid antibody, pregnancy outcome, invitro fertilization, embryo transfer

Introduction

The definition of Subfertility when the husband and the wife couldn’t conceive following one year of unprotected sex affair (and there is no other cause, such as breastfeeding or postnatal amenorrhea) (1). It affects 12 –15% of all couples (2). Subfertility developed due to many factors and cases including both male and female factors. It classified to primary subfertility and Secondary subfertility (3). It has been estimated that subfertility affects 12-15 percent of all couples (4), where seventy percent struggle with initial subfertility, i.e. with no conception in the past and theirt percent secondary subfertility when the couple had conceived previously and whatever the outcome (5). The couple suffering infertile are advised to be tested for the elements that might be impairing fertility. The results of these measurements could be used as this information by the specialists of infertility to advise the husband and the wife regarding the possibilities of subfertility etiologies and to provide special plan for treatment for the special treatment of the couple. Its crucial to notice that the
husband and the wife can have many influences that contribute to subfertility; thus, a full primary diagnostic test must be be taken to find the main subfertility’s causes, the couples evaluations is performed on the same time, the treatment, evaluation, and recognition of subfertility makes the partners stressed and worried. The emotional state of the couple should not be ignored by the clinicians which may include marital discord, anxiety, anger, and depression. Information must be informative supportive.

Treatment of subfertility included both male and femal and include medical and surgical approaches. The conception of Assisting is the advice of normal conception through various forms of science research. The advancement of the enhanced approaches, specifically in forms of stimulations of controlled ovarian and ovulation induction, enabled the success process of anovulatory female treatment. Assisted conception includes three primary types; injection of intracytoplasmic sperm, insemination of intrauterine, and in vitro fertilisation. Previous studies showed some links between Female infertility and the thyroid dysfunction, therefore we tried in this work to examine the influence of antithyroid antibody on pregnancy results utilizing the technique of embryo transmit and in vitro fertilization among Iraqi women with subfertility.

Methods and patients

This study was planned as a prospective study performed in Al-Sadder Teaching Hospital/fertility center, Najaf, Iraq during period from 20th March till 31st December 2019. These patients were eightyone subfertile couples who were underwent Intracytoplasmic sperm injection

Inclusion criteria:

1. Age ranged from eighteen to forty-five years
2. The female has not been through treatment of adjuvant like glucocorticoids and thyroid hormones at the the research is being taken.
3. Normal TSH
4. Negative for LAC “lupus anticoagulant” and ACA “anticardiolipin antibody” before the start of the induction of ovulation
5. Exist of morphologically normal spermatozoa within sperm (male factor)
6. Normal utrine cavity

Exclusion criteria

1. Female partner with thyriod dysfunction
2. Female partner with hyperprolactinemia
3. Azoospermia
4. Confirmed endometriosis.

All women were asked to be seen at cycle day 2 (CD2) to evaluate if she was suitable for ICSI program, the history was taken from the patients included name, age, menstrual history, type of subfertility whether primary or secondary, duration and causes of subfertility, history of previous IVF and its outcome, family history, drug history. Examination had been done to each patient including body weight and height. The Body mass index (BMI) measured as individual body weight in Kg divided by square of her height in meters. Trans-vaginal ultrasound (TVUS) scan was performed to all patients using vaginal probe (5-7 MHZ). The baseline scan done to measure the endometrialthickness(mm), number of antral follicles (AFC), check the uterus and ovaries for any pathologies like fibroid, polyp, or ovarian cysts. All women sent for hormonal assay include FSH, LH, estradiol, Thyroid stimulating hormone (TSH), prolactin, anticardiolipin antibody, lupus anticoagulant and antithyroid antibody. Also routine screening blood tests of both partners for human immune deficiency virus (HIV), hepatitis B virus, (HBV) and hepatitis C virus (HCV). Before treatment, all women partners sent for seminal fluid analysis

Controlled ovarian hyperstimulation protocol

Using of one of following protocols in study.

1. Agonist GnRH protocol (short protocol)

GnRH agonist has been initiated by giving 0.1mg/day of triptoreline (decapetyl) from the cycle day two. The gonadotropins are started from the cycle day three with one of the following drugs: Recombinant FSH or HMG and doses according to patient till the follicle maturation monitoring by transvaginal ultrasound once
the follicles (dominant follicle) were reached diameter 18 or more, trigger was given to the patient. Ovum pickup was done using transvaginal ultrasound at 34 hours after trigger was given in dosing differed, depending on the age of patient and the response to stimulation.

2. Agonist GnRH protocol (Long protocol)

The agonist GnRH is given in late luteal section at cycle day 21 of preceding cycle. When the pituitary is down regulate. Transvaginal ultrasound was done to follow the maturation of follicles then added HCG, a minimum 3 follicles turned to be diameter 18 or more then ovum picked up after 34 hours.

3. Antagonist protocol:

On antagonist protocol gonadotrophin (human menopausal gonadotropin, recombinant FSH) started at day 3 of cycle, antagonist regime by used cetrotide (0.25 mg) starting after a week or at the time the dominant follicles reach the with a diameter of 14 mm. Once the follicles were have reached diameter 18 or more, trigger was given to the patient. Ovum pickup was done using transvaginal ultrasound at 34 hours after trigger was given in dosing differed, depending on the age of patient and the response to stimulation.

Ova pick up (OPU): Oocyte collection was performed 34 to 36 hours after trigger given; the procedure of oocyte retrieval was performed under general anesthesia. Under ultrasound guidance, aspiration of follicles done by using thin needle (REPRO Line, Germany) the researchers aspirated the fluid of follicular using gentle suction. The aspirated fluid then sent immediately to laboratory to be tested using a microscopy by embryologist to detect the oocytes and then the collected oocytes were transferred into culture medium in incubator. After that denudation process was performed by phenol red, the embryologist scored the oocytes using the inverted microscope, also he noted the maturation phases of the oocytes. Meanwhile sperm preparation was done; semen specimen was obtained after 3-5 days of the sexual abstinence in labeled standard sterile disposable plastic container at the day of pickup. Semen analysis was evaluated using the criteria of WHO pre and post the preparation process of semen. The preparation of semen included rinsing from seminal plasma, leukocytes, and bacteria. this approach can remove prostaglandins that cause uterine contraction.

ICSI: Intracytoplasmic semen injection was done on the whole oocytes which are morphologically intact that thrusted out the polar body number one (metaphase II). The procedure ICSI was as follow, a spermatozoon with single motile was chosen and immobilized thru pushing tail among dish’s bottom and the 33 microneedle. After that, the tail-first was aspirated by the cell of the sperm into the pipette injection, a mature oocyte which was matured was installed thru grabbing the pipette with the body of first polar at the position of six o’clock. The plan of oocyte at 3 o’clock position, the pipette of injection was introduce at 3 o’clock and oolemma rupture was achieved by small suction. The cell of sperm was given into the oocyte accompanied with thee minimal volume of medium and the pipette could be withdrawn cautiously, the procedure conducted in a dish of plastic microinjection including 10-μl droplets of (ferticult TM-HEPES, Belgium) buffered medium covered with mineral oil. After injection steps, oocytes were cultured and washed in micro-droplets wrapped with oil which was light paraffin. They are incubated at 37°C in an environment of PH of 7.2-7.4 5%CO2, and 5%O2. Next is embryo cleavage and fertilization, the oocytes were examined for fertilization next day after ICSI. Oocytes were deemed to be natural fertilized as 2 polar bodies were presented simultaneously accompanied with 2 clear observable pronuclei (two PN).

Intracytoplasmic sperm injection was carried out on all morphologically intact oocytes that have extruded the first polar body (metaphase II). In Intracytoplasmic sperm injection (ICSI) procedure, a single motile spermatozoon is selected and immobilized by pressing its tail between the 33 microneedle and the bottom of the dish. The sperm cell is then aspirated tail-first into the injection pipette, a mature oocyte is fixed by holding pipette with the first polar body at the 6 o’clock position. The plan of oocyte at 3 o’clock position, the injection pipette is introduce at 3 o’clock and rupture of the oolemma is ascertained by slight suction. the oocyte is delivered into the semen cell with minimal volume of medium and the pipette can be outgoing accurately, the steps executed in a plastic microinjection dish involving 10-μl droplets of (ferticult TM-HEPES, Belgium) buffered medium covered with mineral oil. in accordance with injection steps, oocytes cultured and rinsed in micro-droplets...
enveloped with paraffin oil. They sperm are brood at 37°C in an an weather of 5% O2, 5% CO2 and PH of 7.2-7.4. Subsequent is embryo cleavage and fertilization, the oocytes were investigated the next day for fertilization after ICSI. In addition, they are deemed oocytes to be normally fertilized when two polar bodies are presented together with two clearly visible pronuclei (two PN).

Fertilization is assessed sixteen–eighteen hours post the ICSI and the cleavage rate was tested two–three days after the retrieval of oocyte. Transformation of embryo was conducted after the retrieval of oocyte process on the fifth day at the phase of blastocyst. The subjects of the study were scheduled for embryotransfer (embryos were transferred by using trans-cervical catheter either fresh or freeze-dried embryos (Cook catheter Ob/Gyn, USA) to the uterus under abdominal ultrasound guidance). The pregnancy was assured by measuring the serum HCG concentration 12 days after the transfer process of embryo. The phase of Luteal was supplied by 50mg progesterone in oily injection IM and lasted till the detection of fetal heartbeat.

Main outcomes measures: In this study were duration of stimulation (days), numbers of (75 IU) gonadotropin ampules, estradiol levels on day of hCG, mature follicles numbers, endometrial thickness, numbers of oocytes retrieved, numbers of total embryos, number of embryo transfer, +ve pregnancy test, then u/s to confirm pregnancy and follow up until 12 weeks. Also measure Women’s serum samples for antithyroid antibodies.

Regarding the thyroid peroxidase antibody, as being <9 IU/ml and for thyroglobulin antibody as being <4 IU/ml, the normal values were accepted. The samples of Blood taken from venous blood from your arm IU/ml after collection of the whole blood allow the blood to clot by leaving it undisturbed at room temperature this usually taken 15-30 minute removed the clot by centrifuged at 1000-2000 x g for 10 minute in a refrigerated centrifuge the resulting supernatant is a serum then send to laboratory to measure value of antithyroid antibody

**Results**

A total of 81 patients were enrolled in the study. The parameters were summarized in the table (1):

There were no significant difference in basal hormones level (s.FSH, s.LH, s.TSH, s.prolactin and E2 at day of trigger) between antithyroid positive and antithyroid negative groups (table 4). and there was significant difference in total gonadotrophin dose and basal E2.

Statistical analysis appeared there were no essential difference regarding duration of stimulation, number of retrieval oocytes between two groups.

In the antithyroid positive group, the fertilization rate, the number of available embryo and the number of transfer embryo were dramatically lower than antithyroid negative group.

Regarding the outcome in patients in antithyroid positive groups and antithyroid negative groups, the antithyroid negative groups had higher rate of abortion compared to antithyroid positive groups (P value <0.001) while the continuity of pregnancy was higher in the antithyroid negative groups compared to antithyroid positive groups (P value <0.001) (figure 1).

In contrast to that there was no essential difference in the failure to get pregnancy between antithyroid positive groups and antithyroid negative groups (figure 1).

![Figure (1): The outcome in patients in antithyroid positive groups and antithyroid negative groups.](image)
Discussion

The present cross section study assessed the relationship between antithyroid antibody and pregnancy outcome intracytoplasmic sperm insemination (ICSI), hence a total of eighty-one Iraqi women were enrolled in this study of them 22 positive antithyroid antibody, 59 negative antithyroid antibody were undergone ICSI in Al-sader infertility center the group of the study contained only euthyroid female with no clinical manifested autoimmune illness.

It seems unlikely that antithyroid antibody (ATA) decreases the rate of pregnancy (no significant difference regarding failure to get pregnant among antithyroid positive groups and antithyroid negative groups). (p-value 0.493).

Hypothyroidism (subclinical define as upper normal level of TSH with elevated level of free T4) may be associated with negative results such as failure to conceive, pre-eclampsia, perinatal mortality, preterm birth, and miscarriage. Moreover, normal TSH, subclinical hypothyroidism, were reported until two prevent of pregnancies.10(11)

The limitations of the current research is the assessment of results of pregnancy after ICSI–embryo transmit cycle and moderately low quantity of patient because narrow time of follow up.

Confounding thyroid dysfunction was excluded in this study by including only women with normal TSH concentrations. Relationships between thyroid autoimmunity and unexplained infertility, miscarriage, recurrent miscarriage, preterm birth and maternal post-partu thyroiditis were reported independently from thyroid hormone concentrations(12).

In the study antithyroid positive group, the rate of fertilization, the available number of embryo and the quality of transfer embryo were dramatically lower than antithyroid negative group. The receptors thyroid hormone were labelled in human oocyte and can help in the trophoblastic differentiation and stimulation in the function of granulosacell (13). It was recommended that antithyroid antibodies have the responsibility for reducing fertility possible thru restricting the receptors(12). Therefore, the effect of the antibodies on the IVF cycles results were examined. despite the ATA existing is related with low result of IVF.

The antithyroid negative groups had higher rate of abortion compared to antithyroid positive groups (P value <0.001).

ATA presence is connected with the high risk of miscarriage in spontaneous pregnancy(14). Anyway, the rate of miscarriage is not higher in pregnancy of IVF attained in ATA-positive women compared with ATA-negative women in another metanalysis.

Studies found that the stimulation of ovarian might have suppressive impact on the immunity of humoral during the transfer of embryo despite the fact that the number is limited, the study have not negative effect of antithyroid antibodies on the rate of miscarriage in females considered by transfer of ICSI–embryo (15).

Alexander EK et al (2017) in infertile female, preconceptional TSH 2.5 mIU/L is not connected with contrary reproductive results; anyway, anti-TPO are connected with miscarriage high risk and reduced possibility of live-birth. This study is disagree with our study. (16)

K. Łukaszuk et al (2015) individuals diagnosed of anti-TPO antibodies regarding the rates of live birth, rates of pregnancy, implantation, fertilization revealed there was no significant differences also, no high danger regarding miscarriage after IVF-ET comparing with the negative for anti-thyroid antibodies compare with our result disagree(17)

Benaglia L et al (2013) the research showed that sick female diagnosed with anti-TPO antibodies regarding rates of live birth, rates of pregnancy implantation, fertilization there was no significant differences, moreover, regarding miscarriage, no high danger was found following IVF-ET comparing with the adverse for anti-thyroid antibodies this study disagree with our study. (18)

R. C. Smallridge et al (2013). Due to the unclear evidence, the study can’t suggest screening for the euthyroid treatment or thyroid autoantibodies for patients with positive thyroid autoantibodies at the pregnancy time.(19)
Prummel MF et al (2012) the antithyroid antibody existing is harmful for the results of pregnant after IVF-ET, therefore, duture research to examine suitable treatments to control function of the immune of ATA positive individuals to diagnosed enhance the result of IVF agree with our research.\(^{(20)}\)

Grtner, et al (1)(2009) Anti-thyroid antibodies, although it is not connected with thyroid dysfunction, are supposed to lead to a poor results of in vitro fertilization this agree with our study.\(^{(21)}\)

Limitations of the current research could be described as the pregnancies results assessment of using ICSI–embryo transfer cycles and relatively low number of patient because narrow time of follow up.

**Conclusions**

The antithyroid antibody’s presence is harmful for the results of pregnancy using ICSI-ET in euthyroid infertile women in the absence of other autoimmune disease. Hence we recommended further studies with estimated freeT4 in addition toTSH and large sample size and prolong time for follow up further studies should investigate suitable treatments to design immune function of ATA positive patients to improve IVF result.

The Effect of Conventional Method on the Length of Treatment Days for Children Underwent Circumcision at Poniran Khitan Centre Bengkulu

Ferasinta¹, Andri Kusuma Wijaya¹, Desri Suryani²
¹Expert assistant, Nursing Study Program, Faculty of Health Sciences, Muhammadiyah University Bengkulu, ²Lecturer, Department of Nutrition Politeknik Kesehatan Kementerian Kesehatan Bengkulu

Abstract

Background: Circumcision is a minor surgical procedure that is most widely performed in the world, namely a method of cutting all or part of the prepuce of the penis for specific indications and purposes.

Study Design: This study was used one-group pretest-posttest pre-experimental research design, with a total sample 15 respondents.

Results: Based on the results of the bivariate analysis using the Dependent T test, it was found that there was an effect conventional method with a value (p value = 0.000) on the on the length of days of care for circumcision wounds in children undergoing circumcision at the Poniran Khitan Centre Bengkulu.

Conclusion: The role of the Poniran Khitan Center will greatly assist in facilitating children in treating wounds who undergo circumcision

Keywords: Children, Circumcision, Conventional method

Introduction

Circumcision (circumcision) is the process of cutting the foreskin or prepuce of the penis by leaving the mucosa (inner layer of the skin) from the coronarious sulcus towards the head of the penis, which aims to prevent the buildup of smegma on the penis for social, religious or cultural reasons.

According to the United Nation of Acute Immuno Deviency Syndrome almost 30% of men are circumcised, and two out of three men are Muslim. The practice of circumcision is generally known in the Asian region, one of which is Indonesia. The implementation of circumcision can be influenced by several factors, including health, religion, sexuality and the application of social norms and the timing of circumcision in different countries and regions, depending on country and ethnicity.

Medically there is no age limit for circumcision. In the Indonesia World Health Organization, the most common age for circumcision is 5-12 years. The incidence of circumcision in each country varies according to religion, ethnicity, socio-economic status for medical, religious, social and cultural reasons. In 2013, it was found that 2.7 million people in 14 priority countries in eastern and southern Africa performed medical circumcision on men. Whereas in Indonesia 10.2 million perform circumcision. The prevalence of circumcision in the world is most prevalent in the world where the population is Muslim, namely 70%. In America 71.2%, Africa 44.7%, China 14%, Spain 6.6%, Australia 26.6%, India 13.5%, Japan9%, Afghanistan 99.8% and Thailand 23.4%.

Circumcision has many benefits, one of which reduces the risk of HIV transmission from women to men by 50-60% in Africa. The effectiveness of postcircumcision tissue wound repair is at the core of the problem that must be achieved in the current development of health science, so that the treatment of circumcision itself has attracted the attention of generations of health services in each country, including various technical strategies to improve and accelerate the healing time of...
circumcised patients.

The initial survey, which was conducted on July 29, 2019 at Poniran Khitan Center Bengkulu, obtained data in 2019 as many as 252 children. In 2018 there were 148 children, while in 2017 there were 163 children. Previously at the Poniran Khitan Center Bengkulu, a study was conducted to see the length of treatment days for children undergoing circumcision. Based on the above background, the researcher is interested in taking a research entitled The Effect of Conventional Methods on the Length of Care Days in Children Underwent Circumcision in Poniran Circumcision Center Bengkulu.

**Method and Method**

This research is a quantitative research with the type of pre-experimental research one-group pretest-posttest. This research conducted in June 2020 which was conducted at the Poniran Khitan Center, Bengkulu. The population in this study were children who underwent circumcision. The sampling technique in the study used non-probability sampling techniques, namely consecutive sampling. Sample selection is done by establishing inclusion criteria. Inclusion Criteria:

a. Children who underwent the clamping method who were willing to become respondents

b. Children who undergo circumcision do not experience interference with the visual and hearing system

This research data collection procedure starts from administrative procedures where getting a letter of passing the ethical test, processing a research permit to the Poniran Khitan Center Bengkulu. Furthermore, selecting potential respondents based on inclusion criteria, asking the child’s family’s willingness to become respondents and explaining the research objectives. Furthermore, the researcher asked the identity of the respondent, explained about the research on circumcision wound care and then observed it for 14 days of treatment.

**Result**

**Univariate Analysis**

The results of the univariate analysis of this study used to see the description of the frequency distribution of clients based on the conventional method before intervention and after the intervention in children who underwent circumcision at the Poniran Khitan Center Bengkulu:

<table>
<thead>
<tr>
<th>Table 1: Distribution of Respondents Based on Age</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age</td>
</tr>
<tr>
<td>-------</td>
</tr>
<tr>
<td>7</td>
</tr>
<tr>
<td>8</td>
</tr>
<tr>
<td>Total</td>
</tr>
</tbody>
</table>

Based on table 1, the frequency distribution of the age respondents children who underwent circumcision, Bengkulu, It is known that the age of the respondent is 7 years old as many as 10 respondents (66.7%), 8 years old as many as 5 respondents (33.3%).

**Bivariate Analysis**

The results of the bivariate analysis were used to see the effect of conventional methods on the treatment of circumcision wounds in children undergoing circumcision at Poniran Khitan Center Bengkulu. The results of these researchers themselves can be seen in the following table 2:

<table>
<thead>
<tr>
<th>Table 2: Distribution of Average circumcision wound care rates Respondents Before and After the Intervention in the conventional method Children</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable</td>
</tr>
<tr>
<td>-------------------</td>
</tr>
<tr>
<td>Conventional Method</td>
</tr>
<tr>
<td>Pre Intervention</td>
</tr>
<tr>
<td>Post Intervention</td>
</tr>
</tbody>
</table>

Based on table 3, the results of the analysis of the average pre-intervention wound care result was 17.53 with a standard deviation of 1.807. After giving the treatment intervention, it was obtained an average of
8.93 with a standard deviation of 1.163. The results of the statistical test with a p value of 0.000, it is concluded that there is a significant influence between conventional methods before and after giving wound care interventions to children undergoing circumcision at the Poniran Khitan Center Bengkulu.

Discussion

Univariate Analysis

Based on table 1, it is known that the age of the respondents. The results of this study are one of the manifestations that most of the children who undergo circumcision are 7 years old.

According to Wong (2008), the characteristics of school-age children can be seen from several aspects, including in terms of independence and spiritual development. School-age children are able to do coping effectively and are able to cooperate with health workers. Although school-age children have an independent nature that is able to work with health workers, there are several factors that can make him anxious.

According to Hockbenberry (2015), States that the younger the child is, the more difficult it is to adjust to a new environment, in this case an unfamiliar environment and action procedures. According to researchers, the age of the child undergoing circumcision is the sooner the better. This is because it makes it easier to heal wounds.

Bivariate Analysis

Based on the results of the dependent t statistic test, it is known that conventional wound care before the intervention was 17.53 with a standard deviation of 1.807. After giving the intervention, the average circumcision wound care was 8.93 with a standard deviation of 1.163. The statistical test results obtained p value of 0.000, so it can be concluded that there is a significant influence between wound care before and after giving intervention to children undergoing circumcision at Poniran Khitan Center Bengkulu.

In line with Maizels’ (2019) research on “Outcome of circumcision for newborns with penoscrotal web: oblique skin incision followed by penis shaft skin physical therapy shows success” results obtained from 828 boys who came for circumcision, 652 (79%) were registered because they were suitable for circumcision: 355 (43%) in the normal group and 297 (36%) in the web group. The remaining 176 (21%) were excluded because they had penile anomalies: buried penis (125), chordee (40), and hypospadias (11). Follow-up was carried out for 6 months. In the web group, follow-up data were obtained for 263 of 297 (89%) cases, with 261 of 263 (99%) showing success, and in the normal group, follow-up data were obtained for 327 of 355 (92%) cases, with all 327 (100%) indicated success. Two cases in the web group (0.7%) failed to undergo surgical reconstruction.

Another study by Alpert (2018) on Combination treatment for cicatrix after neonatal circumcision: An office-based solution to a challenging problem with the results of research namely the formation of a cicatrix, which can form after neonatal circumcision to trap the glans penis, presents a therapeutic challenge. Previous studies in the literature have described the use of topical steroid creams or stretching of scar tissue with instruments but not a combination of the two modalities. Based on our experience, monotherapy has caused significant relapses and/or requires further treatment. We present our successful experience combining cicatrix stretching with hemostats using local anesthesia in the office followed by topical steroids for several weeks with a minority of patients requiring additional therapy.

According to researchers, the process of treating a circumcision wound will be fast if it is according to the procedure between the child who is undergoing circumcision and the treatment so that the wound will recover quickly. In accordance with the theory, the length of wound care days is 14 days from the time the wound is opened, so in this study the length of wound care is in accordance with the days of wound healing.

Conclusion

The frequency distribution of child respondents who underwent circumcision with conventional methods was 7 years old as many as 10 respondents (66.7%) and 5 respondents (33.3%) aged 8 years.

The average value of wound care using conventional methods, namely the average value before that is 17.53 and the average value after intervention is 8.93.
There is an effect of conventional methods on the length of days of care for children undergoing circumcision at the Poniran Khitan Center Bengkulu.

Neutrophil Lymphocyte Ratio and Acid-Fast Bacilli in Tuberculosis

Haerani Harun1, Muhammad Nasir2, Sumarni3, Rosa Dwi Wahyuni1, Dita aridhatamy4, Nur Aulia Pratiwi4

1Lecture, Department of Clinical Pathology, Faculty of Medicine, Tadulako University, Palu 94148, Indonesia, 2Lecture, Department of Tropical Infection and Traumatology, Faculty of Medicine, Tadulako University, Palu 94148, Indonesia, 3Lecture, Departement of Medical Nutrition, Faculty of Medicine, Tadulako University, Palu 94148, Indonesia, 4Student of Medical Education Program, Faculty of Medicine, Tadulako University, Palu 94148, Indonesia

Abstract

Background: Tuberculosis (TB) is one of the top 10 causes of death in the world and the most common cause of death with single infectious agent. The neutrophil-lymphocyte ratio is a cheap and fast marker of inflammation that has been widely studied in TB. The aim of this study was to investigate Neutrophil-lymphocyte ratio (NLR) in TB with positive Acid-Fast Bacilli (AFB) and negative AFB. Methods: This was a retrospective study that included TB patients data from the medical records in two hospitals in Palu, Indonesia. A total of 150 TB patients were involved in this study consisting with positive and negative AFB TB suspect. Neutrophil, lymphocyte and NLR data were compared with the Mann-Whitney test. Results: The study shows a significant difference of neutrophils and lymphocytes percentage between positive AFB TB patients (80 subjects, 53.3%) and negative AFB TB patients (70 subjects, 46.7%) with (p < 0.001) as well as NLR (p < 0.001). The percentage of Neutrophils was significantly higher in positive AFB TB compared to negative AFB tuberculosis (81.18 ± 8.52 vs. 55.02 ± 9.80), lymphocyte percentage were found to be significantly lower in positive AFB TB compared with negative AFB TB (12.72 ± 7.51 vs 28.69 ± 12.01). Additionally, NLR were significantly higher in positive AFB TB compared with negative AFB TB (10.20 ± 9.53 vs 2.47 ± 1.56). Conclusion: There is a significant increase in the number of neutrophils, a decrease in lymphocytes and an increase in NLR among positive AFB TB compared with negative AFB TB.

Keywords: Tuberculosis, Acid-Fast Bacilli, Neutrophil, Lymphocyte, Neutrophil Lymphocyte Ratio

Introduction

Tuberculosis (TB) is one of the top 10 causes of death in the world and the most common cause of death with single infectious agent more than human immunodeficiency virus (HIV). Millions of people suffer from TB every year. In 2017, TB was estimated to cause 1.3 million deaths in HIV-negative patients and 300,000 deaths in HIV-positive patients (1). The activation progress of TB is a combination of bacterial virulence factors and host immune system factors. Recently advanced knowledge of immunology in TB provides an overview of abnormalities in hematology (2).

One of the criteria for TB is by examining acid-fast bacilli (AFB). High quality and sufficiency of sputum sampling is very important to obtain good result. Therefore, patients need to understand good sputum sampling. Good sputum is sputum containing material from the lung when productive coughing and not from the nasopharynx only. One of methods to determine quality of sputum sample is to assess sputum leukocyte...
levels \(^{(3)}\), but this is time consuming and costly. Despite its lack of sensitivity compared to sputum culture, AFB is still the mainstay of diagnosis of tuberculosis with positive AFB among the pulmonary tuberculosis suspect patients in many regions \(^{(4)}\). The use of AFB examination alone without confirmation by culture, the quality is needed to fully assured in its use \(^{(5)}\).

Various factors can influence the results of AFB examination, including the quality of the sample and the competency of the examiner so that the AFB examination has its own constraints in determining the diagnosis of TB patients. The number of bacteria in sputum may be related to bacterial virulence, higher virulence bacteria have better endurance and replicate in macrophages or neutrophils faster than low virulence bacteria \(^{(6, 7)}\). Cellular immune responses especially those produced by T lymphocytes play an important role in controlling the replication of *Mycobacterium tuberculosis* (MTB) as well as neutrophils play a role in innate immunity to MTB. Lymphopenia, neutrophilia and monocytosis are the most common hematological abnormalities in TB \(^{(8, 9)}\).

The neutrophil-lymphocyte ratio (NLR) is an inflammatory marker that can be used to estimate various clinical conditions including cancer and coronary heart disease and also shows differences based on the type of infection. In addition, NLR is also useful to predict and detect inflammatory conditions and infections. NLR of miliary TB patients at the time of hospital admission can be used as a marker of mortality and the risk of acute respiratory distress syndrome (ARDS) \(^{(10-12)}\). Other studies have also shown that NLR is found to be increased in patients newly diagnosed with TB and NLR can be used as an inflammatory marker that can help management of TB patients and to determine the severity of TB disease \(^{(2, 9)}\). AFB and NLR obtain from leukocyte differential count are widely used and more affordable in Indonesia specially in rural areas. The objective of this study was to see differences of NLR in TB with positive AFB and negative AFB.

**Method**

This research is a retrospective study utilizing data from medical record of TB patients in two hospitals in Palu City, Indonesia (Undata Hospital in 2016 and Anutapura Hospital in 2017). TB patients were included and examined whether they had carried out AFB examinations, then divided into 2 groups based on examination AFB, positive AFB and negative AFB. Hematological examination data of the two groups was taken to determine the levels of neutrophils and lymphocytes. The patients were excluded from the study if AFB and hematologic examination were unavailable. Generally these patients have undergone TB therapy. 88 samples were taken from the Undata Hospital and 62 samples were taken from Anutapura Hospital, the total number of samples was 150 TB patients.

Data distribution was tested by the Kolmogorov-Smirnov Test. Data with normal distribution has a value of \(p > 0.05\). The Kolmogorov Smirnov test show that the distribution of neutrophils, lymphocytes and NLR data is not normal. The statistical test used to compare the two groups was the Mann-Whitney test because of abnormal data distribution.

**Result**

The total number of samples was 150 TB patients consisting of 80 smear of positive AFB TB and 70 negative AFB TB. The age of positive AFB TB patients was 43.20 ± 13.16 years with a range of 21-72 years, the age of patients with negative AFB TB was 41.32 ± 14.07 with a range of 17 - 63 years. Male in the positive AFB TB group was 60% and 40% female, in the negative AFB TB group male was 56% and female 34% (table 1).

The Mann-Whitney test showed a significant differences of neutrophils and lymphocytes percentage between positive AFB TB patients and negative AFB TB \((p < 0.001)\), as well as NLR \((p < 0.001)\). Neutrophils percentage was significantly higher in positive AFB TB compared with negative AFB TB \((81.18 ± 8.52 vs. 55.02 ± 9.80)\), lymphocytes percentage were significantly lower in positive AFB TB compared with negative AFB TB \((12.72 ± 7.51 vs 28.69 ± 12.01)\). NLR were significantly higher in positive AFB TB compared with negative AFB TB \((10.20 ± 9.53 vs 2.47 ± 1.56;\) table 2).

Discussion

Tuberculosis is an infectious disease which the progression and the outcome depend on the immune reactivity of the host (13). The immune system helps control the proliferation of MTB. Reactivation of latent TB occurs in individuals who experience a decrease in the immune system (14, 15).

Inflammation plays an important role in the pulmonary TB pathogenesis as in protection and pathology. Yaranal et al showed that hematologic abnormalities were often found in severe TB cases. Hemoglobin levels, platelet counts, lymphocytes and neutrophils counts change in the chronic inflammatory process and return to normal with effective therapy. These parameters can be used as indicators to assess treatment (2, 13, 16, 17). In the early stages of the disease proinflammatory cytokines and chemokines released by various cells, induce migration of immune cells to infected areas, form granulomas and initiate host response protection. The cellular population increases in response, involving alveolar macrophages, dendritic cells, neutrophils, NK cells, epithelial cells and other cells (13).

Jadoon et al. showed that decreased lymphocyte levels and increased neutrophil levels were associated with the severity of TB disease (18). The immune response often has a certain pattern, which were an increase in the number of neutrophils and a decrease in the number of lymphocyte cells. When infection persists, neutrophil production increases and the possibility is not apoptosis. Neutrophil apoptosis in sepsis is beneficial, whereas lymphocyte apoptosis provides a loss (19). Polymorphonuclear cells (PMN) are cells that play a role in phagocytosis and are the first line of defense against microbes. The highest PMN in the blood is neutrophils. In TB infection, PMN will be attracted to infected areas along with interleukin 8. In patients with active pulmonary TB, PMN becomes the dominant cell found in the lungs (20).
The role of neutrophils in TB is still debatable. Several studies demonstrated the involvement of neutrophils in granuloma formation, initiation of T cell responses, amplification of antimicrobial activity of macrophages, secretion of antimicrobial peptides and killing of tuberculosis. This implies that neutrophils have many different roles in each phase of TB, mediating protection in the onset phase of infection and pathology induction in the later phase of TB. There are some mechanisms of neutrophil induction of pathology in TB, neutrophils were suggested to play the role of trojan horse by hiding MTB from active macrophages. With increasing neutrophils and precursors, neutrophils are likely to suppress T cell responses (21). Neutrophils help early CD4 activation of T cells by working with dendritic cells in mice infected with virulent MTB. Neutrophils are predominant cells infected with MTB in TB patients and these bacteria replicate intracellular (7, 22). Research by Xu et al. showed that the percentage of regulatory T cells increased in patients with negative AFB compared with patients with positive AFB. Regulatory T cells are thought to play a role in preventing inflammation which causes damage to host tissues in TB (23, 24).

Calculations of NLR are easily obtained from the results of routine laboratory examinations, and can be done in many hospitals. NLR is also easier to obtain and cheaper than other inflammatory markers such as C-reactive protein and procalcitonin (2, 25). The role of NLR as an inflammatory marker in TB has been widely investigated (26-30). This study showed that higher neutrophils percentage and lower lymphocyte percentage were found in positive AFB TB compared with negative AFB TB. Both of these contribute to the increased value of NLR in positive AFB TB. Tuberculosis with positive AFB is considered to have more bacterial load in sputum and could be more virulent than negative AFB TB. The NLR in this study can illustrate the level of inflammation of TB infection but there are findings that shows high numbers of neutrophils play a role in the replication of TB bacilli.

The limitations of the study include the absence of the duration or type of TB patients treatment, the severity of clinical symptoms and radiological features. Further research is needed to analysis NLR in TB patients based on therapy, relapse, HIV co-infection, nutritional status, molecular test and TB drug resistance. Research with more patients is needed to determine the cut-off value of NLR in positive AFB and negative AFB TB.

Conclusion

This study indicates that in positive AFB TB has an increase in neutrophils percentage, a decrease in lymphocytes percentage and an increase in NLR compared with negative AFB TB.

Conflict of Interest: The authors declare that they have no conflict of interest.

Acknowledgments: We thanks to the contribution of the management of Undata Hospital, Palu, Indonesia and Anutapura Hospital, Palu, Indonesia. We would like to express our sincere thanks to the Indonesia Tuberculosis International Meeting (INATIME) event which facilitated us to present this research on 5-7 April 2019 at Surabaya, Indonesia.

The Extent of the Need for Teaching Forensic Sciences for Law Students in Jordanian Universities

Hamzeh Abu Issa¹, Ma’en Juwaihan²
¹Assistant Professor of Criminal Law, and Dean of faculty of law at Applied Science Private University, Al Arab st. 21-Amman –Jordan, ²Faculty of Law/ Petra University/ Jordan

Abstract

This article examines the actual need for teaching forensic sciences to Bachelor of Law students in Jordanian universities, where the research extrapolated the study plans for the specialization of law in the faculties of law in Jordanian universities, which amount to 20 faculties, to know the faculties that teach forensic sciences. It was found that only one faculty offered forensic sciences as an elective requirement, and that 13 faculties included among their study plans the course of forensic medicine as an elective requirement.

Also, a questionnaire was designed and distributed to a random sample of 120 lawyers in Jordan. The questionnaire contained 9 multiple-choice questions, the most important results are that only 39% of the sample studied one of forensic sciences subjects at the bachelor’s level, and 36% of them know the work of forensic experts, and 92% support that the forensic sciences to be as a compulsory requirement course for law students.

The article discussed the results of the questionnaire in a scientific discussion and concluded the necessity to design a subject specialized in forensic sciences for students of law, provided that it is a compulsory requirement because of its great importance in the work.

Keywords: Forensic sciences, Education, Justice, Law study.

Introduction

Forensic sciences are considered one of the modern sciences of distinctive importance due to the important services it provides to justice through the use of scientific means to uncover crimes. It’s distinguished by the fact that it uses various modern means and techniques to uncover crime.

By forensic sciences, we mean those sciences that assist in uncovering crimes, clarifying their mysteries, determining the methods of their commission, and tracing the perpetrator and tracing his traces through physical evidence¹. These sciences play an important role in revealing the truth, especially in criminal cases, and to the extent that these sciences are advanced, the results reached by the judiciary are identical to reality, thus achieving reassurance in judgments².

It is noticeable that forensic sciences has developed remarkably in the modern era, expanding its scope to include several branches of the sciences American Academy of Forensic Sciences, for example, includes the following specific areas of expertise: pathology and biology, toxicology, criminalistics, questioned documents, forensic odontology, anthropology, jurisprudence, psychiatry, and a general section. Other sections are developing in such fields as engineering, geology, and microscopy³.

There is no doubt that the use of Forensic sciences at present time has become very important, as most courts resort to these sciences to reach the certainty of truth, and this is what leads us to raise the topic of this article,
which is, is it now necessary to teach Forensic sciences for law students?

The article used two methods to arrive at results. Initially, a survey study of the study plans for the Bachelor of Laws program was conducted for all 20 Jordanian universities, to know the reality of teaching Forensic sciences in law faculties. After knowing the results of this study, I designed a questionnaire that contained 9 multiple-choice questions, with the aim of the reality of lawyers knowledge of forensic sciences and the extent to which they needed to study forensic sciences or not.

A random sample of 120 Jordanian lawyers was selected, all of whom were graduates of Jordanian law schools, whose experience in the profession ranged from one to thirty years.

The questionnaire contained the following questions:

- Have you studied forensic sciences or one of its branches in the Bachelor?

- Do you have interests and following new information in forensic sciences?

- When you want to know any information in the forensic sciences, your method for that is:

- Do you have the ability to discuss forensic experts with scientific information?

- Have you ever asked the court to resort to forensic evidence to deny the accusation?

- What are the most important cases in which you think forensic sciences have a role?

- Have you ever seen how forensic experts work?

- What kind of evidence have you dealt with the most in your cases?

- Do you think it is necessary to study forensic sciences as a compulsory course at the undergraduate level?

**Result**

The study plans for all law faculties in Jordanian universities (government and private), totaling 20 faculties, were reviewed in each of the following universities: University of Jordan, Yarmouk University, Mutah University, Al Al-Bayt University, Al-Balqa Applied University, Al-Hussein Bin Talal University, Applied Science Private University, Al-Ahliyya Amman University, University of Petra, Israa University, Al-Zaytoonah University, Middle East University, University of Islamic Sciences, Philadelphia University, University of Jerash, Irbid National University, Jadara University, Ajloun National University, Zarqa Private University, and Amman Arab University.

It turns out that one university, which is Applied Science Private University, teaches criminal science as an elective course for law students. According to the description announced by the faculty, “This course is devoted to the study of one of the auxiliary criminal sciences chosen by the teacher: Criminology, penology, criminal policy, judicial psychology, a criminal investigation, criminal medicine, etc”.

It was also found that thirteen universities teach (forensic medicine) as an elective course for students of the Faculty of Law. These universities are: University of Jordan, Yarmouk University, Mutah University, Al Al-Bayt University, Al-Balqa Applied University, Al-Hussein Bin Talal University, University of Petra, Al-Isra University, Al-Zaytoonah University, Jerash University, Irbid National University, Ajloun National University, and Amman Arab University. The description of the course was the same in all these universities, which “This course aims to study the definition, means of requesting help from forensic medical doctors in judiciary proceedings and investigations including medical reports, inspection of dead bodies, their autopsy and reasons of death”.

As for the results of the questionnaire, it was as follows:

1- (39%) of the study sample studied one of the forensic sciences subjects at the bachelor’s level, compared to (61%) of them did not study any of its branches.

2- (80%) of the study sample have an interest in forensic sciences and follow up on new information.

3- (55%) of the study sample obtains their information in forensic sciences from the Internet, and
(37%) of them through asking experts, while (8%) of them resort to specialized books and journals.

4- (58%) of the study sample believes that they can discuss scientific information with forensic experts.

5- (49%) of the study sample had previously asked the court to resort to scientific evidence to deny the accusation from the accused.

6- (52%) of the study sample believed that the cases that most need resort to forensic sciences are those related to murder and abuse, while (46%) of them believe that are the cases related to sexual crimes, and (2%) believe that are cases related to property crimes.

7- Only (36%) of respondents know how forensic experts work.

8- The experience of Detecting Forgery And Counterfeiting constituted the most scientific expertise that the sample members dealt with (65 people), followed by the experience of traffic accidents (22 people), then the experience of the genetic fingerprint (14 people), and then the other experiences, and the experience of weapons came as the least type of experience dealing with Frequently (one person from the sample).

9- (92%) of the study sample believed that it is necessary to study forensic sciences as a compulsory course at the bachelor’s level, compared to (8%) of them who do not believe it is necessary.

Discussion

It seems that the study plans for the Bachelor of Laws program at Jordanian universities are still traditional so that still contain legal courses explain the texts of law, meaning that the basis for studying law in these universities stems from the legal text only, so these plans lack many of courses that helps law student to practice his profession. Therefore, it is important to include assistive courses that develop student’s skills, not only in interpreting and analyzing legal texts but also in linking all sciences with the science of law.

There is a clear neglect of forensic sciences during the study of law, and even with a number of faculties that teach forensic medicine as an elective requirement, this is not sufficient, as forensic medicine is only a branch of forensic sciences. In connection with the results of the questionnaire, there are branches of forensic sciences that are more used than forensic medicine, so the student must be familiar with them.

There is no doubt that there is recognition of the existence of a large gap between the scientific and legal disciplines, on the other hand there is recognition of the need to bridge this gap. As the legal experts realize the importance of resorting to scientific disciplines to solve their cases, it is evident from the results of the questionnaire that there is a desire of lawyers for the course of forensic sciences to be a compulsory course during their studies due to the importance they have seen on the ground.

Conclusion

Nothing can establish the foundations of justice in societies as far as revealing the truth that has become within reach by the development of science. From here appears the importance of studying forensic sciences for law students, a course that is lacking in our Jordanian university. With the awareness of those working in the legal field of this, it has become necessary to design a special curriculum for forensic sciences for law students, and we mean by a special curriculum that the presentation of information is consistent with the legal mentality, and this is what many writers who have written books in forensic medicine have directed especially for law students (for example See: Batrawy, 2004).

From this standpoint, we call on law faculties in Jordanian universities to amend their study plans to include at least a compulsory course in forensic sciences aim to introducing law students to modern scientific evidences.

Does Husband/Partner Matter in Reduce Women’s Risk of Worries?: Study of Psychosocial Burden of COVID-19 in Indonesia

Hario Megatsari1, Agung Dwi Laksono2, Yeni Tri Herwanto3, Kinanty Putri Sarweni4, Rachmad Ardiansyah Pua Geno4, Estiningtyas Nugraheni4, Mursyidul Ibad5

1 Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, 2 Researcher, National Institute of Health Research and Development, the Indonesian Ministry of Health, Jakarta, Indonesia, 3 Researcher, The Indonesian Public Health Union, Makassar, Indonesia, 4 Researcher, Faculty of Health, Nadlatul Ulama University, Surabaya, Indonesia

Abstract

Several previous studies have found that women are more susceptible to psychosocial burden than men. The study was aimed at analyzing the influence of having a husband/partner on the psychosocial burden of COVID-19 among women in Indonesia. The study involved 5,061 women collected through a rapid online survey. The psychosocial burden was reviewed based on worries level on 5 aspects of daily life, namely economic, religious, educational, employment, and social aspects. Four independent variables were included in the analysis, including husband/partner ownership, age group, education level, and employment status. A multivariate test using the binary logistic regression was done at the final stage. The results show that women who have a husband/partner have a risk of 1.377 times compared to women who do not have husbands/partners to experience worries. Women in the 40-49 age group had 0.630 times the risk of women with ≤19 age groups to experience worries. Meanwhile, women with the ≥50 age groups had a 0.327 times risk than women with the ≤19 age groups for experiencing worries. Women with higher education have a risk of 0.610 times compared to women with secondary education for experiencing worries. It could be concluded that having a soulmate is a risk factor for women to experience the psychosocial burden of COVID-19 in Indonesia. The analysis also found that younger age and lower education were risk factors for women to experience the psychosocial burden of COVID-19 in Indonesia.

Keywords: women’s health, psychosocial burden, mental health, online survey, COVID-19.

Introduction

It is estimated that the decline in the number of COVID-19 incidents at the global level is far from over. Data from www.worldometers.info/coronavirus/ accessed on 11 August 2020, in the last 7 days, show that the global average rate of increase in new cases of COVID-19 has reached approximately 200,000 cases/day. In addition to the high daily average number of cases, at the global level, the average death rate due to COVID-19 in the last 7 days has reached approximately 6,000 deaths/day.

The situation is more or less the same in Indonesia. Based on the official website of the Indonesian government, www.covid19.go.id, which was accessed on 11 August 2020, the average number of new cases of COVID-19 in the last 7 days has reached approximately 2,000 cases/day. The average death rate due to COVID-19 in the last 7 days has reached approximately 70 deaths/day.

The Indonesian government has made various efforts to reduce the rate of spread of COVID-19. One of
the strategies undertaken by the Indonesian government is to issue the Minister of Health Regulation Number 9/2020 concerning Guidelines for Large-Scale Social Restrictions in the Context of Accelerating Handling of Corona Virus Disease 2019. This regulation emphasizes the existence of restrictions on community movement. The implication of this regulation is the closure of several locations, including educational institutions (schools), offices, tourist attractions, and so on.

The Minister of Health Regulation Number 9/2020 was strengthened by the existence of Presidential Instruction Number 6/2020 concerning Increasing Discipline and Law Enforcement of Health Protocols in the Prevention and Control of COVID-19. This Presidential Instruction ensures that there is a clear legal umbrella for the government to enforce discipline in the community so that it complies with existing health protocols, namely using masks, applying physical distancing, diligently washing hands.

Both regulations have an impact on various aspects of life in society, including religious, economic, social, and educational aspects. The phenomenon of the impact of this regulation can be seen from the existence of several reports in the mass media, including the existence of several people who work even though in their territory it has been forbidden to work\textsuperscript{1,2}. The duration of implementing social restrictions has been quite long. This condition triggers boredom so that there is a tendency for violations to occur\textsuperscript{3}.

In addition to the potential for violations to occur during the period of limitation, people also have the potential to experience depression and worries\textsuperscript{4}. The existence of hoax information also has a role in the occurrence of anxiety, so that this worsens the situation and conditions in society\textsuperscript{5–7}. This hoax news was then added to by the phenomenon of the conspiracy theory echoed by the leaders of the superpowers\textsuperscript{8}.

Worry is a psychosocial burden. The public health problem that needs attention. World Health Organization formulates the definition of healthy, one of which also includes mental dimension\textsuperscript{9}. Given the situations and conditions above, it is necessary to pay more attention to see the conditions of the psychosocial burden during the COVID-19 pandemic.

Several previous studies have found that women are more affected psychosocial under various uncertain stresses such as the current COVID-19 pandemic condition\textsuperscript{10–12}. Women are considered more vulnerable because of several conditions, including the incidence of female workers experiencing a decrease in productivity compared to male workers when working from home, besides that women are also burdened with domestic affairs in the household\textsuperscript{13–15}. The study was aimed at analyzing the influence of husband/partner ownership on the psychosocial burden of COVID-19 among women in Indonesia.

Materials and Methods

The study uses a rapid online survey to collect data about the worries felt by women in Indonesia. Data were collected for 8 days (June 6-13, 2020), until 5,061 women were obtained. In this study, the psychosocial burden was measured based on the worries level. The worries level was a self-assessment of anxiety in 5 aspects of daily life, namely economic, religious, educational, employment, and social aspects. Each aspect was assessed based on the choice of answers using a Likert scale. The worries level composite variable was composed of scores from 5 aspects measured. The total score was divided into 2 classes of the same size, which are not worries and worries. Four independent variables were included in the analysis, including husband/partner ownership, age group, education level, and employment status.

At the initial stage, a bivariate test with chi-square was carried out to see the relationship between the husband/partner ownership variable and other variables. In the final stage, a multivariate test using binary logistic regression was carried out to determine the risk factors for the psychosocial burden of COVID-19 among women in Indonesia. SPSS 22 software was used in all statistical credentials.

Results and Discussion

Table 1 is a display of bivariate analysis between husband/partner ownership and all variables involved in the analysis. It can be seen that in both categories of husband/partner ownership is dominated by women who experience worries. Meanwhile, based on the age group, women who don’t have husband/partner dominated by the 20-29 age group, and women who have husbands/
partners dominated by the 30-39 age group.

Based on the education level, women who don’t have a husband/partner dominated by secondary education, and women who have husbands/partners dominated by higher education. Furthermore, in the base on employment status, it can be seen that the two categories of husband/partner ownership are dominated by employed women.

Note: ‘p<0.05; ‘’p<0.01; ‘’’p<0.001.

Table 2 displays the results of the binary logistics regression of the psychosocial burden on the COVID-19 among women in Indonesia. Based on the ownership of a husband/partner, women who have a husband/partner have a risk of 1.377 times compared to women who don’t have a husband/partner to experience worries (OR 1.377; 95% CI 1.096-1.730). The results of this analysis inform that having a husband/partner is a risk factor for women to experience the psychosocial burden of COVID-19 in Indonesia.

Having a husband/partner should be a place to share worries, but the results of the analysis show contradictory findings. Having a husband/partner increases the risk for women to experience the psychosocial burden of COVID-19. This condition is possible because of the increased worries as a result of the increasing number of family members. For a single woman, worry is only for herself. This condition is different for women who have a husband/partner, the burden of worries increases on the number to be worried about, not only husband/partner...
but also children. The findings in this study contradict several studies conducted in the United State regarding marital status. The studies inform that unmarried patients, including those who are divorced, separated, widowed, or never married, have an increased rate of adverse cardiovascular events when compared to their married counterparts.16–18

Note: ’p<0.05; “p<0.01; “”p<0.001.

Based on the age groups, women with the 40-49 age groups had 0.630 times the risk of women with ≤19 age groups for experiencing worries (OR 0.630; 95% CI 0.411-0.965). Meanwhile, women with ≥50 age groups had a 0.327 times risk than women with ≤19 age groups for experiencing worries (OR 0.327; 95% CI 0.214-0.500). This information indicates that the younger the more the risk is for women to experience the psychosocial burden of COVID-19 in Indonesia.

Old age is synonymous with a more complete experience in dealing with the ups and downs of life. Senior age is considered to have a more complete coping mechanism. This condition is considered to be able to minimize worries that occur.19–21

Furthermore, women with higher education had a risk of 0.610 times compared to women with secondary education for experiencing worries (OR 0.610; 95% CI 0.491-0.758). These findings inform that better education reduces the risk for women to experience the psychosocial burden of COVID-19 in Indonesia.

Having a better education goes hand in hand with a better understanding of COVID-19. This condition minimizes the occurrence of worries because of the increased ability to recognize risks and preventive behavior so that they can anticipate more readily. Including the impact of psychosocial burden due to the quarantine process.12,22,23 In general, education was reported in several studies as a positive determinant of
program performance in health24–26. Meanwhile, the low level of education is a barrier to various performance in the health sector to achieve better results27,28.

Conclusions

Based on the results and discussion it could be concluded that having a husband/partner is a risk factor for women to experience the psychosocial burden of COVID-19 in Indonesia. The analysis also found that younger age and lower education are risk factors for women to experience the psychosocial burden of COVID-19 in Indonesia.

Abstract

Background: One aspect of development in children is fine motor development. Delays in fine motor skills can make children have difficulty exploring the environment, barriers to learning, lazy writing, lack of creativity. This study aims to determine the effectiveness of playing Origami interventions to improve preschool children’s fine motor skills in PAUD Aisiyah VI Bengkulu City.

Study Design: This research is a Quasi-Experimental study with a research design of “one group pretest and post-test without control group design”, a sample of 26 preschool children using purposive sampling. The intervention was given for two weeks as many as six meetings with 30 minutes per session. Data on children’s fine motor development were collected using the DDST II screening format.

Results: Analysis using the Wilcoxon test obtained ρ value 0.000 (α 0.05). In conclusion, Origami play intervention is statistically effective in improving the fine motor skills of preschool children.

Conclusion: Teachers and parents should pay more attention to and increase the stimulation of preschool children’s fine motor skills by facilitating children to play folding, sticking, and paper cutting more often.

Keywords: Origami, Playing, Fine Motoric, Preschool Children

Introduction

Children are unique individuals, always cheerful, full of abilities, optimistic, and curious in their development. Children are the hope for the nation’s future and as the next generation in the future1. The child development aspect is an essential part of achieving the Sustainable Development Goals (SDGs) target. Child development means talking about the growth and development of children2.

One crucial aspect of development is fine motor development, which involves the smaller muscles and coordination of the eyes, hands, and fingers. This skill requires great precision. The development of children’s motor skills depends on the child’s maturity level. At the age of preschool, children’s fine motor skills begin to develop where children can draw and write, color, paint, eat with a spoon, color with fingers, and cut3.

A child can experience developmental delays in only one developmental domain or more. About 5 to 10% of children are thought to have developmental delays. It is estimated that about 1-3% of children under five years of age have general developmental delays (GDD)4. Motor development needs to be a severe concern for parents and teachers because this development is sometimes rarely noticed.

Several studies have shown that preschool children’s fine motor skills are related to cognitive abilities, mathematical abilities, and even literacy abilities of children in the future. Children who have not acceptable motor delays will have difficulty exploring the environment and experience obstacles in learning, writing, and creativity. As a result, children feel inferior,
doubters, and often misgivings about their environment. Furthermore, children can experience concentration and socializing problems when the child is in elementary school later. Fine motor development requires adequate stimulation. Some play activities that can be done in preschool children can be applied to practice fine motor skills such as playing puzzles, cutting, pasting pictures, sewing, paper folding or origami, coloring, finger painting and playing toy wax or plasticine. Origami play activity is a technique and art for folding a sheet of paper into an object or shape. The folding article appears to be a simple action but requires planning, precision, coordination of the eyes, and fingers, including muscle strength, sense of taste, and touch. Origami is the art of paper folding originating from Japan that trains children’s creativity, fine motor skills, coordination of the child’s brain and hand muscles, trains the accuracy and strength of the fingers, and teaches children’s patience.

The initial survey conducted by researchers at PAUD Aisyiyah VI Bengkulu City through interviews with teachers and three parents, from the three parents it was found that if their children had never been tested for development, the results of interviews with teachers were obtained that in PAUD children are rarely invited to play origami, children usually geared towards drawing and coloring with crayons.

Researchers are interested in knowing the effect of Origami play interventions on children’s fine motor development. Given that the right fine motoric product will affect children’s outcomes in the future, it should be stimulated frequently. The purpose of this study was to determine the effectiveness of playing Origami interventions to improve the fine motor skills of preschool children in PAUD Aisyiyah VI Bengkulu City.

**Materials and Methods**

This research is a quantitative research using the Quasi Experiment method with the research design “one group pretest and post-test design,” the study was conducted at PAUD Aisyiyah VI Bengkulu City during implementation March-August 2020. The sample in this study were 26 children who were taken using the purposive technique. Sampling. Data on the good motoric development categories of children were obtained using the DDST II (Denver Development Screening Test II) format.

Before the intervention was carried out, the researcher first measured the child’s fine motor development according to its age. After being given the intervention, the researcher again estimated the child’s fine motor development using the same format. The materials needed for the intervention are origami paper of various sizes and colors, a ruler, and scissors. Playing time is 30 minutes, carried out in 6 meetings for two weeks, origami is made to adjust to objects or animals that are liked by children.

**Result**

**Category of Children’s Motor Development Level Before and After Origami Play Intervention**

Table 1. Fine motor development level category of preschool children before intervention playing origami

</tbody>
</table>

From the table above, it is known that the average score category for the level of fine motoric development before the Origami Play Intervention was 2.27 and increased to 2.81 after the intervention, with a ρ value of 0.000 (α = 0.05).
It can be concluded that playing Origami interventions are effective in improving fine motor development of preschool children.

**Discussion**

**Category of Children’s Motor Development Level Before and After Playing Origami Intervention**

From table 1 above, it is known that there are three children (11.5%) who have the untestable fine motor development category, 13 children (50.0%) are included in the suspect category. There are ten children (38.5%) included in the fair motor development category origami play.

There are several factors according to researchers that cause children to get suspect and untestable results at the time of the first test (pretest) in this study; the first is the effect of the child’s age when tested and the child’s experience of the components tested based on the child’s age, given the Denver II test component—based on the child’s age line. This is by the research results Yılmaz (2016), where the difference in the child’s age when tested affects the social skills, language, and movement of the child. The child’s stimulation and environmental factors also play a role in determining this test. Parents’ role is an essential part of providing early stimulation for children’s intelligence and development in the future.

Children who get more developmental stimulation from parents and caregivers will make their children develop better, considering that development in early childhood is something that can be trained, stimulated and intervened as often as possible. Parents and or caregivers’ involvement in providing stimulation to children is essential. Given the development of children’s motor skills, both gross and fine motor skills that develop well from an early age, affect the development of children’s language skills during infancy and toddlerhood.

Table 2 above provides information that there were five children (19.2%) who had the suspect fine motor development category after the Origami play intervention, and 21 children (80.8%) were included in the normal fine motor development category. From this data, it is known that there has been an increase in the development of children’s good motor categories before and after giving Origami play interventions.

The product is an increase in the development of fine motor skills after giving origami play interventions, likewise with research Claudia (2018), which shows an increase in fine motor skills in PAUD children after playing origami. Origami is an activity that trains creativity, fingers, arm, and wrist movements. Origami teaches art to children, trains eye coordination and small muscles of children’s fingers so that if this stimulus is done regularly and continuously, it will introduce the child’s fine motor skills.

Based on table 4, the mean rank of the increase in fine motor skills above is known as no children who experience a decrease in the category of adequate motor development ability before and after the intervention (Negative Ranks). Fourteen children had an increase in the fine motor development category (Positive Ranks), and 12 children had the fine motor development category that did not change (Ties). The 14 children who experienced an increase in most of the suspect development level categories increased to normal. In comparison, the 12 children who were recorded as not sharing the development category mostly came from the normal development category when measured before the intervention, so that there were no changes in the level of development. The Wilcoxon test results obtained a $p$ value of 0.000 ($\alpha$ 0.05), which means that playing origami effectively improves children’s fine motoric development. Increase in the mean score of the level of child development category.

During the second test (post-test) using the Denver II format, it was seen that the child succeeded (Passed) in answering and carrying out the examiner’s orders, this increased ability was because the child had been trained in fine motor skills using paper folding media or origami. The coordination of the eyes, wrists, and fingers is essential when folding paper, origami makes the development of the fingers and arms increase. Playing origami also requires children to be patient, repeat if they are wrong, and try again, so that in addition to increasing psychomotor abilities, children’s thinking and cognitive skills also develop. This is what makes children’s motor skills increase compared to before.

Given that fine motor development is an essential part of child development. The story of the preschooler’s small muscles and to carry out functions such as writing,
using a spoon, coloring, drawing. Good fine motor skills affect the level of children’s development in the future.\textsuperscript{13}

When the right stimulus is given continuously from an early age, the child will get used to practicing fine motor skills. At an early age, children’s brain development increases rapidly. The provision of origami playing interventions and their effectiveness in improving children’s fine motor skills is in line with the results of research conducted by Widayati (2019) there is an increase in the child’s fine motor skills after being given paper folding play intervention.\textsuperscript{14}

**Conclusion**

Based on the results of the research and discussion above, it can be concluded that the intervention playing origami is effective in improving the fine motoric development of preschool children in PAUD Aisyiyah VI, Bengkulu City. The Wilcoxon test results obtained a value of \( \rho \) value 0.000 (\( \alpha \) 0.05). Teachers and parents should pay more attention to and increase the stimulation of fine motor skills of preschool children by facilitating children to play folding, sticking, and paper cutting more often.

The *ITGA2B* gene Polymorphism Associated with Glanzmannthrombasthenia in Sample of Iraqi Patients

Hayderkareemkataa Al-Aidy¹, EhabDawood Salman², Zaid Jamal Mahmood ³

1-MSC Molecular biology, Wassit Health Department, Ministry of Health, Iraq, 2-Department of Biotechnology, College of Science, University of Baghdad, Iraq, ³M.B.ch.B, FIBMS, Congenital Bleeding, Children Welfare Hospital, Medical City

**Abstract**

Case control study was used, with healthy individual control (n=20) and Glanzmannthrombasthenia patients (n=15). The diagnosis was depending on the clinical, hematological parameters and molecular analysis. All patients were severe bleeding symptoms with normal Hemoglobin, and platelets count and prolonged bleeding time.

It was successfully identified three SNP in *ITGA2B* gene the first SNP c.2653 T>G (rs5911) was presented with three genotypes (TT, TG and GG). The genotype frequencies of TT in control group (60.0 vs. 90.0%) show significant difference (p ≤0.05) compared with GT patients. It was also noticed the frequency of mutant allele (G) revealed a significant difference (p ≤ 0.01) in GT patients compared with controls group (33.3 vs. 7.5%; OR = 6.17; EF = 0.44; 95% C.I. = 1.55 - 24.53) respectively.

The c.641T>C (rs137852911) was given with three genotypes (TT, TC and CC). The frequencies of these genotypes show non-significant difference (p ≤0.05 between control and GT patient, while the mutant allele (C) show significant difference (p ≤ 0.01) in GT patients compared with controls group (10 vs. 7.5%; OR = 1.37; EF = 0.11; 95% C.I. = 0.26 – 7.14).

The c.6438G>A showed three genotypes (GG, GA and AA) with two alleles (G and A).

The frequencies of these genotypes GG (60 vs. 95 %), GA (33.3 vs. 5.0%) and the third genotype (AA) 26.6 vs. 0% show significant difference (p ≤0.05) between control and GT patient. It was also found the mutant allele (A) revealed a significant difference (p ≤ 0.01) in GT patients compared with controls group (33.3 vs. 2.5%; OR = 11.87; EF = 0.35; 95% C.I. = 1.41 – 99.80) respectively.

**Keywords:** Glanzmannthrombasthenia, genotypes, revealed, bleeding time, frequencies

**Introduction**

Glanzmannthrombasthenia (GT) is a rare, inherited disorder of platelet function characterized by absence of platelet aggregation, and prolonged mucocutaneous bleeding tendency, caused by qualitative or quantitative defects of the platelet membrane integrin αIIbβ3(¹, ²).

The molecular basis of GT is linked to qualitative and/or quantitative abnormalities of αIIbβ3 integrin that between binding of the adhesive proteins lead to aggregating platelets and clot formation at position of wound (¹). Patients have been separate into three groups: type I where platelets absence αIIbβ3 (have <5% of the normal platelet content), type II with residual αIIbβ3 (5–15%) that may be functional or not, while in type III with αIIbβ3 fails to function despite platelets possess upto 100% of normal levels (³).

Many Heterozygous or Homozygous mutations found in *ITGA2B* gene and these mutations are led to splice defects and stop codons truncate or lead to the loss...
mRNA synthesis(3).

It was reported that GT appear in many ethnic populations such as Iranians, Indians, Iraqi Jews, Jordanian Arabs, and Palestinians in high frequency(4).

As a mention above this study was aimed to investigate the ITGA2B gene polymorphism in a sample of Glanzmann thrombasthenia Iraqi patients.

Materials and Methods

Case control study was used, with healthy individual control(n=20) and Glanzmann thrombasthenia patients(n=15) were recruited at the Division of pediatric teaching hospital in Baghdad and Karama Teaching Hospital in wassit. Both laboratory data and clinical of every patient were gathered from their clinical records which included gender, age, age at determination, period of beginning, bleeding manifestations, and consanguinity of parents. Samples of patients and the control group were collected in EDTA, tubes, and hematology tests (Hb and platelets count) were performed by Coulter automated analyzer and the bleeding time examination was done.

Isolation of DNA from the EDTA blood of patient samples and control groups using DNA Kit from Promega. regions of ITGA2B gene were amplified by PCR using primers. Which was designed using the program PRIMER3. Genomic DNA was used as the template for 25 PCR reaction system containing 12 µM of Master Mix, 10 µM each of oligonucleotide primers, 8.5µM Nuclease Free Water and 2 µM Taq DNA Polymerase. Thermocycling conditions of primers F5'-TATGTCAGTGCTTGGAGCCC-3' and R 5'-CAGAGAGCCTGCTCACTACGA-3',andprimers F5'-GTGCTTTGGGTACAAGAATG-3' and R 5'-TCCTCCACCAAGTCTCTAATAATC-3' were as follows: an initial denaturation at 95 °C for 5 min, followed by 30 cycles of denaturation , annealing, and extension at 95 °C for 45 s, 60 °C for 45 s, and 72 °C for 45 s Respectively. A final extension step (72 °C, 7 min) was performed at the end. other primers F 5'-CTCCAGGTGATGAGACCGG-3' and5-R5'-TCTGGAATGCCGGTGTACC-3' have same thermocycling conditions but have different annealing temperature (65 °C).

Using ABI3730XL, a Sanger sequencing analysis was performed on the PCR product by Macrogen Corporation - Korea, and the results were analyzed using a genious program.

All data was analyzed statistically by using SPSS software (Statistical Package for Social Sciences) version 20 and p-values were set at 0.001. Data are presented as Mean ± SD (standard deviation). The results were analyzed using analysis of variance (ANOVA).

Depending on Hardy-Weinberg equilibrium, the difference between the expected and observed frequencies of the genotype was determined as well with respect to the expected and observed alleles at the control and patient groups. Alleles and genotypes of ITGA2B genes were presented as percentage frequencies, and significant differences between their distributions in GT patients and controls were assessed by two-tailed Fisher’s exact probability (P). In addition, odd ratio (OR), etiological fraction (EF) and preventive fraction (PF) were also estimated to define the association between ITGA2B and ITGB3 alleles and genotypes with the disease, these estimations were calculated by using the WINPEPI computer programs for epidemiologists, which is available free online at http://www.brixtonhealth.com.

Result

GT was diagnosed depend on of Clinical signs and data of each patient. The results of the hemoglobin test and platelet count were within the normal range. Where were the results of an examination HB mean 11.7±1.7 of patients and mean 12±1 of control group. While the average platelet count test values were mean 217.1±9.2 of patients and mean 296±9.9 of control group. The platelet count and the hemoglobin parameters and indexes measured in the current work were not significantly different ( p<0.001) between Glanzmann patients, and control groups.

Whereas, there was a significant difference between the values of bleeding time result (mean 13.9±3.2) for patients compared to the control group (mean 4.7±1.5).

The results showed that after ethidium bromide staining, a main band (length 980 bp) appeared on the gel, which represented the amplification of the restricted
region from 44375568 to 44376560 in the ITGA2B gene containing exons 23, 24 and 25 with introns between these exons. The other result of the amplification of the DNA fragments by the primers is the region between 44384919 and 44385928 with a band of 1000 bp on the gel and the exons 3, 4, 5, 6 and 7. The DNA fragment between 44383196 and 44384189 was amplified by PCR and primer set. The length of the product DNA fragment was 990 bp, including exons 11 and 12 figure(1).

Sequencing analysis can detect a total of 3 different mutations in the ITGA2B gene. c.2653 T>G mutation is the replacement of nucleotide T allele in position chr17:44375697 (GRCh38.p12) in exon 24 with G allele, which causes the amino acid isoleucine to become a serine substitution at position 874 of the GPIIb figure (2). c.641T>C mutation at position chr17: 44385193 (GRCh38.p12) revealed that the mutation changed T>C in exon 6 and caused the amino acid leucine to become proline at position 214 in the polypeptide chain figure (3). c.6438G>A mutation of chr17:44383668 (GRCh38. p12) of exon 12 was detected by sequencing analysis, and caused the amino acid at GPIIb 345 to replace methionine with isoleucine figure (4).

Figure 1: PCR products of amplification fragment DNA on 2% agarose gel at 70 voltages for one hour of ITGA2B gene in the confined areas: A- from 44375568 to 44376560 which contains exons 23, 24, and 25 of GT patients with band have 980 bp. B- from 44383196 to 44384189 which contains exons 11, and 12 of GT patients with band have 990 bp. C- from 44384019 to 44385928 which contains exons 3, 4, 5, 6 and 7 of GT patients with band have 1000 bp. Marker: ladder marker DNA 100 bp.
Figure 2 Nucleotide sequencing analysis of ITGA2B gene. Results for nucleotides are shown for the GT patient. The nucleotide substitution T>G at position 2653 in exon 24 and the corresponding amino acid change from Ile874 (ATC) to Ser874 (AGC) are indicated.

c.2653 T>G (rs5911)

Figure 3. Nucleotide sequencing analysis of ITGA2B gene. Results for nucleotides are shown for the GT patient. The nucleotide substitution T>C at position 673 in exon 6 and the corresponding amino acid change from Leu 214 (CTT) to Pro 214 (CCT) are indicated.

c.641T>C (rs13782911)
The SNP (c.2653 T>G (rs5911) at position 2653 in exon 24 was presented with two alleles (T and G) and three genotypes (TT, TG and GG). These genotypes showed deviation from HWE in GT patients, because there was a significant difference between the observed and expected genotype frequencies (p ≤ 0.01), it was also noticed a deviation from HWE in controls treatment with significant difference (p ≤ 0.01).

Comparing GT patients to controls revealed that genotype frequencies of TT (60.0 vs. 90.0%) and TG (13.4 vs. 5.0%), while the third genotype (GG) was observed with a frequency 26.6 vs. 5.0% in patients and control group respectively. The genotype TT in control group was significant difference (p ≤ 0.05) compared to GT patient, but TG and GG were show non-significant difference (p ≤ 0.05) compared between control and GT patient. It was also noticed the frequency of mutant allele (G) show a significant difference (p ≤ 0.01) in GT patients compared to controls (33.3 vs. 7.5%; OR = 6.17, EF = 0.44; 95% C.I. = 1.55 - 24.53) that mean (G) allele (OR = 6.17) is risk factor associated with GT patients and negatively associated with healthy subject, while in the control group the frequency of (T) alleles show a significant difference (p ≤ 0.01) compared to GT patients (92.5 vs. 66.6; Reciprocal of OR = 6.17, EF = 0.932; 95% C.I. = 0.04 - 0.65). In this case the (T) allele associated with healthy subject and considered as protective factor, but in GT patients group was negatively associated with Reciprocal of OR = 6.17 (Table).

The SNP rs137852911 (c.641T>C) at position 9313 in exon 6 was presented with two alleles (T and C) and three genotypes (TT, TC and CC). These genotypes showed deviation from HWE in GT patients, because there was a significant difference between the observed and expected genotype frequencies (p ≤ 0.01), it was also noticed the genotypes frequencies (TT, TC and CC) show deviation from HWE in controls group with significant difference (p ≤ 0.01).

Comparing GT patients to controls revealed that genotype frequencies of TT (86.6 vs. 90.0%) and TC (6.6 vs. 5.0%), while the third genotype (CC) was observed with a frequency 6.6 vs. 5.0%. These genotypes were non-significant difference (p ≤ 0.05) compared between control and GT patient. It was also noticed the frequency of mutant allele (C) show a significant difference (p ≤ 0.01) in GT patients compared with controls (10 vs. 7.5%; OR = 1.37; EF = 0.11;
95% C.I. = 0.26–7.14), while in the control group the frequency of (T) allele show a significant difference (p ≤ 0.01) compared to GT patients (90 vs. 92.5; Reciprocal of OR = 1.73, EF0.71; 95% C.I. = 0.14–3.8). In this case the (T) allele associated with healthy subject and non-associated with GT patients (Reciprocal of OR = 1.73) and considered as protective factor (Table).

The c.6438G>A at position 6582 in exon 12 was presented with three genotypes (GG, GA and AA) and two alleles (G and A). These genotypes showed deviation from HWE in GT patients, because there was a significant difference between the observed and expected genotype frequencies (p ≤ 0.01), it was also noticed a deviation from HWE in controls treatment with significant difference (p ≤ 0.01).

Comparing GT patients to controls revealed that genotype frequencies of GG (60 vs. 95%), GA (33.3 vs. 5%), and The third genotype (AA) 26.6 vs. 0% and The third genotype (AA) 26.6 vs. 0%. The GA and AA genotypes were show non-significant difference between healthy subject and GT patient, while the genotype GA was significant difference (p ≤ 0.05) compared between control and GT patient. It was also noticed the frequency of mutant allele (A) show a significant difference (p ≤ 0.01) in GT patients compared to controls (33.3 vs. 2.5%; OR = 11.87; EF = 0.35; 95% C.I. = 1.41–99.80) that mean (A) allele is risk factor associated with GT patients and negatively associated of healthy, while in the control group the frequency of (G) allele show a significant difference (p ≤ 0.01) compared to GT patients (66.6 vs. 97.5; Reciprocal of OR = 11.87; EF0.98; 95% C.I. = 0.01-0.71) and positively associated of health and negatively associated of GT patients (Table).

Desiccation

GT has been reported among Iraqi patients by several groups (5, 6), including a series of 12 patients from Iraqi-Jewish which was described in 1991(7), and other group from Iraqi-Jewish was described in 2001 (8). The average age of patients was 20 years in this study and this is consistent with Al-Rahal and Giath 2015, which stated that this disease affects children and young adults. Most of the cases were caused by the consanguineous marriage to the parents. Consanguineous marriage is a common behavior in Iraqi populations, also prevalent in some populations, such as Iranians, Saudi Arabia, and Southern Indians (6). Consanguineous marriage between parents is an important risk factor for GT (5).

The normal level of Hb was expected in Glanzmann, because the defects of these diseases directly affect platelets, not directly affect the level, number and nature of red blood cells. However, in some samples, the level of hemoglobin has decreased, especially in some women, the common problem that troubles women with Granzman is menorrhagia (9). The platelet count results of all patients and the control group were normal, and the difference was not statistically significant and this is result correspond with Sabhan et al. 2017.

Regarding prolonging the bleeding time of patients (n = 15), statistical analysis showed a significant difference (p ≤ 0.01) compared with the control group. Prolonged bleeding time suggests delayed primary hemostatic thrombosis due to poor platelet aggregation (5).

As a mention above my be Rs5911 T > G considered as missense mutation that causes the substitution of isoleucine at position 843 of the GPIIb heavy chain with a serine amino acid. Therefore, rs5911 may work by affecting post-fibrinogen binding events, including cytoskeletal reorganization and clot retraction, and in some way affect the stability of platelet/fibrinogen interaction (10) depending on this finding the (G) allele considered as risk factor associated with GT patients while the (T) allele associated with healthy subject and considered as protective factor.

The c.641T>C mutation results in the creation of a proline-glycine-alanine-proline (PGAP) sequence at the amino-terminal end of the b-turn structure. The rigidity of the two proline residues linked by flexible glycine and alanine residues may create a twist in the secondary structure affecting the conformation of the b-turn. The inability of mutant GPIIb/IIIa receptors to be recognized by conformation-dependent antibodies, to be activated into a high-affinity ligand binding conformation, and to adhere to immobilized fibrinogen suggests that this structural alteration affects ligand-binding and that the Leu214Pro mutation has either an indirect or direct effect on this site (11). In this study, it was show the (C) allele considered as risk factor associated with GT patients while the (T) allele associated with healthy subject and considered as protective factor.

c.6438G>A mutation in exon 12 was lead to substitution amino acid Methionine to Isoleucine acid at position 345 of the GPIIb. The change in the amino acid Methionine to Isoleucine may lead to a change in the structure of the receptor and thus affect the function of the receptor.

In this result, it was found the (A) allele considered as risk factor associated with GT patients while the (G) allele associated with healthy subject and considered as protective factor.

Abstract

Drug abuse or overdose in accidents is a serious social issue. This study concerned the adsorption behaviour of the Valium drug in both simulated gastric and intestinal pH onto the untreated eggshell powder by using UV spectroscopy. The effects of various experimental parameters such as contact time, pH-solution, an adsorbent dosage of Valium and temperature range (300-320k) on the adsorption capacities have been investigated. The suitability of Langmuir and Freundlich adsorption models to the experimental equilibrium data at different solution temperatures were calculated. The adsorption was well described by the Freundlich isotherm model and Langmuir, $S_1$ for the stomach and $S_2$ for the intestine according to the Giles classification. Thermodynamic parameters such as $\Delta H^\circ$, $\Delta G^\circ$, and $\Delta S^\circ$ results showed that the adsorption of the drug increases by increasing the temperature in the stomach solution, i.e., the endothermic reaction decreases by increasing the temperature at the intestinal solution, i.e., the reaction is exothermic. Experimental data were also tested in terms of adsorption kinetics, the results illustrated that the adsorption process was following pseudo-second-order kinetics in the stomach solution and first order in the intestinal solution.

Key words: Adsorption, Langmuir, Freundlich, Kinetics, Thermodynamics

Introduction

Sorption and adsorption process have been extensively studied as a low cost, effective method for removing a wide variety of hazardous materials from aqueous solutions. Principle considerations in the manufacturing of a drug product include the therapeutic goal, the position of application, and systemic drug sorption from that position. The drug should preferably be entirely and steadily absorbed from the Stomach and intestine sites. Valium is a trading name for Diazepam drug which widely used to treat various types of epilepsy, insomnia, and anxiety, and muscular spasms. Overdose Valium can have serious consequences that can cause a number of side effects and hence death in some cases.

Figure(1): Structure of Valium
Diazepam is one of the most widely prescribed 1,4-benzodiazepine. The consumption of Valium along with other substances such as alcohol is known to increase its sedative effects and its increased absorption rate. To alleviate these effects a range of analytical approaches has been investigated to determine the adsorption of diazepam on the surface of safe substances like an eggshell powder. Adsorption is a highly effective, economical, promising method that applied for purification wastewaters. Different conventional and non-conventional adsorbents have been used such as Hen egg-shell. Hen egg-shell typically consists of ceramic...
materials constituted by a three-layered structure, namely the cuticle on the outer surface. The chemical composition of the eggshell has been reported by weight as follows: calcium carbonate (94%), magnesium carbonate (1%), calcium phosphate (1%), and organic matter (4%) (4). Sorption–desorption studies were carried out for five cycles by Vijayaraghavan and et al. using domestic eggshell to remove copper from aqueous solution in an up-flow packed column (5). Another study has been described the adsorption isotherms by Otun et al. using Powdered eggshell (particle size 63 μm) as an adsorbent to remove three metal ions Pb (II), Ni (II), and Cd (II) from aqueous solution and from natural water in a batch process (6). Based on reported research in the literature, it was found that there was a high sorption capacity as compared to other adsorbents for a low-cost sorbent eggshell to remove Cr (III) ions from aqueous solutions (7). In this work, the equilibrium adsorption characteristics of Valium on the crushed eggshell’s surface have been evaluated in batch experiments. The adsorption isotherms, temperature effect, pH adjustment, Kinetic measurements (determined by the pseudo-first-order, pseudo-second-order) and thermodynamic parameters have been calculated.

Waste eggshells have used as adsorbate due to their recycling; it has the potential to reduce environmental pollution while acting as a low cost, safe effective material to reduce Valium absorption by the Digestive.

Experimental methods of adsorption

Chemical materials

Hydrochloric acid (Sigma Aldrich, 99.0%), Sodium chloride (Sigma Aldrich, 99.0%), Sodium hydroxide (Sigma Aldrich, 97.0%), Potassium phosphate (Alfa Aesar, 97%).

Adsorption characterization

All spectral and absorbance measurements were conducted on Shimadzu Uv-Vis 1700 digital double beam recording spectrophotometer (Italy) using 1cm glass cells. this technique provides information about the adsorption of adsorbate on the adsorbent surface whether it is physical or chemical adsorption. The results of the current study show the susceptibility of the eggshells surface to the adsorption of the Valium by using UV spectroscopy. A digital pH meter 720 WTW 82362 has also been used to adjust the acidity or alkalinity of a solution.

Absorbate solutions preparation

Stock solutions of Valium were prepared by dissolving 50 g in distilled water to give a concentration of 100 mg/L and that diluted with distilled water when necessary to prepare other concentrations. The drug may be precipitated with pH between (7.2 – 7.4). To assess the suitability of the approach, the selected pH is important to consider. In the stomach, the pH is about 1 - 2 and in the duodenum, the pH is between 5 to 7.5. so, the degree of solubility is also likely to be influenced as the drug passes through the intestines (8).

To prepare stomach fluid, 2g of sodium chloride and 7ml of hydrochloric acid have been dissolved in distilled water until the pH solution adjusted to 1.2. To prepare intestinal fluid, 0.89 g of sodium hydroxide and 6.8g of anhydrous potassium phosphate (KH₂PO₄) have been dissolved in distilled water until the pH solution adjusted to 6.8.

Preparation of biological sorbent

Eggshells were collected from kitchen waste and washed thoroughly in running water for several times and then rinsed with deionized water until no foreign material remained behind. After washing with distilled water, the sample was dried in an oven at 60 °C for two hours to drive off any moisture. The dried eggshells were crushed and milled in an agate mortar and pestle to form a fine powder with a high specific surface area, then passed through a (200 μm) sieve, the portion which passed through the mesh is retaining in a tight container. The chemical compounds of the eggshell are: \{%W:Na₂O=0.489, MgO=0.845, Al₂O₃=0.055, SiO=0.010, P₂O₅=0.181, SO₃=0.747, K₂O=0.50, CaCO₃=97.015, Fe₂O₃=0.029, SrO=0.140, Cl=0.138\}.

Sorption Experiments

Series of batch adsorption tests were conducted to determine the effects of contact time, initial concentration of the drug dosage, amount of adsorbent, and operating temperature on adsorption performance. Therefore, various amounts of egg-shells (0.05, 0.1, 0.15, 0.2, 0.3, 0.4, 0.5, and 1g) were introduced into a series of conical
flasks each filled with 25 mL of Valium solution with 40 ppm at pH 1.2, and pH 6.8 to determine the amount of adsorbent. The flasks were then placed in a thermostat water bath shaker and agitated up to a total contact time of 30 min at a fixed agitation speed of 90 rpm. Drug concentration in the samples was analysed by atomic absorption spectrophotometer. Initial drug concentration was determined by shaking (25mL) of different initial concentrations (10–50 ppm) of Valium solution placed in five conical flasks with 0.1 g of eggshells at (pH = 1.2), and pH 6.8, for 30 min at 310 k. Equilibrium data were obtained after the solution was filtered and analyzed. In addition to these experiments, the effect of contact time on the drug adsorption was also investigated. Batch adsorption tests were carried out at different contact time from 10 to 120 minutes, 30 min was found to be the best period of contact at equilibrium.

Another experiment, 25 mL of drug solution with a concentration of 40 ppm was added to a fixed amount of adsorbent (0.1 g of eggshells in (50 mL) conical flask and agitated in thermostat shaker with a speed 90 cycle/minute until reaches equilibrium after (30 min) at 310 k temperature, then the solution was filtered and analysed by measuring absorbance at a maximum wavelength of (358 nm) and (413 nm) for stomach and intestinal solutions respectively. The residual Valium concentration in the supernatant was determined using a UV/Vis instrument. The amount of Valium adsorbed was calculated by measuring the difference in concentration between samples that were obtained at two consecutive time intervals over the period of the adsorption experiment.

Again, the experiment was repeated at different temperatures (300 and 320) k to investigate the operating temperature on adsorption performance and to calculate thermodynamic parameters (ΔH°, ΔG°, ΔS°). The sorption capacity was calculated by the following equation (10,11)

$$Q_e = \frac{(C_0-C_e) V_{sol}}{M}$$

Where: $C_0$: is the initial concentration (mg/L), $C_e$: is the equilibrium concentration (mg/L), $V_{sol}$: is the volume of drug solution (L), and $M$: is the weight of eggshells (g).

The experimental data were calculated to describe adsorption equilibrium isotherms by using two main theories, Langmuir and Freundlich models. The main assumption of the Langmuir adsorption model is that the surface of the adsorbent is covered with a monolayer of adsorbed molecules. Langmuir isotherms which represented by the linear equation:

$$\frac{C_e}{q_e} = \frac{1}{a K_l} + \frac{1}{a C_e}$$

Where $a$ and $K_l$ represent Langmuir’s constants related to limiting adsorption capacity when the surface is fully covered with a monolayer adsorbate and rate of adsorption respectively. $C_e$ (mg/L) is the equilibrium concentration of the adsorbate, $q_e$ (mg/g) is the amount of Valium adsorbed per unit mass of adsorbent. Langmuir’s equation assumes the formation of one layer of adsorbate molecules on the surface while the Freundlich isotherm explains the behaviour of adsorption by the formation of more than one layer and consider the heterogeneity of the surface. The linear form of Freundlich isotherm is:

$$\log Q_e = \log K_f + \frac{1}{n} \log C_e$$

Where $K_f$ and $n$ are Freundlich constants that depend on the nature of the adsorbent and the gas at a particular temperature which characteristics of the system, including the adsorption capacity and adsorption intensity, respectively (12). In other words, $K_f$ can be defined as the distribution coefficient and represents the quantity of drug adsorbed onto eggshells at equilibrium concentration.

The equilibrium constant ($K_{eq}$) for the adsorption process at each temperature is calculated by using the relationship as follow:

$$K_{eq} = Q_e \frac{W_{ts}}{V_{so}} \frac{(C_0 - C_e) V_{sol}}{M}$$

Where ($W_{ts}$) is the weight of eggshell, ($V_{so}$) is the volume of drug solutions.

2.5.1. Thermodynamic calculations

Thermodynamic parameters (ΔH°, ΔG°, ΔS°) were calculated using three different temperatures 300, 310, 320 K to evaluate the feasibility of the adsorption process. The change in free energy ($\Delta G^0$) could be calculated at absolute temperature (T) with the gas constant 8.314 J.mole$^{-1}$.K$^{-1}$ as shown in following equation:

$$\Delta G^0 = -RT \ln K_{eq}$$
\[ \Delta G^o = -RT \ln K \]  \hspace{1cm} (6)  

\[ \Delta G^o = 2.303 RT \log \frac{Q_e}{C_e} \]  \hspace{1cm} (7)

Vant Hoff’s\(^{(13)}\) and Gibbs equations were used to determine the heat of adsorption \(\Delta H^o\) and change in entropy \(\Delta S^o\) respectively as shown in the equations below. Where \(K\) is the equilibrium constant when \((C_e)\)-approaches zero at a certain temperature, \((X_m)\) is the maximum uptake of adsorption at a certain value of equilibrium concentration \((C_e)\).

\[ \ln K = \frac{-\Delta H^o}{RT} + \text{constant} \]  \hspace{1cm} (8)

\[ \log X_m = -\frac{\Delta H^o}{2.303 RT} + \text{Con.} \]  \hspace{1cm} (9)

\[ \Delta G^o = \Delta H^o - T \Delta S^o \]  \hspace{1cm} (10)

**Kinetics calculations**

The effect of time on Valium adsorption was investigated. Adsorption experiments were carried out at 310 k for a period of time ranged between (5-50 minutes) while other conditions were held constant. At the end of each adsorption period, the suspension was centrifuged and filtered. The residual amount of drug in the solutions after adsorption was determined spectrophotometrically, at the maximum wavelength of 314 and 358 nm for the stock solutions of intestinal and gastric fluids respectively. In order to determine the kinetics of Valium adsorption on eggshells, pseudo-first-order (PFO), pseudo-second-order (PSO) were applied. Lagergren\(^{(14)}\) suggested a pseudo-first-order equation for the sorption processes of a liquid-solid system based on the solid surface capacity. The pseudo-first-order model equation is:

\[ \log(q_e - q_t) = \log q_e - k_1 t/2.303 \]  \hspace{1cm} (11)

The other hand pseudo-second-order model is expressed as\(^{(15)}\):

\[ \frac{t}{q_t} = \frac{1}{k_2 q_e^2} + \frac{1}{q_e} * t \]  \hspace{1cm} (12)

where \(k_1\) (\(\text{min}^{-1}\)), \(k_2\) (\(\text{mg} \cdot \text{g}^{-1} \cdot \text{min}^{-1}\)) is the rate constant of the model (PFO), and (PSO) respectively, \(q_t\) is the amount of solute adsorbed (\(\text{mg}/\text{g}\)) on the adsorbent at time \(t\), and \(q_e\) is the amount of adsorption (\(\text{mg}/\text{g}\)) at equilibrium. In recent years, the linear forms of the pseudo-first order PFO, and pseudo-second order PSO are the most widely used in liquid-phase sorption processes on solid surface to determine the most fitted kinetic model for the adsorption process.

**Results and Discussion**

**Valium absorption Spectra and Calibration curve**

Firstly, The UV detection wavelength at \(\lambda_{max}=314\) for the stock solutions of intestinal fluid and \(\lambda_{max}=358\) for the stock solutions of gastric fluid were defined. The calibration curve of the drug solutions has prepared to calculate the concentrations of the samples from each experiment, five different concentrations were prepared, and the absorbance was measured via UV/Vis spectrophotometer from(400 to 700nm). The maximum absorbance and calibration curves were plotted against the concentrations of Valium for the simulated gastric fluid and the simulated intestinal fluid.

**Valium Adsorption isotherms**

Equilibrium studies determine the capacity of the adsorbent and describe the adsorption isotherm by constants which values express the surface properties and affinity of the adsorbents. Equilibrium adsorption isotherms of Valium have been studied as a function of concentration. The results in figure 3 showed that the adsorption uptake increase with increasing drug initial concentration. This was because when the initial concentration increased, the mass transfer driving force would become larger, and that resulting in higher molecules adsorption. Whereas, at lower initial concentration, a high number of active vacant sites available on the eggshell’s surface were sufficient to absorb most of the Valium molecules. As observed from the results in figure(2), the shape of the isotherms was \(S_3\) in simulated gastric fluid and \(S_2\) in a simulated intestinal fluid according to Gilles classification\(^{(16)}\).

Results in figure(2) demonstrate that the adsorption of Valium continue over the initial stage of the contact time period until reaching the equilibrium. This occurrence was due to the presence of a large number of vacant surface sites was available for adsorption during the initial stage, and near the equilibrium time, the same trends of molecules adsorption were observed in the stock solutions of intestinal and gastric fluids.

Change of pH solution affects the surface charge of the adsorbents as well as the degree of ionization
of adsorbate material. The adsorption of ions such as hydrogen, hydroxyl, and other ions are affected by the pH of the solution. As the pH increases, it is usually expected that the cationic ion adsorption also increases due to increasing of the negative surface charge of adsorbents\(^{(17)}\). Benzodiazepine is a weakly basic or neutral drug\(^{(18)}\). With increasing pH values the adsorption of Valium on eggshell tends to decrease, which can be explained by the electrostatic interaction of anionic species with the negatively charged hydrolysed eggshell composite surface. Experimental data absorption was better fitted to the Freundlich isotherm more than Langmuir in a simulated intestinal fluid SIF and fitted to the Langmuir more than Freundlich in simulated gastric fluid SGF. It can be concluded that the drug was effectively adsorbed onto eggshell at both solutions with significantly higher adsorption in simulated gastric fluid.

Freundlich and Langmuir adsorption isotherm

Analysis of adsorption isotherm is essential importance to describe how adsorbate molecules interact with the adsorbent surface. Adsorption studies were performed at two pH values 1.2 and 6.8 to simulate the environments in the gastrointestinal tract (stomach and intestine). Monolayer adsorption uptake onto a surface containing a limited number of adsorption sites has been assumed by Langmuir. When \(\frac{C_e}{q_e}\) is plotted against \(C_e\), a straight line with a slope of \(1/a\) and intercept of \(\frac{1}{K_f}\) is obtained as shown in figure(2) Langmuir plots exhibited excellent \(R^2\) value compared to Freundlich plots at pH =1.2 of SGF, indicating excellent fitting of the model to the experimental data. The Freundlich isotherm is a mathematical expression for the adsorption equilibrium between liquid and solid heterogeneous surfaces. It is supposed that the powerful binding sites are occupied first and consequently, the binding strength decreases with the increasing degree of site occupation\(^{(19)}\). Figure(2) shows that the drug concentrations on the eggshell adsorbent will increase and be more than one layer as long as there is an increase in the drug concentration in the liquid. The value of (n) represents the favourability of the adsorption process and \(K_f\) is giving an indication about the quantity of drug adsorbed onto eggshell at equilibrium concentration. The slope of 1/n is a measure of the adsorption intensity\(^{(20)}\), Table(1) demonstrates the values of \(R^2\) for each isotherm in different pH and gives an indicator about the best adsorption isotherms. By comparing the results presented in this table, greater correlation \(R^2\) value for Langmuir isotherm has registered than those of Freundlich isotherm in the SGF solution. While in SIF solution, the greater correlation \(R^2\) value was for the Freundlich isotherm.

**Fig(2):** Effect of (contact time, Calibration curve, Isotherm, Freundlich) on adsorption of Valium onto eggshell powdered in both simulated gastric SGF and intestinal fluid SIF at 310 k.
Kinetic models for the adsorption process

Equilibrium of sorption rate is an important factor for the selection of adsorption kinetics that must be taken into account to determine the sorption kinetic constants. The experimental data of the drug adsorption process kinetics Pseudo-first-order PFO and the pseudo-second-order PSO kinetic equations have been investigated in this study. After the data were fitted to kinetic equations, the highest average regression coefficients ($R^2=0.881$) were obtained for the pseudo-second-order kinetic equation in SGF solution. The lowest $R^2$ value was for the pseudo-second-order kinetic equation in SIF solution (figure.3).

Equilibrium analysis of adsorption is required for evaluating the possibility or capacity of a sorbent. However, an ideal sorbent for drug control must have not only a large sorption capacity but also a fast sorption rate. (Table.1) shows, in acidic solution (pH=1.2) are likely to be second-order because of the experimental value of $q_e$ approximately equal to the theoretical value, higher value of correlation coefficient. In contrast, very low correlation coefficient was observed for the simulated intestinal fluid. Therefore, the adsorption processes followed well pseudo second-order kinetics for the simulated gastric fluid as shown in figure(3).

**Fig(3): Kinetic of Pseudo first and second Order**

Effect of temperature on drug adsorption and Thermodynamic data

Effect of temperature on adsorption studies were carried out at (300, 310, and 320K) for Valium. The sensitivity of the adsorption process towards temperature is presented in figure (4). It was found that $q_e$ decline with increasing temperature in simulated SIF fluids, which was probably related to desorption of Valium occurred at high temperatures. These results indicate that the exothermic nature of the process (negative $\Delta H$), that occurs may be due to the tendency of drug molecules to escape from the solid phase to bulk phase with an increase in temperature of the solution.(21). The thermodynamic parameters for the drug adsorption on eggshells powder at various at three different temperatures were calculated and listed in table (2). The values of free energy change $\Delta G^*$, enthalpy change $\Delta H^*$ and entropy change $\Delta S^*$ were calculated Based on the available equations to assess the thermodynamic feasibility of the process and to confirm the nature of the adsorption process, Based on the following literature available equations(22).

Fig(4)-displays the Van’t Hoff plot for the adsorption of drug from aqueous solutions at different pH. Table 5 shows negative ΔH˚ values in SIF which indicates the exothermic nature of drug adsorption, in contrast with the value in SGF which is endothermic process. This finding was consistent with the results obtained earlier where the drug uptake increased and or decreased with increasing solution temperature depending on pH solutions. Senthilkumaar, et. al(23) have reported that the increase in adsorption uptake with increase in temperature was due to the possibility of an increase in the kinetic energy of the adsorbate molecules.

The positive value of free energy change shows a non-spontaneous adsorption process at the range of temperatures(24). On the other hand, the negative ΔG˚ values give indication about the spontaneous nature of adsorption process which indicates that better adsorption is obtained at low temperature. The negative ΔS˚ values suggest the decrease in adsorbate concentration in solid–solution interface.

Conclusion

Currently, adsorption has been regarded as an effective technology method for the removal of soluble heavy molecules from aqueous solution. The present results in this study showed that eggshells powder was a promising safe low-cost adsorbent to be used in reducing the effect of drug abused from aqueous solutions. Equilibrium data has revealed that the drug adsorption depends on the pH solution as well as the ambient temperature. Drug adsorption was highly temperature dependent. Equilibrium data fitted well to Freundlich
isotherm in SIF solution, which suggests heterogeneity in the sorption sites. kinetics model of the adsorption process was found to follow the PSO in simulated gastric fluid at pH =1.2, while in simulated intestinal fluid at pH =6.8 was fitted to PFO kinetic equations.

Housing for Elderly in Nursing Home on the Level of Satisfaction in the work Area of Social Service of Surabaya

Hidayatus Sya’diyah1, Sukma Ayu Candra Kirana1, Diyan Mutyah1, Ayu Citra Mayasari1

1Lecturer Sekolah Tinggi Ilmu Kesehatan Hang Tuah, Surabaya- Indonesia

Abstract

A large number of elderly suffer degenerative brain function decline with the characteristics of progressive loss of memory function and other cognitive abilities. The number is increasing in almost several. The purpose of this study was to look at the effect of housing for the elderly in Nursing Home on the level of satisfaction of the elderly in the Social Service area of Surabaya.

The research design used was “Pre-Experimental” design. The variable in this study was the intervention variable that was the housing for the elderly in the Nursing Home and the output variable that was the satisfaction of the elderly. The population was all the elderly in the work area of the Surabaya Social Service, with the criteria for the age limit of the elderly 60 years and over, with a probability sampling technique. The statistical test used was the Wilcoxon Signed Rank Test.

The results of the study obtained were divided into before and after the housing. Before the housing treatment, there were 133 respondents (88.6%) who were at good satisfaction level and there were 17 respondents (11.4%) who were at very good satisfaction levels. After the housing treatment, the results showed that there were 107 respondents (71.3%) who were at good satisfaction level and there were 43 respondents (28.7%) who were at very good satisfaction level. In addition, the results of the Wilcoxon sign rank statistical test was 0.00. It indicated that there was an effect of housing for the elderly on their level of satisfaction.

Keywords: Elderly, Nursing home, satisfaction

Introduction

A large number of elderly suffer degenerative brain function decline with the characteristics of progressive loss of memory function and other cognitive abilities. The number is increasing in almost several countries. Elderly people tend to experience physical decline and emotional increase, so in terms of architecture, they are certainly different from humans when they were young. According to the Law of the Republic of Indonesia Number 13 of 1998 concerning Elderly Welfare (Undang-undang Nomor 4 Tahun 1965 tentang Pemberian Bantuan Penghidupan Orang Jompo), efforts to improve the welfare of the elderly are still limited to the provision of efforts referred to in Law Number 4 of 1965 concerning the Provision of Livelihood for the Elderly, which is currently found to be inadequate then the development of elderly problems. Therefore, those who have experience, expertise and wisdom need to be given the opportunity to play a role in development. Based on some observations conducted, there are problems at the Nursing Home that make the elderly feel uncomfortable. Therefore, several studies were conducted to obtain the design criteria for the Werdha Nursing Home.

The elderly in 2000 amounted to 7.28% and is projected to increase to 11.34% in 2020, while the population with dementia in 2030 is around 75.6 million and will increase 3 times in 2050 (135.5 million). It shows a fairly high increase which requires immediate treatment and prevention. Meanwhile, around the world, the elderly with dementia reaches almost 47.5 million, from which 58% live in the countries that have low or medium-income per capita (Vega SFD, et al, DOI Number: 10.37506/ijfmt.v15i1.13568

including in Indonesia. Furthermore, Korean government provides subsidies for families who adopt the elderly to be treated at home.²

Broadly the changes experienced by the elderly are divided into 3: physical, psychological and cognitive changes. Physical changes include changes in the sensory system, musculoskeletal system, cardiovascular system, and respiration as well as changes in metabolism; psychological changes include experiencing anxiety, loneliness, and depression; while cognitive changes experienced by the elderly are in the form of decreased memory, IQ (Intelligence Quotient), learning ability (learning), comprehension ability (comprehension), problem-solving, decision making, wisdom, performance, and motivation. As a result, the changes experienced by the elderly cause various disorders, and will have an impact on their satisfaction and quality of life.³ Oliver defines satisfaction as the level of one’s feelings after comparing the performance or the results that he feels with his expectations. The level of satisfaction is a function of the difference between perceived performance and expectations. Individual perceptions of life in society in the context of existing cultural and value systems are related to goals, expectations, standards, and concerns and become a very broad concept that is influenced by individual physical conditions, psychological, level of independence, and the relationship of individuals with the environment. It is referred to as quality of life (World Health Organization Quality of Life (WHOQOL)).⁴ Quality of life is an important indicator to assess health care interventions in terms of prevention and treatment. Low quality of life of the elderly is a result of various diseases that have an impact on decreased productivity and they can not carry out daily activities normally in terms of physical, psychological or mental, social and spiritual, a burden for the family both socially and economically, decreased mental capacity, change in social roles, senility. Depression in the elderly is influenced by several factors namely age, sex, physical ailment, economic, spiritual, insomnia and level of independence.⁵

Panti Werdha (nursing home) is one of the solutions to entrust elderly parents to be cared for and socialize with their peers. Some of them sometimes want to be alone since they do not want to bother their family or relatives and want to spend their old age in peace. Panti Werdha itself, in general, is considered negative by Indonesians. This negative view is compounded by the current condition of the Panti Werdha which is still unfit for habitation without paying too much attention to the comfort and safety. The natural and fostered human environment has a major influence on feelings, behavior, general health problems, and productivity. Humans respond consciously and unconsciously to their homes and workplaces. When a person’s sense of comfort is fulfilled, he will usually respond positively to his environment and people are more receptive to space and content if they provide comfort.⁶ It can be concluded that the environment, both natural and fostered environment more or less bring influence to humans. A comfortable environment will also have a positive impact on the psychological inhabitants. Therefore, in architectural design, an understanding of the characteristics of its inhabitants is needed so that a built environment (architecture) that is suitable for its residents is produced. It also can have a positive impact and create the desired behavior. Likewise, the Nursing Home, by understanding the characteristics of the elderly, is expected to create residential buildings suitable for the elderly. If housing for the elderly in the institution is established and managed effectively, it will be able to increase satisfaction both for patients and for caregivers (nurses). It can also support good development for the cognitive and physical function of patients. A research conducted in 2014 proves that elderly adult patients who do home care are reported to have high levels of life satisfaction and low levels of loneliness and stress levels, compared to those who do not do home care. To maintain quality of life and improve prognosis, care is needed that involves family or home care that is ongoing and uninterrupted from hospital care.⁷

Method

The research design used was “Pre-Experiment” which was one form of research design which intended to uncover a causal relationship from the effect of housing for the elderly in nursing home on the level of their satisfaction. The population in this study was all elderly in the work area of the Surabaya Social Service. The sample of this study was the elderly in the work area of the Surabaya Social Service. Probability sampling technique was simple random sampling. The intervention variable was housing for the elderly in the
nursing home and the output variable was the satisfaction of the elderly. The instrument in this study included; the intervention variable used instrument for housing for the elderly, while the output variable used the instrument for the level of satisfaction of the elderly. This research was conducted in the work area of the Surabaya Social Service. The research was carried out on July 1-20, 2019. The data were then processed and tested using the Wilcoxon Signed-Rank with a significance level of $p \leq 0.05$ (SPSS program).

Ethical issues to guarantee the rights of respondents in conducting this research included: the consent sheet that was given to the subject; the researcher did not include the subject’s name; the confidentiality of the information provided by the subject was guaranteed by the researcher.

**Results**

1. Characteristics of Respondents by Age

Table 1 shows that the respondents were mostly in the seniors category between 60-75 years old with the total of 82 elderly (54.6%), while the rest were in the old age category between 75-90 years with the total of 68 elderly (45.4%).

2. Characteristics of Respondents by Gender

Table 2 shows that there were 79 male respondents (52.6%) and 71 female respondents (47.4%).

3. Characteristics of Respondents Based on Length of Stay

Table 3 shows that from 150 respondents, 28 respondents (18.6%) had lived for 1 year, 63 respondents (42%) had lived for 2 years, and 59 respondents (39.4%) had lived for 3 years or more.
4. Characteristics of Respondents Based on Frequency of Family Visits

Table 5 shows that of the 150 respondents, 133 respondents (88.6%) were in the good satisfaction category and 17 respondents were in the very good satisfaction category (11.4%). Details of each aspect of the questionnaire can be seen in the appendix.
2. Elderly Satisfaction Level after treatment

Table 6 shows that out of 150 respondents, 107 respondents (71.3%) were in the good satisfaction category and 43 respondents were in the very good satisfaction category (28.7%). Details of each aspect of the questionnaire can be seen in the appendix.

3. Effect of housing for the elderly in the nursing home on their level of satisfaction

Table 7 shows that a significance value of 0.00 means that there is an effect of housing for the elderly in nursing home on their level of satisfaction.

Discussion

The researcher designed this study to find out the effect of housing for elderly in nursing home on their level of satisfaction in Surabaya Social Service Work Area in accordance with the research objectives. This sub-chapter will discuss the following issues:

1. Elderly Satisfaction Level before treatment

Table 5.5 shows that out of 150 respondents, 133 respondents (88.6%) were in the good satisfaction category and 17 respondents were in the very good satisfaction category (11.4%). Details of each aspect of the questionnaire can be seen in the appendix.

These results indicate that the level of satisfaction of the elderly before getting the treatment in the very good satisfaction category is 88.6%. The facilities or infrastructure available at the Panti Werdha Jambangan are quite adequate, for instance, there are bedrooms per room for 6-8 elderly which are distinguished between men and women. The bathroom is also equipped in each room, and each bathroom has a handle for the elderly. Therefore, it seems that the results were similar with the results before getting the treatment. However, if the results were observed in more detail, it was found that each respondent experienced an increase in the number even though the interval was good satisfaction.
Criteria that can be done to create a home layout for the elderly:

1. Reducing high-risk furniture
2. Additional handrails (toilets, stairs, corridors)
3. Bathroom/toilet seats
4. Good lighting
5. Non-slip/non-slippery floor (carpet and mat stick to the floor)
6. Bright colors
7. Location of the bedroom (downstairs, close to the bathroom)
8. Enlarge the space to walk
9. Pictures of joint activities are posted
10. Family rooms such as recreation rooms are equipped with entertainment facilities.
11. Avoid stacks of decorative objects or statues or objects that can block their space from standing.
12. Avoid stairs
13. The park is equipped with reforestation and therapy support

Conclusion

1. Level of satisfaction of the elderly before treatment in both categories at the Surabaya Social Service
2. The level of satisfaction of the elderly before treatment in both categories at the Surabaya Social Service
3. There is an influence of housing for the elderly with the level of their satisfaction in the Social Service of Surabaya

Abstract

Smile beauty is considered the main goal in many cosmetic or orthodontic dental treatments. However many objective and sujectives methods were developed to evaluate smile attractiveness depending on many variables. The purpose of this study was to develop a new method based on digital smile design teeth outlines ratios for smile esthetic evaluation and to correlate this method with Q-sort assessment method and smile mesh variables. Frontal posed smile photograph of 48 individuals were subjected to smile mesh measurements, digital smile design (DSD) and Q-sort assessment method. The areas of DSD teeth outlines were measured using image J software in addition to the teeth areas lie in the outlines to calculate the ratio of each individual tooth area to its outline area and the total teeth areas to total outlines area.

The results showed a significant correlation between the new method and Q-sort asessment method, additionally there was a significant difference in individual and total teeth outlines ratios between the pleasant and unpleasant smile groups.

Conclusions It was found that Digital smile design teeth outline ratios method could be considered as a valuable tool for evaluation of smile esthetics.

Key words: Digital smile design, Q-sort, Smile mesh, Tooth outline.

Introduction

One of the main objectives of any cosmetic dental treatment is to obtain a beautiful smile. the pleasant smile necessitate a harmonious and balanced relationship among the lip framework, the gingival scaffold and the teeth¹.

Peck and Peck’s (²) introduced a smile classification based on previous studies about facial expressions and concluded that smile can be either spontaneous or posed, additionally Ackerman et al. (³) classified the smile into posed or social smile and the enjoyment or unopposed smile.

Many authors have referred the unstrained social smile as a reliable reference for measurement and characterization of the smile (⁴, ⁵).

It is necessary to quantify the smile characteristics which considered a distinctive facial feature to help orthodontists and cosmetic dentists not to judge it wholly subjectively due to the absence of a morphometric quantifying tool. Many experimental and clinical studies were performed to identify the esthetic quality of the pleasant smile achieved by cosmetic or orthodontic treatment based on many potential characteristics such as gingival display, incisor protrusion, smile arc and buccal corridors which can greatly influence the esthetic perception of persons (⁶).
Additionally many diagnostic tools that aid in aesthetic diagnosis and prognosis and used for objective smile evaluation such as Objective Grading System (OGS), Diagram of Facial Aesthetic References (DFAR), smile mesh and Digital smile design (DSD). The smile mesh was developed by Ackerman and Ackerman to test the reproducibility and reliability of the posed smile, it comprised five horizontal lines and seven vertical lines superimposed on the posed smile image. This analysis showed that the smiles were reproducible, also it showed high correlation coefficient and high intrarater and interrater reliability between repeated measures (3, 5).

Digital smile design (DSD) planning permit the esthetic evaluation of the intra and extra-oral digital photographs to establish an even gingival contour and proper dental alignment. This final dental outline provides greater predictability to the final result and assisting as a guide to fabricate the diagnostic wax-up and mock-up (7).

**Materials and Method**

Approval for the study was obtained from the scientific committee of orthodontic department in Kufa University faculty of dentistry. The recruited subjects were 48 dental students (28 females and 20 males) to satisfy the Q-sort method design. The sample power was 0.80 as determined by G-power software with respect to correlation tests (Type I error = .05) 5. All 48 subjects included in the study had many characteristics such as: age ranging from 18 - 24 years ; no missing or malformed teeth ; Pleasing faces ; normal occlusion ; no history of previous orthodontic treatment. Additionally many exclusion criteria were considered such as : gummy smile ; canting in the maxillary occlusal plane ; craniofacial anomalies ; history of orthognathic surgery/ cosmetic treatment ; Obvious facial asymmetry (8).

Three photographs were required for smile analysis as follows: full face with a wide smile, full face at rest, and retracted view of the full maxillary arch with teeth apart (9).

Photos were taken by digital camera (Nikon D7100, Japan) with Macro lens (105mm, Sigma), camera settings and patient positioning were performed as mentioned by Vachiramon et al, 2007 (10). While scale measurement and dental photography guidelines were followed as mentioned by Soni et al (11). The subjects were instructed to smile before photographs taking. Ackerman et al. demonstrated the reproducibility of the posed smile obtained from the static photograph 3.

The Smile Mesh parameters were measured via image J software as described by Schabel et al (5) : Maximum incisor exposure ; Upper lip drape ; Lower lip to incisor ; Inter labial gap ; Inter canine width ; Smile width and Smile index.

Then the standardized photos were subjected to digital smile design as describes by Coachman and Calamita (12) and Choachman et al (13). After creating the tooth out line for each of the 8 anterior teeth the image j software used again to measure the area of each tooth outline separately and the total teeth outlines area. Additionally the area of each tooth (of the eight anterior teeth) that lies inside the tooth outline was measured separately in addition to the total teeth area. The ratio of each tooth area to its outline area was calculated in addition to the ratio of total teeth area to the total teeth outlines area. The ratio of individual tooth or total teeth represent the degree of fitness to ideal tooth or teeth outlines and to what extent the tooth or teeth form and position close or far from the ideal smile design.

For Q-sort assessment, the attractiveness of the 48 images was ranked by the panelists (25 orthodontists) from 0-8 according to the method developed by Stephenson which is based on various subjective criteria (14). The average of cut points between attractive and unattractive smiles was calculated to generate the overall demarcation between unattractive and attractive smile images (15). However it was 3.2 in the present study. The samples that have scores less than 3.2 were considered unattractive while those that have 3.2 or above were considered as an attractive smiles.

**Statistical Analysis**

Descriptive statistics included mean and standard deviation. The correlations among variables were examined by Pearson correlation Coefficient. Independent sample t test was used to compare means of all variables. The level of significance for all statistical tests was set at 0.05. All statistical tests were performed with a software program (SPSS version 12.0).
Results

Descriptive statistics of smile mesh variables, DSD ratios and Q-sort scores are shown in table 1. Pearson correlation didn’t show any significant correlation between DSD teeth outlines total ratio and smile mesh variables, while there were a significant correlation with Q-sort assessment (table 2).

After obtaining the average of cut points for Q-sort assessments of the panelists which was 3.2 the total sample was divided into two groups unattractive smile group (<3.2) and attractive smile group (≥ 3.2). An independent samples t test between attractive and unattractive smile groups was done (table 3), for smile mesh variables only upper lip drap and smile width showed a significant difference between the two groups. While for DSD outlines ratios all variables showed a significant differences between the two groups except the tooth 14.

Discussion

This study was conducted to evaluate the correlation among a new method for smile evaluation using DSD teeth outlines ratios, Q-sort assessment and smile mesh variables. Additionally to compare the variables of these three methods between pleasant and unpleasant smiles.

For DSD analysis there was a significant positive correlation between Q-sort assessment and with most individual teeth outlines ratios and total ratio. However this indicates that high individual teeth outline ratios results in high total ratio which reflect the degree of fitness of the patients teeth to the planned ideal teeth outline according to the guidelines and this ratio can reflect how close or far the patients smile from ideal, unfortunately no previous studies were conducted on DSD to identify a discrepancy index for smile evaluation and analysis; however the reason for significant correlation of individual and total teeth outlines ratios could be explained by that dental, skeletal or soft tissue discrepancies in vertical and/or horizontal dimensions such as asymmetries in the dental arch might play a role in smile attractiveness from visual inspection as mentioned by Schabel et al (16). While for smile mesh variables there was no significant correlation with the total outlines ratio. However this may be due to that these variables are mostly vertical linear measurements and even for horizontal measurements it is difficult to detect asymmetry with this method.

Additionally despite McNamara et al (17) focusing on the role of the lips in the evaluation of the smile, aligned teeth could attract the attention of raters more than the lips, features (16), however this finding could be supported by another one who reported that a greater number of teeth displayed during smiling can give more attractive smile in comparison to fewer teeth (18). Additionally deviation in incisor angulation, incisal plane asymmetry and canting and which were considered as the most noticeable criteria in smile attractiveness evaluation (19, 20) that could affect teeth outlines ratios more than smile mesh variables.

The direct comparison between attractive and unattractive smile groups failed to find any significant differences between the 2 groups of subjects in smile mesh variables except for upper lip drape and smile width this was in disagreement with Schabel et al and McNamara et al (16, 17), but when Schabel et al compared the 11 most attractive smiles with the 11 most unattractive smiles they found that the maxillary incisors to lower lip and the smile index were significantly different, this could be attributed to many factors like the age of individuals which were ranging from 18-25 in the present study compared to 12-20 years in Schabel et al study, also the patients in this study were not treated orthodontically while in Schabel et al study they were finished their orthodontic treatment and finally the comparison in the present study done between all the two groups scores not between the 11 most attractive and 11 most unattractive photos. On the other hand there was a significant difference for all DSD ratios between attractive and unattractive smile groups.

Conclusions

Teeth outlines ratios were significantly correlated Q-sort assessment of smile esthetics. Teeth outlines ratios were significantly increased in pleasant smile group. Teeth outline ratios could be considered as a valuable tool for evaluation of smile esthetics.

Pulmonary Artery Hypertension in Acyanotic Congenital Heart Disease Underwent Transcatheter Closure at Dr. Soetomo Hospital

I Ketut Alit Utamayasa¹, Mahrus A Rahman¹, Taufiq Hidayat¹, Teddy Ontoseno¹
¹Lecturer and Consultant in Paediatric Hepatology Division Department of Child Health, Faculty of Medicine, Universitas Airlangga/ Dr. Soetomo General Hospital, Surabaya, Indonesia

Abstract

Background: Pulmonary artery hypertension (PAH) is common complication of congenital heart disease. Echocardiography before and after transcatheter closure procedure is needed for further evaluation.

Objective: To evaluate the PAH before and after transcatheter closure procedure by echocardiography at Dr. Soetomo Hospital.

Methods: Medical record patients with acyanotic congenital heart disease with PAH and already done transcatheter closure procedure in 2010 – 2014 were reviewed. Data taken were demographic, clinical, and echocardiography. Tricuspid regurgitation pressure gradient (TRPG) was evaluated. Statistical analysis using t test comparative study; P<0.05 was considered significant.

Results: There were 46 patients underwent transcatheter closure, ASD closure 22/46, VSD closure 16/46, PDA closure 8/46 patients. Ten patients with PAH (10/46), 4/10 ASD, 4/10 PDA and 2/10 VSD. Boys were 6/10, median age was 60 (range 4-144 months). Median TRPG before procedure was 32.4 (range 25-43 mmHg). Median TRPG after procedure was 21.5 (range 15-26.9 mmHg). There was significant decreased in PAH after transcatheter closure procedure (P=0.01).

Conclusion: Transcatheter closure procedure in acyanotic congenital heart disease was important for decreasing the pressure gradient of PAH.

Keywords: Pulmonary artery hypertension, acyanotic congenital heart disease, tricuspid regurgitation, transcatheter closure

Background

Pulmonary arterial hypertension (PAH) is a common complication of congenital heart disease (CHD), particularly in patients with left-to-right (systemic-to-pulmonary) shunts. Persistent exposure of the pulmonary vasculature to increased blood flow and pressure may result in vascular remodelling and dysfunction. This leads to increased pulmonary vascular resistance (PVR) and, ultimately, to reversal of the shunt and development of Eisenmenger’s syndrome.¹ The estimated prevalence of CHD is approximately six to 10 per 1,000 live births and 4–15% of patients with CHD will go on to develop PAH²⁻³. The development of PAH in patients with CHD is associated with increased mortality and high morbidity, reflected in a substantial increase in health service utilisation. While successful early closure of a cardiac defect prevents the development of PAH, have led to a marked decrease in the prevalence of PAH-CHD in western countries, the number of patients with CHD surviving into adulthood has increased.⁴⁻⁵

The interventional approach has become increasingly preferred for the treatment of many congenital heart defects (CHDs), including atrial septal defects (ASDs), ventricular septal defects (VSDs), and patent ductus arteriosus (PDAs). Transcatheter closure of congenital heart defects has been widely accepted as a preferred treatment; however, the high cost of these devices limits their clinical application in some countries. Echocardiography plays crucial role in the safety and efficacy assessment of transcatheter treatment. The advantage of TEE guidance and assistance during the closure procedure is shorter fluoroscopic time. The transcatheter closure of heart defect is nowadays accepted as a safe and effective treatment modality. In the process of selection of eligible defects play crucial role, the closure procedure should be performed by TEE guidance and follow-up of closure results by monitoring of TTE.

This study was designed to evaluate PAH before and after transcatheter closure procedure by echocardiography at Dr. Soetomo Hospital.

Methods and Materials

The cross-sectional study was conducted during January 2010–December 2014 at Division of Cardiology Department of Pediatrics Dr. Soetomo Hospital. Patients were selected based on inclusion and exclusion criteria. The inclusion criteria were 1) patients with acyanotic congenital heart disease 2) underwent transcatheter procedure in Dr. Soetomo Hospital. Patients were excluded if 1) Had multiple congenital anomaly, 2) had a severe infection or severe condition. There were 46 patients acyanotic heart disease diagnosed by echocardiography and underwent the transcatheter closure procedure. The characteristic data including age, sex, chief complaint, physical examination laboratory, chest X-ray and data from echocardiography were collected from medical records. The data taken from echocardiography were include type of congenital defect, size, pressure gradient, and ejection fraction.

A total of ten patients got PAH as complication of congenital heart disease, they were compared pressure gradient before and after transcatheter closure procedure. Statistical Analysis used t-test comparative study, with P<0.05 considered significant. All analyses were conducted in SPSS version 21.

Result

During the study period, 46 patients acyanotic congenital heart disease were included in this study. The basic characteristic in this study (table 1) found that sex was dominated by Male (58%), the age of children mostly in >5 (45%) years old and the median age was 5 years. Dyspnea was the most common main complain in our study 73.9%, and followed by recurrent cough 17.3% and fatigue were 8.08%. The atrial septal defect were affected on 22 (47%) patients, ventricular septal defects were 16 (34%) patients and patent ductus arteriosus 8 (17%) patients. The patients were found mostly with malnutrition status (52%), however found well nourish patients (40%), and severe malnutrition (8%). Ten patients had complication pulmonary artery hypertension (PAH). Four patient had PAH with ASD, 4 patient PAH with PDA and two patients less with VSD. Typed Degree of Tricuspid Regurgitation were dominated with mild (90%) and less of moderate (10%).

**Discussion**

In this study, the patients who got acyanotic congenital heart disease during January 2010 – Desember 2014 at Division of Cardiology Department of Pediatrics Dr. Soetomo Hospital were 46 patients and most of all was male (58%). Based on study on Kathmandu university of Nepal in 2008 showed that presentation of acyanotic congenital heart disease was dominated with male with male : female ratio = 1.5:1 8. The number of age patients was most above than 5 years old (45%) and ASD was the most presentation in our study despite of PDA and VSD. It could be caused by our participants is from tertiary care center as a main referral from all patients in east region of Indonesia. Most of the patients came to our hospital not from earlier age. The former studies are usually passive, in that diagnosis is made in large regional high-quality pediatric cardiology center but relies on referral of patients from local doctors. Thus, if a local physician is comfortable with the management of tiny VSD that patient might not be referred to a center and so not be countered. The relative frequency of acyanotic congenital heart disease shows from the
highest was VSD, ASD, and PDA respectively 35%, 35%, 33%. In research reported that VSD, PDA and ASD Most lesions in infants born alive are 34%, 23.7% and 10.8%, while most lesions on stillbirth is ASD (17.7%), VSD (14.6%), and TOF (13.8%). In addition, some lesion with subtle physical findings, such as ASD might not be detected until they appear in adult life. 9,10

In our study the patients were found mostly with malnutrition status (52%), however found well nourish patients (40%), and severe malnutrition (8%). Patients with increasing blood flow to the lung and had pulmonary hypertension will suffered from malnutrition and stunted growth associated with hypoxia patients. This situation will facilitate infection that worsen the condition. Anorexia, inadequate nutrition, hypoxemia tissue, hipermetabolik status, acidemia, and cation imbalances, decreased peripheral blood flow, chronic cardiac decompensation, malabsorption and protein loss, tract infections recurrent respiratory, hormonal factors, and genetic will eventually lead to malnutrition condition 11

Dyspneu was the mostly main complain in our study (73.9%) recurrent cough (17.3) and the less was fatigue (8.08%). Most frequently, patients congenital heart disease complain of progressive shortness of breath. For example a studies have shown a reduction in maximum oxygen consumption in the unrepaired ASD population because of the inherent inefficiency of a continuously preload-reduced LV in combination with a volume overload in the pulmonary circulation. After repair of the ASD, exercise capacity improves within days to weeks. 12

In our study, complication of PAH associated with congenital heart disease was (21.7%). In the French National Registry of PAH, PAH-CHD was the second most commonly associated form of PAH (after connective tissue disease-associated PAH). Data from European registry studies give the overall prevalence of PAH in adult patients with CHD as 4–28% and the prevalence of Eisenmenger’s syndrome as ,1–6% 13,14

Median degree of Tricuspid Regurgitation Pressure Gradient (TRPG) before procedure in our study was 32.4 (range 25-43 mmHg). Median TRPG after procedure was 21.5 (range 15-26.9 mmHg). There was significant decreased in PAH after transcatheter closure procedure. Correction of an underlying congenital heart defect in infancy can prevent the development of PAH-CHD; however, a proportion of patients with left-to-right shunts are not recognized until later in their life, when they already have changes to the pulmonary vasculature and increased PVR. In those patients with increased PAP and Qp, but with a PVR within normal limits or only slightly raised, pulmonary vascular changes are likely to be minimal and the patient may benefit from surgery. Conversely, those patients with high PAP and high PVR are likely to have extensive changes to the pulmonary vasculature and corrective surgery is contraindicated. There remains, therefore, a population of patients with medium-to-large defects and moderate increases in PVR in whom the extent of pulmonary vascular changes and their potential to be reversed are unknown and so, in whom, the benefits or otherwise of corrective surgery are unclear. Improvements in the diagnosis of CHD and its surgical and medical management have led to a significant increase in the number of patients surviving into adulthood. The best therapy for PAH-CHD remains prevention through a “timely” repair of the defect. 15 This study had limitation that not enough sample and participants so need further longitudinal and multicenter study.

**Conclusion**

In our conclusion, children with acyanotic heart disease commonly associated with complication of PAH. Transcatheter closure procedure in acyanotic congenital heart disease was important for decreasing the pressure gradient of PAH. But this study need further research to identifying, assessing and accurately deciding on management strategies.

Correlation between Elevated Serum Progesterone in the Day of Hcg Injection, Metaphase II Oocytes and Their Impact on The Success of ICSI

Ibrahim Badr, Hesham Sayed1, Yahia Mohammed2, Ahmed Mohamed2, Mohammed Shehata3

1Professor, Department of Obstetrics & Gynecology, Faculty of Medicine, Cairo University, Egypt, 2Assistant Professor, Department of Obstetrics & Gynecology, Faculty of Medicine, Cairo University, Egypt, 3Professor Clinical & Chemical Pathology Faculty of Medicine, Cairo University

Abstract

Objective: In this study we tried to understand the effect of progesterone level at the time of ovulation trigger on intracytoplasmic sperm injection (ICSI) outcome. We expected identifying cut off values for serum progesterone level the day of hCG injection (P-hCG) & P-hCG per mature oocyte ratio (P-hCG / MII), as predictive tests of ICSI success. 

Methods: 200 women 18-40 years old and attending IVF unit of Kasr el Aini hospital for management of infertility were included in the study. They were scheduled for ICSI after controlled ovarian induction with GnRH- agonist protocol. Inclusion criteria were tubal factor of infertility, unexplained infertility, polycystic ovarian syndrome and BMI ≤ 30 kg/m2. Exclusion criteria were severe male factor infertility, hyperprolactinemic patients, high basal FSH > 11 IU/L, frozen embryo transfer cycles, uterine anomalies or synechia. Primary outcome parameter included correlation of serum progesterone on day HCG administration, number of MII oocytes and calculated progesterone/ MII oocyte ratio with success of ICSI.

Results: 193 cases underwent embryo transfer, 7 cases cancelled. Clinical pregnancy was reported in 52 (27.9%) cases. Higher P-hCG was observed in cases who didn’t get pregnant compared to those who got pregnant (p= 0.01) with cut off value of 1 ng/ml correlated well with the clinical pregnancy rate after ICSI with 61% sensitivity and 59% specificity (p=0.004). A significantly lower P-hCG/MII ratio was found in the pregnant women group compared to that found in the non-pregnant group (p=0.001) and cut off value of 0.18 correlated best with clinical pregnancy after ICSI with sensitivity 70.5% and specificity 61.2% (p<0.001).

Conclusion: We demonstrated negative correlation between P-hCG and P-hCG/MII and clinical pregnancy rate after ICSI.

Keywords · ICSI; Infertility; P-hCG/MII oocytes ratio;

Introduction

Futile infertility treatment is associated with psychological and financial burdens. Thus, several studies were conducted to search for an accurate marker for ICSI success (eg. D3 FSH/LH ratio, serum progesterone level on the day of hCG injection (P-hCG), number of mature oocytes retrieved …etc.) which would allow suitable selection of stimulation protocols and appropriate counseling before attending the stressful and expensive course of IVF. This is particularly important for patients belonging to lower and middle socioeconomic classes and cannot afford multiple cycles of IVF.

Outcome of IVF depends on number and quality of oocytes and endometrial receptivity. Moderate increase in serum progesterone in the peripheral circulation occurs in most super-ovulated cycles on the day of HCG injection. Ubaldi et al (1996) concluded the higher FSH exposure in the IVF cycles and the subsequent higher FSH-induced LH receptivity in granulosa cells might be one of the factors inducing premature luteinization but this didn’t cause adverse effects on IVF outcome.
Bourgain & Devroey (2003) concluded that “the endometrium of IVF cycles showed premature secretory changes in post-ovulatory phase of IVF cycles followed by dys-synchronous glandular and stromal differentiation in the mid-luteal phase.” This suggests a profound modification of luteal endometrial in stimulated cycles.  

The time of maximal endometrial receptivity “the implantation window” is characterized by the expression of endometrial products, among which pinopodes, integrins and leukemia inhibitory factors are most described. Premature expression of pinopodes and integrins are observed with precocious luteal transformation and increased progesterone level following ovarian stimulation. 

There is debate about origin and significance of elevated serum progesterone in stimulated cycles. It has been believed that increased LH in late follicular phase cause increased progesterone and the use of gonadotropin-releasing hormone (GnRH) agonists and antagonists to prevent the rise of LH and premature luteinization was tried. Results of this premature elevation of serum progesterone on IVF outcome is controversial. 

Several authors did not find any negative effect of this on IVF outcome. Other authors reported that pregnancy rate has been inversely related to P-hCG. 

In this study we tried to understand the effect of progesterone level at the time of ovulation trigger on intracytoplasmic sperm injection (ICSI) outcome. We expected identifying cut off values for P-hCG & P-hCG per mature oocyte ratio (P-hCG /MII), as a better predictive tests of ICSI success.

**Materials and Methods**

Following ethical approval of scientific committee of OB/GYN department, Kasr Al-Aini hospital, Cairo University, Egypt, 200 women aged 18-40 years old and attending the IVF unit of Kasr el Aini hospital (2015-2018) for management of infertility were included in the study after obtaining informed consent. All women were scheduled for ICSI after controlled ovarian induction. **Inclusion criteria** were normal serum prolactin level, tubal factor of infertility, unexplained infertility, polycystic ovarian syndrome and BMI ≤ 30 kg/m2. **Exclusion criteria** were severe male factor infertility, hyperprolactinemic patients, high basal FSH > 11 IU/L, frozen embryo transfer cycles, uterine Anomalies or synechia, repeated implantation failure in ICSI (more than 3 failed trials), thyroid dysfunction, history of ovarian surgery. 

All women included in the study were subjected to careful history taking and general and local examination, AFC & AMH were recorded and BMI calculation was done. All patients were tested for basal serum FSH, LH, & E2 levels on the third day of a spontaneous cycle. Patients was subjected to testing of basal serum progesterone on day 3 of the down regulated cycle (E2<50 pg/ml) before stimulation with HMG and then repeated again on day of hCG administration to determine possible deleterious effect arising from elevated LH levels on pregnancy rates. Serum FSH, LH, E2 and Progesterone were measured using chemiluminescent enzyme immunoassay (Immulate 2000 Siemens Medical Solutions Diagnostic). Endometrial thickness on the day of hCG injection was determined using Sonoace x4 ultrasound machine (Samsung Medison Co., Ltd. Seoul, South Korea), duration of stimulation, total dose of gonadotropins used, number of retrieved, fertilized oocytes, embryo grading, number of transferred good quality embryos, & cancellation rates per cycle were determined. 

The standard long GnRH agonist protocol was used for patients with predicted normal response based on clinical & hormonal profile; 1 mg of leuprolide acetate daily s.c injection (Lucrin ®; Abbott, Hoofddorp, The Netherlands) was applied from the mid luteal phase onward till the day of HCG injection. Gonadotropins in the form of HMG (Merional ®, IBSA, Institut Biochimique SA, Lugano, Switzerland) was given IM from the 2nd day of menstruation, The starting dose range from 150 to 450 IU depending on the basal FSH level, AFC, Patient’s age and BMI. In all protocols, stimulation was monitored by Tran-vaginal ultrasonography and serial E2 measurements starting from day 7 of the cycle and the gonadotropin dose was adjusted individually according to follicular response. After the development of at least three leading follicles≥18 mm, 10,000 unit of HCG (Choriomon, IBSA, Institut Biochimique SA) was given IM, and transvaginal ultrasound-guided oocyte retrieval was performed 36 hours later. Progesterone pessaries
400 mg twice daily (Cyclogest 400 mg ® Actavis plc. Dublin, Ireland) was given as a luteal support starting from the day of embryo transfer and continued for 16 days after. Pregnancy was defined as the occurrence of a positive β-HCG >10 IU on day 12 after embryo transfer and a second higher value 2 days later, followed by ultrasonography confirmation of cardiac activity at 6 weeks gestation (for clinical pregnancy).

**Primary outcome parameter included** Correlation of P-hCG and calculated P-hCG/ MII ratio with Success of ICSI and ROC Analysis to determine accuracy of these tests in predicting clinical pregnancy in ICSI Cycles. **Secondary outcome parameters included** cut off levels for P-hCG and P-hCG/MII in predicting successful IVF outcome (clinical pregnancy).

**Statistical analysis:** Data were statistically described in terms of mean ± standard deviation ±SD), median and range, or frequencies (number of cases) and percentages when appropriate. Comparison of numerical variables between the study groups was done using Student *t* test for independent samples in comparing 2 groups of normally distributed data and Mann Whitney *U* test for independent samples for comparing not-normal data. For comparing categorical data, Chi-square (χ²) test was performed. Exact test was used instead when the expected frequency is less than 5. Accuracy was represented using the terms sensitivity, and specificity. Receiver operator characteristic (ROC) analysis was used to determine the optimum cut off value for the studied diagnostic markers. *p* values less than 0.05 was considered statistically significant. All statistical calculations were done using computer program IBM SPSS (Statistical Package for the Social Science; IBM Corp, Armonk, NY, USA) release 22 for Microsoft Windows.

**Results**

Two hundreds patients meeting the inclusion criteria included in the present study divided into 2 groups, 193 cases underwent embryo transfer, 7 cases cancelled (all in group A (FSH/LH ≥3) due to failure to yield mature follicle for fertilization. Clinical pregnancy was reported in 52 (27.9%) cases. Primary infertility was the type of infertility in 148 patients (74%) and it was secondary in 52 patients (26%). The indications for ART treatment included male factor infertility (40.5% n=81), PCO (24.5% n=49), unexplained infertility (16% n=32) and tubal factor infertility (19% n=38).

**Demographic characteristics:** The mean age was 29.83±4.43 years old, the mean BMI was 26.5±2.9 kg/m², the mean duration of infertility was 4.63±2.59, the mean FSH was 6.55±1.54 mIU/ml, the mean LH was 4.77±1.5 mIU/ml and the mean FSH/LH ratio was 1.57±0.8. The mean E2 was 36.13±10.1 pg/ml, the mean AMH was 3.9±3.15 ng/ml, the mean AFC was 13.7±SD5.9. The mean basal serum progesterone was 0.76±0.25 ng/ml while the mean serum progesterone in the day of hCG injection was 1.4±0.9. Table 1 shows ovarian stimulation parameter.

Figure (2): ROC curve for P-hCG/MII ratio as a predictor of clinical pregnancy after ICSI in our study patients (AUC =0.71 and p<0.001). At a P-hCG/MII ratio threshold of 0.18 sensitivity was 70.5% and specificity 61.2%.
Discussion

In our study, we tried to evaluate the role of serum progesterone in day of hCG injection in predicting ICSI outcome. We were also able to determine the optimal cut off value for P/MII oocyte ratio which might give us better prediction of ICSI success.

Higher P-hCG was observed in cases who didn’t get pregnant compared to those who got pregnant (1.57±0.98 vs 1.23±0.76 respectively, P= 0.01) and cut off value for P-hCG of 1 ng/ml correlated well with the clinical pregnancy rate after ICSI with 61% sensitivity and 59% specificity (p=0.004).

There has been an ongoing debate regarding the impact of preovulatory P on IVF outcome. Its clinical influence has been highly controversial for many years.

Schoolcraft et al., 1991, showed that the premature progesterone elevation was related to a lower pregnancy rate when using GnRH agonist for pituitary suppression. Progesterone levels more than 0.5 ng/ ml were associated with a lower rate of pregnancy (20%) compared with less than 0.5ng/ml (54%). These results showed that ovarian hyperstimulation might cause advanced luteinization and an adverse cycle outcome even with low-LH levels.12

Venetis et al. (2007) published an early systematic review and meta-analysis and revealed a lower pregnancy rate in patients with high serum progesterone, but the difference was not statistically significant.13 However, Kolibianakis et al., (2012) in a more recent analysis found that women undergoing ovarian hyperstimulation using GnRH antagonists and gonadotropins, progesterone rise on the day of hCG injection is significantly associated with a lower possibility of clinical pregnancy.14

In an analysis on the outcomes of 2,566 cases after their first IVF/ICSI cycles managed with long or short protocols of GnRH agonists it was found that a premature progesterone elevation negatively correlated with live birth rate in fresh embryo-transfer (ET) cycles. However, live birth rates in frozen-thawed ET cycles showed no significant difference between case with or without progesterone rise implying that progesterone rise in stimulated cycles may have deleterious effects on endometrial receptivity.15 In a big analysis of more than 4,000 cycles, it was found that clinical pregnancy rates following IVF/ICSI cycles were inversely associated with serum progesterone levels on the day of hCG injection, regardles the GnRH analogue used. In particular, patients with serum progesterone levels < 1.5ng/ml had significantly higher clinical pregnancy rates than those with progesterone levels >1.5ng/ml.16

Although many studies have showed an adverse relation between elevated progesterone levels and IVF/ICSI pregnancy outcomes, the precise endocrinological mechanism is not clear. It has been theorized that progesterone in the late follicular phase might influence endometrial development which may lead to an asynchrony between the endometrium and the implanted embryo.17 Li et al in 2011 from micro RNA and microarray analysis of endometrium suggested dissimilar endometrial changes in patients with high progesterone levels on the day of hCG injection, and had poor pregnancy rates.8

On the other hand, several authors failed to demonstrate any negative effect of progesterone rise on IVF outcome.18,19,20,21 Using a previously described breakpoint in serum progesterone concentration of 0.9 ng/ ml in an earlier study, it was found that an elevated serum progesterone level on the day of hCG does not adversely affect the quality of oocytes or resulting embryos. The results suggest that the pregnancy rate in the elevated serum progesterone group is at least equal to the observed rate in the low progesterone group.22

A later investigation demonstrated that in the presence of an adequate response to ovarian stimulation progesterone levels > 0.9 ng/ml were not associated with lower pregnancy rates, indicating that good embryo quality may compensate for the adverse endometrial effects of elevated progesterone. However, when the response to ovarian stimulation was weak, premature progesterone elevation led to drastically reduced pregnancy rates.19,20

Another study found that there is no association between late follicular serum progesterone concentration on the day of hCG and the biochemical and clinical pregnancy rates obtained after ovarian stimulation for IVF/ICSI. Instead, a strong significant association was found between the number of follicles/oocytes and serum progesterone concentration, suggesting that each individual follicle contributes to the collective concentration observed in the circulation. Paradoxically,
the highest pregnancy rate in the study was found in the group of patients who had the highest late follicular progesterone concentrations (i.e.47nmol/l) and thus developed many follicles.\(^{18}\)

Some authors concluded that serum progesterone cutoff value that negatively affect the outcome of IVF should be considered according to the ovarian response; which can be “normally higher” (about 1.75 ng / ml) in the cycles with ovarian hyper responsiveness.\(^{23,24}\)

Based on these findings, It seems that elevated serum progesterone concentrations are a frequent event in GnRH analogue treated cycles and this elevation seems to be directly related to the number of oocytes obtained. According to various studies because the main sources of progesterone are follicles, stimulated by FSH, the level of progesterone produced per mature oocyte would be a better predictor for IVF outcome.\(^4\)

Thus, we tried to evaluate the impact of the ratio between P-hCG and the number of mature oocytes retrieved on ICSI outcome. We found that significantly lower P-hCG/MII ratio (mean=0.19±0.17) was found in the pregnant women group compared to that found in the non-pregnant group (mean=0.3±0.3) (P=0.001). Cut off value of 0.18 correlated best with clinical pregnancy after ICSI with sensitivity 70.5% and specificity 61.2% (p<0.001).

**Conclusion**

Our study showed significant difference in P-hCG and P-hCG/MII oocyte ratio among patients with clinical pregnancy and those who didn’t get pregnant, however these tests have low diagnostic accuracy in predicting clinical pregnancy.

Using the above data, larger groups of patients can be analyzed to confirm our findings in larger studies. This study is also limited by its non-randomized design; future larger randomized trials are required to evaluate the role of P- hCG/MII oocyte ratio as a valuable prognostic tool in IVF over P levels alone.

Abstract

Acute Respiratory Infections (ARI) are a health problem that has not been handled properly in Indonesia, every year the incidence of acute respiratory infections is still high, which can be fatal, namely death. Several factors cause acute respiratory infections such as nutritional status, dust exposure, length of exposure to dust, and years of service for workers in industries who have a high risk of acute respiratory tract infection problems. This study aims to determine the risk factors for acute respiratory infections in the industry. This study uses a cross-sectional approach with a sample of 89 respondents, where the results will be analyzed using the chi-square test. The result of this study is that there is a relationship between nutritional status, dusty workspace, length of exposure to dust, and length of work with the incidence of acute respiratory infections in industrial workers. Based on the results of this study, it is hoped that workers and the industry will pay attention to the use of PPE to minimize dust exposure to workers in the industry.

Keywords: nutritional status, dust, acute respiratory infections

Introduction

Industry in Indonesia is currently experiencing very rapid development, where industrial growth in Indonesia is currently experiencing an increase of 7% from the previous year. The industry is one that has become a mainstay and has received special attention from the Indonesian government. Along with the development of the industry not only has a positive impact but often has a negative impact caused by negligence from both managers and workers. Work accidents and occupational diseases are problems that have not been handled properly until now1,2.

Every workplace always contains various potential hazards that can affect the health of workers or cause occupational diseases. One of the potential hazards in the workplace that can cause health problems is the potential for chemical hazards, especially those used in the production process3. These potential hazards can enter or affect the body of the workforce through inhalation (through breathing), ingestion (through the mouth to the digestive tract, and skin contact (through the skin). The effect of potential chemical hazards on the workforce depends on the type of chemical or contaminant, the form of potential hazards (dust, gas, vapor, and smoke), toxicity, and entry into the body4.

Dust produced from industrial processes is a particle that is easily inhaled by workers so that it can irritate the respiratory tract. The textile-producing industry is one of the industries that produce exposure to dust particles from the production process, this is one of the triggers for the occurrence of acute respiratory infections (ARI). The incidence of ISPA in Indonesia is one of the diseases that many people experience which can cause death4,5. A person

DOI Number: 10.37506/ijfmt.v15i1.13574
who lives in a rural area is attacked by ARI in one year on average three times and for urban areas, it can be up to six times. For people who work with exposure to dust particles have a much greater risk of getting an ARI\textsuperscript{7,8}.

ARI in industrial areas occurs due to several factors, one of which is the extrinsic factor. The first is the state of the material being inhaled (gas, dust, vapor). Dust that enters through inhalation can cause extensive fibrosis in the lungs and is antigenic. Other extrinsic factors are smoking behavior, length of exposure, behavior in using personal protective equipment (PPE), especially those that protect the respiratory system and exercise\textsuperscript{9}. Intrinsic factors from within humans, especially those related to the lung defense system, both anatomically and physiologically, history of illness, gender, body mass index\textsuperscript{10,11}.

**Material and Method**

This study uses a cross-sectional study. The population in this study were 89 workers who were taken by random sampling, using data analysis, namely chi-square. This research was conducted in an industry in Indonesia, West Java Province. The variables studied were nutritional status, workspace, dust exposure, and years of service to the incidence of ARI among workers in the industry.

Discussion

Nutritional Status

The results of the study found 12 workers with normal nutritional status (38.7%) suffered from ARI, while 24 (41.4%) workers with abnormal nutritional status suffered from ARI. The analysis showed that the p-value was 0.001 < α 0.05, which means there was a relationship between nutritional status and the incidence of ARI.

If a person lacks food intake, it will cause the immune system to become weak, making it easier for that person to get infectious diseases. In the case of malnutrition, individuals will be more susceptible to infection due to decreased immunity to invading pathogens12.

Dusty Workspace

The results of the study found that 19 (38%) of workers with dust-free workspaces suffered from ARI, while 27 (49.1%) of workers with dusty workspaces suffered from ARI. The results of the analysis show that the p-value is 0.000 < α 0.05, which means that there is a relationship between dusty workspace and the incidence of ARI.

Dust is a material that is often referred to as particles floating in the air with a size of 1 micron to 500 microns. In the case of air pollution both inside and outside the building, dust is often used as an indicator of pollution. Used to show the level of danger both to the environment and to occupational health and safety13–15.

Exposure to dust can cause acute respiratory problems, one of which is industrial products that can pollute the air such as coal dust, cement, cotton, asbestos, chemical substances, toxic gases, dust in rice mills (organic dust) and others. Various factors influence the emergence of disease or airway disorders due to dust16,17.

Duration of Dust Exposure

The results of the study found that 17 workers exposed to dust <8 hours/day (43.6%) suffered from ARI, while 19 workers who were exposed to dust ≥ 8 hours/day had ARI (38%). The results of the analysis show that the p-value is 0.000 < α 0.05, which means that there is a relationship between dust exposure and the incidence of ARI.

The longer a person works, the higher the risk level for pulmonary function disorders. Besides, the length of service determines the length of time a person is exposed to the risk factors of exposure to dust, so the greater the length of time a person is exposed, the greater the risk of developing lung disease13,18,19.

The threshold value (TLV) for dust content is the standard of work environment factors that are recommended in the workplace so that workers can still receive them without causing illness or health problems, in daily work for a time not exceeding 8 hours a day or 40 hours a week (Permenakertrans RI No.13 of 2011). For dust particles, it has been stipulated in the Minister of Manpower and Transmigration Regulation No. PER 13/MEN/X/2011 concerning the threshold value for physical and chemical factors in the air of the working environment is that TLV dust levels should not exceed 3.0 mg/m³. The threshold value for dust that only interferes with work enjoyment is 10mg/m³. TLV of dust concentration in ambient air in Indonesia is also regulated in the Decree of the Minister of Health of the Republic of Indonesia Number 1405/MENKES/SK/XI/2002 concerning health requirements for office and industrial work environments, amounting to 10mg/m³ for an average measurement time of 8 hours2,4,8.

Years of Service

The results of the study found that 6 (35.3%) of workers with a working period of <5 years suffered from ARI, while workers who had a work period of ≥ 5 years suffered from ARI as much as 30 (41.7%). The results of the analysis show that the p-value is 0.043 <α 0.05, which means that there is a relationship between years of service and the incidence of ARI.

The effect of dust on the respiratory tract has shown that dust levels are associated with the incidence of respiratory symptoms, especially coughs. In the respiratory tract, the dust that settles to accumulate mucosal edema on the walls of the respiratory tract, causing respiratory constriction20,21.

The effect of industrial dust levels on the work environment must be watched out for because the dust in the environment is in the air and is always...
inhaled by workers every day\textsuperscript{9}. If workers who work in an environment with high dust concentrations for a long time will have the risk of developing respiratory problems, especially with workers who have worked for more than 5 years in a work environment with high concentrated respiratory dust\textsuperscript{22} The length of exposure in a day is one of the risk factors in the occurrence of pulmonary function disorders in workers. That the longer the working period of a person, the higher the risk level in the occurrence of pulmonary function disorders\textsuperscript{1,21,23}.

Conclusion

The results showed that nutritional status, dusty workspace, years of work, duration of dust exposure were related to the incidence of ARI among industrial workers.

Expression of FOXP1 and p53 in Reactive Lymphoid Lesion and B-cell Non-Hodgkin Lymphoma, Large Cell Type

Ita Ellyana1–3, Nila Kurniasari4,5,6
1Resident, Department of Anatomical Pathology, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia, 2Resident, Universitas Airlangga Hospital, Universitas Airlangga, Surabaya, Indonesia, 3Resident, Dr. Soetomo General Academic Hospital, Surabaya, Indonesia, 4Lecturer, Department of Anatomical Pathology, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia, 5Lecturer, Universitas Airlangga Hospital, Universitas Airlangga, Surabaya, Indonesia, 6Lecturer, Dr. Soetomo General Academic Hospital, Surabaya, Indonesia.

Abstract
Lymphoproliferative lesions that have morphology between benign and malignant are difficult to diagnose even with immunohistochemical and clonality testing. The correct diagnosis is necessary for the prompt treatment. These lesions can also serve as instructive models of lymphomagenesis. FOXP1 plays an important role in B-cell development, has a potential oncogene in B-cell Non-Hodgkin lymphoma, and p53 protein has a crucial role in the regulation of cell cycle, DNA repair, apoptosis, and senescence tumor suppression activity. In this study, we analyze the role of FOXP1 and p53 expression in reactive lymphoid hyperplasia and B-cell Non-Hodgkin lymphoma, large cell type. 68 paraffin blocks samples from patients diagnosed as reactive lymphoid hyperplasia and B-cell Non-Hodgkin lymphoma, large cell type. 68 paraffin blocks samples from patients diagnosed as reactive lymphoid hyperplasia and B-cell Non-Hodgkin lymphoma, large cell type was sectioned and stained with immunohistochemistry for FOXP1 and p53, and the percentage of nuclear cells showing positive staining were evaluated. Expression of FOXP1 and p53 in B-cell Non-Hodgkin lymphoma, large cell type is higher than in reactive lymphoid hyperplasia with p=0.001 and cutoff point 45%(CI=95%) for FOXP1 and p=0.001 and cutoff point 7.5%(CI=95%) for p53. There is a significant correlation between the expression of FOXP1 and p53 in reactive lymphoid hyperplasia and B-cell Non-Hodgkin lymphoma, large cell type (p=0.001). Our findings suggest that high expression of FOXP1 and p53 in B-cell Non-Hodgkin lymphoma may demonstrate the role of FOXP1 and p53 in lymphomagenesis and these markers may help to distinguish benign and malignant lymphoproliferative lesions.

Keywords: reactive lymphoid hyperplasia, B-cell Non-Hodgkin lymphoma, FOXP1, p53

Introduction
Lymph nodes are major components in the immune system. They react to various stimuli by undergoing reactive changes[1]. Recent research identifies lymphoproliferative lesions that interface between benign lesions and malignancies[2]. Distinguishing the reactive lymph node from a neoplastic lymphoproliferative process is one of the very crucial things in order to avoid harmful treatment for patients who do not need the therapy and vice versa[3]. Detection of clonality in a suspected lymphoproliferative lesion is important in diagnostic criteria[4], such as Bcl2/IGH and CCND1/IGH translocation associated with in situ forms of follicular lymphoma and mantle cell lymphoma, but sometimes clonal populations of B and T lymphocytes have been identified in many reactive or infectious disorders, and many lymphoma- or leukemia-associated translocations have been identified in the peripheral blood of healthy individuals[2].

The aim of this research is to study the role FOXP1 and p53 in lymphomagenesis, so this may help to distinguish borderline lesions between atypical...
lymphoproliferative lesions and malignant lymphoma. FOXP1 has an important role in regulation of B-cell development and maturation\textsuperscript{5}, also known as an oncogene in various types of B-cell Non-Hodgkin lymphoma\textsuperscript{6}, while p53 is the most important molecular marker in malignancy including diffuse large B-cell lymphoma. Loss of normal p53 activity is associated with lymphomagenesis and mediates tumors resistant to chemotherapy\textsuperscript{7}. In this study, the truly benign lesions (reactive lymphoid hyperplasia) and truly malignant lesions (B-cell Non-Hodgkin lymphoma, large cell type) were used to represent the benign lymphoproliferative lesions and malignant lymphoproliferative lesions.

**Materials and Methods**

This study had been approved by the Health Research Ethic Committee of Dr. Soetomo General Hospital, Surabaya, Indonesia (0040/LOE/301.4.2/VI/2020).

**Research Design and Sample**

This was an analytic observational research with a cross-sectional approach. There were 68 samples, each of 34 formalin-fixed, paraffin-embedded tissues were obtained from patients diagnosed as reactive lymphoid hyperplasia and B-cell Non-Hodgkin lymphoma, large cell type patients during 2017-2018 in Anatomical Pathology Laboratory, Dr. Soetomo General Hospital, Surabaya, Indonesia.

**Immunohistochemical Staining**

The formalin-fixed, paraffin-embedded tissues were cut into 4 mm sections, deparaffinized with xylol for 5 minutes three times, and rehydrated through graded alcohol. Antigen retrieval was achieved by microwave treatment in sodium citrate buffer (pH 6.0) for 10 minutes. The tissue sections were then incubated with monoclonal antibodies for FOXP1 (CMC35032010; dilution 1:400; Cell Marque, Abcam Technology) and p53 (DS-0337-C; dilution 1:100; Diagnostic Bio System) overnight, followed by secondary antibody for 10 minutes at room temperature. Sections were then counterstained with hematoxylin and dehydrated with alcohol.

**Evaluation of Immunohistochemical Expression**

All samples were evaluated blindly by 2 observers. This study assessed the expression of FOXP1 and p53 by calculating the percentage in the entire field of view using a light microscope, Olympus (40× magnification)\textsuperscript{8,9}. The percentage of FOXP1 and p53 in the entire field of view was calculated using a semiquantitative method by dividing the number of mature lymphocyte cells in reactive lymphoid hyperplasia and tumor cells in B-cell Non-Hodgkin lymphoma, large cell type that are stained brown in the nuclei by the total population of the sample cells.

**Statistical Analysis**

All statistical analyses were calculated using SPSS v25.0. The comparison of FOXP1 expression in reactive lymphoid hyperplasia and B-cell Non-Hodgkin lymphoma, large cell types was tested using unpaired T test. The comparison of p53 expression in reactive lymphoid hyperplasia and B-cell Non-Hodgkin lymphoma, large cell type was tested using Mann Whitney U test. The correlation was analyzed using Spearman test, with a significance level <0.05 (p <0.05).

**Results and Discussion**

The clinicopathological characteristics of the patients are shown in Table 1. FOXP1 was expressed at the nuclei of mature lymphocytes in the reactive hyperplasia and nuclei of tumor cells in Non-Hodgkin lymphoma (Figure 1). A significant difference of FOXP1 expression was found between reactive lymphoid hyperplasia and B-cell Non-Hodgkin lymphoma, large cell type (\( p = 0.001 \)) (Table 2), which was higher in B-cell Non-Hodgkin Lymphoma, large cell type than in reactive lymphoid hyperplasia, with cutoff point 45\%(CI=95\%). Pearson correlation test showed a significant correlation between FOXP1 expression of reactive lymphoid hyperplasia and B-cell Non-Hodgkin lymphoma, large cell type (\( r_p = 0.793, p = 0.001 \)). The expression of p53 was expressed at the nuclei of mature lymphocytes in the reactive hyperplasia and nuclei of tumor cells in Non-Hodgkin lymphoma (Figure 2). A significant difference of p53 expression was found (\( p = 0.001 \)) (Table 3) and expression in B-cell Non-Hodgkin lymphoma, large cell type is higher than in reactive lymphoid hyperplasia with cutoff point 7.5\%(CI=95\%). Spearman correlation test showed a significant correlation between p53 expression in reactive lymphoid hyperplasia and B-cell Non-Hodgkin lymphoma, large cell type (\( r_s = 0.768, p = \)
The expression of FOXP1 and p53 in reactive lymphoid hyperplasia and B-cell Non-Hodgkin Lymphoma, large cell type has a significant positive correlation ($r_s = 0.640$, $p = 0.001$) and shown in Table 4.

Figure 1. Immunohistochemical expression of FOXP1(brown staining in nuclei) (400× magnification). A,B. Immunohistochemical expression of FOXP1 in reactive lymphoid hyperplasia (A: 30% staining, B: 60% staining). C,D. Immunohistochemical expression of FOXP1 in B-cell Non Hodgkin Lymphoma, large cell type (C: 90% staining, D: 98% staining). Black arrows: FOXP1 expression; bar: 50 μm.
Lymphoproliferative lesions with similar morphologic feature could be a difficult area in histopathology. Therefore, detection of clonality in these cases plays important role to diagnostic criteria. The key characteristic of cancer is the monoclonality of tumor cells, which derivatives of transformed malignant cells, which should be done in the dubious conditions[4]. Ideally, further immunohistochemical examination also needed to determine the subtypes of Non-Hodgkin lymphoma with similar morphology[10], for example, the subtypes of DLBCL are determined by gene expression profiling, which is the gold standard for identifying the GCB and ABC subtypes, but is not routine practice[3].

Our study showed that FOXP1 expression was higher in B-cell Non-Hodgkin lymphoma, large cell type than reactive lymphoid hyperplasia and both of them showed significant correlation. Patzelt et al stated that FOXP1 transcription factors are important in the early development of B-cell. FOXP1 is deregulated through chromosome translocation in mature B-cell lymphoma, including diffuse large B-cell lymphoma (DLBCL). Deficiency of FOXP1 in early lymphoid precursors results in the cessation of pro-B cell transitions to pre-B and reduces peripheral matured B-cell. Overexpression of FOXP1 in DLBCL and B-cell suppresses several proapoptotic genes such as Bik, Eaf2, and Hrk, in collaboration with NF-κB activity to support B-cell resistance. It is suspected that high expression of FOXP1 in lymphoma cells prevents cells from undergoing apoptosis. FOXP1 knockdown on DLBCL cells induces an increase in MHC II expression, so that it can have an effect on immunosurveillance tumors during lymphomagenesis[11].

Figure 2. Immunohistochemical expression of p53 (brown staining in nuclei) (400× magnification). A,B. Immunohistochemical expression of p53 in reactive lymphoid hyperplasia (A: 20% staining, B: 30% staining). C,D. Immunohistochemical expression of p53 in B-cell Non Hodgkin Lymphoma, large cell type (C: 90% staining, D: 98% staining). Black arrows: p53 expression; bar: 50 μm.
Expression of p53 also showed higher in B-cell Non-Hodgkin lymphoma, large cell type than reactive lymphoid hyperplasia and both of them are significantly correlated. This result is similar with research by Kanavaros et al. who found that in non-neoplastic conditions, the role of p53 besides inhibiting the cell cycle is also involved in apoptosis. The p53 protein influences the expression of Bcl2 and Bax, which are involved in the regulation of apoptosis. Bcl2 which acts as an antiapoptotic undergoes downregulation, whereas Bax which induces apoptosis experiences upregulation by p53. The proapoptotic effect of Bax arises through performing activity as opposed to Bcl2. Bax also works as a tumor suppressor gene. Several studies have shown that Bcl2 and Bax proteins play a role in lymphoid malignancies[12]. Genetic factors that disrupt DNA repair or apoptosis can increase precancerous risk[13].

The wild type p53 is tightly controlled at the post translational stage. Under physiological conditions, the level of wild p53 is low due to constitutive degradation by E3 ubiquitin ligase MDM2 which is a target of wild type p53 transcription. Conversely tumors that have mutant p53 are typically characterized by a substantial accumulation of p53 protein[14]. The p53 gene mutation and dysregulation of the p53 pathway are important in the pathogenesis of cancers including lymphomas. TP53 dysfunction in lymphoid malignancies can occur at the level of DNA, mRNA, or protein in cis or trans. Many mutant p53 work in a dominant-negative way to inhibit the function of wild-type p53. Single allele mutations are often followed by loss of heterozygosity, which then supports tumor development. The p53 mutation points in lymphoma malignancies occur most often in the p53 DNA-binding domain (DBD). Simultaneously, p53 and inactivation of other genes, for example p21, cause a poor prognostic effect. The combination of p53+/p21-immunophenotype can reflect the p53 mutation with prognostic value[15].

We found that FOXP1 and p53 expression in reactive lymphoid hyperplasia and B-cell Non-Hodgkin lymphoma, large cell type was significantly correlated. Study by He et al., described the activity of FOXP1 depends on miR34a downregulation, which allows the development of B-cell. Inactivation of miR34a influences the pathway of B-cell development, consistent with the abnormality seen with the expression of FOXP1, p53, and Bcl2 that affect the development of mature B-cell and supports malignant transformation associated with B-cell lymphoma[16]. Networks of p53 through FOXP1 and Bcl2 are connected by miR34a which is a tumor suppressor. The effect of miR34a on FOXP1 which suppresses p53 is potentially oncogenic on post germinal center B-cell. Parallel effects also occur on the role of miR34a as a link between p53 and the oncogenic protein Bcl-2. The effect of p53 on the B-cell developmental pathway is consistent with the abnormalities found in p53 deficiency, namely the increasing number of pre-B cell as well as B-cell, which is also a consequence of the loss of miR34a function[17]. The effect of miR34a on FOXP1 in the form of the mechanism of p53 suppressing tumor cells implies a connection between p53 and FOXP1 through the action of miR34a[16].

Conclusion

In summary, the expression of FOXP1 and p53 in B-cell Non-Hodgkin lymphoma, large cell type, is higher than in reactive lymphoid hyperplasia. This suggest that FOXP1 and p53 have a role in lymphomagenesis and these markers may help to distinguish benign and malignant lymphoproliferative lesions. The suspicion for lymphoid malignancy will be raised if the expression of FOXP1 is above 45% and p53 is above 7.5%. Further investigation in other types of lymphoma such as low-grade lymphoma should be carried out because they have different biology behavior.

Conflict of Interest: The authors declare that they have no conflict of interest.

The Correlation between Body Mass Index and Lifting Frequency with Low Back Pain Complaints on Rice Transport Workers in Warehouse of Perum BULOG Subdivre Pematangsiantar

Ita Riyana Limbong1, Noeroel Widajati2
1Student of Public Health Bachelor Program, Public Health Faculty, Airlangga University, 60115, Surabaya, East Java, Indonesia, 2Department of Occupational Health and Safety, Public Health Faculty, Airlangga University, 60115, Surabaya, East Java, Indonesia

Abstract

Introduction: Rice transport workers are at risk for Low Back Pain (LBP) complaints because their work is lifting heavy loads repeatedly and affected by individual characteristics. This research aimed to analyze the strength of the correlation between body mass index and lifting frequency with LBP complaints on rice transport workers in Perum BULOG Pematangsiantar Subdivre.

Methods: This type of research was an observational research with a cross sectional design. The sampling technique used total populated sampling with 30 respondents. The variables researched included body mass index, lifting frequency, and LBP complaints.

Data were collected by observation, filling out research questionnaires, and Nordic Body Map (NBM). The data analysis used was the Spearman correlation.

Results: The strength of the correlation between body mass index with low back pain complaints had a value of r = 0.203, the strength of the correlation between the lifting frequency with low back pain complaints had a value of r = 0.415.

Conclusion: Body mass index with LBP complaints had a weak and positive correlation. The lifting frequency with LBP complaints had a moderate and positive correlation.

Key words: body mass index, lifting frequency, low back pain complaints

Introduction

Occupational diseases are diseases caused by work or the work environment, including work-related diseases. The work-related disease has several causative agents with occupational factors or the work environment playing a role together with other risk factors. Musculoskeletal disorders are one of the occupational diseases. Musculoskeletal disorders are complaints of parts of the skeletal muscles that are felt by a person ranging from very mild to very painful complaints.

In a survey conducted on workers in the UK, it was found that 498,000 workers had work-related musculoskeletal disorders, and as many as 40% had work-related musculoskeletal disorders on the back. Low Back Pain (LBP) is often reported in jobs that require routine heavy lifting, especially when combined with other stressors, such as unnatural positions (awkward positions) or exposure to whole-body vibrations. Truck
Drivers, nurses, construction workers, cleaners, and warehouse workers are at high risk for back pain due to work. The prevalence of LBP in Indonesia is 18% and increases with age. Low Back Pain is a complaint that can reduce human productivity. Around 50-80% of workers worldwide have experienced low back pain, which has a negative impact on socio-economic conditions by decreasing working day and decreasing productivity.

Factors that can affect the emergence of low back pain include individual factors, namely age, gender, body mass index (BMI), work period, smoking habits, and physical activity, as well as work factors, namely workload, work position, repetition, and duration. Based on the results of research conducted by Mayasari on fishers in the Kangkung Village, Bandar Lampung showed that there is a correlation between the lifting frequency with LBP complaints.

Musculoskeletal disorders in the back generally arise due to manual material handling. Manual handling is any activity of lifting or supporting a load by hand or body strength in lifting, putting, pushing, pulling, carrying, or moving activities.

Badan Urusan Logistik (BULOG) is a state-owned public company engaged in food logistics. Perum BULOG Subdivre Pematangsiantar is assigned to carry out public service activities, plan and develop business activities, especially in the rice sector. Perum BULOG Subdivre Pematangsiantar is located at Asahan Street KM. 3.5, Pematangsiantar, North Sumatra, Indonesia.

Perum BULOG Subdivre Pematangsiantar had two warehouses. The warehouse of Perum BULOG Subdivre Pematangsiantar was used to store commodity items. There were activities carried out manually at the Perum BULOG Subdivre Pematangsiantar, namely the loading and unloading processes. This loading and unloading processes were carried out where the workers place the rice sack on the workers back. The workers will walk towards the truck, arriving at the truck the workers will lower the rice sack by dumping it down on a low pile of rice or asking other workers for help if the rice pile is high, and vice versa when transporting rice from trucks to warehouses. Transport workers take turns carrying out this activity.

There were 30 transport workers at Perum BULOG Subdivre Pematangsiantar and were daily workers. Transport workers worked when there were items in and out, in a week the rice transport workers work for about four days. Rice transport workers start at 8 am and stop working when the unloaded or loaded rice runs out. Transport workers can carry 50 kg of rice sacks with a transport distance of approximately 20 meters.

Transport workers had complaints of pain in the lower back, neck, shoulders, knees, and calves. From observations, it was known that the transport workers’ work position when lifting rice, such as the bent neck, raised arms, slightly bent back, and alternately bent legs. The loading and unloading work was done repeatedly, and this could result in excessive exertion and could cause body aches. Based on the problems explained in the introduction above, the researcher has carried out the strength of the correlation analysis between body mass index and lifting frequency with low back pain complaints on rice transport workers in warehouse of Perum BULOG Subdivre Pematangsiantar.

Materials and Methods

This research was an observational research with a cross-sectional design. This research was conducted on rice transport workers in the warehouse of Perum BULOG Subdivre Pematangsiantar, North Sumatra, Indonesia, in May 2020. The sampling technique in this research used total population sampling and obtained a sample of 30 people.

Measurement of Body Mass Index (BMI) was carried out by filling out a research questionnaire. Before filling out the research questionnaire, respondents were given an explanation of the research conducted and asked to fill out an informed consent if the respondent agreed to take part in the research. Measurement of the lifting frequency was carried out by observation, then categorized into two according to the median data. BMI was categorized into severe underweight (BMI <17), mild underweight (BMI 17-18.4), normal (BMI 18.5-25), mild overweight (BMI 25.1-27.1) and severe overweight (BMI> 27) 7. Then the lifting frequency was categorized into <103 times and ≥ 103 times.
Nordic Body Map (NBM) method was used to assess LBP complaints. NBM has been used to assess LBP complaints in several studies including research conducted by Setyawan with the title of the correlation between work attitudes and transport loads on low back pain (LBP) complaints in fish transport workers (manol) in Muncar Beach Fishing Port (PPP), Banyuwangi District. In addition, NBM was also used by Riningrum in her research titled the influence of work attitude, age, and work period on low back pain complaints, with garment sewing workers of PT. Apac Inti Corpora, Semarang District as respondents. In the research, NBM method used was only on lower back. This research was also used part of NBM which was on lower back part, because this research focused on low back pain.

The data analysis technique in this research was univariate and bivariate analysis. Univariate analysis was conducted to determine the frequency distribution of each variable. Meanwhile, bivariate analysis was carried out to analyze the strength of the correlation between BMI and lifting frequency with LBP complaints using the Spearman correlation test.

Result and Discussion

Body Mass Index

Table 1. Distribution of Transport Workers Based on BMI

</tbody>
</table>

Table 4 showed that most transport workers with normal BMI had slightly hurt LBP complaints as many as six workers (33,3%) and hurt LBP complaints as many as six workers (33,3%). Based on the statistical analysis result with the Spearman Correlation test, it was obtained correlation coefficient value of 0,203 which means that the correlation between BMI of transport workers with LBP complaints had a weak strength of correlation. Based on the direction of correlation, it was obtained that the correlation between transport workers’ BMI with LBP complaints have a positive correlation which means that the higher transport workers’ BMI, then the level of LBP complaints experienced by
workers in Warehouse of Perum BULOG Subdivre Pematangsiantar would increase.

When body weight increases, the spine will be pressured to receive the burdens that weigh so can lead to easily occurred damage and danger to the structure of the spine. One of the areas in the spine most at risk from the effect of obesity is lumbal vertebrae\(^1\).

This was in accordance with the research conducted by Mayasari which states that there is a correlation between BMI with LBP complaints on fisherman in Kangkung Village, Bandar Lampung\(^11\). This research was also in line with research carried out by Maulana which indicates that there is a correlation between BMI with level of pain in patients with Low Back Pain (LBP) in Poliklinik Saraf RSUD Dr. Zainoel Abidin, Banda Aceh\(^10\).

**Correlation between Lifting Frequency with Low Back Pain Complaints**

The following is cross tabulation of data between lifting frequency with low back pain complaints.

<table>
<thead>
<tr>
<th>Lifting Frequency (times)</th>
<th>Low Back Pain Complaints</th>
<th>r</th>
</tr>

</tr>
<tr>
<td>≥103</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Total</td>
<td>5</td>
<td>16.7</td>
</tr>
</tbody>
</table>

Table 5 showed that the majority of transport workers with lifting frequency of ≥103 times that had hurt LBP complaints were as many as seven workers (43.8%). Based on the results of statistical analysis with the Spearman Correlation test, it was obtained correlation coefficient value of 0.415 which means the correlation between lifting frequency with low back pain complaints had a moderate strength of correlation. Based on the direction of correlation, it was obtained that the correlation between lifting frequency with LBP complaints had a positive correlation which means the more transport workers lift weight then LBP complaints experienced by transport workers in Warehouse of Gudang Perum BULOG Subdivre Pematangsiantar would increase.

The movement frequency that is too often will encourage fatigue and muscle tensions in the tendon. Muscle tensions in the tendon can be relieved when there is a rest period used to stretch the muscle. The impact of repetitive movements will increase if the movement is performed in awkward positions with heavy loads repeatedly. The occurrence frequency of posture is related to the number of times repetitive motion in doing work. Muscle complaints happen because muscle receives pressure caused by loads repeatedly without having a chance to relax\(^3\).

This result is in accordance with research conducted by Mayasari which states that there is a correlation between lifting frequency with low back pain complaints in fisherman in Kangung Village, Bandar Lampung\(^11\).
In research done by Coenen states that there is a correlation between lifting frequency with low back pain occurrences.

Constant repetitive movements give cumulative workloads, can lead to a sense of pain in impaired muscles function and other soft tissues. Problems arising from repetitive work or excess muscle pressure include muscle fatigue, changes in tissue density, and tissue tension. Physiological evidence suggests that the level and degree of tissue damage depends on the amount of force, repetition, and duration of exposure.

**Conclusion**

Based on the research result, it can be seen that most rice transport workers in Warehouse of Perum BULOG Subdivre Pematangsiantar had normal body mass index (18.5-25) and lifting frequency of ≥103 times. The majority of rice transport workers in Warehouse of Perum BULOG Subdivre Pematangsiantar had LBP complaints category of hurt.

There is a weak and positive correlation between body mass index with LBP complaints in rice transport workers in Warehouse of Perum BULOG Subdivre Pematangsiantar. There is a moderate and positive correlation between lifting frequency with LBP complaints in rice transport workers in Warehouse of Perum BULOG Subdivre Pematangsiantar.

It is suggested that rice transport workers, specifically who have worked for a long time to do some exercise or muscle stretching before doing any lifting and transport activities for at least 10 minutes because stretching muscles is very good for flexibility of the spinal muscles. The recommended exercise to prevent low back pain complaints is ≥3 times per week. Transport workers was expected to have enough rest and meet their nutritional needs before working.

**Acknowledgments:** Thank you to all parties that are involved in the research, especially rice transport workers in Warehouse of Perum BULOG Subdivre Pematangsiantar who have been willing to become respondent in this research.

**Ethical Clearance:** This research was approved and obtained ethical permission from the Faculty of Dentistry, Airlangga University, Surabaya, Indonesia.

Abstract

Based on the 2010 Indonesian Population Census, there are 1,300 ethnic categories with various sub-tribal details. Ethnic diversity is important in terms of identification, such as natural disasters, accidents, crime, and the discovery of unidentified corpses that may come from various tribes. Forensic Medicine views genetic diversity and variation as one of the challenges in identification. Genetic variation and kinship in Banjar Hulu tribe have never been done. The aim of the study are identify and analyze the genetic variation of Banjar Hulu tribe through nucleus DNA examination of short tandem repeat (STR) Loci combined DNA index system (CODIS). This study is a descriptive observational study that aims to explain the genetic variation of Banjar Hulu tribe. The design of this study is cross-sectional. This study was conducted in two stages, the first stages is to obtain information on family tree from the study subjects conducted by interview. Then the second stage is to draw blood from the study subjects’ criteria. Blood is drawn from peripheral vein. Then, there will be DNA examination and analysis of genetic variation. Result of the study show THO1 allele 9.3 locus, D3S1358 allele 12 locus, and D16S539 allele 12 locus, D8S1179 allele 12 locus are typical marker for Banjar Hulu tribe. Banjar Hulu tribe have specific loci and alleles.

Keywords: Banjar Hulu tribe, STR, CODIS.

Introduction

Indonesia is a maritime country that has more than 17,000 islands between the Pacific Ocean and the Indian Ocean. Indonesia has 730 regional languages and various tribes, Indonesia is one of the most diverse countries on earth in terms of ethnicity, linguistics and genetics.1-4 Based on the 2010 Indonesian Population Census there are 1,300 ethnic categories with various sub-tribal details.5 Ethnic diversity is distributed on various islands in Indonesia, most of which are found on five major islands, namely Sumatra, Kalimantan, Java, Sulawesi and Papua.6-8 Kalimantan Island is divided into five provinces, one of them is South Kalimantan Province. Most of the population in the South Kalimantan region is the Banjar tribe.9 South Kalimantan has several disaster-prone areas. The disaster consisted of floods, whirlwinds, fires, landslides, and forest fires. Disasters in South Kalimantan are increasing every year and have an impact on society and destruction. Disasters can leave corpses that may be intact, half intact, decomposed, separated in fragments, burned to ash, half burned, buried or a combination of various conditions. so that it is necessary to use identification methods that have a high degree of accuracy and resistance to various
Identification through DNA analysis has several advantages over other identification methods because DNA testing is more specific, more stable, can be propagated in vitro and distributed throughout the body cells. In the aspect of forensic medicine, DNA profile analysis also plays a role in the identification of the perpetrators of murder, sexual violence, victims of mutilation, victims of mass disasters and determination of offspring.

In population studies, analysis of genetic variations based on DNA profiles plays a role in analyzing human origins, migration, and evolution. It also can be used to find out the genetic structure, variation and affinity of a population. From the point of view of forensic genetics, population is defined as a group of humans from the same common ancestor. When discussing in the context of populations, there are differences in DNA sequences known as polymorphisms that can occur in the part of the DNA that encodes or the part that does not encode the protein. DNA polymorphisms can also refer to very diverse parts of chromosomes from one individual to another.

Genetic variation is a genetic difference between individuals which is inherited from one generation to the next, so that it can be used as a differentiator between one individual and another individual. Conversely, if there are two people whose DNA profiles are similar, it could be that the kinship between the two people is very close, maybe one mother, one grandmother, or one ancestor, therefore DNA polymorphism can be used in making genetic maps of a population. The existence of a genetic map of a population obtained from different DNA profiles can help track the similarities between victims and existing data. The purpose of the analysis of variations genetic (polymorphism) in the case of forensics is to find a DNA profile that has a high level of discrimination, ideally it will produce a unique DNA profile for each individual. This is very useful for matching biological evidence from the scene of a crime to the identity of someone with a high degree of trust and can be a very strong forensic evidence.

In October 1998, the Federal Bureau of Investigation (FBI) began a DNA mapping project using the Combine DNA Index System (CODIS). This index is not a database of criminal records but is a system that provides genetic information that is needed to match medical evidence with suspected victims or perpetrators. The FBI has recommended DNA analysis using the CODIS STR loci in the identification process.

Until now the genetic variation data and specific STR loci for identification of the Banjar Hulu tribe is unknown. By conducting DNA analysis through the STR CODIS locus, it is expected to be able to find and explain the genetic variation of the Banjar Hulu tribe, and the specific STR loci for identification of the tribe. The existence of genetic variation data is expected to help the process of identification of forensics of unknown individuals, especially in the event of a mass disaster that occurred in Kalimantan. The aim of the study are identify and analyze the genetic variation of Banjar Hulu tribe through nucleus DNA examination of short tandem repeat (STR) Loci combined DNA index system (CODIS)

Methods

This type of study is descriptive observational which is one type of study that aims to provide an explanation and real facts in the field that depend on the situation about the genetic variation of the Banjar Hulu Tribe. The design of this study is cross sectional or momentary because each sample is only examined once. The population of this study is the Banjar Hulu Tribe. The sample size is calculated by the Lemeshow formula (1997). From the sample size calculation, the minimum number of samples needed for the Banjar Hulu Tribe is 35 people. The sampling technique with Probability Proportional to Size (PPS) is a sampling technique that highly considers the size of the group or population. The sample of this study came from the Banjar Hulu Tribe who lived in Banua Kepayang Village, Labuan Amas Selatan District, Hulu Sungai Tengah, South Kalimantan Province.

The sample of this study has an inclusion and exclusion criteria.

Inclusion criteria, namely:

1. Men or women who agree to be the subject of study
2. Minimum age 21 years old.
3. Healthy born and inner
4. A native descendant who has ties up to 3 generations above with the Banjar Hulu Tribe.

Exclusion Criteria, namely:
1. Men or women who have a phobia of needles
2. Men or women who have indications of psychiatric disorders

Sampling was carried out in Banua Kepayang Village, Labuan Amas Selatan District, Hulu Sungai Tengah Regency, South Kalimantan Province. The study was conducted at the Laboratory of Genetics of the Institute of Tropical Disease (ITD) Airlangga University Surabaya, March 2018 to September 2018. This study was conducted in two stages, first obtaining information on the family tree from study subjects conducted by interview, then the second stage was carried out by taking blood on study subjects that fit the criteria. Before conducting the study, an ethics feasibility test must first be conducted and declared to have passed an ethics feasibility test.

At the time of the interview, the subjects were given an explanation of the study procedures and filled out informed consent. Then the subjects were interviewed and genealogy drawing was made from the subject. Blood sampling is performed on eligible subjects. Blood sample is taken from peripheral blood from vein mediana cubiti. Then blood sample is analyzed and DNA examination is done.

The selection of DNA extraction method with DNAzol because this method is practical and easy to implement. Measuring the level and purity of DNA through the UV-Spectrophotometer. For PCR DNA amplification TR and GM nuclei used STR CODIS primers (CSF1PO, D18S51, D21S11, D21S11, D3S1358, FGA, D8S1179, D5S818, D7S820, D13S317, D16S539). On DNA PCR results that have been amplified using STR CODIS primers were electrophorized using a polyacrilamide composite gel to determine the success of DNA amplification and continued analysis of each electrophoresis result. Data were analyzed based on the frequency of the allele description of each locus.

Results and Discussion

In the results of this study it is known that the Banjar Hulu Tribe has a variety of alleles at several loci. At the TPOX locus the Banjar Hulu tribe has a dominant allele of allele 8 and 9 of 91.43% and the lowest allele of allele 6 and 7 of 0%. The THO1 locus of the Banjar Hulu tribe has a dominant allele, which is allele 9.3 as much as 100% and the lowest allele is allele 10.3 and allele 11 is as much as 2.86%. The Banjar Hulu tribe has a distribution of all alleles at the THO1 locus, namely alleles 8.3, 9, 9.3, 10, 10.3 and 11. The Banjar Hulu FGA locus found dominant alleles, namely allele 21 as much as 40% and the lowest allele was 18.3, allele 19.3, allele 20.2, allele 21.2, allele 23, allele 23.1, allele 23.3, and allele 25.2 as much as 0%. At the CSF locus of the Banjar Hulu Tribe, it is known that the dominant allele is allele 29.2 as much as 45.7% and the lowest allele is seen in allele 8, allele 10.3, allele 11 and allele 28.2 which is as much as 0%. Locus D5S818 have a dominant allele of the Banjar Hulu tribe, namely allele 11 as much as 77.14%. The lowest allele is in allele 9 as much as 2.86%. The Banjar Hulu tribe has all the alleles at the D5S818 locus as can be seen in the picture. The VWA locus have a dominant allele that is the allele of the Banjar Hulu 16 Tribe as much as 91.43% while the lowest allele is found in alleles 13 and 15.1 which is as much as 0%. Locus D18S51 Banjar Hulu tribe has two dominant alleles namely 15 and 16 alleles as much as 37.14% and the lowest alleles are allele 9, 13, 18 and 20 as much as 0%. The D21S11 locus have a dominant allele in the Banjar tribe that is allele 31 as much as 42.86% and the lowest allele at allele 34 as much as 0%. The D3S1358 locus has a dominant allele that is allele 16 in the Banjar Hulu Tribe by 100% and does not have an allele 15.2 at the D3S1358 locus. Locus D13S317 have a dominant allele that is allele 8 as much as 97.14% in the Banjar Hulu Tribe. The Banjar Hulu tribe has more varied alleles at loci D12S317 allele 8; 8.1; 9; 10; 11; 12. The lowest allele is in allele 11 and allele 12 as much as 2.86%. The D8S1179 locus in the Banjar Hulu Tribe has 100% of alleles 12 and 11.43% of alleles 13. The D16S539 locus of the Banjar Hulu tribe has a dominant allele that is allele 11 as much as 82.86% and the lowest allele is in the 10 allele and 13.1 allele as much as 2.86%. At the D16S539 locus the Banjar Hulu tribe has a greater allele variation of 10; 11; 12; 13; 13.1; 13.3. The D7S870 locus in the Banjar Hulu tribe has a
dominant allele that is allele 9 (34.29%). 7.3 alleles; 8 and 12.1 never appeared in the Banjar Hulu tribe at the D7S870 locus.

Based on the results of study that has been done, the Banjar Hulu tribe has loci and alleles that are owned by everyone in the population, namely locus THO1 allele 9.3, locus D3S1358 allele 16 and locus D8S1179 allele 12. Alleles at these loci are typical markers for the tribe Banjar Hulu. So, to be able to determine an individual is a member of the Banjar Hulu tribal community must refer to the existence of these three loci / alleles.

The Banjar Hulu tribe does not have alleles 6 and alleles 7 at the TPOX locus, alleles 18.3, 19.3, 20.2, 21.2, 23, 23.1, 23.3, 25.2 at the FGA locus, alleles 8, 10, 11 at the CSF locus, alleles 9, 13, 16, 20 at the D18S51 locus, allele 34 at the D21S11 locus, allele 15.2 at the D3S1358 locus, alleles 7.3, 8, 12.1 at the D7S870 locus. Whereas at several loci, the Banjar Hulu tribe has alleles that are normally distributed. At THO1 locus has distribution on all alleles, at allele 8.3, 9, 9.3, 10, 10.3, 11, locus D5S818 at allele 9, 10, 11, 12, 13, 14, 15, 16, locus D13S317 at allele 8, 8.1, 9, 10, 11, 12, locus D8S1179 at allele 12 and allele 13, locus D16S539 at alleles 10, 11, 12, 13, 13.1, 13.3.

For the purposes of forensic identification, the presence of THO1 locus allele 9.3, locus D3S1358 allele 16 and locus D8S1179 allele 12 which are always present in the population of the Banjar Hulu Tribe is very significant. Likewise the TPOX locus at allele 6 and allele 7, FGA locus at alleles 18.3, 19.3, 20.2, 21.2, 23, 23.1, 23.3, 25.2, CSF locus at alleles 8, 10.3, 11, locus D18S51 alleles 9, 13, 18, 20, locus D21S11 allele 34, locus D3S1358 allele 15.2, locus D7S870 allele 7.3, 8, 12.1 which are not found in the population of the Banjar Hulu tribe.

In the results of this study, it is known that the Banjar Hulu tribe has 376 heterozygous alleles and 79 homozygous alleles, this shows that the Banjar Hulu tribe has a heterogamous pattern of marriage. This is in accordance with Daud (1997) which states that the Banjar tribe has an exogamous pattern of marriage.

The Banjar Hulu tribe are the inhabitants who inhabit in the valley area of river branches from the Negara river that flows into the Meratus Mountains. In the beginning their settlement area was a distance from each other, around the settlement there was also a Dayak tribe settlement. Concentration of a large population is located on the banks of the river, at river cliffs that are relatively higher than the surrounding area in the form of swamps. The Banjar Hulu tribe inhabit the Negara, Tabalong, Batang Alai, Labuan Amas, Amandit, Tapin and Martapura areas.

The pattern of exogamic Banjar Hulu marriages is strongly influenced by the teachings of the Islamic religion they profess. Unlawful women are married by men because of hereditary ties consisting of mothers, grandmothers of both fathers and mothers, daughters and their offspring, sisters in line or one father / one mother, daughter, and sister’s daughter. In addition to being related to kinship, there is also a prohibition on marrying brothers and sisters. The Mahram for men are mother-in-law, stepmother, stepmother, daughter-in-law, stepdaughter, and sister-in-law.

Marriage is something that is considered sacred by the Banjar tribe. When a man has reached the time to get married, then the closest family will hold a process of Basusuluh, which is a process to obtain information about the desired prospective wife, which is generally based on the choice of the man with the family’s consent. There are four things that are the object of the Basusuluh namely about her religion, offspring, ability to manage the household and the beauty of her face. About religion, does she come from a descendant who is devout in practicing her religion (Islam). About his descendants, whether she comes from a good offspring, kind, and patient and responsible. About the ability of her household, whether she comes from a rich or underprivileged family, About the beauty of his face,
how is her physical condition. The influence of the teachings of Islam and traditionalism causes Banjarese very rarely married to his closest relatives.26

Geographical and cultural factors, especially marital patterns, as described above can explain the uniqueness and diversity of the genetic identity of the Banjar Hulu tribe and the allele patterns that tend to be more heterozygote.

**Conclusion**

Based on the analysis of the genetic variation of the Banjar Hulu tribe through examination of the nuclei locus of the short tandem repeat (str) combine DNA index system (CODIS), it was concluded that the Banjar Hulu tribe has the characteristics of the presence of THO1 locus at allele 9.3, D3S1358 locus at allele 16 and D8S1179 locus at allele 12, so that the existence of alleles at these loci is a reference to determine the individuals who come from the tribe.

This study has study limitations, so suggestions for further studiers need to do further study with a number of different regions to get genetic variation data from the Banjar Hulu tribe and also need to do study on other tribes to get data on genetic variation of the population inhabiting the island of Borneo.

The Changes in Some Hematological Parameters among University Students Due to Stressful Conditions During and after Examinations Period

Jehad F. Alhmoud1, Husni S. Farah2, Talal Al-Qaisi1, Wala’a Hamdan3, Ghaleb A. Oriquat4, Ali Atoom1, Khalid M. Al-Qaisi

1Assistant professor. 2Associate Professor, 3Tutor . 4Professor, Department of Medical Laboratory Sciences, Faculty of Allied Medical Sciences, Al-Ahliyya Amman University, Zip code (19328) / Amman, Jordan

Abstract

Background: Several studies demonstrated that stress can cause an obvious change in the hematological parameters in healthy individuals. In the current study, we determined whether the stress during the exams can produce some hematological changes and how long this effect may take after the end of the exam period.

Methods: Seventy (n= 70) male and sixty (n=60) female student of similar height, weight and age were selected from the department of medical laboratory sciences, Al-Ahliyya Amman university. All students were first had a preliminary medical checkup. Students excluded from the study include those who had a chronic disease and any health issues or habits affecting the studied parameters, such as smoking; fever and high blood pressure. All study participants were between the age group of 20-22 years. Blood samples were taken three weeks before the exam, during and 72 hours after the end of the exam period. Estimations of red blood cells (RBC), white blood cells (WBC), hematocrit, mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), neutrophils, lymphocytes and platelets were accomplished.

Results: Compared with pre-examination results the blood samples taken during exams showed a significant decrease in the readings of lymphocytes (p <0.01) , MCV and MCH (p < 0.05). Significant increase in Neutrophil (p < 0.05) and platelets (p< 0.05). Readings taken after 72 hours of the end of exam period showed significant decrease in white blood cell count (p < 0.01) and further significant increase in the platelet count (p <0.001). No significant changes were observed in the readings of Hemoglobin, Red Blood Cell count (RBC), hematocrit and mean corpuscular hemoglobin concentration (p >0.2).

Conclusion: This study concluded that the stress due to examinations is enough to alter certain hematological parameters. The effect of stress on platelets and WBC remained until the end of the exam period. As the increased platelet count may cause health problems for a person, from bleeding problems to the formation of various clots. We do not know for sure how long the increase in platelet and decrease in white blood cells continue as this may cause health problems for people subject to permanent stress.

Kew words: Examination stress, hematological parameters, university students.

Introduction

In any educational system, improving examination performances of students and reducing their failures is the main goal. In order to achieve better outcomes in any educational system, it is necessary to investigate the factors that contribute to the student’s exam performance. Stress is one of the main notable factors that produced by heavy academic load, stress of everyday exams and
absence of relaxation \(^1\). Physiological studies have recommended that stress of any kind will have a significant impact on hematogenic and endocrine systems\(^2\). Stress can also change the blood cell parameters including neutrophils, platelets, eosinophils, monocytes basophils and lymphocytes in healthy individuals as demonstrated in physiological studies \(^3\). Moreover, several studies prove that the immune system is affected by both stress and emotional reactions \(^4,5\). However, complete blood counts, including the hematopoietic system, leukocyte profile or biochemical markers of stress are all mostly used to recognize possible changes in the immunological system \(^6\). Some other published study demonstrated that stress can impact the number and quality of the cells, such as; leukocyte, platelet and erythrocyte populations which need constant replication to maintain their counts, as in the normal situation these cells characterized a constant turnover of cells \(^7,8\). Stress due to university examinations significantly increases the readings of red blood cells and hemoglobin \(^3\).

A published study on the occupational noise that cause a type of stress on the individuals exposed to noise for several years. Exposure to noise can lead to increase stress, tissue dysfunction, and cause changes in the normal process of secretion of the body’s hormones, thus resulting in significant effects on blood parameters and health\(^9\). This study showed that some hematological parameters such as; MCV, MCH, FBS, and MCHC were declined. While other parameters including cholesterol, RBC, WBC, Hb, and Hct were induced compared with the administrative workers. Therefore, it is obvious that there are noteworthy changes on blood parameters of these workers, which can have harmful effects on their health in the future \(^10\). The literature demonstrated a study mainly focused on observing the changes in hematological parameters and serum cortisol levels after examinations conducted in the medical profession on 1\(^{st}\) year medical students. This result, suggesting that stress is responsible for the changes of these parameters. This published study recommended that proper care and support from both the faculty and the parents is provided, as it is essential for the improvement of the immune system and allow the students to adapt sufficiently to exam stress \(^11\). However, another study focused on investigating the effects of noise and chemical stress on hematological and biochemical parameters of the human body through comparing two groups of people involved in maintenance and transport related work and the other group involved in more responsible duty, working under a continuous chemical and noise stress environment. The results clarify a clear influence of chemical and noise stress on the human body in terms of hematology and biochemistry through showing an increase in total serum protein level, serum urea level, and platelet count in stress exposed group beside a significant decrease in serum triglyceride level in the same group. In addition, it was observed that there is statistically insignificant increase in the count of blood Red blood cells (RBC), White blood cells (WBC), Hematocrit, Mean corpuscular hemoglobin concentration (MCHC) and mean cell volume (MCV) in stress exposed group than normal group \(^12\). As this project helps to understand the role of important hematological parameters in monitoring the stressful conditions, which could affect the student behavior during the exam. Better understanding of the quality of life issues could assist the students to manage their stress in order to perform better in their exams. Our study involved one hundred thirty students \(n=130\) students from both sexes. The blood sampling was conducted before, during and after the exam. However, the study of hematological is essential to assess the physiological status in human. For a fully understand the changes in the mentioned parameters, we have to know the baseline physiological parameters in order to compare the results with the students under stress.

Generally, we are expecting that the parameters investigated during the exam will be different from the parameters measured before or after the exam. The current study focused on the undergraduate students in the 3\(^{rd}\) year and our main target is to observe the changes in hematological parameter including Red blood cells (RBC) count, haematocrit (Hct), hemoglobin (Hb), mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), white blood cells (WBC) count and platelets.

**Methodology**

**Study design and subjects**

The present study was conducted at Department of Medical Laboratory Sciences, Faculty of Allied Medical Sciences, at Al-Ahliyya Amman University/Amman. A random group was chosen from the third
year students in the College of Medical Sciences. All students were first had a preliminary medical checkup. Students excluded from the study include those who had a chronic disease or any health issues or habits affecting the studied parameters, such as smoking; fever and high blood pressure. Finally, seventy (n= 70) male and sixty (n=60) female students of similar height and weight were included in this study between the age group of 20-22 years. All participated students were informed about all the procedures and outcomes of the study.

**Complete blood profiles**

Five milliliters of blood were taken from each student. It was transferred into lavender vacutainer, containing Ethylenediaminetetraacetic acid (EDTA) as an anticoagulant. Blood count was performed on an automated hematology analyzer (Sysmex XP-300) at Sysmex Corporation, Japan. Each count presented the data of white blood cell count (WBC), red blood count (RBC) platelets count (Plt), mean corpuscular volume (MCV), measurement of hemoglobin (Hgb), hematocrit (Hct), mean corpuscular hemoglobin (MCH) and mean corpuscular hemoglobin concentration (MCHC). The determination of blood count was performed for each student three weeks before exam period, during exams and 72 hours after the end of the exam period.

**Statistical Analysis**

The data were analyzed and determine the relationship between various parameters, The un-paired t-test was applied to determine statistical significance. Results were presented as means ± SD. Values <0.05 were regarded as statistically significant.

**Results and Discussion**

This study was carried out to investigate the changes in hematological parameters including red blood corpuscles (RBCs), white blood cells (WBCs), haematocrit, haemoglobin and related RBC indices. A total 130 undergraduate students in the third year medical laboratory sciences were participated in this study. All study participants were between the age group of 20-22 years. The results from this study revealed a significant decrease in WBS count (5.5 × 103 /µl ± 1.9, p < 0.01) 72 hrs. after the end of exam period exam compared with that before exam period (8.6 × 103 /µl ± 2.5) as shown in (Table 1). This such decrease in WBC agreed with the studies of Bopda B et al, Qureshi F et al and Johansson G. et al and contradicts with the reports of Roohi N, Irfan S and Venkappa S, Vasudeva M. The lymphocyte counts

<table>
<thead>

(% ) showed significant decrease during the exam period 
(26.8 ±2.2, p <0.01) whereas the neutrophil counts 
(%) increased significantly during the exam period 
(68.2 ± 4.7, p<0.05) compared to that before the exam 
which agreed with the reports of Viktoriya M. et al 18 
and Nakamura H. et al19. The decrease in the absolute 
numbers of lymphocytes cells has been associated 
with chronic stress which results in redistribution of 
lymphocyte cells and caused them to adhere to the 
20 found an increased number in neutrophils in case of 
chronis stress and attributed this to the increase in both 
acute phase reactants and the functions of TNF-alpha. It 
is very interesting to find a significant increase (322.1× 
106 /µl ±35.5, P<0.05) in platelet count (Table 1) during 
the exam and there has been a further high significant 
increase (365.8× 106 /µl ± 48.2, p<0.001) in their count 
72 hours after the end of the exam period. Their counts 
returned to what they were before the exam (Table 1) 
as none of the previous studies ( (Bhaskara K.3 and 
Johansson G. et al.15) recorded this result, but all were 
satisfied with investigating the effect of stress before 
and during the exam period. We believe that one of the 
reasons for the persistence of high platelets after the end 
of the exam period is the continued rise in the adrenaline 
hormone, which increases as a result of stress. Lande K. 
et al21 showed a close relationship between the hormone 
of adrenaline and the increase in platelet count. We 
think that students during exam may suffer from sleep 
deprivation and there is some evidence (Bangasser D. et 
al 22 and Sharma N, Gupta V 23) that sleep deprivation 
and the increased secretion of cortisol, which is linked 
to the extent of stress, both suppress the immune system, 
which in turn explains a decrease in efficiency of the 
immune function causing a decrease in both WBC 
and lymphocyte counts. Also WBC and Lymphocytes 
possess receptors for adrenaline as its plasma levels 
increase in response to stress. Adrenaline reduces the 
flow of white blood cells, causing a redistribution of 
WBC and lymphocytes between the blood and other 
immune compartments ( Dhabhar F et al. 24) causing the 
free circulating WBC and lymphocytes to decrease. The 
present study showed a significant increase in neutrophils 
during exam period that consistent with the results of 
Bopda B. et al13 and Qureshi F. et al14. We think that the 
type of lifestyle, dietary system and family conditions 
may explain the variable change in the level of stress 
in those students, which is reflected in the results of 
hematological parameters. Pre-examination stress could 
be a quite common condition among University students. 
Several studies were carried out and the changes that 
occur as a result of stress have not been identified fully.

Table 2. Change in Hemoglobin, Red blood cell count, Mean corpuscular volume MCV, Hematocrit percentage, Mean corpuscular hemoglobin MCH and Mean corpuscular hemoglobin concentration MCHC were determined before the exam, during exam and 72 hrs. after the end of exam period. Results show the mean value of 130 students. The significant difference between the count before, during and 72 hrs. after exam is indicated as not significant (NS), *p< 0.05.

<table>

</tr>
</tbody>
</table>
The present study demonstrated a significant decrease in the level MCH and MCV during the exam period (24.4 ± 2.3, p<0.05, 74.3 ± 3.8. P< 0.05) respectively which is consistent with the report of Eun et al., this such decrease was explained by Hisham W and Mohammed A. This deficiency in Glutathione reductase which plays an important role in protecting biological cell membranes of RBC against oxidative damage that results from stressful conditions. Their counts returned to what they were before the exam period (Table 2), which undoubtedly confirm the effect of stress on these parameters. There was no change in the levels of Hb, MCHC and hematocrit all through the study (Table 2) which contradicts the studies carried out by Bopda B et al. and Qureshi F. et al. that recorded a decrease in the levels of these parameters during the examination session.

In this study it was observed that stress affects significantly more female students (75%) than a male one (53.3%). This corresponds to previous report of Lande K. et al. on the impact of stress on women more than men as the emotional nature of a woman plays a role in a woman’s sense of stress and anxiety more than men.

**Conclusion**

A large number of students of the university were affected by examination Stress especially during the exam. The study sample participated in this study showed stress that affects some of the hematological parameters. Our study investigated the effect of stress after the end of the exam period, which none of the previous studies addressed that. This study showed that platelets increased and WBC decreased after the end of the exam period and we do not how long they can take to return to normal level. This result about platelets may explain the fact that the stressful people as exposing themselves to continuous rise in platelets and the risk of high blood clot.

Nurse Educator-Led an Educational Intervention on Critical Care Nurses’ Knowledge Regarding Endotracheal Suctioning

Jihad Jawad Kadhim¹, Fakhria Gaber Mhabes²

¹MSN-NEd, Lecturer at University of Kufa – College of Nursing- Adult Health Nursing, Ph.D. Student at University of Babylon - College of Nursing- Adult Health Nursing, ²Ph.D. Prof. at University of Babylon – College of Nursing - Adult Health Nursing

Abstract

Background: Studies placed a great emphasis on implementing in-service educational intervention for nurses in order to improve their knowledge regarding critical nursing procedures. Therefore, critical-care nurses need to be more knowledgeable and competent in providing patient care. Hence, the researcher (nurse educator) developed structured educational program that mainly focused on endotracheal suctioning based on evidence-based recommended practice guidelines. Endotracheal suctioning is vitally important nursing procedure in terms of maintaining airway patency and preventing complications. Objectives: to evaluate the effectiveness of endotracheal suctioning educational program on critical-care nurses’ knowledge. Methodology: a quantitative, quasi-experimental one group pre-test and post-test design was used. Convenience sample of 87 critical-care nurses are recruited from three hospitals at AL-Najaf AL-Ashraf City. The study conducted over the period of time that started on December 10, 2019 and ended on January 22, 2020. Results: most of the participants had inadequate to moderate knowledge at pre-test. While after implementing the educational intervention, the participants gained more knowledge and statistical findings indicated that all nurses have adequate knowledge regarding endotracheal suctioning. Conclusion: Endotracheal suctioning is a widely performed technique for mechanically ventilated patients in critical care units. Nurses must be competent and well educated to perform this procedure in order to prevent patient potential complications and achieve best outcomes. Educational intervention that led by nurse educator has a positive influence on nurses’ knowledge. Recommendations: the researchers are highly recommended implementing ongoing educational program by using recent clinically recommended evidence that focuses on areas where knowledge expansion can be achieved to staff nurse. In Iraq, creating postgraduate degree focusing on nursing education is a cornerstone to engage in the health care team and articulate new scientific approach by using researches in the clinical setting and apply research findings in clinical practice.

Keywords: Critical Care Nurses; Effectiveness of Educational Program; Endotracheal Suctioning; Knowledge; Nursing Education.

Introduction

Patients who admit to the hospital are suffering from a wide range of health problems. Some patients can be critically ill and require immediate interventions to save their lives and prevent deteriorations. It is, consequently, imperative that well educated and well trained nurses provide high quality of nursing care for critically ill patients to overcome complications of complex health status. Critically ill patients are commonly hospitalized in the intensive care units (ICUs). These patients are usually exposed to adverse effects as a result of therapeutic or diagnostic procedures. The role of nurse is not only providing comprehensive high quality critical care, but also preventing complications and working effectively on restoring patient to steady state of health condition.

However, one of the most performed procedures in critical care units is endotracheal suctioning (ETS). Suctioning is a crucial nursing procedure that maintains a patent airway by aspiration accumulated secretions from respiratory system to keep its function and effective gas exchanges. Many researchers have asserted that there are
discrepancies and variations among critical-care nurses’ knowledge and practices regarding ETS. Therefore, inadequate knowledge and lack of commitment related to ETS of recent evidence-based recommended practice guidelines are existed and may jeopardize patient safety. Mwakanyanga et al., (2018) emphasized on the need of continuing education program for ICU nurses in order to enhance their knowledge and bridge the gap between practice guidelines and actual practices. Another clinical trial conducted by Gilder, Parke, and Jull, (2018) has also demonstrated that educational intervention regarding ETS is crucial to foster nurses’ knowledge and achieve desired patient outcomes.

Need of the study:

Unluckily most of ICU patients suffer from complications associated with ETS. This can increase burden on both patient and hospital. In order to prevent or minimize ETS related complications, structured educational program has been designated to improve nurses’ knowledge in order to provide quality care. In spite of many studies implemented educational program, there is no single study in Iraq that provided educational intervention to critical care nurses in regard to ETS. This study is intended to evaluate the effectiveness of educational program on critical care nurses’ knowledge regarding ETS of patients who are mechanically ventilated in hospitals at AL-Najaf AL-Ashraf City.

The research question posed for the current study is “Do critical care nurses gain more knowledge after implementing educational program regarding ETS as compared to their pre-test knowledge?” Moreover, we hypothesized that there will be a statistically significant improvement on the level of critical-care nurses’ knowledge regarding ETS after implementing educational program as compared to their level of pre-test knowledge. General System Theory has been adopted as conceptual framework to guide this study.

Materials and Methods

Research Design:

This study is conducted by utilizing a quantitative, quasi-experimental one group of pre-test and post-test design. The quasi-experimental design resembles experimental design but it lacks the true random assignment of subjects into group. In this study also the ETS educational program was the intervention (manipulation) which is the independent variable (IV), and critical-care nurses’ knowledge about ETS is a dependent variable (DV). The study conducted by evaluating nurses’ knowledge at pre-test and on month after implementing ETS educational program (post-test). The study design is formulated as follow:

Pre-test (O1) ® Educational Intervention (X) ® Post-test (O2).

Study Setting and Sample:

The population for this current study is nurses who are working in the selected hospitals. The target population is nurses who are working in critical care units in hospitals at AL-Najaf AL-Ashraf City, Iraq. The accessible population is nurses who are met inclusion and exclusion criteria and who are working in AL-Sadder Medical City, AL-Hakeem General Hospital, and Middle Euphrates Hospital. The sampling technique was a non-probability, convenience sample of 87 out of 172 critical-care nurses who were willing to participate in this study.

The inclusion criteria for sample selection include:

1. All male and female nurses who were working in critical care units at selected hospitals.
2. Critical-care nurses who were willing to participate in this study.
3. Critical-care nurses who were available at the period of data collection.

The exclusion criteria were as follow:

1. Nurses who were holding administrative position.
2. Nurses who were not available during the period of data collection.
3. Nurses who were not working in the critical care units.
4. Nurses who were not attending the ETS educational program.
5. Critical-care nurses who were selected for Pilot
Study

Structuring the Educational Program and Developing Knowledge Tool:

The purpose of developing an endotracheal suctioning educational program is to provide critical-care nurses with a cohesive body of knowledge based on recent evidence-based practice guidelines that is necessary for nursing profession. Extensive literature review has been done to include the most reliable evidences regarding ETS between publications years from 2010 to 2020. The educational program consists three sections: section one briefly describes the anatomy and physiology of respiratory system, section two explains mechanical ventilation (MV) and the most commonly used modes, and section three discusses ETS procedure in detail such as practices prior to suctioning event, infection control practices, practices during suctioning episode and post suctioning practices. The data collection tool has been developed based on each section with main focuses on section three. The tool includes 40 multiple choice questions with 4 options and one correct answer. Consequently, four questions are about anatomy and physiology of respiratory system, six questions are regarding MV, and the main section contains 30 questions about ETS.

The instrument has been developed and exposed to ten experts in nursing and medicine as well as linguistics due to it is written in Arabic format to accommodate all nurses with different level of education qualifications in order to ensure its validity and consistency. The tool includes the most commonly and mandatory performed steps regarding suctioning procedure for patients who are mechanically ventilated and highlights into ETS educational program in terms of concentrating on need to know rather than nice to know.

A pilot study is conducted for the reliability of the instrument and is analyzed by using test retest method, which measured the coefficient of internal consistency. The obtained value for the instrument score was $r = 0.88$.

Method of Data Collection/Procedure:

The approval was obtained from the institutional review board (Scientific Postgraduate Committee University of Babylon/ Faculty of Nursing Council) after completing the approval forms. The formal ethical application forms contained restricted rules to ensure safety and confidentiality for the participants. Moreover, the study approval from the AL-Najaf Health Directorate was also obtained before the actual data collection period. A brief explanation and discussion about the purpose and procedure of the study were given to the participants. Participants are asked to fill the demographic sheet and knowledge questionnaire before implementing ETS educational program. Then, the researchers provide ETS educational program with aid of learning-teaching strategies: lecture, PowerPoint presentation, guided group discussion, handouts, and showing video. Data are collected during December 10, 2019 and ended on January 22, 2020. Nurses’ knowledge is evaluated according to the sum of scores for 40 items (100%) as follow: $0 – 13 (<33\%) = \text{Inadequate knowledge}$, $14 – 26 (36 – 65\%) = \text{Moderate knowledge}$, $27 – 40 (68 – 100) = \text{Adequate knowledge}$. Evaluation of nurses’ knowledge according to the mean of scores: Adequate knowledge (mean 0.68-2.1), Moderate knowledge (mean 0.34-0.67), Inadequate knowledge (mean 0-0.33).

The finding in table (1) shows the average age was 31.77. Moreover, 64 nurses were male (73.6%). Majority of them was holding diploma in nursing (70.1%). Only two nurses out of 87 had attended training/education program. All of participants (100%) stated that there were no available guidelines to follow. Only eight nurses reported they are self-educated and using internet and online journal to update their knowledge. According to the participants’ total work experience, figure 1 illustrated that the majority (33.3%) had less than one year experience in critical care units.

SD = Standard Deviation; HS = Highly Significance; IR = Improvement Rate = ($Mean$ at the posttest - $Mean$ at the pretest)*100.

**Discussion of the Results**

According to gender the majority of participants (73.6%) were male and the remaining (26.4%) were female. This finding supports Majeed (2017) who conducted a research study to assess intensive care unit nurses’ knowledge and practices regarding ETS and reported that the majority of studied nurses were male (70%). According to subjects’ educational qualification majority (70.1%) of the respondents were holding diplomas in nursing. This agreement with Aboalizm and Elhy (2019) who found that diploma nurses are more common than any other degree nurses in critical care units.4

Furthermore, findings from this study demonstrated that the majority of the sample (97.7) did not participate previously in training or educational program regarding ET suctioning and only (2.3%) have attended educational program. This also is indicated in Haza’A, Mohammed, Abdel-Aziz, & Ibrahim (2015) study who stated that the majority of ICU nurses (73.3%) have not attended any previous instructional or training program regarding ETS.5 Another study by Varghese & Moly (2016) also reported that the majority (78%) of critical-care nurses did not attend training program about ETS previously.6
The findings from this study indicated that all participants did not follow ETS guidelines (100%). Several researchers identified that in spite of many published practice guidelines on suctioning but nurses are unaware of current evidence-based practice recommendations and clinical performance is frequently based on experience, habitual and tradition as contrasting to empirical evidence. Gilder, Parke and Jull (2018) stated that accessible practice guidelines on suctioning intubated patients are not being applied into most clinical settings worldwide. Availability of most recent evidence-based practice guidelines regarding endotracheal suctioning procedure may not be enough to ensure the accurate implementation by nurses, there must be training or education program focusing on step by step performing the procedure as well as emphasizing on the benefits of correct application to prevent avoidable hazardous complications.

According to participants’ statements, almost all of critical-care nurses (90.8%) did not take a self-education responsibility regarding their fundamental tasks as a critical-care nurse, only (9.2%) of them utilized internet and research journals to update their knowledge based on evidence-based current practice. This could be one of the main factors of having poor to moderate knowledge. Regarding the critical-care nurses’ work experience, the result showed that (33.3%) had less than one year experience in critical care units.

Concerning to critical-care nurses’ knowledge before implementation of ETS educational program, the current study findings show that overall knowledge score at the pre-test was moderate. The overall mean pre-test knowledge score was (0.53) as indicated in table (3). This finding supports the study conducted by Ansari, Alavi, Adib-Hajbagheri, and Reza, (2012) that aimed to assess nurses’ knowledge and practices regarding endotracheal suctioning in ICUs of Kashan Hospital. The researchers found that (47.8%) of nurses had moderate knowledge. Another study that was conducted by Parihar (2015) has also shown that pre-test nurses’ knowledge in field of endotracheal suctioning was average with the mean score (17.07). Moreover, several research studies had also shown that most of nurses had poor to moderate knowledge regarding suctioning procedure before delivering educational program. The reason for that could be because almost all the participants of this current study did not receive ETS educational program previously.

Notwithstanding, the most interesting result was found after implementation ETS educational program. There was a remarkable enhancement of knowledge among studied percipients after providing educational intervention. The result showed that overall knowledge score after educational intervention was adequate. The overall mean post-test knowledge score was (0.84) as illustrated in table (3). The findings of post-test confirmed the effectiveness of ETS educational program in terms of significantly improving critical-care nurses’ knowledge. This result corresponds well with studies carried by Aboalizm & Elhy (2019); Sharma et al, (2014); and Vinayaka and Bernet (2016), who noted that following educational or teaching program significant improvement were perceived in knowledge level as compared to preliminary assessment.

The continuing nursing education department in each hospital should place a great emphasis on providing in-service education program periodically in order to embrace change, bear accountability, and enhance nurses’ knowledge in terms of achieving desirable outcome. The education and training strategies are two essential components of staff development that occur after nurses’ indoctrination.

Regarding to subdomain analysis of knowledge, the results showed that critical-care nurses had an adequate knowledge at pre-test regarding anatomy and physiology of respiratory system with the overall mean score was (0.71). Whereas after presenting ETS educational program (post-test), the level of nurses’ knowledge raised to higher score with the overall mean was (0.90) as shown in table (2). This enhancement in nurses’ knowledge in field of anatomy and physiology of respiratory system was due to an appropriate focusing of the educational intervention that led by the researcher. Additionally, this supports the findings of a previous research study conducted by Elsaman (2017) who found that improvement of participants’ knowledge after providing endotracheal suctioning guidelines which reflected on patients’ respiratory status. Another study in Egypt that was carried by Hassan et al, (2018) aimed to determine the effect of educational program
on nurses’ knowledge regarding endotracheal tube of adult patients. The researchers declared that there were highly statistical significant differences between pre and post implementation of educational program regarding anatomy and physiology of respiratory system with the P<0.0001. This confirms our finding in terms of enhancing nurses’ knowledge.

Concerning the knowledge of mechanical ventilation (MV) aspect, the results of this study showed that most of the respondents (n=43, 49.4%) had inadequate knowledge at pre-test. While at the post-test, the majority of the nurses (n= 54, 62.1%) had an adequate knowledge as showed in table (2). Similarly, the study conducted in Australia by Guilhermino, Inder, Sundin, and Kuzmiuk (2014) which aimed to determine the effect of educational resources provided regarding invasive mechanical ventilation on novice and expert ICU nurses’ knowledge. The researchers underlined that the vast majority of ICU nurses (63%) did not receive education about MV before recruiting in ICU and their knowledge was limited, but after providing education regarding MV the participants’ perceived it as valuable and beneficial for safe and effective practices.

Thus educational intervention plays a pivotal role in improving knowledge and practicing safe care to critically ill patients who are under MV. Knowing the working principles and settings of MV can prevent avoidable complications that may happen during suctioning episode. Critical-care nurses must be aware that inappropriate mode of MV may jeopardize patients’ health status. Intubated mechanically ventilated patient requires continuous monitoring to keep patent airway and intervene rapidly when needed. Hence, providing periodic continuing education strategy regarding MV is an essential aspect of promoting nurses’ competencies.

Regarding nurses’ knowledge about endotracheal suctioning (ETS), the results of current study showed that 40 nurses (46.0%) out of total sample 87 (100.0%) had an inadequate knowledge, 40 nurses (46.0%) had moderate knowledge and only 7 (8.0%) had an adequate knowledge before implementing ETS educational program at pre-test period. Consequently, the total mean score of nurses’ knowledge in field of ETS was (0.40). Meanwhile, after implementing the structured ETS educational program at post-test period, the statistical result of nurses’ knowledge regarding endotracheal suctioning aspect showed that the vast majority (n = 81, 93.1%) of participants had an adequate knowledge, five nurses (5.7%) had a moderate knowledge and only one nurse (1.1%) had an inadequate knowledge. Therefore, the overall mean score of nurses’ knowledge concerning ETS at post-test was (84), and these results are portrayed in table (2).

The statistical significance found congruent with the study carried by Harjot, Kumar and Krishan, (2016) that aimed to assess the effectiveness of teaching intervention on nurses’ knowledge and practices regarding ETS. The researchers concluded that teaching intervention implied positive change on nurses’ knowledge and practices. The authors reported that there was a statically significant score between nurses’ knowledge before and after application the teaching program regarding ETS. The mean score of pre-test was (19.23±4.180), while the post-test mean score was (27.26±4.046). This is evidence that educational intervention has the potential to increase knowledge of staff nurses regarding ETS procedure.

**Conclusion and Recommendation**

Our ETS structured educational program proved its effectiveness by articulating highly statistical significant score after implementation in terms of increasing level scores of critical-care nurses’ knowledge. The main focusing of our educational intervention was to examine its effectiveness in terms of improving nurses’ knowledge regarding suctioning procedure. We hypothesized that there will be a statistically significant improvement on the level of critical-care nurses’ knowledge regarding ETS after implementing educational program as compared to their level of pre-test knowledge. Accordingly, the research hypothesis is accepted at (P = 0.0001) level of highly significant and null hypothesis is rejected as illustrated in table (4). According to participants’ knowledge scores after implementing ETS educational program, our finding indicated that there was a statistically significant improvement as compared to baseline variables (pre-test) table (4).

Therefore, there are two conceivable explanations for this result: The first explanation according to Bertalanffy’s general system theory (GST), to improve individual (nurse) knowledge and practices the emphasis
should be designed on information (energy) in order to assist nurses in terms of knowledge acquisition. The selection of GST was best choice to guide this study due to it draws an avenue to guide the process of educational intervention. All concepts of the theory were consistent to delineate the research process and its objectives. However, according to the GST the input is conceived as information or material entering the system. The area of input was the ETS educational program that has been designed to meet critical-care nurses’ need in terms of increasing their level of knowledge about suctioning procedure.

The finding indicates that no matter of the level of participants’ educational qualification the objectives are the same and have been met; however, the teaching-learning strategies for the provided educational program were formulated to meet each participant’s learning needs. The educational intervention promoted knowledge integration and critical problem-solving approach which are important in critical care units. The processes within the system that transform the input into output are called as throughput. In our modified conceptual framework, the throughput consists of the desired change in knowledge regarding ETS and was achieved after applying the educational program, which in that situation transformed the input to output. The output is the end product of the system. It consists of information or materials transformed to achieve the system’s goals. In this case, the output reflected the improvement in participants’ knowledge which considered as a part of feedback loop that involves into input again. The feedback concept is the perceiving of attaining or not attaining the preset system objectives. Thus, feedback is crucial in embracing change and is a source of motivation to continue or terminate the activity. In this study, the feedback is considered as a summative evaluation process (post-test) which indicated by statistical results that the ETS educational program was effective in terms of achieving the study’ objectives and answer the research question.

The second explanation could be that the nurse educator (researcher) utilized open-ended questions to allow the nurses to discuss and answer their questions during teaching period with appropriate guidance from the researcher. In nursing education using questions is an important approach to promote critical thinking skills. Furthermore, the cornerstone of nursing profession is nursing diagnosis and the application of nursing process. Hence, the ETS educational program placed a great emphasis on indications, complications, monitoring and application evidence-based recommended practice related to ETS guidelines that play an important role in achieving best outcomes.

We are strongly recommended providing evidence-based practice guidelines and educational sessions that led by competent nurse educator to embrace positive change on best quality care through improvement of nurses’ knowledge.

Strengths and Limitations of the Study:

The strengths of the present research study are adding a body of consolidated knowledge to the previous published research studies that supported the benefit of using ETS educational program in critical care units. The implemented program can be feasible in different healthcare settings and can be provided as a self-learning package. The results of the present study provided the trustworthy and valuable evidence toward applying in-service educational program that enhance nurses’ knowledge. Using recent evidence-based recommended practice guidelines in structuring the ETS educational program was the most important aspect in terms of keeping with up to date of knowledge worldwide. Nonetheless, despite of many research studies regarding the effectiveness of ETS educational program have been conducted internationally and regionally, our study is considered the first study in Iraq that implemented an educational intervention about ETS. Finally, the educational program demonstrated its effectiveness and feasibility in terms of bringing improvement to the suctioning technique and has a positive influence on nurses’ knowledge.

The main limitations of the current study include the following: some of the critical-care nurses were excluded from this study because they were not able to attend the ETS educational program. This study was conducted in three different hospitals in one city. It is suggested that future research include more hospitals in different cities such as Middle Euphrates Governorates hospitals. The small number of critical-care nurses (87) participated in this study limit the generalizability of the finding to other population. It is recommended for future studies
to include a large number of samples. Lastly, most of the participants were holding diploma degrees in nursing. It is recommended that future research include academic and postgraduate nurses.

Relationship of Low Maternal Vitamin D3 Level and Adverse Early Neonatal Outcomes

Kawakib Hussein Noamam¹, Thikra Najim Abdulla²
¹ Residents doctor Department of Obstetrics & Gynecology, faculty of medicine, Al-Elwiya Maternity Teaching Hospital, Baghdad, Iraq, ² Ass. Pro. Department of Obs. & Gyn., Al-Kindy College of Medicine, Baghdad University

Abstract

Background: Low serum vitamin D [25 (OH) D] levels have been shown to have multiple health-related implications in females at childbearing age, during pregnancy, as well as in their children. Aim of the study: To assess the inverse relationship between vitamin D3 level and adverse neonatal outcomes using parameters such as fetal birth weight, head circumference, Apgar scores, fetal respiratory distress syndrome, and rate of neonatal admission.

Materials and methods: A prospective study was conducted on 100 early- and full-term pregnant women at Al-Elwiya Maternity Teaching Hospital in Baghdad from 1st of April 2017 to 31st of March 2018. Maternal vitamin D deficiency was confirmed based on levels <20 ng/mL.

Results: The vitamin D3 levels in the studied pregnant women were categorized as follows: normal (45%), insufficiency (31%) and deficiency (24%). The significant adverse neonatal outcomes associated with vitamin D3 deficiency were low Apgar score (54.2%), low birth weight (91.7%), small head circumference (91.7%), respiratory distress syndrome (66.7%), and neonatal intensive care unit admission (66.7%).

Conclusions: vitamin D3 deficiency among pregnant women is associated with prominent adverse neonatal outcomes.

Keywords: Vitamin D3, term pregnancy, neonatal outcome, Apgar score

Introduction

Hypovitaminosis D is prevalent worldwide, especially in Asia and the Middle East despite their tropical climate with abundance of sunlight. This suggests the prevalence of specific risk factors for hypovitaminosis D in these regions. These include the classic predictors and the conservative concealed clothing style in women in general and in men from Gulf countries in particular. The lack of governmental regulation regarding food fortification with vitamin D in these regions is also a potential risk factor.¹

Literature from Saudi Arabia, Kuwait, United Arab Emirates, and Iran revealed that 10-60% of mothers and 40-80% of their neonates had undetectable to low vitamin D levels (0-25 nmol/L) at the time of delivery.² In Iraq, hypovitaminosis D occurred in more than 65% women of childbearing age.³

A developing fetus is entirely dependent on the mother as a source of vitamin D. About 60 to 70% of the maternal plasma level of 25- hydroxyl-vitamin D [25(OH) D] acts as a source of vitamin D in the developing fetus. However, pregnant women have been reported with an unacceptably high prevalence of vitamin D deficiency and insufficiency.⁴ ⁵ This, in turn, has been reported to increase the risk of adverse maternal and neonatal outcomes.⁶

Many observational studies have indicated that maternal hypovitaminosis D (as defined by maternal
25(OH) D levels <20 ng/ml) is a significant risk factor for adverse neonatal outcomes including underdevelopment according to gestational age, preterm birth, detrimental effect on bone and teeth development, etc. 4, 7 Several studies have associated low 25(OH) D level to the risk of respiratory and other infectious diseases. 8 Vitamin D deficiency also puts children at a higher risk of diseases such as asthma and sepsis. 9, 10

Many Iraqi researchers have reported significant adverse effects of hypovitaminosis D during pregnancy like preterm labor, preeclampsia and risk of gestational diabetes mellitus. 11, 12 In addition, optimum vitamin D level has been shown to have a vital role in limiting the occurrence of preeclampsia and other hypertensive disorders during pregnancy. 13

Aim of Study

To assess the inverse relationship between vitamin D3 levels and adverse neonatal outcomes, especially regarding fetal birth weight, head circumference, Apgar scores, fetal respiratory distress syndrome, and neonatal admission.

Patients and method

Design, settings and sampling

This prospective clinical study was conducted at the Al-Eleiya Maternity Teaching hospital, Baghdad, Iraq between first of April 2017 and 1st of March 2018.

Ethical consideration: Oral informed consent and signed paper was taken from each participant prior to their enrollment in the study.

All pregnant women admitted to the obstetrics wards at Al-Elwiya Maternity Teaching Hospital for elective cesarean section were enrolled in the study. A total of 100 term pregnant women were selected based on the inclusion and exclusion criteria.

The inclusion criteria included women with singleton and full-term healthy pregnancies.

Women presenting with preterm, multiple pregnancies, congenital abnormalities, taking any long-term drugs, smoking habit, obstetrical or medical complications (diabetes, pre-eclampsia, anemia, antepartum hemorrhage, premature rupture of membrane, polyhydramnios, etc.) were excluded.

Cesarean section of all participants was carried out under spinal anesthesia to eliminate any side effects of general anesthesia on the neonate. All participants were asked questions according to a special questionnaire prepared specifically for the study based on previous similar studies.

A detailed history was obtained from women, including the age, occupation, residence, and clothing style of selected pregnant women.

A detailed obstetrical history was taken from the participants: It included number of parities and antenatal care visits. Gestational age was determined according to last menstrual period and early ultrasound report; it was confirmed by late ultrasound (which was done to ensure viability and first-time pregnancy and exclude any congenital abnormalities). A thorough physical examination was performed for all the participants to exclude any other underlying pathology.

A 5 ml blood sample was drawn from each participant and was sent for cholecalciferol (25(OH) D3) level analysis to the Laboratory of Al-Elwiya Maternity Teaching Hospital. High-performance liquid chromatography methods quantitated 25-hydroxy vitamin D2 and D3 levels. Confirmation of vitamin D deficiency diagnosis was based on levels <20 ng/mL; vitamin D insufficiency was defined as levels ranging from 20 to 29.9 ng/mL, while normal level was 30 ng/mL and more.

Each neonate was assessed and followed up by a senior pediatrician post delivery or after admission to the neonatal intensive care unit (NICU). All respondents were assessed for weight, head circumference, Apgar score at 1 and 5 minutes, respiratory distress syndrome, and admission to NICU. The Apgar score was classified according to WHO definition into <7 and >7. Neonates with Apgar scores of <7 had compromised vital functions (appearance, pulse, grimace, activity and respiration).

Neonatal weight less than 2.5 kg was regarded as low and was measured using the UNICEF weighing scale.

The head circumference of neonates was classified into small (<34.5 cm for males and <33.8 cm for
females) and normal values (>34.5 cm for males and >33.8 cm for females). Respiratory distress syndrome, NICU admission, and duration of NICU stay were also assessed.

**Statistical Analysis**

MS-Excel and Statistical Package for Social Sciences (SPSS) version 23 were used to collect and analyze the data. Chi-square test was used for comparison between categorical data (Fisher’s exact test was applied when expected variable was less than 20% of total). One-way ANOVA analysis was used to compare more than two means. The level of significance (p value) was set as ≤ 0.05.

**Results**

Vitamin D3 levels of the participants were as follow; normal (45%), insufficiency (31%) and deficiency (24%). *(Figure 1)*

![Figure 1: Vitamin D3 level distribution.](image)

A highly significant association was observed between the age of the pregnant women and vitamin D3 insufficiency (p<0.001), as 96.8% of women with vitamin D3 insufficiency were in the younger age group. In addition, we found that 95.8% of women with vitamin D deficiency were housewives.

It was shown that women with abnormal BMI (overweight and obese) suffered from vitamin D3 deficiency (p<0.001). Pregnant women living in rural areas were significantly associated with vitamin D3 deficiency (p<0.001), (95.8%). A highly significant association was also observed between vitamin D3 deficiency and veiled pregnant women, high parity and irregular antenatal care visits (p<0.001) *(Table 1)*.

Discussion

The present study showed that 31% of term pregnant women had vitamin D3 insufficiency and 24% had vitamin D3 deficiency. These findings were lower than the findings of Al-Jebory et al. done in Iraq, which reported that 38% of term pregnant women had vitamin D3 insufficiency and 40% had vitamin D3 deficiency. Moreover, it is lower than another Iraqi study by Hilali et al., in which 50-65% of Iraqi women of childbearing age had vitamin D3 deficiency while 25% of them had vitamin D3 insufficiency.
The vitamin D3 findings in our study were lower than the results of Naseh et al. who found that 37% of pregnant women had vitamin D3 deficiency and 63% of pregnant women had vitamin D3 insufficiency in Iran.

Our study results were consistent with the results of Bassil et al. who reported 30.8% deficiency and 40% insufficiency. They also stated that vitamin D3 deficiency and insufficiency were prevalent in the Middle East countries, especially among children and women of childbearing age.

Vandevijvere et al. reported that 74.1% of women were vitamin D3 insufficient, 44.6% were vitamin D3 deficient and 12.1% were severely vitamin D3 deficient.

Choi et al. found that total prevalence of vitamin D3 deficiency among pregnant women in South Korea was 77.3%. Nageshu et al. found that 58.3% of pregnant women in India had vitamin D3 insufficiency and 13.8% pregnant women were deficient in vitamin D3.

The discrepancies in vitamin D3 prevalence between different countries have been attributed to differences in culture, nutritional habits, altitudes, sun exposure, and quality of antenatal care services. The deficiency and insufficiency of vitamin D3 are common worldwide. Many authors detected high prevalence of vitamin D3 deficiency in women, particularly during pregnancy and lactation periods.

Our study showed a highly significant association between pregnant women of younger age and vitamin D3 insufficiency (p<0.001), as 96.8% of pregnant women with vitamin D3 insufficiency were aged 20-29 years. This finding is consistent with the results of Ginde et al.’s study, which reported that adolescent and younger age pregnant women represented 95% women in the USA with vitamin D3 insufficiency. Fouda et al. carried out a study on women of childbearing age in Saudi Arabia and revealed that severe vitamin D deficiency was higher (92%) among younger age women. High prevalence of vitamin D3 deficiency in younger age pregnant women may be because women in their adolescence and younger age have a higher need for vitamin D for their growth and maturation, while pregnancy increases the burden and severity of vitamin D3 deficiency.

The current study revealed a highly significant association between housewives and vitamin D3 deficiency (95.8%; p<0.001). This is similar to the results of Bener et al.’s study done in Qatar who reported that pregnant housewives showed a higher prevalence of vitamin D3 deficiency and 88% of pregnant housewives had vitamin D3 deficiency. Dave et al. conducted a study on 110 pregnant women in India and documented that 98% of the pregnant housewives had a higher prevalence of vitamin D3 deficiency.

The strength of the present study was the prospective design while the main limitations of this study were inconsistent follow-up and a single-center study.

**Conclusion**

This study successfully showed that vitamin D3 deficiency among pregnant women can be directly linked with adverse neonatal outcomes like low Apgar score, low birth weight and head circumference, and respiratory distress syndrome. Monitoring the vitamin D3 levels can be beneficial both to the mother (pre and post pregnancy) and the newborn.

**Recommendations**

Emphasis on regular vitamin D and calcium monitoring of pregnant women during antenatal period and vitamin D supplementation campaigns for pregnant women should be encouraged.

Younger age, housewives, obese, rural residents, high parity and veiled pregnant women must be labeled as high-risk patients who require regular monitoring and vitamin D supplementations.

Further large nation-wide studies are needed to assess the relation between the effect of D3 deficiency on the mother and her own neonate.

Caries Risk Assessment in Children Aged 6-12 years based on Parental Knowledge and Its Relationship with BMI and DMFT in Ahvaz

Leila Basir¹, Targol Amini², Shabnam Rasti³

¹Associate professor, department of Pediatric Dentistry, School of dentistry, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran, ²Pediatric dentistry Resident, Pediatric Department, Faculty of Dentistry, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran, ³Pediatric dentistry Resident, pediatric department, faculty of dentistry, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran

Abstract

Background: The prevalence of dental caries in childhood is one of the problems related to children’s oral health. The aim of this study was to determine the risk of caries in children aged 6-12 years based on parental information and its relationship with BMI and DMFT in Ahvaz.

Methods and materials: The necessary permits were obtained from the Ahvaz Education Department, and then 300 samples of the city’s primary schools were selected. Students were examined with a disposable dental mirror and the number of decayed, missed, and restored permanent and deciduous teeth was recorded in the DMFT table. After that, the questionnaire was completed with the help of parents. The validity of this questionnaire was confirmed by 5 pediatric dentists and the reliability of this questionnaire was confirmed by conducting a pilot study on 10 children based on Cornbach coefficient of 0.85.

Results: Maternal occupation was associated with moderate caries risk (p = 0.007). Economic situation was associated with low risk (p = 0.0001). The mean weight of the child in the high risk group was significantly higher than the low risk groups (p <0.001) and medium risk (p <0.001). The mean DMFT in the low risk group was significantly lower than the medium risk (p <0.001) and high risk groups (p <0.001). The mean BMI in the high risk group was significantly higher than the medium risk groups (p <0.001) and low risk (p <0.001).

Conclusion: Economic status, mother’s job and child’s weight are associated with caries risk. Also, DMFT and BMI index have a direct and significant relationship with the risk of caries.

Keywords: Caries risk assessment (CRA), DMFT, BMI

Introduction

Tooth caries are the most common infectious disease in human societies.¹ Scientists have focused more on caries prevention and have achieved significant success in this regard.² One of the topics that has always been considered and questioned by researchers has been the issue of predicting the occurrence of caries using risk factors for this complication and great successes have been achieved.³ Given that caries is a multifactorial and complex disease; therefore, various researchers have tried to determine the susceptibility of people to tooth decay by examining each of the caries factors and their impact on the incidence of this complication, and thus predict future dental caries.⁴

The causing factors of caries including cariogenic microorganisms, fermentable carbohydrates, and susceptible hosts have been reported.⁵,⁶ In addition, ecologically, tooth decay, like other diseases, is due to

Corresponding Author:
Targol Amini
targol.amini@iran.ir
an imbalance between the attacking agent that causes the primary lesion, and the inherent or acquired factor that changes the strength and susceptibility of the enamel. And the modifying factor that is present in the environment adjacent to the teeth, called plaque and saliva. Some types of foods and eating habits can increase the risk of weight gain and tooth decay in children. Therefore, nutritional patterns among obese children may be considered as a risk factor for obesity and dental caries.

Todays, there are two strategies for preventing disease: Whole population strategy and High risk strategy. Experience and research have shown that in the first type of prevention, most of the prevention costs that are spent on low risk people are actually wasted; so during the last two decades, the attention of prevention experts has been attracted to high risk strategy. Caries Risk Assessment (CRA), which is performed to identify people at risk of caries, has received a great deal of attention in research centers and dental schools over the past 20 years, and many dental schools around the world are performing this evaluation.

Performing CRA for all children, especially primary school children who are in mixed dentition period and need special care, can pave the way for faster achievement of prevention goals while identifying susceptible individuals. The aim of this study was to determine the risk of caries in children aged 6-12 years based on parental information and its relationship with BMI and DMFT in Ahvaz.

**Methods and Materials**

In the present descriptive epidemiological study, samples from primary schools in the city were selected by multi-stage cluster sampling method (300 people). Exclusion criteria of this study include unwillingness to cooperate, children with inherited and acquired underlying diseases.

Students were examined with a disposable dental mirror and the number of decayed, missed, and restored permanent and deciduous teeth was recorded in the DMFT Table 1. The DMFT index indicates the number of decayed permanent teeth (D), lost due to decay (M), and restored due to decay (F), and the higher the number, the worse the oral health and the lower the culture of prevention in society.

The questionnaire, which was written based on McDonald’s Children and Adolescents Dental Book 2016 and Pinkham 2019 was completed with the help of parents. The validity of this questionnaire was confirmed by 5 pediatric dentists and the reliability of this questionnaire was confirmed by conducting a pilot study on 10 children based on Cornbach coefficient of 0.85.

The questionnaire consists of 2 parts:

1- Demographic and background information questionnaire that includes questions about age, parents ‘education, parents’ occupation, economic status, birth rank, number of visits to the dentist, oral hygiene, fluoride consumption, consumption of different types Sweets and dates of the last filled teeth

2- The second part of the questionnaire was prepared based on the guidelines of the American Association of Pediatric Dentists to assess the risk of caries. This guide consists of three main sections, which include biological, protective, and clinical findings.

This study has been approved by the ethics committee of Ahwaz University of Medical Sciences. The study process was explained to all parents and informed consent was obtained from them.

After data collection, SPSS software version 20 and analysis of variance ANOVA and Tukey, chi square were used to analyze the data. Values of p <0.05 were considered as significant levels.

**Results**

There was no significant difference in caries risk (p <0.05) with the variables of Parent’s education, father’s occupation, gender, number of siblings, immigration, Seat belt, low birth weight, high birth weight, comorbidities, drug use, child age, mother age, father age, child height. Maternal occupation was associated with moderate caries risk (p = 0.007). Economic situation was associated with low risk (p = 0.0001). The mean weight of the child in the high risk group was significantly higher than the low risk groups (p <0.001) and medium risk (p <0.001). The mean weight of the child was not significantly different between the two groups of moderate and low risk (p = 0.548) (Table 1 and Figure 1).

Fluoride levels, fluoride toothpaste, fluoride treatment, dentist, toothache, overnight breastfeeding, Teeth sucking, Tooth hurt, Timely growth, Tooth disorder, Decay treat ex, bruxism, Sugar drink food, Clean tooth gum, Brushing supervision Tooth brushing, Untreated mom, Untreated dad, Child tooth decay, Brushing together and Common dishes did not differ significantly in different caries risk groups (p < 0.05). The mean DMFT in the low risk group was significantly lower than the medium risk (p < 0.001) and high risk groups (p < 0.001). The mean DMFT level was not significantly different between the moderate and low risk groups (p = 0.869).

The mean BMI in the high risk group was significantly higher than the medium risk (p < 0.001) and low risk groups (p < 0.001). The mean BMI was not significantly different between moderate and low risk groups (p = 0.735).
Discussion

The issue of caries prediction over the past two decades has been the focus of researchers and experts in prevention. The average DMFT increases with the risk of caries; so by being low risk, this index has a lower number than being the medium and high risk; so the higher DMFT in patients with high caries risk indicates a direct and effective relationship between environmental factors and dental caries. The findings of the present study showed that economic status, maternal occupation and child weight are associated with low, moderate and high caries risk status. Along with the present study, in the study of Khodakarami et al., the level of education of mothers had a significant relationship with students’ attitudes toward oral health. In the study of Shirazi et al., The mother’s education had significant effects on dental plaque index. According to a study by Farsi et al., Previous caries, enamel demineralization, and socioeconomic status are important risk factors for caries. Although Pourhashemi in his study did not find a significant relationship between children’s dental health in the study area with occupation and level of education, but in the present study similar to the studies conducted in Iran and other countries, a significant relationship was found between the variable of maternal education and caries risk.

In the study of Pinto et al, the research on children, no significant relationship was shown between tooth decay and their weight. Also, Kopycka-Kedziersawski et al, did not report a significant relationship between tooth decay and the risk of overweight in American children aged 2-18 years. In a systematic study, Kantovitz et al identified only one study that had sufficient evidence to determine the association between weight and dental caries. However, in the present study, it was found that with increasing BMI, the risk of caries also increases, so that in the high risk group, this rate is higher than the average and low risk groups.

On the contrary, the study of Yousefi et al acknowledged that the dmft + DMFT index has an inverse and significant relationship with the body mass index of children. In the study of Pourhashemi et al, there was no clear relationship between body mass index
and childhood caries; in some cases, with increasing body mass index, the frequency of caries increased and in some cases decreased.\textsuperscript{20} In a study by Sheller et al, examining the relationship between body mass index and childhood caries in the United States, there was no association between dmft index values and the number of teeth with pulp involvement or BMI grouping, which is inconsistent with the findings of the present study.\textsuperscript{21} In another study in German primary schools, a significant and direct relationship was reported between body mass index and the incidence of dental caries in their primary and permanent teeth, which is consistent with the present study.\textsuperscript{22} Gerdin et al also reported a significant relationship between dental caries and Swedish children’s BMI.\textsuperscript{27}

Most of studies focused on different communities. Also, other criteria for body fat distribution such as waist circumference and waist to hip ratio have not been evaluated in this study. Obesity and overweight depend on many genetic and environmental factors.\textsuperscript{28,29} Obviously, it is not possible to differentiate and detect the effects of these factors in a cross-sectional study such as the present study; therefore, comparison is not possible. However, it may be assumed that depending on the society, children who are highly prone to obesity and the role of environmental factors is important in their obesity, may be at risk of caries due to poor eating habits and carbohydrate intake.

Finally, without considering genetic factors, some environmental factors are associated with the occurrence of caries and it is possible to assess the risk of caries with the help of these factors; But more articles and research are needed in this area.

**Conclusion**

It can be concluded:

1. Some environmental risk factors such as economic status, mother’s job and child’s weight are associated with caries risk.

2. The DMFT index increases with increasing caries risk, so by being low risk, this index has a lower number than the medium and high risk.

3. BMI is directly and significantly related to the risk of caries.

Perianal Care Proven to Reduce the Incidence of Diaper Dermatitis

Lina Mahayaty1, Nani Nurhaeni2, Dessie Wanda2, Fitria3
1Teaching Staff, Sekolah Tinggi Ilmu Kesehatan William Booth Surabaya, 16241, Indonesia, 2Lecturer at the Department of Child Nursing, Faculty of Nursing, Universitas Indonesia, Depok, 16424, Indonesia, 3Surabaya Health Office, East Java, Indonesia

Maintaining a clean perianal area is an attempt to prevent and treat diaper dermatitis. The purpose of cleaning the perianal area is to prevent irritation. The practice of cleaning the perianal area is done by considering the physiology of the skin such as, normal flora, bacteria, and skin pH. Cleaning the perianal area can use water and a soft cloth without rubbing the skin hard. The purpose of applying evidence based in nursing practice is to identify the effect of perianal care by using water against diaper dermatitis with skin integrity issues. Search evidence of nursing practice used the PICO analysis. Thirty-four toddlers were divided into two groups: the intervention group (n = 17) and the control group (n = 17). The analysis used was Wilcoxon, and Mann-Whitney test. There was no significant difference in diaper dermatitis score in the intervention group and control group (ρ> 0.05). Cleaning the perianal area using water and tissues can be used to prevent and treat diaper dermatitis.

Keyword: diaper dermatitis, skin integrity, perianal care

Introduction

Diaper Dermatitis (diaper rash, napkin dermatitis, nappy rash) is an acute inflammatory disorder of the skin of baby - that is common in babies and children/toddlers of 1 - 3 years old.1 Diaper dermatitis is a non-immunological response to skin irritants that cause skin cell hydration disorders.2 Diaper dermatitis can occur in patients who use diapers and patients who experience incontinence. The highest incidence of diaper dermatitis occurs at the age of 9 to 12 months.1,3 Diaper dermatitis is common in children, but this condition can cause pain in children and cause problems for their parents or caregivers - some of which are itching sensation, discomfort, and pain that causes the child to be restless and fussy. Diaper dermatitis is easy to treat with good skin care, but if diaper dermatitis is not treated, it can result in worse conditions such as pain, bacterial and fungal infections, and erosive Jacquet’s dermatitis.4

The prevention and treatment management are very important for patients. Cleaning the perianal area with water is an independent action that nurses can do - by involving parents - to prevent and reduce the incidence of diaper dermatitis. The use of water to clean the perianal area is an effective intervention that does not require large costs and does not cause irritation. This innovation project aimed to determine the effectiveness of cleaning the perianal area using water against diaper dermatitis in toddlers with diarrhea.

**Method**

This research was a scientific evidence-based nursing care application or Evidence Base Nursing Practice using the Patient, Intervention Comparison, and Outcome (PICO) approach and literature studies through review of journals related to cleaning the perianal area to prevent and manage diaper dermatitis. The PICO model is a method for identifying and formulating questions about a problem (Gardner, Kanaskie, Knehans, Salisbury, & Doheny, 2016).

Based on the PICO model, the following problems identified in the implementation of the EBNP are: 1) Patients: 34 patients under five who experience diarrhea. 2) Intervention: The intervention in implementing the EBNP is to clean the perianal area with water. 3) Comparison: Cleaning the perianal area with wet tissues. 4) Result: Cleaning the perianal area with clean water is proven to reduce and prevent diaper dermatitis. The results of applying/implementing [the intervention on]

---

**Results**

The results on the characteristics of the patient respondents in the application/implementation of EBNP of cleaning the perianal area to reduce the incidence of diaper dermatitis that was carried out on 34 respondents who were divided into two groups, namely the control group and the intervention group - are as follows:

Table 3.1 shows that in the control group most of the respondents are in the baby age category, with 15 respondents (88.3%); similarly, the intervention group is mostly consisted of most of respondents in the baby age category, with 9 respondents (52.9%). Based on the type of diaper, the respondents in both groups are 100% using the absorbent diaper type. Based on the use of barriers, the respondents in the control group mostly do not use barrier, with 9 respondents (52.9%), similarly, in the intervention group most of the respondents (11 people (64.7%)) also do not use a barrier.

The analysis of differences in diaper dermatitis scores in the intervention group and the control group was aimed to analyze the diaper dermatitis scores before and after the action. The homogeneity test used was the Levine test; the test results show that the variables of age, diaper type, and barrier use have the same variants in the two groups. Meanwhile, the data normality test used was the Shaphiro-Wilk analysis. The results of the data normality test show that the diaper dermatitis score - both before and after the intervention - have a p value of < 0.05, which means that the data in this research were not normally distributed. Therefore, for data that were not normally distributed, the type of statistical test used was the non-parametric test, namely Wilcoxon test to test a paired comparison between two groups.
Based on Figure 1, it can be seen that the decrease in diaper dermatitis scores in the intervention group is better than in the control group.

**Table 2. The Analysis of Difference in Diaper Dermatitis Score between the Intervention and Control Groups in the Second, Third and Fourth Days (n = 34)**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Group</th>

<td></td>
</tr>
<tr>
<td></td>
<td>Control Group</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>0.179</td>
</tr>
</tbody>
</table>

Based on table 2, it can be seen that there is no significant difference in the difference in diaper dermatitis scores between the intervention group and the control group (p > 0.05).

**Discussion**

Damage to skin integrity often occurs in children who suffer from diarrhea. Due to the frequent defecation, the area of the skin around the perianal is more often exposed to feces, resulting in irritation and redness of the skin. Feces can cause skin irritation. Bacterial enzymes present in feces reduce urea and release ammonia. This causes an increase in pH and activates fecal proteases and lipases. This enzyme causes erythema, damages skin integrity, and increases the incidence of diaper dermatitis. Diarrhea is one of the causes of diaper dermatitis. Another study also explains that diarrhea is a significant factor that increases the risk of diaper dermatitis in children aged 1-24 months.

Diarrhea is a disease that can cause injury or damage to the skin. Injuries to the skin or the presence of damage to the skin can be considered as indicators of the quality of care in an acute care setting. Patients who use diapers and experience diarrhea are at risk of experiencing damage to skin integrity in the perianal area - or what is often called as diaper dermatitis. Preventing damage to the skin requires proper procedures. Efforts that can be made to prevent and manage patients with diaper dermatitis - one of which is by cleaning the perianal area regularly with water. After defecating, rinse the perianal area gently with water without rubbing it hard.

There are many variations that can be used to clean the perianal area, such as: cleaning with soap and water, cleaning with disposable or wet tissue, and cleaning
with the traditional way which uses water. Nowadays, many parents prefer to use tissue to clean the perianal area of their babies/children. A study on 117 children aged 6-24 months which was aimed to investigate the effectiveness of tissue and water [in cleaning the perianal area] against the incidence of diaper dermatitis, reveals that no significant is found in the difference of diaper dermatitis severity between the tissue and water groups. However, few diaper dermatitis in the area of *candidiasis intertriginosa* is found in patients who used tissue.\(^5\)

Similarly, based on the results of the innovation project implementing the EBNP, it is found that there is no significant difference between cleaning the perianal area using water and tissue (\(p > 0.05\)). The results of this research are in accordance with the research by Adalat, which concludes that there is no significant relationship between the use of tissue, water, or a combination of both. Another similar study also shows that there is no significant difference in skin hydration in the two groups, although there is mild dermatitis found in babies who are cleaned using cotton and water.\(^13\)

A study has suggested that there is a significant relationship between perianal skin care and the risk of damage to perianal skin integrity in babies with diarrhea. Perianal skin care carried out in this study was by using water and cotton to clean the perianal area. This result indicates that the risk of damage to skin integrity in the perianal area of children/toddlers with diarrhea and receive skin care according to practice standards is lower than in children/toddlers with diarrhea and receive skin care according to hospital habits.

This study reveals that there is not enough evidence to support or reject the use of water to clean the perianal area to prevent and treat diaper dermatitis in children under five. This can be caused by several factors, among others, the inadequate number of respondents, the age of the respondents, the use of barriers, and the type of diaper.

In this implementation of the EBNP, the results show that the majority of respondents’ ages are in the baby age category. This is consistent, that the peak incidence of diaper dermatitis is between the ages of 9 and 12 months. The highest prevalence of diaper dermatitis occurs in babies aged 9 to 12 months; this may be due to the introduction of solid foods during this period which causes high frequency of bowel movements and urination in some babies. Breastfeeding also plays an important role in the prevention of diaper dermatitis because the feces of exclusively breastfed babies have a lower pH and protease and lipase activity.\(^14\)

Another factor that can affect the incidence of diaper dermatitis is the use of diapers. Most of the respondents in this EBNP implementation research use an absorbent type diaper. Indeed, in order to prevent diaper dermatitis, experts recommend minimizing the use of diapers and if you use diapers [for your babies] choose the disposable diapers and you should change [your babies’] diapers more frequently.\(^14\) The use of disposable diapers is recommended because they contain absorbent components, such as hydrocellulose gel, which is very good for preventing moist conditions in skin.\(^15\) Disposable diapers with super-absorbent gel, an external porous cloth layer, and an absorbent outer layer have been shown to reduce the incidence of diaper dermatitis.

Besides the use of diapers, the use of skin barriers is another factor that can cause the incidence of dermatitis. Based on the results of this implementation of the EBNP, it is found that some respondents use a barrier as an effort to prevent diaper dermatitis. Ersoy-Evans, Akinci, Dogan, and Atakan explain that the use of skin barriers such as creams is an important method to prevent and treat diaper dermatitis. Besides preventing contact between skin and urine and feces, creams can improve the healing of diaper dermatitis, especially in babies. These creams usually contain zinc oxide, petrolatum jelly, cod liver oil, dimethicone, and dexpanthenol which can cure diaper dermatitis.

A study found that water is not statistically significant for cleaning perianal area but clinically water is shown to reduce the diaper dermatitis score when it is compared to using a tissue (wet tissue). Wet tissue can cause complications, especially because of the presence of preservatives such as methylisothiazolinone. The use of wet tissue (baby wipes) to clean the perianal area is as light as using water where there is no change in skin condition. But wet tissue contains preservatives and fragrances which have the potential to be sensitized topically, thus using wet tissue is not recommended if
damage to skin integrity has occurred.\textsuperscript{11}

Finally, using water to clean the perianal area is an effective intervention that does not require large costs and does not cause irritation. Nurses must be able to identify risk factors, preventive measures, and treatments that will be given to prevent diaper dermatitis – one of which is by regularly cleaning the perianal area.\textsuperscript{14}

**Conclusion**

There is no significant difference in the dermatitis diaper scores after being given perianal care – both in the intervention group and the control group. However, the use of water has been clinically proven to lower the diaper dermatitis score when compared to the use of wet tissue.

LIP Prints Patterns: A Study among the Aryan and Dravidian Ethnic Population in India- A Cross Sectional Study

Lubna Fathima1, Suganya P1, Sunayana Manipal 2, Prabu D3, Bharathwaj4, Raj Mohan5

1Post Graduate Student (Master of Dental Surgery), 2Master of Dental Surgery, Reader, 3Master of Dental Surgery, Professor and Head, 4Master of Dental Surgery, Senior Lecturer, 5Master of Dental Surgery, Reader, Department of Public Health Dentistry, SRM Dental College and Hospital, Ramapuram, Chennai, India

Abstract

Background: Lip prints are subjected to be unique for all the individuals except monozygotic twins; hence they can be an important indicator for human identification. Since, Aryan population are descendants of north India and Dravidian population are descendants of south India. Aim: The aim of the study was to assess the uniqueness of lip prints among Aryan and Dravidian ethnic population. Materials and method: A cross sectional study was conducted among 192 individuals of Aryan and Dravidian population. Convenient sampling was used to select the study population among the Tamilnadu and Chandigarh states in India. The lip prints were recorded with the help of lip sticks and glue portion of the cello tape. Statistical analysis was done using spss software version 20.0. Results: In the present study, branched lip print pattern was predominantly seen in males of Dravidian population. In contrast, least commonly predominant was partially vertical pattern which was absent in both the males and females of Aryan population. Conclusion: Lip prints are a unique feature for human identification. In this study, it was found that branched lip print pattern was higher in males of Dravidian population and the partially vertical type was least predominant among the males and females of Aryan and Dravidian population.

Keywords: Lip prints, Aryan, Dravidian, ethnic population, males, females.

Introduction

Lip prints vary from person to person and are used as a diagnostic tool in forensic odontology to augment human identification criteria. The classification of Lip prints is based on lip wrinkles and lip grooves. The lip-print pattern has been used as a tool for determination of gender, geographic origin, the number of people who created a mark, forensic investigation, detection of tactical and criminalist information. Cheiloscopy is a term subject to the patterns of wrinkles and grooves present on the labial mucosa. R.fischer was the first person to notice the biological phenomenon present in the red part of labial mucosa. Followed by in 1932, Edmond Locard a France criminologist identified the use of lip print for identification of person and in 1950 Le Moyne Snyder proved in a criminal case that lip print serves as an important identification to find out the person. Tsuchihasi in Japan studied about the lip print impression which led to the classification of lip print in 1974. Lip prints can be recorded in number of ways which includes the photography method, applying the lipstick on labial mucosa and recording the lip print pattern, using a finger printer, detecting the lip print using magna brush or magnetic powder. The various pigments in the labial mucosa can be analysed by using thin layer chromatography and Ultraviolet light. In dentistry, Lip prints can be used for comparison of homicide cases where the victims do not have teeth or readily available dental records for easy identification of the victim. According to the literature, prevalence

of dental abnormalities was reported in Dravidian population was 31.5% in which 6.6% of people had microodontia\(^1\). The dental disease more common among the Dravidian population was malocclusion\(^2\) and periodontitis\(^3\). There was no enough literature in the field of dentistry to support the same among the Aryan population. Further knowing the importance of lip prints in the field of dentistry, the common lip print pattern among two different populations existing in India was a question of concern. The gene most predominant in Aryan population was R1A1 and the gene predominant in Dravidian population is still in question. Since the north Indians are descendants of Aryan population and the south Indians are descendants of Dravidian population, the objective of the study is to analyse the uniqueness in lip prints among the Aryan and Dravidian ethnic population in India.

**Materials and Method**

A cross sectional study was conducted to assess the uniqueness of lip print pattern among the Aryan and Dravidian population. Decision tree methodology was designed before conducting the study. Since Aryan was predominant in Chandigarh while Dravidian population lived in large amounts in Tamilnadu, the data was collected from respective states of India. Ethical clearance was obtained from the Department of Public Health Dentistry, SRM dental college and hospital, Ramapuram. The study was conducted in the month of January 2020. Convenient sampling technique was used and data samples were obtained. Subjects without any abnormality in the lips were included in the study based on their willingness to participate. The exclusion criteria were the individual whose parents or grandparents had a history of inter-caste marriage were excluded from the study along with individuals having cleft lip, individual with any inflammation, individual allergic to the lip stick. According to Suzuki and tsuchihasi 1974 classification of lip prints was categorized as vertical, partially vertical, branched, intersected and reticular. The individual were made to sit relaxed and the lips were cleaned with cotton and a thin layer of dark red colour lip was applied in the lips and they were asked to spread uniformly. The glue portion of the cello tape was stuck into the surface of the lip under firm pressure so that the cello tape firmly sticks to the lip surface. Two duplicate prints were taken to avoid improper recording of lip print. Consecutively, the lip prints were analysed and verified by the experts for whom the Intra reliability was calculated using kappa statistics was found to be 0.89. Descriptive statistics was done to find out the overall number and percentage of study sample distribution among the Aryan and Dravidian population and gender distribution was also analysed using spss software version 20.0. Inferential statistics was performed by using Chi square to find out association of lip print pattern between the male and female and p value <0.05 was found to be statistically significant.

Discussion

Lip print is found to be unique from individual to individual except the monozygotic twins. Lip print always serves as an important diagnostic tool in finding out the age, demographic details and some important aspects in forensic odontology. Lip prints always remain as a standard approach in finding out many detective crimes and forensic branch always establish accurate ways for classification of lip furrows, lip grooves and wrinkles that constitute the human lip. The study was an attempt conducted to known the prominent lip print pattern seen among the Dravidian and Aryan ethnic population and found that an overall highest lip print pattern among the males and females of Aryan population was branched lip print pattern which was found to be 7.7% and 8.2%. In Dravidian population, branched lip print pattern was found to be highest among the males and vertical lip print pattern was found to be highest among the females which are found to be 14.3% and 12.8% which coincided with the study conducted by Venkatesh et al14 among the students of Karnataka and Bangalore. When comparative analysis was done between the Aryan and Dravidian population, it was found that highest lip print pattern was branched lip pattern reported among the males of Dravidian group which was 14.3% and lowest was recorded among females of Dravidian group which had partially vertical lip print pattern and one type of lip print pattern was not recorded among the males and females of Aryan group and also the males of Dravidian group which was portical lip print pattern which coincides with the study conducted by Prathibha Prasad et al15 among the Aryan-Dravidian population. Association between the gender difference and lip print among the Aryan and Dravidian population was assessed and p value was found to be statistically significant which was 0.011; the partially vertical type was not added in the analysis of p value since no record was found among the males and females of Aryan population. Association between the lip print pattern among the Aryan and Dravidian population was found to have a p value of 0.031 which was statistically significant. Sivapathasundharam et al study also concluded that branched lip print was common among the Indo-Dravidian population which coincided with our study which also gave a result that branched lip print was common among the study population. Limitation of the study was the sample size was not calculated according to confidence interval so reflection of the study cannot be applied to the generalised population.
Conclusion

Lip prints serving as a diagnostic tool to identify the human victims. The present study shows that branched lip print pattern was common and found to 15.9% among males and females of the Aryan population 22.5% in males and females among the Dravidian population. Second most common was the vertical lip pattern which was 10.2% and 13.3% among the Aryan and Dravidian population. Least common was partially vertical lip print pattern which was not found in Aryan population and 3.3% was reported among the Dravidian population.

Detection of Endometrial TB in Patients with AUB using PCR Method of Assessment of Menstrual Blood Flow of Iraqi Females

Maad Mehdi Shallal,1 Farah Abdul Hussein Salih Al-Asadi2, Mohammad Ibrahim Mizaal3

1PROF. M.B.Ch.B, F.I.C.O.G, College of Medicine/University of Baghdad, 2Lecturer M.B.Ch.B, F.I.C.O.G, College of Medicine/University of Baghdad, 3Ph.D Molecular Genetics, Iraqi society for Molecular Biology and Genetics ISMBG

Abstract

Background: Iraq still considered one of the countries in the region with high prevalence of TB, there are about 20000 patients, accounts for 3% of the total number of cases, and the estimated death from TB exceeds 4000 per year. TB in Iraq until nowadays considered a health, public and social problem, and because of the wars and political problems, many programs, campaigns, and researches were hindered by this situation.

Objective: To detect endometrial Tuberculosis in women complaining from AUB (abnormal uterine bleeding) using real time PCR method of assessment via taking an endocervical swab.

Patients and methods: Prospective cross-sectional study carried at Department of obstetrics and gynecology in Baghdad teaching hospital /medical city over a period of eight months starting from October 2019, to August 2020. A total of 60 women complaining from abnormal uterine bleeding (AUB) who were scheduled to have endometrial biopsy for histopathology by dilatation and curettage (D&C), endocervical swab assessed for female genital tuberculosis (FGTB) by real time PCR.

Results: Out of 60 samples taken 6 were positive by real time PCR 10%, while there was only one case positive by histopathology 1.66% which was also positive by PCR the same patient gave history of pulmonary TB and received a nine month course of treatment, according to these findings the sensitivity of PCR found to be 100% while the specificity 92% and an accuracy of 92%.

Conclusion: Real time PCR considered one of the valuable diagnostic tools for mycobacterium tuberculosis, and because Iraq still showing high incidence of the disease, one should suspect mycobacterium tuberculosis in any women complaining from abnormal uterine bleeding and offer PCR in addition to other diagnostic modalities, luckily it will allow treatment at an early stage of the disease.

Keyword: Endometrium, TB, AUB, PCR

Introduction

Iraq still considered one of the countries in the region with high prevalence of TB, there are about 20000 patients, accounts for 3% of the total number of cases, the estimated death from TB exceeds 4000 per year (1).

TB in Iraq until nowadays considered a health, public and social problem, and because of the wars and political problems, many programs and campaigns and researches were hindered by this situation (2).

Tuberculous PID is largely limited to patients from developing countries. Pelvic infection usually occurs secondary to hematogenous spread from an extragenital source. Nevertheless, occasionally Mycobacterium tuberculosis can be transmitted sexually (3).
Genital TB occupy about 9% of extrapulmonary TB (4), TB endometritis occupy about 50-60% of genital TB and tends to be sporadic lesions whereas ulceration, caseous changes and bleeding seen later on to ends up by adhesion and amenorrhea (5). Diagnosis of genital TB suspected depending on patient’s symptoms with infertility being at the top of the list, then AUB whereas dyspareunia and dysmenorrhea at the bottom of the list (6).

One of the conventional methods used for diagnosis of tuberculosis is acid–fast bacilli staining which mainly relied on identification of *Mycobacterium tuberculosis* by microscopy or its growth on culture medium (7). Culture still considered a gold standard method in the diagnosis of genital TB with a low detection rate contributes to the paucity of mycobacteria in the genital tract and delay in the diagnosis due to slowly growing pathogen which requires about 3-6 weeks (8). histopathology required the presence of epithelioid granuloma in the examined tissue and because of the shedding of the endometrium there might be no time for the granuloma to be formed so the endometrial aspirate and endometrial sample will be negative and many cases will be missed for this reason (9).

PCR method are widely used nowadays, a rapid procedure requires few hours for the results to be obtained and can identify the nucleic acid sequence specific to mycobacterium tuberculosis and other mycobacteria in female genital TB, with a high detection rate <10 bacilli/ml including dead bacilli (10). Compared to acid–fast bacilli staining by Zeihl-Neelsen stain which needs 104-106bacilli/ml on the other hand culture requires 10-100bacilli/ml of tissue/fluid sample for the diagnosis (5). It is possible now to catch hidden genital tuberculosis by PCR, real time PCR noticeably decreases the false positive results because the amplification and detection takes place in the same reaction tube with a sensitivity reaches about 90-94% and specificity of 70-78% (11).

**Material and Methods**

Our prospective present study carried out in the department of obstetrics and gynaecology/ Baghdad teaching hospital, from October 2019 till August 2020, a total of 60 patients aged between 30-68 years attends the gynecology outpatient clinic complaining from abnormal uterine bleeding all were prepared for diagnostic dilatation and curetage(D&C) and endometrial sampling, after full history taking including any positive history for pulmonary TB and received a 9-month course of anti-TB drugs. after patient consent endocervical swab was taken before commencing D&C, the swab then kept in 1 ml of transport medium then diagnostic curetage was done and endometrial sample sent for histopathology after being fixed with formalin.

Swabs then sent for laboratory for processing by real time PCR using AmpliSens MTC-FRT PCR kit, mycobacterium tuberculosis detection by the PCR is based on the amplification of pathogen genome specific region using specific mycobacteria tuberculosis primers. AmpliSens MTC-FRT PCR kit is a qualitative test that contains the internal control (internal control STI-87) (12).

**Results**

Table 1 show that age group between (40-49) years was the main group (61.6%) with the mean age (47.3±5.6) years, blood group A+ represented (41.7%), parity between (4-6) was the main group, while Menorrhagia was the most common symptom (85.0%) and the (means ±SD) of endometrial thickness was (9.27±4.5) mm.

Fisher exact test
Discussion

The incidence of FGTB differs worldwide; this is due to differences in studied groups, social stigma, the type of tests used to diagnose TB and its sensitivity and specificity, and the time at which the sample was taken with respect to the menstrual cycle. Although genital TB occurs secondary to pulmonary TB through hematogenous and lymphatic routes, primary genital TB can occur rarely when the male partner has genital TB such as TB epididymitis by transmission of infected semen.

Diagnosis of TB endometritis needs high index of suspicion because the disease is a symptomatic in majority of cases in addition to the paucity of the bacteria that’s why the diagnosis require a test with high sensitivity and specificity to detect the disease in early stages. (13, 14)

Depending on the fact that real time PCR has a high sensitivity and specificity in detecting mycobacterium tuberculosis and histopathology usefulness in detecting endometrial pathologies we conducted this study. In Histopathology the diagnosis of tuberculous endometritis based on the presence of epitheloid cell granulomas with or without Langerhans giant cells, and caseation necrosis which is seen on late disease (1).

In our study, out of 60 patients complaining from abnormal uterine bleeding in form of menorrhagia, metro menorrhagia and polymenorrhoea, endocervical swabs revealed that 6(10%) of those women were found to be positive for mycobacterium tuberculosis by real time PCR while histopathology detect only one case(1.7%) which is also positive by real time PCR and have positive history of pulmonary TB, the low detection rate of histopathology, in the current study, can be explained either to an early stage of the disease or the continuous shedding of the endometrium specially in our study when all the PCR positive women complain from menorrhagia, or due to presence of focal lesions which may be missed by curette. meaning that histopathology is false negative in 5 patients and thus give a sensitivity and specificity for real time PCR of 100% and 92% respectively.

These results when compared to study conducted by Malhorta et al (8), who reported an overall positivity by real time PCR alone 23.78% which is higher than in our study (10%) and a sensitivity of 94.28% which is approximate to current study.

Whereas Thangappah et al (9) study showed tuberculosis were positive in 36.7% by PCR and 6.9% for histopathology giving a lower sensitivity 57.1% for PCR and higher sensitivity for histopathology10.7% as compared to our study which was explained by Thangappah as cyclic shedding of the endometrium resulting in to poor formation of the granuloma and thus the endometrium will not show evidence of tuberculosis in all cycles so multiple specimens from different locations is advisable.

Our efforts in this study was to decrease the false positive cases, all the patients complain from abnormal uterine bleeding, have no clinical sign or symptoms of TB except one known case of pulmonary TB.

The other five out of six positive cases detected by PCR could be explained by early stages of the disease and the bacteria known to be indolent in genital tract or latent disease detected by PCR and the patient still without symptoms.

Other sources of false positivity could be due and the presence of dead bacillus or previous infection which was excluded by past medical history other causes could be the contamination which was overcome in this study by the type of PCR kit which includes the enzyme uracil-DNA glycosylase to reduce the risk of contamination, also the kit contains internal control (STI-87) used in the extraction procedure in order to control the extraction process of each sample individually and thus recognition of any reaction inhibition, furthermore the kit uses (hot-start) which greatly reduces the frequency of nonspecifically primed reaction (9)(12).

Conclusion

Real time PCR considered one of the valuable diagnostic tools for mycobacterium tuberculosis, and because Iraq still showing high incidence of the disease, one should suspect mycobacterium tuberculosis in any women complaining from abnormal uterine bleeding and offer PCR in addition to other diagnostic modalities, luckily it will allow treatment at an early stage of the disease.

Nasal Polyps: An Etiological Analysis

Magda Abd El-latif1, Sayed Kadah2, Ahmed Yehia3

1Professor, ENT Department, Al-Azhar university, Cairo, Egypt, 2Assistant Lecturer, ENT department, Armed Forces College of Medicine

Abstract

Nasal polyps, the prolapsed linings of nasal mucosa are one of the commonly encountered conditions in the outpatient department of otolaryngology. The aim of this study is to study the etiology of nasal polyps and also to compare between the different methods used for diagnosis of nasal polyps.

This study was submitted prospectively on 100 patients diagnosed with nasal polyps (diagnosed either clinically or radiologically) with evidence of nasal obstruction, rhinorrhea and headache. From April 2015 till April 2017. All patients had been selected from the outpatient clinics of Al-Zahraa University Hospital and Kobry El Koppa military hospital. The study was approved by the ethics committee of Al Azhar Faculty of Medicine.

A total of 100 patients were analyzed, age range 18 to 56 yrs with a mean age of 38.5 yrs. There were 83 male and 17 female. The main presenting symptoms are nasal obstruction and rhinorrhea. Most of the cases was bilateral nasal polyps, The commonest clinical diagnoses were non-neoplastic simple nasal polyps 84% and about 13% were benign neoplastic, 3% were malignant. The commonest histological diagnosis among non-neoplastic nasal polyps was simple allergic nasal polyp, among benign neoplastic was inverted papilloma. Most of neoplastic lesions were presented by unilateral nasal polyps, where epistaxis was noticed mostly with vascular tumour and malignant ones. The results show that most of nasal polyps were simple non-neoplastic lesions especially bilateral ones, also for proper evaluation of nasal polyps clinical, radiological and histopathological evaluation should be done in all patients.

Keywords: nasal polyps, histopathology, inverted papilloma.

Introduction

Nasal polyps, the prolapsed linings of nasal mucosa are one of the commonly encountered conditions in the outpatient department of otolaryngology.

They are a common cause of nasal obstruction in the adult, while the diagnosis in children is so rare (0.1%). In the general population, the prevalence of NP is considered to be around 4%. It predominantly affects adults usually those older than 20. Cancers of the nose and paranasal sinuses account for less than 1% of all malignancies and about 3% of all head and neck cancers. It has a geographic tendency to affect the African, the Japanese, and the Arab. It is rarer in Western Europe and America. There are a variety of conditions ranging from benign lesions to malignant nasal tumors which may mimic simple nasal polyps.

It is impossible to determine clinically what pathology lies underneath. Therefore, nasal endoscopy, radiology and histopathology are employed to help us reaching the diagnosis.

The histopathological examination of the removed tissue helps to determine the actual pathology of the varied conditions labelled as nasal polyps.

The aim of the work:

The aim of this work was To study the etiology of nasal polyps and This will be reached by performing full nasal polyps examination pre and postoperative.

Patients and methods:

The study was approved by the ethics committee of Al Azhar faculty of medicine. The study was submitted
prospectively on 100 patients during the period from April 2015 till April 2018. All patients had been selected from the outpatient clinics of Al -Zahraa University Hospital and Kobri-El kobba military hospital. All patients underwent complete ear, nose and throat examination. Using the headlight and nasal endoscope, the nasal cavity was carefully examined for presence of nasal polyps.

The preoperative evaluation had included history with inquiry about the main complaint (nasal obstruction) and other nasal symptoms, (sneezing, rhinorrea , Post-nasal drip, Headache and nasal itching). Diagnostic nasal endoscopy was done.

CT Scan nose and paranasal sinuses and MRI was done in selected cases. Each patient had been managed by functional endoscopic sinus surgery. The procedure was done under general anesthesia followed by histopathology of the removed polyps.

**Data management and Analysis**

Quantitative data were shown as mean, SD, minimum and maximum. Qualitative data were expressed as frequency and percent. Chi- square test and Fisher exact test were used to measure association between qualitative variables as appropriate. P (probability) value was considered to be of statistical significance if it is less than 0.05.

**Results**

One hundred patients were included in the study, there were 83 males and 17 females, ranged in age between 18 and 56 years with a mean age of 38.5 years.

Discussion

Nasal polyposis is a relatively common condition found in 1-4% of the general population (3). Our 100 patients of non-neoplastic and neoplastic lesions of the nose presenting as nasal polyps were studied in relation to the age-sex distribution, presenting symptoms, nasal endoscopy, radiological and histopathological findings. Mean age was 38.5 ± 8 years and more common in male than females. This was found to be similar to the study done by Larsen et al (4) whom study was conducted on 252 patients, they observed NP was more common in patients who were 40–60 years and more common in males than females (1.68 male and 0.82 female).

In another study done by Bakari et al (1) whom study was conducted on 76 patients, they found female preponderance (M:F ratio of 1:1.2). In our study the most frequent symptom was nasal obstruction (100%) and rhinorrhea (90%), followed by 71% with itching, 63% with smell disorders, 20% with epistaxis, 82% with headache and 4% with proptosis, 24% with mouth breathing and 4% with change of voice. Thahim et al (5) also found nasal obstruction in their 100% of cases, while nasal discharge was present in 90% of their patients. Bakari et al (1) whom study was conducted on 76 patients with sinonasal polyps, the main presenting symptoms were nasal obstruction (97.4%), rhinorrhea (94.7%). Out of 100 cases studied, 84 (84%) were non-neoplastic and 16 (16%) were neoplastic. Among the non-neoplastic conditions, allergic nasal polyps was the most common. Among the neoplastic lesions, 12 (12%) were benign and 4 (4%) were malignant. Among the benign neoplastic lesions, inverted papilloma was the most common, so non-neoplastic lesions was more common than neoplastic ones. This finding was similar to the study done by Lathi et al (6) whom study was conducted on 112 patients, they found that non-neoplastic was in 80 cases (71.4%) of the study subjects and neoplastic in 32 (28.6%) patients. In our study inverted papilloma was more common then angiofibroma then heamangioma.

Our results also coincided with the results of Sharma et al (7) whom study was done on 50 cases with sinonasal polyps, they found that non neoplastic lesions was more common (86%) of cases. Among benign neoplastic sinonasal masses, inverted papilloma was more common, it was found in 4% of cases then nasopharyngeal angiofibroma in 2% cases. Malignancy was found in 3 cases (6%).

Also the results coincided with a study done by Rawat et al (8), they found that found 68.56% of histopathological diagnosis as non neoplastic, 22.72% as benign and 8.71% as malignant.

As regards Comparison of Clinically diagnosed cases with Histopathological diagnosis in Non-neoplastic cases (N=84), in 35 cases diagnosed clinically as fungal polyp, histopathological diagnosis was consistent with fungal polyp in 24 cases (68.6%) with significant p value (p<0.0001), 11 cases (31.4%) were diagnosed as allergic nasal polyp (eosinophil rich infiltrate) with non significant p value (p=0.063). In 45 cases diagnosed clinically as non-specific nasal polyps, histopathological diagnosis was consistent with non-specific inflammatory nasal polyps in 12 cases (26.7%) with significant p value (p<0.0001), 33 cases (73.3%) was diagnosed histopathologically as allergic nasal polyp (eosinophil rich infiltrate) with significant p value (p<0.0001), in 4 cases diagnosed clinically as antrochoanal polyps, histopathological diagnosis was consistent with antrochoanal polyp in 4 cases (100%) with significant value (p<0.0001).

As regards comparison of Clinically diagnosed cases with histopathological diagnosis in neoplastic cases. (N=16), in 7 cases diagnosed clinically as inverted papilloma, histopathological diagnosis was consistent with inverted papilloma in 6 cases (85.7%) with significant p value (p<0.0001), 1 case (14.3%) diagnosed histopathologically as adenoid cystic carcinoma. In 5 cases diagnosed clinically as angiofibroma, histopathological diagnosis was consistent with angiofibroma in 5 cases (100%). in one case diagnosed clinically as hemangioma, histopathological diagnosis was consistent with hemangioma in also one case, in 3 cases diagnosed clinically as malignant lesion of nose and paranasal sinuses, histopathological diagnosis was consistent with malignant lesion in also 3 cases.

These results matched with results of a study done by Vaishali et al (9) histopathological diagnosis in Non specific polyps was consistent with clinical diagnosis in 12 (80%) cases while inconsistent in 3 (20%). In Allergic fungal polyps histopathological diagnosis was consistent in 7 (58.3%) and inconsistent in 3 (41.7%).
In diffuse polyposis with chronic rhinosinusitis 5(62. %%) and 3(43. 5%) were found consistent and inconsistent respectively with the histopathological diagnosis. All the clinically diagnosed cases of antrochoanal showed consistent reports with the histopathological diagnosis.

Comparison of Clinically diagnosed cases with Histopathological diagnosis in Neoplastic cases (n=6) showed only a single case clinically diagnosed of having malignancy of nose and PNS, histopathologically proved as cementoosiifying fibroma of the nose and PNS. Rest all the diagnostic consistency were the same as the clinical diagnosis. Further, it was analyzed that in Non-neoplastic cases(n=44) the Histopathological consisteny was in 33(75%) and inconsistency in 11(25%)This difference was statistically not significant.

The histopathological diagnosis correlated with clinical diagnosis in the present study in 55 cases(55%), in study done by Vaishali et al(9). the histopathological diagnosis correlated with clinical diagnosis in the present study in 38(76%) patients. In the study by Kale et al and Diamantopoulos II et al(10) the clinico – histopathological correlation was in 99. 7% and 98. 8% respectively. In our study the relatively lower clinico-pathological correlation, when compared to the other studies can be attributable to the lesser number of cases included in the study.

Conclusion

Non-neoplastic lesions was more common than neoplastic lesions, they are also more common in young ages and also are bilateral but neoplastic lesions are more common in the elderly and mostly unilateral. Sinonasal polyps are more common in males than females. because a lesion in the nasal cavity clinically presented as nasal polyp can either be neoplastic or non neoplastic and a significant lesions can be missed on either clinical or radiological evaluation ,so a thorough histopathological evaluation should be done in all cases of nasal polypoidal lesions for accurate diagnosis and management.

A Study of Thyroid Function test and Lipid Profile in Pregnancy

Mahantesh Patil1, Arpitha M R2, Dayananda R3, Meera S4

1Associate Professor, 2Tutor, Department of Biochemistry, 3Associate professor, Department of Forensic Medicine, 4Professor & Head, Department of Biochemistry, Mysore Medical College and Research Institute, Mysore

Abstract

Pregnancy is known to create profound changes in the body. It causes hormonal changes in the body which may lead to changes in lipid profile. TSH levels are usually suppressed due to very high levels of Human chorionic gonadotropin (hCG) during the first half of the pregnancy. Thyroid dysfunction may result in various changes in triglycerides, phospholipids, cholesterol and other lipoproteins. Dyslipidemia, a consequence of thyroid dysfunction, generally increases the risk for cardiovascular disease.

The study was conducted in the Department of Biochemistry, MMC&RI, Mysore. 100 women with a singleton pregnancy irrespective of parity and graida were enrolled and cases like chronic hypertension, Diabetes mellitus, Renal Disorders and Thyroid Disorders, Obstetric and Foetal Complications (Hydrops foetalis, congenital foetal anomalies) were excluded from the study. Blood was analysed for thyroid and lipid profile.

Conclusion: T3, T4 and TSH levels are within normal range during pregnancy. There is a positive correlation between TSH levels and cholesterol. This suggest that regular TSH and cholesterol estimation is very important during pregnancy to reduce the maternal and fetal complications.

Key words: cholesterol, dyslipidemia, HDL, LDL, lipid profile, VLDL and thyroid function test.

Introduction

Pregnancy is known to create profound changes in the body. It not only increases demand for metabolic fuels for the foetal growth and development but also causes hormonal changes in the body which may lead to changes in lipid profile1.

During early pregnancy, there is rise in serum estrogen and progesterone levels. And also, there is hyperinsulinemia leading to increased peripheral utilization of glucose, increased glycogen accumulation in the liver as well as increased storage of lipids and decreased lipid breakdown2.

The thyroid gland is an important endocrine gland in the human body because of its ability to produce the hormone triiodothyronine (T3) and tetraiodothyromine (T4). These hormones are important in regulating functions like growth, differentiation, cellular metabolism and general hormonal balance of the body, maintenance of metabolic activity and the development of skeletal and organ system. Over 99% thyroxine in the blood is bound to protiens like thyroxine binding globulin (TBG), albumin and prealbumin. Approximately 0.3% T4 is in the free unbound state in the blood. This free fraction is physiologically active due to its ability to enter target cells and influence calorigenesis and protein, lipid and carbohydrate metabolism. T4 also functions in the peripheral tissues as a prohormone by being further metabolized to another most active thyroid hormone, tri-iodothyromine (T3) and other inactive metabolites reverse T33.

During pregnancy controlled hyper-stimulation of the ovaries results in a rise of serum TBG, T4 and T3 concentrations while there was a fall in serum free T4 concentration and a small rise in serum TSH concentrations (usually within the normal range). Also, TSH levels are usually suppressed due to very high levels of Human chorionic gonadotropin (hCG) during the first half of the pregnancy, especially the first trimester. Thyroid dysfunction without any primary thyroid disease may result in various qualitative or quantitative changes of triglycerides, phospholipids, cholesterol and other lipoproteins. Dyslipidemia, a consequence of thyroid dysfunction, generally increases the risk for cardiovascular disease.

Aim: The present study was undertaken to find out whether there is any significant variation in the thyroid function test and lipid profile during pregnancy and to establish a relation between TSH & lipid profile.

Materials & Method

The study was conducted in the Department of Biochemistry, MMC&RI, Mysore. This study was undertaken after obtaining the Institutional ethical clearance. The study was conducted for a period of 5 months. A total of 100 pregnant women were enrolled in the study after informed consent.

Inclusion criteria: All pregnant women with a singleton pregnancy who came to our hospital irrespective of parity and gravida.

Exclusion criteria: Pregnant women with diseases or complications like chronic hypertension, Diabetes mellitus, Renal Disorders and Thyroid Disorders, Obstetric and Foetal Complications (Hydrops foetalis, congenital foetal anomalies).

Collection of Blood Sample: 3ml of fasting blood was collected under aseptic precautions from the cubital vein. Serum was separated after centrifugation and analysed. T3, T4 and TSH were analysed by ECLIA method. The serum total cholesterol by enzymatic CHOD-PAP method, serum triglycerides by enzymatic GPO-PAP method, serum high density lipoprotein (HDL) cholesterol by Direct enzymatic method, very low density lipoprotein (VLDL) by calculation method (triglycerides/5) and low density lipoprotein (LDL) cholesterol was calculated by Fredrickson-Friedwald formula \{total cholesterol - HDL cholesterol - (triglycerides/5)\}.

Statistical Method: The data was entered in excel format and analysed using epi-info software. Descriptive statistics like frequency and percentage were calculated. Association between qualitative variables was tested by chi-square test. P value less than or equal to 0.05 was considered as significant. Correlation was used for quantitative variables. The values between 0 to +1 was considered as positive correlation and 0 to -1 as negative correlation.

Pregnancy is a stress condition to the maternal thyroid gland, due to increase in thyroxin binding globulin, increased demand for iodine and thyroid stimulation by HCG. Thyroxin is an important hormone for fetal brain development, growth and lung maturation. Thus if maternal levels are not well maintained in pregnancy, fetus is at risk. Hence regular measurement of thyroid profile is important.

Table 1 & 2 shows Thyroid function test of study subjects. Out of 100 subjects, 90% were euthyroid, and 8% & 2% were hypothyroid & hyperthyroid.
respectively. The mean T3 level was 171.72 + 48.07ng/dl, mean T4 was 10.73 + 2.16µg/dl and mean TSH was 2.18 + 1.37 µIU/ml. Patwari M et al also showed similar results. According to Patwari M et al, the mean T3, T4 & TSH was 71-175ng/dl, 3.6-9.0µg/dl & 0.1-4.0 µIU/ml; 84-195 ng/dl, 4.0-8.9µg/dl & 0.4-5.0 µIU/ml; 97-182 ng/dl, 3.5-8.6µg/dl & 0.23-4.4 µIU/ml in 1st, 2nd and 3rd trimester respectively. When average values of all the 3 trimesters were considered the results were in agreement with present study.

Thyroid hormones play an important role in synthesis, mobilization and metabolism of lipids. Therefore, hypothyroidism is a major cause of secondary dyslipidemia. The risk of developing atherosclerosis is directly related to the plasma cholesterol. Increased level of cholesterol for prolonged period will favor deposits in subintimal regions of arteries. The oxidized LDL (ox-LDL) gets deposited in the walls of arteries, which are degraded by nonspecific uptake by macrophage. There is also smooth muscle cell proliferation and fibrosis. So, this adversely affects the pregnancy. In the present study we have carried out the lipid profile and found dyslipidemic features.

Table 3 & 4 shows lipid profile of subjects. Out of 100 subjects, 70% were Hypercholesterolemia. The mean total cholesterol was 223.32 + 58.87mg/dl, triglycerides was 198.38 + 76.46 mg/dl, HDL 60.9 + 11.89 mg/dl, LDL was 106.8 + 26.47mg/dl and VLDL was 39.67 + 15.29 mg/dl. There is a consensus regarding elevated levels of total cholesterol, triglycerides, LDL and VLDL between the present study and the study done by Pusukuru, R et al., on 200 pregnant women. Pusukuru, R et al. learnt that the average values of total cholesterol, triglycerides, high density lipoprotein, low density lipoprotein and very low density lipoprotein in 2nd and 3rd trimester was 228.61mg/dl, 202.73 mg/dl, 46.09 mg/dl, 115.11 mg/dl & 32.24mg/dl respectively.

Table 5 shows association between TFT and Lipid profile. Out of 90 euthyroid subjects 60 were in Hypercholesterolemic status but it was statistically not significant (p > 0.05).

Table 6 shows correlation between TSH and cholesterol levels and we observed a positive correlation between total cholesterol and HDL. This indicates that the TSH and Cholesterol & HDL are positively associated. When TSH level increases, cholesterol levels also increases. Garduno-Garcia JJ et al. concluded that TSH is significantly associated with lipid profile in the euthyroid population and they showed TSH is positively correlated with TC, TG & LDL and negatively correlated with HDL.

Pregnancy is a phase of life, where the emotions are high not only to the pregnant lady but to the other family members. If there is any untoward incidence during pregnancy, then allegations of medical negligence are often cited as the reason. Hence, the study which establishes association between TFT and lipid profile to maternal and fetal complications are need of the hour. It is recommended that forensic experts consider regularly examining the thyroid gland histologically, particularly a cause of death there is no apparent anatomic cause of death in pregnant women.

Conclusion

T3, T4 and TSH levels are within normal range during pregnancy. There is a positive correlation between TSH levels and cholesterol. This suggest that regular TSH and cholesterol estimation is very important during pregnancy to reduce the maternal and fetal complications. The documentation in the form of tests of Thyroid function tests and Lipid profile will serve as a arsenal to the doctors in cases of alleged Medical Negligence. Lack of documentation can be an achille’s heel even though doctor would have taken all precautions.

Limitations: The sample size is less to establish proper correlation between thyroid status and dyslipidemia and its related complications. Hence, the study should be conducted on large sample size and these parameters should be considered in all trimesters and postpartum period as well.

Caracteristics, Diagnosis, Management and Output of Persistent Pulmonary Hypertension of the Newborn at Dr. Soetomo Hospital

Mardiyan Aprianto¹, Mahrus A Rahman¹, Martono Tri Utomo¹

¹Resident in Department of Child Health, Faculty of Medicine, Universitas Airlangga Medical School/ Dr. Soetomo General Hospital, Surabaya, Indonesia, ²Lecture and Consultant in Paediatric Cardiology Division Department of Child Health, Faculty of Medicine, Universitas Airlangga Medical School/ Dr. Soetomo General Hospital, Surabaya, Indonesia, ³Lecture and Consultant in Paediatric Neonatology Division Department of Child Health, Faculty of Medicine, Universitas Airlangga Medical School/ Dr. Soetomo General Hospital, Surabaya, Indonesia.

Abstract

Background Persistent pulmonary hypertension of the new-born (PPHN) is a failure of lung circulation in new-born. However the data related the characteristics of clinical profile, diagnostic, management and the outcome was still limited.

Objective To investigated the characteristics, diagnostics, management and outcome from PPHN.

Methods Retrospective observational study. Neonates with PPHN from January 2015 to December 2019 were identified from medical record. After the data was excluded, the characteristics, diagnostic, management and the outcome was collected. The statistical analysis to known the frequency and the chi-square test used to analyse the association between the treatment and the outcomes ($P < 0.05$).

Results 37 medical records enrolled the study, with the characteristics; 62.2% babies was boy, 70.3% with term infant, 70.3% with normal birth weight, 24.3% with maternal history of eclampsia. 62.2% babies born by C-section, 21.9% with history of asphyxia and MAS. 78.4% with differences between pre- and post-ductal saturation. From echocardiography result, 13.5% diagnosed as mild PPHN, 54.1% as moderate PPHN and 32.4% severe PPHN. From the management consisted of 5.4% with O₂ nasal, 32.4% O₂ CPAP and 62.2% O₂ ventilator, 24.3% with sildenafil, 5.4% with combination sildenafil and illoprost, 5.4% with combination sildenafil, illoprost, and surfactant, 2.7% with combination sildenafil, illoprost, surfactant, and inotropic, 24.3% with combination sildenafil, illoprost, and inotropic, and 37.8% with combination sildenafil and inotropic. The outcomes was obtained 35.1% babies was died and 64.9% babies was cured, with oxygenation supplementation had significantly affecting the outcomes ($P=0.02$)

Conclusion The characteristics of PPHN was dominated by baby boy, term infant and good birth weight, history of asphyxia and MAS, maternal history of eclampsia, C-section delivery and the differences between pre- and post-ductal saturation. The diagnosis commonly with moderate PPHN. The management with O₂ ventilator and combination sildenafil-inotropic. The outcome mostly the babies was cured.

Keywords: Persistent pulmonary hypertension of the new-born, Characteristic, Diagnostic, Management, Outcome

Introduction

Persistent pulmonary hypertension of the newborn (PPHN) is a syndrome lung circulation failure to transition from fetal circulation to neonatal circulation.
Indian Journal of Forensic Medicine & Toxicology, January-March 2021, Vol. 15, No. 1

The incident PPHN is quite rare, in worldwide ranging from 1-6 over 1000 of live births. Based on medical record from 2015 to 2016 In Dr. Soetomo Hospital were found 20 cases. This condition generally life-threatening with the prognosis tends to be poor, especially in developing countries\(^1,5,14,22\). Samudro and Mulyadi (2012) in their study explained, PPHN with the delivery history followed with low birth weight, presence of infection, and labor procedures with C-section, tends to have a poor prognosis. However, the data in Indonesia is still incomplete\(^20\).

In the world the mortality rate infants with PPHN is around 10% and will increases if followed by congenital anomaly such as diaphragmatic hernias. For the morbidity rate it was around 25% consist of developmental disorders, pulmonary hypertension and neurological disorders\(^1\).

Walsh-Sukys MC (2000), infant with PPHN have several clinical profile characteristics, commonly happened in baby boy and white race ethnic\(^23\). Another clinical profile that PPHN could presence in parenchymal lung disease in the newborns, include of meconal aspiration syndrome (MAS) and or respiratory distress syndrome (RDS). That is the reason why PPHN could occur in preterm or term infants \(^8,20\). In addition, characteristic of infant with history of intrauterine growth restriction (IUGR), hypoglycemia, polycythemia, or oligohydramnios are also suspected as the risk factors of PPHN \(^2,20\).

Diagnosing PPHN is not easy, sometimes it can underdiagnosed and considered a congenital heart disease (CHD), so the close initial evaluation is needed especially in infants with history born with hypoxia. Characteristic of maternal history also important, because mother with diabetes, asthma, hypertension, eclampsia, obesity and drug used during pregnancy was suspected as a risk factor, history of delivery, physical examination by measure the pre- and post-ductal oxygen saturation also important to know. As the gold standard to diagnosed PPHN, echocardiography still preferred. With echocardiography examination we can found the anatomical disorder and also to monitor the effectiveness of the therapy was given \(^9\).

After the diagnosed already established, the therapy for PPHN will be given based on the severity. The goal of the PPHN management are to overcoming circulatory failure and improving oxygenation needed. However, in Dr. Soetomo Hospital there were known several combinations therapy and the clear data about the right combination therapy in order to obtain the best outcome is still unknown. Management therapy at Dr. Soetomo Hospital currently includes many combination therapy consist of oxygenation supplementation, with surfactants, or vasorelaxants, or phosphodiesterase inhibitors, or illoprost inhalation and or inotropes administration\(^1,13,19,20,22\). Therefore, to obtain a good outcome babies with PPHN, the proper diagnosis and good management evaluation are needed to achieve optimal conditions \(^1,19\).

The aimed of this study to investigated the characteristics of clinical profile, diagnostics, management and outcome from PPHN.

**Material and Methods**

A retrospective observational study, with the neonates who diagnosed as PPHN that hospitalize in NICU room and the data was collected based on medical records. The data was collected from January 2015 to December 2019. The inclusion criteria for the medical record consist of the infants with aged since birth to 30 days old and already diagnosed as PPHN, confirmed by echocardiography, then got management therapy according to applicable guidelines. The statistical analysis was to calculate the frequency (by presentation) and the chi-square test used to analyse the association between the treatment and the outcomes \((P < 0.05)\).

**Operational Definition**

**Persistent pulmonary hypertension of new-born** defined as increased pulmonary vascular resistance in neonates characterized respiratory distress, followed by shunting of blood circulation from the right to the left heart chamber with clinical severe hypoxemia \(^16\), and already confirmed by echocardiography \(^18\).

The characteristics PPHN are clinical profile included sex and the risk factors during gestational age, infant birth weight, history of delivery, maternal history (eclampsia, premature rupture of membranes (PRoM), oligohydramnios, bleeding during pregnancy, and history of drugs consumption), history of labor procedure (spontaneous or C-section), history of natal
Indian Journal of Forensic Medicine & Toxicology, January-March 2021, Vol. 15, No. 1

1245

(RDS, asphyxia, MAS, congenital heart disease, HIE and diaphragmatic hernia), and complications during hospitalization.

The diagnosis of PPHN in infants based on clinical symptom with respiratory distress followed by hypoxia that occurs in the first 6-12 hours after birth and the history of risk factors PPHN, from physical examination with differences more 10% between pre- and post-ductal saturation, confirmed with echocardiography. From echocardiography result of shunting from right to left through patent ductus arteriosus (PDA) and or patent foramen ovale (PFO), increased right ventricular pressure and pulmonary artery pressure with tricuspid regurgitation (TR), or found right ventricular dysfunction. The severity of PPHN are divided into mild PPHN (echo result mild TR), moderate PPHN (moderate TR) and severe PPHN (severe TR)

The management therapy of PPHN included oxygenation (administration through nasal canul / CPAP / mechanical ventilator) and drug administration (sildenafil; sildenafil with illoprost; sildenafil, illoprost, and surfactant; sildenafil, illoprost, surfactant and inotropic; sildenafil, illoprost and inotropic; and sildenafil with inotropic). The purpose of management to increase oxygen supply, reduce oxygen demand, facilitate adequate gas exchange in the lungs, reduce pulmonary vascular pressure by increasing vasodilation of pulmonary blood vessels, improving mixing of flow in the cardiac atrium and through PDA and improving metabolic disorders.

The outcome of PPHN after evaluation and treatment defined as recovery (without sequelae or with sequelae) or died.

Results

In this study, were found 56 medical records infants with PPHN, but only 37 medical record still remained. The characteristics in this study based on sex 62.2% dominated with baby boy with a boy to girl ratio was 1.6 : 1. Based on the maternal history in this study consisted of 24.3% with eclampsia, 18.9% with PRoM, 13.5% with oligohydramnios, 5.4% with bleeding during pregnancy, 70.3% with appropriate gestational age consisting of term-infant 70.3% and preterm infants 29.7%. Based on the history of childbirth 62.2% babies were born with C-section and 37.8% were born spontaneously, and according to birth weight 70.3% with normal birth weight, 24.3% infants with low birth weight and infants with very low birth weight (5.4%) (Table I).

The characteristic of perinatal history, there were 21.6% infants with asphyxia neonatorum, 21.6% with MAS, 10.8% with RDS, 5.4% with hypoxic ischemic encephalopathy (HIE), 2.4% with diaphragmatic hernia and 2.7% with congenital heart disease. The complications during hospitalization consist of pneumonia (45.9%), and sepsis (43.2%), with length of stay about 10 days.

Table II showed the diagnostic from babies with PPHN based on differences between pre- and post-ductal saturation, confirmed with echocardiography as the gold standard diagnostic. From this study was found 78.4% with the differences between pre- and post-ductal saturation and from echocardiography was confirmed 13.5% with mild PPHN, 54.1% with moderate PPHN dan 32.4% with severe PPHN.

### Discussion

Research on persistent pulmonary hypertension of the newborn (PPHN) has been widely carried out, but the results obtained are still unsatisfactory. The occurrence of pulmonary vascular disorders in infants is known to be the cause of PPHN. Based on the pathophysiology, the disorder is divided into three, namely under-development of pulmonary vascularization during the intrauterine period, the presence of mal-development (abnormalities of the vascular structure), and or the presence of maladaptation (generally due to vascular spasm triggered by perinatal hypoxia). Currently, several characteristics was thought to be the predisposing factors for PPHN have been identified. In this study, the characteristics of PPHN based on gender 62.2% was boy and 37.8% girls with a ratio of 1.6: 1. Choudhary’s (2015) in his study, baby boy were also dominated 65% from all sample, as well as in Harish and Kamalarathnam’s (2018), where the ratio of between boy and girl was 1.5: 1.

The characteristic of PPHN based on maternal history, in this study was found 24.3% with eclampsia, 18.9% with history of premature rupture of membranes (PRoM), 13.5% oligohydramnion and 5.4% with placenta previa. Eclampsia and bleeding during pregnancy caused intrauterine hypoxia due to reduced oxygen supply that was distributed to the foetus. It will exacerbate the pulmonary transition process as a risk of developing PPHN that occurs when the baby was born. Bleeding during pregnancy will also cause foetal anemia, it will lead into the abnormalities pulmonary vascularization development (known as mal-development). The mother’s condition followed by PRoM can cause pulmonary hypoplasia in infants as the results from oligohydramnios that occur during PRoM progress. It will lead to the abnormalities in parenchyma and the development of the pulmonary vascular. It also will decrease the number of blood volume and trigger vasoconstriction of pulmonary blood vessels. This process is known as underdevelopment that can caused PPHN. For management this condition required generally prolonged cardio-respiratory support because sometime not responding to vasodilators administration. Gestational age also known as the characteristic of PPHN. In this study, PPHN 70.3% occurred at term infant compared to babies born preterm. Research by
Roofthooft (2011) found PPHN occurred mostly at term infant than preterm infant. Harish S and Kamalarathnam C (2018), also showed 82.3% of PPHN occurred in term infant. The characteristics of the gestational age babies with PPHN in each health care facility can be different. The preterm babies, generally all the organs in an under-development condition, especially the lung. The under-development of the lungs will trigger hypoxia that in long term could be the risk factor of chronic lung disease as the secondary cause of PPHN. It will be worsened if followed by high pulmonary vascular resistance (PVR) due to failure of the post-natal transition. In term infants the mechanism of PPHN is quite different, it due to maladaptation of the pulmonary parenchyma (eg, in MAS or RDS conditions) that also caused high PVR during the post natal transition.

The history of labor, included the procedure of delivery and the birth weight also known as the characteristic of PPHN. In this study 62.2% PPHN was found in C-section compared to spontaneous delivery was only 37.8%. Choudhary et al (2015), 57.89% PPHN found in babies who’s born by C-section, as well as in research of Harish S and Kamalarathnam C (2018), the incidence of PPHN in babies with history of C-section about 68.9% PPHN in infants who’s born by C-section is caused by the interference of endogenous catecholamine secretion. Endogenous catecholamine in infants are important during the transition process. Disruption of it caused delayed the transition process, and also trigger exchange disorders in the lungs due to the lack of stimulation of the lung and significantly triggers immaturity of the lungs. The differentiated with spontaneous delivery can provide mechanical stimulation in the form of manual compression on the chest wall and stimulates the baby to breathe, also helps to expelling amniotic fluid in the respiratory track. However, this does not conclude that C-section is prohibited, because there are several indications that require the procedure to be performed.

In this study, PPHN occurred in 70.3% babies with normal birth weight, then low birth weight. Harish S and Kamalarathnam C (2018) found, 68.5% incidence PPHN happened in babies with moderate birth weight compared to babies with low birth weight. PPHN in sufficient birth weight occurs due to secondary factors that cause maladaptation of the lung (babies born with MAS or transient tachypnea of newborn). But it didn’t mean PPHN couldn’t occurred in low birth weight infant, it just happen due to the under-development of the lungs tissues and vascularisation. The PPHN in low birth weight that identical to intrauterine growth retardation (IUGR), was caused by under-development mechanism of the lung. So, the infants with sufficient birth weight or less, each of them has the possibility to suffer PPHN.

The perinatal history related to PPHN, in this study was found that neonatal asphyxia and MAS had the same incidence of PPHN (21.6%), followed by RDS, hypoxic ischemic encephalopathy (HIE), diaphragmatic hernia and congenital heart disease. Other characteristics are complications that occur during the hospitalization. The complications in our study consist of pneumonia (45.9%) and sepsis (43.2%). Sharma (2011), PPHN most often occurs in infants with a history of asphyxia and MAS because clinical hypoxia which can trigger pulmonary vascular spasm. In the normal physiological condition, the air exchange process was done by placenta would be replaced by the lung, after the baby born, followed by increased of pulmonary oxygenation through complex biochemical mechanisms and processes. This will facilitate the transition process from the new born, but if it got disruption it will lead to failure of pulmonary development as well as vascular dysfunction. The mechanism known as maladaptation.

Roofthooft et al (2011) in their research, as addition infections (pneumonia, and or sepsis), congenital disorders such as diaphragmatic hernia and congenital heart disease can cause PPHN. These factors caused maladaptation of pulmonary development. In addition, there was other mechanisms that could trigger PPHN due to abnormalities in the development of pulmonary vascularization (maldevelopment) which are generally idiopathic, for example in chronic foetal hypoxia, foetal anemia, or with congenital heart disease (PDA). The third mechanism that can trigger PPHN is the underdevelopment mechanism, for example in the condition of lung hypoplasia that occurs in infants with diaphragmatic hernias and infants with infections. Infection is a risk factor of sepsis, as well as pneumonia. Infection will cause damage of lung parenchyma through surfactant inactivation mechanisms, release of pro-inflammatory mediators, and other chemical...
reactions that increase the secretion of vasoconstrictors such as endothelin and thromboxane. If the condition is exacerbated by hypoxemia that occurs since birth, it will aggravate vasoconstriction of the pulmonary vascular. On the other hand, if the sepsis not resolved, will decrease the systemic vascular resistance (SVR) with clinical hypotension. If the condition followed by an increase in PVR, it will be trigger shutting via from the right to the left heart and made the PPHN more severe. Konduri and Kim (2009) explained that sepsis in PPHN was caused by infection with Group B Streptococcus and gram-negative organisms that acquired during hospitalization. The bacterial endotoxin released in the bloodstream caused pulmonary hypertension, these mechanisms made thromboxane, endothelin and cytokines release and the over-activation of nitric oxide. It also cause worst effect such as multi-organ failure including myocardial dysfunction.

Diagnosis of PPHN is not easy, from history taking of maternal and childbirth followed by a physical examination, supporting the diagnosis to detect PVR which is the characteristic of PPHN, as well as to find the condition of blood flow and myocardial function. Supportive non-invasive examinations are recommended PPHN. The recommendations suggest the pre- and post-ductal ratio of oxygen saturation (\(\text{SpO}_2\)) and echocardiography as the gold standard. From saturation that showed 5-10% difference between the right upper limb (pre-ductal) and the lower left (post-ductal) limb indicated the PPHN, but the disadvantages of this examination is unable to confirm heart structural abnormalities. This saturation measurement was carried out during the first 6-24 hours of life, after clinical signs of hypoxia were found. This examination is very helpful as the initial screening of PPHN, especially in limited health facilities before confirmed by echocardiography. In this study, it was found that 78.4% of the newborn with differences of pre- and post-ductal saturation and 21.6% were not have it. The difference in pre- and post-ductal saturation in PPHN infants occurs due to episodic changes in circulating pulmonary blood flow and shunting from the right to the left heart chamber. If the changes of pulmonary circulation occur more intense, it mean the condition developed severely.

Echocardiography still recommended by 95% of respondents as the gold standard to diagnosed PPHN. This examination is easy to use and can be done bedside if the patient’s condition was unstable. This examination is also used to assess progressivity or how the response of therapy that has been given. Echocardiography used to determine the cardiac structural abnormalities and to rule out the differential diagnosis as cyanotic CHD, because from the physical examination, both of it can followed by systolic murmurs due to tricuspid regurgitation or continuous murmurs from PDA. From echocardiography we can diagnosed PPHN if there was right ventricular hypertrophy, deviation of the interventricular septum to the left side, tricuspid regurgitation (TR), and right to left bidirectional shunting via PFO and PDA. In this study was found, from echocardiography 13.5% patient with mild PPHN, 41.1% with moderate PPHN, and 32.4% with severe PPHN.

Oxygenation therapy in this study was found 5.4% infants received nasal \(\text{O}_2\) therapy, 32.4% infants received \(\text{O}_2\) CPAP and 62.2% with mecanical ventilator. The purpose of oxygenation management is to fix hypoxemia and improve the blood pressure, which it will effect reduction of the heart shunting from the defect. If the condition followed by persistent hypoxia, with clinical possibility of PPHN, then the first step is to provide oxygenation until the diagnosis of PPHN has been confirmed. Oxygen supplementation acts as a potent vasodilator and to assist post-natal physiological adaptation processes based on oxygen needs. However, during the oxygenation therapy it important to monitoring and choose the right way to give the oxygenation according to the severity so the oxidative stress could be prevented. Because if oxidative stress occurs, it will form reactive oxygen species which cause the opposite effect (vascular vasoconstriction).

The management of PPHN, in this study consisted 24.3% received a combination of sildenafil and illoprost, 5.4% received a combination of sildenafil, illoprost, and surfactant, 2.7% received a combination of sildenafil, illoprost, surfactant and inotropic, 24.3% received a combination of sildenafil, illopros, and inotropic and 37.8% infants received sildenafil and inotropic combination. Indication of therapy based on the clinical condition of patient and
the availability of the therapy in dealing with PPHN in each hospital. In this study, sildenafil commonly used in all infants especially with mild to severe PPHN. Sildenafil known as a phosphodiesterase inhibitor type 5 (PDE5) which selectively to reduce PVR and increase cyclic guanosinemonophosphate (cGMP), it cause a vasodilating effect the vascular. If the administration of sildenafil was combine with oxygen supplementation, it will give improvement and oxygenation needs 25.

Surfactant in PPHN especially indicated for infants with a history of MAS. Physiologically 5% -24% of the newborn can experience meconium staining of amniotic fluid (MSAF), 5% of this MSAF could develops into MAS and caused hypoxemia due to obstruction of the airway and surfactant inactivation 14. Surfactant administration in the newborn will expected to stimulate the release of meconium from the airways, improve lung oxygenation and reduce shunting flow from the right to the left heart 14, 19.

The other recommended therapy in management of PPHN is the administration of vasorelaxants, which namely as illoprost. Vasorelaxants act by inhibiting the transport of calcium ions in lung and systemic vascular smooth muscle cells. The effect is to reduce vasoconstriction of blood vessels, but during the administration it needs to be monitored closely because can make systemic side effect in the form of hypotension. Illoprost can be given by inhalation especially in PPHN with severe hypoxia suspected caused by unclear cyanotic heart disease. When it got combined with sildenafil will give better results 1, 19. In PPHN with clinical symptom persistent hypoxemic and hypotension. We could suspected increased of shunting right to left shunt was occur. Hypotension caused by systemic vascular resistance (SVR) was decrease and followed with increased shunting form. Inotropic agents is one of the methods to reduce the shunting, but depends to considerably in each health care facility, because there is no clear evidence which group is the best. Nakwan (2016), said the inotropes dopamine was choose as the first-line therapies, dobutamine and epinephrine will be selected as the second and third line therapies 16.

The outcome in this study was found that 24 patient was recovered, which 37.8% infants cured without sequelae, and 13 patient was died. The outcome of the patient who died especially in limited health care facilities tended to be high. Harish and Kamalarathnam (2018), in their study in India, said that the mortality rate of PPHN could reached 42.3% even though these babies had received sildenafil therapy and mechanical ventilators. Harish and Kamalarathnam (2018) suspect that the cause of death is due to inappropriate therapy. Ideally, oxygenation therapy should be accompanied by iNO (inhaled nitric oxide) or using the HFO (high frequency oscillation) or ECMO (extracorporeal membrane oxygenation) method. The obstacle is, the modality of the therapy is expensive and requires inexpensive technicalities 4, 5, 7. iNO known has the fast effect and selective working site at pulmonary vascular (Luecke and Mcpherson., 2017). This mechanism caused vasodilator by involves the production of cyclic guanosine monophosphate (cGMP) in the muscularis lining of blood vessels, then it will activates cGMP kinase and causes calcium pump inhibitors in blood vessels. Decrease of calcium ions that enter the smooth muscle cells will trigger relaxation and vasodilation of pulmonary blood vessels. If the therapy combined with sildenafil, the effect of suppression of cGMP regulation will be prevented and the vasodilation can have a long half-time 26. The other mechanism of iNO is to preventing anaerobic metabolism during hypoxia, by changes the hemoglobin binding that effect oxygenation supply improved 27. The ECMO and HFO ventilation also can provide improvement for the lung oxygenation up to 53%, compared to regular mechanical ventilation in PPHN infants, with recovery rates from 81-82% 11, 27. The combination of HFO and iNO also give the advantage, because with low pressure it can quickly corrected arterial oxygenation saturation 1, 3.

In this study, the oxygenation supplementation had a significant effect to the outcomes. Oxygenation is the first line therapy which acts as a major stimulant of the nitric oxide and prostacyclin pathways of the pulmonary vasodilator cascade. The advantage from oxygenation to PPHN are fast action and selective onset as a vasodilator for pulmonary vascularization and provides negative feedback to vasoconstriction stimulation in the central nervous system 27. This oxygen supplementation can be adjusted based on mild to severe PPHN condition, for example in mild PPHN oxygenation can be given using a nasal cannula, followed by closed monitoring to the response as a consideration whether it is necessary
to increase the oxygen supplementation or not \(^{14,19}\). In this study, it was also known that nine babies received sildenafil without combined with other therapies, with the good outcome. The reason are, it depends on the severity of PPHN itself and as the sample if the baby’s was suffered from mild to moderate PPHN. The severe PPHN mostly tends to give a poor outcome due to the maladaptation and mal-development processes that aggravate the condition, thus condition will needing a therapy including illoprost, surfactants and inotropes \(^{18}\).

Complications during hospitalization suspected can effecting the outcome babies with PPHN. In this study were seen, 13.5% of PPHN infants died followed by sepsis and 21.6% followed by pneumonia. But, even though both of it have a fairly high incidence but there was no association with the outcome. Sepsis and pneumonia can cause high mortality and morbidity in PPHN, but it needs other circumstances conditions such as condition during pregnancy, labor history or perinatal history that could influenced the outcome \(^{12,18}\).

The aim of this study are to become the reference for further research which can be experimental study research to prove the association between of each characteristic, diagnostics and management to the outcome of PPHN.

**Conclusion**

The characteristics of PPHN in dr. Soetomo Hospital consist of, baby boy, with term infant, normal birth weight, perinatal history of asphyxia and MAS, with the complications of pneumonia, maternal history of eclampsia, and delivery procedures by C- section. PPHN could diagnosed with differences in pre- and post-ductal saturation, confirmed by echocardiography followed with the results moderate PPHN. The management of PPHN in dr. Soetomo Hospital was received oxygenation supplementation using mechanical ventilator and \(O_2\) CPAP, with drug combination frequently used sildenafil with inotropic, sildenafil with illoprost and inotropic, and also sildenafil single administration. With the outcome of PPHN were in a cured condition.

Abstract

Pulmonary tuberculosis is an infectious disease caused by Mycobacterium tuberculosis, which can attack the lungs and other organs. Pulmonary tuberculosis is still one of the world’s public health problems even though TB control efforts have been implemented in many countries since 1995. The target of the national pulmonary TB prevention program is eliminated in 2035 and Indonesia free from pulmonary TB in 2050. Purpose of Research, this is to find out the factors that influence the incidence of pulmonary tuberculosis in the Jati Health Center Area. This study uses secondary data taken from data from the Jati Health Center and the analysis in this study uses the CHAID Exhaustive method. The results of this study indicate that the number of pulmonary tuberculosis patients with a positive smear suspicion when viewed from the type of sufferers is mostly new cases as many as 216 people. Associated with the type of patient who came for treatment at the Teak Health Center, all patients seeking treatment received a cure category of 99.6% which is a new patient treatment category. So the factors that influence the incidence of pulmonary tuberculosis are the type of patient and treatment results.

Keyword: exhaustive CHAID, tuberculosis, treatment results, type of sufferer

Introduction

Pulmonary tuberculosis is an infectious disease caused by Mycobacterium tuberculosis, which can attack the lungs and other organs. Lung tuberculosis is still one of the world’s public health problems even though TB control efforts have been implemented in many countries since 1995. The national pulmonary TB prevention program targets are eliminated in 2035 and Indonesia free from pulmonary TB in 2050.¹

Data from World Health Organization² states that every year, millions of people in the world have been infected with pulmonary tuberculosis. One of the countries with the most pulmonary TB sufferers in the world is Indonesia. The population reported with the highest cases (43% of the total number of pulmonary tuberculosis cases in Indonesia) is found in the provinces of West Java, Central Java and East Java.³

The notification rate for all cases of pulmonary TB in the population of Central Java Province in 2017 is 132.9 per 100,000 population, this shows that the discovery of pulmonary TB cases in Central Java has increased compared to 2016 which was 118 per 100,000 population.⁴ Data on pulmonary TB cases that obtained from 19 public health centers in the Kudus Regency area in 2014 stated that as many as 495 people were infected with pulmonary tuberculosis.⁵

Method

This study uses secondary data taken from data from the Jati Health Center. The population in this study was all people in the working area of the Jati Health Center who came for treatment at the Puskesmas and conducted sputum checks. While the sample in this study is the entire community in the work area of the Jati Health Center with the incidence of pulmonary tuberculosis.
The analysis in this study used the CHAID Exhaustive method. Exhaustive CHAID is an exploration method for classifying data by building a classification tree that can provide information in the form of independent variables that significantly influence the dependent variable. Exhaustive CHAID has three stages, namely: the merging stage, the splitting stage, and the stopping stage.\(^{(6)}\)

The dependent variable in this study is the incidence of pulmonary tuberculosis. While the independent variables in this study are age, sex, type of patient, and treatment results.

</table>
The results of the Exhaustive CHAID analysis showed that the independent variables that significantly affected the incidence of pulmonary tuberculosis were the treatment outcome variable and the type of sufferer. While gender and age variables do not affect the incidence of pulmonary TB, so these variables are automatically discarded. The number of nodes formed is 5 (five) pieces, the number of terminal nodes is 3 (three) pieces and the depth of the trees formed there are 2 (two) branches.

Figure 1 shows that from a sample of 313 people studied, the results obtained were 267 patients with positive smear suspected (85.3%) and 46 patients with negative smear suspected (14.7%). The treatment outcome variable is the best predictor variable to explain the incidence of pulmonary tuberculosis, so the variable is used as an insulating variable. The treatment outcome variable is divided into two nodes (nodes 1 and 2), node 1 is the patient whose treatment results is cured. For node 2 is a patient with complete treatment.

At node 1, it is continued by patient type variables which are divided into two nodes (nodes 3 and 4) with a recurrence category (node 3) and a new category (node 4). Whereas on the second node, the partitioning process is stopped because all cases contained in the node have identical values for each predictor variable, so the second node becomes the last node.

Growing Method: EXHAUSTIVE CHAID
Dependent Variable: Tuberculosis

Table 3 is a classification performance evaluation can be determined by looking at the overall accuracy value generated in the Exhaustive CHAID analysis of 87.2%. The accuracy between observations and predictions for the incidence of pulmonary tuberculosis with a positive smear suspect category was 85.4% with mis-classification errors of 14.6%. While the accuracy between observations and predictions for the incidence of pulmonary tuberculosis with a negative smear suspected category was 97.8% with mis-classification of 2.2%.

Discussion

In this study respondents aged <= 25 years were 72 (23%), while those aged> 25 years were 241 (77%). This shows that in terms of age, respondents in the work area of the Teak Health Center were mostly of productive age. This is consistent with previous WHO reports two-thirds of TB cases occur in the economically productive age group, which is 15 - 59 years. (7)

In this study, respondents who were male were 173 (55.3%), while those who were female were 140 (44.7%). This shows that the average gender of pulmonary TB respondents in the Jati Health Center area is male. Similar to the results of research from Susilayanti et al in BP4 Lubuk Alung, respondents were male as many as 784 (70.8%), while those who were female were 324 (29.2%). (8)

Other studies have shown that men are more susceptible to M. tuberculosis infection. This can be related to greater smoking habits in men, which causes interference with the respiratory system immunity so that it becomes more susceptible to infection. Disturbances in the respiratory tract immunity can be in the form of mucociliary damage due to toxic cigarette smoke and decrease the response to antigens, thereby increasing the susceptibility to pulmonary tuberculosis. (9)

The number of pulmonary TB patients with suspected smear positive when viewed from the type of sufferer mostly in the form of 216 new cases. This is probably due to the number of patients who come to the Puskesmas Jati who have never come for treatment and have never received pulmonary TB treatment. The results of this study are consistent with Karolina’s research at the Kabanjahe Health Center in Karo District that the largest proportion of pulmonary TB sufferers in new cases is 97.5%. (10)

In addition to new cases, the number of pulmonary TB sufferers with suspected smear positive also there were 92.9% recurrence patients. Results This study is in accordance with research Sukmaningtyas, et al (11) that patients who complete treatment with less / more than 6 months (not on time) have a 5% risk of recurrence to
patients who complete treatment exactly 6 months. In a systematic review study, the largest recurrence rate occurred in India, which was 10%, which is the highest among other Countries.\textsuperscript{(12)}

Associated with the type of patient who came for treatment at the Jati Health Center, all patients seeking treatment received a cure category of 99.6% which is a new patient treatment category. The choice of treatment category adjusts to the type of patient and the result of smear examination. Research by Laily et al\textsuperscript{(13)} at the Tuminting Health Center in Manado showed that 194 patients had been treated regularly (99%) and the remaining 2 patients (1%) had irregular treatment. This shows that the awareness of the Tuminting community for treatment and recovery is good. Regularity of treatment is closely related to the results of treatment to be achieved by patients.

**Conclusion**

1. Patients with pulmonary TB who are suspected of having BTA positive who seek treatment at Jati Health Center are mostly of productive age.

2. Patients with pulmonary TB with suspected BTA positive who seek treatment at Jati Health Center are mostly male.

3. Factors that influence the incidence of pulmonary TB in the Jati Health Center area are the type of patient and treatment outcome.

4. In general, the type of pulmonary TB sufferers with the most positive smear suspects found in Jati Health Center are new cases and relapse sufferers.

**Suggestion**

It is necessary to educate the public about the pulmonary TB disease, so that they know the cause of pulmonary TB disease. In addition, the community must also prevent pulmonary tuberculosis by maintaining a healthy environment and promptly taking treatment if there are symptoms of pulmonary TB disease, so it is not transmitted to others.

Study the Role of pH in Curli Biogenesis Gene Expression in Enterobacter Cloacae Local Isolates

Marrib N. Rasheed1, Basima Qasim Hasan Al-Saadi1, Osama Mohammed Hasan2, Noor Yahy Salman1, Sara Faisal1

1Doctor at Institute of Genetic Engineering and Biotechnology for Postgraduate Studies, University of Baghdad, Baghdad, Iraq, 2Doctor at Basic Medical Science Department, Collage of Dentistry, Mustansiriyah University, Baghdad, Iraq

Abstract

Enterobacter cloaeca is the most common pathogenic species of the genus Enterobacter, identified in hospitalized and enfeebled patients as the etiologic agent of many infections and considered as a significant bacterial pathogen in recent years. E. Cloaeca are typical gram negative opportunistic forms of bacteria that cause illness after another infection or injury has influenced the host immune system and are related with nosocomial infections. The infection may be caused by GIT, UTI or cross contamination of the blood. The present study focused on the existence of the main curli biogenesis gene (csgA) and the role of pH as an environmental factor in the gene expression (csgA) for curli biogenesis. In this study, urine samples from 75 patients in Baghdad city clinically diagnosed with urinary tract infection, for gram staining, Api20System and gene expression (csgA) gene in Standardized pH7 and acid pH4 RT-PCR was performed with specific primers. Conventional gram staining techniques, agricultural methods and System API 20E showed good results for E. Cloaeca. For the 75 patients, 10 (13.3%) the findings find the highest gene expression fold values for the (csgA) gene in pH7 while the lowest fold value for (csgA) at acid pH4 (0.1577) thus the modify conditions growth such as pH of bacteria E. Cloaeca triggers gene expression changes for biogenesis process. the findings of rpoB gene expression, which was used as a control gene, indicated that this gene was good as a housekeeping gene.

Introduction

E. Cloaeca is also a common nosocomial pathogen responsible for bacteraemia and lower respiratory, urinary and intra-abdominal infections, as well as endocarditis, septic arthritis, osteomyelitis and skin and soft tissue infections. And endocarditis, septic arthritis, osteomyelitis and diseases of the skin and soft tissue infection. The skin and gastrointestinal tract are the most frequent places where E. Cloaeca can be infected [1]. E. Cloaeca are often isolated from nosocomial infections, including pneumonia, urinary tract and bloodstream infections [2]. Curli is a new class of bacterial surface structures which is expressed in E. Cloaeca, Escherichia coli and Salmonella spp. and is specified by its ability to bind to serum protein fibronectin [3]. Curli Fimbriae is a new class of surface compositions on the surface of E. Cloaeca, E.coli and Salmonella, which are characterized by their ability to bind with protein serum fibronectin [4]. Associated with the adhesion and assembly of bacterial cells on surfaces. As well as being an essential part of the extracellular matrix, that contributes to the formation of the biofilm. The curly cilia is a distinctive element of virulence, because it interacts with a wide range of host proteins, including cell-based intercellular proteins and link-phase proteins, thus helping bacteria

spread to the host. Curly cilia owned toll like receptors, which activates the innate immune system, therefore this considered as a molecular type associated with the pathogen (PAMPs) [5].

**Material and Methods**

**Samples:**

A total of 10 isolates from 75 urinary cultures were collected in this study in patients with UTI admitted to governmental AL-Kathumia pediatric hospitals in Baghdad, these isolates were obtained from April to September 2017. We obtained the sample and stored it. Identification of Bacteria as Enterobacter Traditional biochemical methods (API20 E, Biomerieux, France) were used to conduct cloacae. Bacterial isolates have been maintained for further analysis by inoculation of single pure isolated colony to brain heart infusion agar (BHIA) slant incubated at 37 °C during the night, stored at 4 °C for a few weeks [6,7].

The optimal pH which affected on (csgA) gene expression:

Approximately 0.1 mL of each strain’s nutrient broth culture was applied to 10 mL of BHI broth and incubated at specific pH 4 and 7 with temperature tolerance and 24-hour incubation at 37 °C, Extraction of RNA was done using General RNA Extract-ion Kit (Disbio, China).

Complete RNA extraction with TRIzol:

Complete RNA was collected from all samples using the General RNA Extraction Kit (Disbio, China) using the manufacturer’s pro-protocol. Synthesis of cDNA from mRNA: By Using Wiz ScriptTM RT FDMix Kit, the complete RNA was reversely transcribed to complementary DNA (cDNA). The treatment was conducted in a 20μl reaction volume, as advised by the manufacturer. 20μl was the complete amount of RNA to be reversely transcribed. Thermal cycler steps of cDNA Reverse Transcriptase conditions are shown in Table 1.

Real time qRT PCR study the expression of rpoB and csgA genes ∆∆CT

The 2^−DDCt method has been used to compare the transcript levels between various samples [8–10]. The interest gene CT has been normalized to that of the internal control gene. The variance between the rpoB (internal control gene) and the csgA (interest gene) cycle threshold (Ct) values was Analysed by using the qPCR software, QIAGEN Real-time PCR system ((Rotor Gene Q, Germany). The rates of gene expression and the alteration of the fold were quantified by the threshold cycle (Ct) and the ∆∆Ct was used to assess the fold of gene expression.

Gene expression of csgA in Different environmental factors

Volume equal to 0.1 mL of a nutrient-broth culture overnight of each strain was added to 10 mL of BHI broth, a shaking incubated at different pH. The extraction of RNA complete by RNA extraction kit was carried out in the same steps, then cDNA synthesis for mRNA was completed. RT master Mixed and programs used under standardized conditions.

Results and Discussion

Enterobacter species, especially Enterobacter cloaceae, are important nosocomial pathogens that are responsible for approximately 13.20 percent of UTI Iraqi patients according to previous study [11]. Several surface structures of bacteria, including curli, flagella, pili and exopolysaccharide; Play roles in different aspects of development of biofilms [12]. Biofilms can be a problem in the food industry and in hospital environments Curli allow the adherence of Salmonella enteriditis to Teflon and stainless steel, which can contribute to the creation of biofilms and contamination of surfaces frequently used in the food industry [13], the strain’s ability to form biofilm relied on csgA. These researchers indicated curli were essential during the attachment process in the initial stages of biofilm growth [14]. RpoB rRNA expression has been shown to be strongly dependent on the physiological state of the bacterial cell in bacteria, one of the most widely used housekeeping genes in accordance with gene expression results., The essential principle for the use of housekeeping genes in molecular experiments is that their expression in the cells or tissues under investigation remains constant [15]. Variation of total change in RpoB rRNA expression was analyzed. In various researchers using the 2-Ct value and the 2-Ct ratio, the expression fold for the rpoB gene was 1, 0.933 under variable PH conditions, respectively pH7 and pH 4. Little variability in the gene expression fold makes the gene RpoB a reliable reference gene as shown in (Table 4).

RT-qPCR expression for csgA gene
The expression csgA is highly regulated. \textit{E. Cloacae} isolates were efficiency. Biofilm- forming, significantly correlated with the csgA and csgD gene mRNA expression rates. The curli protein fimbriae emerged as tangled fibers and the curli-proficient strain formed mature biofilms \cite{16}. Various environmental factors, including incubation period, incubation temperature and pH-effect on virulence expression \cite{15}. By using Relative quantitative RT- PCR assay, we analyzed the mRNA expression of csgA genes by comparing bacterial growth with different pH factors as a variable factor for each sample, we studied the role of pH on csgA biofilm gene expression. The Ct values of gene amplification were reported from the quantitative RT PCR software. Relative quantification used to measure the gene expression fold change \cite{8}. This depends on the standardization of Ct values determining the rpoB gene, which is the difference between the mean Ct values of each case’s csgA cDNA amplification replica and the rpoB gene.

</tr>
</tbody>
</table>

The results in table (5) showed gene expression folding for the csgA gene by comparing bacterial growth with different pH factors for each sample as variable factor. The gene expression fold in pH4 was in (0.1577) times lower than normal. These findings suggest a substantial decrease in the expression of the csgA gene at pH 4 relative to control (Tm37, pH7). This suggests that acidity is an important factor in bacterial pathogenicity as pH has been identified as a regulator for the expression of virulent genes and is likely to be express curli and Suggest that this virulent factor could play a major role in the pathogenesis and invasiveness of \textit{E. Cloacae} \cite{16}, suggests that curli fimbriae expression in \textit{E. Cloacae} plays an significant role in the development of biofilms Which is the first stage of bacterial pathogenicity.

Neonatal Death Incidence in Healthcare Facility in Indonesia: Does Antenatal Care Matter?

Masruroh1,2, Ah Yusuf3, Nikmatur Rohmah4, Irfansyah Baharudin Pakki5, Anita Dewi Prahastuti Prasojo6, Qurnia Andayani1, *Agung Dwi Laksono7

Abstract

Despite having carried out maternity care in healthcare facilities, neonatal deaths still occur. A study was conducted to analyze the effect of antenatal care (ANC) on neonatal death incidence in healthcare facilities in Indonesia. The study used the 2017 IDHS data. With stratification and multistage random sampling, 13,104 women aged 15-49 years with live births in the last 5 years, who performed maternity care in the healthcare facility, were sampled. Apart from ANC, other independent variables analyzed were a type of place, age, education, wealth, employment, parity, and complication during pregnancy. The final stage employed a binary logistic regression test. The analysis found that women who made complete ANC visits during pregnancy (≥4 times) were 0.486 times more likely than women who did not complete ANC visits (<4 times) (OR 0.486; 95% CI 0.266-0.887). The results of this analysis inform that carrying out a complete ANC visit is a protective factor for women who perform maternity care in healthcare facilities in Indonesia from neonatal death incidence. Apart from ANC, 2 variables were also found to have a significant effect on neonatal death incidence in healthcare facilities in Indonesia. These two variables are the age group and complications during pregnancy. Meanwhile, education level, wealth status, employment status, and parity proved insignificant. It was concluded that ANC is a determinant of neonatal death incidence in the healthcare facility in Indonesia. Complete ANC visits are a protective factor for women who perform maternity care in healthcare facilities in Indonesia from neonatal death incidence.

Keywords: neonatal death, antenatal care, healthcare, pregnancy care.

Background

Neonatal is the most vulnerable period for a child’s survival. The neonatal period, which is defined by WHO as beginning at birth and ending at the full 28 days of life. Child health services start from the time of pregnancy to childhood, which involves the mother as an inseparable part of the child. The infant mortality rate is an indicator of the quality of child health services in a country. Infant mortality is a deadly incident that occurs in the period from the time the baby is born until the baby is not exactly one year old. In 2016, 2.6 million deaths, or about 46% of all under-five deaths, occurred during the neonatal period. More than 40% of all deaths in children under 5 years of age occurred during the neonatal period1–3.

Indonesia has a high rate of neonatal mortality, the 2017 Indonesia Demographic and Health Survey (IDHS) shows that 15/1000 live births. The figure accounts for almost half of the under-five mortality rate in Indonesia4. WHO reports that there are approximately 7,000 newborn deaths per day with three-quarters of neonatal deaths occurring in the first week, and one-third dying within the first 24 hours of birth5. The current trend is that more than 60 countries will miss the SDG target of
reducing neonatal mortality to at least 12/1000 live births by 2030. About half of them will not meet the target by 2050. Identifying the causes of neonatal mortality is essential for intervening. prevention to decrease infant mortality.

Neonatal mortality can be caused by various factors, including maternal factors, socio-culture, services, and health facilities. The Ethiopian study put the proportion of neonatal deaths in health facilities at 20%. The causes of neonatal mortality included preterm birth 28.58%, birth asphyxia 22.45%, neonatal infection 18.36%, meconium aspiration syndrome 9.18%, respiratory distress syndrome 7.14%, congenital malformations 4.08%.

Previous studies reported that neonatal mortality in health facilities was 13.3% or about 30 deaths per 1000 live births. The causes of death were 60.4% low birth weight (LBW), and 55.8% preterm birth. Similar information was also reported in Ethiopia, which reports the causes of neonatal death are preterm birth, birth asphyxia, and infection. Meanwhile, in Iran, it was reported that the highest causes of neonatal death were preterm birth, LBW, and anomalies.

The causes of neonatal mortality in Southeast Asia, in order from the largest, are premature, asphyxia, congenital abnormalities, and sepsis. In previous studies in Indonesia, several factors were associated with an increased risk of neonatal mortality, namely neonatal complications at birth, lack of maternal knowledge about danger signs for neonates, history of complications during pregnancy, delivery carried out at home. Information on several cases of neonatal death shows several reasons that can be prevented by monitoring during pregnancy by doing ANC. Based on the background description, this study was aimed at analyzing the influence of ANC on neonatal death incidence in a healthcare facility in Indonesia.

Materials and Methods

The study employed secondary data from the 2017 IDHS as analysis material. The 2017 IDHS sample was determined through stratification and multistage random sampling. The analysis unit was women in childbearing aged, 15-49 years old, who had given birth in the last 5 years in a healthcare facility. Several 13,104 women were sampled. The 2017 IDHS has received ethical approval from the National Ethics Committee. All respondent identities have been deleted from the dataset. Respondents have signed and agreed to their involvement in the 2017 IDHS. Utilization of 2017 IDHS data for this research has received permission from ICF through the website: https://dhsprogram.com/data/new-user-registration.cfm.

Neonatal death is death in the neonatal period or the first twenty-eight days of life. ANC was the respondent’s acknowledgment of the amount of ANC utilization during pregnancy. The ANC utilization was divided into 2 criteria, namely <4 and ≥4. Apart from ANC, other independent variables involved in the analysis were the type of place of residence, age group, education level, wealth status, employment status, parity, and complication during pregnancy.

Parity is the number of living children a woman is born with. In this study, parity was divided into two, namely primiparous (<2 children) and multiparous (≥2 children). Complications during pregnancy were the respondent’s acknowledgment of complications experienced during pregnancy until delivery. These problems consist of: prolonged labor, vaginal bleeding, fever, convulsions, baby in the wrong position, swollen limbs, faint, breathlessness, tiredness, and others.

This study conducted 2 stages of analysis. The first stage, performed bivariate with chi-square to analyze the relationship between ANC and other variables involved in the analysis. The second stage, multivariate with binary logistic regression to determine the effect and see the odd ratio of the independent variable to the dependent variable. All stages of analysis employed IBM Statistic SPSS 21.

Findings

Table 1 displays descriptive statistics of neonatal death incidence in a healthcare facility by ANC in Indonesia. It appears that the two categories of ANC are dominated by women who do not experience neonatal death. Based on the type of place of residence, both ANC categories are dominated by women who live in urban areas. Meanwhile, based on the age group, the two ANC categories were dominated by women in the 30-34 age group.
Based on the education level, both ANC categories are dominated by women who have secondary education. Based on wealth status, women who made incomplete ANC visits (<4 times) were dominated by the poorest women. Otherwise, women who have complete ANC visits (≥4 times) are dominated by the richest women. Meanwhile, based on employment status, both ANC categories were dominated by unemployed women. Based on parity, the two ANC categories are dominated by multiparous women. Finally, based on complications during pregnancy, both ANC categories are dominated by women who do not experience a complication during pregnancy.

Table 2 shows the results of the binary logistic regression of neonatal death incidence in a healthcare facility in Indonesia. It appears that women who made complete ANC visits during pregnancy (≥4 times) were 0.486 times more likely than women who did not complete ANC visits (<4 times)(OR 0.486; 95% CI 0.266-0.887). The results of this analysis inform that carrying out a complete ANC visit is a protective factor for women who perform maternity care in healthcare facilities in Indonesia from neonatal death incidence.

Complete ANC visits (≥4 times) according to government recommendations, at least 4 visits during pregnancy, helping pregnant women to monitor and control risks during pregnancy. ANC provides routine monitoring of height and weight gain, identification of maternal or fetal medical problems, counseling on tobacco or substance use, providing psychosocial support, nutritional advice, and early intervention that can reduce adverse pregnancy output, including the occurrence of neonatal death. This finding is in line with previous findings conducted in urban areas in Indonesia.

Apart from ANC, 2 variables were also found to have a significant effect on neonatal death incidence in healthcare facilities in Indonesia. These two variables are the age group and complications during pregnancy. Meanwhile, education level, wealth status, employment status, and parity proved insignificant.

Note: ‘p<0.05; “p<0.01; ““p<0.001.

Based on complications during pregnancy, women who experience complications during pregnancy are 2.269 times more likely than women who do not experience complications during pregnancy to experience neonatal death incidence (OR 2.269; 95% CI 1.500-3.434). This information shows that experiencing complications during pregnancy is a risk factor for neonatal death incidence in healthcare facilities in Indonesia. This finding information reinforces the results of previous studies that found similar results\(^2\text{1-}\text{23}\). It is necessary to strengthen the early identification of obstetric complications and urgent intervention to prevent neonatal mortality\(^2\text{4}\). The results of this analysis again to confirm the importance of quality ANC during pregnancy\(^1\text{7}\).

**Conclusions**

Based on the research results, it could be concluded that ANC is a determinant of neonatal death incidence in healthcare facilities in Indonesia. Apart from ANC, 2 other variables were also proven to be determinant determinants of neonatal death incidence in the healthcare facility, namely age group and complication during pregnancy.

Abstract

Sexual desire could be affected by many psychological and physiological aspects. This research aims to find out the relationship between sexual desire and premenstrual syndrome in young female. A Descriptive design cross-sectional study was carried throughout the present study in order to achieve the study objectives. The period of the study is from 20th September 2019 to 28th April 2020, included 200 young married women in the reproductive stage, with ages between (17-31) years. Sexual Desire Inventory 3 (SDI-3) has been used to assess sexual desire after modification to meet the cultural and social considerations. The current study revealed that it explains that the highest percentage of the women subgroup are: women with ages between (21-24) years old (50%), those who the age of their husbands (23-26) years old (46.5%), those who live urban residents (84%), those who they and their husbands work as employee (58.5%), those with barely sufficient monthly income (38.5%), those who are graduated from college or above. The results showed that there is a significant association (p <0.05) between sexual desire of women and each of: backache, dysmenorrhea and mood instability; while there is no significant relationship with each of: (backache, breast tenderness, headache, irritability, sadness, aloneness, bloating, vaginal pain, vaginal dryness). It is concluded that sexual desire may affected by some symptoms of the premenstrual syndrome. Further studies may be needed to confirms these results.

Keywords— premenstrual syndrome, sexual desire, young women

Introduction

Sexual Desire is the operative force in nearly all sexual expression. Desire is closely related to the concept of lust, and at its most powerful it approaches the concept of passion. There are people whose previous experiences may make it difficult to recognize or acknowledge desire (¹). Sexual desire is a conscious longing for sexual activity with the object of desire, resulting in sexual satisfaction. Sexual desire can result in rapid or gradual psychic arousal, the resulting physiological changes (rapid breathing and pulse, lubrication, erection), a need to approach the object of desire, physical contact that brings satisfaction, and the possible release (²). Sexual and reproductive health and well-being are essential if people are to have responsible, safe, and satisfying sexual lives. Sexual health requires a positive approach to human sexuality and an understanding of the complex factors that shape human sexual behavior. These factors affect whether the expression of sexuality leads to sexual health and well-being or to sexual behaviors that put people at risk or make them vulnerable to sexual and reproductive ill-health (³). Reproductive health is a state of complete physical, mental, and social well-being and not merely the absence of disease and infirmity, in all matters relating to the reproductive system and to its

functions and processes. Reproductive health therefore implies that people are able to have a satisfying and safe sex life and that they have the capability to reproduce and the freedom to decide if, when and how often to do so. The presence or absence of premenstrual syndrome (PMS) complaints have also been used as indirect indicators of hormonal profiles that may affect sexual behavior (4). The current study aimed to investigate the relationship between sexual desire and premenstrual syndrome

Methods

A Descriptive Design Cross-sectional study was carried throughout the present study in order to achieve the study objectives. The period of the study is from 20th September 2019 to 28th April 2020.

A Non-Probability (Purposive Sample) of 200 young married women in the reproductive stage, those who lives in Al-Najaf Al-Ashraf City, Southern of Iraq. The final study instrument consists of three parts:

Part 1: Demographic Data

A demographic data sheet, which consist of (8) items, include: Age of wife, Body mass index, Residential environment, Educational status of wife, Occupational status of wife, Age of husband, Occupational status of husband, Monthly income.

Part 2: Reproductive Health Data

The second part of the questionnaire is consists of (10) items, include: Age at marriage, Marriage duration, Number of children of participants, Status of breastfeeding, Menstrual cycle characteristic, Ovulation, Pregnancies, Mode of delivery, Birth control use, Gynecological History.

Part 3: Sexual Desire Inventory3 (SDI-3).

The researcher has developed Sexual Desire Inventory 3 (SDI-3) version from the original version that was initially suggested by Specter et al. (1996) to meet the cultural and social considerations.

Statistical Analysis

Descriptive statistics presented as mean, standard deviation, frequencies and percentages. Chi-square test was used to compare frequencies. Pearson’s correlation test was used to assess the correlations. Level of significance of ≤ 0.05 was considered as significant difference or correlation.

Results

Table (1) shows statistical distribution of study sample (women) by their socio-demographic data, it explains that the highest percentage of the women subgroup are: women with ages between (21-24) years old (50%), those who the age of their husbands (23-26) years old (46.5%), those who live urban residents (84%), those who they and their husbands work as employee (58.5%), those with barely sufficient monthly income (38.5%), those who are graduated from college or above.

According to table (2) and figure (4.3), The classification of women according to their total scores of sexual desire scale is as follows: (low 7%); (moderate 72%) and (strong 21%).

Table (3) shows relationship between sexual desire of women and their premenstrual symptoms, it shows that there is a significant association (p < 0.05) between sexual desire of women and each of: backache, dysmenorrhea and mood instability; while there is no significant relationship with each of: (backache, breast tenderness, headache, irritability, sadness, aloneness, bloating, vaginal pain, vaginal dryness).

Discussion

According to table (1), women with ages between (21-24) years constitute the majority of the sample; with a range between (17-31) years; it means that the present study aims to investigate the young women which represent the typical women at the reproductive age; this age range is usually classified as the (peak reproductive age) according to STRAW +10 (Stages of Reproductive Aging Workshop +10) which is a new staging system for categorizing women reproductive ages (6). The age category of the current study may explain other result that the high percentage of women are graduated from college or above (32.5%), and that the majority of them and their husbands work as employee (58.5%); and they
have somewhat sufficient monthly income (38.5%).

Researchers had experienced difficulties in the measurement of sexual desire; some studies have assessed sexual desire by investigating self-reported behavior such as number of intercourses for a specific time (7). The real attempt to quantitatively measure sexual desire is Kinsey and his colleagues, they described sexual desire as a psychosomatic tension that needs to be released, their measurement relied on the how many times sexual activities with orgasm have been achieved (8). Among the widely used measurement to evaluate female sexual dysfunction, is the Female Sexual Function Index (FSFI), in which six sexual domains related to sexual desire are included (9). Some measurements used one-item Likert scale for assessing sexual desire by asking one cognitive questions (like: have you noticed any changes in sexual desire?), the measure assumed that sexual desire is unidimensional (8). The currently used third version of the Sexual Desire Inventory in this study is designed to assess dyadic sexual desire (i.e. having sexual activity with a partner), so that solitary sexual activity (i.e. masturbation) is excluded; another scale that investigate is dyadic sexual desire only is the Hulbert index of Sexual Desire (HISD) with a score ranges between 0-100 (10).

According to table (2), the results of the present study revealed that (72%) have moderate sexual desire, (21%) have strong sexual desire; this may be due to the age of the studied sample in which the majority of their ages between (21-24) years (table 4.1), this results agrees with those obtained by Zegeye et al. (11) who studied a sample of women with ages between (15-25) years, and found that (43.9%) of them have moderate sexual satisfaction, while (43.6%) had extreme sexual satisfaction.

Table (3) shows that cervical discharge may be associated with moderate to high sexual desire; this result comes in agreement with the previous studies that indicated a significant effect of fatigue and weakness on sexual desire in women during the menopausal transition (16); it is clear that sexual activities require good psychological and physical conditions; so that fatigue, weakness and any body disorders may negatively affect the sexual desire.

**Conclusions**

It is concluded that sexual desire may affected by some symptoms of the premenstrual syndrome. Further studies may be needed to confirms these results.

Efficiency of Determination of Elemental Composition of Metals and their Topography in Objects of Biological Origin Using Spectrometers

Mikhailenko O.V.1, Roshchin H.H.2, Dyadik O.O.2, Irkin I.V.2, Malisheva T.A.3, Kostenko Ye.Ya.4, Gunas V.I.5, Hel A.P.5

Romodanov of the “NAMS of Ukraine, 4Uzhhorod National University of the Ministry of Education and Science of Ukraine; 5Department of Pathological Anatomy, Forensic Medicine and Law, National Pirogov Memorial Medical University, Vinnytsya

Abstract

Bodily injuries, caused by firearms and special non-lethal means, which are provided for law enforcement agencies and special services and they are available to the civilian population as well (pistols for firing ammunition equipped with elastic bullets, stun guns, etc.,) and the consequences of torture using various methods and the traumatic factors that caused by them have to get expert objective assessment. Among other laboratory studies, it is important to determine the characteristics of the composition of chemical elements in objects of biological and non-biological origin by performing X-ray fluorescence spectral analysis using modern spectrometers. The object: to determine the characteristics of the elemental composition of metals and their topography in injuries caused by gunshots and stun gun by conducting X-ray fluorescence spectral analysis using spectrometers “ElvaX CEP-01” and “M4 TORNADO”. Conclusions: the use of spectrometers increases the accuracy and objectivity of expert examinations of injuries caused by firearms and electric shock device as they have a wide range of chemical elements detection in the composition of the products of the shot and the electro tag from sodium to uranium. Using X-ray fluorescence spectral analysis, it is possible not only to detect metals in the layers of soot on injuries, but also to conduct a targeted “microscopic” study of their topography for partial group identification of firearms and the installation of electrode metal, which acted as a contact body conductor. X-ray fluorescence spectral analysis is a non-destructive research method.

Key words: gunshot wound, electric trauma, X-ray fluorescence spectral analysis.

Introduction

Terrorism, local wars and internal conflicts, in which law enforcement officers act as one of the parties, are becoming more and more serious problems for all countries of the world. 4, 11, 16 This leads to a wide range of damages caused by the action of weapons on the standard equipment of certain law enforcement agencies, including an action of so-called “non-lethal weapons”, such as means of shock and trauma, equipped with elastic bullets, electric shock devices and more. Situations of excessive use of force and torture, in which firearms and electrical devices can act as a traumatic factor have a special significance in these conditions. 2, 15 Therefore, due to consistently significant number of injuries caused by firearms, special non-lethal means, which are provided for law enforcement agencies and special services and they are used in torture and they are available for locals, it is important to make assessment of the damage of objects of biological origin objectively with the use of highly efficient laboratory equipment, in particular, modern spectrometers.

Many countries around the world use highly sensitive spectrometers based on the use of physicochemical methods of analysis to determine the factors that accompany a shot from a firearm or the consequences of an electric shock device: atomic absorption
spectrophotometry (AAS), mass spectrometry with bound plasma (ICP-MS), atomic emission spectrometry (AES) or neutron activation analysis (NAA). In many cases, the instruments are equipped with scanning electron microscopy in combination with X-ray fluorescence microanalysis (SEM-EDX).

As practice shows, among many factors that characterize the features of gunshot wounds, detection of metals from bullets, shell casings, barrels of firearms formed during firing, and components of powder charge combustion, which are defined as “factors accompanying the shot” or “shot products” are provided sufficiently complete information.3, 12, 14, 17

It is essential to use the methods of elemental analysis and evaluation of the electrotag, which can act as an additional method of research that confirms the mechanism of damage, and even to some extent it indicates the electrode material that caused the damage.7, 8, 13, 18

Detection of chemical elements of metals in the composition of the shot products, electric tags and their identification is performed in the forensic laboratory by a set of methods and techniques known since the twentieth century. These are X-ray fluorescence analysis 4, 10, spark mass spectrometry, atomic absorption analysis, neutron activation analysis, flame emission photometry, emission spectrographic method, infrared spectrometry, etc.1, 4, 5, 19, 21, 22. The methods are highly sensitive and can detect almost the full range of chemical elements. One of their significant disadvantages is the preparation of the sample, which is accompanied by the inevitable destruction and loss of the object of study.

It should be noted that X-ray spectral analysis is a fairly effective and non-destructive method of studying metals from the fragments of explosive devices, bullets, shell casings, barrels of firearms in the composition of the products of the shot and electric tags.9 Its essence is the X-ray irradiation of the object of study and the detection of the spectral composition of secondary radiation, which reflects the quantitative and qualitative indicators of the chemical elements of the object that is under a study.

However, conducting X-ray fluorescence spectral analysis using modern spectrometers is insufficient way to get information about the qualitative and quantitative composition of metal elements and their topography in objects of biological origin, formed as a result of gunshots and electric shock devices.

The object of this paper: to determine the characteristics of the elemental composition of metals and their topography in injuries caused by gunshots and electric shock devices by conducting X-ray fluorescence spectral analysis using spectrometers “ElvaX CEP-01” and “M4 TORNADO”.

**Materials and Methods**

The archival material of the Department of Forensic Medicine of the Kyiv City Clinical Bureau of Forensic Medical Examination was used in the work number 15 “Expert Conclusions” on bodily injuries from shots fired from short-barreled weapons (pistols) and 12 “Expert Conclusions” regarding electric shock devices in cases of domestic and industrial electric injuries with a known contact electrode.

The material of the study in cases of gunshot wounds were 25 pieces of skin and 5 fragments of skull bones removed from the areas of gunshot wounds in people who have died being shot with 9 mm bullets from pistols. The distance of the shot ranged from 30-50 cm.

The study of chemical elements, formed in objects of biological origin due to the gunshot wounds, was performed by X-ray fluorescence spectral elemental analysis on a spectrometer “M4 TORNADO” company Bruker (Germany) using a package of standard analytical techniques.

Pieces of skin and fragments of skull bones with perforated fractures, which were removed from the areas of gunshot wounds in people who being killed by 9mm bullets from pistols, were placed in the working chamber of the spectrometer, where a vacuum pump created a pressure of 20 mbar. Using autofocus, the samples were translated into the focal plane. In the video images of skin flaps and fragments of skull bones with wounds, the scan plane was set, and the horizontal scan lines consisted of 600 points. As a result, the spectra of P, S, K, Ca, Fe, Cu, Zn and Pb. were obtained from the scanning plane of the wound area. Subsequently, the detected elements were mapped in the areas of wounds and perforated
fractures on fragments of skull bones. Photo illustrations were made using a personal computer with a Pentium-4 processor, followed by production of prints.

The materials of the study in cases of electric shock devices were 12 flaps of skin with electrogamps, selected from fatal cases of electric shock devices with known contact electrodes through which the transmission of electrical energy to the human body starts to occur. All 12 cases were selected, among others, taking into account the “material of the contact electrodes”, due to which there was an electric shock (a typical metal wire with a predominance of copper in the chemical composition). The study of chemical elements, formed in objects of biological origin due to damage by electric shock device, was performed by X-ray fluorescence spectral elemental analysis on a spectrometer “ElvaX CEP-01” (country of manufacture is Ukraine). Before the study, flaps of skin with electrogamps were exposed to low temperature in the freezer (-20°C) in order to preserve. After thawing at room temperature and calibration of the spectrometer, skin flaps were placed in the working chamber of the spectrometer. As a result, the spectra of Fe, Cu, and Ni were obtained from the damage sites. The analysis of the obtained data was performed using the integrated RStudio system. Analysis of variance was used to determine differences in the concentration of elements. The boundaries of the differences were determined using the Tukey’s criterion. The distribution of residues was checked for normality using the Shapiro-Wilk test. The standard methods of variation statistics were used in the work.

Results and Discussion

In the study of skin flaps and fragments of skull bones removed from the areas of gunshot wounds in people who were killed by shots fired from 9 mm pistols at close range, the obtained maps of the distribution of elements showed an increased content of iron, copper, zinc and lead, which topographically in maximum concentrations were located at the edges of the wound of the skin (Fig. 1) and the entrance of the skull (Fig. 2) and around them in the form of irregularly shaped belt.

Fig. 1. Maps of distribution of iron (Fe), copper (Cu), zinc (Zn) and lead (Pb) on the edges of the wound on a piece of skin in the area of a gunshot wound due to a 9 mm bullet.
Fig. 2. Distribution maps of iron (Fe), copper (Cu), zinc (Zn) and lead (Pb) along the edges of the wound on a fragment of the skull bone in the area of the perforated fracture after a shot with a 9 mm bullet.

Subsequently, the detected elements in the wound area were mapped on skin flaps, for this purpose, a scan area was set on the object under study. On the received maps of elements distribution, the increased content of iron which in the maximum concentrations is located on edges of elements of damage on skin flaps was noted.

Thus, when applying X-ray fluorescence spectral analysis on the surface of the scan area on skin flaps in the areas of the entrance gunshot wound and on fragments of skull bones in the areas of perforated fracture was revealed elevated levels of iron, copper, zinc and lead, which were unevenly distributed at maximum concentrations on edges of wounds and perforated fractures in the form of irregularly shaped belt.

Detection and targeted “microscopic” study of the topography of chemical elements of iron (Fe), copper (Cu), zinc (Zn) and lead (Pb) in the layers of soot at the edges of the entrance gunshot wounds and in areas of perforated skull fractures caused by shots of 9 mm bullets, allowed not only to detect metals on injuries, but also to conduct a partial group identification of firearms, therefore, identify the weapon itself.

Among the twelve flaps of skin examined in the case of electric trauma, in six cases the electrotags had the appearance of an area of exfoliated dry epidermis of gray color. In two more cases, similar lesions with a slightly greenish tinge were identified. The crater-like form of damage was observed in three cases, and in one observation the damage had the appearance
of a superficial elongated abrasion. In the study of the elemental composition of metals on flaps of leather with electrodes caused by electric current through electrodes with a predominance of copper in their composition, using a spectrometer “ElvaX CEP-01”, the following distribution of trace elements in the area of damage in percentage (Table 1).

Distribution of the elemental composition of metals on 12 pieces of leather with electrical tags (%).

After statistical processing of the obtained data, a normal distribution of values with p.value 0.5417 was established, with a significant predominance in the elemental metal composition of the areas of electrical labels of copper content, the average value of which was 85.72417% with a standard measurement uncertainty of 0.474046.

Our own experience has shown that X-ray fluorescence spectrometers “M4 TORNADO” by Bruker (Germany) and “ElvaX CEP-01” (Ukraine) are successfully used recently in Ukraine. They are used to determine the qualitative and quantitative composition of metal elements and their topography in objects of biological origin, formed as a result of shots from firearms and the action of electric shock devices. This opened new opportunities for laboratory diagnosis of gunshot wounds, weapons and ammunition, as well as damages investigations caused by electric shock devices. The results obtained by us make one deepen and supplement the previously known scientific and practical research. 3, 9, 12, 14, 17
When using X-ray fluorescence spectral analysis in cases of electric shock device applying, opens up opportunities not only to confirm the effect of electric shocker on the body, but also determine the conformity of the metal composition in the area of damage to the metal composition of the electrode, which may be important in establishing circumstances and conditions of injury. Thus, in our study, the constancy and conformity of the metal elemental composition in the areas of electric shock damage to the contact electrode metal was confirmed.\textsuperscript{6, 20}

**Conclusions**

The use of spectrometers increases the accuracy and objectivity of expert examinations of injuries caused by firearms and electric shock devices, as they have a wide range of detection of chemical elements in the composition of the products of the shot and the electric tags from sodium to uranium. Using X-ray fluorescence spectral analysis, it is possible not only to detect metals in the layers of soot on injuries, but also to conduct a targeted “microscopic” study of their topography for partial group identification of firearms and the installation of metal electrode, which acted as a body conductor. X-ray fluorescence spectral analysis is a non-destructive research method, as it does not involve the preparation and study of a control sample.

Abstract

Objective: Analyzing the association between pure tone audiometry and distortion of otoacoustic emission (DPOAE) in students after shooting practice.

Methods: This study was conducted at the East Java State Police Academy, Mojokerto, Indonesia, from August 2018 to January 2019. Participants were examined for pure tone audiometry and DPOAE two weeks after shooting training. Participants previously had undergone shooting training for 5 months, with schedule of 4 times per week. The statistical test used an independent t test or Mann Whitney test with \( p < 0.05 \).

Results: All participants were men, with an average pure tone audiometry value of 27.50 ± 10.43 dB. The results of pure tone audiometry examination found that most participants had normal hearing (58.00%). This finding was inversely proportional to the results of DPOAE examination, in which most participants had “Refer” (78.00%). The mean pure tone audiometry value on participants with DPOAE “Refer” was 20.36 ± 3.47 dB and DPOAE “Pass” was 29.51 ± 10.87 dB (\( p = 0.008 \)). Most participants had “Refer” DPOAE with normal pure tone audiometry as much as 36.00%, followed by participants with “Refer” DPOAE but mild hearing loss of pure tone audiometry as much as 24.00% (\( p = 0.002 \)).

Conclusion: There is a significant association between pure tone audiometry with DPOAE. Many participants have normal audiometry but “Refer” DPOAE, and followed by participants experiencing mild hearing loss with “Refer” DPOAE.

Keywords: acoustic trauma, pure tone audiometry, DPOAE, police

Introduction

Patients with acoustic trauma often have abnormal distortion product otoacoustic emission (DPOAE) with normal audiometric examination (1). A routine pure tone audiometry examination for shooting athletes cannot predict the risk of hearing loss. Patients with average audiometry have experienced hearing loss. This often causes the athletes to have hearing loss and late treatment(2).

Acoustic trauma is a clinical condition of persistent or permanent hearing loss after exposure to impulses or loud sound waves (3, 4). Acoustic trauma causes organic ear damage due to very large sound energy. Cochlea injury occurs due to excessive physical stimulation in the form of very large vibrations that damage hair cells. In repetitive exposure, damage does not only occur due to physical processes, but also chemical processes in the form of metabolic stimuli that excessively stimulate hair cells that results cells dysfunction which leads to a temporary hearing loss. Damage to hair cells can also result in permanent hearing loss (5).
Hearing loss caused by acoustic trauma often results in permanent disability in army and police personnel \(^{(4)}\). Exposure to firearms eruptions, both large and small caliber, can cause acoustic trauma. Noise from gunfire eruptions, including pure impulsive noise with light gun eruption, has intensity ranging from 150 to 190 decibels (dB). Exposure to high-intensity sound can cause excessive vibration in tympanic membrane that leads to a risk of tympanic membrane perforation. The vibration is then continued to the middle ear through hearing bone that results in a risk of dislocation and damage to hearing bone. The vibration is then delivered to the perilymph and endolymph to vibrate the basilar membrane. This will cause stimulation of hair cells on tectorial membrane excessively that results in reversible hair cell damage. Repeated acoustic trauma can cause hair cells to atrophy and permanent damage \(^{(6)}\).

Based on the description above, this study aimed to determine the association of pure tone audiometry examination with DPOAE in students after shooting practice at the East Java State Police Academy.

**Methods**

Participants of this study were students of the East Java State Police Academy of 2017/2018. Participants should meet the inclusion and exclusion criteria of the study. Inclusion criteria included active participants in shooting training for 5 months and had intact tympanic membrane. Exclusion criteria included patients experiencing ear infections (otitis media), patients experiencing flu and tympanic membrane perforation. Participants have received an explanation regarding the objectives, benefits, rights, and obligations of the participant during the research process. Participants who were willing to take part in the research first filled in informed consent.

This research was conducted at the East Java State Police Academy, Mojokerto, Indonesia, from August 2018 to January 2019. This study employed a cross-sectional design with a total sampling method. The number of participants in this study were 50 participants. The researchers conducted an ethics test at the ethics committee Dr. Soetomo General Academic Hospital, Surabaya, Indonesia, prior to the study. Participants were examined for participant characteristics, pure tone audiometry, and DPOAE. The examination was carried out after the participants had joined shooting exercises for at least 5 months, and the exercises were carried out 4 times a week. Pure tone audiometry and DPOAE examinations were performed two weeks after shooting practice.

Pure tone audiometry is a subjective hearing examination to determine the degree of hearing loss with an audiometer (Interacoustics AD226 Clinical Audiometer; Assens, Denmark). The examination was carried out in a soundproof room at the East Java State Police Academy, Mojokerto, Indonesia. The room’s noise level was 40 to 45 dB. Pure tone audiometry check started at 1kHz 40 dB. If the participant did not respond, the frequency was raised by 5 dB until the hearing threshold was obtained, and the participant responds was reduced by 10 dB. The valued frequency of air conduction was at frequencies of 250Hz, 500Hz, 1kHz, 2kHz, 4kHz, and 8kHz. The evaluated bone conduction frequencies were 500Hz, 1kHz, 2kHz, and 4kHz. The results were grouped according to severity based on the International Standard Organization (ISO) and the American Standard Association (ASA), with the following categories: normal (<25 dB), mild degree (26-40 dB), moderate degree (41-60 dB), severe degree (61-80 dB), and profound (>81 dB).

DPOAE examination is a hearing examination that can detect damage to outer cochlear hair cells using the AuDX-I Bio-logic tool (Natus Medical Inc; CA, USA). DPOAE occurs when two pure tone stimuli with different frequencies are given simultaneously (f1 and f2). Previously set DPOAE filtering parameters include SPL 65/55 dB stimulus intensity levels for lower f1 frequencies (L1) and higher f2 frequencies (L2). The overall passing criteria are DPOAE for the difference in noise level of 6 dB for three of the four f2 test frequencies (f2 of 5, 4, 3, and 2 kHz) \(^{(7)}\). DPOAE is normal if “Pass”, and declared abnormal if “Refer”. Participants were asked to sit in a comfortable chair, and the probe was placed in the participant’s ear canal. Participants were encouraged to be calm and not move their heads during DPOAE recording \(^{(8)}\). This test took around 1 - 5 minutes in ideal conditions, with optimal test techniques \(^{(9)}\).

This research had been declared feasible to be carried out because it passed ethical approval from The Ethics Committee Dr. Soetomo General Academic
The results of the study were presented in the form of mean ± standard deviation (SD) or median (Quartile 1 - 3) and percentage (%). Statistical analysis used an independent t test or the Mann Whitney test (95% CI). Static analysis used IBM SPSS Statistics software version 23.0 (IBM Corp., Armonk, NY, USA). Statistical test results were significant if \( p < 0.05 \).

**Results**

**Characteristics of Participants**

The participants age ranged from 18 years to 21 years, and most students aged 20 years (42.00%). All students were male. There were participants who experienced a momentary hearing loss (10%). Most participants experienced momentary tinnitus as much as 96.00%. Most participants experienced acoustic trauma as much as 56.00% (Table 1).

**Audiogram Results**

The average audiogram examination results for each frequency were as follows: 250Hz at 26.60 ± 10.47 dB, 500Hz at 26.50 ± 8.64 dB, 1kHz at 25.00 ± 8.33 dB, 2kHz at 28.50 ± 11.44 dB, 4kHz at 31.10 ± 14.15 dB, 6kHz at 26.40 ± 14.88 dB, and 8kHz at 25.70 ± 14.92 dB. The average audiogram results were 27.50 ± 10.43 dB. Audiometry examination results showed that some participants experienced mild to moderate hearing problems. Most participants had an audiometric value within the normal limit (58.00%; Table 1).

**DPOAE Results**

The results of DPOAE examination were as follows: Pass and Refer, where most participant had Refer result (78.00%), while 22% of participants were in “Pass” category (Table 1).

**Association of Pure Tone Audiometry with DPOAE**

This study found a significant difference between the results of pure tone audiometry examination with DPOAE, with a mean participant value with DPOAE “Pass” and “Refer” at 20.36 ± 3.47 dB and 29.51 ± 10.87 dB, respectively (\( p = 0.008 \)). The results of pure tone audiometry results were higher in the “Refer” DPOAE group compared to “Pass” group (\( p < 0.05 \)). The examination results of each frequency could be seen in Table 2.

The pure tone audiometry examination results were categorized into three. Most participants had a normal result (58.00%). Most DPOAE examination results belonged to “Refer” category as much as 78.00%. Most students had “Refer” DPOAE but with normal pure tone audiometry (36.00%), and followed by participants with “Refer” DPOAE but with mild pure tone audiometry in pure tone audiometry results (24.00%; \( p = 0.002 \); Table 3).

Discussion

This study found a significant association between pure tone audiometry and DPOAE in students of East Java State Police Academy, Mojokerto, Indonesia. Police is a job with a risk of being exposed to excessive noise especially during shooting practice (10). At the moment, weapons shooting training is capable of producing noise around 132-165 dB with a frequency spectrum between 150 to 2500 Hz. Noise exposure can cause acoustic trauma. If the condition lasts for a long time, it can cause police to become a group that is at risk of hearing loss (11). Acoustic trauma will trigger damage to hair cells in cochlear organ. Hair cells are circular structures that will vibrate by acoustic signals of sound. Such mechanical vibrations are converted into electrical waves in the auditory nerve (1).

Acoustic trauma causes damage to basal hair cells due to high intensity noise exposure at high frequencies, whereas apex damage is caused by high intensity noise at low frequency. Differences in damage to basal and apex hair cells can be caused by tonotopic differences in the basal area to the cochlea apex, such as the condition of outer hair cell viability, vascularization, intrinsic susceptibility of basal hair cells to free radicals that make basal receptors more sensitive to damage. Antioxidant levels in basal are lower than in the apex, so that damage due to high frequencies is more easily occur in basal part (12).

Damage to outer hair cells makes DPOAE not appear even if given acoustic stimulation. Some cochlea can produce sounds spontaneously as internal sounds are processed and then amplified. Recording sound in cochlea requires a combination of earphones and microphones that can deliver vibrations of sound that enter cochlea and are returned to tympanic membrane that functions as a stethoscope. The installed probe must be impermeable so as to prevent outside sounds enter the ear (13). Damage to cochlear hairs was identified by the DPOAE examination, in which most of participant had “Refer”. This condition was supported by results of pure tone audiometry, showing a higher DPOAE “Refer” compared to DPOAE “Pass” at each frequency. This condition is in accordance with the existing theory, in which acoustic trauma is difficult to be identified only by using audiometry but also by using DPOAE as confirmation. A short-term examination audiometry examination cannot optimally describe the condition of participant’s hearing condition with acoustic trauma disorders. However, pure tone audiometry can give a picture of decreased hearing threshold after acoustic trauma. Thus, both methods have a significant association in examining patients with acoustic trauma.

Conclusions

This study found a significant association between pure tone audiometry and DPOAE. Most participants have normal audiometry but DPOAE “Pass”, and followed by mild hearing loss and DPOAE “Refer”.

Pharmaceutical Mini-Tablets Overview

Mohammad F. Bayan¹, Hala M. Sbaih¹ and Mohamed J. Saadh²
¹Faculty of Pharmacy, Philadelphia University, Amman, Jordan, ²Faculty of Pharmacy, Middle East University, Amman, Jordan

Abstract

Oral dosage forms are considered as the most preferred dosage forms to various age groups of patients. However, conventional solid dosage forms (tablets and capsules) have been associated with some issues; such fluctuation in the plasma drug concentration and swallowing difficulty for some patients. This advocates the need for the continuous development and improvement of tablets and capsule to enhance therapeutic efficacy and increase patient acceptance. Mini tablets technology has been developed to minimize these problems. It aims to facilitate oral administration with minimal swallowing difficulty (especially in pediatrics and geriatrics) and deliver a therapeutic agent, selectively and effectively, to be targeted in a certain position in the body. The most benefit of this technique is the ease of production with facilitated control of stability problems. The size and shape uniformity, with smooth surface area, make minitablets attractive to be incorporated with different medications for the efficient treatment of chronic diseases. This overview outlines properties, production requirements, formulation options and evaluation methods of mini tablets.

Keywords: Mini Tablets, multiple unit dosage forms, compressed mini tablets.

Introduction

Oral solid dosage forms have several advantages compared to other dosage forms. This includes; high patient contentment to administer the dosage, ease of transport, as well as the pattern of drug release, which can be comfortably managed and facilely controlling of stability. Using conventional solid dosage forms, for example: capsules or tablets can cause fluctuation in the plasma drug concentration; thus reducing the therapeutic efficacy. Increasing the dosing frequency decreases patient’s compliance and may end up with an adverse or toxic effect. In order to decrease fluctuation in the concentration, single unit or multi-unit dosage forms with varied release profiles are improved to obtain the desired pharmacological effect. In single unit systems, the controlled drug release is achieved utilizing membrane or matrix systems. In multi-unit systems (mini tablets), drug dose is divided into small subunits. Problems of conventional tablets may be solved using mini-tablets system. Mini tablet technology aims to deliver a therapeutic agent effectively with minimal swallowing difficulty (especially in pediatrics and geriatrics) and reduced dosing frequency; and therefore the maximum therapeutic effect will be obtained as well as a minimum of possible adverse effect. Additionally, a controlled drug delivery system can be developed using mini-tablets systems for the selective and effective treatment of chronic diseases (Figure 1).
Drug delivery systems aim to deliver a therapeutic agent, effectively and selectively, to a specific site in the body; thus minimizing dosing frequency, improving treatment efficiency and reducing potential toxicity. Conventional dosage forms have failed to achieve this and they have been associated with inconsistent plasma drug levels, which may be ineffective or toxic levels[1]. Multi-unit dosage forms have shown the ability to conquer this obstacle, especially when the ingredients represent synergistic or additive impact, and reduce the therapeutic doses into a single unit dosage form. This advocates the advantage of preparing mini tablets dosage units to enhance the therapeutic efficacy and reduce potential side effects. Multi-unit dosage forms have greater bioavailability compared to single units due to the higher credible dissolution profile[2]. Figure 2 shows a comparison among the characteristics of multi- and single- unit dosage forms[3].
**The definition, characteristics, and processing apparatus of mini-tablets**

Mini tablet is an expression used to describe a tablet with small diameter, 3 mm or less (Figure 3). Mini tablets are described for many pharmaceutical applications, such as oral, controlled and targeted drug delivery systems. They can be loaded in capsules, sachets or pressed in large tablets\[1, 4\]. Different dosages and sizes of Mini tablets are generally manufactured easily utilizing rotary tablet press machines with various punches\[1, 2\].

![Figure 3: Comparison of the diameters of conventional tablets and mini tablets](image1)

The usage of multiple punches is advantageous as it shorten the filling time and thus reducing the possibility of powder segregation. The benefits of using multiple punches are presented in Figure 4\[4, 5\].

![Figure 4: Advantages of multiple punches usage in mini tablets production.](image2)

Multiple punches are available as multi-part associated or as monoblocks (Figure 5). Multi piece assemblies exhibit low risk of contamination and they are classified into two types; the first one is the internal cap fixing (Figure 5-1), which is immobilized into the punch body. The second type is the external cap fixing (Figure 5-2). The internal fixing contains fewer pins as well as provides comfortable disassembly and mounting compared to the external one. Monoblock punches (Figure 5-3) are simpler to clean and require less installation time.
Additionally, they are stronger and more resistant against breakage and abrasion compared to multiple punches. The eroded edges can be easily renewed in multiple punches without any requirement to renew the punches. The improper installation is the main cause of eroding and punches damaging. The elevated ratio of length/diameter of the punches makes them nondurable to non-axial stresses. The device speed and length/diameter ratios should be adjusted carefully to minimize this risk. Mini tablets require fewer pressures compared to normal tablets. The process should begin with minimum pressure rates due to the durable diameter of a single punch, which is approximately 2-3 mm and may elevate to 2-3 kN axial force\cite{4}. Figure 6 presents the main advantages of mini tablets\cite{3, 6}.

**Figure 5: Types of staples used in mini tablet production**

Formulation and production requirements

Mini tablets have different parameters compared to conventional tablets. These parameters include; cylindrical hole length, die diameter, size distribution, particle size, length-width ratio as well as bulk and tapped densities. The most important characteristics of mini tablets are the cylindrical hole length and die diameter. There is a proportional relationship between diameter size and bulk flow rate, if diameter is large (4 mm) therefore the bulk flow rate increases, and vice versa. The cause of the flow rate differences is the elevated negative pressure gradient in punch. The environmental factors, such as temperature and humidity, must be taken into account during processing\cite{7}. It is very important to achieve good and reproducible followability, in order to ensure uniformity of content and die filling.

**Figure 6: Advantages of mini-tablets**

During tablet manufacturing, powders should be provided with mechanical resistance to facilitate the process of coating and capsule filling; this resistance can be obtained via good selection of formulation components such as binders and lubricants. Additionally, particle size plays an important role in mechanical resistance. A study carried out in 1998 by Lennartz and Mielck to improve the compact ability of paracetamol powder...
mixtures, they discussed the role of tablet content, size and pressure on capping tendency and tensile strength. It was found that particle size reduction has increased the mechanical resistance and decreased capping tendency, which can be explained by the elevated ratio of surface area/volume in mini tablets compared to that in conventional tablets. Therefore, increasing amount of mixture will increase the friction in punch and die wall; thus leading to obtain a homogeneous distribution of densities[8, 9].

**Formulation types of mini-tablets**

Mini tablets can be formulated into compressed mini tablets, encapsulated mini tablets and biphasic drug delivery systems[1]. Mini tablets can be pressed into tablets or loaded within capsules (Figures 7-1 & 2).

**Compressed mini tablets**

Mini tablets can be easily proceeded into tablets; this will save the high cost of hard gelatin capsules. There are several characteristics of mini tablets, which make them more attractive than pellets and granules such as low porosity, smooth shapes, good mechanical resistance, uniform particle size and smooth surfaces. Release profile of mini tablet can be comfortably modified according to the external phase characteristics, which provide filling of the cavity. Biphasic drug delivery systems are improved via employing several release properties. The first phase in this system works for rapid action and immediate release, whereas the second phase sustains the drug release, which maintains continuous action and decreases dose frequency[1, 10, and 11].

**Encapsulated mini tablets**

Encapsulated coated mini-tablets (Figure 7-2) are developed due to their great ability to improve therapeutic efficacy, patient compliance and dosage regimen. Multifunctional systems, composed of gelatinized hard capsule of minitablets, can be developed such as Rapid-release Mini-Tablets (RMTs), Sustained-release Mini-Tablets (SMTs), Pulsatile Mini-Tablets (PMTs), and Delayed-onset Sustained-release Mini-Tablets (DSMTs) [12, 13].
Tablet coating

Coating is the final step of tablet manufacturing and it has a role in cost elevation (Figure 8). The advantages of coating tablets are illustrated in Figure 9. Tablet coating includes four operations; coating via sugar, film coating, coating with pressure and enteric coating.

Many factors determine the importance to carry out the coating step, such as tablet core strength, the cost of coating material and the desired therapeutic effect[1]. It is complicated to manage the release pattern within the matrix systems in mini tablets because of the high surface area to volume ratio. A study was performed to examine the film-coated matrix mini-tablets for the extended release of a water-soluble drug. It is discussed the role of theophylline-containing mini matrix tablets and non-matrix tablets using different concentrations of ethyl cellulose, and they concluded that it is able to extend the release of water-soluble drugs from mini matrix tablets employing a convenient quantity of film coating[14].

Compressed mini tablets as biphasic drug delivery systems
The production of mini tablets as compressed tablets can reduce the production cost significantly compared to filling them within capsules. It is possible to merge among immediate and controlled release in the biphasic drug delivery systems, the immediate release provides rapid action at the beginning, whereas the controlled release ensures the continuous action in constant rate for certain period of time. Biphasic systems can be modified to be fast - slow or slow –fast\[15, 16\]. The correlation between weight of the mini tablets and amount of powder that will surround them is very important to be considered, this ratio is recognized to be at least 3/1. Filling the gap among mini tablets requires high amount of powder, if small amounts are used, this will end up with fracture after compressing\[2\].

**Mini tablets and modified drug delivery**

To modify the release of active ingredient from dosage form, several techniques can be used, for example: delayed release, targeted drug release, prolonged release as well as pulsatile and bimodal release\[4\].

**Extended release mini tablets**

In this system, the active substance is gradually released for a long time. This can be achieved via extending transition time over the gastrointestinal tract or by modifying the drug diffusion from dosage form. The slow release in extended release tablets can be obtained via changing the dissolution and diffusion of the drug over barrier coating, or matrix system\[17\].

Using lipid excipients is important to achieve extended release in tablets, hydrophobic substances follow diffusion principle (Fickian release) and hydrophilic substances follow diffusion and erosion principles.

(Non-Fickian release). The release of extended-release mini tablets will be slow, increasing system hydrophobicity will slow down the drug release, hydroxypropyl methyl cellulose (HPMC) is a hydrophilic polymer, which performs an important role in forming a resistant or less permeable hydrogel layer\[18,19\].

Drug solubility plays a critical role in the release profile. Weakly acidic and basic drugs exhibit pH-dependent solubility. This type of solubility tends to alter the ionic or non-ionic drug ratios according to pH in the release medium or the gastrointestinal fluid. In pharmaceutical production of extended release dosage forms, it is good to achieve solubility which is pH independent\[20\]. In order to obtain pH independent solubility from pH dependent solubility, microenvironments should be created using a pH modifying substance. Immediate and extended release profiles can be easily controlled by pH modifiers.

If salt ingredients are introduced in the formulation of an immediate release dosage forms, it will decrease the dissolution of less soluble compounds. To achieve a pH-independent release for the extended release of weak acidic or basic drugs, pH modifiers may be introduced, which can be combined with a basic drug for example to enhance the solubility significantly at high pH values\[21\].

**Pulsatile and bimodal release**

Fluctuations in drug concentration can occur because of the physiological factors (heart rate, blood pressure, hormone, enzymes and plasma proteins) and circadian rhythms in pathological situations. To solve this problem, several drug delivery systems are produced\[22\]. To obtain a Chrono therapeutic effect, pulsatile drug release is used to delay release in a programmed manner. This system is known as a time controlled system\[23\]. Pulsatile drug delivery is considered as a perfect choice for the treatment of diseases, which require a chronotherapy principle (such as bronchial asthma and angina pectoris). Pulsatile release is obtained using a controlled releasing polymer for coating tablets, which acts as a protective layer. Depending on the drug physicochemical characteristics, the release happens at certain times\[24, 25\]. Pulsatile release coatings may be rupturable, erodible, permeable and semipermeable film coating (Figure 10).
In case of multiple release profiles, pulsatile release systems should be utilized, as in elevated metabolism with first pass effect and pharmacologically tolerated drugs. The advantages of drug administration in divided doses are reduction of bacterial resistance as well as enhancement of biological tolerance\cite{26}.

Pulsatile release prevents the possible interaction between the dosage forms and the gastrointestinal tract\cite{27}. Coating a drug core with functional polymers results in multiple releases from pulsatile system (Figure 11).

**Figure 10: Performance of oral coated drug delivery systems with pulsatile release**

*Figure 10: Performance of oral coated drug delivery systems with pulsatile release*

In case of multiple release profiles, pulsatile release systems should be utilized, as in elevated metabolism with first pass effect and pharmacologically tolerated drugs. The advantages of drug administration in divided doses are reduction of bacterial resistance as well as enhancement of biological tolerance\cite{26}.

Pulsatile release prevents the possible interaction between the dosage forms and the gastrointestinal tract\cite{27}. Coating a drug core with functional polymers results in multiple releases from pulsatile system (Figure 11).

*Figure 11: Multilayer coated pellets*
Bimodal drug delivery systems exhibit several release properties within a single unit to enhance therapeutic efficacy and patient tolerance. It is possible to have multi delivery systems such as rapid, prolonged, extended and delayed release systems. The drug release rate in zero order kinetic system is independent of blood concentration; this system is recognized as a perfect condition to maintain the desired amount of drug in the blood. The absorption rate varies with different digestive parts; it is usually slow in the stomach, too slow in the distal part of the gut and high in the proximal part of the gut. This means that drug release rate should be changeable according to site of action to obtain a constant drug plasma concentration. Bimodal systems provide such a volatile release\[28, 29\].

**Floating mini tablets targeted to the gastrointestinal system**

Drug absorption can be increased using floating systems in the stomach, which extend the drug’s residence time. This system is beneficial for drugs, which have poor solubility and/or stability problem at intestinal pH. It is also beneficial for drugs act locally in stomach and it can decrease the possible local irritation that may occur as an adverse effect for certain drugs\[30, 31\]. Medicines that have narrow absorption windows, low solubility at intestinal pH and high absorption rate in the stomach as well as the ones act locally in the stomach are considered as good candidates to be prepared as floating drug delivery systems. The density of this system is lower than that of the aqueous medium of the gastrointestinal tract (usually less than 1 g / ml) and therefore capable to float at the surface of the stomach fluid. Floating systems are classified into two subtypes: effervescent and non-effervescent systems and they can be single- or multi-units\[31,32\]. Matrix-forming polymers are employed in non-effervescent systems such as polysaccharides and hydrocolloids. The result of adding these polymers is that the system swells once subjected to stomach fluid, whereas protecting the integrity shape. The drug release is controlled via the air, which introduces the swollen polymer and permits floating to occur. The external fluid introduces the dosage via swelling the system and permits drug dissolution. After that, the dissolved drug diffuses through the hydrated gel layer\[33\].

**Mucoadhesive mini tablets**

Mucoadhesive systems are advantageous to achieve local and systemic effect. This system permits prolonged drug existence at the active site; thus increasing the local effect and enhancing the therapeutic efficacy\[34, 35\]. Bioavailability can be increased by introducing mucoadhesive polymers, which adhere to the gastric mucosa surface; thus increasing drug residence in this site for long time\[36\]. Highest mucoadhesive power had been shown with using thiolate polymers; they raised bioavailability more than penetration enhancers\[37, 38\].

**Evaluation of mini tablets properties**

Evaluation of powder mixture is carried out using three measurements; bulk density, tapped density and powder compressibility (Carr’s index and Hausner ratio).

**Bulk density**

It is the ratio of powder mass to the bulk volume of untapped powder; it involves the inter-particulate void volume. Many factors influence the bulk density, such as the powder density and the arrangement of the interstices among the particles in the powder bed. Measurement of bulk density is very sensitive, fine shaking of dust mass can alter density. The bulk density of a certain weight is discussed largely in the American Pharmacopoeia, using different methods (graded cylinder, volumetric method and a container measurement). The bulk density is usually represented by g/ml or g/cm\(^3\). In case of powder weight expressed by M and the initial powder volume is expressed by V\(_0\), bulk density is represented as: M/ V\(_0\). Calculating the average of at least three separated measurements is usually performed to have a representative correct value.

**Tapped density**

It is the ratio of powder mass to the volume occupied by the powder after it had been tapped for a certain time. After determining the initial powder volume, compression of powder is taking place. In case of powder weight expressed by M and the compressed final powder volume is expressed by V\(_F\), Tapped density is represented as: M/ V\(_F\). Calculating the average of at least three separated measurements is usually performed to have a representative correct value.
Measurement of the compressibility of powders

Powder flow and batch characteristics are affected by possible particles interaction. Information about powder flow and particle interactions can be obtained from the bulk and tapped densities. This comparison is performed using the Compressibility Index (Carr’s Index) and Hausner Ratio (Table 1). The Compressibility Index and Hausner’s Ratio can be calculated using the following formulas\[^{[39]}\]:

- Compressibility index: \(100\left(\frac{V_0 - V_F}{V_0}\right)\)
- Hausner’s Ratio: \(\frac{V_0}{V_F}\)

Mini Tablets control

Weight Variation

Depending on European Pharmacopoeia, 20 randomly samples are selected and weighed, then the weight average is calculated, percentage variation can be observed in up to two of these weights but it must not vary by more than twice that percentage (Table 2).

Uniformity of tablets

To ensure uniformity of content (uniformity of active pharmaceutical ingredients (API) in each tablet); thus obtaining the desired therapeutic effect without loss of efficacy or any possible toxic effect. There are two methods to recognize the uniformity of tablets: weight variation or content uniformity. The drug’s contents are examined to define if the single contents are in limits; Content Uniformity (CU) and weight variability (MV) tests of various dosage forms are illustrated in Table 3.

**Friability**

This experiment is carried out under specific situations to confirm the existence of lamination or fractures in uncoated tablet or any surface damage. It is performed once and if there is any fracture or crack in a sample, this sample is considered to fail the friability test\(^{[39]}\).

**Dissolution test**

It is performed to define the dissolution rate of the active pharmaceutical ingredients (API) in solid dosage forms (capsules or tablets). Many factors should be recognized to prepare a sample for this test:

The utilized device, rotating speed, sampling method, analysis method and amount of (API) required to be dissolved\(^{[39]}\).

**Disintegration test**

It is utilized to confirm if the solid dosage form (tablet or capsule) are dispersed in a specific time, when they are subjected to a liquid medium, under the test situations demonstrated in Figure 12\(^{[40]}\).

![Figure 12: the conditions of disintegration occurrence](image-url)
Mini-Tablet Drug Delivery System for Pediatric Dosage Form (PDF)

Pediatric have a problem of swallowing difficulty, and therefore the most prescribed dosage form for them is the liquid dosage form which provides ease of administration. Because of the lack of stability of the liquid drugs and inaccurate dosing intake; mini-tablet technique provides the facility of delivering drugs for pediatrics in an accurate dose as well as in high stability in a comparison with the bulk dosage form[41].

Few drugs commercially available as minitablets, for examples: capsules of Propafenone HCl as antiarrhythmic, Sachet of Terbinafine HCl as Antifungal, capsules and sachet of Sodium Valproate for epilepsy, capsules of Fenofibric acid for cholesterol and Stick Pack of Ivacaftor for Cystic Fibrosis (CF)[41].

Conclusion

Pharmaceutical mini-tablets provide several benefits compared to conventional tablets, which make them as excellent alternatives for granules and pellets. They have low porosity and high mechanical strength. They can be formulated into tablets or filled in capsules. Mini-tablets can be used to deliver incompatible drugs for the effective treatment of different chronic disorders. It enhances the therapeutic efficacy and patient compliance. As discussed in this review article, mini tablets technology represents a promising field, which requires high interest from pharmaceutical researchers because of the wide therapeutic applications. As such, mini-tablets seem best implemented for small volume, high value products, particularly for pediatric patient populations that would benefit by this unique dosage form.

Relationship Between High Sensitivity TNF-α WITH clinical outcome During Admission In Acute Ischemic Stroke

Mohammad Saiful Ardhi¹, Mohammad Saiful Islam¹
¹Neurologist, Consultant Neurovascular, Department of Neurology, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo General Hospital Surabaya, (60131) Indonesia

Abstract

Background: Tumor necrosis factor alpha (TNF-α), together with other pro-inflammatory cytokines such as Interleukin-1b (IL-1b), IL-6 and IL-8, play a role in the ischemic injury of the central nervous system. TNF-α has adverse effects on ischemic brain tissue. The mechanism generated is a multicomplex process. In other studies, an increase in TNF-α can actually have neuroprotective effects. This study aims to determine the relation between the levels of the High Sensitivity TNF-α with clinical outcome in acute ischemic stroke.

Method: Thirty patients with acute ischemic stroke patients who admitted in Dr. Soetomo hospital Surabaya during the period December 2011 to February 2012. 2 cc of vein blood for examination High sensitivity TNF-α was drawn during admission from acute ischemic stroke. Clinical outcome in acute stroke was measured by NIHSS score.

Results: From 30 research samples, the mean age of patients was 59.53 ± 11.51 years. The mean High Sensitivity TNF-α level in the study subjects was 2 ± 0.99 pg / ml. NIHSS examination showed the median value of the NIHSS was 5 with a range of 2-19. There is a correlation but not statistically significant with the strength is very weak between High Sensitivity TNF-α with the NIHSS in patients with acute thrombotic stroke (r = 0.100 and p = 0.600).

Conclusion: There is relationship between serum levels of High sensitivity TNF-α with clinical outcome in acute ischemic stroke patients.

Keywords: TNF-α, HS TNF-α, clinical outcome, acute ischemic stroke.

Introduction

At present, stroke is ranked as the second leading cause of death worldwide. In the first year after a stroke, about 20% of patients die.¹ The number of ischemic stroke sufferers is greater than hemorrhagic stroke. In western countries, the number of ischemic stroke sufferers is around 80-85% of all stroke sufferers. Ischemic stroke is caused by a decrease in cerebral blood flow resulting in death and brain cell dysfunction.² Other problems are associated with the risk of infection in stroke patients.³

Tumor necrosis factor alpha (TNF-α), together with other pro-inflammatory cytokines such as Interleukin-1b (IL-1b), IL-6 and IL-8, play a role in the ischemic injury of the central nervous system. Some experimental studies have shown that TNF-α has adverse effects on ischemic brain tissue. The mechanism generated is a multicomplex process.⁴ In other studies, an increase in TNF-α can actually have neuroprotective effects.⁵

The problem that arises is whether there is a correlation between serum TNF levels and neurological deficits that occur in patients with acute thrombotic stroke. NIHSS is a score frequently used in the evaluation of stroke clinical outcome.⁶

Method

This research is an analytic study with cross sectional design. Inclusion criteria include: Patients with acute thrombotic strokes, having suffered a thrombotic stroke 4 hours until the 7th day and are willing to sign informed consent. Exclusion criteria include: Having an infection before an attack (eg, injury, heat), having acute
ischemic heart disease, having a history of malignancy, metabolic disorders (electrolytes, liver function and kidney function), using immunosuppressive drugs, NSAIDs. Based on the formula for calculating the correlation sample, the minimum sample size is 16.97 rounded up to 30 people.

All study subjects underwent the same clinical and laboratory examinations. High Sensitivity TNF-α serum examination was carried out in the Prodia Surabaya laboratory which was carried out by the ELISA-Sandwich method. The normality of data distribution was examined by the Saphiro Wilk test. Spearman’s statistical test was used to determine the correlation between the two variables that were not normally distributed.

**Results**

This study involved a total sample of 30 acute ischemic stroke patients who came to the Emergency room Dr. Soetomo hospital who met the inclusion criteria and did not meet the exclusion criteria. General characteristics and laboratory tests are shown in Table 1.

**Discussion**

The design of this study was cross sectional. Selection of consecutive sampling as a method of selecting research subjects because this method is the best non-probability sampling and easy to do.\(^7\)

During approximately 4 months of research, 30 subjects were found to meet the research criteria. Of these 30 subjects, 20 (66.7\%) of them were male and 10 (33.3\%) were female. The ratio between male and female subjects is 2:1 (table 1). This research shows that men experience more acute thrombotic strokes than women. In accordance with the epidemiological data of stroke, men suffer more strokes than women.\(^8\,9\) Other literature studies state that the percentage of thrombotic strokes in women in India and Southeast Asia is 33\% to 36\%.\(^10\)

From 30 research samples, the mean age of patients was 59.53 ± 11.51 years (table 1). In accordance with the epidemiological data of stroke that many stroke suffered by patients aged over 45 years.\(^10\,11\) Baseline data that has been collected is then tested for normality first with the Kolmogorov-Smirnov test (KS test). This test aims to determine the distribution of normal or abnormal data.\(^12\)

Analysis using the KS test found that the distribution of the study data was normal. Therefore an analysis to determine the correlation between High Sensitivity TNF-α and NIHSS levels in acute strokes was performed using Pearson correlation analysis.

A positive correlation was seen with a very weak correlation strength of 0.100 between High Sensitivity TNF-α and NIHSS levels in patients with acute stroke, which was not statistically significant at \( p = 0.600 \). This means that the higher the High Sensitivity TNF-α level, the greater the NIHSS value, but not statistically significant.

The results of this study are supported by other studies\(^13\) which state that the increase in TNF-α in liquor fluids and serum of patients in acute stroke has a correlation with the severity of stroke as measured by the SSS (Scandinavian Stroke Scale) and BI (Barthel Index). In addition there are other studies that show a TNF-α correlation with stroke outcomes using mRS (modified Rankin Scale) and BI (Barthel Index) in the first week of stroke.\(^14\)

**Conclusions and Recommendations**

There is a positive correlation with the correlation coefficient \( r = 0.100 \) between High Sensitivity TNF-α and functional expenditure as measured by NIHSS in acute ischemic strokes even though it is not statistically significant \( p = 0.600 \). Further research is needed to measure High Sensitivity TNF-α levels with NIHSS 1, 7 and 30th day of stroke sufferers. So that it can be known the actual neurological outcome level, as well as with a larger sample size so that it can provide more representative results.

Study the effect of purified alginate from *Pseudomonas aeruginosa* on Hep G2 and A549 cell lines.

Mohammed S. Ismaieel1, Muthanna Hamid Hassan2

1Research scholar 2Assist. Prof. Dr. Department of Biology - College of Science - University of Anbar -Iraq

**Abstract**

Alginate was extracted from highest alginate producer of *P. aeruginosa* 29 isolate, it was determined by biochemical method (Carbazole-borate assay) and molecular method (PCR), where the amplified *algD* gene samples showed that clear bands at one level for all the produced isolates and molecular weight were 313 on the leader scale. Partially purified of alginate using gel filtration chromatography (Sephadex G-200) showed the present of single peak and initial alginate fraction at 17 to last fraction 28 of alginate concentration, where the highest alginate concentration was at fraction 23. The cytotoxic effect of different concentrations of purified alginate on cancer cells (HePG2, A549) and normal cells WRL68 was tested. The result of half-maximal inhibition concentration (IC50) values of purified alginate treated WRL68 and HepG2 cells after 24, 48, 72 hours of incubation at 37ºC were (187.8, 62.0, 83.07) μg/ml, (102.3, 42.5, 61.03) μg/ml as respectively. While, the IC50 of purified alginate treated WRL68 and A549 cells after 24, 48, 72 hours of incubation at 37ºC were (126.2, 63.57, 90.31) μg/ml, (117.8, 57.06, 65.7) μg/ml as respectively.

**Key words:** *P. aeruginosa*, Alginate, cytotoxicity

**Introduction**

Alginate is one of the few polymers produced by some prokaryotic and eukaryotic organisms. The marine algae is mainly the eukaryotic source of alginate. Moreover, amongst the prokaryotes, two bacterial genera *Azotobacter* and *Pseudomonas* are recognized to including some species ability to produce alginates (1). Bacteria produce a wide range of extracellular polysaccharides to adapt to and thrive in diverse niches of the environment. Many of these polymers have attracted great attention due to their implication in biofilm formation, capsule formation, virulence, or for their potential medical. One important exopolysaccharide, alginate, is produced by various *Pseudomonas spp.* and *Azotobacter vinelandii*. Alginate is of particular interest to cystic fibrosis patients because of its role in the pathogenesis of *Pseudomonas aeruginosa* lung infection (2). These polysaccharides have a chemical structure composed of subunits of (1–4)-β-d-mannuronic acid (M) and its C-5 epimer α-l-guluronic acid (G) (3). *Pseudomonas aeruginosa* is responsible for many nosocomial infections as a common opportunistic pathogen. It converts to a mucoid phenotype after infection of the lungs of patients with cystic fibrosis (CF), characterized by overproduction of the exopolysaccharide alginate. Alginate not just protects the pathogen against antibiotics and host immune defenses, but can also block the lungs of the patient. Such infections are extremely difficult to remove and always contribute to the patient’s death (4, 5). Extensive applications are outcome of alginate rheological properties, as well as from biocompatibility, biodegradability and toxicity absence. Their pharmacological and biological properties, such as antioxidant activity, antimicrobial ability, anticancer and immune stimulatory properties and strong free radical scavenging, have led to the advancement of alginate research’s in the biomedical field (6, 7).

**Material and Methods**

**Collection of samples.**
In this study, 180 samples were collected from clinical cases including both males and females with different ages, from Al-anbar teaching Hospitals and general Al-amiriyah hospital. Bacterial identification was achieved by gram stain, Cultural characteristics, biochemical tests and vitek2 technique (8).

**Alginate extraction** was done according to the method mentioned by Pedersen et al., (9) The precipitated alginate washed twice with isopropanol and re-suspension with normal saline(0.9%). the alginate concentration of this suspension was determined by the Carbazole-borate assay (10).

**Molecular determination of algD gene.**

The primer forward sequence (5’to3’) algD-F was CGTCTGCGCGAGATCGGGGT and the primer reversed sequence (5’to3’) algD-R was GACCTGACGGTGCTCGGA, it was designed according to (11), the algD gene was determined by polymerase chain reaction (PCR) through Master Mix, Primer and the reaction program showed in following table :

**Table (1 ): PCR program for alg D gene amplification**

**Purification of alginate;** Sephadex G-200 was prepared as recommended by Pharmacia Fine Chemicals Company. A quantity of Sephadex G-200 was suspended in 0.01 M Tris-HCl buffer, pH 8, degassed, and packed in a glass column (1.5x20 cm), then equilibrated with the same buffer. Five ml of extracted alginate solution obtained from the extraction step was applied on to the column. Elution was achieved at a flow rate of 0.5 mL/min and the same buffer was used for equilibration. Eluted fractions (4ml) were collected and assayed for uronic acid content by carbazole-borate assay of alginate fraction by measuring the absorbency at (525 nm).

**Cytotoxicity assay:** The assay of MTT was used to determine the cytotoxic effect of purified alginate concentrations on cellular lines, Hepatoblastoma-derived cell line (HepG2) , human cell lung cancer (A549), with normal cell line (WRL68) , where purified alginate concentrations were 6.25, 12.5, 25, 50, 100, 200, 400 µg/ml at 37 °C during 24, 48, 72 hours(12,13).

**Results and Discussion**

**Isolation and identification:** In this study, 180 samples were collected from clinical cases including both males and females with different ages, where, collected from different sources; wounds, burns, abscess, cystic fibrosis, ear infection, vaginal infections and urinary tract infections. The isolation results showed that the number of samples showing positive bacterial growth on the used media was 125 samples (69.45%), while 55 samples (30.55%) of total samples did not demonstrate bacterial growth. Alginate production; All 25 bacterial isolates obtained from different sources were have investigated ability it’s to produce alginate. The results of the study showed 13 (52%) ps. aeruginosa isolates were producer of alginate ,while ps. aeruginosa isolates were 12 ( 48%) not producer. In order to select the efficient isolate in the production of alginates, the
capability of these thirteen isolates were examined in the alginate production medium by determining the concentration of crude alginate in the culture medium following the isopropanol precipitation. The results indicated local isolate of *Ps. aeruginosa* 29 (ps.a29) yielded higher alginate production (123.6 µg/ml). From these findings it was determined that *Ps. aeruginosa* 29 was the most active in alginate production because it was isolated from the cystic fibrosis tissue and alginites are required in this tissue to invade the tissue. Because of the importance of alginate in the formation of biofilms and also in resistance of antibiotics and phagocytosis (14). This results agreed with Al-Janabi, (15) that also reported different concentrations of produced alginate from *ps. aeruginosa* isolates and detect higher alginate production from cystic fibrosis isolate. Detection of algD by PCR; The results of the electrophoresis of the amplified gene algD samples showed that clear bands at one level for all the produced isolates and molecular weight were 313 on the leader scale. While the isolated samples were not produced, the algD gene bands did not appear at any level except for one isolate that showed one algD gene band as silent gene not expressed of phenotype, it shown in figure(1). The reason may be to suppression of same algD gene or the others genes responsible for alginate formation; like, alg44 gene is role important of alginate biosynthesis, Alg44 has a cytoplasmic PilZ domain that binds to the c-di-GMP cofactor and is needed to activate the Alg44 function and to alginate production. Point mutations in the PilZ domain lead to the loss of c-di-GMP binding which results in the loss of alginate production (16).

**Figure(1): Agarose gel electrophoresis for 60 min (2 % agarose, 75 V/cm2) of amplified algD gene (313bp)**

Purification of alginate; Extracted alginate of highest alginate production by local isolates of *P. aeruginosa* (Pa29) was partially purified using gel filtration technique. For this purpose 5ml of extracted alginate solution was added to sephadex G-200 column and eluted by Tris-HCl buffer Eluted sample were collected as fractions 4 ml with flow rate 0.5 ml/min and assayed for uronic acid by carbazol borate assay to detect alginate positive fraction, the results in figure(2) showed the percent of single peak and initial alginate fraction at 17 to last fraction 28 of alginate concentration, where the highest alginate concentration was at fraction 23 and used in the cytotoxicity study.
Cytotoxic effect of purified alginate on Hep G2 and A549 cell lines: Various concentrations of purified alginate determined its toxic effect on cellular lines Hepatoblastoma-derived cell line (HepG2), human cell lung cancer (A549), with normal cell line (WRL68). The assay of MTT was used to determine the cytotoxic effect of purified alginate on these cancer cell lines. Where those concentrations were 6.25, 12.5, 25, 50, 100, 200, 400 µg/ml at 37°C during 24, 48, 72 hours. In graph pad prism, data analyzes conducted in µg/ml and log values of µg/ml were plotted using log (Inhibitor) versus normalized response Curve. For the most significant values of IC 50 the best values were chosen. MTT colorimetric assays determined the cell viability at every time point. As shown in figure(3), the half-maximal inhibition concentration (IC 50) values of purified alginate treated WRL68 after 24,48,72 hours respectively of incubation at 37°C was 187.8, 62.0, 83.07 µg/ml and the IC 50 value of purified alginate treated HepG2 cells after 24,48,72 hours respectively of incubation at 37°C was 102.3, 42.5, 61.03 µg. The results showed that the IC50 of purified alginate treated A549 cells after 24,48,72 hours respectively of incubation at 37°C was 117.8, 57.06, 65.7 µg/ml and the IC50 of purified alginate treated WRL68 cells after 24,48,72 hours respectively of incubation at 37°C was 126.2, 63.57, 90.31 µg/ml shown in figure-4. Through a comparison of the half-maximal inhibition concentration (IC 50) between the Hep G2 cancer cell line and normal WRL68 cell line for three incubation times, the highest difference between IC50 concentrations was shown within 24 hours of incubation, while other times were the lowest difference between the inhibition concentrations of each incubation time. From these results, it was found that there clear effect of purified alginate on Hep G2 cells higher than normal WRL68 cells. The results showed clear effect of purified alginate on cells viability for these two cell lines and this effect increased with increase concentration. While, comparison of the half-maximal inhibition concentration (IC 50) between the A549 cancer cell line and normal WRL68 cell line for three incubation times, the highest difference between IC50 concentrations was shown within 72 hours of incubation. In general, cytotoxicity effective of Purified alginate( in vitro) was more effect on HepG2 cancer cells and less effect on A459 cancer cells with compared WRL68 normal cells.

![Figure (3): Cytotoxicity effect of purified alginate on HepG2 and WRL68 cells after 24 and 72 hrs of incubation at 37°C.](image)

Other study on supernatant fraction of secreted virulence factors from *P. aeruginosa*, at concentration 3.42 µg / ml, the supernatant cytotoxicity only showed significant impact on the A549 cells after 48h of incubation. In this case, the HB13 strain in all incubation periods was unable to achieve any significant cell death. Whereas, supernatant cytotoxicity at the 20.50 µg/ ml concentration demonstrated a significantly higher percentage of cell death compared to the prior concentration (3.42 µg / ml) (17). Also, three factors analyzed (copper oxide nanoparticles, alginate biopolymer, and stirring time) exhibited a significant effect in inhibiting cancer cell growth. The effects of factors including copper oxide nanoparticles, alginate biopolymer and stirring time on the inhibitory effect on the growth of MCF-7 cancer cells in the structure...
of alginate-copper oxide nanocomposite were 69.01%, 66.04% and 65.80%, respectively. Hence the synthesized nanocomposite can be used in the design of new anticancer drugs under optimal conditions\(^{(18)}\)

**Figure (4): Cytotoxicity effect of purified alginate on A549 and WRL68 cells after 24 and 72 hrs of incubation at 37°C**

---

**Conclusion**

cytotoxicity effective of Purified alginate\( (\text{in vitro})\) was more effect on HepG2 cancer cells and less effect on A459 cancer cells with compared WRL68 normal cells.

Efficacy and Safety of Sacral Neuromodulation in Treatment of Refractory Overactive Bladder

Mohammed Bassil Ismail1, Wameedh Qays Abdullhussein2

1Lecturer, CABMS (Urology), College of Medicine/University of Baghdad,
2Specialist CABMS (NEUROSURGERY), Medical City Complex, Baghdad

Abstract

Background: Overactive bladder syndrome is a urinary disorder that occurs more frequently in women and older people and is characterized by feeling an urge to urinate (sudden urge to urinate, with the feeling that you cannot get to the bathroom in time), doing it many times throughout the day (more than six) or having episodes of urinary incontinence (involuntary loss of urine) and nocturia (waking up several times during the night to urinate). In addition, other secondary symptoms may also occur, such as headache, dry mouth or blurred vision, among others. It is a problem that has a clear impact on the quality of life of those who suffer it and that can lead them to significantly reduce their social activity and negatively condition their work.

Overactive bladder (OAB) is defined as urinary urgency with or without urgency urinary incontinence, nocturia, and/or frequency in the absence of UTI or other obvious pathology. Sacral neuromodulation is a newer surgical therapy for refractory OAB.

Aim of Study: Is to assess the sacral neuromodulation (SN) safety and efficacy in refractory overactive bladder patients.

Patients and Methods: In the period from November 2015 to May 2017, the unit of neurogenic bladder and neuromodulation in (Gazi Al_Hariry) surgical specialty hospital, medical city complex 27 patient aged from (17—55) year old were complaining from refractory overactive bladder. All the 27 patients underwent stage1 & stage2 SNS devices implantation.

Results: Patients of urgency incontinence (group1) demonstrated that the number of leak was significantly reduced (p=0.01) after implantation of SN, (11.6_2.7) leak/day pre& post SN, numbers of pads (6.9 _ 0.8) pad/day pre&post SN. Patients with urgency frequency (group 2), numbers of voids/day pre & post SN implantation decreased significantly (p=0.01) (14.7 _ 6) voids /day. The voided volume increased significantly (p=0.02) from (136.4 _ 371.8) ml/void. The urgency episodes were decreased significantly (p=0.01) from (6.4 _ 2.1) episode/day. The complications occurred in 5 patients (18.5%). Two patients (7.4%) developed pain after trauma to the back, lead migration, lack of efficacy of device, treated by reprogramming the device, one patient (3.7%) get infection at the site of device implantation, SN was removed , there was one female patient (3.7%) got pregnancy and devise was deactivated. One patient (3.7%) complaining from pain and discomfort at the device site was treated conservatively.

Conclusion: Sacral neuromodulation is FDA approved as option for treatment of refractory OAB. There is expanding of utilizing of SN in the past two decades. According to multiple studies in addition to our study results. The sacral neuromodulation is safe and efficacious treatment option for refractory OAB.

Keyword: Neuromodulation, OAB, UTI, incontinence

Introduction

Overactive bladder syndrome is a urinary disorder that occurs more frequently in women and older people and is characterized by feeling an urge to urinate (sudden...
urge to urinate, with the feeling that you cannot get to the bathroom in time), doing it many times throughout the day (more than six) or having episodes of urinary incontinence (involuntary loss of urine) and nocturia (waking up several times during the night to urinate). In addition, other secondary symptoms may also occur, such as headache, dry mouth or blurred vision, among others. It is a problem that has a clear impact on the quality of life of those who suffer it and that can lead them to significantly reduce their social activity and negatively condition their work.

During the nineteenth of the 20th century the Overactive bladder was described as a group of bladder storage symptoms consisting of urgency, frequency, nocturia, and urinary incontinence. These symptoms without diagnosis due to detrusor overexertion, which was an objective urodynamic detection of involuntary detrusor activity. Overactive Bladder (OB) is defined as urgency of urination with incontinence or no seizures, night and/or frequency in the absence of IPS. Another obvious pathology. Wet OAB is defined as involuntary loss of urine associated with a strong desire to empty.3 Wet OABs have a huge gradient of severity and can have a significant negative impact on quality of life due to significant annoying symptoms and sudden loss of urinary control. (4)

OAB, specifically moist OAB, symptoms now disturb a significant rate of the population, and the overall prevalence of OAB has been shown to be comparable between men and women. A study conducted in the United States showed a prevalence of OAB in 16% of men and 16.9% of women. (4)

Milsom et al. in their study agree with that mentioned by the population of Europe, with an estimated prevalence of OAB (15.6%) in male and 17.4% in female on reviews finished by patients with in age older than 40 years. A correlation has been found between increasing age and prevalence of OAB wet symptoms. (5) Stewart et al found that the prevalence of wet HF symptoms increases with age for both men and women, and increases significantly after age 44 for women and age 64. For men. Stress and mixed urinary incontinence are also more common in the elderly, but patients with purely moist OAB are more likely to need treatment. (4)

The US Food and Drug Administration approved CH in September 1997 to treat nausea incontinence for those patients who were unsuccessful in managing their symptoms with more conservative therapies. They later approved HF for urinary retention syndrome and urgency. (6)

SN uses electrical stimulation to stimulate the bladder pacemaker, which is the sacral nerves that supply the pelvic floor and lower urinary tract muscles. Using electrical stimulation, you can inhibit or excite neural reflexes. (7)

**Aim of the Study:** Is to assess the sacral neuromodulation (SN) safety and efficacy in refractory overactive bladder patients.

**Patients and Methods**

In the period from November 2015 to May 2017, the unit of neurogenic bladder and neuromodulation at (Gazi Al_Harriry) surgical specialty hospital, medical city complex 27 patient aged from (17_55) year old complaining from refractory overactive bladder (Patients not responed or not tolerate conservative treatments for more than 3 months). All patients undergone full detailed history with physical examination with emphasis on the genitourinary and neurologic examinations, voiding diaries, urodynamic Studies, lumbosacral MRI, and flexible cystoscopy.

**Exclusion criteria:** -

1. Mechanical bladder outlet obstruction, bladder anatomical abnormalities.
2. Patient’s planning to undergo diathermy (shortwave; microwave; ultrasound) or MRI in the future.
3. Inadequate response during test stimulation intra op.
4. the patient unable to operate the device.
5. patient age less than 16 years.
7. Anatomical bony abnormalities of the sacrum, in which trans foraminal access could be difficult or impossible.
After that we divided these patients in two groups.

- Group1 (16 Patients with urgency incontinence.
- Group2) 11 Patients with urgency frequency.

All the 27 patients underwent stage1 & stage2 SNS devices implantation. After taking the informed consent from the patients.

Patients are taught keep a bladder diary during the trial stage (2weeks) to assess if there is a significant and worthwhile improvement in OAB symptoms.

If the test stage success in reducing the symptoms of bladder overactivity by at least (50%) in at least one of the following then we can proceed to permanent pulse generator implantation:

The advantage of the test stage is the ability to test out the SNS device over several days to see if it is suits the individual before committing to the treatment.

The patient and doctor decide together before the 2nd stage procedure if the SNS device has made enough of a difference to symptoms to proceed to the permanent pulse generator implantation.

All patients were reevaluated using voiding diary after two weeks, one month, three, six months and 1 year after the insertion of permanent SNS device and seeking for complication if found.

**Statistical Analysis**

SPSS version 23 was used for data entry and analysis. Mean and standard deviation were used to represent the numerical data while the frequency and percentage was used to represent the categorical data. Appropriate tests (chi square test, paired sample t test) were used to confirm significance where the significance level was set at \( p < 0.05 \).

**Results**

The results showed that the mean age of group with urgency incontinence was significantly lower than that of group with urgency frequency syndrome (26.6 ±3.6 sd, 36.7±2.8 sd) respectively as well as the results revealed that male patients represented 68.8% of first group and 81.8 of later group but the difference was considered non-significant as seen in table 1.

The results of patients (group1) of urgency incontinence demonstrated that the number of leak was significantly reduced (\( p = 0.01 \)) after implantation of sacral neuromodulation as the mean value of number of leaks was 11.6/day pre implantation of the device and become 2.7 leak/day post implantation of the device with mean difference of 8.9 leaks/day. The same significant difference was reported with mean value of number of pad as it was 6.9 pads/day before implantation and become 0.8 pads/day after device implantation with mean difference of 6.1 pad/day as displaced in table 2.

The findings of current study of patients with urgency frequency (group 2) showed that the numbers of voids/day pre & post SN implantation was decreased significantly (p=0.01) from a mean of 14.7 voids/day to 6 voids/day with mean difference of 8.7 voids/day. The voided volume increased significantly (p=0.02) from a mean of 136.4 ml/void to 371.8 ml/void with mean difference of 235.4 ml/void of voided volume. The urgency episodes decreased significantly (p=0.01) from 6.4 episode/day prior to implantation to 2.1 episode/day after implantation of the device with mean difference of 4.2 urgency episodes/day as displaced in table 3.

Our data indicated that complications were reported with three cases of (group 1) with urgency incontinence. 1st one device was deactivated after pt. discovered pregnancy, 2nd one; patient developed pain & discomfort at device site that treated conservatively and 3rd one; patient got pain after trauma to the back, lead migration and lack of device efficacy treated by reprogramming the device.

While complication reported with two cases of (group 2) with urgency frequency, 1st case developed pain after trauma to the back, lead migration and lack of device efficacy treated by reprogramming the device, and 2nd case developed pain due to surgical site infection where device was removed. as seen in table 4.

When we evaluate the percentage of complication in all patients of OAB included group1 and group 2 underwent SN implantation. We found the complications occurred in five patients (18.5%). Of these complication, 2 (7.4%) patients developed pain after trauma to the back, lead migration, lack of efficacy of device. Treated by reprogramming the device, one patient (3.7%) get infection at the site of device implantation, SN was removed, there was one female patient (3.7%) got pregnancy and devise was deactivated. And One patient (3.7%) complaining from pain and discomfort at the device site was treated conservatively.

Discussion

Many studies were carried to determine the effectiveness of sacral neuromodulation. Latini et al had seen its effects on 41 patients with urgency incontinence; and discovered that 90% of patients had a more than 50% improvement in signs and symptoms of urgency incontinence as noticed by voiding diaries and number of pads. (8)

The frequency of incontinent episodes for the patients in his study declined significantly from a mean of 8.8/day to 2.3/day for 6-month follow-up duration, numbers of pads were also reduced in patients undergone neuromodulator implantation, the mean number of patients’ diapers changed from 4.7 diapers per day to 0.8 diapers/day in follow-up period. (8)

Our results after 1 year of SN. implantation, (group1) patients with urgency incontinence demonstrated that the number of leak was significantly reduced (p=0.01) after implantation of sacral neuromodulation as the mean value of number of leaks was 11.6/day pre implantation of the device and become 2.7 leak/day post implantation of the device with mean difference of 8.9 leaks/day. The same significant difference was reported with mean value of number of pad, as it was 6.9 pads/day before implantation and become 0.8 pads/day after device implantation with mean difference of 6.1 pad/day.

Urgency & frequency symptoms get similar benefits for those with urgency incontinence. Charter_Kastler et al, in his study to evaluate the efficacy of SN for 9 patients with urinary frequency and found the voids/day decreased from (16.1 void/day to 8.2 void/day). And increase in max.bladder capacity from 244 mL to 377 mL and increase in the ability of patient to hold a greater volume between voids and over active bladder episodes (9)

Worldwide clinical study in seventeen centers van Kerrebroeck el la. 25 patient with urgency-frequency
underwent SN implantation, mean number of voids/day decreased significantly from 19.3 to 14.8, with (40%) clinically success after five years. Volume voided per void also increased (92.3 ml to 165.2 ml) with clinical success (56%) after five years. The clinical success rate in decreasing episodes of urgency (56%). An important finding in this study is the high correlation between success rates for treated patients for one and five year; indicating durable response with SN\(^{(10)}\)

Our study’s results of patients with urgency frequency (group 2) showed that the numbers of voids/day pre & post SN implantation decreased significantly (p=0.01) from a mean of 14.7 voids/day to 6 voids/day with mean difference of 8.7 voids/day. The volume voids increased significantly (p=0.02) from a mean of 136.4 ml/void to 371.8 ml/void with mean difference of 235.4 ml/void of voided volume. The urgency episodes were decreased significantly (p=0.01) from 6.4 episodes/day prior to implantation to 2.1 episodes/day after implantation of the device with mean difference of 4.2 urgency episodes/day

Hassouna et al. take of 51 patients post SN implantation from 12 centers underwent baseline assessment, including a detailed voiding diary, urodynamic evaluation that was showed improvements in cystometry study and life quality according Health Survey. It was shown that the effects were attributed to SN because of when SN were deactivated their patients symptoms returned to baseline. after reactivate the stimulator the benefits were returned again\(^{(11)}\)

There were numbers of complications that occurred in some patients who underwent SN implantation like any surgical intervention.

At a mean follow-up of ~3 years, White et al. followed up 221 patients for 3 years and found that 30.3% developed complication that required surgical intervention. These complications such as pain; infection; device malfunction; hematoma and lead migration. Of these complications (3.5% surgical site infection), (2.7% pain which was related to the device) and (5.9% lead migration). According this classification, they found the total complications rate (30.3%) and suspect that would represent the upper percentage end of complication\(^{(12)}\)

In our study; when we evaluate the percentage of complication in all patients of OAB included group1 and group 2 underwent SN implantation. We found the complications occurred in 5 patients (18.5%). Of these complication, One patient (3.7%) got infection at the site of device implantation, SN device was removed, And One patient (3.7%) complaining from pain and discomfort at the device site was treated conservatively by simple analgesia. Two patients (7.4%) developed pain after trauma to the back, lead migration, lack of efficacy, treated by reprogramming the device. Lead migration is usually resolved by reprogramming and usually does not require a new lead to be inserted. This can also define the problem at each electrode and is handled by reprogramming to move the circuit of stimulation away from the broken or migrated electrode\(^{(13)}\)

During follow up of our patient there was a female patient (3.7%) who got pregnancy. Device was deactivated to be activated after delivery. It is unclear whether SN is safe in pregnant patients or not. Also, it’s unclear whether it is teratogenic or not; especially in the first trimester. Wiseman et al. looked at six pregnant patients with SN that didn’t deactivated in the first trimester of pregnancy. This study shows that one of the six cases delivered a premature baby by 6 months but with no fetal abnormalities seen in any of these cases. This result promising that SN has no harmful effects to the pregnant women and her fetus. However, the manufacturers recommend that the pulse generator should be deactivated in female patient getting pregnancy\(^{(14)}\).

**Conclusion**

Sacral neuromodulation is FDA approved as option for treatment of refractory OAB. There is expanding of utilizing of SN in the past two decades.

According to multiple studies in addition to our study results, sacral neuromodulation is safe and efficacious treatment option for refractory OAB.

Retinoic Acid Treatment of Human Hematological Malignancies Induces Caspase Dependent and Independent Apoptotic Cell Death

Mohammed S. Mohammed¹, Maha Fakhry Altaee², Ahmed Majeed Al-Shammari³

¹Lecturer/Al-Kufa Technical Institute, Al-Furat Al-Awsat Technical University, ²Assistant Professor/Biotechnology Department/College of Science/University of Baghdad/Iraq, ³Assistant Professor /Experimental Therapy Department, Iraqi Center for cancer and medical genetics research, Mustansiriyah University.

Abstract

The unprejudiced of this education is to gauge the ability of the retinoic acid to induce apoptotic cell death in hematological tumors through caspase dependent or independent apoptotic pathway. The cytotoxicity effects of retinoic acid of different concentrations (400,350,300,250,200,150,100,50,25,12.5 µg/ml) and exposure for all hematological malignancy cell lines (Human non-Hodgkin lymphoma SR and human multiple myeloma (COLO 677) and Human Monocytic Leukemia THP1 and Acute promyelocytic leukemia NB4) have been determined using a microtetrazolium (MTT) assay. Propodeum iodide and alcidine orange (AO/PI) paired discoloration was used to study the ability of retinoic acid to induce apoptosis in the infected cells and examined under fluorescence microscope and quantified for the percentage of apoptosis induction. Quantitative immunocytochemistry assay was used to study the caspase dependent and independent proteins expression in infected and control cells. Cells treated with Retinoic Acid showed increased cell death percentage compared to the untreated cells as quantified by MTT assay. AO/PI results revealed that Retinoic Acid had powerful effect on inducing apoptosis significantly (p<0.001) in human cancer cell lines tested, compared to control cell. Immunocytochemistry in Retinoic Acid infected human hematological cell lines revealed remarkable increase in expression of caspase 8,9 (dependent pathway) and AIF, ENDOG (independent pathway) induces a significant (p<0.002) as compared untreated cell.

This study, which shows the role of the Retinoic Acid in inducing apoptosis through a dependent and independent pathway in cancer cells, we anticipation these annotations will shanty light on the impending exploration of retinoic acid in cancer hindrance and rehabilitation.

Keywords: Retinoic Acid, SR, NB4, THP1, COLO677, Apoptosis

Introduction

A trademark variation from the norm of leukemia cells is that they are hindered at a beginning period of their advancement and neglect to separate into useful develop cells. During the 1970s and 1980s, a few logical accomplishments promoted the procedure of actuating harmful cells to defeat their square of separation and enter the apoptotic pathways as an exquisite option in contrast to murdering disease cells by cytotoxic therapies[1]. This mediation could hypothetically confine introduction to undesirable reactions of cytotoxic chemotherapy, and all the more significantly, improve total reduction and fix rates, endeavors to clarify substances to control the separation of myeloid leukemia,2 and the principal proof of the separating properties of retinoic acid[2, 3]. The potential for separating treatment to improve fix rates in leukemia is exemplified by the advancement of all-trans retinoic corrosive for the focused on treatment
of intense promyelocytic leukemia. One of the most amazing aftereffects of starting in vitro analyses was accomplished in separating HL-60 cells per ATRA, which bent terminal separation in 90% of cells per 10−6 M retinoic acid\[2\].

Retinoids are a class of normally happening aggravates that are fundamentally identified with nutrient An (or retinol). Retinoids control a wide scope of organic procedures, including improvement, separation, multiplication, and apoptosis \[4\]. ATRA is the dynamic metabolite of nutrient An and intercedes its organic impacts by enacting at least one of the firmly correlated retinoic corrosive receptorse (RARα, RARβ, and RARγ) that aptitude as ligand-subordinate transcriptional controllers. These receptors structure heterodimers with rexinoid receptors (RXRα, β, and γ) and tie to retinoid responsive reaction components situated in the advertiser district of retinoid target qualities to animate quality translation \[4\].

A functioning common retinoid, all-trans retinoic corrosive, is viable in separation treatment for intense promyelocytic leukemia \[5\], is a subtype of intense myeloid leukemia, which is portrayed by a particular chromosomal variation from the norm t(15,17) related with a hereditary revision between retinoic corrosive receptor α (RARα) (quality image, RARA) and the promyelocytic leukemia quality PML\[6\]. RARα assumes a job in granulocytic separation of hematopoietic cells and the irregular illusory receptor PML-RARα has been involved in APL pathogenesis by obstructing the myeloid separation program and upgrading self-reestablishment of leukemic cells\[7, 8\]. Pharmacological portions of ATRA instigate separation of APL cells into granulocytes through corruption of PML-RARα and recuperation of physiological RARα flagging \[7\].

Nutrient An is particularly significant in light of the fact that it can’t be combined by creatures and must be provided from an eating regimen that incorporates plants \[9\], suppress malignant transformation in vitro \[10\]. Sure of these mixes restrain the development of changed cells \[11\] and actuate separation of mouse embryonal carcinoma cells in vitro \[12\]. The antineoplastic impacts of retinoids recommend that these mixes could be utilized restoratively for the chemoprevention of malignancy \[2\]. ATRA actuates terminal separation of leukaemic cell lines, so ATRA-based treatment can prompt total reduction in APL \[13\]. Tumor improvement, angiogenesis and metastasis are the organic capacities hindered by retinoic acid \[14\]. It has likewise been found that retinoic corrosive directs mitochondrial porosity, passing receptors, ubiquitination, and types of responsive oxygen, etc.\[15\]. The inhibitory effects of retinoic corrosive are believed to be cultivated by initiating the receptor of retinoic corrosive (RAR) or the receptor of retinoic X. rar and rxr structure ligand restricting heterodimers and aptitude, o change downstream quality articulation, rar and rxr travel into cell cores and tie to the retinoic corrosive response components (Uncommon) set in the 5’ downstream qualities of retinoic corrosive\[16, 17\]. Actuating the old style pathway above will bring about cell separation, capture and eventually apoptosis \[16\]. The pathways on that RA demonstrations need adjusted convergences of this retinoid, and distortion on the degree of retinoic corrosive from ordinary outcomes in irregular development and advancement \[18\]. The activity of retinoic corrosive relies upon different procedures, just as combination and degeneration of RA, phosphorylation and debasement of RA receptors, and enrolling of chromatin remodelers and procedures worried inside the vehicle, spread, and cell ingestion of retinoids \[19\], notwithstanding the previously mentioned great pathway, retinoic corrosive can likewise control downstream quality articulation by adjusting other interpretation factors, for example, NF-b, IFN-J, TGF-b, MAPK, and even chromatin rebuilding \[20\]. RARs/ RXRs heterodimerize and control the motioning of these accomplice receptors, including non-exemplary or non-genomic forms, These accomplice receptors some of the time have opposite capacities to RARs/RXRs, including retinoid flagging and digestion, cell bond, cell-grid collaboration, and cytoskeleton renovating in their appearance microarray assessment\[21\].

**Materials and Methods**

**Preparation of cells and cell culture**

This investigation remained affirmed via Baghdad College, School of Science, biotechnology office. The human cell line non-Hodgkin lymphoma SR (CD20 –) was generously given by Dr S.J. Russell, Mayo Center, Atomic Drug Office (Rochester, M N, USA) and refined in altered Falcon’s media (US Organic, Salem, Mama,
USA) with 5% fetal ox-like serum (Capricorn Logical).

The human various myeloma (COLO 677) was initially portrayed as being gotten from a tumor in the left axillary lymph hub of a 39-years-old male with little lung cell carcinoma in 1989. Be that as it may, DNA fingerprinting recommends cross-sullying with cell line RPMI-8226; RPMI-8226 was built up from the fringe blood of a 61-year-old male with various myeloma in 1966. The THP1 (Human monocytic leukemia) Got from the fringe blood of a 1-year-old male with intense monocytic leukemia.[22]

The NB4 cell line Intense promyelocytic leukemia (APL) is a well-characterized substance among intense leukemia, cytogenetically described by a t(15;17) (q22;q11-12) translocation [23], was acquired from the Division of Test Treatment, Iraqi Community for Disease and Restorative Hereditary Exploration (ICCMGR; Baghdad, Iraq). Every one of the cells were refined in Roswell Park Commemoration Establishment 1640 medium (US Natural) with fetal calf serum 10%, penicillin 100 u/ml, and streptomycin 100 μg/ml, and brooded at 37°C.

Retinoic Acid

In this study Retinoic acid (RA) was used as a chemotherapeutic agent by dissolving 7 mg of RA powder in 5 ml (1%DMSO and complete free serum medium RPMI and filtered by syringe filter 0.2 μm to prepare stock solution 5mM. Then diluted with 3 ml of serum free medium until before using for in vitro studies[24]

Cytotoxicity Assay

The cells remained seeded in 96well saucers and were eroded with phosphate cradled saline before vaccinating with and without the Retinoic Corrosive at various focus (400,350,300,250,200,150,100,50,25,12.5). Following 72 hours brooding, the intermediate was suctioned and an absolute of100 µl of MTT arrangement (5 mg/ml in PBS, pH 7.2) remained supplementary to separately well and the plates were hatched for 2 hours at 37 °C. After hatching, 50 µl of dimethyl sulfoxide was supplementary to each well, trailed by delicate shaking for 45 min to dissolve the color of formosan. The receptiveness was resolved on a microplate peruser at 584 nm wavelength. The examine was achieved in triplicate for each of the ailment[25], The repressing pace of cell development (the cytotoxicity level was determined as (IG%) = (a-b)/ax100, where a is the mean optical thickness of untreated wells and b is the optical thickness of treated wells [26]

Apoptosis quantification using acridine orange and propidium iodide double staining:

Acridine orange is an interposing color that can infiltrate equally animate and dead cells. AO will recolor every single nucleated cell to create green fluorescence.

Propidium iodide can just arrive departed cells with poor layer honesty, so it will recolor all dead nucleated cells to produce red fluorescence. Cells recolored with both AO and PI fluoresce red because of extinguishing, so all live nucleated cells fluoresce green and all dead nucleated cells fluoresce red. 1μl Acridine orange stock (5mg/ml) and 1 μl propidium iodid stock (3mg/ml) blending with 1 ml PBS (phosphate cushion arrangement). We included AO/PI to the tried wells after media expulsion from each well and including 50 μl of blend arrangement. Following 20 second we expelled the stain from the well, and quickly saw under fluorescent microscope[27]

Immunocytochemistry

For the disciple cell lines (NB4 and SR) were refined on coverslipes. The cells were permitted to build up a one layer. After this introduction of RA (IC50), after 72hrs. At that point, the cells were fixed with cold CH3)2CO at 2 – 5 minutes, and then expelled cold CH3)2CO and eroded with phosphate-cushioned saline for multiple times and late to dry. Then slides were hatched in a humidified chamber for 10 minutes with H2O2 1% after obsession, eroded a few times with PBS, and brooded with 1.5% blocking reagent for thirty to forty minutes at room temperature. At that point, the essential immune response of the CAS-8, CAS-9, AIF and ENDO G counter acting agent for 1 - 1:30 hrs., eroded a few times with PBS, A while later, include auxiliary immune response and remain for two hrs. It was recolor by the ImmunoCruz™ mouse ABC recoloring framework. Later counterstained with Hematoxylin for thirty to sixty seconds after eroded widely with PBS, and. The slides were mounted with Distyrene, a plasticizer, and xylene, investigated utilizing light microscopy, and
Results

Cytotoxicity of Retinoic Acid:

In this examination, the cytolytic impacts of Retinoic Corrosive on hematological danger cell lines, ordinary HBL – 100 cell line, were dictated by estimating the cytotoxic portion that execute half of the cell populace when contrasted with the untreated control for 72 hr. utilizing colorimetric cytotoxicity test (MTT). The examine was rehashed multiple periods. The level of feasible cells was conspired against RA and the various fixations (400, 350, 300, 250, 200, 150, 100, 50, 25, 12.5 µg/ml). qualities were resolved after 72 hr. RA indicated cytotoxicity impact on lymphoma SR cell line and human different myeloma (COLO 677) and Human monocytic leukemia (THP1) and Intense promyelocytic leukemia (NB4) cell lines and HBL-100 ordinary cell line in portion subordinate way. The outcome was a noteworthy (p<0.0001) increment in RA cell passing and cytotoxicity sway on hematological threat and low cytotoxic on HBL-100 typical cell line. (Figure 1, A, B, C, D and E)

A: Showing the RA’s cytotoxicity impact on the cell line COLO677
B: Showing the RA cytotoxicity impact on NB4 cell line

C: Showing the RA cytotoxicity impact on the SR cell line
D: cytotoxicity effect of the RA on THP1 cell line

E: Cytotoxicity effect of the RA on HBL-100 normal cell line.

Figure 1: Cytotoxicity effect of the Retinoic Acid on Five different cell lines, represented by (A, B, C, D, and E).
Quantification of apoptosis using propidium iodide and acridine orange double staining:

This examination was done to recognize the changes in morphology and the extents of apoptotic, necrotic and typical feasible cells in the number of inhabitants in SR and NB4 discilpe cell lines presented to RA at IC50 for 72 h contrasted with untreated cells. AO will recolor every single nucleated cell to create green fluorescence. Propidium iodide can just arrive departed cells with pitiable film integrity, so it will recolor all dead nucleated cells to produce red fluorescence. Cells recolored per equally AO and PI fluoresce red because of extinguishing, so all live nucleated cells fluoresce green and all dead nucleated cells fluoresce red. The percentage of viable SR cells unprocessed with RA gave 76.615% at 72 h but the percentage of apoptotic cells had significantly (p < 0.001) and gave 117.519%, at 72 h. On the other hand, The percentage of viable NB4 cells untreated with RA gave 75.105% at 72 h but the apoptotic cells percentage had significantly (p < 0.0001) and gave 105.62% at 72 h. as shown in (Figure 2).

Figure 2: The apoptotic by use acridine orang stain: (A) control viable green cells SR cell line, (B) cell infected with RA red cell SR cell line, (C) control viable green cells NB4 cell line, (B) cell infected with RA red cell NB4 cell line
Immunocytochemistry

Immunocytochemistry results showed that NB4 and SR cell lines were sure for ward pathway CAS-8 and CAS-9 and positive for free pathway AIF and Endonuclease G this test was done to affirm that focused treatment utilizing Retinoic Corrosive is compelling and the focused on antigen is available. The outcomes exhibited that the action of caspase-8 was altogether (P>0.0001) and caspase - 9 was essentially (P>0.001) (expanded in both cell lines treated with RA (Figure 3).

This affirmed by utilizing explicit monoclonal antibodies for caspase 8, 9 (ward) and AIF and Endonuclease G proteins for apoptosis. lymphoma SR cell line, Intense promyelocytic leukemia NB4 cell line were recolored positive for articulation of caspase 8,9, AIF and Endonuclease G proteins in the tumor cells, This test was done to distinguish RA prompting apoptosis component in various cells in vitro after 72 hr. from contamination, (Antigens in tainted cells stains dark colored). Uninfected cells do not stain. (Nuclei stain blue by counter stain).

Figure 3: Immunocytochemical study of lymphoma SR cell line (A1) control, (A2) CAS-8 antibody, (A3) Analysis, (B1) control, (B2) CAS-9 antibody, (B3) analysis, (C1) Control, (C2) AIF antibody, (C3) Analysis, (D1) Control, (D2) EndoG antibody, (D3) Analysis, (DAB stain) Magnification: 20×.
Discussion

The aim of this study was to investigate the involvement of caspase dependent or independent way of apoptosis through infection by Retinoic Acid.

In this investigation, we have assessed the potential antitumor impacts of the RA in leukemic cell lines. Our information demonstrate that RA applies antiproliferative and proapoptotic or separation initiating impacts in hematological cell lines. High convergences of RA gave low cytotoxicity practically identical with low Focuses, which was trailed by cell passing following 72 hours. Conversely, low convergences of RA instigated apoptosis. These information demonstrated that RA applies portion subordinate proapoptotic and antiproliferative impacts in leukemic cells. Moreover, a factually huge lower cell executing of typical HBL-100, It is discovered that, RA have been explored widely for their utilization in strong tumor disease counteractive action and treatment[29].

Retinoic destructive may be gained from either through the consistently use of plants in a reasonable eating regimen or through supplement upgrades. Under common conditions in the body, retinoic destructive does preventive kill threatening development course of action. After dangerous development course of action, retinoic destructive transforms into an attacker to illness cells, one that discourages their advancement and division moreover triggers their partition and going through express pathways[30].

In general, RA causes a square in the cell cycle stage G1, with an expansion in the extent of cells in the stage G0/G1 and an abatement in the extent of cells in the stage S [31]. RARβ2 is inducible to RA and is the prevalent receptor that intercedes the inhibitory effects of RA on cell proliferation [32, 33].

In this study, we showed that RA repress the development and actuate the apoptosis of RA-safe hematologic tumor, gave that they are additionally fit for initiating the caspase ward or caspase free pathway. The apoptotic cells concoction and morphological changes can be separated from any other cell demise through numerous strategies. In this investigation, affirmation of apoptosis started by RA was finished utilizing the minute assessment. AO/PI recoloring affirms that RA in cell societies instigates cell passing by means of the apoptotic pathway, the quantity of apoptotic cells uncovered that in treated hematologic cell lines the level of apoptotic cells relatively expanded with post-immunization time. Identification of the acridin orang and propidium iodid strategy (AO/PI) gives an early sign of the commencement of cell apoptosis[27].

RA is viable at the phone multiplication and separation just as the counter malignant growth capacities during the procedure of carcinogenesis (Zhu and Luo, 2016). RA have various receptors RAR, RXR and RARγ act with various pathways as Wnt/β-catenin and β-catenin/TCF, the RAR and RXR receptors restrain Wnt/β-catenin, while RARγ receptor goes about as a tumor oncogene lead to the actuation of Wnt/β-catenin pathway [34], these methods the RA demonstrations in two inverse ways, relied upon its receptors. While, RA repress malignancy cell expansion [34].

Retinoic acid likewise initiates the NF-κB endurance pathway [35, 36], ATRA prompts the outflow of cIAP2 and TRAF1 within the sight of elevated levels of cIAP1 and TRAF2 mRNAs, The attending articulation of these variables is thought to build up a complex at the TNF-R1 that prompts actuation of NF-κB by means of the NIK-IKK-IκB flagging course with the outcome that TNF-α, rather than inciting apoptosis, sets up a NF-κB–interceded autocatalytic endurance loop[37].

Quantitative picture examination for the immunocytochemistry test uncovered expanding in articulation of caspase-8 and caspase-9 (caspase subordinate pathway) in SR and NB4 cell lines. Caspase-8 was distinguished as an initiator caspase activated by death receptors. Along these lines, the initiation of caspase-8 recommended that RA may instigate apoptosis through the outward demise receptor-pathway. cells was seen in the immunocytochemistry measures, as contrasted and untreated cell Examinations of the component of RA-prompted cell passing demonstrated mitochondrial depolarization, translocation of phosphatidylserine to the cell surface, enactment of caspases, and DNA discontinuity, proposing apoptotic cell demise. To explicitly inspect the job of caspase-8,9 in RA-prompted apoptosis[38]. Late investigations have demonstrated that RA instigated Ca2 discharge from the endoplasmic reticulum in skin, bosom, and lung...
malignancy cells, and that Ca2 chelation hindered the apoptogenic impacts of CDDO [38]. Strangely, Ca2 can trigger AIF discharge from the mitochondria [39], which could conceivably provide a link between endoplasmic reticulum stress and caspase-independent cell death.

Notwithstanding the counter apoptosis exercises of BCL2A1 and NFκB, retinoic corrosive invigorates the articulation of the apoptosis inhibitors cIAP2 as well as of NAIP. Overexpression of IAPs restrains apoptosis instigated by master apoptotic BCL-2 relatives through their immediate official to the effectors casp-3 and casp-7, the initiator casp-9, and its expert enzyme19. Additionally, the retinoic-corrosive induced39 articulation of casp-8, which transfers TRAIL activity in the Plate, may encourage TRAIL–interceded destruction of leukemia blasts[40].

In conclusion, our study suggests that the Retinoic Acid is a very promising anti-hematological malignancy agent that found to act by inducing apoptosis through caspase dependent and caspase independent pathways of apoptosis.

Non-Hodgkin’s Lymphoma in the Parotid Gland Similar to Benign Lymphoepithelial Lesion: A Case Indonesian Male

Muhammad Arif Sudianto Utama¹, Widodo Ario Kentjono²
¹Resident, ²Assistant Professor, Department of Otorhinolaryngology - Head and Neck Surgery, Faculty of Medicine, Universitas Airlangga - Dr. Soetomo General Academic Hospital, Surabaya 60286, Indonesia

Abstract

Background: Primary parotid non-Hodgkin’s lymphoma (NHL) is a very rare case. Case presentation: A 66-year-old Indonesian male with a complaint of a lump in front of the right ear about 1 year with a history of postoperative primary parotid NHL 3 years ago. Patients underwent Fine Needle Aspiration Biopsy (FNAB) examination, showing a distribution of lymphoid cells with a diverse population (benign lymphoepithelial lesion / BLL) different from the results of FNAB 3 years ago. The patient underwent a right superficial parotidectomy, and the results of the histopathological examination revealed mature lymphocyte cells mixed with histiocytes, forming foci of the follicle in part with an active germinal center. Conclusion: NHL reports are necessary to minimize misdiagnosis between primary parotid NHL and BLL.

Keywords: non-Hodgkin’s lymphoma, benign lymphoepithelial lesion, parotidectomy

Introduction

Non-Hodgkin lymphoma (NHL) is found in 86% of all lymphoma cases, with a rough estimation of 90% covering B cell lymphoma. About 2-5% of primary NHL occurs in the head and neck region, one of which is in the parotid gland. Parotid gland NHL cases are very rare, limited to small and closed case series reports. Primary parotid gland NHL accounts for only 0.5-0.87% of all NHL cases, with increasing prevalence in the last few decades [1,2].

The diagnosis of primary parotid gland NHL in patients is difficult because of the extremely rare number of cases. In NHL case, lymphatic nodules are generally biopsied, whereas computed tomography (CT scan) / magnetic resonance imaging (MRI) only infoms about the origin of the malignancy and extraparotid expansion. To date, there have been no pathognomonic findings that indicate lymphoma on CT or MRI scans [3-5]. The purpose of reporting this case is to inform that there are similarities between the diagnosis of primary parotid gland NHL and benign lymphoepithelial lesion (BLL).

Case Presentation

A 66-years-old Indonesian male with complaints of a lump in front of the right ear about 1 year. The lump is enlarged slowly. The patient had surgery for the right parotid gland tumor 3 years ago. The results of the Fine Needle Aspiration Biopsy (FNAB) at that time showed the distribution of lymphoid cells of various maturity with some forming germinal centers. Visible groups of salivary gland epithelial cells also showed BLL.

The results of histopathological examination of postoperative tissue showed pieces of tissue consisting of dense proliferating lymphoid cells, small to medium sized, monotonous, smooth chromatin, diffused narrow cytoplasm, infiltrative between salivary glandular tissues. There were still follicles with germinal centers among them. Mitosis was difficult to find, and there

Orcid id: 0000-0002-1378-089X
was a normal salivary gland remained at the edge. A low-grade lymphoma was found in accordance with the description of lymphoepithelial sialadenitis (Mikulicz disease). Advice from anatomic pathology to ensure immunohistochemical examination in this preparation. Immunohistochemical results showed positive CD20 in lymphocyte cells surrounding the epimyoepithelial island, positive CD3 in T cells between follicles, and Ki67 was limited to germinal center. In accordance with the description of benign lymphoepithelial lesion (Mikulicz disease).

Physical examination found no abnormalities in ear, nose, and throat, as well as no cervical lymph node enlargement. The parotid gland had a mobile mass with a size of about 3x2x2 cm, dense and springy, flat surface, no tenderness. Intact right facial nerve (House-Brackmann scale grade I). Physical examination of axillary and inguinal glands did not reveal a mass (Fig. 1). Laboratory test results were normal, serological hepatitis B virus and negative hepatitis C virus.

FNAB showed smears with diverse lymphoid cells distribution. Unclear epithelial cells; showed lymphoid hyperplasia. Tumor excision was recommended for histopathological and immunohistochemical confirmation if necessary, because it had not been able to get rid of low-grade lymphoid neoplasms. MRI examination with contrast obtained a solid mass of size 5.4x1.7x3.9cm; indistinct border of irregular edge in the right parotid region. Contrasting obtained heterogenous contrast enhancement. The lesion appeared attached to the right masseter muscle. The conclusion supported the picture of benign parotid mass of the right muscle (Fig. 2).

Based on available data, a BLL type of parotid tumor was established. A week after the diagnosis, a right superficial parotidectomy surgery was performed with Blair’s modified incision. The skin incision was deepened into the subcutaneous tissue and platelet musculature to identify and preserve the right facial nerve branches, then proceeded with tumor removal (Fig. 3). The size of the tumor obtained was about 40 cm². The tumor tissue was sent to the anatomic pathology installation for histopathological examination (Fig. 4).

The results of post-operative histopathological examination showed extensive infiltration of lymphocytic cells surrounding the remaining glands and ducts that were pinched to form epimyoepithelial nests. Lymphoid tissue consisted of mature lymphocyte cells mixed with histiocytes, forming foci of the follicle with some active germinal centres. This description supported Mikulicz disease or lymphoepithelial sialadenitis, concluded Lymphoepithelial sialadenitis/BLL (Mikulicz disease).

Furthermore, the patient was recommended to have immunohistochemical examination. The results showed negative CD3 in tumor cells, positive in mature lymphocyte cells, positive CD20 in diffuse and condense on tumor cell membranes, and Ki67 etched 505 in tumor nuclei, immunoarchitecture supported non-Hodgkin lymphoma B cell type which could come from MALT lymphoma.

The results of the data obtained concluded that the patient was diagnosed having a right parotid NHL, postoperatively obtained right facial fascia (House-Brackmann scale II-III) which was subsequently recovered with physiotherapy, especially the submandibular marginal branches and right buccal. Subsequent therapy included chemotherapy with a combination regimen according to NHL for 6 cycles. Control in the second month after surgery showed that the function of right facial fascia nerve had begun to recover, although it still looked a little paresis (House-Brackmann scale grade II), especially the right lip corner. Control in the fifth month after surgery did not show any residual mass on the right parotid, the right facial nerve function was visible again (House-Brackmann scale grade I).
Figure 1. Physical examination shows a mass in the right parotid gland

Figure 2. MRI with contrast shows indistinct solid borderline lesions, irregular margins in right parotid region
Discussions

In this case, a CT scan was not performed but an MRI examination was immediately performed. A solid border lesion was found with an irregular border in the right parotid region. A heterogeneous contrast enhancement appeared; the lesion was attached to the right masseter muscle. The radiological features of parotid gland NHL were rarely well described. According to Corr et al., who presented a cohort study of 10 HIV-infected children with parotid gland NHL, a CT scan of the lesion contained a muted hypoechoic solid nodule, which was similar to hyperplastic lymphoid tissue or lymphoma. These lesions are cystic (from compression of the parotid duct terminal with adjacent hypoplastic or neoplastic lymphoid tissue) and separate with calcification, both intracystic and parenchymal can coexist. These radiological features have been described in the BLL found in patients with AIDS or Sjögren’s syndrome [4,6-8].

An FNAB examination had been conducted twice, with first examination showing a Mikulicz disease. The second test was carried out three years ago because a lump appeared again in the same place, and the conclusion was a lymphoid hyperplasia. The results of this FNAB indicated the origin of a malignancy that leads to NHL, as this finding is consistent with the literature. Preoperative FNAB from a suspected tumor and radiological examination in certain cases is part of the preoperative examination of parotid gland lesions. Parotid gland NHL is difficult to diagnose through FNAB cytology. FNAB examination for head and neck region NHL is the subject with the highest error rate of all FNABs in the head and neck, with a false-negative rate of 32%. Although FNAB can definitively diagnose...
lymphoma in some patients, tissue biopsy has a much higher accuracy \[4,6,7,9\].

A parotid surgery was conducted with a superficial parotidectomy approach with the aim of the diagnostic process and the therapeutic process. Patients with localized parotid gland tumors, in general, is highly recommended for surgical or surgical management to diagnose parotid gland NHL because histological evaluation is very important to treat NHL. Parotid surgery is recommended for therapy as well as to confirm histological diagnosis and further follow-up planning. The prognosis of patients with parotid gland NHL so far will be good if diagnosed immediately. Limited data shows that 80% of patients have a five-year survival rate \[3,4,6,7\].

This case, after being diagnosed as NHL type MALT parotid gland, immediately performed chemotherapy with NHL-compliant regimens. The patient was followed during chemotherapy and no residual mass was found after control for 6 months, showing an excellent therapeutic response. Diagnosis of NHL must involve an in-depth evaluation of the involvement and spread of the same disease must be carried out in other locations before starting local therapy. Radiotherapy and chemotherapy must be considered after surgery to eradicate spread or residue. Irradiation in cases of lesions localized in the early stages and chemotherapy in the advanced disease stage. Isobe et al., treated 37 patients with stage 1E extragastric MALT LNH with only radiotherapy, and around 97.3% of patients received an increase in the number of free survival rates over a three-year period of 91.9%. So far chemotherapy in patients with NHL is still a very sensitive therapy using the CHOP protocol (cyclophosphamide, doxorubicin, vincristine, and prednisone) \[2,5,10\].

This case has no lymph nodes or involvement of other organs, but only limited to the history and physical examination of the axillary and inguinal glands. This indicates that this NHL case is not a systemic type and is limited to the right parotid gland or primary to the parotid gland. Salivary gland NHL tends to be more aggressive and can occur in regional or distant lymph nodes in other organs. According to Wenzel et al., therapy with local surgery of patients with head and neck NHL has a relatively high risk of experiencing initial spread or recurrence \[2,5,10\].

**Conclusions**

A very rare and suspicious parotid NHL case has been reported as a transformation from BLL or Mikulicz disease. Primary and secondary NHL in the parotid gland are clinically indistinguishable from benign tumors or other malignant lesions. The imaging modality and cytology of FNAB does not always help, so the majority of patients require parotidectomy for diagnosis and therapy.

Abstract

Smoking cases at the age of children less than 18 years will have a very fatal impact because considering the age of the child who is still growing. GETAR (Movement without Smoking) spiritual approach uses the concept of religion, which in this case is exemplified by Islam by helping individuals to find their nature. The purpose of this study is to analyze the effect of the GETAR spiritual approach on smoking behavior of junior high school students in Palu City, Indonesia. This type of research is a quasy experiment. The sample consisted of 35 smokers in grade 7, 8, and 9 at SMPN 1 Palu as an intervention group, with saturated sampling technique, and 35 students in grade 7, 8, and 9 at SMPN 4 Palu. The data were analysis with paired sample t test and independent sample t test. This study showed that there are differences in knowledge (p = 0.000), attitudes (p = 0.000), and actions (p = 0.000) students of SMPN 1 Palu about smoking before and after GETAR spiritual intervention. And there are differences in the knowledge (p = 0.000), attitudes (p = 0.020), and actions (p = 0.000) between students who were given GETAR spiritual intervention (students of SMPN 1 Palu) and those who were not given GETAR spiritual intervention (students of SMPN 4 Palu). It concludes that there is a difference in the knowledge, attitudes, and actions of SMPN 1 Palu students about smoking before and after the spiritual intervention of GETAR. And there is a difference in the knowledge, attitudes, and actions of students between those who were given the spiritual intervention of GETAR (students of SMPN 1 Palu) and those who were not given the spiritual intervention of GETAR (students of SMPN 4 Palu).

Keywords: GETAR, Spiritual, Smoking, Behavior

Introduction

Smoking cases at the age of children less than 18 years will have a very fatal impact because considering the age of the child who is still growing. In addition to having an impact on health, it will also have an impact on the child’s future, because children have a strategic position in the life of the community and nation. There is no reason to assume that only those who deviate have the urge to do so, even people who have a good understanding of religion sometimes have the urge to behave deviantly, especially those who have less understanding of religion.

Interventions at the age of children tend to be more effective in preventing children from smoking when compared to adults who, if addicted to smoking, are very difficult to stop. Smoking, from ancient times until now for students is a serious offense. Anyone caught...
smoking, be prepared to receive punishment. As the rules for smoking prohibition in school environments get tighter, it turns out that the number of child smokers continues to grow.4

A spiritual approach is a solid foundation to build future generations of excellence. The advantage of GETAR spiritual intervention is that students are provided with assistance and provided with various educations about the verses of the Al-Quran and Hadiths about the prohibition and dangers of smoking and its impact on negative behavior and health. Suitable for children because they are still in their growing age and can form a good perception as early as possible about the dangers of smoking and non-smoking behavior through the presentation of interesting intervention materials, accompanied by interesting language and pictures. The substance of GETAR spiritual approach is material about the history of tobacco, various ways of smoking, smoking motivation, various kinds of diseases caused by smoking, children and the dangers of smoking, Islamic attitudes towards smoking, the benefits of leaving cigarettes, and how to avoid smoking.

WHO (World Health Organization) data in 2015 shows that the prevalence of active smokers in the world currently reaches 17.4%. The National Basic Health Research (Riskesdas) data in 2018 shows that the prevalence of Indonesian smokers in the population aged 10-18 years continues to increase, namely in the Riskesdas data in 2013 of 7.2%, 2016 National Circular Survey data of 8.8% and in the data Riskesdas in 2018 increased to 9.1%. The data presented shows that there is an increase in the prevalence of smokers aged ≥ 10 years in Central Sulawesi, by 30.7% with the number of smokers every day at 26.2% and smokers sometimes at 4.5%. Data related to age starting smoking every day for ages 10-14 years, the city of Palu ranks third largest in Central Sulawesi at 13.5%.

Seeing the problem above, the researcher was interested in conducting research on is there an effect of GETAR spiritual approach on the smoking behavior of junior high school students in Palu City, Indonesia. The purpose of this systematic review is to analyze the effect of the GETAR spiritual approach on smoking behavior of junior high school students in Palu City, Indonesia.

MATERIALS AND METHODS

This type of research is a quasy experiment. The sample consisted of 35 smokers in grade 7, 8, and 9 at SMPN 1 Palu as an intervention group, with saturated sampling technique, as a control group, and 35 students in grade 7, 8, and 9 at SMPN 4 Palu. The data were processed using univariate and bivariate analysis with paired sample t test and independent sample t test.

Table 4 showed that because the \( p = 0.000 \) (knowledge and action) and \( p = 0.020 \) (attitude). This means that there is a difference in the knowledge of students between those who were given GETAR intervention (students of SMPN 1 Palu) and those who were not given GETAR spiritual intervention (students of SMPN 4 Palu).

**Discussions**

Knowledge is the result of knowing, and this happens after someone senses a certain object\(^8\). Based on research results, GETAR spiritual intervention has been proven to increase students’ knowledge about smoking. GETAR intervention can be a differentiator in determining students’ knowledge about smoking.

In line with the research of Nuradita et al which shows that there is an effect of health education on knowledge about the dangers of smoking in adolescents at SMP Negeri 3 Kendal with \( p \) value = 0.000\(^9\). A research states that there are differences in the knowledge of adolescents before and after health promotion about the impact of smoking on school children at SMPN 1 Klari\(^{10}\). Fahrosi’s research shows that there are differences in the level of knowledge about the dangers of smoking in junior high school adolescents in rural and urban areas in Jember Regency. There are differences in the level of knowledge of adolescents in rural and urban junior high schools due to differences in information obtained from adolescents. The difference in media that can be accessed by teenagers is also a factor that affects the level of adolescent knowledge about the dangers of smoking. Other factors that cause differences in the level of knowledge include age and gender\(^{11}\).

Peer-led interventions are effective in increasing respondents’ knowledge regarding smoking. Continuing health education programs must be prepared in schools\(^{12}\). Sherman et al.bast research shows that pharmacy students and community leaders showed increased knowledge after smoking cessation educational interventions, and pharmacy students experienced an increase in self-confidence scores. Developing a coalition of health care providers and community leaders, with a focus on their respective roles, may be productive in initiating smoking cessation programs\(^{13}\). Ghrayeb research shows that health education is effective in increasing smoking knowledge. It is recommended that community-based health education programs and continuing schools about smoking should be implemented by health professionals\(^{14}\).

Attitude is a reaction or response that is still closed from a person to a stimulus or object\(^8\). Based on research results, GETAR spiritual intervention has been proven to increase students’ attitude about smoking. GETAR intervention can be a differentiator in determining students’ attitude about smoking.

In line with the research of Hidayati et al which showed that there was an influence before and after health education was carried out on attitudes about the dangers of smoking at YWKA high school in Palembang in 2019 (\( p = 0.000 \))\(^{15}\). A research shows that interventions in the form of counseling and giving leaflets to students has a good influence on students’ attitudes about smoking at SMK Negeri 2 Bitung City\(^{16}\). Sulastri & Rindu’s research states that there are differences in adolescent attitudes before and after health promotion regarding the impact of smoking on school children at SMPN 1 Klari\(^{10}\).

Chaaya et al. research’ suggests that educational campaigns, smoking cessation services and strict enforcement of policies may be needed to increase their effect further reducing student attitudes towards smoking\(^{17}\). A Research shows that peer-led interventions are effective at improving respondents’ attitudes regarding smoking. Continuing health education programs must be prepared in schools\(^{12}\). Girls are overall more positive for the attitude component of smoking prevention interventions. Our findings highlight the importance of considering differences in intervention
preferences for boys and girls in future health prevention initiatives\textsuperscript{18}.

Action or practice is an attitude that has not been automatically manifested in an action (overt behavior)\textsuperscript{8}. Based on research results, GETAR spiritual intervention has been proven to increase students’ action about do not smoking. GETAR intervention can be a differentiator in determining students’ action about do not smoking.

In line with the research by Puspitasari et al which shows that self-management training can reduce adolescent smoking behavior, namely 6.5 cigarettes in two weeks. The role of School Health Enterprises (UKS) must be increased by collaborating with educational institutions, especially school counseling teachers, in providing periodic smoking hazard education programs so that adolescents are able to reduce and or stop smoking and prevent other teenagers from having smoking behavior\textsuperscript{19}. To increase the motivation to quit smoking in adolescents, health education can be used in the form of media such as Facebook and leaflet media\textsuperscript{20}. Also, there are significant differences in the psychomotor actions of adolescents before and after being given peer education at SMAN “X” Denpasar. can be used in schools as a method of providing information through peer education to be more effective so that it can influence friends not to smoke and avoid smoking behavior\textsuperscript{21}.

Peer pressure-based interventions reduce the proportion of low-educated adolescents who start smoking. Therefore, influencing social norms and peer pressure would be a promising strategy for smoking prevention among adolescents. The results also suggest that additional interventions in subsequent years are needed to maintain their effect\textsuperscript{22}. Research by Bast et al shows that X: IT intervention has the potential to prevent cigarette absorption among adolescents. Intervention X: IT performed shows the overall effect of smoking prevention. Some of the interventions appear less attractive to children from low socioeconomic families\textsuperscript{23}. Research by Raji et al shows that peer-led interventions are effective at increasing respondents’ actions not to smoke. Continuing health education programs must be prepared in schools\textsuperscript{12}. Students show an overall positive attitude towards public action. Saudi Arabian teenagers have higher smoking rates than those in industrialized countries. They also have uneven knowledge about its negative effects, but show positive attitudes towards public actions on smoking\textsuperscript{24}.

**Conclusions**

Based on the results of this study, it concludes that there is a difference in the knowledge, attitudes, and actions of SMPN 1 Palu students about smoking before and after the spiritual intervention of GETAR. And there is a difference in the knowledge, attitudes, and actions of students between those who were given the spiritual intervention of GETAR (students of SMPN 1 Palu) and those who were not given the spiritual intervention of GETAR (students of SMPN 4 Palu).

Teaching-Learning Styles & Aids Student’s Preferences among first Year Undergraduate Medical Students in the College of Medicine, University of Missan, Iraq

Mustafa M. Al-Yassiry¹, Farah K. Aloraibi², Haider Saadoon Qasim Alhilfi³

¹Head assistant of Clinical Biochemistry Department/Medicine college/University of Missan (government)/ Misan, Iraq, ²Head assistant of Dentistry Department/Almanara College University (private)/ Misan, Iraq. ³Assistant Professor; F.I.B.M.S, Academic Dean Assistant, Faculty of Medicine, University of Misan, Misan, Iraq

Abstract

Objectives: to collect feedback from first year medical students on their perceptions and preferences of different teaching, learning, and aids methods that are currently used in medical chemistry teaching course. The aim of our study was to compare the more acceptable teaching & aids methods among the first stage medical students, Missan Medical College. So that best teaching aid and method can be adopted to improve their academic performance.

Materials and Methods: a well-structured electronic questionnaire based study was carried out on undergraduate medical students at department of clinical biochemistry, medical college, Missan University, Missan province, Iraq in second semester of academic year 2020-2021. 197 students participated out of 204 total, giving 97% response rate, the questionnaire was properly explained. The students were asked to grade teaching, learning, and aids methods that were used to teach Medical Chemistry module. The responses was analysed according to the Likert scale to detect their preferences and favourites toward the statements in the questionnaire.

Results: In our study many items with high satisfaction and least preferences grades was noticed for combination of teaching, learning, and aids methods. The majority (76%) of the students like the subject of medical chemistry. Exams preparation techniques, practical exercise lectures, various teaching aids and other methods have been found excellent and very good methods by the majority of the students. For effective teaching of medical chemistry, students opinions and preferences were suggesting a clear mandate in different issues such as usefulness of more preparations techniques for main exams, using more than one teaching aids (white board + power point presentation) in the lecture. By understanding students perceptions, teaching learning precesses in medical chemistry can be improved.

Keywords: Medical Chemistry, Biochemistry, teaching methods, Medical Student, learning style, Teaching Aids, First year.

Introduction

One of the essential components during the initial year in medical schools is the medial chemistry as a part of the Iraqi and worldwide curriculum. The medical chemistry course consisted of teaching analytical chemistry, organic chemistry, and basic biochemistry such as basic principles and applications of analytical chemistry in the medical field, and detection of inorganic elements by qualitative techniques, using specific reagents to distinguish between organic compounds evaluations acid-based concentrations by using titration methods as a quantitative technique. While In basic biochemistry students need to learn basic biochemistry objectives including carbohydrates, lipids, and proteins with its classifications and general properties. Normally the term of learning styles refers to the learning methods of gathering, organisation, and processing, interpreting think about information or to a set of factors including attitude, behaviour that makes the learning for individuals easier. In general identifying or knowing
the learning style is very important for understanding the differences amongst the learners and making the learning process stronger in the area of power and supporting the weaknesses in every style giving the learning tool better design and developments. According to Fleming (1995): Students who prefer visual learning are able to process the information best if they can see it with best understanding and learning from using materials presentation such as chart, graphs, pictures and diagrams on the other hand some students likes to get their learning through presenting and discussion of the information and they process it through attending tutorials, listening to the lectures and playback recorders of any learning sessions. Other types of students called “r” are learners who prefer to process information through reading and writing as well as some students also called kinaesthetic learners “k” better understanding of the information by experience and material practicing that have linked to the reality and they preferred the examples and the application to be from the concrete type every faculty members needs to address this concern by understanding the learning attitude and styles preference of their students where the learning style can be recognized as the manner and conditions under making the learner most efficiently and effectively perceives, stores, processes and recalls what they’re attempting to learn. Learning styles is a complex field with more than 70 different models and aspects and the most successful methods that meet the students preferences and likeness targeting better academic grades and performance. Furthermore, medical students currently represent a wide spectrum in regards of experience, ethnicity, age, culture and preparation level alongside with their learning preferences and styles. This diversity is more welcome as well as it challenges the instructor to meet the educational needs of all the students, where the student can improve with the learning preference and styles with the adopted instructions together. Therefore the instructor is responsible to be familiar with that diversity of learning styles and develop appropriate learning approaches.

Materials and Methods

This study was carried out among undergraduate first year medical students, the students were asked to complete the questionnaire and the students were informed that their participation in this study was voluntary. The questionnaire (25 statements) consisted of two parts, the first part was views or opinion questions about current teach-to-learn processes of current Medical Chemistry module and get the relevant information depending on the students’ responses to target future improvements and modifications. The second part of the questionnaire was about teaching learning methods & aids split into two halves (10 questions, five questions each) primary, regarding various learning styles like best methods exams or exam preparations and next concerning teaching aids and students preferences methods of delivering lecture such as, whiteboard, power point presenter, scientific videos, pictures and models. The Medical Chemistry modal was mainly twice a week (3h) and once a week for practical classes based on a pre-formatted time table. The aim of this study was explained to the students without unfolding the possible result as we asked the students in the beginning of this questionnaire about their names, sex. Then their responses were assessed by Likert type scale from 1 to 5 (Strong disagree, Disagree, Neutral, Agree, Strongly agree), only one question were on yes or no or neutral basis, this question is Do you like medical chemistry? The Microsoft excel worksheet was used to analyze the collected data.

Results

The questionnaire was consented and completed by total of 204 first stage medical students among them only 197 questionnaire responds were completely filled up and taken into analysis, consisting 74 males and 123 were female participate students. See figure 1.
In regards in the degree of liking and references to the medical chemistry module, the only question which was responded by all students was the first question and the results showed as following 76% of the students liked the subject of medical chemistry, 6% didn’t and 18% neutral.

Teaching learning methods & aids in Medical Chemistry

Various teaching learning methods were found by students preferences to be most popular, interactive, and very useful in the students minds such as monthly exams with a lesser topics, having an pre- exam (marks countless) before the main exams, preparing to the main exams through a lot of problems solving duties or homework’s, and using viva voce exams could facilitate understanding learning, as well as supersizing or prepared quizzes got a good percentages of Students’ acceptance and preferences as the Quizzes help students identify what they know and what they don’t know, and will give the students a better idea how they should grasping the materials and give them the motivation for more studying. See figure 2
The following part of the questionnaire outcomes was an overall assessment by encouraging the student’s to put their own observations related to the most appreciated and least appreciated method or aids, as useful suggestions was provided by the learners making the lecture session more interactive by inclusion of using educational materials in the medical chemistry lecture. The medical students of Missan medical college clearly preferred to use the educational method which is white board only\textsuperscript{17}. See figure 3.

![Graph showing opinion of 1st medical students towards the various teaching aids used for Conducting Medical Chemistry theory classes.](image)

On other hand, the whiteboard + PowerPoint presentation method was the most preferred method among first stage medical college and was much appreciated. Furthermore the questionnaire results present more affinity towards using diagram, picture, and videos in the lecture. From the main reason of preferring the method that contains whiteboard, this method can make the student & teacher interaction develop and there will be less chance of attention diversion, maintenance of a good eye contact and the contents are easy to understand, while with the PowerPoint method being in favour from students to this technique because it can provide text, diagram and images on the same slide with good quality, so it is clearly legible and more interesting\textsuperscript{18}. The medical students of Missan medical college clearly preferred to use the educational method the use of white board only, while the (whiteboard + PowerPoint presentation) method was the most preferred method among first stage medical college and was much appreciated. Furthermore the questionnaire results present more affinity towards using diagram, picture, and videos in the lecture. From the main reason of preferring the method that contains whiteboard, this method can make the student & teacher interaction become better and there will be less chance of attention diversion, maintenance of a good eye contact and the contents are easy to understand, while with the PowerPoint method being in favour from students to this technique because it can provide text, diagram and images on the same slide with good quality, so it is clearly legible and more interesting\textsuperscript{19}. 

---

\textsuperscript{17} The study of medical chemistry for the first stage is considered useful and easy for first stage medical students.

\textsuperscript{18} Are first-stage students facing difficulty in the English language offered and translated in medical chemistry lectures?

\textsuperscript{19} Do your instructors give enough opportunity to clarify doubts of students in the Medical Chemistry lectures?

\textsuperscript{18} Do you think that the language of lectures presentation is simple to the student to learn?

\textsuperscript{19} Does the character and strength of the lecturers influence his improvement in his teaching method of medical chemistry?
Perceptions and opinions towards improving teaching learning of Medical Chemistry:

The results come out with High percentage of agreements and support from the students which were appeared from their responses related to how much beneficial for the first year students to study medical chemistry, the English language during learning process of medical chemistry is difficult, chances obtaining and enough time was given to the students to get the answers for their questions, the scientific language that is used in the medical chemistry lectures simple to learn and understandable, there much effect of lecturer characters strength on the students which improve his teaching methods. See figure 4.

![Figure 4: Perceptions and opinions towards improving teaching learning of Medical Chemistry](image)

Additionally, the collected data was also shown the student approval and acceptances to supporting summaries of the topics should be given at the beginning of medical chemistry lectures, outlined concepts are understandable to the learner as the summarization of key concepts at the end of the lectures is so important, while the responses in regard the division of Medical Chemistry subject into three sections which consist of Biochemistry, Analytical, and organic chemistry was displayed the most students felt that that division is necessary, for better understanding of the Medical Chemistry various and interesting aspects, also, students feel that the practical side of medical chemistry is very valuable where the experiments are an essential part of the undergraduate medical curriculum, See Figure 5.
Discussion

Student’s perceptions and views in the present study about their experience toward the teaching learning methods & aids during the first year of study in Missan (Government) university, medical college, were documented. The publications on the student’s preferences and opinions about medical chemistry objective very less. Currently the medical chemistry module is being taught of 1 year in medical colleges of Iraq. However the issues that are discussed in this article and the students perceptions about it are unlikely to differ significantly with the other countries even in case of different curriculum or in case of a longer duration of the cause.

Conclusion

The feedback that are given by the students was very helpful and had facilitate a change about the currently used teaching learning and aids principles in the preconceived notions and their opinions and preferences needs to be taken into consideration to fill the gaps between and the current medical education system and to make the teaching learning processes more meaningful and students friendly. Recommendation, will be very useful to the teaching learning & aids community to do further studies on validating the students perception & preferences. The results of our survey reports, it’s showed there was difference of perception towards teaching methods between the students. This study actually highlighted some students preferred learning methods &
aids clearly confirmed that a good understanding of the lecture doesn’t rely on teaching methods but it depends on the teacher. Because if the teacher is attentive and deferential and well trained any method he uses would be effective, teaching is the quality of a teacher not the quality of teaching technology. In teaching technologies formal training is needed to improve the presentation leads the student for more interactive, motivation and high level of academic performance.  

Acknowledgements: Thanks and appreciation to all undergraduate first stages medical students, Medical college, Missan University, academic year 2020-2021, for their perfect collaboration and participation to answer the questionnaire statements and expressing their suggestions with preferences to have more interactive and informative lectures.

The Exposure of Gap Competence causes in Stunting Children Ages 0-12 Months in Makassar Indonesia: Cross-Sectional Study

Mustamin¹, Sirajuddin², Mahmud³

¹Associate Professor, Department Dietetic Health Polytechnic of Makassar, at Paccerakkang KM14 Daya Makassar, South Sulawesi Indonesia, ²Associate Professor, Department Nutrition and Dietetic Health Polytechnic of Makassar, at Paccerakkang KM14 Daya Makassar, South Sulawesi Indonesia, ³Scientist, Department Community Nutrition Health Polytechnic of Maluku, at Laksdya Leo Wattimena, Negeri Lama - Ambon Indonesia.

Abstract

Introduction, The parenting gap is believed to be one of the variables that influence stunting. The Objectives of this study to identify gaps in care (feeding practices, care, hygiene, and treatment of children) and incidence of stunting. Method this study is a cross-sectional, conducted in March-June 2020 in Makassar City Indonesia. The sample size was 82 people, of children aged 0-12 months. The data collectors are alumni of applied nutrition and dietetics degrees, trained for 2 days in health protocol, interviews, and anthropometry. The instrument in this study was developed from the UNICEF. The result, found that mothers and fathers graduated from high school, 43% and 59.8%, respectively. The work of mothers as housewives is 84.1% and fathers are private employees as much as 36.6%. The parenting competency gap in the feeding practice of children aged 0-6 months, 7-9 months, and 10-12 months is 20.9%, 71.79%, and 92.31%, respectively. The results of statistical analysis showed that there was an effect of parenting competency gaps on stunting ($p = 0.000$). The conclusion is that the parenting competency gap is proven to affect the incidence of stunting. The suggestion is that it is necessary to increase the capacity of mothers in child care practices.

Keywords: Parenting Competency Gap, Stunting

Introduction

Currently, the most serious nutritional problem in Indonesia is stunting. The national prevalence of stunting is 36% and South Sulawesi reaches 30.8%. The impact caused by stunting is low academic potential, high risk of non-communicable diseases, high-cost burdens on health services, and low productivity. The problem of stunting must be prevented because the incidence of stunting from birth is difficult to treat. This means that starting from pre-pregnant and pregnant should intervene with nutrient-rich foods of local potential (1), (2), (3).

Prevention of stunting is best done through the consumption of foods of sufficient quality and quantity during pregnancy up to 2 years (3), (4). The problems faced in meeting the quality and quantity of food according to nutritional needs are income, preferences, availability, and nutritional knowledge. Sufficient income guarantees food diversification and food availability. The problem is only in consumer preferences, which limit a variety of food choices, including children’s food. If the caregiver does not understand how to feed the child, the effect was low consumption of nutrients. The longer this happens, the exposure, the greater the risk of stunting (5), (6), (4).

Maternal competence is not only feeding practice but also hygienic practice and child care practice (7), (8), (9). This competency component should be owned by mothers before having children. In this context, it stands to reason that maternal nutritional literacy is urgently needed (10). Studies are needed to measure the effect of...
the competency gap above the risk of stunting.

**Objectives**

Analyzing the effect of competency gaps on stunting of children aged 0-12 months

**Methods**

**Design and Procedure**

The research design was a survey with a cross-sectional study. The sample size is calculated based on the following sampling formula (11). Based on the sampling formulation above, it was determined that the sample size of the mother was 84 people. Procedure data collected; (1) 2-day Enumerator Training with materials on Health Protocols for the Prevention of COVID-19, Research Interview and Anthropometric Measurement, (2) Field Officer Coordination Meeting with Enumerators, (3) Selection and randomization of participant numbers between 0-12 mo. All enumerators are provided with a mask and a hand sanitizer as well as for all nannies. Data collection was carried out for 7 days with details of 10 enumerators with a target number of 82 people or the equivalent of 10 people and one enumerator for the seven days of the survey. Supervisors make field visits to ensure that health protocols are carried out properly.

**Statistical Analysis**

To Analysis of the effect of GAP on Competence with Stunting tested by the Chi Square test. The competency gap in child feeding practice is measured by the frequency, amount, consistency, and variation of child feeding compared to the fact of child feeding with the standard of child feeding by UNICEF with indicators. And The ability of caregivers to know the concept of child care and implement it in child care according to the principles of child care includes the use of cleaning tools (soap), washing hands, using child masks, mother masks, masks of other family members, bathing and washing hair. The score for caring practices was 6-14 pints of the 7 question items.

Competency of hygiene practice can be defined as the ability of caregivers to know the concept of children’s hygiene and sanitation and implement it in children according to the principles of individual hygiene includes bathing children, stimulating toilet training, and using foot mats. The hygiene practice competency score is 5-9 points from 4 question items.

Health seeking behavior competence can be defined, the ability of caregivers to know the right treatment-seeking concept implements it in the pattern of seeking treatment for children when they are sick. The medical competency score is 1-2 of 1 question.

Based on the results of this study, it is known that there is an effect of competency gaps on the incidence of stunting in children aged 0-12 months (p = 0.000)
Discussion

The important outcome in this study is the gap in the competence of care for feeding, hygiene, care, and treatment. The gap in the competence of child feeding practices for caregivers found in this study is that the older the age, the feeding gap becomes more pronounced because the percentage of children who are not good at feeding practices increases from 20% to 92.3% at age 0-6 months to 10-12 months of age. Almost the same as the gap in children’s caring practices competence for caregiver mothers, the percentage of mothers with poor care practices from 67.4% at 0-6 months of age, and an increase of 10-12 months to 75%. The gap in children’s hygiene competence for caregivers is the only competency that is getting better day by day from 41.9% good status at 0-6 months to 50% in the 10-12 month age group. The gap in children’s health-seeking behavior for caregivers, in general, is very good 100% at 10-12 months of age and only 88.4% is good in the 0-6 month age group. The results of the analysis of the effect of the influence of the competency gap on stunting of children aged 0-12 months were found that there was an effect of the parenting competency gap on the incidence of stunting in children aged 0-12 months.

The results of previous studies that are in line with the findings in this study are research conducted by Sirajuddin, Nursalim, et al (2020), which states that the practice of complementary feeding that is owned by mothers is very important to prevent stunting. The research of Sirajuddin et al. (2000) explained that the way mothers feed their children, especially complementary foods, affects the incidence of stunting. This study also found evidence that overall parenting competence is also an integral part of child feeding practices. Competence in feeding practice is in line with a study by Sukmawati and Sirajuddin,(2020) when children eat, ideally, they should still be accompanied by the mother, not only those who are still being fed, but also for children who can feed themselves without being fed.

The competence of child feeding care is related to the mother’s ability to continue to breastfeed exclusively and also to overcome all breastfeeding problems. This condition is very beneficial at the same time there is a threat of decreasing purchasing power due to the COVID-19 pandemic. For mothers who have decided to wean their children, of course, they will face purchasing power (14). It is suspected that some families affected by the pandemic have lost their jobs and daily income (Pérez-Escamilla, Cunningham, and Moran 2020). However, there are advantages for those who are still exclusively breastfeeding, as evidence from previous studies that in poor families, breast milk is very helpful in supplying children’s needs so that they are not prone to becoming stunted, especially in the first 1000 days of life (12).

A longitudinal study conducted in Cambodia in 2020, found that competence in child feeding parenting should increase in each age group. Mothers who can increase their capacity in childcare based on the child’s age can assure that their child’s nutritional consumption will be fulfilled. The practice of feeding children based on 4 indicators of child feeding globally was not taken seriously in this study by caregivers (15). The same study also reported from Guatemala, 2014 that the indicators of the quality of child feeding always differ between regions. It is desirable that observations that are not only carried out quantitatively on these 4 indicators but should also be combined with a qualitative approach. This is aimed at exploring local practices as indigenous customs of the surrounding communities. The use of local food ingredients and special methods that have developed naturally in the community (16). Improvements in nutritional status, especially stunting, not only pay attention to nutrient intake but also hygiene and sanitation as factors that directly affect children’s stunting status. (16), (17),(18).

The limitations of this study are that it cannot make intensive observations on the practice of parenting. This is due to the limited access to house visits by enumerators due to the social distancing policy that was enforced during the COVID-19 pandemic in Makassar City in April-June 2020. Enumerators have been trained to interview before the interview was conducted. Several attempts were made by researchers to anticipate the weaknesses of this study.

The generalization (generalizes) in this study is that there is very strong evidence of gaps in parenting competence to mothers. This gap increases with increasing children’s age. The reason is that there is no effort to increase the capacity of mothers on how to care...
for children based on age groups. Ideally, the capacity of mothers will be improved with increasing age of the child, because the complexity of care is greater and requires seriousness in every childcare practice.

**Conclusions**

The effect of the competency gap on the stunting of children aged 0-12 months is that the more real the competency gap is, the greater the risk of children becoming stunted. Capacity building for caregivers is needed according to the child’s age. Capacity building in the practice of feeding and caring for children through mentoring activities at the household level.

The Interleukin-6 (rs1800797) Variant in Healthy Individuals at Medan City, North Sumatera Province

Mutiara Indah Sari1*, Siti Syarifah2, Milahayati Daulay3, Zaimah Z Tala4
1Senior Lecturer and Head of Department of Biochemistry, 2Senior Lecturer of Department of Pharmacology and Therapeutics, 3 Senior Lecturer of Department of Physiology, 4 Senior Lecturer and Head of Department of Clinical Nutrition, Faculty of Medicine, Universitas Sumatera Utara, Medan, Indonesia

Abstract

The Interleukin-6/IL6 (rs1800797) variant play a role in several diseases pathogenesis. The frequency genotype of IL6 (rs1800797) varied based on different race, ethnicity, and underlying character in population. This study aimed to assess the frequency of genotype and allele of IL6 (rs1800797) in healthy individuals at Medan city, North Sumatera Province Province and this study can be used as a reference in determining of several diseases for further studies. Genotyping of IL6 (rs1800797) in the promoter region using polymerase chain reaction and restriction fragment length polymorphism method, analysis using FokI restriction enzyme. This study showed that the genotype frequency of GG, GA, and AA were 95.8 %, 4.2 %, and 0 %, respectively. The allele frequency of G and A were 97.9 % and 2.1 %, respectively. The results indicated that the homozygous wild-type (GG) of IL6 (rs1800797) was higher than the heterozygous mutant (GA) and there was absent of homozygous mutant (AA) in this population. The frequency of G allele also higher than A mutant allele.

Keywords: Interleukin 6 (rs1800797), variant, gene, polymorphism, healthy

Introduction

The Interleukin-6/IL6 (rs1800797) gene variant play a role in several diseases pathogenesis such as febrile seizures, type 2 diabetes mellitus (T2DM), diabetic nephropathy, hyperandrogenism, cancer, and etc.1-5 IL6 is a pleiotropic cytokine that consists of 212 amino acid with molecular weight ranging from 21 to 28 kDa. The gene of IL6 gene is located on chromosome 7p21, consisting of four introns and five exons, and there are some of very rare polymorphisms in this sequence. The IL6 (rs1800797) gene polymorphism consist of single nucleotide change from G (guanine) to A (adenine) at position -597 in the promoter region. IL6 (rs1800797) gene was found three variant such as homozygous wild-type (GG), heterozygous mutant (GA) and homozygous mutant (AA).6,7

The frequency of the rs1800797 mutant variant varied based on different race and ethnicity in population and character that underlies that population. The previous study of rs1800797 showed that the frequency of homozygous mutant (AA) was not found in the healthy subject of Chinese and Thailand population,8,9 differ from the genotype frequency of Czech and Swedish population.10,11 Association of genotype or allele of IL6 (rs1800797) with several diseases also known to vary according to race or ethnicity. In a meta-analysis by Wang et al. (2019) showed IL6 (rs1800797) gene variant may be associated with an increased risk of liver diseases in the non-Asian population.12 Other meta-analysis showed that cancer diseases such as breast cancer, non-Hodgkin’s lymphoma, B-cell lymphoma and diffuse large B-cell lymphoma in Caucasian but not in Asia population were associated with IL6 (rs1800797) gene variant.5

Base on genotypes of the IL6 (rs1800797) gene variant may vary according to race or ethnicity on the differences in population and also on the underlying
characters, and the variant genotype may be involved in several diseases, so the present research aimed to find out assess the frequency of genotype and allele of IL6 (rs1800797) in healthy individuals among Medan city, North Sumatera Province. We hope, these results study can be used as a reference in determining of association of IL6 (rs1800797) with several diseases for other next studies by other researchers.

**Materials and Methods**

**Ethics**

This study was carried under the ethical provision of the Declaration of Helsinki. The study was approved by the Ethical Committee of Faculty of Medicine, Universitas Sumatera Utara (No. 447/KEPK-FKUSU-RSUPHAM/2019 Informed consent was taken from the participant that agree to participate in this study.

**Study Design**

This study was an observational with a cross-sectional study design. Healthy subjects in this study were gym participants from several gyms in Medan city, North Sumatera Province, staffs and students in the Faculty of Medicine, USU. Inclusion criteria were male or female, aged 20-65 years, and fasting blood glucose <126 mg/dl. However, subjects who have malignant disease were excluded from this study.

**Genotyping of The IL6 (rs1800797)**

Analysis of IL6 (rs1800797) variant was carried out in Molecular Biology Integrated Laboratory at Medical Faculty of Universitas Sumatera Utara (USU) from March to December 2019. DNA isolated from leukocyte using isolation kit and DNA purification (Promega, USA).

Polymerase chain reaction (PCR) process in IL6 gene amplification using primer (F) 5’- GGA GTC ACA CAC TCC ACC T -3’ (R) 5’-CTGATT GGAAACCTTATTAAG-3.13 PCR reaction solution consists of primer forward one μL, primer reverse one μL, PCR master mix 12.5 μL, dH2O steril 8.5 μL, DNA template two μL. PCR program carried out with pre-denaturation at 95°C for 4 minutes, then denaturation at 95°C for 30 seconds (30 cycles), annealing at 57°C for 30 seconds, extension at 72°C for 30 seconds, continued by a final extension at 72°C for 5 minutes.13 PCR product found at 525 bp and continued the digestion by FokI enzyme (ThermoFisher). The RFLP visualization result using UV transilluminator (Gel Doc, BIO-RAD Laboratories USA), were GG genotype (525 bp), GA genotype (525 bp, 468 bp, 57 bp), AA genotype (468 bp, 57 bp).

**Statistical Analyses**

Frequency of IL6 (rs1800797) variant was displayed descriptively after calculated by direct counting. Distribution of genotypes and alleles were analysis using SPSS program version 22.

**Results and Discussion**

PCR-RFLP products of IL6 (rs1800797) showed in Figure 1 and 2.

IL6 (rs1800797) variant distribution of one hundred and twenty healthy subjects in this study showed in Table 2.
The present study showed that the homozygous wild-type (GG) of IL6 (rs1800797) was higher than heterozygous mutant (GA) (95.8% vs 4.2%) and there was absent of homozygous mutant (AA) in this population. The frequency of G allele also higher than A mutant allele (97.9% vs 2.1%).

Interleukin-6 (IL-6) is a pro-inflammatory cytokine that has been implicated in various conditions such as cardiovascular disease, diabetes mellitus, etc. Circulating levels of IL-6 may be influenced by common genetic variants of the IL-6 gene promoter. Several IL-6 gene SNPs in the IL-6 promoter region have been identified, such as SNP rs1800797 (-597 G/A or -598 G/A). The IL6 (rs1800797) was found three variants. The genotypes and mutant alleles could be vary based on race and ethnicity of the population of study and the underlying character. Ethnic differences were found in IL-6 (rs1800797) variant.

The present study has conducted to analyze the variant distribution of IL6 (rs1800797) in the healthy population at Medan city, North Sumatera Province. Most population in this city is dominated by Batak and Melayu ethnic. This study showed GG genotype of IL6 (rs1800797) was higher than GA genotype (95.8% vs 4.2%). The previous studies in healthy population of Chinese, Tunisia, Brazil, and Egypt showed the same results, i.e. GG genotype higher than GA genotype. This present study showed absent of AA genotype. Other previous studies were found the same where the AA homozygote of IL6 (rs1800797) promoter region completely absent in healthy Thailand and Chinese population.  

Our study also showed that G allele was higher than A allele, this was in line with the previous study in healthy population of Thailand, Chinese, Tunisia, Brazil, and Egypt. But, in India, there was found A allele higher than G allele. Studies in several countries in the world showed the difference in distribution frequency of genotypes (GG, GA, AA) and alleles (G and A) of the IL6 (rs1800797) in the healthy population (Table 3).

To date, experts suggest that several diseases were associated with IL6 gene polymorphism. IL6 (rs1800797) increased the risk of atherogenesis and thrombosis in several diseases, such as coronary artery disease, deep vein thrombosis, acute ischemic stroke. IL6 (rs1800797) also play a role in the pathogenesis of several types of cancer, there were found a significant association between IL6 (rs1800797) variant with breast cancer, non-hodgkin’s lymphoma, but not gastric cancer.

Association of distribution of IL6 (rs1800797) variant with several diseases are known to vary according to race or ethnicity. In the meta-analysis by Wang et al. (2019) showed IL6 polymorphism (rs1800797) may be associated with an increased risk of liver diseases in the non-Asian population. Other meta-analysis showed IL6 (rs1800797) variant associated with several cancer such as breast cancer, non-Hodgkin’s lymphoma, B-cell lymphoma and diffuse large B-cell lymphoma in Caucasian but not in Asia. Other study showed that IL6 (rs1800797) associated with T2DM in the German population but did not associated in North India population. A study by Phillips et al. (2010) showed that IL6 (rs1800797) associated with metabolic syndrome in French populations, but Boeta-Lopez et al. (2017) showed that there was no association between IL6 (rs1800797) with metabolic syndrome in Mexican-Americans of South Texas population.

Further studies are needed in a larger population to analyze IL6 variation based on ethnic and its association with susceptibility of diseases.

### Conclusion

The present study concluded that GG genotype of IL6 polymorphism was higher than GA, and there is absent of AA genotype in this population. The frequency of G allele also higher than A mutant allele. This study has differences and similarities with previous studies in other countries, and it was possible because the ethnicity in each country varied. This results study can be used as a reference in determining of association of IL6 (rs1800797) with several diseases for another next study by other researchers.

Abstract

Objective: To evaluate the effect of \textit{Malus sylvestris} extract on improving the degree of steatosis and portal inflammation histopathological features of hypercholesterolemic \textit{Rattus norvegicus} strain wistar. Method: Forty-two male rats were divided into 6 groups randomly. Hypercholesterolemic fatty liver induced by giving high-fat diet (HFD) for 46 days on groups 1 to 5, while group 6 given standard diet with the same amount of time. Simvastatin was administered in group 2 at a dose of 0.36 mg/day. Groups 3, 4, and 5 were given \textit{Malus sylvestris} extract (MSE) as a treatment at doses of 90 mg/day, 180 mg/day, and 360 mg/day in sequential order. Simvastatin and MSE were administered for 14 days, from day 33 to 46. On day 47, all rats were sacrificed and the liver was removed for histopathological slides preparation with hematoxylin-eosin (HE) staining. Histopathological results were analyzed using Kruskal Wallis test followed by Mann Whitney test. Result: Histopathological analysis showed that \textit{Malus sylvestris} extract improved steatosis and portal inflammation features compared to HFD-fed rats in group 1 (p<0.05). Conclusion: \textit{Malus sylvestris} extract improved the degree of steatosis and portal inflammation histopathological features of hypercholesterolemic rat fatty liver.

Introduction

Non-alcoholic fatty liver disease (NAFLD) is the accumulation of excess fat in the liver with more than 5\% of hepatocytes containing visible lipid vacuoles or steatosis affecting at least 5\% of the liver weight without heavy alcohol consumption or other secondary causes\textsuperscript{1}. The disease can progress from harmless simple non-alcoholic steatosis (NAS) to non-alcoholic steatohepatitis (NASH), a form of inflammation that damages the liver cells\textsuperscript{2}. Liver cell damage then can lead to fibrosis, cirrhosis, and eventually hepatocellular carcinoma (HCC), which require liver transplantation\textsuperscript{3}. Although cirrhosis due to hepatitis C is the leading cause of liver transplantation in the United States, NAFLD rank the second. As prevalence continues to increase, NAFLD will become major health problems and the major cause of liver transplantation in the future\textsuperscript{4}. This will also increase the demand for liver transplantation with fewer good-quality organs, as more donors have steatotic livers\textsuperscript{5}.

NAFLD has emerged as the most common chronic liver disease in developed countries. However, the prevalence of NAFLD continues to increase even in developing countries due to worldwide epidemic of obesity and other metabolic syndromes\textsuperscript{6}. The prevalence of NAFLD worldwide is approximately 25.24\%, with highest prevalence in the Middle East (31.79\%) and South America (30.45\%)\textsuperscript{7}. In Asia, there is almost 10\% increase in prevalence from the initial 25.28\% in 1999-2005 to 33.90\% in 2012-2017\textsuperscript{8}. The data have shown that the cases will always increase and become a problem not only in Western countries but also in Asia.
due to urbanization. Urbanization will lead to sedentary lifestyle with excessive dietary consumption resulting in obesity, a risk factor for NAFLD. Apart from obesity, NAFLD also accompanied by hyperlipidemia, hypertension, type 2 diabetes, cardiovascular disease, and other metabolic syndromes that may affect not only the liver but also the person’s systemic condition.

Environmental factors play an important role in the development of NAFLD, such as eating habits, daily activities, and socioeconomic factors. Dietary patterns of high sodium and fat with low consumption of fresh fruit have been found in NAFLD patients. By eating fruits and vegetables, especially apples, can reduce the risk of NAFLD due to fiber and chemical contents in apples such as flavonoids, polyphenols, and carotenoids, which have antioxidant and anti-inflammatory effects to prevent and protect the liver from NAFLD. So far, there are only few studies regarding to the effect of apples on treating NAFLD and there are no studies specifically using Malus sylvestris. Hence, this study aimed to evaluate the effect of Malus sylvestris extract on improving histopathological features of hypercholesterolemic Wistar rat (Rattus norvegicus) fatty liver.

Materials and Methods

Malus sylvestris collection and extraction:

Malus sylvestris were collected from apple farm in Junggo Village, Bumiaji, Batu, Indonesia. The apples were washed, drained, and weighed. Malus sylvestris with their skins were cut into thin strips and air-dried in the shade. To maximize the drying process, apple slices were roasted at 45°C for about 48 hours or until completely dried. The dried apple slices were crushed in a blender and sieved into powder. Malus sylvestris powder then extracted with 96% ethanol using percolation technique. Extraction process was continued with rotary evaporator to removed the alcohol content and a thick extract will be produced.

Experimental Animal:

Forty-two male Wistar rats around 2-3 months old weighing between 125-200g were used for the study. They were cared for in clean well-ventilated cages with light/dark cycle 12 h respectively and were given water and either a standard or high-fat diet (HFD) ad libitum. Before the experiment began, they will be acclimatized for seven days with a standard diet in the Experimental Animal Unit of Pharmacology Laboratory within Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia.

Experimental design:

Forty-two Wistar rats were randomized and divided into 6 groups each containing 7 rats. Group I received HFD served as negative control rats. Group II received HFD and simvastatin at dose of 0.36 mg/day served as positive control rats. Group III received HFD and Malus sylvestris extract at dose of 90 mg/day. Group IV received HFD and Malus sylvestris extract at dose of 180 mg/day. Group V received HFD and Malus sylvestris extract at dose of 360 mg/day. Group VI received standard diet served as normal control rats. Standard or high-fat diet for the rats was given for 46 days. Simvastatin and Malus sylvestris extract (MSE) were administered orally by using oral gavage for 14 days (day 33-46). On day 47, all animals were euthanized using chloroform and sacrificed by cervical dislocation. The liver was removed for histopathological analysis.

Histopathological studies:

All livers were fixed by immersing it in 10% neutral buffer formalin for 24 hours. Histopathological preparations continued with dehydration, clearing, impregnation, and then making paraffin blocks, which were cut by microtome with thickness of 4-5 μm. The tissue slices were attached to glass object and then stained with hematoxylin-eosin (HE). Histopathological slides were observed per field of view under light microscope at 100x magnification to determine the observed area and 400x magnification to observe the cells more clearly. Observation of liver cells used semi quantitative scoring system to evaluate steatosis and portal inflammation features.

Statistical Analysis:

Statistical analysis was performed using SPSS 20 for windows and the results were represented as mean. All results were analyzed statistically by Kruskal Wallis test, followed by Mann Whitney test to determine the significant difference between groups.
Result

The results were considered to be statistically significant when p<0.05. Mean rank value of steatosis and portal inflammation from statistical analysis can be seen in Table 1.

Values are represented in mean. Different superscript letters indicate significant difference (p<0.05).

Under the microscope, rats in normal control groups showed normal liver histology with minimal steatosis and portal inflammation features (Fig. 1F and 2F). Rats fed with HFD in positive control group showed severe fat vacuoles accumulation (steatosis) in liver cell cytoplasm (Fig. 1A) as well as inflammatory cell infiltration in portal area (Fig. 2A). However, Fig. 1B and 2B showed reduced fatty change and inflammatory cell in the portal area in simvastatin group, this suggest that the drug could alleviate steatosis and portal inflammation. All doses of MSE also showed similar result as simvastatin group by improving steatosis (Fig. 1C, 1D, 1E) and portal inflammation (Fig. 2C, 2D, 2E) features compared to positive control group.

(F) Liver tissue of normal control rats.

Discussion

Accumulation of lipid droplets in liver cells can be macrovesicular or microvesicular, which is rich in triacylglycerol (TAG). Liver does not store TAG in normal conditions, but exposure to stress due to excessive intake of fat or carbohydrates such as HFD consumption may cause fat accumulation in the liver. This is associated with lipotoxicity because it increases mitochondrial stress. Mitochondrial dysfunction increased reactive oxygen species (ROS) production, which reduces antioxidants that act as a defense against oxidative stress in the liver. Ongoing oxidative stress may lead to lipid peroxidation that causes lesions to liver cells leading to degeneration and necrosis. The end products of lipid peroxidation, malondialdehyde, have chemoattractant properties that activate stellate cells as collagen producers and pro-inflammatory cytokines such as tumor necrosis factor alpha (TNF-α) that activates c-Jun N-terminal kinases (JNK) pathway and nuclear factor kappa light chain enhancer of activated B cells (NF-κB), induce the release for more pro-inflammatory cytokines mediating liver inflammation. This may lead to NASH with mixed lesion of necrosis, inflammatory infiltrates, and fibrosis, in addition to steatosis.

This study showed that MSE give hepatoprotective effect by improving steatosis and portal inflammation features compared to rats fed with HFD. This might be due to the presence of polyphenols and pectin in Malus sylvestris, which have metabolic regulatory, antioxidant, and anti-inflammatory properties. Polyphenols reduce TAG accumulation by various mechanisms, including inhibition of lipogenesis and promotion of fatty acid catabolism by down-regulating sterol regulatory element-binding protein 1c (SREBP-1c), which has a major role in lipogenesis. Dietary fiber has also been shown to reduce the risk of NAFLD. Pectin is one of the dissolved dietary fibers found in apple in high concentrations, which increase the amount of intestinal microbiota that ferments pectin into short chain fatty acids (SCFAs) in large intestine. SCFAs containing 2-5 carbons such as propionate inhibit carbohydrate response element binding protein (ChREBP), acetyl-coenzyme A carboxylase (ACC), and fatty acid synthase (FAS) which plays role in liver lipogenesis.
Polyphenols showed anti-inflammatory effect through several signaling pathways, such as by suppressing the activation of the NF-κB pathway, decreasing JNK phosphorylation protein, reducing levels of serum inflammatory cytokines, and increasing antioxidant defenses via the nuclear factor erythroid 2-related factor 2 (Nrf2) pathway. In addition to polyphenols, other components in apples, such as pectin and its fermented products (SCFAs), can inhibit the secretion of TNF-α and NF-κB activation that suppress the progression of liver damage.

The ability of apple extract on improving histopathological features of fatty liver can also be seen from previous studies with similar results with this study. In addition, apple extract also showed lower levels of serum total cholesterol, low-density lipoprotein cholesterol (LDL-c), and triglycerides (TG) compared to Western diet (high fat and sugar) group. Further research is needed to investigate certain active ingredient isolates in *Malus sylvestris* extract, which have dominant role on ameliorating NAFLD histopathological features. It is also necessary to examine the effects of *Malus sylvestris* extract other than histopathological studies, as the diagnosis of NAFLD may be made by other tests.

**Conclusion**

*Malus sylvestris* extract improve the degree of steatosis and portal inflammation histopathological features of hypercholesterolemic rat fatty liver. This shows that *Malus sylvestris* provide hepatoprotective effect that could act as a potential treatment for NAFLD.

Abstract

Background: Hyperglycemia is a recognized side effect of the corticosteroids and asparaginase given during induction chemotherapy for pediatric acute lymphoblastic leukemia (ALL). The ALL is the malignant tumor with the highest incidence in the childhood. The aim of this study is to investigate the impact of hyperglycemia during induction chemotherapy in childhood ALL.

Methods: This prospective study was done in Dr. Soetomo hospital from January to April 2018. The subject was newly diagnosed as ALL under the age of 18 years, treated with Indonesian childhood ALL 2013 protocol (Standard Risk (SR) group and High Risk (HR) group). Hyperglycemia was defined as at least two separate random plasma glucose levels > 200 mg/dL, which was evaluated before and during induction chemotherapy. Statistical analysis using Paired T-test for parametric and Wilcoxon Test for nonparametric.

Results: Thirty-three children were enrolled, 18/33 boys with mean age 5.8 (SD 3.78) years, compromised as ALL-L1 30/33. They were treated with ALL-HR 19/33 and ALL-SR 14/33. In overall groups, the mean random blood glucose level significantly increased from 108 (SD 21.3) mg/dL to 147 (SD 48.1) mg/dL, (mean difference 38.67 mg/dL; 95% CI 18.08 to 59.26 mg/dL, P=0.008). In SR group, there was a significant increased of mean random blood glucose level from 102 (SD 13.5) mg/dL to 133 (SD 37.3) mg/dL, (mean difference 31.8 mg/dL; 95% CI 8.78 to 54.8 mg/dL; P=0.01). In HR group, the mean random blood glucose level increased from 113 (SD 51.9) mg/dL to 165 (SD 25.4) mg/dL, (mean difference 51.9 mg/dL; 95% CI 18.6 to 85.2 mg/dL, P=0.004).

Conclusion: Blood glucose level is significantly increase during induction chemotherapy in both SR and HR

Keyword: Hyperglycemia, acute lymphoblastic leukemia, childhood.

Background

Hyperglycemia is a common side effect of acute lymphoblastic leukemia (ALL) therapy. It has long
been recognized as a consequence of corticosteroids (either prednisone or dexamethasone) and asparaginase, chemotherapeutic agents key to ALL treatment. These medications are usually administered concurrently in high doses during the initial induction phase of chemotherapy. As a result, hyperglycemia frequently develops during this phase, with resolution after the steroids and asparaginase have been discontinued or reduced in dose.\(^1\^-4\) The potential causes may include beta cell dysfunction caused by chemotherapeutic drugs such as L-asparaginase, increased insulin resistance and hepatic gluconeogenesis induced by corticosteroids, or synergistic effects of these medications, given that these pharmacological agents are usually combined during initial induction therapy.\(^1\^-4\) The spectrum of hyperglycemia can range widely from transient isolated episodes to severe life-threatening complications such as diabetic ketoacidosis or nonketotic hyperglycemic hyperosmolar syndrome.\(^5\^-7\) Transient hyperglycemia developed during this period largely resolves as the chemotherapy is discontinued.\(^3\) However, affected children may need longer hospitalization and delay in chemotherapy; they may experience increased infective incidence and may even have poorer survival outcomes.\(^8\^-9\)

Previous studies have documented hyperglycemia induced by chemotherapy occur in 0.2-16%. Few published data have referred to the epidemiology of treatment-related hyperglycemia in Indonesian childhood ALL. The purpose of the current study is to evaluate the incidence of hyperglycemia during the induction chemotherapy for childhood ALL in Dr. Soetomo Hospital.

**Methods**

This is a prospective study involving of consecutive patients, age younger than 18 years, in whom ALL was diagnosed and who were admitted to Dr. Soetomo Hospital, Surabaya between January and April 2018.

We excluded patients with previously diagnosed diabetes mellitus (DM) or who were treated with glucocorticoids were also excluded. Medical records were reviewed to obtain relevant clinical data, including demographic information, such as age at diagnosis, sex, weight, height, and clinical parameters, such as initial white blood cell count (WBC), initial C-reactive protein (CRP) level, initial plasma glucose level, immunotyping of leukemic cells, and risk classification. Hyperglycemia was defined as at least two separate random plasma glucose levels ≥200 mg/dL according to the published guidelines for childhood diabetes.\(^10\) Plasma glucose level was evaluated before and during induction chemotherapy. BMI was calculated by dividing weight in kilograms by height in square meters. Using reference standards from the Centers for Disease Control and Prevention (CDC), each subject’s body mass index (BMI), BMI percentile for age, and BMI z-score for age were calculated. Per current CDC guidelines, subjects with BMI greater than or equal to the 95th percentile for age and gender were defined as overweight and those with BMI greater than or equal to the 85th percentile for age and gender were defined as at risk for overweight.\(^11\) All patients were treated according to the Indonesian childhood ALL 2013 protocol. The 1\(^{st}\) day of treatment was designated when the use of steroids was started. The entire procedure was approved by the Ethic Committee Dr. Soetomo Hospital, Surabaya.

All of the data collected were entered into an SPSS database (SPSS version 21.0.0.0). Descriptive statistics about the subject population were calculated, including data such as sex, age, and BMI at diagnosis. Presence of hyperglycemia was defined as above. Proportions of subjects with hyperglycemia overall and within each population category group (High risk and standard risk group) were calculated. For this analysis, subjects were divided by high risk and standard risk group as defined above. Chi-square analysis was used to determine the magnitude of difference in prevalence of hyperglycemia between groups. Statistical analysis using Paired T-test for parametric and Wilcoxon Test for non parametric. P values < 0.05 were regarded as significant.

**Results**

Thirty-three children were enrolled during our study period. All study subjects were newly diagnosed with ALL and received induction chemotherapy between January and April 2018. There were 18/33 boys and 15/33 were girls, the mean age of the patients when initially diagnosed was 5.8 (SD 3.78) years old. The patients compromised as ALL-L1 30/33 patients. They were treated with ALL-HR 19/33 patients and ALL-SR 14/33 patients. Baseline characteristics at the time of
testing are shown in Table 1.

In overall groups, 6/33 patients experienced hyperglycemia during induction chemotherapy, five of them treated with ALL-HR regimen and one treated with ALL-SR regimen. There is no significant incidence of hyperglycemia between ALL-HR and ALL-SR with p value 0.117 (Table 2). In overall groups, the mean random blood glucose level significantly increased from 108 (SD 21.3) mg/dL to 147 (SD 48.1) mg/dL, (mean difference 38.67 mg/dL; 95% CI 18.08 to 59.26 mg/dL, P=0.008).

Discussion

In this study, 33 children with newly diagnosis of acute lymphoblastic leukemia that treated in Dr Soetomo hospital and were in induction chemotherapy of their treatment, evaluated for hyperglycemia. These Children followed for six weeks and were assessed for growth parameters, and blood sugar. Hyperglycemia defined when at least two random glucose level >200 mg/dl. According to these criteria, there were six cases with hyperglycemia (18% of the subjects). In a study by Banihashem et al, 32 patients with a diagnosis of acute leukemia, and 17.2% of patients had hyperglycemia.\textsuperscript{12}

In this study, there was no significant difference between incidence of hyperglycemia and type of treatment according to Indonesia childhood ALL protocol 2013 (chi-square p=0.117). This result similar with Banihashem study, which is there was no significant difference between incidence of hyperglycemia and different protocol of chemotherapy that used for treatment of children (chi-square p=0.983).\textsuperscript{12} The similar study was a study by Baillargeon et al. that evaluated transient hyperglycemia in Hispanic children with Acute Lymphoblastic Leukemia, and 11.0% of the study cohort developed hyperglycemia during induction chemotherapy.\textsuperscript{4}

In this study, the blood glucose level is significantly increase in all groups during induction chemotherapy, overall with p value 0.008, p value 0.004 and 0.01 in HR groups and SR groups, respectively.
At a literature by Lowas et al. Prevalence of transient hyperglycemia during induction chemotherapy for pediatric acute lymphoblastic leukemia was assessed. Transient hyperglycemia (TH) is a recognized side effect of the corticosteroids and asparaginase given during induction chemotherapy for pediatric acute lymphoblastic leukemia (ALL). This study examined the prevalence of TH in a cohort of pediatric ALL patients and the impact on TH of type of steroid or asparaginase.

Hyperglycemia and diabetes induced by chemotherapy occur in the range of 0.2% to 16% (see table 4). Pui et al reported hyperglycemia in 9.7% of the pediatric ALL patients in the induction period of chemotherapy, after receiving prednisone and L-asparaginase. Weiser et al documented an incidence of hyperglycemia in 37% of patients during induction chemotherapy. According to Pastore et al 50% of ALL children may develop hyperglycemia, whereas Banihashem et al reported that 27.5% of the pediatric patients showed either diabetes mellitus or hyperglycemia.

There is a complex pathophysiology mechanism that explains the development of hyperglycemia in the pediatric population receiving induction chemotherapy. DeFronzo et al have described a series of events that lead to genesis of diabetes as follow: 1) some patients showed a predisposition to enhance insulin resistance and propensity for β-cells failure, 2) specific risk factors such as preexisting obesity reinforce these defects, 3) diabetes mellitus comes up, when a concomitant insulin secretory defect is present, regardless of the etiology.

During the standard treatment of ALL, children receive 3 drugs in the first month of the therapy. These include L-asparaginase, Vincristine and steroids as prednisolone. Children in high risk group of ALL receive a fourth chemotherapy drug, mostly daunorubicin. During the standard treatment of ALL, children receive 3 drugs in the first month of the therapy. Additionally, intrathecal chemotherapy using commonly methotrexate is performed. L-asparaginase inhibits insulin protein synthesis. L-asparaginase may directly reduce the glucose-stimulated release of insulin from β-cells and indirectly reduce insulin production by causing pancreatitis. Furthermore, it is known, that corticosteroids induce insulin resistance. These effects may lead to the development of diabetes mellitus in children receiving chemotherapy, and more often in those with additional risk factors.

Hyperglycemia occurs commonly in the pediatric population receiving induction chemotherapy, but a combination of glucocorticoids and L-asparaginase may cause diabetes mellitus. Physicians should be aware of these risk factors and perform an early and careful screening for hyperglycemia (fasting glucose levels) during the treatment of the patients with ALL.

Furthermore, application of the right treatment for hyperglycemia, such as insulin, permits an early clinical and biochemical normalization and enforces thereby the continuation of the chemotherapy. The use of insulin may reduce the period of hyperglycemia and therefore the possible future metabolic side effects.

**Conclusion**

The incidence of hyperglycemia is not significant in this study, but blood glucose level is significantly increase during induction chemotherapy in both SR and HR Indonesian childhood ALL 2013 protocol. Therefore, we recommend clinicians should be aware of the risk of hyperglycemia in childhood ALL during the induction chemotherapy. Future investigations of pediatric cohorts are needed to evaluate the influence and outcome of transient hyperglycemia as well as diabetes mellitus for long-term survival and metabolic syndrome.

Correlation of Hot Work Climate with Dehydration on Bricks Workers

Nesya Shera Putri Iksani1, Endang Dwiyanti2
1Research Scholar, 2Associate Professor, Department of Occupational Safety and Health, Faculty of Public Health, Universitas Airlangga, Campus C, Mulyorejo, 60115, Surabaya, East Java, Indonesia

Abstract
Each workplace must have its own source of danger which can cause health problems or occupational diseases due to the exception of informal sector workers such as brick workers. Health problems that can be experienced are dehydration caused by exposure to hot working climate. Incidence of dehydration can cause workers to get tired quickly and decrease productivity. The purpose of this study was to analyze the correlation between hot working climate with dehydration on bricks workers in one of Mojosulur’s brick home industries. Methods of his research is an analytic observational study, with cross sectional design. The subjects of this study were all brick workers in one of the brick home industries in Mojosulur by 30 respondents. The results of the study showed that most brick workers were dehydrated, varying in level, both moderate and severe dehydration. The results of statistical analysis show that the correlation coefficient (r = 0.638) which can be interpreted as a work climate factor has a strong correlation with the incidence of dehydration Conclusion of this research on work climate and dehydration of brick workers in one of Mojosulur’s brick home industries have a very strong correlation.

Keywords: bricks, dehydration, work climate, workplace,

Introduction
The progress of science and technology in Indonesia is currently taking place very rapidly, as is the process of industrialization of Indonesian society which is increasingly increasing. The development of industry in Indonesia is marked by the increasing number of small-scale industries that have sprung up both in the formal and informal sectors. But often the occupational safety and health of informal sector workers receive less attention, therefore there is a need for labor protection to be done to protect workers from work-related hazards 1.

The Central Statistics Agency in February 2018 released official statistics on employment in Indonesia, and based on the data released 58.22% or 73.98 million people worked in the informal sector and 41.78% were workers in the formal sector [2]. From the results these calculations show that in Indonesia more workers are working in the informal sector. One example of work in the informal sector includes the home industry making red bricks.

Each workplace must have its own source of danger which can cause health problems or occupational diseases due to the exception of informal sector workers such as brick workers. Based on research conducted by Wahyuni in 2016 on hazard analysis and the assessment of the need for personal protective equipment in brick workers in Demak, it was found several hazards, one of which was the danger of hot working climate and exposure to solar radiation caused by the presence of outdoor work climate and the presence of the process of burning bricks carried out in a long time 3. This makes dehydration and heat stress possible for workers.

Dehydration is a condition of lack of fluids in the body and can have an impact on the existing regulatory processes in the body 4. This is because there is exposure...
to hot temperatures at work followed by excessive sweating. Based on research conducted by THIRST (The Indonesian Regional Hydration Study) in Indonesia shows that many Indonesian people experience mild dehydration, especially in the group of adolescents aged 15-18 years and adults aged 25-55 years. That matter supported by research conducted by Hardinsyah which states that as many as 46.1% of Indonesian people experience mild dehydration, and among them are people who live in low-lying areas such as in Jakarta, Surabaya and Makassar.

In addition, Indonesian people’s water consumption is still relatively low, this is indicated by the results of research conducted by The Indonesian Regional Hydration Study (THIRST) which also shows that as many as 49.1% of research subjects experienced less water or mild hypovolemia, and in adults reached as many as 42.5%. Also reported that 43% of adults are in a state of dehydration at work.

The condition of dehydration that takes place continuously can cause a person experiencing muscle spasms. Fatigue in workers is also one of the effects caused by the occurrence of dehydration, someone who experiences fatigue makes the body become weak and lazy to do physical activity. If the condition is left and continues to increase the risk of kidney stone disease, urinary tract infections, cancer, colon, obesity constipation, cerebral vascular stroke and other health problems. The Other studies mentioning that if the body experiences a lack of fluids reaching more than 2% of the total fluids in the body will affect the quality of work done by the worker and if dehydration reaches 3.1% can reduce the quality of someone at work by 48%. In the study also mentioned that. If someone does not consume fluids during their activities for 6 hours can cause dehydration of 6.4% and reduce the quality of work by 25%.

Decreased cognitive performance, decreased physical and psychomotor endurance are also one of the effects of dehydration. Dehydration with weight loss of 1-2% has been shown to reduce short-term memory and the decline in cognitive function including short-term memory will cause a person’s difficulties in working and completing tasks.

Unnoticed dehydration can be experienced by people who perform physical activities exposed to heat and exposed to hot climate in the workplace. The working climate is the result of a combination of temperature, humidity, speed of air movement and heat radiation due to the level of heat expenditure from the body of the workforce as a result of his work. Weather or work climate that is not comfortable and not in accordance with labor standards and provisions that have been in force will result in a decrease in the capacity of workers, causing a decrease in work efficiency and productivity.

According to Tarkawa excessive hot work climate can cause fluid in the body to come out through sweat continuously and experience an increase can result in dehydration and other health problems. In addition, workers who carry out their work without realizing it can experience a decrease in fluid intake by losing a lot of body fluids such as sodium and this can lead to dehydration.

Regarding several studies Regarding the status of dehydrated workers. Research conducted by Sari shows the effect of heat work has a significant effect on the incidence of dehydration. This is indicated by the number of 66.67% or 10 respondents who experienced mild dehydration in the boiler section and the results of the Man Whitney test showed a related effect of heat work on dehydration (p = 0.023). Subsequent research conducted at PT Indo Acidatama Tbk, Kemiri showed that respondents who were dehydrated based on measurements of the concentration of urine color in hot work climates that exceeded the NAV were more numerous than the number of respondents who were not dehydrated. This is indicated by the results of the study that there are 6 workers who are dehydrated and 4 other respondents are not dehydrated.

Brick artisans are one example of industrial workers in the informal sector. Making bricks is one type of work that most of the activities carried out in the outdoor environment, it is possible for workers to be exposed to heat in each production process, especially in the process of grinding, drying, molding, structuring and burning. In addition to basic materials, the quality of bricks also depends on the combustion process carried out. The burning process that lasts for a long time can even take...
up to 1 day. During combustion it is necessary to have adequate heat and the flame must always be considered to produce good quality and not cause a fire, this results in workers being required to work watching the fire all day. Continuous exposure to heat from the sun at work, especially at milling, structuring, drying and burning processes can enable workers to become dehydrated, in addition to that found several symptoms in brick craftsmen such as dry skin, dry mouth and sometimes feel very thirsty. Based on these data, the researchers are interested in conducting research on the correlation of hot work climate with dehydration events.

**Methods**

Research carried out including observational research types, with cross sectional approach because it is carried out at a certain time. The location of data collection was carried out in one of Mojosulur’s brick home industries in Mojokerto Regency. The population of this study is all workers, amounting to 30 people.

In this study there are two variables in the independent variable, namely the work climate and the dependent variable dehydration events. Collecting work climate data using heat stress apparatus questemp 36. The measurement results will produce a wet ball temperature index (ISBB) that exceeds or is less than the NAV must be considered by looking at the workload of workers and working hours settings applied at the workplace. Then adjusted to the ISBB Table contained in Minister of Manpower Regulation 2018 Number 5 Year 2018. Dehydration in workers is measured by taking a urine specimen shortly after work and compared with a urine color indicator card by Armstrong 19. The measurement results are then recorded and categorized into 4 criteria: no dehydration, mild, moderate and severe dehydration in accordance with the card indicators listed. The more concentrated the color of urine the heavier the person is dehydrated. The questionnaire distributed was used to obtain supporting data about the characteristics of the respondents. Observations, interviews and secondary data used to find out about the general description of the Mojokerto Bricks industry.

The research data that has been obtained will then be analyzed by statistical tests to determine the relationship between variables. In this study there are 2 variables: work climate as an independent variable and dehydration as the dependent variable. Based on the objectives of the research conducted, this study uses the Spearman correlation test. The test is used to determine the strength of a relationship between variables by analyzing the value (r) of the correlation coefficient, so that it can be determined the strength of the relationship between the work climate and the dehydration status of workers.

**Findings**

**Overview Bricks Home Industry Mojosulur**

Home Industry Mojosulur Bricks is one of the small industries that produce red bricks that have been established since 2002. Home Industry Mojosulur Bricks. This Home Industry manufactures brick presses labeled MRH and still uses traditional methods. This Home Industry is located on Jl. Teuku Umar RT 01 / RW 07 Mojosulur Village, Mojosari District, Mojokerto. In the process of making red bricks in the home industry entirely using human labor from the stage of processing land and raw materials to the finishing process. There are 5 stages in the process of making bricks including the process, mixing materials, grinding, molding, drying and burning bricks. The bricks produced by this home industry have several advantages, which are high density, more economical, durable and have good adhesion and are suitable for all soil textures.

**Identification of Respondent Characteristics**

Identification of Respondent Characteristics. The results of the questionnaire showed that there were 5 people (16.7%) who were aged in the 26-35 years age group. There were 10 people (33.3%) who were around 36-45 years old, there were 12 people (40%) who were around 46-55 years old, and 3 people (10%) were in the 56-65 years age group. The age of workers in the Mojosulur brick industry is the most workers in the age group of 46-55 years with a total of 10 people (33.3%). The results of the questionnaire based on gender showed that in the brick home industry there were more male workers as many as 19 people (63.3%) and 11 people (36.7%) were female workers. Based on the results of interviews with respondents as many as 20 people (66.7%) have worked > 2 years and 10 people (33.3%) worked ≤ 2 years.
The Frequency Distribution of Work Climate

The measurement of the working climate is done by using the Temp Temp 36 tool and the measurement is done at 5 points, namely at each stage of the brick making process, Point A is located at the mixing point of the brick material. Point B is located in the brick material mill. Point C is located at the place where the brick material is placed, Point D is located at the brick drying area and point E is located at the brick kiln.

Table 1. Work Climate Mesurement on the Mojosulur Home Bricks Industry 2020

<table>
<thead>
<tr>
<th></th>

<tr>
<td>Bricks Burning</td>
<td>26,9</td>
<td>32,9</td>
<td>48,9</td>
<td>31,9</td>
<td>47</td>
</tr>
</tbody>
</table>

From the measurement results on Table 1, it can be seen that the highest ISBB is at point E where the brick kiln process is 31.9 °C. This is due to the additional heat from the brick kiln and the lowest ISBB is 28.4 °C at point C, which is located at the site the process of laying bricks which is indeed a workplace is an indoor workplace. Setting working hours in the brick brick home industry is an average of 50-75%. Thus the NAV for hot working climate is 31.0 °C in the category of light workloads, 29.0 °C for workers with moderate workloads, and 27.5 °C for workers with workloads hard.

Table 2. The Frequency Distribution of Work Climate (NAV)

<table>
<thead>
<tr>
<th>Category</th>
<th>Frequency</th>
<th>Percentage (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>≤NAV</td>
<td>10</td>
<td>33,3</td>
</tr>
<tr>
<td>&gt;NAV</td>
<td>20</td>
<td>66,7</td>
</tr>
<tr>
<td>Total</td>
<td>30</td>
<td>100,0</td>
</tr>
</tbody>
</table>

From table 2, It can be seen that the results of ISBB NAV determination in Mojosulur brick home industry are 20 respondents (66.7%) who are exposed to heat > NAV and 10 respondents (33.3%) are exposed to heat temperature ≤NAV.

The Frequency Distribution of Dehydration

Dehydration measurement is done when the worker has finished his work, and will move home from work. Dehydration measurement is done by asking the worker urine sample and seeing the urine color density which is then compared with the urine color indicator which has 8 colors and then categorized into 4 categories not dehydrated, mild, moderate and severe dehydration. Following are the results of the distribution of respondents based on the measurement of dehydration level showed on table 3.

Table 3. The Frequency Distribution of Dehydration

<table>
<thead>
<tr>
<th>Category</th>
<th>Frequency</th>

<td>26,7</td>
</tr>
<tr>
<td>Severe</td>
<td>5</td>
<td>16,7</td>
</tr>
<tr>
<td>Total</td>
<td>30</td>
<td>100,0</td>
</tr>
</tbody>
</table>

From the results of dehydration measurements in table 3 shows that as many as 7 people (23.3%) experienced mild dehydration, 8 people (26.7%) experienced moderate dehydration, 5 people (16.7%) experienced severe dehydration. This shows that the highest number of brick craftsmen workers is moderate dehydration, namely as many as 8 people (26.7%)
**Correlation of work climate with dehydration**

Based on the work climate measurement results are grouped into 2 namely for setting working time 50-75 ≤ NAV (For light workloads ≤ 31.0 °C, moderate workloads ≤ 29.0 °C, and heavy workloads ≤ 27.5 °C) and> NAV (For light workloads> 31.0 °C, moderate workloads> 29.0 °C, and heavy workloads> 27.5 °C) While work dehydration status is categorized into 4 categories namely no dehydration, dehydration mild, moderate dehydration, and severe dehydration. Below is a cross tabulation between the hot work climate and the dehydration of Mojosulur’s brick home industry workers showed on table 4.

<table>
<thead>
<tr>
<th>Work Climate</th>
<th>Dehydration Level</th>
<th>Total</th>

</tr>
<tr>
<td>&gt;NAB</td>
<td>3</td>
<td>15</td>
</tr>
<tr>
<td>Total</td>
<td>9</td>
<td>30</td>
</tr>
</tbody>
</table>

Based on the table above shows that in the measurement of hot work climate ≤ NAV many workers experienced mild work dehydration, namely as many as 3 workers with a percentage of 10%. Then in the measurement of heat stress> NAV experienced the most moderate dehydration as many as 7 workers with a percentage of 23.3%.

**Table 5. Correlation Between Work Climate And Dehydration**

<table>
<thead>
<tr>
<th>Work Climate</th>
<th>Dehydration</th>
<th>Conclusion</th>
</tr>
</thead>
<tbody>
<tr>
<td>Value Spearman Correlation</td>
<td>0.638</td>
<td>Very Strong</td>
</tr>
</tbody>
</table>

Analysis conducted using statistical calculations, based on the Spearman correlation test that has been done, the results obtained correlation coefficient (r) = 0.638. These results indicate the resulting correlation coefficient approaching 1 which means that there is a strong relationship between the hot work climate with the incidence of dehydration in home brick workers in Mojosulur, Mojokerto Regency.
Discussion

Work Climate

In the Heat Stress measurement using the ISBB (Ball and Wet Temperature Index) method using the Questemp 36 at 5 points in accordance with the worker’s job. The lowest Ball and Wet Temperature Index results are obtained at 28.4°C at Point C, where the brick laying process is included in the indoor work area and the highest Ball and Wet Temperature Index at 31.9°C is at point E, at the outdoor work area. who worked on the brick burning process. According to Permenakertrans No. 5 of 2018 concerning NAV (Threshold Value) Physical and Chemical Factors in the Workplace, the NAV of the working climate is determined by measurement, workload and also work time. The working time in the brick brick home industry in Mojosulur is 50-75% due to workers not working full hours 8 hours a day. So for NAV that is in accordance with the workplace conditions in the brick brick home industry for light workloads of 31.0°C, medium workloads of 29.0°C, and heavy workloads of 27.5°C. Therefore, it can be concluded that the most measurement is> NAV of 20 people (66.7%).

The temperature at work can be influenced by work processes and work environment factors themselves. As long as the worker’s body is active, the body will directly try to keep up with the temperature in the environment and try to balance the heat temperature environment received by the body with the heat in the body through the process of heat loss in the body. A comfortable temperature for Indonesians at work is between 24-26°C. A hot work climate can cause heat stress to be received by workers who are working in the workplace environment as an additional heat load (in addition to the heat load generated by the body which can result in many negative effects on workers in the form of work disorders or health problems such as dehydration, increased pulse, dizzy headaches, dizzy eyes, rapid stomach nausea Tired. When workers are exposed to hot temperatures it will reduce agility, extend reaction time and slow down decision-making time, interfere with brain work accuracy, interfere with coordination motor sensory nerves, and make it easier for emotions to be stimulated.

Dehydration

Dehydration is a condition in which the lack of fluids in the body due to the amount of fluid that exits is greater than the amount of fluid that enters. If the body loses a lot of fluids, the body will become dehydrated. Measurement of dehydration work done on brick workers in the Mojosulur brick home industry was carried out by the observation method through observing the color of the workers’ urine, then categorized as not dehydrating, mild dehydration, moderate dehydration and severe dehydration. Then the measurement results obtained are 7 people (23.3%) not dehydrated status, 7 people (23.3%) mild work dehydration status, 8 people (26.7%) moderate dehydration status, and severe dehydration status 5 people (16.7%).

A worker who is exposed to heat and without using proper personal protective equipment will be disturbed by his endurance. The body will neutralize body heat by sweating which results in reduced fluid and electrolyte salts in the body. Consumption of adequate drinking water can reduce the effects of dehydration due to heat pressure. This is because in drinking water there are electrolyte salts in the form of cations and anions needed by the body. The main cations contained in drinking water are sodium (Na+) and Potassium (K+) while the main anions are chloride (Cl-). One of the dangers of brickworkers’ workplaces is hot workplace temperatures due to direct exposure to sunlight and the additional heat from the combustion process so as to accelerate the dehydration experienced by workers. Therefore there is a need for control by home industry owners so that work dehydration can be reduced so that there is no decrease in work productivity.

Relationship of Work Climate with Dehydration

According to the Regulation of the Minister of Manpower and Transmigration of the Republic of Indonesia Number 5 Year 2018 Regarding NAV Physical and Chemical Factors in the Workplace, the NAV of the working climate with a working time of 50% - 75% ie 31°C for light workloads, 29°C for moderate workloads and 27.5°C for heavy workloads. Based on work climate measurements that have been made on the Mojosulur Bata Home Industry workers there are 20 respondents (66.7%) who work in working climate conditions> NAV and 10 respondents (33.3%) who
work in working climate conditions ≤ NAV. Workers who work in working climate conditions > NAV are more dehydrated, compared to workers who work in working climate conditions ≤ NAV. In working climate conditions > NAV

Using statistical calculations, based on the spearmen correlation test, the result \( r = 0.638 \) shows that there is a strong correlation between hot working climate and dehydration events. This is in line with the results of research conducted by Megayani Puspita Sari. The results of the analysis obtained information on the value of Pearson chi square with sig 0.00 < 0.05 so that Ho was rejected that’s mean there have correlation between hot working climate and dehydration.

In addition there are other studies that are in line with the results of this study, namely research conducted by Nensi which shows that there is a correlation between environmental physical conditions, namely between temperature and humidity at work with dehydration levels with the results of the value of the temperature contingency coefficient and dehydration level of 0.603 which means that the correlation between temperature and dehydration is very strong.

According to Suma’mur, workers who work in a workplace that exceeds the NAV of the working climate can experience the effects of heat stress. The effect of heat stress occurs as a result of the body’s process of maintaining body heat to no avail. The effect of heat stress can be in the form of subjective complaints due to heat stress such as complaining of heat, lots of sweat, always thirsty, feeling bad and loss of appetite caused by loss of fluid from the body by evaporation of sweat. Exposure to a physical work environment such as a hot work environment that continues can lead to health problems, one of which is dehydration.

**Conclusion**

Conclusion Based on the results of research conducted showed a strong correlation between the work climate with the dehydration incident experienced by workers at the Mojosulur Brick Industry, Mojokerto Regency. Most workers in the Mojosulur brick home industry are dehydrated in the moderate category, and only 7 workers are not dehydrated. Suggestions for home brick industry owners need to provide additional protection in a workplace that has a work climate that exceeds the Threshold Value so workers are not exposed to direct sunlight and the hot work climate can be reduced to less than the Threshold Value and needs to provide some a place for workers to take their drinks close to their work area so that when workers are feeling thirsty or dehydrated they can easily take the drinking water and drinks can be added with electrolyte salt.

Equality of Suffrage for People with Mental Disorders in Malang City

Nofi Sri Utami¹, Nanik Prasetyoningsih², Kuswanto Kuswanto³
¹Lecturer, Faculty of Law, Universitas Islam Malang, ²Lecturer, Universitas Muhammadiyah Yogyakarta, ³Lecturer, Universitas Darul Ulum

Abstract

Constitutional Court of Indonesia in 2015 established Constitutional Court’s Decision Number 135 / PUU-XIII / 2015 that revoked the provisions of Article 57 paragraph 3 letter a of Indonesian Law Number 8 of 2015 concerning Amendment of Law Number 1 concerning the Stipulation of Government Regulation in Lieu of Law Number 1 of 2014 which the substance prohibited person with disabilities for voting in election. Then, Law Number 7 of 2017 concerning General Elections, which exclusively gave political rights for people with disabilities to implement their political rights.

Qualifications for people with mental disabilities in elections of The Constitutional Court decides that the phrase “mental disorders/ memory impairment” must be interpreted as “experiencing mental illness and/ or permanent memory impairment which according to mental health professionals, has abolished one’s ability to vote in elections”. It means that sufferers with mental disorders and/ or impermanent memory impairment must still be registered as voters and they have the opportunity to use their voting rights in elections.

Equality of political rights for people with mental disorders (Orang Dengan Gangguan Jiwa (ODGJ)) in elections is very important because general election gives opportunity to increase participation and change public perception for the ability of people with disabilities. As the result, people with disabilities can have stronger political voice and they are recognized more as equal citizens. Moreover, this research was in category of normative research with normative juridical approach.

In conclusion, the equality of political rights for people with mental disorders (Orang Dengan Gangguan Jiwa (ODGJ)) in elections is very important because general election gives opportunity to increase participation and change public perception for the ability of people with disabilities. As the result, people with disabilities can have stronger political voice and they are recognized more as equal citizens.

Keywords: Voting Rights (suffrage), People with Disabilities, General Election

Introduction

Democracy in Indonesia is different from Western democracy. Western democracy is liberal or free democracy. Democracy in Indonesia is built from Pancasila, as a fundamental norm that is explained in law and regulation norms. Disabilities are part of Indonesian citizens who have rights for respect, protection, and fulfillment of their basic rights as what is guaranteed in the 1945 Constitution of the Republic of Indonesia. In legislative and presidential and vice presidential elections in 2014, people with disabilities still experienced discriminations and one of them was discrimination in using their right to vote in general elections. The cause was the absence of regulations that protected rights for people with disabilities. According to Abdul Rasyid Thalib, there are two authorities in Constitutional Court’s main authority, which are authority in examining law against the Constitution of the Republic of Indonesia and authority in interrupting

on authority dispute of state institutions. \(^{(2)}\)

In 2015, the Constitutional Court determined Constitutional Court (Mahkamah Konstitusi (MK)) Decision Number 135 / PUU-XIII / 2015 that revoked the provisions of Article 57 paragraph 3 letter a of Indonesian Law Number 8 of 2015 concerning Amendment for Law Number 1 concerning the Stipulation of Government Regulation in Lieu of Law Number 1 of 2014, which the substance prohibited people with disabilities to vote in general election. Based on this Decision, people with disabilities obtain political justice and it refers to this Decision. The Government enacted Law Number 7 of 2017 concerning General Elections, which exclusively gave political rights for people with disabilities to use their political rights. In Article 5 of Indonesian Law Number 7 of 2017 stated that: “Person with disabilities who qualifies have same opportunity as Voter, as candidate for House of Representative, as candidate for Regional Representative Board, as candidate for President/ Vice President, as candidate for Regional House of Representative, and as Election Organizer”. \(^{(3)}\) The provisions of Article 5 of Law Number 7 of 2017 were in accordance with the provisions of Article 75 paragraph (2) of Law Number 8 of 2016 concerning Person with Disabilities which stated that, “Central Government and Regional Government must guarantee the rights and opportunities for Person with Disabilities to elect and to be elected”. Discriminatory provision in provision of Article 57 paragraph (3) letter a of Law number 8 of 2015 was submitted to the Constitutional Court (Mahkamah Konstitusi (MK)) of Indonesia to be conducted material test against provisions in the 1945 Constitution of the Republic of Indonesia, especially against Article 28D paragraph (1). Petition of material test was submitted on 20th October 2015. Then, on 27th September 2016, the Constitutional Court issued Decision Number 135 / PUU-XIII / 2015 against the petition. In Decision of amar (verdict), it was conveyed that the Court granted some petitioners, especially in stating that Article 57 paragraph (3) letter a of Law Number 8 of 2015 did not have binding legal force as the phrase of “mental disorders/ memory impairment” is not interpreted as “experiencing mental disorder and/or permanent memory impairment which according to mental health professionals, has abolished someone’s ability to vote in general elections”.

The Constitutional Court’s decision views person with disabilities in general, but what is being debated today is the participation of the person with mental disabilities in general elections as voter, which is called as People with Mental Disorders (Orang Dengan Gangguan Jiwa (ODGJ)). General Election Commission (Komisi Pemilihan Umum (KPU)) of Indonesia had stipulated Election Commission Regulation Number 11 of 2018 concerning the Compilation of Voter Lists which stipulated to allow people with mental disabilities to use their suffrage. General Election Commission (KPU) had included people with disabilities (ODGJ) in Permanent Voter List (Daftar Pemilih Tetap (DPT)) in general election in 2019. Around 5,000 people with mental disabilities had been registered in Permanent Voter List (Daftar Pemilih Tetap (DPT)). Although General Election Commission only included voters who qualified administrative requirements on the voter list, as long as the people with disabilities qualified the requirements, they must be given their suffrage. \(^{(4)}\)

However, being allowed for the people with disabilities (ODGJ) to vote in general elections caused procontra in legal experts, politicians, educators, students, communities, and all groups of community because there were fears of ODGJ vote which could be misused later by irresponsible elements. Some people believed that ODGJ could not vote. This opinion was based on the provisions of Article 433 of the Civil Code which stated that people with mental disorders must be with tutelage. Thus indirectly, ODGJ could not vote. According to Civil Code, person who is under control by tutelage is considered incapable in doing legal actions. In other words, the person with disabilities cannot be accountable for his/her actions. According to the provisions of Article 1330 paragraph (2) of Civil Code, person who is under tutelage is stated that he/she is not capable in law, such as a crazy person or memory loss person. \(^{(5)}\) All legal actions for people who are under the tutelage are represented by their tutelage as what is stipulated in the provisions of HIR Article 145 and Article 171 of Law 8/1981 concerning Criminal Procedure Law. Article 145 of HIR stipulates that one of the people who cannot be heard in court as witnesses is crazy people, even though the crazy people sometimes had bright memories. Thus, it might be understood that ODGJ is not capable in law.
**Method**

**Research Type**

Type of this research was empirical juridical research. In this research, the researcher examined the equality of political rights for people with mental disorders (orang dengan gangguan jiwa (ODGJ)) in regional elections in Malang City.

**Research Approach**

Type of this research approach was sociological juridical approach. Juridical approach in this research aimed at analyzing Indonesian Law Number 7 of 2017 concerning Elections, then, sociologically looking at the implementation of these regulations in Malang City people who were as participants in the election of Regional Government.

**Data Source**

- **Primary Data Source**

  Data was obtained from parties which were related directly with this research and the parties were:
  1. Batu City people
  2. Batu City people who became part/ who suffered from mental disorders.

- **Secondary Data Source**

  Supporting data were such as books, archives, documents, and many more which were obtained during research process.

**Technique of Data Collection**

- **Primary Data**

  Techniques which were used to collect primary data were observation, documentation, and question and answer verbally and directly which were open, dialogic, and systematic through in-depth interviews in order to explore more closely regarding the equality of suffrage for people with mental disorders in Batu City.

- **Secondary Data**

  Data was obtained through literature research which was collecting and studying literature in accordance with this research as a comparison of literature and theory studies.

**Discussion**

Mental disorders are indicated by person’s inability to assess reality. It is caused by a disturbance of neurochemical balance in nerve cells in human brain that makes the person is disrupted and unproductive in society. In Indonesia, implementation of human rights is guaranteed by the 1945 Constitution of Republic of Indonesia as well as Law Number 39 of 1999 concerning Human Rights, specifically in article 23 which states that everyone (including people with mental disorders) has rights to elect and political beliefs. In 2005, Indonesia also had ratified International Convention on Civil and Political Right (ICCPR), and had become an active legislation that was Indonesian Law Number 12 of 2005 in article 25 (b) which stated that every citizen had right and opportunity to elect and to be elected in honest periodic general elections with universal and equal suffrage.

In Indonesian Law Number 18 of 2014 concerning Mental Health, people who suffer from mental disorders/ memory impairment are called as People with Mental Disorders (Orang Dengan Gangguan Jiwa (ODGJ)) and determination (diagnosis) as ODGJ can only be conducted by certain professionals such as Psychiatrists, Doctors, and Clinical Psychologists. The diagnosis must be referred to Guidelines for the Classification of Mental Disorders in Edition III (PPDGJ III).

Clinically, in order to assess whether someone is considered to have capacity to make choice or not, at least, he/she must be able to state 4 things, which are understanding the choice that is given, being able to state their choice, having reasons why to choose the choice, and knowing the consequences from that choice. This capacity must be checked specifically for specific purposes or situations. The example of clinical situation is sufferer’s capacity needs to be examined in order to determine whether the sufferer has capacity to determine treatment type that will be given, or to determine his/her willingness to participate for the research. Of course, the sufferer must be given a complete explanation until he/she understands what the consequences from the treatment or the consequences from the participation in the research. The capacity in making choice aims...
to guarantee the choice that will be taken is the best choice for him/her and at the same time, it protects him/her from bad consequences that may arise. No one knows more about him/her, except for himself/herself. Therefore, the best choice for him/her can be different from ordinary people.

Psychosis people with mental disorders (Orang dengan Gangguan Jiwa (ODGJ)) can still function normally for most of his/her life. Generally, psychotic mental disorders are chronic and episodic (recurrent). In ‘relapse’ condition, the ODGJ experiences hallucinations, has wrong thoughts, or behaves improperly.\(^\text{(10)}\) The content of his/her thought becomes difficult to be understood, even his/her ideas and actions are specific only for him/her. Sometimes, sufferers can be difficult to be directed and they can behave uncooperatively.\(^\text{(11)}\) In serious clinical condition like this, the sufferers must get treatment without being asked about his/her willingness. Sufferers are considered not to have capacity to determine the treatment. If the period of this severe relapse is occurred on Election Day, it is certainly not possible to force sufferers to come to the voting place to participate in voting. However, out of the relapse period, the sufferer’s thoughts, attitudes, memories, and behavior can be normal.\(^\text{(12)}\) Regarding registration process for the voter, which until election day is begun for quite long period of time (3-6 months), removing someone from the voter list will remove the sufferer’s rights which on election day, he/she is most likely to be in good condition and able to vote.\(^\text{(13)}\)

**Conclusion**

Voting in elections is not a difficult thing. There are no wrong choices, which have bad consequences either for sufferer or for society. Each person’s choice is very personal and cannot be accused or blamed. A person is not determined by diagnosis or symptoms which are experienced by the sufferers, but it is from cognitive ability. It means that psychosis people with mental disorders (Orang dengan Gangguan Jiwa (ODGJ)) such as schizophrenics, bipolar, or severe depression do not automatically lose the capacity to make choice. The capacity can be reduced or considered to have no capacity for only sufferers who suffer from serious cognitive dysfunction. However, it needs to be known that cognitive function can be improved by learning and training. A person who is deemed not to have capacity can be educated and trained repeatedly, thus, his/her capacity can

Determining the Exposure of Benzene, Toluene, Xylene (in Condensate) in a Chemical Laboratory of Natural Gas Company by Chemical Health Risk Assessment (CHRA)

Nora Putri Sabilla1, Noeroel Widajati2

1Research Scholar, 2Professor of Department of Occupational Health and Safety, Public Health Faculty, Airlangga University, 60115, Surabaya, East Java, Indonesia;

Abstract

Introduction: Chemical risk assessment is needed to find out how high the hazard level of chemicals in the laboratory. This chemical health risk assessment will assess how often the chemical is exposed to workers, how much exposure it is so that the level of risk can be understood. The purpose of enabling decisions to be made on appropriate control measure, training of employees, monitoring and surveillance activities as may be required to protect the health of employees who may exposed by hazardous chemicals to health at work.

Methods: This research is research with a qualitative approach. Based on the data collected, this study is observational. This study uses the Chemical Health Risk Assessment (CHRA) method. This method is carried out by identifying chemicals, determining Hazard Rating, evaluating exposure, assessing the adequacy of the control measures that have been carried out, concluding the CHRA results, and identifying the efforts that need to be made.

Result: In this study, there are three work units, namely a wet laboratory, oil laboratory, and gas laboratory. The chemicals analyzed are benzene, toluene, and xylene in the condensate. The hazardous chemical have significant risk now and already adequately controlled could increase in future (C2) which mean that the employees are at risk due to hazardous chemicals and it adequately controlled but the risk can increase in the future.

Conclusion: Therefore, several steps can be taken to control the risk of health hazards from benzene, toluene, and xylene in the condensate, for example: determine precaution to maintain controls and minimize chances of higher exposure occurring; determine additional measures for regaining control if a high-risk event occurs despite precaution; identify measures, procedures, and equipment to prevent or control any accidental emission of chemical hazardous to health, determine if monitoring or health surveillance is required to check on the effectiveness of controls; and review assessment every five years or when is a change in circumstances.

Key words: Hazardous chemicals, risk assessment, BTX, CHRA

Introduction

Natural gas processing companies are one of the industries that have laboratory facilities to support their production. However, the laboratory is one place where various chemicals gather in one place. Chemical exposure can have the potential to cause health problems for workers. Chemical laboratory workers have a significant risk of exposure to hazardous chemicals1.
inhale toluene can cause euphoria, drunkenness, dizziness, trembling, convulsions, respiratory disorders, and tremors. Through ingestion, toluene can cause oropharyngeal and digestive tract. On the eyes, it can cause lacrimation and corneal damage, while it may cause erythema and dry skin through dermal exposure. Effects due to chronic exposure to toluene via inhalation are damage to the liver, kidneys, and nerves, while to the skin it may cause contact dermatitis and irritation. Refinery natural gas workers are exposed to significant levels of benzene, toluene, ethylbenzene, and xylene (BTEX)\(^4\).

Chemical risk assessment is needed to find out how high the hazard level of chemicals in the laboratory. To carry out this risk assessment, all chemicals used must be identified, evaluated, and controlled against the hazards of chemicals that exist. This risk assessment is carried out as an effort to prevent health problems that may arise from exposure to chemicals. This chemical health risk assessment will assess how often the chemical is exposed to workers, how much exposure it is so that the level of risk can be understood.

**Material and Method**

This research is research with a qualitative approach. Based on the data collected, this study is observational. This study uses the Chemical Health Risk Assessment (CHRA) method. This method is carried out by identifying chemicals, determining Hazard Rating, evaluating exposure, assessing the adequacy of the control measures that have been carried out, concluding the CHRA results, and identifying the efforts that need to be made\(^5\).

The procedure in carrying out a DOSH, 2000 Chemical Health Risk Assessment (CHRA) is consists of ten aspects below:

**Chemical Identification and Hazard Rating (HR) Assessment**

The results of chemical identification are used to classify chemicals based on the health impacts that each chemical can cause. The grouping results will be assessed using the Hazard Rating (HR). Hazard Rating has a rating scale of 1 to 5, with the understanding that the rating scale of 1 is a scale for chemicals that are not dangerous to the health of the workforce, up to a rating scale of 5 which is a scale for chemicals that are very dangerous to the health of the workforce. Hazard Rating in the analysis of health risks due to chemicals is used to determine priorities based on the potential health hazards caused by chemicals.

**Duration of Exposure (Duration Rating / DR)**

Identifying the duration of exposure is done to assess the effects of chronic or routine exposure to the chemical used. Chronic effects assessments can use the total duration of exposure. The total duration of exposure is the product of the number of exposures in one week and the average duration of each exposure.

**Degree of Release or Occurrence of Chemicals**

The degree of release or appearance of chemicals in the environment can be estimated from information, including the physicochemical information contained in the Chemical Material Safety Data Sheet, the characteristics of the work process in the description of the chemical process, the number of chemicals used, the method of chemical use, environmental conditions workplace.

**Degree of Absorption or Contact with Chemicals**

Chemicals that are absorbed through the skin include organic solvents and some pesticides. The assessment of the degree of absorption or contact with chemicals must be based on the results of observations on the chemical that has the highest degree.

**Magnitude Rating (MR)**

Qualitatively, the Magnitude Rate or the amount of exposure is assessed based on the estimated dose of chemicals that are absorbed through inhalation and absorption on the skin. The absorption of chemicals through the eyes and skin comes not only from direct contact with chemicals but also from contaminated air, smoke, or particulates.

**Exposure Rating (ER)**

Exposure Rating (ER) is assessed through cross-tabulation based on the duration of exposure or Duration Rating (DR) and the amount of exposure or Magnitude Rating.
Assessment of the Adequacy of Controls That Has Been Done

Assessment of the adequacy of the control measures are evaluated for each work unit. This assessment is carried out simultaneously with the assessment of chemical exposure. The adequacy of the control that has been carried out is assessed by examining the control measures that have been made, checking the air inspection records, biological monitoring, and checking the inspection records, as well as testing the control equipment used.

Risk Rating (RR)

Determination of the risk level or Risk Rating is used to conclude the results of the chemical risk assessment that has been carried out. The risk level assessment is carried out based on the results of the exposure level or Exposure Rating and Hazard Rating that have been done. The level of risk will be evaluated based on “significant” and “insignificant”. The risk that is evaluated is “insignificant” if occupational exposure cannot cause health problems in the workforce.

Conclusion of Risk Assessment Results

The conclusion of the chemical risk assessment results can be made after the Risk Rating has been assessed. Based on the results of the Risk Rating assessment and assessment of existing control measures, there are 4 types of conclusions that can be reached in this assessment. The four types of conclusions are denoted by C1, C2, C3, C4, and C5.

Identification of Control Measures That Can Be Taken

The control measures that can be taken are identified based on the results of risk decisions resulting from the risk assessment that has been carried out. Some of these control efforts include:

a. Take appropriate measurements to control exposures that exceed safe limits.

b. Take measurements to eliminate intolerable risks.

c. End the assessment and set a new schedule to re-evaluate or review the assessment that has been done.

d. Decide whether exposure monitoring or health surveillance is more necessary.

e. Create a strategic long-term plan to control exposure to as low as reasonably practicable (ALARP).

f. Gather information or advice from specialists on a specific problem.

g. Maintain control equipment to keep working properly to implement a preventive maintenance program.

Result

In this study, there are three work units, namely a wet laboratory, oil laboratory, and gas laboratory. The chemicals analyzed are benzene, toluene, and xylene in the condensate. In this assessment, the chemical hazard will identify the type of chemical, the degree of exposure, and the adequacy of existing control measures. Based on these parameters a conclusion can be formed so that it can be used as input for efforts to reduce the risk of hazardous chemicals. The results of the following qualitative assessments obtained from the MSDS are shown in tables 1, 2, 3, and 4 below.

</table>
Based on the qualitative assessment results table above, it shows that the risk evaluation of benzene is included in the risk significant-category 2. Risk significant-Category 2 means that this hazard cannot be tolerated and must be eliminated, but if this is not possible, several efforts can be made such as the substitution of the hazardous chemical with a less hazardous chemical, total enclosure of process and handling system, or isolation of the work to control the emission of chemicals hazardous to health. Besides, the risk evaluation of toluene and xylene is included in the significant risk category-1. This means the risk has to be controlled to below permissible exposure limits or to as long as reasonably practicable (ALARP) where no limits are specified.

According to table 4, it shows that benzene, toluene, and xylene in condensate have a C2 conclusion, this means the risk is significant but adequately controlled. This conclusion applies to conditions where adverse health effects could increase in the future, due to control measure failure or deterioration; plant, equipment, or system failure; human error, from lack of awareness, monitoring failure or inadequate training; changes in methods or rate of work; and a significant increase in the number of chemicals hazardous to health used.

**Conclusion**

According to DOSH, 2000 the conclusion risk of Benzene, Toluene, and Xylene (in the condensate) is C2 which means the risk is significant but already adequately controlled could increase in the future. Therefore, several steps can be taken to control the risk of health hazards from benzene, toluene, and xylene in the condensate, for example: determine precaution to maintain controls and minimize chances of higher exposure occurring; determine additional measures for regaining control if a high-risk event occurs despite precaution; identify measures, procedures, and equipment to prevent or control any accidental emission of chemical hazardous to health, determine if monitoring or health surveillance is required to check on the effectiveness of controls; and review assessment every five years or when a change in circumstances.

Control measures are a way to reduce exposure to chemicals in labor. Prevention efforts that are carried out include eliminating chemicals that are hazardous to health, substituting hazardous chemicals with less hazardous chemicals, using controlled engineering equipment, isolation of hazardous chemicals, conducts health surveillance of workers, rotates employees if needed, and last uses personal protective equipment. Every control effort is carried out following the control hierarchy and according to the priority of chemical hazards that can be caused.

**Acknowledgements:** Thank you to all parties that are involved in the research, especially to the Laboratory of Natural Gas Company which has allowed the data collection.

**Ethical Clearance:** The study was approved by ethical clearance certificate Number 301 / HRECC. FODM / VI / 2020 from the Faculty of Dental Medicine Health Research Ethical Clearance Commission Universitas Airlangga.

Abstract

Introduction: The Government of India has passed special law, The Protection of Children from Sexual Offences (POCSO) Act, 2012 which provides strong shield for protection of children from heinous crimes of sexual assault, sexual harassment and pornography, thereby safeguarding the interest of children at every stage of judicial proceeding.

Methodology: A questionnaire based study was carried among 100 healthcare professionals working at the tertiary care Hospital, randomly selected. The questionnaire had 15 Multiple Choice Questions about Child Sexual Abuse related to POCSO Act. Collected data was analysed statistically.

Objective: The study is aimed to assess knowledge and attitude about Child Sexual Abuse related to POCSO Act among healthcare professionals.

Result: Greater percentage of healthcare professionals have knowledge about major aspects of POCSO Act, as related to its full form (75%), enactment (62%), definition of child (62%), different types of sexual offence (86%), its mandatory reporting (81%), and trial in child friendly special courts (64%). But in few areas, knowledge related is scarce as only 40% participants knew punishment scales of POCSO Act and 46% knew failure to report is punishable offence. 84% participants suggest multidisciplinary approach is the need of hour to tackle cases of child sexual abuse.

Conclusion: To curb this menace educating health care professionals along with children, spreading knowledge and awareness at community level with strict law enforcement will play a key role.

Keywords: POCSO Act; Child Sexual Abuse; Knowledge; Attitude; Questionnaire; Healthcare Professional.

Introduction

The World Health Organisation (WHO) defines Child Sexual Abuse (CSA) as the involvement of a child or an adolescent in sexual activity that he or she does not fully comprehend and is unable to give informed consent to, or for which the child or adolescent is not developmentally prepared and cannot give consent, or that violates the laws or social taboos of society1. The CSA is one of the most alarming concern globally, as same holds true for India. India has one of the largest proportions of population in younger age groups globally. As per Indian Census 29.5% of the population of the country has been in the age group 0-14 years and 41% of the population account for less than 18 years of age2. Therefore nation bears huge responsibility to safeguard them from every kind of child abuse.

Corresponding author:
Dr. Nowshen Goni, NIMS Girls Hostel, NIMS University, Jaipur-Delhi highway.
E-mail: gnowsheen@gmail.com.
India’s first study on child abuse was reported in 2007, it reported 53.22% children having faced one or more forms of sexual abuse and most of children did not report the matter to anyone. Crime against children in India is following steady upward trend with a significant increase of more than 500% over a period of the past one decade (1,06,958 cases in 2016 over 18,967 cases in 2006), where Uttar Pradesh tops the list with 15% of recorded crimes against children, Maharashtra and Madhya Pradesh closely follow with 14% and 13% respectively.

The children who are promising future of a country are suffering inequity mainly in developing countries among which sexual abuse is the most heinous crime. In 2012, Indian government enforced a revolutionary act in Protection of Children from Sexual Offences (POCSO) Act, which has demarcated sexual abuse in child from that of adult. In India prior to enactment of POCSO Act there was no child specific act related to CSA followed nationwide. The Goa Children’s Act, 2003, was the only child abuse confined law with its state specific enactment in Goa. All the crimes related to child sexual abuse were punished under various Indian Penal Code (IPC) legislations (IPC 375- rape, IPC 354- outraging modesty of woman, IPC 377- unnatural sexual offences) were put in force for dealing with child sexual abuse. The POCSO Act brought all forms of sexual offences related to children under one umbrella of legislation right from reporting to judgement. The principle POCSO Act, 2012 is a comprehensive law which provides the protection of children from the offences of sexual assault, sexual harassment and pornography, while safeguarding the interest of the child at every stage of the legal proceedings by incorporating child-friendly system for reporting, recording of evidence, investigation and speedy trial of offences through designated Special Courts. It defines a child, as any individual below the age of eighteen years with no gender bias which is in accord with UN Convention on Rights of Children, the most validated children rights treaty worldwide. The POCSO Act identifies six types of sexual offences in children:

1. Sexual Assault: When a person with sexual intent touches the vagina, penis, anus or breast of the child or makes the child touch the same for that person or someone else. The punishment is minimum imprisonment of 3 years which can go up to 5 years and fine.

2. Aggravated Sexual Assault: When the sexual assault is carried by a person who in position of trust like relative, police officer, a member of armed force, public servant, management or staff of hospital or educational or any other religious institution. The punishment is minimum imprisonment of 5 years can go up to 7 years and fine.

3. Penetrative Sexual Assault: Whoever causes insertion of penis/ object/ another body part in child’s vagina/ urethra/ anus/ mouth, or asking the child to do so with him or someone else. The punishment is minimum imprisonment of 7 years which can go up to life-time imprisonment and fine.

4. Aggravated Penetrative Sexual Assault: When the penetrative sexual assault is carried by a person who in position of trust like relative, police officer, a member of armed force, public servant, management or staff of hospital or educational or any other religious institution, it constitutes aggravated penetrative sexual assault. It also covers any grievous hurt caused to child, penetrative sexual assault on already pregnant child, repeated assault and penetrative assault on child below the age of 12 years. The punishment is minimum imprisonment of 10 years which can go up to life-time imprisonment and fine.

5. Sexual Harassment: Whoever passes sexuality related remark, sexual gesture/noise, repeatedly following, flashing, or makes the child exhibit any part of his body so as it is seen by such person or any other person. The punishment is imprisonment up to period of 3 years and fine.

6. Using Child for Pornographic Purposes: Whoever uses child in any form of media for the purpose of sexual gratification. The punishment is imprisonment up to 5 years and fine.

According to National Crime Record Bureau, crime against children is increasing in India each successive year, in major metropolitan cities total of 18247 cases of crime against children were seen in 2015, which increased to 19081 cases in 2016, further increased to 19544 in year 2017. Moreover, in 2018 records of NCRB India, crimes under POCSO Act were among leading crime heads of Crime against Children and contributed 34% to it. The rate of crime has increased per lakh children
population from 28.9 in 2017 to 31.8 in year 2018\textsuperscript{10}, such a rising surge each year where every single rise in number means silent massacre of innocence. It led Government of India take great initiative to amend POCSO Act by introduction of capital punishment for aggravated sexual offences and adding various new clauses to the principle act making it more stringent with respect to punishment standards\textsuperscript{11}. To control this endless crime, with the efforts of Government in formulation and implementation of new legal provisions, public knowledge and attitude are equally significant as procedural tools in preventing and eliminating such offences.

**Material and Methods**

Setting: This study was conducted at National Institute of Medical Sciences and Research (NIMS) Hospital, a tertiary care Hospital in Jaipur.

Study design: The study design is cross sectional questionnaire-based study. Participants of study consisted of 100 healthcare professionals (doctors) working at NIMS Hospital in Jaipur. The survey conducted is about knowledge and attitude about CSA related to POCSO Act in health care professionals. These professionals were randomly selected from all those working at NIMS hospital, with only criteria of minimum MBBS (Bachelor of Medicine and Bachelor of Surgery) qualification. The questionnaire had multiple choice questions (MCQs) related to POCSO Act, these were distributed among participants in their respective department with the help of volunteers from undergraduate students of third-year MBBS. The questionnaire comprised of basic demographic profile along with 15 multiple choice questions, among which first 12 questions were related to knowledge, two related to attitude and one related to source of information. Pretesting of questionnaire was done on 20 randomly selected healthcare professionals of the hospital. The questionnaire was finalised after modifying unsuitable questions based on the pre-test result.

Data collection: One hundred and twenty questionnaires were distributed among healthcare professionals from which 100 respondents were included in the study, who filled all criteria of questionnaire properly remaining were discarded. One day was given for data collection with no specific time followed.

**Results**

Response rate was 83% as out of 120 distributed questionnaires among which 100 participants responded properly fulfilling all criteria and same were included in study population. Demographic details of health care professionals are summarized in Table No. 1.

As per knowledge based questions asked, 75% healthcare professional knew the abbreviation POCSO stands for. Both the year in which POCSO was enacted and the age related definition of child under POCSO Act was known to 62% participants. 86% of healthcare workers knew offences that come under POCSO Act. 81% participants knew that reporting child sexual abuse is mandatory but only 46% had knowledge that failure to report is punishable offence. Only 40% of healthcare professional were aware that punishment is graded as per magnitude of offence under POCSO Act. Trial of cases under POCSO Act are held at child friendly Special courts was correctly marked by 64% people. 95% participants were aware that POCSO Act is gender neutral. Child helpline number of India was known to 64% of healthcare professionals. 72% professional knew Child sexual abuse is punished under POCSO Act. Only 56% healthcare workers were aware that POCSO Act was amended in 2019. Figure No.1 gives graphical representation of knowledge-based response in healthcare professional.

The present study regarding attitude of healthcare professionals about CSA revealed, 4% healthcare professionals opine Government Organizations will play a vital role in supporting sexually abused child while as 9% say Non-Government Organizations (NGO) will, whereas 21% healthcare workers say child welfare committee should play the key part, but majority of healthcare professional 66% suggest that community as a whole including fore mentioned all Organizations together should play vital role to support sexually abused child. In view of 5% participants it is educating the children from primary level is need of hour to reduce CSA, 8% respondents say strict law enforcement is most important to follow, 3% suggest spreading of awareness.
at community level is more important, whereas majority of healthcare workers (84%) agree that collective effort of all of the above measures is required. Data is represented in graphically in Figure No.2.

![Figure No. 2: Attitude-based response given by Healthcare Professionals](image)

Lastly, about source of knowledge about POCSO Act, 41% of respondents said it was a teacher at an educational institution who provided them knowledge about POCSO Act, 33% got it from electronic media (internet, television, radio, etc.), 19% from print media (newspapers, journals, books, etc.) Whereas family and friend discussion in 7% respondents was the source of information related. Graphically shown in Figure No.3.

![Figure No. 3: Source of knowledge related to POCSO Act among Healthcare Professionals](image)

### Discussion

Child sexual abuse is menace worldwide, making it issue of global concern with short-term and life-long consequences on the physical as well as mental health of a child. An epidemiological overview by Mannat M Singh et al (2014) reported the prevalence of CSA was found to be high in India as well as throughout the world. CSA is an extensive problem and even the lowest prevalence includes a huge number of victims. The POCSO Act practices no discrimination in the provision of care towards abused child, irrespective of sex, race, ethnicity, religion, sexual orientation, and socioeconomic status.
which is in accordance with WHO guidelines.7,13 The World Health Organization (WHO) has been working for years to challenge gender stereotypes and combat gender inequality, identify and eliminate gender-related barriers to healthcare, and implement gender-responsive care. Knowledge about gender neutrality of victim in POCSO Act was reported by 95% of respondents in our present study which shows promising number for good practice when dealing with CSA cases.

Mandatory reporting under POCSO Act will break the silence on child sexual abuse which is still a taboo, greater number of concealed cases will pop up and verdict of justice will prevail. In India a large number of cases on child sexual abuse go unreported due to socio-cultural and ethical stigma related to it. Delanthabettu et al in 2017 conducted a questionnaire based study on Child Sexual Abuse in school going children, which showed among 1336 students, 165 reported sexual abuse, among which 51.7% victims remained silent or ignored it while just 17.2% children informed their parents. This silence encourages the perpetrators to become more fearless and continue the more severe forms of sexual abuse. But under POCSO Act, failure to report any case of child sexual abuse is punishable offence, one may be punished with imprisonment up to period of six months with or without fine.7 Same ideology is put forth by Paradise J S in his article related to CSA that the physicians must report all cases of suspected sexual abuse to United States child protective services agencies as failure to do so can incur legal penalties.15 This shows not only in India but in other countries too reporting of CSA is mandatory. Another study on CSA by Arya and Chaturvedi (2017) reported that lack of proper training to handle the victim of CSA may add to the problems of doctors.16 Therefore knowledge about POCSO Act in doctors is not only important from victims prospective but also for safeguarding themselves from the legal penance.

Government of India has shown many great effort in safeguarding rights of children, one among which is Child helpline, 1098. This child-line is developed and managed by CIF (Child India Foundation), it is a 24x7, emergency, free phone outreach service linking children in need of care and protection, to relevant organisations run by government departments and civil society organisations for long-term care, protection and rehabilitation.17 This helpline has been life saviour for many victims as its easy accessible one point contact between distressed person and responsible authorities. Along with parents and guardians, people who are related to children and their rights need to be aware about it, among our study good percentage (62%) of participants had knowledge about this child-line number.

Healthcare professionals are first-line support to sexually abused children. As per WHO guidelines regarding first- line primary psychological support to all children and adolescents who disclose sexual abuse, a healthcare provider should be able to provide minimum level of psychological support with validation of their experience.18 In accord with same Indian legislation has set forth the guidelines under POCSO Act for medical professionals, who are to deal with sexually abused children.19 Medical practitioner who provides medical assistance to victim is liable to show proficiency in: (1) history taking in child friendly manner; (2) collection of evidence after a thorough medical examination; (3) treatment of physical and genital injuries if present; (4) evaluation for mental health status and referral for psychiatric counselling sessions if required. Sometimes age assessment of victim is also mandated by court. A study by Moirangthem S et al (2015) reported issues and concerns related to child sexual abuse, which stated training all the stakeholders is one of the important variables in providing comprehensive care and justice under POCSO Act.20 In the special article related POCSO Act by Seth and Srivastave (2017) supported same fact stating Paediatricians and health care professionals need to acquire necessary expertise for clinical evaluation of CSA, as they are usually first point of contact with sexually abused child.21 Thus initiatives for training of practising health care professionals along with medical students should be considered important for better structured approach of abused victims.

Punishment section of every crime holds great importance, as it keeps crime in check. Same is true for CSA, for which in India POCSO Act defines punishment scale. Our present study result showed poor awareness in health care professionals about punishment section and amendment (2019) of POCSO Act. Similar results were observed by Singh Jaswinder et al (2019) who aimed to ascertain level of knowledge and perceptions in MBBS course students at Bareiley, which reported
limited knowledge in participants related to legal aspects of CSA, reporting and preventive measures of such crimes. Another research study report by Kailash Satyarthi Children’s Foundation (KSCF) on Awareness and Perceptions about Child Sexual Abuse among 987 young adults of India disclosed three out of every four young adults do not possess a basic understanding about CSA, very few were aware that even teasing is a crime. Among surveyed participants 90% were aware that the CSA is a punishable offence but only 72% had awareness of the POCSO Act, which shows similarity with our study results where 75% of healthcare professionals had awareness about POCSO Act. Study by Minakshi Bhosale et al (2018) in medical students about CSA showed variance with our study results as it reported only 20.4 % participants were aware about the POCSO Act. Therefore, such dispersed result data suggest that there is still an immense need to aware general population along with medical professionals about CSA and related legislation (POCSO Act), as awareness about sexual abuse can go a long way in prevention of CSA. The Gupta et al (2013) reported POCSO casts a duty on the central and state governments to spread awareness through media including the television, radio and the print media at regular intervals to make the general public, children aware of the provisions of this act. The study by KSCF reported electronic and print media, were main source of information to respondents about CSA whereas our study reported 41% respondents had a teacher who was their primary source of information about POCSO Act closely followed by electronic media in 31% respondents.

Conclusion

Basic knowledge regarding POCSO Act is present in majority of healthcare professionals but knowledge related to deeper aspects is scarce which includes punishments related to POCSO Act and amendments it has gone through. This knowledge gap could be filled by introducing POCSO Act in basic MBBS curriculum and to refresh same in practising medical professionals by conducting regular CME (Continued Medical Education), seminars, symposiums and workshops related to CSA mainly focusing on POCSO Act. Nonetheless educating children from primary level about good and bad touch, spreading knowledge and awareness at community level is equally important to curb CSA. Multidisciplinary approach involving primary healthcare workers, police officers, legal agencies, lawyers, child welfare committee workers, paediatricians, gynaecologists, forensic experts, psychiatric specialists, NGOs, are essential to handle the cases of CSA for its better structural approach and improved outcome. Moreover, for rehabilitation of sexually abused children supportive environment at school and home need to be nurtured.

Acknowledgement: We would be obliged and thankful to all the medical-practitioners who cooperated with us and became part of our research study.

Conflict of Interest: All the authors declare that they have no conflict of interest.

Informed Consent: Informed consent was obtained from all the study participants.

Level of Knowledge and Family Support toward Medication Adherence among Patient with Diabetes Mellitus in Malang, Indonesia

Nur Lailatul Masruroh1*, Alifia Fatehana Pangastuti2, Nur Melizza1, Anggraini Dwi Kurnia1

1Lecturer, 2Nursing student, Department of Community Health Nursing, Faculty of Health Science, University of Muhammadiyah Malang, Jl. Bendungan Sutami 188A Malang, Indonesia

Abstract

Patient compliance with long-term therapy for chronic diseases in developing countries is still low. Efforts to control blood sugar levels remain normal with medication adherence depending on family support and patient knowledge of the disease. This study aimed to determine the relationship between the level of knowledge and family support with medication adherence in patients with diabetes mellitus in Malang, Indonesia. The study design was cross-sectional. The sample of this study was 48 people with diabetes mellitus recorded in Ciptomulyo Health Center. This study uses a simple random sampling technique. The questionnaire used consisted of demographic data, knowledge, family support, and medication adherence. The results of the study were that there is no relationship between the variable level of knowledge and medication adherence in patients with diabetes mellitus with a significance value of p = 0.561. There was a relationship between family support and medication adherence in patients with diabetes mellitus with a significance value of p = 0.000 and a Correlation Coefficient value of 0.616 which indicates a significant relationship with a strong degree of relationship strength. There is a relationship between family support and medication adherence in patients with diabetes mellitus at the Ciptomulyo Health Center. The better the family support, the more obedient the patient is undergoing treatment.

Keywords: Knowledge, Family Support, Medication adherence, Diabetes Mellitus

Introduction

The global diabetes prevalence in 2019 is estimated to be 9.3% (463 million people), rising to 10.2% (578 million) by 2030 and 10.9% (700 million) by 2045. The prevalence is higher in urban (10.8%) than rural (7.2%) areas, and in high-income (10.4%) than low-income countries (4.0%). Indonesia became Top 10 countries or territories for number of people with diabetes (20–79 years) in 2019, 2030 and 2045. In addition to the world and Indonesia level, the increase in the incidence of Diabetes Mellitus in the data based on the diagnosis of doctors, the prevalence of Diabetes Mellitus in the population of all ages by the province in 2018 especially in the province of East Java was recorded as much (2%), the average age of 55-64 years sufferers (6.3%), male (1.2%) while the female (1.8%). In urban areas more (1.9%) and rural areas only (1.0%). The prevalence of Diabetes Mellitus according to the 2015 Consensus consensus in the population aged ≥ 15 years was recorded at 10.9%. According to WHO, it is predicted that there will be an increase in Diabetes sufferers in Indonesia from 8.4 million in 2000 to 21.3 million in 2030.

WHO reports that the average patient adherence to long-term therapy for chronic diseases in developing countries is still low, whereas in developed countries it reaches 50%. Several reasons can affect diabetics who do not routinely take OAD / insulin injections, among others: feeling healthy, not routinely going to a health care facility, taking traditional medicine, often forgetting, not being able to take side effects, not being able to buy...
drugs regularly, and the unavailability of drugs in health care facilities. Successful management of Diabetes Mellitus can be seen from adherence to the glucose diet and also depends on the patient himself. Things that can affect the attitude in going on a diet or treatment are adequate levels of knowledge from sufferers about their illness, controlling blood sugar levels, and preventing complications to live healthier and more quality.

Compliance with medication in patients with diabetes mellitus against treatment programs that have been recommended by doctors or health workers can worsen the condition of the disease. Efforts to control blood sugar levels remain normal also depend on motivation, family support, and patient knowledge of the disease. Someone who is making a choice is also related to the knowledge that is related to the behavior that will be taken. The knowledge in question is the patient’s knowledge about the causes, signs, how to treat, and where to seek treatment. Meanwhile, family support can increase a patient’s positive emotional response to the management of his illness due to the help and motivation. Patient compliance with taking drugs plays a very important role in the success of treatment to maintain blood glucose levels and blood pressure in the normal range.

The purpose of this study was to determine the relationship between the level of knowledge and family support with medication adherence in patients with diabetes mellitus. The results of this study can be used as a reference for community nurses in providing education for people with diabetes mellitus about the importance of increasing knowledge about their illnesses and the importance of family support for adherence to taking medication for people with diabetes mellitus. As a result, blood sugar levels remain stable and normal.

**Method**

**Study design and Sampling**

The research method used is a correlational research design with a cross-sectional approach. The sampling technique used in this study was carried out with the Simple Random Sampling technique. Samples obtained as many as 48 respondents from 54 populations in RW 2. The number of samples was obtained from the results of calculations using the Slovin formula.

**Level of knowledge questionnaires**

This questionnaire uses The Diabetes Knowledge Questionnaire (DKQ-24) related to the client’s knowledge of the cause of the disease, symptoms or signs of the disease, how to treat or where to seek treatment by respondents who were adopted from the Menino (2017) that was modified by the researcher. This questionnaire has 24 statement items. In this questionnaire using a scoring of 3 categories that are worth <56% (Less), 56% -75% (Fair), 76% -100% (Good) with a score of 1 correct answer and 0 on the wrong answer.

**Family support questionnaires**

Family support for Diabetes Mellitus patients was measured using a social response questionnaire adopted from Kurniawan (2016) and modified by researcher. This questionnaire has 4 criteria for answers starting from options always to never using multiple-choice types. This family support questionnaire includes 3 family support domains with 12 question items. The scope of the family support domain in this questionnaire includes the domain of informational support, instrumental support, and emotional support and self-esteem. The scoring in this questionnaire uses four scales worth 1-4. Value 1 (never), 2 (rarely), 3 (often) and 4 (always). The highest total score is 48 and the lowest is 12.

**Medication adherence questionnaires**

Medication adherence for patients with diabetes mellitus measured using MMAS-8 (Morisky Medication Adherence Scale) is used to assess compliance with taking drugs that have been translated and validated in the Indonesian version by Ardanti (2016) about research into drug adherence in DM patients consisting of four aspects i.e. forgetting / not taking medicine as much as 4 questions with item number 1,2,4,5; stop taking medicine for 2 questions for items number 3 and 6; treatment interferes with 1 question on item number 7 and it is difficult to remember taking medicine on item number 8. This questionnaire contains 8 questions, each question has a choice of the answer “yes” or “no” and one question with 5 Likert scales (never / rarely, several times, sometimes, often and always). Response categories consist of “yes” or “no” for question items number 1-8. In question items, number 1-4 and 6-8 the value is 1 if the answer is “no” and 0 if the answer is
“yes”, while question number 5 is valued 1 if “yes” and 0 if “no”. The interpretation of this questionnaire is stated to be compliant (value = 8), less compliant (value = 6-7) and non-compliant (value = <6) 11.

Data Analysis

Research data were analyzed using descriptive and analytical analysis with the Spearman Rank correlation test. Data analysis using Statistical Package for Social Sciences (SPSS) software version 23.0. A p-value <0.05 was considered statistically significant.

Table 5 explained that the frequency of medication adherence variables in patients with diabetes mellitus is in the category of poor adherence as many as 25 people (52%) and the category of non-adherent as many as 15 people (31%).
Crosstabulation of the level of knowledge, family support, and medication adherence

Table 6 shows the results between the level of knowledge and family support with medication adherence in patients with diabetes mellitus, it is known that the highest score on the variable level of knowledge is in the category of lack of knowledge and adherence to taking medication that is less adherent as many as 19 respondents from 48 respondents. Meanwhile, the family support variable is lacking in the category, and adherence to taking medication that is not compliant is 20 respondents out of 48 respondents.

Correlation between Level of knowledge and medication adherence

Based on table 7, it is known that the Spearman rho correlation test results obtained p-value = 0.05 smaller than alpha (0.05), then meaning that there is no relationship between the level of knowledge and adherence to taking medication with patients with diabetes mellitus.

**Discussion**

The results showed that the majority of respondents had a lack of knowledge. The level of knowledge can be influenced by several things, such as experience, education level, beliefs, and facilities. The majority of respondents in this study fall into the category of adult age, adulthood is the age at which individuals re-evaluate life experiences and redefine themselves in their roles and values. This is confirmed by research conducted by Sulistin (2015) using adult respondents with a high level of knowledge and there is a significant relationship between the level of knowledge and people’s attitudes about schistosomiasis. Research respondents who are in RW 2 Ciptomulyo Public Health Center in Malang, it can be concluded that diabetes mellitus patients have a lack of knowledge, this can be influenced by age and education factors, where the majority of patients including 28 elementary school graduates. In line with a previous study reported that people with diabetes mellitus had poor level in diabetes knowledge (31.5%). Based on the results of the study, it was found that the family support of patients with diabetes mellitus at the Ciptomulyo Health Center is classified in the poor category. This is likely due to instrumental and emotional family support being classified as low. This study in line with Iloh (2018) that reported 22.5% did not have family support among diabetic patient.

It was found that adherence to taking medication in patients with diabetes mellitus was classified as less compliant as many as 25 people (52%). According to Alqarni (2019) reported that 21.4% had low medication adherence among diabetic patients in the Bisha governorate of Saudi Arabia. Factors recorded in this study, which can be called influential on adherence to taking medication for patients with diabetes mellitus are knowledge, which can be seen from the data filling questionnaire level of knowledge that the majority of patients included in the category of fewer than 33 people (69%).

The results of this study can be concluded that the relationship between the level of knowledge with medication adherence in patients with diabetes mellitus in Ciptomulyo Health Center is uncorrelated because the variable level of knowledge has a significance value > 0.005 and with a very weak correlation strength. In this
study, the variable level of knowledge with medication adherence does not have a significant relationship because Factors recorded in this study are internal factors, it was found that the majority of patients with diabetes mellitus in Puskesmas Ciptomulyo graduated from elementary school as many as 28 people (58.3%), not working as many as 33 people (68.8%), aged 18-65 as many as 34 (71%). These factors affect the level of knowledge of patients regarding adherence to taking the medication they live. So it can be concluded that in this study Ho was accepted that there was no relationship between the level of knowledge with medication adherence in patients with diabetes mellitus in Ciptomulyo Health Center.

Based on the results of the study, it is known that the highest score on the variable family support with the category of lack and adherence to taking the category of medication less adherent as many as 20 respondents from 48 respondents. Developmental stage in patients with diabetes mellitus in Puskesmas Ciptomulyo RW 2, including at the stage of family life with old age, at which stage the patient adjusts to losing a partner and maintains intergenerational ties, so that the majority these patients only live alone and are often left traveling by family and children, both for work, family matters, etc. Meanwhile, in terms of education and the level of knowledge of the majority of diabetes mellitus patients in Ciptomulyo Public Health Center there are 28 elementary school graduates (58, 3%) and with a level of knowledge of the category of fewer than 33 people (69%). Results from the Spearman Rank correlation test can be concluded that family support with medication adherence in patients with diabetes mellitus correlates with a significance value <0.005 and with sufficient correlation strength. The results of tests that have been carried out can be concluded that the better the support provided by the family will increase the compliance to take medication for patients. In line with a previous study that perceived family members engage in more unsupportive behavior is associated with less adherence to one's diabetes treatment regimen, and being less adherent is associated with poorer glycemic control. 17

Conclusions

There is no relationship between the level of knowledge and adherence to taking medication and the relationship between family support with adherence to taking medicine that is with the strength of a strong relationship. In mean that family support should be improved to provide medication adherence among diabetes patient. Family support have a main role improving medication adherence among patient with diabetes mellitus. As a result, nurse should work together with the family member to prevent the diabetes complication through medication adherence,

Influence of Exercise Classics on the Development the Volume of Attention of Schoolchildren Aged 8-9

Polevoy G. G.
Candidate of Pedagogical Sciences, Associate Professor, Department of Physical Education, Moscow Aviation Institute (National Research University), Moscow, Russia

Abstract

The aim of the study: To determine the influence of exercise Classics on the development of the volume of attention of children 9-10 years old in physical education lessons.

Methods and Material: The study was conducted over a period of 9 months, in which 40 9-10-year-olds took part. Physical education classes were held 2 times a week for 40 minutes each lesson. The level of development of coordination abilities was assessed on the «Shuttle run» test, and the indicators of attention volume on the «Schulte Table» test. The programs bio-stat 2009, Microsoft excel 2016 and t-student were used for mathematical and statistical processing of results.

Results: Before the beginning of the pedagogical experiment, the indicators of school children between the groups did not have significant differences (P>0.05). After the end of the study, the indicators in both groups improved. In CG, in the «Shuttle run» test, the indicators improved from 10.2±0.6 to 9.9±0.5 (P>0.05), and in the volume of attention test, the indicators improved by 6.1% (P>0.05). In EG, in the «Shuttle run 3x10 m» test, the indicators improved from 9.9±0.5 to 8.5±0.4 (P<0.05), and in the «Schulte Table» test, the indicators improved by 32.1%. These results indicate the effectiveness of using exercise Classics in physical education lessons in working with younger schoolchildren.

Conclusion: if schoolchildren will perform exercise Classics in physical education classes at school, they will improve not only coordination abilities, but also the volume of attention.

Key Words: volume of attention, coordination abilities, schoolchildren, physical education, Classics.

Introduction

A healthy lifestyle includes several components, including motor activity. It should be noted that insufficient motor activity, even in childhood, can lead to serious negative consequences for health. Unfortunately, there are more and more first-graders who have abnormalities in their health, usually due to lack of movement. Physical education at school is an integral part of the modern education system. The main form of physical exercises in school is a physical culture lesson. At the lesson, schoolchildren receive the necessary minimum of knowledge, skills, and skills provided for in the school curriculum, and increase their level of physical development. The main goal of the lesson is that children, starting from their earliest childhood, grow up healthy, strong, harmoniously developed, so that they learn well. Physical culture plays a major role in improving a person’s health1,2.

Today, there is a physical education program for schoolchildren from the first to the eleventh grade. In each age group, a detailed description of the load on schoolchildren and the exercises that they must master is given3.

Despite the versatility of modern physical education programs, they have shortcomings, for example, to implement some tasks, you need a large gym, which is not in every school, there is not enough space for physical education, which reduces the motor density of classes. How to increase physical activity of children in such conditions? Despite the fact that some authors suggest replacing the standard program with modern
methods, we believe that it will only be enough to slightly supplement the existing program. It is proved that the exercise Classics allow you to solve this problem.

Exercise Classics allow you to implement an individual and differentiated approach to schoolchildren, which is important for each of them. It allows you to open and increase the reserve capabilities of physical abilities.

We should also mention the development of coordination abilities for children of primary school age. Coordination abilities are the ability of a person to quickly master new movements and reconstruct motor activity in accordance with the requirements of a changed situation. The level of development of coordination abilities determines the effectiveness of human movement, its rationality of actions, speed and other aspects of movement. Coordination abilities are also necessary for mastering movement techniques in any sport. The higher the level of development of coordination abilities, the more effective the athlete will act.

At the age of 7-11 years, it is necessary to lay the Foundation for the growth of the development of the body and abilities involved in school, since this age is favorable for the development of most physical abilities.

Physical education and sports have a positive impact on the cognitive processes of schoolchildren. However, despite the established relationship, it is important to study the influence of Classical exercises on the volume of attention of schoolchildren.

Aim of the study – to determine the influence of exercise Classics on the development of the volume of attention of children 9-10 years old in physical education lessons.

The hypothesis of the study. It is assumed that if you use the Classic exercise in physical education classes, the indicators of the volume of attention of schoolchildren will improve.

**Material and Methods**

**Participants:**

Boys and girls 9-10 who participated in the study were healthy and admitted to physical education classes. The schoolchildren studied in grade 3, at secondary school Number 60, in the city of Kirov (Russia).

All procedures conformed to the ethical standards of the Helsinki Declaration of 1964. Informed consent was obtained from all parents of schoolchildren included in the study.

**Procedure:**

The study continued for nine months (September-may). A total of 56 physical education classes were held. Classes were held 2 times a week. Each lesson lasted for 40 minutes.

Prior to the study, 2 study groups were formed:

1. the Control group (CG) consists of 20 children from class 3A. These schoolchildren were engaged in a standard physical education program at school.

2. Experimental group (EG) – children of the 3B class in the amount of 20 people. These schoolchildren were engaged in a standard program, but in addition to each lesson, they performed an exercise Classics. The exercise is presented in table 1.

Square 1  Square 2  Square 3
**Exercise Classics:**

In the gym, there are three large squares on the floor. The side of one square is 180 cm. Inside each large square there are nine small squares, the side of the small square is 60 cm. Inside each small square are numbers from 1 to 9.

Task: the schoolchild must use jumps from square to square to get from number 1 to number 2, then to number 3, and so on, to number 9. After that, it should jump on the same squares in reverse order (from number 9 to number 1). You can move around the squares in any way (from one leg to the other, jump on one leg or on two). If the schoolchild makes a mistake, he returns to the previous square. During the lesson, each schoolchild must overcome three large squares. The numbers in the squares must be changed by the teacher before each lesson. You can perform the exercise in any part of the lesson.

Before and after the pedagogical experiment all schoolchildren took control tests:

1. «Shuttle run 3x10 m» (indicator of coordination abilities)\(^{14}\).

2. «Schulte Tables» (indicator of the volume of attention)\(^{15}\).

On an ordinary sheet of A4 paper, 25 cells are drawn, and the numbers 1-25 are randomly written in each cell (table 2).

Option 1
Option 2

At the signal, children must cross out all the numbers in order, from 1 to 25. After the last digit, the test stops. The result is the time that the schoolchildren completed the task. One attempt. If an error is made, the test is repeated.

**Statistical Analysis**

In the course of the study, we used the program Microsoft excel 2016, and bio-stat 2009. The detection of arithmetic averages in the tests of both groups was carried out using Microsoft excel 2016. Bio-stat 2009 allowed using the parametric criterion t-student (confidence at P<0.05)\(^{16}\).

**Results**

Before the beginning of the pedagogical experiment, schoolchildren from class 3A and 3B passed two control tests Shuttle run 3x10 m and Schulte Tables. The difference between the indicators was not significant (P>0.05). However, after the pedagogical experiment, the indicators in both groups differed significantly (table 3).

<td>35.4±5.1</td>
</tr>
</tbody>
</table>

Table 3 shows that the results of 9-10 year olds in both groups changed from the beginning to the end of the study. The performance of coordination abilities in the «Shuttle run 3x10 m» test in CG improved, but not significantly from 10.2±0.6 to 9.9±0.5 (P>0.05), in contrast to children from class 3B. In EG, the indicators of coordination abilities improved from 9.9±0.5 to 8.5±0.4 (P<0.05). The situation in the «Schulte Table» test is the same. The volume of attention of schoolchildren in class 3A improved, but only by 6.1% (P>0.05), and for schoolchildren in class 3B by 32.1% (P<0.05). Such results may indicate that the standard physical education program at school is not very effective, at the same time, the results in EG show the effectiveness of implementing exercise Classics in the educational process of younger schoolchildren, which significantly improved the indicators of coordination abilities and the volume of attention.

Discussion

Children’s health is an important issue in society today. This problem can be solved, first of all, by physical education and physical exercises. In General, physical education is aimed at a comprehensive harmonious development of a person and his preparation for work in life\cite{1,2}. In the Russian Federation, physical education classes at school are mandatory. And the physical education program at school covers a very large set of skills and abilities of physical abilities of children, which need to be developed through physical exercises\cite{3}. However, some authors believe that the standard physical education programs at school are very outdated and they need to be completely replaced with modern methodics and new sets of exercises\cite{4}. This approach seems to us not quite correct, the correct option would be to Supplement existing programs. One of the most effective additions to the standard physical education program at school is the exercise Classics. The introduction of this exercise has had a positive effect in our previous research\cite{5}.

In this study, the effectiveness of using exercise Classics in physical education classes at school is proved. Namely, there was an improvement in indicators not only of children’s coordination abilities, but also improved indicators of the volume of attention of schoolchildren. Thus, the hypothesis that the development of physical abilities has a favorable effect on the development of cognitive and mental processes is confirmed\cite{11-13}.

It is also worth noting the positive impact of the coordination exercise of the Classics in primary school age, which is sensitive for the development of most of the abilities of schoolchildren\cite{10}.

The new study confirms the effectiveness of using a differentiated approach in working with schoolchildren, which ensures individual physical development of the optimal level of each schoolchildren\cite{6,7}.

Conclusion

If at each lesson in physical culture at school, schoolchildren will perform a Classic exercise, then the indicators of not only coordination, but also the volume of attention of children will improve. This will significantly increase the effectiveness of standard physical education lessons at school. The research is relevant and promising for further research in the field of physical education and sports.

The Possibility of Healing Deep Wounds in Rats Using Helium Neon Laser

Rabab Hajwal Al-Zamily
M.Sc. Physics/ Lecturer, Department of physiology and medical Physics College of Medicine, Al-Qadisiyah University, Iraq

Abstract
Laser treatment is generally used for tissue restoration. Restorative soft tissues include objective, practical and difficult responses.

The goal of the research have being to estimate the irradiation capabilities the helium neon laser irradiation on three different types of wounds depth.

Sixty young male rats were used in this study, divided into three groups. (20 per group) Wounds were created with different depth for the first, second and third group have been irradiated by the laser using He-Ne energies flowing 4 minutes, five out of twenty animals left without radiation is considered to control.

Biopsy was taken from all rats for histological examination at 1, 3 and 7 days after surgery. The results showed a clear enhancement of treatment wounds from control, Helium neon laser failure in the treatment of very deep wounds.

Key words: laser treatment, deep wounds, wound healing

Introduction
Laser therapy is a procedure to obtain the improvement in medical treatment body, acupuncture, dentistry, veterinary practice involves the recruitment and refers to the relationships between the laser and biological tissue radiation monochromatic light in biological tissue to get the effect biomodulative within the soft tissue(1,2)

Investigation effects have varied for various reasons, including the use of different doses of the waves and the use of animal models healthy(3).

It has been improved wound remedial by applying of laser power (4). An assuring analyses for laser to stimulate the healing of ulcers and other wounds on the skin involved(5).

Produces laser radiation modified dynamically, which means that it can stimulate or discourage. So can be laser low dose is ineffective, while the excess energy may prevent healing rather than stimulated. Can treat acute injuries frequently (daily) (6)

Although accelerating tissue healing, the effects of hyperplasia did not appear. During the healing wounds of the laser contained a larger amount of collagen and tensile strength. Therefore, when using health goals, the results may be silent (7).

In spite of several intelligences of certain effects after examinations led in the test center, in animal styles and in medical randomized regulated ordeals, is motionless provocative LLLT(8).

The influence of the laser be contingent on the energy intensity, exposure period and radiated area. The laser wavelength affects the depth of the energy...
Applying low levels of visible light to reduction pain, inflammation and promote wound remedial, tissue and deep nerves, and avoiding soft tissue harm(10).

Studies have shown the number of negative results and positive

The application of laser irradiation technology, He-Ne daily on the wounds till healing has occurred to verify the full deductions at a low level energy by reducing injuries(11).

Researchers emphasized that tissue restoration develops extra active when dealing with low-level laser. They exposes that the laser beam catalyze create of the fibroblast growing element and the frequency these cells. Exposure to chromatic laser radiation faster the remedial procedure, with better collagen fibers increases collagen installation, along per earlier epithelial(12).

Through our previous studies on radiation wound treatment (The study includes the first research of wound healing using laser helium neon confidential 1 cm depth and a length of 1 cm and the second by argon laser) indicating an important speeding in the field dynamic of range OF wound remedial(13, 14), This third paper examines the efficiency of He- Ne laser in treating deep wounds so I dealt with three types of wounds of different depths.

Materials and Method

The use of continuing helium neon laser mechanism made in China type of (Jgq) no. (250) a radiation-point 2 mm in the radius of the wave length from 632.8 nm and power $85 \times 10^{-3}$ W.

Sixty young rats male, age of less than five months, weight approximately of less than fifth hundred gram be there operated applied. Rats have being distributed about three groupings (a), (b), (C). A surface wound 10mm distance be prepared at Thigh all anesthetize rats into all groupings, but the depth was made into (11-15) mm in the first group a, and (15-20) mm second group b, third grouping was performed on (20-30) mm.

All rats in the cage were clean net to prevent pollution.

All Groups (a), (b) and (c) contains (20) rat, fifteen rats exposed using laser helium neion of Energy 0.2 J (Energy Density $= (0.2) / (0.126) = (1.6) J/cm^2$) for 4 min. Another five Non-radioactive animals were considered as a controller grouping. A biopsy of all rats was taken for histological Test analysis at 1, 3 and 7 days after surgery. Tissue Test analysis histopathology be there Conducted for assess the quantity of Inflammatory cells, the appearance of microscopy properties Fibroblasts, Granular tissue plus epithelial cells for every model.

Results

Figure (1): Test analysis histopathology (a) and (b) groupings exposed laser therapy advantage wounding corrective. Indicated a positive reactions began after the firstly post-operative day throughout the decrease from Inflammatory cells by induction Epithelial cells creation after together edges of the injury in comparable the grouping (c) and controller grouping.

On the third day, the consequences of injure remedial were seemed primary on the treated grouping (a, b) in comparly per the treated grouping (c), then controller grouping .The marks designated Inflammatory cells as well as Fibroblasts propagation creation by Fibrous connective soft tissue full in Collagen. Furthermore evident quantity of tissue Granulation be there observed since together edges from incision and Epithelization it was initiated, fig (2). Control Grouping exposed reduction apparition Restorative marks injure, wherever wounding edge full by attacked lifeblood coagulate thru great numeral of Fibroblasts , inflammatory cells permeation by creation a small amount quantity of Epithelial and Granulated tissue after together edges of wound

By the seventh Days after surgery grouping (a), (b) showed Granulated tissue created after Fibroblasts retractor has proliferated, the Receptacles bloody crowded. Within addition to emergence a full restoration of the wound with the restoration of the skin, then there comes about various therapeutic combinations between these groupings. This approved together with another papers. (15)

But it was seen as a Scar tissue in the form of a tinny cover the incision edge then severe hyperplasia in the epithelial cells that come to be larger usual in
the circumscribing soft tissue, was observed and Fibrous connective tissue, cellular in wounding line of controller grouping, fig 3.

But in a very deep wound, it showed the group that received treatment (c) at the 1 be there -3 -7-days after the operation of any reduction in the size of the wound, a very thick blood clot on both sides of the tip. The results showed not any marks of recovery, and a laser he ne failure applying this energy in this style of wounding therapy, fig (4).

**Figure 1.** Firstly days after the operative, comprising grouping (a), (b) slice revealed the edge of wound be fulfilled by blood clot, and explained in Fibroblasts and the spread of blood clotting. Groupings (C) afterward days firstly the slice showed life blood coagulate on the managed location.

**Figure 2.** Grouping (a), (b) slice on the Third day after operation Infiltration made a small number of small inflammatory cells numeral of fibroblasts proliferation and the creation of little fibrous connective tissues. Controller grouping (C) which a blood clot started in the Emergence the beginning of epithelial cells proliferation of fibroblasts with inflammatory cells since together locate.
Figure 3: Grouping (a) a thin layer (b) on the seventh day is the restoration of the completion of the skin including the formation of collagen small connective fibers of connective tissue and not at all inflammable groups in the detection of control showed assembly tissue scar, inflation observed in epithelial cells and connective tissue fibroblasts in the cell line.

Figure 4: Grouping (c) reveal excessive blood clotting for in both locations the wound with a thick edge.

Discussion

In the current paper, the possibility of laser helium neon in the treatment of different depths of wounds.

The development of the Collagen production and prevent inflammation resulted from examination of laser treated tissues.

That guided experience HelumNeion laser (632.8) Nano-meter display rapider stages proliferative inflammatory. Then there was healing great failures in the first stage on the first day of the group (c). That means lacking efficiency in the treatment of a very deep wound (Dogan, SK. et al) and other revealed disadvantage in remedial with laser therapy (16-20). In many animal pattern experiments, lasers have been accepted as a supplement to additional operation in curative treatment, as low-level lasers are used to accelerate wounding remedial (21).
By contrast Status information and medical experiences thru human being may have great results in action laser therapy in wounding restorative\(^{(22)}\).

(Liao X, and Xie GH) who found that healing were completely healed, laser therapy seemed to accelerate the restoration stage of remedial, in which the intensity of the granulation tissue would be pretentious, \(^{(23, 24, 25)}\)

(Ty Hopkins et al) Laser therapy is an active healing to promote partial reduction of wounds from corrosion. Additionally accelerates wounding reduction of non-exposed wounding off the same arm, showing an indirect influence happening the surrounding area tissue \(^{(26)}\).

Numerous hypotheses can benefit clarify the reduction of injuries recover As well In vitro reports have presented an improve in the proliferation of fibroblasts after treatment

**Conclusion**

Laser detection and treatment using long wavelength Helium -neon 632.8 nanometer (1.6) J / cm\(^2\) Energy density exposed for 4 minutes to advance injury to therapeutic incentives in rat, and then Make any benefit results in a very deep wounding using wound related technology.

The Role of Legal Sociology in Terms of Covid-19: Large-Scale Social Restrictions (PSBB) in Indonesia

Rahayu Hartini¹, Yusufa Ibnu Sina Setiawan²

¹Professor, Faculty of Law Universitas Muhammadiyah Malang East Java Indonesia,
² Master of Law Student, Universitas Muhammadiyah Malang East Java Indonesia

Abstract

The study of legal sociology is a study that has legal phenomena, but uses social science and sociology theory. The role of Legal sociology is so tight when juxtaposed with a problem that is emerging, namely the global pandemic Coronavirus Disease (Covid)-19. The juridical normative research with a method of approach to the law, conceptual and comparative. Legal materials that have been collected are analyzed by content analysis. Some affected countries that successfully handled the COVID-19 pandemic, including: South Korea, New Zealand, Singapore. Italy and United States containment strategy for handling Covid-19 are contradictory from those countries above. PSBB has been applied in Indonesia and other countries. The PSBB must be accompanied by other programs so that the government can successfully handle COVID-19. PSBB does not guarantee that the community will obey the regulation. The most effective action with all the consequences is regional quarantine or lockdown accompanied by other supporting programs from the government.

Key words: PSBB, Legal Sociology, COVID-19

Introduction

Basic Concepts of the Perspective of Legal Sociology (conceptually and theoretically) there is no single definition related to the perspective of legal sociology. But certainly, the perspective of legal sociology is to understand the reality of law from the perspective of social sciences, especially sociology or in other terms the social science of law. The study of legal sociology is a study that has a legal phenomenon, but uses optical social science and sociological theories. This science is the study of the reciprocal relationship between law and other social phenomena empirically analytic (1)

In essence this is an overall object of the sociology of law so that there is no doubt that a legal system is a reflection of the social system where the legal system was the parts. But the problem is not that simple because it needs to be investigated in the circumstances of how and by how the social system influences the legal system as a subsystem and the extent to which the process of influencing influence is reciprocal (2)

The role of legal sociology is so thick when juxtaposed with the problem that is now emerging, namely the global pandemic Coronavirus Disease (Covid) -19. Every day cases increase, both positive confirmed by COVID-19 infection and death cases. Once the magnitude of the ability of this virus to infect and spread is evidenced by the record that so far there are still many people infected with COVID-19 with increasing numbers. The total number of COVID-19 cases in the world totaled 1,074,290 cases with a death of 56,987 people (3)

Seeing how dangerous COVID-19 is, the social science approach that still prioritizes law as its object becomes very important. In sociology studies, the focal point for COVID-19 is on behavior, practice and institutions. Broadly speaking, it functions to investigate legal phenomena by using the methods and
Theories offered by social science. The use of social science methods in handling COVID-19 involves one main element: Involves serious efforts to overcome a complete perspective through the collection, analysis and interpretation of empirical problems.

The Government, through the Minister of Health, issued regulations in the framework of accelerating the handling of corona virus disease 2019 (COVID-19), namely Permenkes Number 9 of 2020 Concerning Large-Scale Social Limitation Guidelines (PSBB). These actions include restrictions on certain activities of the population in an area suspected of being infected with COVID-19 including restrictions on the movement of people and / or goods for one particular province or district / city to prevent the spread of COVID-19. The restrictions are at least carried out through the consolation of schools and workplaces, restrictions on religious activities, and or restrictions on activities in public places or facilities.

Indonesia has adopted a policy of implementing Large-Scale Social Restrictions which, in principle, is implemented to reduce the widespread spread of COVID-19, based on epidemiological considerations, threat magnitude, effectiveness, resource support, operational technical, economic, social, cultural and security considerations. The policy is in the form of Government Regulation Number 21 of 2020 concerning Large-Scale Social Restrictions in the Context of Accelerating the Handling of Corona Virus Disease 2019 (COVID-19). Seeing the importance of the role of legal sociology with the COVID-19 pandemic conditions, the author is interested in taking up the theme and is associated with the Large-Scale Social Restrictions (PSBB) by the government. The author wants to know whether or not the enactment of these regulations and the very likely impact arising when the regulation is enforced. But in this article we are not considering to compare the law system, economy and demography factors between the countries.

From the explanation above, the writer wants to formulate a problem consisting of: 1). What is the Form of PSBB in Indonesia? 2) What is the form of handling COVID-19 in other affected countries? 3) What is the Role of Legal Sociology in the existence of Large-Scale Social Restrictions (PSBB)? 4). What impacts will occur when the regulation is enforced?

Finding and Discussion

Legal Sociology

Legal sociology, has the object of study of legal phenomena. Legal sociology basically refers to the behavior of individuals and society, as written by Curzon, that Roscou Pound shows the study of legal sociology as a study based on the concept of law as a means of social control. Law in the study of sociology views regulation as a control. Social control here generally means legally questioning whether a behavior is morally good and legally binding. But from a sociological point of view, it can also be viewed in a non-legal form, i.e. simply we can see behavior that is not appropriate “in general” in society as bad behavior.

Coronavirus Disease 2019 (COVID-19)

Coronavirus novel or better known as Corona Virus Disease (COVID) 19 is a disease that first appeared in China in early December 2019. This disease was officially announced on December 31, 2019 which resulted in pain in 41 people with detail 1 (one) person dies. The virus is suspected by WHO as coming from animals which are traded freely in Wuhan, China. One reason is the transmission or spread through bats which are then consumed by humans. This disease quickly spreads throughout China to Europe, the United States, Southeast Asia and Africa. COVID-19 spreads through droplets (particles) that come out through the human mouth when talking to others. This virus can infect anyone if the person is in contact with a positive sufferer COVID-19. Because the level of virulence (strength of the virus causing infection) COVID-19 is so high, contact such as intense communication or long group discussion, risks becoming a place to attach the virus, especially in the mucosal area (tongue, oropharynx, nasal cavity and conjunctiva). Once COVID-19 attaches and eventually infects, if a person’s immunity is low, then that person will very easily experience symptoms of COVID-19.

Strategy Containment of COVID-19 in Indonesia and Other Countries

South Korea
The government through the Prime Minister, the Minister of Health, the Minister of Welfare and the Korean Central and Disease Center, actively communicates and supports one another so that the procurement of Rapid PCR can be produced in mass quantities and quickly and has been approved by the FDA K (Food and Drug Administration) of Korea. The proof is that after the 100th case, Korea can conduct and attach results as many as 1,581 positive cases per day, until finally reaching 11,290 cases in early April (9)

Expanding the range of checks to prevent transmission of contacts in the community includes contact tracing, quarantine and isolation. Koreans have experience in dealing with Pandemics before, namely SARS-CoV, MERS, so with self-awareness to trace contacts from the smallest group by a small group on a massive scale. Tracking the not surrender was emphasized by the government. Openness to one another increases the government’s ability to track down even small districts. In addition, tourists or migrants from outside Korea are not prohibited from entering, but are required to carry out quarantine controlled by the government for 14 days (7) (9)

New Zealand

New Zealand has several steps to deal with COVID-19, namely: 1) Having an approximate modeling of the possibility of a New Zealand population being infected with COVID-19. In New Zealand have used disease modeling to increase these estimates, because modeling can take into account more factors than basic data, including the fact that populations take steps to protect themselves; 2) Elimination System for COVID-19. The government introduced a four-level response system on March 21 and the country was placed on a ‘level 2’ response (which involved restrictions on mass meetings and encouraging increased physical distance). The country then rises rapidly to ‘level 4’ (broadly described as ‘closure’ which involves the closure of all schools, unimportant workplaces, social gatherings and severe travel restrictions) which take effect on the night of March 25, 2020. Emergency national announcements were also announced, giving additional authorities the power to enforce control measures. This approach has a strong focus on border control, which is clearly more easily applied to island nations. It also emphasizes case isolation and contact quarantine to ‘eradicate’ the transmission chain; 3) Border control with high quality quarantine for incoming tourists; 4) Rapid case detection is identified by extensive testing, followed by rapid case isolation, by fast contact tracking and quarantine for contacts; 5) Promotion of intensive hygiene (cough etiquette and hand washing) and the provision of hand hygiene facilities in the public environment; 6) Intensive physical juxtaposition, currently applied as a lockdown (level 4 warning) which includes schools and workplace closures, restrictions on movement and travel, and decisive action to reduce contact in public spaces, with the potential to relax these actions if elimination is successful; 7) A well-coordinated communication strategy to inform the public about control measures and about what to do if they are not healthy, and to reinforce important health promotion messages (10)

Singapore

Singapore Oversight for COVID-19 aims to identify as many cases as possible using complementary detection methods. First, case definitions to identify suspected cases, in health facilities or through contact tracing, are established based on clinical and epidemiological criteria, and evolve over time as more information becomes available. SARS-CoV-2 RT-PCR laboratory testing capacity was rapidly increased to all public hospitals in Singapore and was able to handle 2,200 tests a day for a population of 5.7 million. Likewise, ROK has also rapidly expanded capacity testing, including setting up drive-through testing stations, and has conducted more than 200,000 tests to date. All suspected and confirmed cases were immediately isolated in the hospital to prevent further transmission. Contact tracing was also initiated to determine their history of movement 14 days prior to the onset of symptoms to isolation to determine the possible source of infection and also to prevent further transmission between close contacts (11)

In terms of improving health services, Singapore coordinated by setting up a Network of 800 Public Health Readiness Clinics (PHPC) enabled to improve the management of respiratory infections in primary care settings, with subsidies extended to Singapore residents to provide incentives for them to seek treatment in these PHPCs (9) (11)
In addition to detecting cases and containing spread, prevention of import cases is important to reduce the power of infection of external sources. In Singapore, the temperature and health checks of tourists who came from Wuhan since January 3, 2020, and extended to all travelers since January 29, 2020, have been in place at all ports. Travelers who meet the definition of a suspect’s case are sent directly to the hospital. Singapore on March 4, 2020, has advised Singaporeans to postpone unnecessary trips to mainland China, ROK, Northern Italy and Iran and impose restrictions on entry to visitors from the same area. Returning residents and long-term passport holders with historical travel to the affected areas are subject to 14 days of quarantine (11).

**Italy**

Italy was the first country in Europe to be affected by COVID-19. The government’s unpreparedness to face COVID-19 because many people underestimate this virus. Besides fulfilling to do the test for COVID-19 is only done for people who have symptoms only. Asymptomatic people who are very likely to transmit are not tested. Suburbs in Italy have not been able to facilitate their communities to get the COVID-19 test. The availability of masks is very limited because masks are not produced in Italy and there are not enough ventilators for all patients who need treatment and more than 2,500 hospital beds for patients in intensive care units will be needed in just 1 week to treat acute respiratory distress syndrome that is caused by SARS-CoV-2-pneumonia in Italy (12, 13).

In recent years, health policy has changed a lot in Italy. The number of beds has decreased, and regional autonomy has emphasized inequality in service quality in the national territory. In addition, hospitals may be the main carriers of COVID-19, because they are quickly inhabited by infected patients, facilitating transmission to uninfected patients. Patients transported by our regional system, which also contributes to the spread of diseases such as ambulances and personnel, quickly become vectors (13).

According to many observers, one of the first obstacles in Italy’s response to the outbreak was its failure to recognize the magnitude of the pandemic, and make decisions in real time, when the crisis was taking place. In late February, several Italian politicians, including center-left Democratic Party leader Nicola Zingaretti - who was later infected by COVID-19 - showed themselves drinking in Milan, promoting the idea that the Italian financial center should continue business as usual in the midst virus. To further complicate what is recognized as an unprecedented crisis, Italy has failed to adopt a coordinated approach to emergencies (14).

**United States of America (USA)**

The United States is too slow in responding to the corona virus and has banned travel from Europe, one of several steps officials should have taken earlier to reduce the virus that spreads rapidly. President Trump has repeatedly heralded his decision on February 2, 2020 to stop traveling from China, where the corona virus first appeared in Wuhan city late last year. However, orders that limit travel from Europe do not officially happen until March 11 - one of the government’s biggest mistakes. In the month leading up to the European travel ban, nearly 2 million people from Italy and other countries arrived in the US, according to a new article released by the CDC, which is responsible for disease tracking and prevention. Limited testing and the slow implementation of social distance are also key factors in accelerating cases in the United States, the article continued. Mass gatherings in February, including scientific meetings in Boston, New Orleans annual Mardi Gras celebrations and Georgia funerals, resulted in dozens and dozens of Americans being infected. In addition, more than 100 people traveling on nine separate Nile River cruises in February and early March have come to the US and tested positive for the virus, almost double the number of cases known at the time (15).

**Indonesia**

In the implementation of health outreach in the region, Indonesia has adopted a policy to implement Large Scale Social Restrictions which, in principle, is implemented to reduce the widespread spread of COVID-19, based on epidemiological considerations, threat magnitude, effectiveness, resource support, operational technical, economic considerations, social, cultural and security. The policy is in the form of Government Regulation Number 21 of 2020 concerning Large-Scale Social Restrictions in the Context of Accelerating the Handling of Corona Virus Disease 2019 (COVID-19).
To implement Government Regulation No. 21 of 2020 concerning Large-Scale Social Restrictions in the Framework of Accelerating the Handling of Corona Virus Disease 2019 (COVID-19) (hereinafter referred to as PP No. 21 on PSBB), guidelines for implementing Large-Scale Social Restrictions are needed which regulates more technically regarding the criteria Large-scale Social Restrictions (PSBB). Considering that during the COVID-19 pandemic there were likely to be many people who had been infected or had not yet been detected, or were in the incubation period, so to prevent widespread spread in an area through personal contact, it was necessary to limit large-scale social activities in the area. The limitation of certain activities in question is limiting the gathering of large numbers of people at a particular location.

Normative science of law related to PSBB is very clear, namely to limit citizens in their activities. Empirically found many facts that PSBB does not function as it should. PSBB here is merely a regulation without a detailed explanation related to the implementation of how this PSBB is carried out. The strength of PSBB which is not binding, because the breakdown of regulations only explains the appeal, not the prohibition. All aspects that are restricted such as dismissing schools and workplaces, is an effective way.

The aim of accelerating the handling of COVID-19 in accordance with Permenkes through PSSB is likely to be difficult to achieve. This is because many of the countries that are infected with COVID-19 in large numbers, do something similar to PSBB, namely quarantine or lockdown area to overcome the problem of COVID-19. The lockdown or quarantine area was carried out in Wuhan, China. The quarantine of the area prohibits all individuals from leaving Wuhan or entering Wuhan. All land and air transportation are frozen. There are no flight routes to and from Wuhan. About 9 million people in Wuhan were isolated for weeks. This very strict regional quarantine is able to minimize the spread of infected and dead populations. The case fatality rate for COVID-19 in China is around 3%, one of which is supported by the quarantine of the Chinese government. In addition to quarantine areas, data tracing can also be done. This is because the key to eradicating the COVID-19 virus is that after finding out that there is a positive confirmation, tracing is carried out immediately to anyone who comes in contact with patients.

In view of some PSBB references in several countries, the current Covid-19 handler approach, including in Indonesia, is to conduct PSBB which can lead to regional quarantine. This is because, in the absence of strict regional quarantine rules, even healthy individuals can be transmitted or infected by other individuals. Because Covid-19 can also be transmitted by asymptomatic individuals (carriers or carriers). If lockdowns are not carried out, then what will happen is a buildup of patients in the hospital, while we know the capacity of isolation beds and ventilators in hospitals throughout Indonesia will not be sufficient to handle all patients infected with Covid.

Impact of Large-Scale Social Limits

Although PSBB have not been fully implemented in all regions, there have been many losses in the economic sector that have an impact on the sociological function of money itself, which is driving social change. This is reflected in the increase in termination of employment (layoffs), cut the amount of monthly salary received, and the death of several sectors of the Small and Medium Enterprises (SME) industry. Minister of Manpower Ida Fauziyah revealed that currently there has been an increase in the number of workers laid off. Now the number of workers / laborers / workers laid off and laid off rises to around 1.7 million people.

COVID-19 has long-term negative impacts on society, the health system, the workplace and the individual itself. The social effects of COVID-19 cannot be estimated when it will end. Therefore, it is indeed very necessary long-term planning to anticipate the social and economic consequences that will be caused.

Conclusion

Many countries have also implemented systems such as the PSBB and some have even implemented such as national quarantine or lockdown. Of the several successful countries, PSBB and regional or national quarantine cannot stand alone, but other supporting programs are needed such as the country’s ability to conduct mass Rapid PCR tests on its citizens; the ability to track patient contacts accurately and continuously; encouragement and enthusiasm to meet
adequate facilities such as ventilators and Personal Protective Equipment (PPE); and economic assistance for affected communities; must be run synergistically. Synchronization of central and local government regulations to achieve the above is needed so that the handling and eradication of COVID-19 to be effective and maximum.

Abstract

Introduction: Pulmonary Tuberculosis (TB) disease remains a public health. In recent years, the prevalence of TB has increase. Dangerous complication of Pulmonary TB can destroy lungs. In 83.3% cases of destroyed lung, the patient are found to have a history of pulmonary tuberculosis. Objective: The aimed of this study was to identify factors affecting the occurrence of Tuberculosis Destroyed Lung in Lampung Province, Indonesia in 2017. Method: This study is an analytic observation with a case control design. The sample were obtained through total sampling. Primary and secondary data were obtained from interview and medical records. The samples were taken from 64 patients in several hospitals in Lampung, Indonesia. Results: The results showed the relationship between age with destroyed lung (p = 0.897), gender with destroyed lung (p = 0.511), education level with destroyed lung (p = 0.754), occupation with destroyed lung (p = 0.060), income with destroyed lung (p = 0.482), cigarette smoking with destroyed lung (p = 0.013), and the presence of multiple diseases with destroyed lung (p = 0.748). Conclusions: There is a significant relationship between Cigarette Smoking to the incidence of destroyed lung.

Keywords: Tuberculosis Lung, Destroyed Lung, cigarette smoking

Introduction

Tuberculosis (TB) is an infectious disease caused by an infection of the bacterium Mycobacterium tuberculosis. Six countries lead 60% of new cases which are India, Indonesia, China, Nigeria, Pakistan and South Africa. Worldwide, the rate of decline in the incidence of TB was 1.5% in 2014-2015. In this case it is necessary to intensify 4-5% of annual decline by 2020 to reach the first indicator of the TB settlement Strategy. The World Health Organization (WHO) reported that about one third of the world’s population has been infected with M. tuberculosis, but only about 5-15% of the 2.3 billion peoples infected will develop active TB disease. It was estimated that in 2015 there were 10.4 million new cases of TB in the world, of which 5.9 million (56%) were men, 3.5 million (34%) were women, and 1 million (10%) were children. In addition around 1.4 million people died of TB in 2015. Although the death rate from TB decreased by 22% between 2000 and 2015, TB was still in the top 10 causes of death in the world in 2015 (¹). The number of cases reported is a number that shows the number of new patients found and recorded among 100,000 residents in a particular area. This number is useful for showing a tendency in increase or decrease findings in the region. The number of notifications of the new cases of bacteriologically confirmed pulmonary tuberculosis in 2015 in Indonesia amounted to 74 per 100,000 population. It decreased compared to 2014 which amounted to 77 per 100,000 population. meanwhile the incident of all tuberculosis cases in 2015 amounted to 130 per 100,000 population, it increased compared to 2014 which amounted to 129 per 100,000 population (²).

The incidence of all tuberculosis cases in Lampung Province in 2015 was 105 per 100,000 population, ranked the lowest 6 of all provinces in Indonesia and also ranked the highest with treatment success rates of 95.2% according to the standard set by WHO 85% (³). One of the complications of Pulmonary Tuberculosis is Destroyed Lung. A study in India showed that 83.3% of cases of pulmonary lesions has a history of...
pulmonary tuberculosis (3). Pulmonary tuberculosis in advanced conditions can cause progressive, extensive and irreversible destruction of pulmonary parenchyma and damage to pulmonary function (4).

Pulmonary tuberculosis in sustainable conditions can cause progressive, extensive and irreversible destruction of pulmonary parenchyma and damage to pulmonary function (4). The term of destroyed lung is usually used to describe damage to the pulmonary parenchyma caused by the sequelae of pulmonary TB that occurs for many years, and is caused by chronic airway obstruction. Radiology can be found in a picture of shrinkage of lung volume, the presence of cavities, bronchiectasis and fibrosis. The response of the fibrosis network can make retraction of the hilum and mediastinum so that it shifts towards damaged lung tissue. Meanwhile other lung parts that are still good compensate for being large (5). Until now, no treatment guidelines were available for patients with pulmonary TB (4). There are various factors that influence the incidence of pulmonary tuberculosis such as; age, sex, education level, occupation, income, cigarette smoking and the presence of multiple diseases (6-8). The researchers aim to determine the factors that influence the incidence of pulmonary tuberculosis in Lampung Province in 2017.

**Methods**

This study is analytical with case control an approached. This research was conducted at the Bandar Lampung, Indonesia (Dr. H. Abdul Moeloek Hospital, Dr. A. Dadi Tjokrodipo Hospital and Harum Melati Clinic Pringsewu). Time of study was February-March 2017. The sample size was 34 patients with destroyed lung and 30 patients with pulmonary TB as controls. The data of this study are primary and secondary from direct interviews and medical records. Bivariate analysis was done using a Chi square test with p < 0.05.

**Results**

Figure 1a above shows the distribution of clinical diagnosis of 64 patients, in which the number of patients with destroyed lung was 34 (53.1%) and patients with pulmonary tuberculosis is 30 (46.9%). Figure 1b shows that the distribution based on the age of 64 patients in which the number of patients with destroyed lung was 21 (61.8%) in productive age and 13 (38.2%) in unproductive age. It also shows the comparison of patients with pulmonary TB of 19 (63.3%) in productive age and 11 (36.7%) in unproductive age.

Figure 2a shows the distribution of patients by gender of 64 patients in which the number of patients with destroyed lung was 22 (64.7%) male and 12 (35.3%) female. It also compares patients with pulmonary TB of 17 (56.7%) male and 13 (43.3%) female. Figure 2b shows the distribution of patients based on education level from 64 patients in which the number of patients with destroyed lung was 25 (73.5%) in low level education category and 9 (26.5%) in high level education category. It also compares patients with pulmonary TB of 21 (70%) in low level education category and 9 (30%) in high level education category.

Figure 3a shows the distribution of patients based on occupancy of 64 patients; in which the number of patients with destroyed lung was 1 (2.9%) unemployed and 33 (97.1%) employed. It compares patients with pulmonary TB of 5 (16.7%) unemployed and 25 (83.3%) employed. Figure 3b shows the distribution of patients based on income from 64 patients in which the number of patients with destroyed lung was 33 (97.1%) with low income and 1 (2.9%) with high income. It compares the patients with pulmonary TB of 28 (93.3%) with low income and 2 (6.7%) with high income.

Figure 4a shows the distribution of patients based on cigarette smoking from 64 patients in which the number of patients with destroyed lung was 23 (67.6%) regular smoker and 11(32.4%) lifelong non smokers. It compares patients with pulmonary TB of 11 (36.7%) regular smoker and 19 (63.3%) lifelong nonsmoker. Figure 4b shows the distribution of patients based on the presence of multiple diseases from 64 patients in which the number of patients with destroyed lung was 3 (8.8%) accompanied by other diseases and 31 (91.2%) not accompanied by other diseases. It compares patients with pulmonary TB of 2 (17.7%) accompanied by other diseases and 28 (82.3%) not accompanied by other diseases. Details of statistical analysis can be seen in table 1.

Figure 2. (A) Frequency distribution of the gender; (B) Frequency distribution of the education level.
Discussions

It can be concluded that there was no significant relationship between age and destroyed lung. However, the mean age was 55.6 years old. A number of patients with pulmonary TB were in the age of 15-55 years old. It is influenced by the relationship of the age group related to employed in the outside environment and without their awareness in contact with a patient with pulmonary regarding TB germs are transmitted through the air (8).

It can be concluded that there was no significant relationship between sex with patients with destroyed lung. Unrelated results can be caused by the small number of the sample. The incidence of destroyed lung in male is more than in female. It is due to the fact that the number of male smokers number was high and they also have a poor behavior to do self prevention from the transmission of TB germs (8).

It can be concluded that there is no significant relationship between the education level of patients and destroyed lung. Unrelated results can be caused by the small number of the samples. Knowledge is the basis of taking prevention and treatment of tuberculosis. Ignorance of the community will hinder attitudes and actions towards the prevention and eradication of pulmonary TB disease as a sick person so that it can eventually become a source of transmission and spread of pulmonary TB disease to people who are around him. The study of Rohayu et al, with the title of analysis of risk factors for positive smear pulmonary TB incidence in coastal communities at Kadatua Health Center in South Buton Regency in 2016 showed no relationship between knowledge (education level) and incidence of pulmonary TB (p = 0.018) (9).

It can be concluded that there is no significant relationship between the patient with destroyed lung and occupation. Unrelated results can be caused by the small number of the samples. The majority of case patients were unemployed. If a patient is unemployed, it will affect the utilization of health services. One’s work will also be able to reflect the small amount of information received. That information will affect
someone in making decisions to utilize existing health services, to provide nutritious food, to keep a healthy home environment and to maintain health status. This can have an effect on the body, spiritually, and socially so that if these needs are not met, it can reduce the health status where the immune system decreases so that it is susceptible to pulmonary TB \(^{(10)}\).

It can be concluded that there is no significant relationship between the patient with destroyed lung and income. Unrelated results can be caused the small number of samples. In the study of Kurniasari et al in pulmonary TB, it is stated that the lack of economic status causes them not to have the ability to make a healthy or fulfilling house, to obtain health information, to get access to health services and to fulfil nutrition which in turn results in low endurance so it’s easy to get an infection \(^{(11)}\).

It can be said that patient with pulmonary TB on cigarette smoking are 3,612 times more at risk of developing destroyed lung. The limitations on air flow in patients with pulmonary tuberculosis are most patently caused by smoking. Indoor air pollution from cigarette smoking can increase the risk of severe infection and lung damage. Cigarette smoking contains more than 4,500 chemicals that have various toxic effects, genital and carcinogenic muta \(^{(12)}\). These substances have a proinflammatory and immunosuppressive effect on the immune system of the respiratory tract. Therefore it can increase the risk of destroyed lung. This study is similar with Sayuti on patient with pulmonary TB stating that smoking in the home is associated with the incidence of pulmonary TB in East Lombok Regency with P-Value = 0.0163 and factors can increase the incidence of TB disease due to indoor air pollution \(^{(13)}\).

It can be concluded that there is no significant relationship between the patient with the destroyed lung and the presence of multiple diseases. Unrelated results can be caused by the small number of samples. The results of this study were similar to the research of Izzati et al which concluded that diabetes mellitus was not associated with the incidence of pulmonary TB in the Andalas Community Health Center work area with p-Value = 0.186 \(^{(14)}\).

**Conclusion**

Based on the data taken, it can be seen that the incidence of pulmonary tuberculosis from 64 patients was 34 (53.1%) have destroyed lungs. Those with destroyed lung were 21 (52.5%) of productive age, 22 (56.4%) male, 25 (54.3%) with low education level, 33 (56.9%) employed, 33 (54.1%) low income, 23 (67.6%) smoker, and 31 (52.5%) Not accompanied by other diseases. There was no significant correlation between age, gender, education level, occupation, income and presence of multiple diseases with destroyed lung in Lampung Province, Indonesia in 2017. A significant association was found between patient with destroyed lung with cigarette smoking.

Abstract

Work is an application of the human being’s responsibility in existing. The type of work may be chosen freely whether it is within the country or abroad. This is a normative law research which is supported by empirical study. The normative law study is used to analyze the constitutional regulations regarding the health rights of the Indonesian migrant workers. Meanwhile, the empiric law study is used to analyze the implementation of the regulations. The health right implementation of the Indonesian migrant workers in Malaysia is applied through health insurances based on the sosco regulations. The payment of the health rights for the Indonesian migrant workers is the responsibility of the employer. The research results show that in the aspect of health, the work agreements do not go according to the contract. The health security of the Indonesian migrant workers in Malaysia is still not effective as it only covers accidents within the working hours.

Keywords: Health Rights, Indonesian Migrant Workers, Law

Introduction

Every person has the right to work and to obtain wages. They also have the right to be treated fairly in working relations as written in the Republic of Indonesia’s 1945 Constitution. The legal protection for the guarantee of adequate living through working opportunities for the citizens have a grand sense in achieving a state’s success. Thus, as mentioned by Izziyana (1) it is an obligation for the government to achieve that right.

Work is an application of the human being’s responsibility in existence. Work may be chosen freely, whether it is in the country or overseas. The state has the obligation to provide work for their citizens well. According to Arinanto (2), it must also bring positive influence for life survival of the citizens without discrimination.

Indonesia is one of the countries with the highest rate of exported migrant workers, as said by Payaman. (3) It may be from the demand of the hosting country or the initiative of the migrant worker outsourcing company overseas, according to the Center of Research and Information Development, the National Body for Indonesian Migrant Worker Placement and Protection. (4)

One of the sectors which has the power to dynamize the economy of Asian countries is the sending of migrant workers, as said by Azmy. (5) The guarantee on legal protection for migrant workers is crucial. According to Agusmidah (6) in line with the increasing interests for becoming Indonesian migrant workers, the rate of inhumane treatments towards the migrant workers has also increased. Cases which are related to the life of the migrant workers become more variative. Worse yet, said Rusli (7) it is now developing towards human trafficking which is a category of violation of the human rights.

The protection of health rights for the migrant workers is a crucial problem. This is because if the Indonesian migrant workers experience health
problems, it will automatically inhibit their abilities in working. It will create a negative impact towards their working relations, which will also impact their wages. The problems faced by the migrant workers are also global problems of humanity. This is because in it, there are various potentials of problems which must be acted upon by the world, starting from human trafficking, black market, fake documents, crime, and also economic problems, according to Calderon. (8) The economic problems are the cause of the international migration of workforces, said Birca. (9)

Nowadays, the sending of migrant workers is also a motive of crime perpetrators in trafficking people, which will lead to the unfulfillment of the health guarantees in the hosting country, as opined by Nuraeny. (10) The cases which happened at that time pushed the government to issue a policy which stops the sending of migrant workers and some certain jobs to Middle Eastern countries on 2015. This is because, said Flambonita, (11) the government considers the aspects of safety, human rights, equal distribution of working opportunities, the fulfilment of workforces according to the demand, and also legal protection.

Indonesian migrant workers are prone to harassment and exploitation. Such fragility causes the migrant workers’ rights to be easily ignored by some parties, such as the outsourcing agent, the employers, and the hosting countries, according to Krustiati. (12) Indonesian migrant workers mostly have low education. Thus, their knowledge and skills are limited, including their knowledge on their rights for health. Migrant workers may bring negative impacts socially, culturally, politically, and economically, thus the government needs to take some actions for anticipation, as said by Kassim in Johari. (13)

The Constitution No. 18 of 2017 regulates the protection on the Indonesian migrant workers comprehensively. The said regulation only places the migrant workers in their hosting countries. It also applies the regulations on foreign workforces, where in it also applies the social security system or the insurance which protects the foreign workers, with the regulation on a written agreement between the hosting country and the government of the Republic of Indonesia as the sending country, said Toruan. (14) Social security is a form of social protection as the rights for the employees regarding the job they have, as opined by Manea. (15) These requirements have the aim to reach legal protection for the Indonesian migrant workers. The focus of this research is to describe the protection of the health rights guarantee for the Indonesian migrant workers in Malaysia through the legal perspective.

**Research Method**

This research is a legal normative study which is supported by empiric research. The method of research is the legal normative method which is used to analyze some constitutional regulations which are applied regarding the health rights of the Indonesian migrant workers. Meanwhile, according to Fajar and Ahmad (16), the legal empiric research method is used to analyze the application of that regulation, whether or not it is applied well, and to describe the problems which arise due to the issuing of that regulation.

**Results and Discussion**

The hosting and the protection of workers overseas is actually related to the relations between countries. Thus, it is clear that the government have the power to manage the placement and the protection of the migrant workers overseas. The government cannot act by themselves. Thus, it must include the roles of the provincial government, the city/regency government, and the private institution.

The sending of the migrant workers overseas have contributions in the social and in the developmental aspects. It may increase the state’s foreign currency. It will open up new working opportunities. It will ease the pressure of problems. The society may experience obtaining high wages, and it may decrease unemployment. If we try to see the sense and the aim of sending Indonesian migrant workers overseas in a wider context, it will not only solve the employment problems in Indonesia, but it is also a form of economic improvement.

Employment Act and the Workman Compensation’s Act regulates the guarantee for working and living appropriateness of the Indonesian migrant workers, under the surveillance of the Department of Workforces. Starting from 2019, the both domestic and non-domestic migrant workers in Malaysia will obtain guarantees from
the Social Security Organization/Sosco. So far, the Sosco social security was only meant for the local workers, as mentioned in a conversation with Ahmad Dahlan (Staff of the Republic of Indonesia’s Workforce Penang, Division of Immigration, on February 26th, 2018). This policy has the aim to fulfil the standardization so that it is according to the ILO convention, which stated that the constitution on workforces must be universal and uniform.

The Indonesian migrant workers in Malaysia are regulated in the Workmen’s Compensation Act 1952 and the insurance policies paid by the employers. The Workmen’s Compensation Act 1952 will soon be revoked, and it will be changed with the Sosco regulation which has a higher beneficial impact. The discourse proclaimed the obligation to pay RM14 to RM15 a month to Sosco to protect the health security aspect of the workers. The workers will obtain much benefit as they are protected by an insurance and they may obtain a life-long compensation. The employers have the responsibility to pay for the Sosco. Socso owns one of the best hospitals in Southeast Asia in Melaka. If there are migrant workers who experienced an accident, they may obtain full treatment until healed, as said by Neni Kurniaty (Staff of the Republic of Indonesia’s Workforce Penang, Executor of Counsellor Function II, on February 26th, 2018).

The health aspect of the migrant workers is not really given attention in the work contract. In reality, sick leave may only be obtained after a written permit from the employer, and that will only happen if they are granted permission, as said by Khazinah, an Indonesian migrant worker in Malaysia, in a conversation (February 24th, 2018). Just like in the case of Nirmala Bonet, the attorney said that there is a point in the work contract regarding health security. Yet, that is no different from social security given from compensations. To obtain compensation from the case of torture, it took ten years, in a conversation with Anis Hidayah (Head of the Center for Migrant Study and Research, April 9th, 2018).

Fringe benefits may also be forfeited if the worker takes sick leave, as mentioned in a conversation with Rubiatun (an Indonesian migrant worker in Malaysia, February 24th, 2018). This shows that there is no difference between sick leave and annual leave. Health security is deemed as not effective enough as it only covers the physical health of the migrant workers who experienced accidents in the working hours. In the view of legal protection theory, the Malaysian policies has not shown enough care for the health of the migrant workers.

**Conclusion**

In the aspect of health security, the migrant workers will obtain much benefits as they are protected by the insurance. They may also obtain life-long compensation based on the Sosco regulation. The payment to sosco becomes the responsibility of the employers. The health aspect of the migrant workers is not really taken care of in the work agreements. Sick leave may only be obtained after a permission from the employee. Fringe benefits may also be forfeiter if the worker still takes this sick leave. This shows that there is no difference between sick leave and annual leave. Health security is deemed as not effective enough as it only covers the physical health of the migrant workers who experienced accidents in the working hours.

Comparison of Clinical Characteristics and Neuroimaging of Cerebral Palsy with and without Epilepsy in Children

Rizka Yulianti¹, Prastiya Indra Gunawan², Darto Saharso³
¹Department of Child Health, ²Resident, Department of Child Health, ³Lecturer and Consultant in Paediatric Neurology Division, Faculty of Medicine, Universitas Airlangga/ Dr. Soetomo General Hospital, Surabaya, Indonesia

Abstract

Background: Cerebral palsy (CP) is one of the main causes of limited activity in children. The prevalence of CP ranges from 2.6 to 2.9 per 1000 live births. Most of children with CP have at least one comorbid, including epilepsy. Epilepsy in CP is difficult to control, and can increase the severity of motor impairment and cognitive function, therefore the prognosis is poor. The incidence of epilepsy in CP is associated with a specific clinical profile. This study aimed to analyze the comparison of clinical characteristics of cerebral palsy in children with and without epilepsy.

Methods: A cross-sectional study was conducted using medical record of children with cerebral palsy in pediatric neurology outpatient clinic in Dr. Soetomo Hospital Surabaya in March - May 2020. Children with CP who met the inclusion criteria were included in this study. The variables studied included sex, perinatal history (preterm birth, low birth weight, and neonatal asphyxia), neonatal seizures, spastic type, level of GMFCS, head circumference, neuroimaging features, hearing loss, and eye abnormalities. The study subjects were divided into two groups. Group 1 consisted of children with CP and epilepsy. Group 2 consisted of children with CP without epilepsy. Data analysis was performed using the Chi-square test and fisher’s exact test using SPSS.

Result: Significant comparison of the characteristics were found in the history of neonatal seizures and the level of GMFCS. The percentage of neonatal seizures was higher in group 1 at 61.3% (p=0.049). The degree of GMFCS in group 1 was dominated by GMFCS III while in group 2 it was dominated by GMFCS IV (p=0.047). Subjects with GMFCS I and II levels were only found in group 2, while in group 1 with higher level of GMFCS, they were GMFCS III, IV, and V. More abnormal neuroimaging was found in group 1, namely 64.3%, while in group 2 it was 57.1%. There was no statistically significant difference of neuroimaging characteristics between the two groups (p= 0.911).

Conclusion: There were differences in clinical characteristics associated with neonatal seizures and GMFCS between CP with and without epilepsy.

Keyword: Cerebral palsy, epilepsy, neuroimaging.

Background

Cerebral Palsy is a chronic disease affecting the center of movement control with clinical manifestations that are visible in the first few years of life and generally do not get worse at later ages. Based on data from NSCH and NHIS, it was reported that the prevalence of CP ranged from 2.6 to 2.9 per 1000 live births¹.
Children with CP suffer from motor problems and other disorders, such as intellectual problems, seizures, behavioral and emotional disorders, speech and language disorders, as well as eye and hearing problems. Previous studies stated that epilepsy is most often found in children with spastic CP. Another study states that 39% of spastic CP in children have epilepsy. The spastic types most often found in children with CP are hemiplegia, diplegia, and quadriplegia. In several studies, it is stated that the most common type of spastic in CP with epilepsy is quadriplegia.

Epilepsy is a major prognostic factor in mental and motor function in children with CP. Gross Motor Function Classification System is a classification of children’s motor abilities and limitations at home, school, and in the environment. GMFCS IV-V levels were found more frequently in CP accompanied by epilepsy. Whereas in CP without epilepsy, the GMFCS level that was mostly obtained was level I-II.

Head circumference abnormalities, namely microcephaly, is one of the most common clinical manifestations of spastic CP patients. Another study states that microcephaly is more common in CP patients with epilepsy, and microcephaly increases the risk of epilepsy in CP.

Other co-morbidities that often accompany CP patients are hearing loss and eye disorders. Children with CP had hearing loss in 10%, and 2% were bilateral deaf. Another study states that nearly 20% of children with CP also have eye disorders, such as strabismus, amblyopia, nystagmus, cortical blindness, and visual abnormalities. Vision screening needs to be performed on children with CP so that these abnormalities can be detected early. Children with CP and epilepsy are more likely to have abnormal brain imaging. Brain atrophy was also reported more frequently in CP with concomitant epilepsy and reached statistical significance in one study. The abnormality of the imaging features in CP is controversial. This study aimed to analyze the comparison of clinical characteristics and neuroimaging of cerebral palsy children with and without epilepsy.

Methods and Materials
A cross-sectional study was conducted using medical record of children with cerebral palsy in pediatric neurology outpatient clinic in Dr. Soetomo Hospital Surabaya in March - May 2020. Children with CP with epilepsy and without epilepsy who met the inclusion criteria were included in this study. Children with multiple congenital anomalies, genetic syndromes, and incomplete medical record (age, sex, body weight, head circumference, perinatal and postnatal history, spastic type, level of GMFCS) were excluded. The study subjects were divided into two groups. Group 1 consisted of children with CP and epilepsy. Group 2 consisted children with CP without epilepsy.

The variables studied included sex, perinatal history (preterm birth, low birth weight, and neonatal asphyxia), neonatal seizures, spastic type, level of GMFCS, head circumference, neuroimaging features, hearing loss, and eye abnormalities.

Data analysis was performed using the Chi-square test and Fisher’s exact test with a significant significance value of p <0.05. All statistical analyzes were conducted using SPSS version 25.

Result
There were 50 subjects included in this study. The characteristics of the subjects were showed in table 1.

* Chi-square; **Fisher’s exact test
Significant comparison of the characteristics were found in the history of neonatal seizures and the level of GMFCS. The percentage of neonatal seizures was higher in group 1 at 61.3% (p=0.049). The degree of GMFCS in group 1 was dominated by GMFCS III while in group 2 it was dominated by GMFCS IV, where there was a significant difference for the clinical characteristics of GMFCS (p = 0.047). Subjects with GMFCS I and II levels were only found in group 2, while in group 1 with higher GMFCS level, they were GMFCS III, IV, and V (Table 2).

In this study, data on EEG examination results were reported only in children of CP with epilepsy. There were 70.9% subjects with abnormal EEG and 29.1% subjects with normal EEG. The most common type of EEG abnormality was sharp waves (16.1%).

Neuroimaging examinations in the form of head MRI and head CT scan were performed on 42 subjects. More abnormal neuroimaging was found in group 1, namely 64.3%, while in group 2 it was 57.1% (p=0.911). The description of neuroimaging abnormalities found in the two groups is presented in Table 3.

### Discussion

In the study of all subjects with cerebral palsy, the percentage was higher in the cerebral palsy group with epilepsy, which was 62%. A study conducted found that 89.9% of cerebral palsy patients developed epilepsy. A meta-analysis study showed the prevalence of epilepsy in CP children of 36% - 62%. There is a close relationship between epilepsy and cerebral palsy. Epilepsy is considered to be one of the most common
Neurological disorders that accompany patients with CP. It is estimated that about 20% of cases of childhood epilepsy are the result of brain lesions that also cause CP. The CP patients in this study were predominantly female, both in the CP group with epilepsy and without epilepsy, namely 61.3% and 57.9%, respectively, and there was no significant difference between the two groups \( (p = 1,000) \). This result is different from the results of another study that male sex dominated both in the CP group with epilepsy and the CP group without epilepsy with a percentage of 57.6% and 60.3% respectively, but there was no significant difference between the two sex-related group \( (p = 0.673) \).

In the perinatal history, the characteristics assessed include preterm birth, low birth weight infants, and neonatal asphyxia. In preterm birth, the percentage was higher in the CP group without epilepsy, namely 42.1% compared to the CP group with epilepsy, which was 29.0% \( (p = 0.522) \). Previous study stated that 20.9% of patients with CP were diagnosed with preterm birth, with most details in the CP group with epilepsy (21.6%) compared to the CP group without epilepsy \( (44.7\%) \)\(^{11} \). Other study reported that a higher frequency of epilepsy in term infants with CP similar to this study, but there was no correlation was found between gestational age and risk of epilepsy in other studies\(^{21} \).

In the characteristics of low birth weight babies, a higher percentage was also found in the CP group without epilepsy (36.8%) compared to the CP group with epilepsy (25.8%) with \( p = 0.611 \). This is also in line with research conducted by El-Tallawy et al., Which did not get a significant difference in terms of birth weight in the two groups\(^{4,12} \).

Neonatal asphyxia was found in 38% subjects. The percentage was more in CP with epilepsy (38.7%) compared to CP without epilepsy (36.8%) and there was no significant difference with \( p = 1,000 \). In a previous study the highest percentage of low apgar scores was in the CP group with epilepsy compared to the group without epilepsy \( (24.4\% \text{ vs } 6.9\%) \) with \( p<0.02 \)\(^{21} \). Asphyxia is a condition that can cause the brain to go into hypoxia, ischemia, and hypercapnia, which can cause brain damage. Brain damage causes CP at a later date and when it hits certain areas such as the cerebral cortex and temporal lobe, it will cause epilepsy\(^{22} \).

Neonatal seizure was found in 52% subjects, and most were found in the CP group with epilepsy (61.3%) compared to the CP group without epilepsy (36.8%) with \( p = 0.049 \). A study was found that there were more patients with neonatal seizures in the CP group with epilepsy than those without epilepsy \( (38.1\% \text{ vs } 17.2\%) \) and there was a significant difference with a value of \( p = 0.000 \)\(^{12} \). In line with the study it was found that neonatal seizures in CP with epilepsy compared to CP without epilepsy were 48.4% vs 7.9% \( (p<0.004) \)\(^{19} \). Some literature states that neonatal seizures increase the risk of death and the occurrence of neurological sequelae in neonates in the form of epilepsy. In various previous studies it was reported that neonatal seizures are a risk factor that plays a role in the occurrence of epilepsy in CP patients\(^{3,18} \). Widiastuti’s research conducted at 3 teaching hospitals in Jakarta found a neonatal seizure mortality rate of 47.4%. Neonatal seizure mortality is related to the degree of clinical condition of the neonate after birth. This study did not find subjects who had neonatal seizures in the CP group with epilepsy. This may be related to the high mortality in neonatal seizures\(^{23} \). Neonatal seizures result in intrinsic lesions in the brain that have the potential to produce epileptogenesis, and epileptogenesis is a process of neural tissue that will develop into recurrent epileptic seizures\(^{24} \). In addition, neonatal seizures will produce more extensive brain damage, and when it hits certain areas such as the cerebral cortex and temporal lobe, it will cause epilepsy\(^{22} \).

In this study, when compared between the CP group with and without epilepsy, it was found that in the two groups the most common types were quadriplegia \( (64.5\% \text{ vs } 57.9\%) \), then diplegia \( (32.3\% \text{ vs } 36.8\%) \), and hemiplegia \( (3, 2\% \text{ vs } 5.3\%) \) with \( p=0.885 \). In line with another study mentioned that the CP group with epilepsy and without epilepsy were both dominated by the spastic quadriplegia type, but the percentages between the two were quite different \( (58.3\% \text{ vs } 34\%) \) with \( p <0.05 \)\(^{4} \). Cerebral palsy with spastic quadriplegia is common in patients who have a high incidence of seizures, ranging from 50 to 94%, which, in turn, may be a reflection of the severity of damage to the brain\(^{25, 26} \). Another study states that the most common type of CP with epilepsy is the type of quadriplegia, which causes the most severe motor disorders and involves all extremities and is associated with mental retardation due to brain damage that is relatively greater than the type of CP without...
In this study, the highest level of GMFCS in all study subjects was GMFCS IV. In the CP group with epilepsy, there were no GMFCS levels I and II, only GMFCS levels III, IV, V. In the CP group without epilepsy, all GMFCS degrees were obtained. The level of GMFCS describes the severity of motor disturbances in CP. Some previous studies have reported that GMFCS degrees IV and V are dominated by CP patients with epilepsy. The same results were also obtained in a study, where GMFCS grade IV-V was found the most in the CP group with epilepsy and grade I-II was mostly found in the CP group without epilepsy, and there were significant differences between the two groups. These studies are in line with this study that obtained a high degree of GMFCS which illustrates the severity of the dominant motor function found in CP accompanied by epilepsy.

The literature states that there is a straight relationship between epilepsy and the degree of motor impairment, as well as a relationship with mental disorders. Epilepsy is the main prognostic factor in mental and motor function in children with CP.

In this study, microcephaly is slightly more common in the CP group without epilepsy compared with epilepsy (50% vs 48.4%) but there was no statistically significant difference between these two groups. In previous study was found the distribution in the CP group with epilepsy and without epilepsy were almost the same. Another study states that microcephaly increases the risk of epilepsy in CP. According to Wibowo and Saputra, in their research, the incidence of head circumference is inversely proportional to the incidence of preterm gestational age and low birth weight. This suggests that head circumference abnormalities in cerebral palsy may occur in the post-natal period, which is caused by disorders when brain development has not been completed, namely at the age of less than 3 years and the most likely cause in this study is CNS infection. According to literature, CNS infection can cause head circumference abnormalities by destroying brain mass causing microcephaly.

Of the 41 study subjects, 17.07% were found with hearing loss, and 16% were found in the group with epilepsy and 18.7% in the group without epilepsy. There was no statistically significant difference between the two groups (p = 1,000). Research conducted by Delacy et al. mentioned as many as 12% of research subjects with CP have hearing loss. Research conducted by Zafeiriou et al., obtained hearing loss as much as 19.1% in the CP group with epilepsy and 12.7% in the CP group without epilepsy. Although it is different from this study which states that hearing loss is more common in the CP group without epilepsy, there is no statistically significant difference between the two groups.

Approximately 12% of children with CP experience hearing loss. The incidence of hearing loss is higher when the etiology of CP is associated with low birth weight, kernicterus, neonatal meningitis, or hypoxic-ischemic encephalopathy. Hearing loss is generally a neurogenic abnormality in high-pitched perception, making it difficult for children to grasp words. In addition, CP children are prone to recurring chronic ear infections which will impair their hearing. Hearing loss also has a negative impact on language development. CP children with intellectual disabilities and abnormal radiological examinations are at high risk for hearing loss. Hearing loss is often diagnosed late, and research shows that more than half of children with severe hearing loss are diagnosed when the child is almost 3 years old.

In the CP group with epilepsy, there were 20% with eye abnormalities and 18.7% in the CP group without epilepsy. There was no significant difference between the two groups regarding eye abnormalities. Research conducted by Zafeiriou et al., found 19.1% eye abnormalities in the CP group with epilepsy and 12.7% in the CP group without epilepsy. The eye disorders in this study were refractive errors, strabismus, and decreased vision. Although the study found a significant relationship between eye disorders and epilepsy, there is no data in the literature on the relationship between eye problems and epilepsy.

Neuroimaging in this study was performed using head CT scan and head MRI. There were 64.3% of the neuroimaging features were abnormal in the CP group with epilepsy, and 57.1% in the CP group without epilepsy and there were no significant differences between the two groups. In line with the study conducted by Senbil et al., It was stated that the abnormal neuroimaging picture was found as much as 74.2% in the CP group with epilepsy and 48.8% in the CP group without epilepsy.
and there was no significant difference between the two groups. The most neuroimaging features found in the two groups were brain atrophy. Other types of disorders found are maldevelopment, encephalomalacia, ventriculomegaly, periventricular leucomalacia, cystic lesion, hydrocephalus, and cerebral infarction. The same results were obtained in this study. Most of the cases with cerebral atrophy are the end result of prenatal or perinatal ischemia globally with extensive neurological damage possibly due to seizure. The effects of imaging abnormalities on CP are controversial. In one study, MRI abnormalities were recorded in 86.7% of patients, and abnormal findings on MRI did not significantly affect epilepsy progression and seizure outcome.

**Conclusion**

There were no differences in sex, perinatal history (prematurity, LBW, neonatal asphyxia), head circumference, spastic type, hearing loss, eye abnormalities, and neuroimaging features between CP with and without epilepsy. There were differences in clinical characteristics associated with neonatal seizures and GMFCS between CP with and without epilepsy.

Association of rs865429 C/T polymorphism in SOST gene with Coronary Heart Disease in Iraqi Type 2 Diabetes Mellitus Patients

Ruaa Ali Mohammed Ali¹, Rasha Shaker Nima²

¹PHD Student, Department Dept. of Chemistry, Faculty of Science, Kufa University. P. O. Box 21, Iraq. ²Assistant Professor;²Department Dept. of pathological analysis, Faculty of Science, Kufa University. P. O. Box 21, Iraq

Abstract

Sclerostin, encoded by the SOST gene, It has also been shown that sclerostin is expressed in aortic VSMC (vascular smooth muscle) and upregulation of SOST gene has inhibitory effects on the aortic aneurysm and atherosclerosis development. Aims: The current study aims to explore potential the association between SOST gene single nucleotide polymorphisms (rs865429 C/T) and coronary artery diseases (CHD) in type 2 diabetes mellitus (T2DM) patients, in addition to the effect of this SNP on the level of serum sclerostin and other glycemic parameters. Material and methods: From the Iraqi population, we enrolled 300 T2DM patients (150 T2DM with CHD and 150 T2DM without CHD). Serum blood glucose, serum insulin, HbA1C, and sclerostin were estimated. Genotyping for rs865429 C/T in SOST gene was achieved by RFLP (polymerase chain reaction-restriction fragment length polymorphism). Results: T2DM patients having CT + TT genotype included in the studied were at increased risk for CHD in T2DM (odd ratio: 0.4444 CI: 0.2800 to 0.7054) and related to a high serum sclerostin level in comparison with type 2 diabetic patients with CC genotype. Conclusions: Type 2 diabetic patients with T allele who have elevated plasma concentrations of sclerostin are at high risk for coronary artery diseases.

Key words: single nucleotide polymorphism, polymerase chain reaction restriction fragment length polymorphism, type 2 diabetes mellitus, coronary artery diseases.

Introduction

Worldwide, the cardiometabolic risk is increased, and it is the leading cause of mortality and disability, such as impaired lipid and glucose metabolism, high blood pressure, obesity, and systemic inflammation. Also, these metabolic features are present in many individuals with T2DM, which may contribute to the approximate doubling of coronary heart diseases (CHD) risk in persons with diabetes. Sclerostin is a glycoprotein (190 amino acids) is the major antagonist of the Wnt- pathway. Sclerostin especially binding to the LRP 5/6 complex inhibits Wnt signalling and lowering β-catenin translocation into the nucleus, as well as a reduction in cholesterol uptake. Osteocytes are a major source of sclerostin, liver, though chondrocytes, kidney, and avascular wall (aorta) may also secrete it. The relationship between Wnt inhibitors (DKK1 and sclerostin) and arterial wall calcification and cardiovascular events is unclear. Higher serum level of sclerostin is observed in T2DM patients when compared with healthy subjects, and serum sclerostin level is correlated positively with the diabetes duration, and glycated haemoglobin (HbA1c). Sclerostin has been reported to have positive negative or no correlation with arterial calcification. Even its connection with cardiovascular events is controversial. Sclerostin, encoded by the SOST gene, It has also been shown that sclerostin is expressed in aortic vascular smooth muscle and upregulation of SOST gene has inhibitory effects on aortic aneurysm and atherosclerosis development. This study is intended to evaluate the association between rs865429 C/T in SOST gene and coronary artery diseases in T2DM patients.
Experimental

Study Design

Three hundred patients (150 Women, 150 Men) age 57.7 ±1.64 years, with a diagnosis of T2DM according to the American Diabetes Association criteria. Subjects, including 150 T2DM patients with CHD (T2DM-CHD), and 150 T2DM patients without CHD (T2DM). The coronary heart disease patients were selected from patients in the catheterization ward of Najaf Center for Cardic Surgery, at Al-Sadder Medical City, Najaf, Iraq (with more than 70% stenosis in each of the main coronary vessels). The protocol of the work was approved by the Ethics Committee of College of Science at Kufa University. Also, each subject signed an informed approval before participating in the study. From the patients, written informed consent was obtained. All patients were Iraqi, without congenital heart disease, cardiomyopathy, severe liver or kidney disease. Patients with vasculitis, connective tissue diseases and familial hypercholesterolemia were also excluded.

Biochemical analysis

At the same time of the day, blood samples were taken for all subjects and after 12-hour fasting. Blood samples collected in two tubes. The first was left to allow clot formation for 10 min, and then centrifuged within 20 min at 3000 Xg, and sera were separated. The reminder blood samples were collected in the tubes containing K₂EDTA for measurement percentage of glycated haemoglobin (HbA1c). The percentage of Hemoglobin A1c was measured by a colorimetric method by using the HbA1c kit (Stanbio, USA). Serum insulin and sclerostin levels were determined using a solid phase enzyme-linked immunosorbent assay kits (Elabscience, USA).

Genotyping analysis

The genomic DNA extraction kit (Promega, USA) was used to extract genomic DNA from the peripheral blood, concerning manufactures guidelines. Genotyping for the studied SNP was accomplished using polymerase chain reaction-restriction fragment length polymorphism (PCR- RFLP). The primer sequences of rs865429 C/T SNP were present in table 1, and the restriction enzymes name and length of the restriction fragments were presented in table 2.

Statistical Analysis

The present study data are expressed as mean ± standard deviation (Mean ± SD). The two groups parameters were compared used students \( t \)-test. All statistical analyses were performed using the statistics is a powerful statistical software platform (SPSS) software (V20;0 IBM Corporation, Armonk, NY. USA). Calculated probability (p-value) less than 0.05 was considered significant. Hardy-Weinberg equilibrium and Proportions of genotypes of alleles were tested using the standard \( \chi^2 \) test, in addition to odds ratios (ORs) and 95% confidence intervals (CI) were calculated.

Results and Discussion

The demographic data and clinical of all participants are existing in table 3. As point out in table 3, the levels of HbA1c and fasting insulin were significantly higher in the T2DM with CHD when compared with T2DM without CHD (\( P < 0.0001 \)). HOMA-IR in T2DM-CHD patients was elevated significantly (11.111 ± 3.617) in comparison to the pathological control group (27.672 ± 9.519). Moreover, T2DM-CHD pointed out a significant increase in the level of sclerostin compared to the non-CHD diabetic pathological control group (181.357±10.959, and 154.285±12.377 Pg/ml, respectively) (\( p \leq 0.0001 \)).

Sclerostin gene was amplified for the detection of rs865429C/T in the patients involved in this study. The amplicon size of the amplification product was 365bp. Then it was digested by Neol restriction enzyme. The digestion products were analyzed by 2% agarose gel electrophoresis. Patients with the wild type homozygote CC exhibited 365bp uncut fragment. While, patients with the of heterozyote CT type showed three bands with sizes of 365bp, 102bp, and 263bp. Those with the homozygote TT type yielded 2 fragments of 102bp, and 263bp fragments (Figure 1).
Figure 1: The PCR product of rs865429C/T SNP in SOST gene analyzed by agarose gel electrophoresis. Lanes A: for patients with the wild type homozygote CC genotype that revealed one fragment with the size of 365bp. Lane B: for patients have the heterozygote GT genotype exhibited three fragments with sizes of 365bp, 263bp, and 102bp. Lanes C: for individuals has the mutant homozygote TT of 253bp, 102bp.

The genotyping of the studied polymorphism in T2DM patients are seen in table 4. Data indicated no significant difference between the observed and expected genotypes. The genotyping results of the studied SNP were found to be consistent with Hardy-Weinberg equilibrium.

To evaluate the gene-disease associations for the investigated SNP, different inheritance models were considered. The selection of the most appropriate model was achieved via the estimation of the odd ratio. The statistical analysis of the genotype distribution of rs865429C/T SNP in the SOST gene under various inheritance models significant differences under co-dominant and recessive models, when the data of T2DM-CHD and T2DM groups were compared. The results were found to be associated with the recessive and dominant models for the rs865429C/T SNP in the SOST gene. Allele association of rs865429 SNP was analyzed for the relevance with the risk of development of coronary heart diseases in diabetic patients. The Results indicated a frequency of the C allele of 36.33% and 23.33% and the T allele of 63.67%, 76.67% in T2DM-CHD and T2DM groups respectively with an insignificant difference (Table 5).

The biochemical characteristics T2DM-CHD patients were analyzed in relevance to the genotype of the selected SNP under the recessive model. For the rs865429C/T SNP in the SOST gene, the recessive model included patients with genotypes CC+CT vs TT. The analysis was carried out with the use of the student’s t-test. The analyses of the data of the rs865429C/T SNP in SOST gene indicated significant elevations (P=0.0001) of levels of fasting blood glucose, fasting blood insulin, HbA1c, and HOMA-IR, in patients have CT+TT genotypes when compared with those of CC genotype (Table 6). Data of sclerostin concentration revealed a significant elevation (P=0.0001) in patients who have TT genotypes in comparison with those of CC+CT genotype.

Table 6. Differences of biochemical characteristics in relevance to the genotypes of rs865429C/T SNP in the SOST gene of T2DM-CHD patients under the recessive model.

The current study assesses the relationship between rs865429C/T single nucleotide polymorphism in the SOST gene with CHD risk in T2DM. Interestingly, in our population, the selected SNP data show similarity with Hardy-Weinberg equilibrium. Statistically, a significant association was observed between the TT genotype with the risk of CHD in T2DM. Iraqi carriers of the TT genotype seem to be more susceptible to the disease. The pooled odd ratios of multiple comparisons of genotyping models, co-dominant, dominant, and recessive were 2.963 (0.906-4.8366, P=10-4), 0.4925 (1.2396- 6.5523, P=0.0834), and 0.444(0.2800- 0.7054, P= 0.0006), respectively. To realize the impact of SOST gene polymorphism (rs865429 C/T) in the development of CHD in type 2 diabetics, we have to focus on mechanisms by which Sclerostin is engaged.

The GWA has proved that SOST gene is one of the hub genes that play a role in osteoporosis pathology. While, Deveci et al.; reported that SOST gene rs865429C/T influences weight and body mass index of Turkish women. And, Pifers et al.; evaluated SOST rs10534024 polymorphism on 783 young and 600 elder Danish men. They reported an interaction between body shape and SOST rs10534024 polymorphism. We also observed an association between CHD in T2DM and rs865429C/T polymorphisms in the SOST gene. T2DM is a major cardiovascular disease risk factor. There are numerous certificates that both genetic and environmental factors contribute to this risk. Gene risk factors identified for cardiovascular diseases is crucial to understand the aetiology of the diseases. Although, mechanisms of atherogenesis in large part stay to be defined. Observational researchers have explained that the progression of the disease involves crisscross between immune cells with both endothelial cells and VSMCs. The fundamental cells inside the media layer of arteries are VSMCs and are important to maintaining the arterial wall integrity of arteries. They take part in the remodeling of the arterial wall and have serious roles in atherosclerosis through all disease stages. The VSMCs display marked plasticity in response to lipoprotein accumulation, vascular injury, and inflammation during progression of disease through re-programming gene expression, i.e., phenotype switching, a shift to a proliferative, promigratory, and activated phenotype. There is rising evidence on the extraskeletal functions of sclerostin, highlighting to its role in many vascular disorders. Recent studies have pointed that under calcifying conditions, the VSMCs are able of producing a phenotypic transition to osteoblast-like cells, under calcifying conditions, which are capable of expressing the typical bone markers, like sclerostin.

Various researchers notified the link between sclerostin level and vascular tissue calcification. Besides the contribution of sclerostin in some disorders associated with processes of vascular calcification, it is controversial in the mechanism by which sclerostin can affect the calcification process, some of them propose that sclerostin has a protective role, while others propose the opposite. In aortic tissue, sclerostin is expressed in VMSCs. While, in atherosclerotic plaques which obtained from carotid endarterectomy, sclerostin is detectable by immunohistochemical staining in VMSCs as well as in macrophages.

It is reasonable to suggest here that this SNP is an important genetic marker that predisposes the occurrence of CHD in type 2 diabetics. Hence, more prospective research should be performed to provide the use of sclerostin and rs865429 SNP in the SOST gene as a good biomarker to identify an increased predisposition to coronary heart diseases in type 2 diabetic Iraqi patients.

**Conclusion**

The present work describes the rs865429C/T SNP in the SOST gene encoding sclerostin in a T2DM patient with CHD. The mutation has a devastating effect on the biological function of sclerostin by increasing extracellular sclerostin levels, thereby, its antagonistic activity on canonical Wnt signalling contributes to the disease phenotype. Also, The association between CHD and rs 865429C>T polymorphism in the SOST gene may open new insights on pharmacogenetics studies of CHD in T2DM.

**Limitation:**

Our study has a limited number of T2DM patients; events might have restricted the power of our study to detect statistically significant associations.

**Acknowledgment:** we are grateful to all the participants.

**Funding Sources:** self.

Knowledge of HIV Transmission and Factors Related to the Incidence of HIV/AIDS in Adolescents in Indonesia

Ruri Kharisma Fitriani¹, Lutfi Agus Salim²

¹ Bachelor Student in Department Biostatistics and Demography, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, ² Associate Professor in Department Biostatistics and Demography, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

Abstract

Adolescents are vulnerable to various health risk, especially caused by social interactions, like juvenile delinquency and drug abuse, premarital sex and unwanted pregnancy to an increased incidence of sexually transmitted infections including HIV/AIDS. The number of AIDS cases in students is 282 cases, more than double prostitutes who are 137 cases. The purpose of this study is to find out how is the knowledge of young people about HIV/AIDS, how HIV are transmitted and what are the factors that associated with HIV incidence in adolescents in Indonesia. This paper uses a qualitative method with literature study or library research, then data obtained is analyzed using descriptive analysis methods. HIV/AIDS can be transmitted through bodily fluids contact and is related to several factors such as gender, family factors, community environment, technology and communication. Cooperation of all sectors, parents, social institutions, and society to support government programs for HIV/AIDS-free Indonesia.

Key words: Transmission, HIV, AIDS, adolescents, Indonesia

Introduction

Adolescents in both men and women experience puberty which is maturation very quickly both physically, psychically and socially in preparation for maturity. One of the characteristics of teenagers is having a high curiosity, liking challenges and adventures, starting to find yourself and daring to risk what is done without thinking long. Based on these traits, if the youth do not have strong faith, do not make decisions or the youth are too free without proper control back from the family or the environment then the youth will very easily fall into a bad thing that can damage their morals and future (1).

Adolescents are derived from the Latin word Adolescentia which means “to grow” or “to grow into adulthood”. Children considered to be adults have been able to perform or conduct reproductive activities (2). When it’s about determining age to define youth, some sources have different age restrictions but the differences aren’t far off. According to the WHO, teenagers are residents aged 10 -19 years. Teenagers are residents aged 13 - 20 years. While according to National Population and Family Planning Board (NPFP), teenagers are residents aged 10 - 21 years. Thus, adolescents are a younger generation or population that is approximately 10 -21 years old and is going through puberty or transitioning from childhood to maturity to be ready to reproduce (3).

Adolescence is a critical phase in the formation of teenage characters in both male and female adolescents as a result of changes in each individual. Physical changes in some parts of the body, psychic changes and ways of thinking up to social and environmental changes have a huge impact on adolescents. Teenagers who are unable to control themselves will easily get carried away by currents that can damage the morale and future of adolescence. Based on this, problems in adolescents are complex and interconnected problems, ranging from large numbers, social problems to health problems (4). The number of youth population in Indonesia every year is increasing. According to Ministry Of National
Development Planning, Central Bureau of Statistic and NPFP, in 2015 the youth population was 66.0 million and in 2016 increased to 66.3 million or about 25% of the total population of 258.7 million (5). This means that one in four people in Indonesia is a teenager. A large proportion of teenagers have their own problems that cannot be ruled out, one of which is social and health problems.

Adolescence is the age of self-search that allows teenagers to connect with peers. Friends and the environment have a profound effect on the condition of adolescents, especially in social lives that have an impact on health. Adolescents tend to experience increased susceptibility to various health risk threats, especially those caused by poor social interactions, ranging from adolescent delinquency and drugs abuse, sexual and reproductive health problems such as premarital sex and out-of-wedlock pregnancies to an increase in the incidence of Sexual Trafficking (STI) diseases including HIV/AIDS (6).

HIV or Human Immunodeficiency Virus is a virus that attacks the human immune system. People with HIV will experience a decrease in the immune system so that it is easily infected with diseases including AIDS (Acquired Immuno-Deficiency Syndrome). The trend of HIV incidence in Indonesia tends to increase every year. In 2014, HIV positive cases in Indonesia totaled 32,711 cases, in 2016 as many as 41,250 cases and 2018 as many as 46,659 cases. As of 2018, the number of HIV positive cases in Indonesia reached 327,282 cases, while AIDS cases reached 114,065 cases. The highest percentage of HIV-positive cases by age group was in the productive age group of 25 - 49 years old by 70.4% followed by adolescents 15 - 24 years old by 18.2%. According to the work, the number of AIDS cases in schoolchildren/students is 282 cases, more than double the number of sex offenders in 137 cases (7).

UNICEF noted that the trend in the number of teen deaths aged 10-19 from HIV/AIDS worldwide was 71,000 adolescents in 2005 and increased to 110,000 in 2012 and there were 2.1 million adolescents in the world living with HIV/AIDS in 2012. The death rate or Case Fatality Rate (CFR) due to HIV/AIDS from year to year tends to decrease. In 2018 CFR AIDS in Indonesia amounted to 1.03%, based on this description, researchers are interested in studying adolescents’ knowledge of HIV/AIDS, HIV transmission and factors related to the incidence of HIV/AIDS in adolescents in Indonesia (8).

**Methods**

This writing uses qualitative methods with the type of writing of literature studies. Data and information are obtained from data libraries or scientific research. In retrieving data or information must ensure that the source taken throughout its contents can be held accountable for its truth and validity.

**Results**

HIV/AIDS disease in the world, especially in Indonesia, is a complex problem. The cause of the occurrence of the disease is strongly related to environmental factors, namely social influence and physical social interaction. Transmission of HIV/AIDS disease from sufferers to others can occur through the exchange of bodily fluids. HIV that enters the body will destroy CD4 cells. CD4 cells are part of white blood cells that serve to fight infection. The fewer CD4 cells in the body, the weaker the immune system, so sufferers will be easily exposed to or contracted other diseases.

</tbody>
</table>

The above data shows that knowledge of the transmission of HIV from mother to child during pregnancy, childbirth and breastfeeding increased in both male and female. The most likely cause of HIV transmission in adolescents is the contact of bodily fluids in the form of blood, semen and vaginal fluids during intercourse. This relates to juvenile delinquency and free association. Many teenagers enter the world of drugs, especially teenage boys. In addition, free sex and prenuptial sex are also increasingly becoming among adolescents so that the incidence of HIV in adolescents is increasing.

The above data shows that there is a comprehensive increase in knowledge in both women and men about HIV/AIDS (knowing that condom use is consistent during sexual intercourse and having only one faithful partner who is not infected with HIV can reduce the risk of HIV transmission as well as rejection of misunderstandings such as mosquito bites and sharing food with HIV sufferers can transmit HIV).

Discussions

HIV/AIDS disease not only occurs in adults and the elderly but can also attack newborns, children and adolescents. The large incidence of HIV in adults indicates that the sufferer contracted in adolescence and began to be detected in adulthood, because the incubation period of HIV takes years. That’s not surprising considering that teenagers are starting to have a lot of friends from different backgrounds and will have a lot of relationships or interact with people. Then from such interactions will have an influence on the adolescent individual, can be a positive influence as well as a negative. Negative influences that can’t be controlled by teenagers can lead teenagers into the world of free association and impact adolescent delinquency including acts of drug abuse, free sex and leading to HIV infection. Adolescent knowledge of HIV/AIDS is a fundamental aspect of HIV transmission prevention efforts.

HIV/AIDS is transmitted through the exchange or entry of infected bodily fluids. Bodily fluids that can be a medium of HIV transmission include:

a. Sperm and vaginal fluids

HIV transmission can occur through sexual intercourse, both homosexual and heterosexual. HIV transmission can occur through intercourse both vaginally, anally and orally. People who have intercourse with a changing partner have a greater risk of contracting HIV.

HIV prevention programs are focused on three aspects of behavior, namely condom use, restricting sexual intercourse to only one partner who is not infected with HIV and has no other partner, and delaying first-time sexual intercourse.

b. Blood

Contact between open wounds, blood transfusions and the use of syringes can transmit HIV. The use of syringes that can transmit HIV is interchangeable use, syringes should be used in sterile and disposable conditions only. But usually users of narcotics injectable (composer) and tattoo maker will use the syringe alternately. In addition, medical patients such as doctors or nurses who are impaled by syringes after use by patients with HIV can also transmit HIV.

c. Mother-to-child transmission

HIV can be transmitted from a mother with HIV-positive status to her child or called Mother to Child Transmission. Transmission can occur in both pregnancy, childbirth and breastfeeding through breast milk. Transmission occurs through the mother’s blood that is directly exposed to her child during pregnancy, the labor process, and through breast milk during lactation.

Various factors related to the incidence of adolescent HIV in Indonesia are largely influenced by the social environment. These factors include:

a. Gender

Teenage boys are more likely to experience HIV incidence than teenage girls. Teenage boys tend to be more daring to perform risky sexual behaviors such as risky courtship behaviors even to have sexual
intercourse by changing partners. In addition, the social environmental factors that are quite influential in teenage boys are free association and drug abuse. Many drug users use syringe media interchangeably to insert substances into the body (composer). The use of syringes is what causes the contracting of HIV.

b. Family

Families especially parents are the closest neighborhood to teenagers. Tatara and family education is the first education that forms the character of youth. Adolescents who have good control and are supervised for their association have a lower risk of developing HIV. In addition, the wholeness of the family also has a connection to the incidence of HIV in adolescents. Teenagers from broken home families are more likely to get HIV because they tend to be stressed and more free to get along.

c. Community Environment

The environment has a considerable connection and influence on the incidence of adolescent HIV/AIDS. The community environment in this case starts from the scope of the school, peers, groups / communities / organizations and the community in general in the environment around the youth residence. Peer and group or community influences are most prone to HIV/AIDS-risk behaviors so desperately need more attention. The scope of the school includes a safe environment due to the monitoring and supervision of the school, especially teachers, during the scope and hours of the school.

d. Technology and Communication

Increasingly today the development of technology is getting more sophisticated especially mobile phones. Advanced technology is like a double-edged knife for teenagers. On the one hand, it makes it easy to access knowledge and information around the world, making it easy to gain insights. But on the other hand, the misuse of smartphone and internet technology by teenagers can have an adverse impact. Teenagers can freely access anything including pornography sites that can then influence his sexual behavior. Coupled with social media that facilitates communication often abused teenagers to transact illicit goods such as drugs for consumption. The wrong way around seems facilitated by the ease of internet access on smartphones. Freedom without control in adolescents will have an impact on free association and juvenile delinquency that can increase risky behaviors for contracting HIV.

According to the description above, teenagers who live freely without control from both themselves and others will be very easily plunged into bad things that can damage the morale and future of adolescence. Especially in adolescents who have less knowledge about things related to adolescents will be more concerned about their future, including the possibility of having an HIV/AIDS disease.

Knowledge of HIV status as early as possible can be a method of preventing HIV transmission in people with HIV-negative status and effective coping or health care for people with HIV-positive status. HIV testing and counseling service called Voluntary HIV Counseling and Testing (VCT) is a service for early detection of HIV and access to supportive therapy, opportunistic infectious therapy and anti-retroviral therapy (ART) for both HIV negative and positive status. HIV tests are intended to ensure the appearance of HIV antibody in the body, while counseling is provided to determine the level of infection risk from this behavior and how it should behave later after learning the results of HIV tests.

Conclusion

Adolescent knowledge of HIV/AIDS is a fundamental aspect that should be instilled in adolescents as early as possible in efforts to prevent HIV transmission. HIV/AIDS infection can be transmitted through bodily fluids such as semen, sperm, vaginal fluids, blood and breast milk. The incidence of HIV/AIDS in adolescents is most transmitted through contact with bodily fluids when intercourse, namely contamination of semen, sperm and vaginal fluids due to free association and juvenile delinquency. Factors related to HIV/AIDS transmission in adolescents include adolescent gender, family factors, soy environmental factors and technological and communication factors.

Therefore, it is expected that the cooperation of all sectors of both parents, social institutions, and society in general to pay attention to and supervise adolescents from juvenile delinquency and free association to save
the future of adolescents as well as an effort to support
government programs for HIV/AIDS-free Indonesia.

Abstract

Diarrheal diseases in children are a major public health concern in developing countries. Especially species of *Candida*, responsible for causing candidiasis infection (diarrhea), require fast and accurate identification. The correct identification of *Candida* species is of great importance, as it presents prognostic and therapeutic significance, allowing an early and appropriate antifungal therapy. This study was conducted to investigate the incidence of *Candida albicans* associated with diarrhea in children.

This study was included isolates of *Candida* spp. from stool of 100 patients samples with diarrhea and 100 without diarrhea evaluated in AL-Batool Teaching Hospital by phenotypic methods, antifungal susceptibility of *C. albicans* and determination of the *C.albicans* genotypes by Nested PCR, discriminating *C. albicans* from the other *Candida* species. The tests used for phenotypic analysis were culture in SDA and CHROMAgar™ Candida, Phenotypic tests showed green colonies in chromogenic medium. The antifungal susceptibility results of 43 *C.albicans* isolates present that all of *Candida* isolates tested were susceptible to Amphotericin B and fluconazole (100%), while no resistance was observed in *C.albicans* to Caspofungin and Micafungin.

Finally, only one isolate was resistant to flucytosine. Genomic DNAs of all *C. albicans* isolates were amplified by PCR to detect their genotypes using, polymerase chain reaction amplification shows four genotypes (A, B, C, and D). A-genotype showed 4 subtypes and most common subgenotypes (1, 3, 4, and 5).

Kew word: *C.albicans*, Nested PCR, Antifungal susceptibility genotype identification

Introduction

*Candida species* is the genus comprises about 150 yeast species, the genus is composed of a heterogeneous group of organisms, and more than 17 different *Candida* species are known to be etiological agents of human infection; however, more than 90 % of invasive infections are caused by *Candida albicans*, *Candida glabrata*, *Candida parapsilosis*, *Candida tropicalis* and *Candida krusei* [14].

*Candida* is a part of normal flora of the human body colonizing various anatomical site like oral cavity, digestive tract, vagina and skin[19]. In cases where there is host debilitation, or where there is a change in the local environment promoting *Candida* overgrowth, this led to *candida* infection referred to as candidiasis) [7].

*C albicans* is the most common yeast species isolated from human feces, being identified in 65% of stool samples from healthy adults. Nevertheless, several reports have suggested that it may cause diarrhea. [3].

Diarrhea is a major cause of child morbidity and mortality in socio-economically developing countries. More than one million episodes of diarrhea occur every year among children under five years of age causing approximately 2.5 million deaths [12][16].

Molecular method for direct identification of *Candida* species has proven to be an accurate and rapid method for detection of candidal infections [16][23].

Nested polymerase chain reaction (Nested PCR) is a modification of polymerase chain reaction intended
to reduce non-specific binding in products due to the amplification of unexpected primer binding sites[5].

**Material and Methods**

**Isolation and Identification of Candida spp.**

Stool sample were collected from diarrheal children under 5 years old came to the microbiology laboratory in AL-Batool Teaching Hospital, general stool examination and Stool culturing during two months period (from 1st September 2018 to end November 2018).

All the collected samples were cultured directly, on Sabouraud dextrose agar (SDA) containing Chloramphenicol. Then incubated for 48 hrs. And the only positive samples were cultured on CHROM Agar (CAC).[13]

**Antifungal susceptibility test**

Antifungal susceptibility test was done according to ( Vitek 2 Compact), The YST identification card is based on established biochemical methods and newly developed substrates [2]. Final identification results are presented in approximately 14-18 hours.

The VITEK 2 cards containing serial twofold dilutions of Amphotericin B, Fluconazole, Flucytosine, and Voriconazole,Caspofungin,Micafungin were provided by the manufacture.

**Molecular Methods – based PCR.**

**DNA extraction.**

Genomic DNAs were extracted from *C.albicans* isolates, using a QIAamp DNA Mini Kit according to the manufacturer’s ( Qiagen DNA extraction kit) modified protocol. The purified DNA was stored at 20 ºC until further analysis. Quantus Florometer was used to detect the concentration of extracted DNA in order to detect the purity of samples for downstream applications.

For 1 µl of DNA, 199 µl of diluted QuantyFlour Dye was mixed. After 5min incubation at room temperature, DNA concentration values were detected, DNA concentration appeared at rate from 2-20 ( ng/µl).

Candida albicans Identification by Nested PCR

In order to identify *Candida albicans* genotypes and subgenotypes on the basis of 25S rDNA, Two sets of primers were used to increase these sensitivity and specificity of the assay. *C.albicans* was classified into five genotypes: A, B, C, D, and E [4],[15].

**Identification of Candida albicans genotypes**

The specific primer pairs used to detect the 25S rRNA were CA-INT-L (ATA AGG GAA GTC GGC AAA ATA CCG TAA) and CINT-R (CCT TGG CTG TGG TTT CGC TAG ATA GTA GAT) [12].

**Identification of Candida albicans subgenotypes**

The primer set ASDcF : 5’-TGATGAACCACATGTGCTACAAG-3’

And pCSCR: 5’-CGCCTCTATTGGTCGAGCAGTAGTC-3’

Is referred to as P-II in this study used for identify subgenotype of *C.albicans* [4].

all primers were synthesized by (Bioneer Co., USA). These primers were suspended in Nuclease-Free water to be 100 pmol/ µl as definitive concentration, as recommended by company protocol, put in freezer until time of use.

**Statistical Analysis.**

All data were statistically analyzed depending on SPSS (Statistical Package for Social Science) version 18 (2009).Chi-square and Yates’s correction was used to compare the variable in this study. Statistical results were considered significant when being under or equal to the 0.05.

**Results and Discussion.**

**Isolation and Identification of Candida spp.**

Morphological culture on SDA, colonies of *C. albicans* on sabouraud dextrose agar were white to creamy, round, soft, and smooth to wrinkled with a characteristic yeast odor as presented in figure 1).[16].
The results of this study are in agreement with [23], in thi-Qar that found the total rate of candida infection was (64.4%) of 264 examined stool specimens at Al-Zahraa health center, Suq Al-Shuyukh district. In another study from Kurdistan, Iraq, 600 stool specimens from children in different age (<2-12 years) were examined not only for Candida spp. but also for enteropathogenic bacteria, parasites, and viruses; Candida spp. could be detected in 1.16% of diarrhea cases [19].

The present study indicate that difference between Candida spp., 43 (64.71%) of the total isolated were identified as C. albicans, 24 (35.82%) isolates were identified as non-albicans, of which Candida tropicalis 8 (11.94%), Candida glabrata 6 (8.95%), Candida krusei 5 (7.46%), Candida parapsilosis 5 (7.46%) as shown in table 1.

Candida species’ well growth on chromogenic medium in this work supported the fact about this medium has a good performance, less time consuming, and sensitive in detection of Candida species [22]. These results also confirmed that chromogenic agar had a major role in the classification of Candida spp. into C. albicans and non-albicans [3][15].

Antifungal susceptibility test.

In this study, Vitek 2 YST was evaluated using 43 isolates of commonly observed species of Candida (C. albicans). The result generated as the Vitek 2 AST-YSO7 Card evaluated the sensitivity and resistance of Amphotericin B, Fluconazole, Micafungin, Caspofungin, Voriconazole, and Flucytosine.

The antifungal susceptibility results of 43 Candida albicans isolates present that All of Candida isolates tested were susceptible to AMB and fluconazole (100%). The resistance was high in C. albicans against
AMB (34.88%) and then against fluconazole and Voriconazole (32.55% & 25.58%) respectively, while no resistance was observed in *C. albicans* against Caspofungin and Micafungin. Finally, only one isolate of each of the following isolates were resistant to flucytosine in percentage (2.32%). as showed below in (figure.2).

These results were disagreement with (Rehab *et al.*;2011) who found that non of *Candida* isolates were resistant to AMB and only few isolates of *C. albicans* were resistant to FCN

Moreover, This result was agreement with [21] in Diyala who found that the antifungal drugs sensitivity test against *C.albicans* showed that all *C.albicans* isolates (100 %) resistant.

**Molecular Method for Detection of Candida albicans.**

Genomic DNAs of all *C. albicans* isolates were amplified by PCR to detect their genotypes using primer pairs (CA-INT-L and CA-INT-R) by targeting the gene 25S rDNA. polymerase chain reaction amplification shows four genotype(A,B,C,D) as its shown in figure[3].

**Figure 3:** Agarose gel electrophoresis of *C. albicans* genotypes by PCR targeting 25S rDNA on 1% A garose gel, 5 volt/cm for 1.5 hr, stained with ethidium bromide dye. Genomic DNA products generated through The primer pairs CA-INT-L and CA-INT-R, of 450 bp for genotype A in lanes: (26,43,45,50,58, 71,73,76,81,90). 840 bp for genotype B in lanes: (28,65). Both 450 bp and 840 bp for genotype C in lanes: (24,48,49,72,74).1040 bp for genotype D in lanes:(9).
For determination of *C. albicans* on the basis of 25S rDNA, primers CA-INT-L and CA-INT-R that span the site of the transposable intron in the 25S rDNA \(^{15}\) were used in this study. This method has been confirmed as a specific and reproducible method of genotype analysis of *C. albicans* \(^{8}\). PCR targeting 25S rDNA allows *C. albicans* to be grouped into five genotypes A, B, C, D and E\(^{8,10,13,15}\).

In this study, gel electrophoresis profiles defined DNA products as following: 450bp for genotype A, 840bp for genotype B, both 450&840bp for genotype C,1040 pb for genotype D, the study considered this isolate to belong to a new genotype ,None of PCR product in this study were genotype E 1080bp.

In addition to above, the most prevalent *C. albicans* genotype among Gastrointestinal candidiasis isolates on the basis of amplification of 25S rDNA was genotype A (52.6%), followed by genotype C (31.5%), and B (10.5%), and D (5.2%), this result agree with \(^{10,21}\) in Diyala that found the *C. albicans* genotype A is the most frequent genotype in patients but disagree there result that genotype A Followed by genotype B and C respectively.

**Identification of Candida albicans subgenotypes**

*Candida albicans* specific primer pairs (ASDc-F and ASDc-R) were able to successfully amplify the region of the 25S rDNA gene. Polymerase Chain Reaction amplification shows four subgenotypes(1,3,4,5) according product size from any of the genotype A,B,C,D *C.albicans* from 4 isolates ,as it shown in Figure-5.

![Figure 4: Agarose gel electrophoresis of C. albicans subgenotypes by PCR targeting 25S rDNA on 1% Agarose gel, 5 volt/cm for 1.5 hr, stained with ethidium bromide dye. Genomic DNA products generated through The primer pairs ASDc-F and ASDc-R.](image-url)
Another study in Turkey by[15] showed that genotype A (50.2%) was the most predominant genotype among invasive isolates non-invasive isolates from sputum, throat, urine, and feces, followed by genotype C (31.9%), and genotype B (17.9%).

Total of 200 children less five years were included in this study. 67 (67%) children had positive Candidiasis. These highly significant differences between Candida spp., 43 (64.17%) were identified as Candida albicans, 24 (35.82%) isolated were identified as non-albicans.

In this study, we used Nested PCR that can specifically identify C. albicans at the species level, and we found 4 sub genotypes (1, 3, 4 and 5) based on PCR amplification generated by primer pair P-II (ASDc-F and ASDc-R) these genotypes were based on the size of product[10],[11].

Result showed that single amplification product size 526bp as subtype 1 for the C. albicans genotype A,C, and single amplification product size 870bp as subtype 3 for the C. albicans genotype A,B, and amplification product size 1042 as subtype 4 for the C. albicans genotype A,B, and amplification product size 1214 as subtype 5 for the C. albicans genotype D.

Conclusions

From this study we conclude that about 67% of diarrheal cases were associated with Candidiasis.the antifungal test revealed that all of C. albicans isolates were susceptible to AMB and fluconazole while no resistant were observed against Caspofungin and Micafungin . polymerase chain reaction amplification shows four genotype(A,B,C,D).A genotype showed 4 types and most common sub genotypes(1,3,4 and 5).

Department of Chemistry and Biochemistry /Al-Nahrain University /College of Medicine / Iraq

Abstract

Subjects /This study is aimed to evaluate the bone resorption marker CTX, B-CTX, and bone formation marker Osteocalcin in relation to the clinical presentation as well as to investigate the evidences of the osteoporotic processes by assessing osteoclast bone markers in the different stages of MM patients and comparing these markers- in relation to standard prognostic markers in sample of MM Iraqi patients. – in addition to interpretation of soluble CD138 in relation to prognosis.

Methods/Sixty-five MM (males=41, females=24) patients distributed to different hematology centers in Iraq were enrolled in this cross-sectional study. Their age range was 39-81 years, twelve of them were newly diagnosed and the others were under treatment and distributed all on three stages from the disease according to the international staging system (ISS) : Group A – Stage I (n=21 patients, age mean 57.14±12.25 years), Group B – Stage II (n= 22 patients, age mean of 56.45±11.33 years), and Group C-Stage III (n=22 patients, age mean 60.59±11.55 years). Seven milliliters of venous blood samples were taken from each patient just prior to starting the chemotherapy for the measurement of blood hemoglobin (Hb), serum Creatinine, Calcium, Beat 2 Microglobulin Osteocalcin (OC), Total and Beta C-terminal telopeptide (CTX, BCTX), Parathyroid hormone (PTH), Syndecan-1 (CD138), and both kappa & lambda Free light chain (FLCκ, FLCλ).

Results/Anemia was a general feature of all patients, with a gradual rise (from stage 1 to 3) in the concentrations of creatinine and B2M P=<0.001, calcium P=0.01 and, all other studied markers CTX, BCTX, CD138, FLCκ and FLCλ has significant elevation in comparison among studied groups P=<0.001 with the exception of Osteocalcin ,which showed a general reduction.

Conclusion/Multiple Myeloma patients have increased in bone remodeling throughout the disease course with progressive increment in relation to disease stage --. Plasma cells in MM leads to disturbance in expression and secretion of CD138 in association with disease advancement.

Key words: Multiple Myeloma , bone turnover and C-terminal telopeptide (CTX).

Introduction

Clonal dissemination from malignant plasma cells in the microenvironnement of the bone marrow with the appearance , in blood and urine, of monoclonal protein, are important features of multiple myeloma (MM) which are usually associated with organ dysfunction , extensive lytic bone lesions and osteoporosis (¹). Patients with MM usually complain of fatigue , bone pain , easy bruisability, bleeding and recurrent infections which are manifested by hypercalcemia, lytic bone lesions, hyperviscosity, thrombocytopenia, hypo-gammaglobulinemia and many others (²,3) .

The myeloma cells are synergized by bone microenvironment which include fibroblasts, osteoblasts and osteoclasts(⁴). Increased rate of bone resorption and remodeling with a morphological assessment of plasma cells are important criteria for the evaluation of symptomatic myeloma (⁵). Precipitation of light chains
casts within the distal and collecting tubules-as a result of increased production of M-protein could be a cause of development of what is called myeloma kidney together with hypercalcemia, free light chain proteinuria, lack of hydration, hyperuricemia, and nephrotoxic medications and consequent recurrent bacterial infections (6,7).

Hypercalcemia can hasten and disturb renal insufficiency (8).

Of the prognostic markers β2 microglobulin its raised concentrations has been consistently reported in conditions characterized by lymphocyte activation and (or) proliferation. It is eliminated via the kidneys (9).

Circulating serum free light chain immunoglobulins are among the prognostic factors. These comprise two types: Kappa (K) and Lambda (λ). The ratio between the two types is increased in plasma cell tumors (10).

Plasma C-reactive protein (CRP) may rise rapidly after an acute inflammatory stimulus, mostly due to increased synthesis by the liver (11), and can serve as an important indicator from survival and post-treatment follow-up in cancer patients (12). Other recent prognostic criteria could be considered for MM as syndican-1 (CD138), osteocalcin, and Beta C-Terminal Telopeptide (BCTX) are still debated.

**Subjects and Methods**

Hospital-Based cross-sectional research was conducted over eleven months from May 2018 to June 2019. A total of 65 Multiple Myeloma (MM) patients participated in the study who were subjected to physical examination and diagnosed by hematologists with multiple myeloma from both genders (based on the Diagnostic criteria of the International Myeloma Working Group - IMWG). They were distributed to different Departments of hematology from Al-Imamain Al-Kadhimain Medical City, Al-Yarmuk Hospital, Baghdad Medical City teaching laboratories, Mirjan teaching Hospital in Hilla, and center of hematology and oncology in Basra.

The age range was 39 – 81 years. A group (12) of newly diagnosed patients emerged. The 65 patients were grouped into 3 stages according to the international staging system (ISS): Group A – Stage I (n=21 patients, age mean 57.14±12.25 years), Group B – Stage II (n=22 patients, age mean of 56.45±11.33 years), and Group C-Stage III (n=22 patients, age mean 60.59±11.55 years).

Full data were collected from each patient using a preformed questionnaire. Initial laboratory results were recorded from tests performed for the patients. Serum urea, creatinine, and calcium were determined by spectrophotometric methods. Moreover, a complete blood count and ESR, serum Immunofixation Electrophoresis, Imaging bone surveys, bone marrow aspirate, and bone marrow biopsy results were registered for each patient.

Patients excluded from the study were those who had Liver disease, active infections (human immunodeficiency virus, HIV, Hepatitis B, or C), and pregnant or breast-feeding women. For each patient the following laboratory tests were done: Free light chains test Kappa (FLC-k) & Lambda (FLC-l), B2Microglobulin (B2-MG), Osteocalcin (OC), C-terminal telopeptide (CTX), Beta C-terminal telopeptide (BCTX), Parathyroid hormone (PTH) and Syndecan-1 (CD138). All tests were done by the ELISA technique.

The Practical part was performed in the Department of Chemistry and Biochemistry, College of Medicine / Al Naharin University Research Laboratories. Test kits were purchased from Cusabio-China for PTH, CD 138, and B2MG, and from Melsin-China for OC & CTX, and from the Bio Vender-Czech Republic for free light chain (Kappa & Lambda). The study approved by IRB at College of Medicine/Al Naharin University.

**Results**

The most prevalent presenting features were anemia (43.08%) followed by back pain (29.23%) and renal complications (13.85%) as in table 1.

A gradual increase in serum B2MG, calcium and creatinine with plasma cells is present from stages I to III (P<0.001), but no marked differences in Hb % and immunofixation results (table-1).

For FLCk, and κ/λ ratio, stage I and II showed a comparable level of these markers with no significant differences, but both stages had significantly lower levels than stage III, (P=<0.001). as in table.
Serum parathyroid hormone, CD138 and total FLC, show comparable levels between stage II and stage III, while both stages were significantly higher than stage I (P<0.001).

There was a gradual increase in the β-CTX marker from stage I to stage III. (P<0.001). as in table

There is a gradual reduction in serum osteocalcin from stage 1 to III (P< 0.001).

The Receiver operating characteristic (ROC) curve was used to evaluate the diagnostic value for the detection of new MM cases. The patients were divided into two groups regardless of staging: newly diagnosed (12 cases) and longstanding (53 cases) the results revealed:

For osteocalcin, the area under the curve (AUC) was 0.553 (95%CI= 0.35-0.756), p= 0.565. The sensitivity and specificity of the test at osteocalcin cut off = 7.4 mg/dl were 0.604 and 0.587 respectively.

For CD138 the AUC was 0.748, 95%CI= 0.629-0.891, p= 0.008. The sensitivity and specificity of the test at CD138 cut off= 330 ng/ml was 0.68 and 0.677 respectively.

better results were obtained from total FLC, FLCκ or FLCλ:

For FLCκ, the AUC= 0.809, 95%CI= 0.64-0.971, p=0.001. The sensitivity and specificity of the test at FLCκ cut off= 9.5 ng/ml was 1.0 and 0.677 respectively.

For FLCλ, the AUC= 0.816, 95%CI= 0.7-0.932, p=0.001. The sensitivity and specificity of the test at FLCλ cut off= 8.3 ng/ml was 0.717 and 0.677 respectively.

while total FLC was the best; the AUC was 1.0, 95%= 1.0-1.0, p<0.001. The sensitivity and specificity of the test at total FLC cut off= 28.35 ng/ml were 1.0 for both.

Beta-2-microglobulin was found to be significantly decreased in longstanding patients compared with the newly diagnosed, and hence it was analyzed with a separated ROC curve. The AUC was 0.601, 95%CI= 0.45-0.751, p=0.279. The sensitivity and specificity of the test at β2-microglobulin cut off= 5.55 mg/L were 0.883 and 0.66 respectively.

Discussion

The distribution of MM patients among the three stages of the disease is more or less, the same which makes the comparision more convenient.

The hypercalcemia shown by the present patients could be attributed to the raise in the osteoclast-activating factor cytokines, Receptor Activator of Nuclear Factor Kappa-B Ligand (RANKL) is a member of the TNF ligand/receptor superfamily \((13)\).

It is a major mediator of osteoclast differentiation and activation and is over-expressed in the microenvironment from myeloma marrow. It is antagonized by osteoprotegerin (OPG), which is downregulated in myeloma lesions. Thus, there is a net increase in RANKL and a decrease in OPG in multiple myeloma, leading to osteoclast hyperactivity \((14)\).

Hypercalcemia associates PTH which is reported to increase in MM \((15)\).

The increase in B2 Microglobulin (B2MG) is a common feature of MM which was attributed to a mutation in the B2MG gene which has been shown to result in hypercatabolic hypoproteinemia. Diseases associated with B2M include immunodeficiency 43 and amyloidosis. High serum B2MG values can be thought of as a result of increased “synthesis” whether owing to increased expression, increased HLA turnover, cell proliferation, cell lysis, or some combination of these and not of decreased renal clearance \((16,17)\).

High levels of B2MG are associated with greater tumor burden and renal failure. This is manifested in this study by the high concentration of serum creatinine which was seen to be more prominent in 25% of myeloma patients \((18)\).

Pathologic injury of myeloma kidney is the presence of monoclonal light chains in the tubules in the type of thick, regularly overlaid, cylindrical throws. These casts contain - Tamm-Horsfall protein \((19)\). Uromodulin, is a protein unique to the kidneys. It coats the epithelium luminal side and is the most abundant in human urine \((20)\).

Osteocalcin is expressed directly by Osteoblasts. Most historical studies have focused on characterizing OC as a fracture indicator and only as a part of bone metabolism \((21)\). Normally bone homeostasis depends on the coupling of OCs and Osteoblasts. This coupling mechanism is lost in MM leading to an expansion of osteoclastic action with consequent bone resorption and diminished arrangement \((22,23)\).

The increase in CTX and Beta-CTX could be due to the secretion of a mixture of acid and neutral proteases by osteoclasts during bone resorption. This had made them specific markers for the degradation of type1 collagen \((24,25)\). This study shows an increase in the CTX and BCTX levels according to MM stages, the highest being in the third stage. These findings agree with Schiano C, Soricelli A. 2019, In vitro evidence supports a role for CD138 (syndecan-1) in the adherence of plasma cells to the stromal matrix of the bone marrow via an association with type I collagen.

From studies on monoclonal antibodies human syndecan-1 seems to be plasma cell-specific among hematopoietic elements and appears to be involved in the process of carcinogenesis \((26)\).

In people with osteoporosis, bone turnover markers may be useful for evaluating the response to anabolic and antiresorptive therapies, for evaluating therapy compliance or for suggesting potential secondary osteoporosis. A great deal remains to be learned about how bone turnover markers can be used to track the impact of stopping bisphosphonate therapy (e.g., determining a threshold above which restart therapy should be taken). several studies are needed to research the use of bone turnover markers to evaluate the bone safety of new drugs \((27)\).

The ROC test, in this study, shows clearly the differences in the specificity and sensitivity of the different bone biomarkers in MM, the net result of this test reveals that the Total free light chain remained the best by getting sensitivity and specificity of 1 for each.

At last we may say that careful monitoring of Bone markers levels at regular intervals is recommended with the emphasis on the control of parathyroid hormone and reduction of serum levels of bone markers by any possible mean.
Therefore, the bone remodeling markers are pivotal in evaluation of progression of MM patient which indeed may attribute in treatment decision as well as the monitoring of treatment results according to specific therapy.

**Conclusion**

Multiple Myeloma patients have increased in bone remodeling throughout the disease course with progressive increment in relation to disease stage. Plasma cells in MM leads to disturbance in expression and secretion of CD138 in association with disease advancement.

Histological Effect of Androgenic Anabolic Steroids on Liver

Sahar Dakhil Yonis1, Asaad Abd Al-Hussain Mohammad Al-Shouk2, Alaa S. Hachem3

1Assist. Lecturer, Department of Anatomy, College of Medicine, University of Al-Qadisiyah, 2Lecturer, Department of Anatomy, College of Medicine, University of Al-Qadisiyah, 3Lecturer, Department of Anatomy, College of veterinary, University of Al-Qadisiyah

Abstract: Anabolic androgenic steroids (AAS) they are the synthetic type of the natural male sex hormone (testosterone), they are widespread used amongst athletes to enhance performance. Abuse of AAS is common amongst players and it is usually accompanied by a many medically based complications. It was reported that hepatic problems include cholestasis, elevation of liver enzymes e.g. aminotransferases, as well as, benign hepatic adenomas, jaundice and to less extent of hepatocellular carcinoma was associated with their use.

A total of (12) adult New Zealand rabbits (Oryctolagus cuniculus) male, aged one year was selected. 2 control animals and 10 were treated with injections intramuscularly of the AAS, nandrolone decanoate (15 mg/kg) three times a week for 12 weeks. At the end of experiment the animals were sacrificed and the liver was dissected out and fixed using 10% buffered formalin-saline to prepare blocks for staining with haematoxylin and eosin for histological examination using the light microscope.

The liver of treated animals reveals that there are a mild to severe vascular congestion. There is swelling of hepatocytes, and inflammatory cell infiltration. Perivascular fibrosis, cellular necrosis was observed in other slides with sinusoidal congestions and extrabiliary bile pigments deposits.

The benefit of AAS comes with unwanted side effects. The total volume of the hepatocytes and sinusoids were increased in the studied animals. The total number of hepatocytes nuclei in experimental group also increased. The damage of the liver cells or at least increased permeability of the hepatocellular membrane which is noticed in the present work could explain the increment of plasma levels of liver enzymes which was studied by other researchers, as they notice an elevation liver enzymes activity such as alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (AP), gamma glutamyl transpeptidase (GGT), and lactate dehydrogenase (LDH).

Patients and physicians must kept in mind that the sequelae of AAS abuse are life threatening. So people should be aware about the complications of AAS use and a periodic examination of liver function and check out should be done to those treated groups.

Keywords: Androgenic anabolic steroid, histology, liver, liver enzymes.

Introduction

Anabolic androgenic steroids they are the synthetic type of the natural male sex hormone (testosterone), have been in commonly use among athletes to improve performance for many years. The hepatotoxicity risk is come to light as the dramatic increase in the use of AAS by athletes and young people. With the widespread use of AAS has come an associated increment of alertness of the adverse effects and sometimes serious sequelae of anabolic androgenic steroids use. Nonetheless, there seems to be a constant increase in the use of AAS by players and for aesthetic functions. Recent evaluations put AAS use in the Sweden and USA at 1% of the population and it can rationally accepted that the amounts of usage in Canada are parallel1. The online shopping using internet has elevates the illegal obtainability of these drugs without medical prescription and the buyers are usually unconscious of the dangers of administrating these drugs. AAS abuse is common amongst sportsmen and is accompanied by a lot of medical problems.. documented

1 DOI Number: 10.37506/ijfmt.v15i1.13621
hepatic disease including cholestasis, benign hepatic adenomas, increment of aminotransferases, jaundice and in rare cases the development of hepatocellular carcinoma. High doses of AAS may lead to temporary sterility, and testicular atrophy. There are 3 common dosage forms in which AAS are administered: oral pills, skin patches and injectable steroids. Oral dosage forms are the most suitable. AAS administered by oral intake is rapidly absorbed, but it is converted largely to inactive metabolites, and only about one-sixth is existing in the active form. AAS can be administered by parenteral route, but it has irregular extended absorption time and greater activity in cypionate ester, enanethate, proionate or undecanoate form. Parenteral steroids are typically administered intramuscularly, not intravenously; to avoid rapid changes in the concentration of the drug in the blood stream. Ciba was introduced Methandrostenolone (Dianabol) as an AAS by in the 1960s. Methandrostenolone was one of the AAS used to improve athletic act by the former East German Olympic programm. many adverse effects of AAS which include acne, gynecomastia, mood changes (aggressiveness) and testicular atrophy were recorded to accompany the use of this AAS. Stanozolol, another carbon-17- alkylated AAS, has been reported previously to cause acute renal failure and severe cholestasis in a young athlete. The use of AAS and vitamin supplementation may associated with acute renal injury as it was reported in two male athletes. Most of the synthetic androgens and anabolic agents are 17-alkyl-substituted steroids. Hepatic dysfunction is often associated with the administration of these drugs, e.g. increase in sulfobromophthalein retention and aspartate aminotransferase (AST) levels. Alkaline phosphatase values are also elevated. These changes occur early usually in the period of treatment, and the amount is proportionate to the dose. Bilirubin levels sometimes elevated until clinical jaundice is apparent. Cholestasis of the intrahepatic bile ducts has been reported to be caused by Methandrostenolone resulting in hyperbilirubinemia elevated aminotransferases, and clinical jaundice. nandrolone decanoate has androgenic: anabolic activity 1:2.5-1:4 compared to testosterone.

Materials and Methods

A total of (12) adult New Zealand rabbits (Oryctolagus cuniculus) male, aged one year with body weight of (1.7-2.2) Kg was selected for the study. Animal were kept in steel cages with grid floor and fed by fresh trefoil diet and water supply ad libitum. They kept at room temperature (25 -27°C) and 12-hr light -dark cycles with good ventilation. Two animals served as control group. The remain 10 were the treated group which received injections of the anabolic-androgenic steroid, nandrolone decanoate (15 mg/kg) intramuscularly three times a week for 12 weeks. At the end of the experiment, the animals were sacrificed by exsanguinations after anesthesia using an intramuscular injection of ketamine (3.5 mg/ kg) and xylazine (5 mg/ kg). The liver was taken and dissected out and fixed using 10% buffered formalin-saline to prepare blocks for staining with haematoxylin and eosin for histological examination using the light microscope.

Results

For the study of the general histology of the liver, haematoxylin and eosin stains were used. The architecture of the liver slides of control group of animals, shows that the liver consist of hepatic lobule, each lobule consists of hepatocytes arranged in rows radiated from the central vein. These hepatocytes are separated by hepatic sinusoids, between adjacent lobules there is the portal area (or triad) a branch ofhepatic artery , branch of portal vein, and bile duct are the content of this triad. On examination of liver of treated animals; it reveals that there are a mild to moderate and some times sever vascular congestion. There is swelling of hepatocytes, and inflammatory cell infiltration. There is swelling of hepatocytes, and inflammatory cell infiltration (figure 2). Perivascular fibrosis, cellular necrosis was observed in other slides with sinusoidal congestions and extrabiliary bile pigments deposits (figure 3 and 4 a &b).

Discussion

The advantages of anabolic steroids, unfortunately associated with unwanted side effects. Many organs demonstrate short and/or prolong side effects, and the use of AAS are accompanied by changes in the liver. The use of Anabolic androgenic steroid is not only by athletes who looking for better performance\textsuperscript{16}, weightlifters and bodybuilders, as well as prisoners are also show a high misuse levels \textsuperscript{17}. The availability of the AAS on the internet marketing and public gyms facilitate the ability of a person to get it in illegal ways, without medical prescription. As a consequence, the patients are able to take AAS without informing the physicians and in the same time, the doctors are less likely to be aware of the possibility of the use of AAS the non athlete population \textsuperscript{3}.

The present study clearly showed the effect of anabolic steroid use/or misuse on the liver histology. The histological changes on the liver which has been considered in the present work range from mild to severe vascular congestion with infiltration of chronic inflammatory cells, liver sinuses were congested, and collections of glycogen fibers and fatty degeneration appeared, some slides showed bile plugs in hepatocytes and canaliculi and also outside the cells and canaliculi. The effect of anabolic steroid had been studied previously on kidneys, pancreas from histological point of view. The side effect of AAS on the liver also studied
thoroughly but mainly concentrated on alterations on liver enzymes and the possibility of developing hepatic adenoma and carcinoma. The hepatic cellular damage caused by anabolic steroid occur also on ultrastructural level as shown by other studies, where the mitochondria showed increase in size and the appearance of crystalline inclusions, also there is increase in cytoplasmic volume. Most of the synthetic androgens and anabolic agents are 17-alkylsubstituted steroids. It is widely known that two chief mechanisms of liver injury induced by drugs;they are intrinsic and the idiosyncratic hepatotoxicity. Hepatocellular damage occurs by Intrinsic hepatotoxins in a way depending on the dose either in a direct way by the drug or indirectly by its metabolite. Some of the drugs, like acetaminophen, cause intrinsic hepatotoxicity, but most of this category agents are due to industrial toxins, household, or environmental toxins. The drugs that lead to idiosyncratic liver injury could be classified into metabolic and immunological categories.

In the first category, the drugs is metabolized into metabolite which is toxic in susceptible persons, while in the later is similar to “drug allergy” or sensitivity following predisposition to the drugs. Hepatocellular necrosis is the manifestation of intrinsic hepatotoxicity with little amount of inflammation. Meanwhile idiosyncratic drug responses usually appears with inflammation-dominant liver injury. These facts explain the damage occurred to hepatocytes and the changes in liver structure of animals treated with anabolic steroids which were observed in previous studies and the present work. The mechanism of action of steroids on the cells, can be summarized by that as they are tetracyclic cyclopenta[a]phenanthrene formed compounds which are able to pass across cell membranes and to bind to the cytoplasmic receptors, to form a new complex which binds to the DNA. After it bind to DNA, the steroid-receptor complex will starts a sequelae of process that finally leads to the making of cellular structures and proteins. positive nitrogen balance is the final result for cells. Inspite of the wide range of reactions caused by the different androgenic anabolic steroids compounds, all androgenic anabolic steroids bind directly to one androgen receptor (AR).

AAS were stimulate the synthesis of DNA in a potency between weak to strong effect and alteration to A-ring structure in a combination with non-polar substitution at 17alpha-positioned looks to be necessary for their activity. Previous studies by Dousta and Noorafshan revealed that liver volume and weight in mice treated with anabolic steroids increased in comparison with that of the control group. the hepatocytes and sinusoids showed increment in their volume in the treated animals, too. The total number of hepatocytes nuclei in experimental group increased by 20%. These findings are consistent with the results in this study as there were congestion of sinusoids and increase of hepatocytes size. The damage of the liver cells which is seen in the present work could explain the increment of plasma levels of liver enzymes which is studied to by other researchers, as they notice an elevation in plasma activity of enzymes of the liver e.g. aspartate aminotransferase (AST), alkaline phosphatase (AP), alanine aminotransferase (ALT), lactate dehydrogenase (LDH), and gamma glutamyl transpeptidase (GGT). These enzymes are found in hepatocytes in high level an increase in the plasma levels of these enzymes is a mark which reflect damage of liver cells or increased permeability of the hepatocellular membrane, at least. The anabolic steroid, as consequence to their effect on the liver, could also affect free fatty acids metabolism by the liver and lead to the accumulation of triglycerides within the hepatocytes. This was appeared in the present work as fatty degeneration of fatty changes of the liver which noticed in some slides, which called steatosis, and it is consistent with other studies that observed such hepatic changes due to anabolic steroids use.

The high doses of alkylated androgens can produce peliosis hepatica, cholestasis, and liver failure. They lower the level of plasma HDL2 and may elevate LDL. Hepatic carcinomas and adenomas also have been reported. Gurakar et al. and another researchers studies showed the hepatotoxic effect of anabolic steroids especially in supraphysiologic doses, as that taken by bodybuild. Some studies reported development of hepatic tumor due to the use of anabolic steroids; this is confirmed by the regression of tumor size and return of liver function to normal by the cessation of steroid usage. Our study did not prolonged enough to elicit such changes in the studied animals. Ramachandran and Kakar study on the liver of patient use anabolic anabolic steroids didn’t show inflammation nor hepatocellular injury, their findings were inconsistent with the results of the present work. We agree with them in part in the occurrence of cholestasis in the anabolic steroids treated livers. Finally, Patients should be noted...
that the sequelae of AAS abuse are life threatening. Meanwhile, the athletes and bodybuilders are aware of the legal and social ramifications of steroid abuse, they must reminded about its medical risks.

**Ethical Clearance:** The animal were sacrificed under the ethical committee approval of college of medicine, university of Al-Qadisiyah.

Teachers’ Attitude Toward Children with Attention-Deficit Hyperactivity Disorder (ADHD) at Primary Schools in Al-Nasiriyah City, Iraq

Saja Mahdi¹, Ali Kareem Al-Juboori²
¹Ministry of Health, Al- Nasiriyah , Iraq. ²Professor, University of Karbala, College of Nursing, Karbala, Iraq

Abstract
The aim of the current study is to identify teachers’ attitude about attention-deficit hyperactivity disorder (ADHD) and its relation to their demographic characteristics. A descriptive study design was carried out among 250 teachers at primary schools in Nasiriyah city was selected by using convenience sample type. The data is collected by using Google classroom through distribution of the attitudes questionnaire to primary school teachers which composed of 22 items. The highest percentage 36.8% of teachers at age 41-50 years old, 52.8% were females, 70.8% were urban residence, 54.5% were married, 53.6% had barely sufficient income, 62.8% had bachelor graduated, 56.4% teach the classes (4-6) and 48.8% teach in male school. The majority 95.6% of teachers had neutral attitude toward ADHD and the grand mean was 1.93. There is significant statistical difference in teachers’ attitude with regard to their gender. Majority of teachers had neutral attitude About ADHD among children. Teachers attitudes is affected by gender. It is important to teach teachers about how to deal with child who had ADHD. Assign work that suits the student’s skill level, and give appropriate supervision to ADHD students.

Keywords: Teachers, Attitude, children, attention-deficit hyperactivity disorder (ADHD)

Introduction
Attention Deficit Hyperactivity Disorder (ADHD) is the most commonly studied and diagnosed psychiatric disorder in children, affecting 3 to 5% of children globally. Childhood ADHD can be a disabling illness. If severe forms are left untreated it interferes significantly with the child’s education, interpersonal relationships and ability to maintain a generally positive sense of self. Ill effects of the illness go beyond the child, having detrimental effect on family relationships. ADHD is associated with significant psychiatric co-morbidity, 50-60% of affected children meeting criteria for at least one additional psychiatric disorder. Thirty to 50% of those diagnosed with ADHD in childhood continue to have symptoms into adulthood.¹,²

Attention Deficit Hyperactivity Disorder is one of the most common psychiatric disorders among children and adolescents; the symptoms are hyperactivity, attention deficit and impulsiveness. ADHD co-occurs with some other disorders and the patients go through many problems at home, school and social environments. Based on a literature review, the prevalence of ADHD was 6.8% among children and adolescents. The overall prevalence is 9.7% among elementary school students of Tabriz, North-west of Iran, with a higher rate among the children of illiterate parents.³

The public stigmatizes children with symptoms of ADHD more than children without ADHD symptoms, adding a diagnostic label is associated with only marginally higher rates of stigma.⁴

Teachers play an additional role as gatekeepers to treatment and may elect to accept or deny access to evidence-based treatments for children. teachers not only struggle in the decision to consent to a medication trial, but often revisit their decision. Teachers report
fears of the long-term negative effects of stimulants, even if their child has a positive response to the medication. Furthermore, teachers report trial-stopping their children’s medication without approval from the prescribing doctor. Clearly, some teachers are ambivalent about employing an evidence-based intervention for their children with ADHD, due to their concerns.\(^{(5)}\)

Teachers attitudes are also important due to their effect on actual treatment-seeking behaviors and subsequent treatment adherence. Positive teacher’s attitudes towards the benefits of stimulant medications for ADHD predict later adherence to medication and perceived medication acceptability. Teachers are less willing to engage in both psychosocial and pharmacological treatments for their children if they do not feel knowledgeable about or endorse the acceptability of these treatments. Unsurprisingly, willingness to engage in treatment for children is positively related to teacher’s views on the acceptability and helpfulness of treatment. These results further support the importance of teacher’s knowledge in predicting treatment-seeking and adherence behaviors\(^{(6,7)}\).

Knowledge and attitudes may impact several important outcomes. For example, it has been suggested that gatekeepers who lack knowledge about ADHD may overlook behaviors signifying a child in need of assistance, and they may provide unreliable information to medical practitioners about the effects of medication. Similarly, it has been suggested that gatekeepers’ attitudes about ADHD may influence their selection of a teaching approach, their willingness to implement interventions, their chosen behavioral management strategies, and classmates’ perception of the child with ADHD\(^{(8)}\).

Teachers play a key role in many aspects of ADHD treatment planning and implementation. Insufficient knowledge and negative attitudes towards ADHD and its treatment among them result in a lack or improper implementation of management recommendations leading to treatment failure. Another explanation for this problem is the teachers’ knowledge about this disorder and their attitude toward treatment, as it has been seen that those teachers who had more knowledge about the disorder used pharmacologic and non-pharmacologic therapies more than the others\(^{(9)}\).

**Methodology**

Descriptive study design carried out among 250 teachers at primary schools in Nasiriyah city, they are selected by using non probability sampling (convenience sample). The study instrument is a questionnaire designed according to the study purpose. The study instrument composed of 2 parts. 1st Teacher’s Demographic Characteristics, 2nd attitude scale composed of 22 items. The attitude questionnaire had been scored and rated on three levels Likert scale, (3) points for agree, (2) points for not certain answer and (1) point for the disagree which assessed by cutoff point (0.66) due to scores (1, 2 and 3) respectively. Scores of responses are categorized according to the following level of attitudes: (1-1.66) = negative level of attitudes, (1.67-2.33) = neutral level of attitudes and (2.34-3.00) = positive level of attitudes. There are some items in reverse sentences in attitude questionnaire, in this case the score will be reversed (1) points for agree, (2) points for not certain answer and (3) point for the disagree. This items are (1,2,5,6,7,8, and 11).

The instrument face validity was determining through a panel of experts. The reliability of the questionnaire determined by Cronbach’s alpha for the internal consistency reliability. The data is collected by using google classroom to communicated with the teachers and gathering information. The data is analyzed by using descriptive and inferential statistical analysis through using (SPSS).

F=Fisher, d.f= degree of freedom, no significant (P>0.05), significant (P≤0.05), high significant (P≤0.01)
The results reveal that there is a significant statistical difference in teachers’ attitude with regard to their gender, whereas no significant difference is found with regard to other socio-demographic variables at p ≤ 0.05 (table 4).

Discussion

According to the socio demographic characteristics of the teachers in table (1). The findings indicate that most of teachers at age (41-51) years. Youssef, Hutchinson, & Youssef (2015) found that the mean of teachers age was at 39 years;(10) Aly, Mohammed, & Ahmed, (2015) found that most of the teachers at age less than 35 years;(11) Al Moghamsi, & Aljohani (2018) found that (53.8%) of teachers at age (31-40) years (12) . This finding not consisted with the present study finding.

According to gender more than half of teachers were females. Youssef, Hutchinson, & Youssef (2015) found that females more than males. Aly, Mohammed, & Ahmed, (2015) found that (61.9%) of teachers were females (11). Khademi et al., (2016) found that 86.8% of teachers were females. (13) These result in same line with our finding. The finding of Amiri, Noorazar, Fakhari, Darounkolaee, & Gharehgoz, (2017) consistent with current finding (14) . They found that majority of teachers were females.

Regarding to the educational achievement of teachers, more than half of the sample had bachelor graduated and teach in class 4-6 in male students’ school. Aly, Mohammed, & Ahmed, (2015) found that most of teachers had high education level (11) . Khademi et al., (2016) found that (60.5%) of teachers had bachelor educational level (13) . Alfageer et al., (2018) found that (86%) of the teachers had bachelor and diploma degree and teaching pupils at grade sixth (15) . Al Moghamsi, & Aljohani (2018) found that (91.3%) of sample had bachelor educational level. (12) Khalil, Alshareef, & Alshumrani, (2019) found that (80.7%) of teachers had bachelor degree (16) . All these findings supported the present study results.

Regarding to teacher attitude about ADHD, the findings show that, they had neutral attitude toward ADHD, the grand mean was 1.93 in (table 2). Finally, majority of teachers had neutral level of attitude toward ADHD in (table 3). Youssef, Hutchinson, & Youssef (2015) found that the attitudes toward children with ADHD were generally positive, although most teachers felt children with ADHD should be taught by specialist teachers (10) . Aly, Mohammed, & Ahmed, (2015) found that 55% of teachers had positive attitude toward ADHD (11) . Khademi et al., (2016) found that 65.1% of teachers had neutral attitude about ADHD (13) . Alfageer et al., (2018) found that Most of the participants in current survey tend to have a positive attitude toward ADHD (15) . These finding is supported the present study result.

Amiri, Noorazar, Fakhari, Darounkolaee, & Gharehgoz, (2017) found that almost half of the teachers believed that the educational system plays a very important role in perpetuating the symptoms of ADHD, while nearly half believed that special schools are needed. Although almost one third of teachers believed that the behavior of children with ADHD is deliberate in nature, fewer believed that punishment is needed and even fewer blamed the children’s family for their behavior (14) . This finding is consistent with the present study.

Conclusions

The study concluded that majority of teachers had neutral level of attitude toward ADHD, and teachers’ attitude is affected by their gender.

Guidelines for Maintaining Physical Fitness During COVID-19 Pandemic

Sakina S. Saifee¹, Angela Kapoor¹
¹Assistant Professor, ²Assistant Professor, Department of Cardio-pulmonary Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Sawangi(M) Wardha, Maharashtra, India

Abstract
The ongoing corona virus outbreak (COVID-19) has turned into pandemic, by rapidly spreading and infecting all over the world. It left no other choice than implementing the lockdown all over the country. This lockdown has led to the development of sedentary lifestyle among the people leaving them with inactivity, anxiety, depression and with an elevated chance of a potential aggravation of the health problems. Therefore, not just modifying people’s lifestyles during quarantine and keeping an active lifestyle at home, it is very necessary for the overall population’s safety, but particularly for those with additional risk factors and the elderly to conduct daily physical indoor activities and exercises. The data was collected from the electronic databases. The review includes the quarantine population of all age group and gender. After reviewing the articles it was concluded that the multi-component full-body programs should be carried out by the population, including aerobic, strengthening, balancing and stretching exercises by modifying and utilizing both the space and material available. Doing physical exercise will help us to stay active during quarantine period so that after the end of the crisis we will be able to resume our work without lethargy.

Keywords: Covid-19; Inactivity; Pandemic; Physical activity; Quarantine; Sedentary lifestyle

Introduction
The Corona virus (Covid-19) was introduced in China (Wuhan) last December 2019, and the infection has spread worldwide (1). The World Health Organization, recognizing the worsening scenario, declared the rapidly spreading corona virus outbreak a pandemic (2). In last three months, the virus raced all over the world with more than 19,80,700 confirmed cases till 14th April 14, 2020, With 1,25,000 deaths, and over 4,65,700 worldwide recovered. Covid-19 infection is serious condition because it is highly and rapidly contagious (3).

In about 80 per cent of those infected, the virus causes mild respiratory infections, though about half of them will have pneumonia. A further 15 percent experience serious illness and a further 5 percent needs urgent treatment (2).

WHO officials recommended countries to implement a strategic combination of “containment and mitigation” (2). The former includes attempts to identify and avoid known transmission chains by isolating cases and tracking their connections, and possibly quarantining them. Mitigation involves steps at Community level such as social distancing and lockdown. Despite the fact that a quarantine period is the best choice and recommendation for stopping the rapid spread of infections, this may have collateral effects on other dimensions of the health of isolated patients, especially those listed as at higher risk (4)(those aged 65 years and those with serious heart disease, chronic lung disease, diabetes, obesity, and chronic kidney and liver disease) (5). The normal routine lifestyle of these people involved physical activity and exercise to ensure an adequate state of health (e.g. in diabetes, hypertension, CVS conditions) (1). Staying for a long time is likely to lead to sedentary behavior, such as
spending more time sitting or lying down for screening exercises, decreasing daily physical activity, leading to an increased risk for future health condition worsening. Therefore, changing people’s lifestyles during quarantine and maintaining an active lifestyle at home is very important for the health of the population as a whole, but particularly for those with additional risk factors and the elderly to perform routine indoor physical activities and exercises as going to be discuss further. There are some research articles published until now, but there was need to compare and summarize all the papers and make a cumulative guideline of all.

Methodology

Data source:- The data was collected from the electronic databases including, Science direct, Google scholar, Pub med, web of science ,etc. The review includes all the quarantine population of all age group and gender. The main focus was on the high risk population.

Discussion

Following the recommendations of the scientific societies, health institutions, and experts is of utmost importance. All the research articles suggest that physical exercise plays a beneficial role in the prevention of diseases, as an adjuvant treatment in chronic diseases and in psychological wellbeing. They also stated that physical exercises have protective effect on immune system especially in chronically ill patients\(^5,6\). Maintaining physical activity is the best way to counteract sedentary conduct and reduce the psychological effects of quarantine, as sedentariness has a well-known detrimental effect on cardiovascular function. In the present quarantine days, the available space and resources need to be modified and utilized.

In his paper, Rodriguez et al suggested conducting Multi component full-body programs like aerobics, strengthening, balance and power, mobility of coordination, and stretching exercises. They are directly related to the physiological activities of the main organs (respiratory, circulatory, muscular, nervous and skeletal systems) and are indirectly involved in the smooth functioning of other systems (endocrine, digestive, immune or renal systems)\(^7\).

Rodriguez et al, accurately summarized the guidelines of the major healthcare institutions for exercise which can be used as a physical fitness protocol\(^5\).

Physical fitness guidelines and recommendations

The indoor physical activities that can be perform during quarantine period are\(^8,9\):

Ø Cardio respiratory fitness exercise
- Walk briskly around the house
- Stair climbing
- Jogging or marching on the place
- Standing or walking while using phone
- Dancing for 15 minutes
- Skipping rope
- Cardio machine (if available)
- Online exercise routines
- Active videogames

Ø Resistance or muscular strengthening exercise
- Squats, sit-to-stand and stand-to-sit from a sturdy chair
- Push-ups to the wall
- Single-leg step-ups on stairs
- Alternating leg lunges
- Strength training video
- Sit-ups or crunches
- Weightlifting (e.g., dumbbells, bottles, packs)
- Exercises by resistance band, or clothes, belt, etc.

Ø As a balanced workout should incorporate pulling as well as pushing motions

The writers have brilliantly proposed an update of the international physical activity guidelines to the present situation. With the knowledge of exercise, it is also necessary to be well aware about the principle
elements of exercise program such as modality, frequency, volume, intensity, duration. In this regard, Jiménez-Pavón et al. performed a critical review of the most acceptable guidelines for elements of exercise, particularly those that address the elderly. He described the guidelines as

Exercise modality:- Multi component exercise program with previously stated elements including cognitive training for elderly.

Exercise frequency:- Recommended 5 days per week for older people, which could be increased to 5-7 days per week with volume and intensity adaptation in this particular quarantine situation.

Exercise volume:- It could be suggested under the quarantine to increase to 200-400 min per week distributed between 5-7 days to compensate for the decrease in the normal daily PA levels.

Exercise Intensity:- Moderate intensity (40-60 per cent heart rate reserve or 65-75 per cent maximum heart rate) should be the ideal choice for older people to enhance the protective role of exercise during quarantine times.

In terms of cardiovascular health, we agree with the statement that, “something is better than nothing”. Chen at al, said the objective should be to do at least 30 minutes of moderate physical activity every day and/or 20 minutes of vigorous physical activity every other day. Ideally we should use the combination of both intensities. Portable health gadgets simplified the quantification and monitoring of exercise routines. Nonetheless, due to the availability of many sites promoting physical activity, it is important to consult knowledge sources established by medical societies, physicians and sports health professionals in order to achieve optimum cardiovascular and skeletal muscle fitness, within the limits permitted by quarantine.

Conclusion

During this on-going COVID-19 pandemic, home stay is an inevitable fundamental safety step that can stop the widely spreading infection. But this prolonged home stay will lead to the development of sedentary behavior leading to inactivity, anxiety, depression which will ultimately lead to chronic health problem. Maintaining the regular physical habit and adapting the new ways of doing physical exercise will help us to stay active during quarantine period and after the end of the crisis we will be able to resume our work without laziness. The population should perform multi component full-body programs including aerobic, strengthening, balance, and stretching exercises.

Abstract

Diabetes mellitus is a worldwide epidemic and is associated with long-term damage and causes dysfunction of several organs like kidney leading to diabetic nephropathy. This study was designed to evaluate some biochemical aspects.

This study was conducted on 95 patients which included (35) HD patients with diabetes and (35) HD patients without diabetes and (25) Type 2 diabetes mellitus patients, who attended at Ramadi General Hospital. For the purpose of comparison, (25) samples as control. Several tests were performed such as FSB, urea, creatinine, glomerular filtration rate (GFR), albumin, sodium ion, calcium ion, Phosphorus ion, potassium ion and magnesium ion were calculated. This study showed the level of urea and creatinine were a significant increase in HD patients with diabetes(128.29±22.59 and 7.1±1.76) mg/dl respectively, and HD patients without diabetes were (125.74±23.28 and 6.80±2.71) mg/dl respectively. The levels of Na⁺ and Ca++ were decrease in HD patients with diabetes (137.6±4.8 mmol/L and 6.72±1.76mg/dl) respectively. The levels of P, K⁺ and Mg++ were a significant increase in HD patients without diabetes(6.26±0.84 mg/dl, 5.52±0.61 mmol/L and 2.2±0.13mg/dl) respectively. The urea, creatinine and GFR are simple and useful biomarkers which can serve as predictor tests for assessing kidney functions in diabetic patients.

Key words: Chronic kidney disease (CKD), Diabetes mellitus (DM), Hemodialysis (HD), Sodium ion, Urea.

Introduction

Diabetes mellitus (DM) is a metabolic disorder of carbohydrate leading persistent high level of blood glucose due to factors that oppose the action of insulin. Presently, DM is a worldwide epidemic and a great challenge to health care systems everywhere [1]. Chronic kidney disease (CKD) is a progressive loss of kidney function over a period of months or years through five stages or defined as decreased GFR and increased urinary albumin excretion. Each stage is a progression through a low and deteriorating glomerular filtration rate (GFR) [2]. Therefore, CKD a major global public health problem. Urea and creatinine are renal function markers indicating normal functioning of the kidney and increase of these substances in the serum indicate kidney dysfunction [3]. Patients with CKD have marked disruption in bone and mineral metabolism resulting in a complex disorder. The biochemical alterations of CKD-mineral bone disorder include elevated serum phosphate and decreased serum calcium [4]. The kidney is the route of potassium and sodium excretion from the body. Advanced renal failure typically results in potassium and sodium retention [5]. The tissue sodium accumulation has different pathophysiologic that may be amenable to therapeutic strategies in CKD patients. While low serum magnesium levels are associated with vascular calcification and increased cardiovascular mortality in CKD patients [6]. Aims of the study to measure and compare the levels of urea, creatinine, albumin, and GFR in study groups and to assess serum electrolytes levels in HD patients and T2DM patients.

Materials and Methods

The samples collection were started from April,
2019 till end of June 2019. The study is designed on 95 patients and (25) samples Control group. Patients divided into (35) hemodialytic patients with diabetes and (35) hemodialytic patients without diabetes and (25) T2DM patients. HD patient with diabetes and HD patient without diabetes samples were collected from the Industrial Renal department and T2DM patients from Diabetes Center at Ramadi General Hospital.

**Blood Samples Collection:**

Before the collection of samples, a careful history was taken from each patient according to a questionnaire and all patients provided written informed consent before participation in this study. From each patient and control, 5 ml of blood were obtained by venipuncture, the blood was dispensed in a gel plain tube and left for 30 minutes to clot at room temperature (18-25°C). Then, it was centrifuged at 3000 r.p.m for 10 minutes to collect serum, the serum were used in the estimation of FBS, Urea, Creatinine, Albumin, Na, Ca++, P, K, and Mg++.

**Biochemical tests:**

Determination of urea, creatinine, albumin, Na, Ca, P, K, and Mg as cited by manufacturing company kits which provided from human company / Germany. FBS determination according to [7] method, which provided with kit from linear company/ Spain.

**GFR Calculated:** According to [8] equation which is:

\[
\text{GFR}= 141^\times \text{min} (\text{Scr/k,1}) \times \text{max} (\text{Scr/K,1}-1.209 \times 0.993 \text{ Age} \times 1.018 \times 1.159 \times 1.018)\]

Scr: Serum creatinine mg/dl, K: is 0.9 man and 0.7 woman, \(\alpha\): -0.411 man and -0.329 women, Min: minimum of Scr/k and max indicates the maximum of Scr/ k.

**Statistical Methods:**

The data were translated into a computerized database structure, and the statistical analyses were carried out SPSS version 25. One way ANOVA test was used to find means and standard deviation (SD) for all variables of the study. The difference significances in proportions analyzed by LSD test, P-value less than 0.05 were considered to be significant.

**Results and Discussion**

Determination of serum Urea, Creatinine, GFR and albumin in four study groups:

This study showed that the FBS was a significant increase in diabetic group (215±11.1)mg/dl, followed by HD patients with diabetes (188.7±18.39)mg/dl. These findings showed mean of urea and creatinine were a significant increase in HD patients with diabetes (128.29±22.59, 7.1±1.76) mg/dl respectively and in HD patients without diabetes (125.74±23.28, 6.80±2.71) mg/dl respectively. While level of GFR was a significant decreased in HD patients with diabetes and HD patients without diabetes (8.22±1.69 and 9.93±1.47) mL/ min/1.73m\(^2\) respectively compared with control and diabetic patients (115.56±4.39 and 113.92±3.14) mL/ min/1.73m\(^2\) respectively. This study indicates the no significant difference in mean of the albumin in groups of the study, as shown in the Table (1).

*Different Letters (a, b, c): Means significant difference at P ≤0.05.
*Similar Letters: Means no significant difference at P ≤0.05.

These results agreed with [9; 10; 3; 11] who recorded that urea and creatinine levels increased in diabetic patients compared with control.

An increase in urea and creatinine levels and decreased GFR is seen when the kidney is not functioning properly. GFR is the best measure of kidney function since it accounts for age, BMI, and sex. Irrespective of its cause, kidney disease is associated with a decrease in GFR, and the severity of kidney disease correlates closely but inversely with GFR [3]. In this study, the HD patients showed higher levels of both urea and Cr compared to controls, as clear evidence for the microvascular abnormalities in the renal system. Elevations in urea occur as the number of functional nephrons decreases[12]. Creatinine is separated by the glomerulus; in this way, the creatinine level is an indirect measure of glomerular filtration. As GFR reduces, there is an ascent in the concentration of urea and creatinine[13]. In this study diabetic patients showed a significantly increase in urea and creatinine compared with control due to hyperglycemia in T2DM starts after the age of forty usually when the kidneys have already suffered the long-term consequences of aging and other promotors of chronic renal injury such as arterial hypertension, dyslipidemia, obesity. This probably might be a cause for increased levels of serum creatinine and urea in T2DM [9]. The inflammatory process is the most widely recognized cause of decreased concentration of albumin, and since DM was known to be an express provocative, this may be one reason that causes the observed decline in Albulmin concentration to occur [14].

Determination of serum Na, Ca++, P, K and Mg++ among four study groups:

This study indicates that mean of Na was a significant decrease in HD patients with diabetes and HD patients without diabetes (137.6±4.8 and 136.6±5.1) mmol/L respectively compared with control (140.75±1.84) mmol/L. The results indicate that mean of Ca++ is a significant decrease in HD patients with diabetes (6.72±1.76) mg/dl and HD patients without diabetes (6.88±1.59)mg/dl compared with control (9.72±0.63) mg/dl. Where P level was a significant increase in HD patients without diabetes and HD patients with diabetes (6.26±0.84 and 6.11±0.75) mg/dl respectively compared with control (4.22±0.67) mg/dl. While K level was a significant increase in HD patients with diabetes and HD patients with diabetes (5.59±0.7 and 5.52±0.61) mmol/L respectively. These results indicate Mg++ level was a significant increase in HD patients without diabetes and HD patients with diabetes (2.2±0.13 and 2.18±0.27) mg/dl respectively compared with diabetic patients and control, as shown in the Table (2).

*Different Letters (a, b, c): Mean significant difference at P ≤0.05.

These results correspond with [15; 16] who recorded sodium level was decreased in HD patients compared with control. These findings agreed with [11; 17; 18] who recorded that the Ca++ showed significant decrease in HD patients, while phosphorus and K were increased in HD patients compared to control. These results no correspond with [6] who found that the mean Na+ was increased, while mean of phosphorus, Mg and potassium were decreased in HD patients compared with control.

CKD is a catabolic state and is associated with progressive nephron destruction and miss of renal function decreases the body ability to release a sodium load, which causes extracellular volume enlargement and sodium retention, and as such, the restoration of sodium balance is one of the key objectives of HD treatments [19]. Where in chronic HD patients, Na+ balance largely depends on interdialytic dietary salt intake and intradialytic Na+ removal[5].

Moreover, it is now recognized that increased sodium intake does not necessarily result in increased urinary sodium excretion and that sodium can exchange for intracellular potassium and accumulate in tissue matrix without any corresponding fluid status changes, the so-called non-osmotic sodium balance [20]. Ca++ plays an important role in the regulation of glucose level in the blood particularly postprandial glucose level, hence Ca++ should be measured in patients with T2DM who have uncontrolled hyperglycemia. There is evidence to suggest that altered Vit D and Ca++ homeostasis may play a role in the development of T2DM [11]. The reduction in serum Ca++ levels were most likely due to several factors: Reduction in insulin levels that impair bone formation due to stimulation of osteoblast proliferation and impairment of Ca++ homeostasis; Hyperglycemia, which increases the excretion of Ca++ and phosphorus in urine [21]. In this study, the serum Ca++ levels decreased in HD patients with/ without diabetes because the serum Ca++ at dialysis initiation to be associated with all-cause mortality after dialysis initiation. Severe hypocalcemia is highly likely to occur during the early period after dialysis initiation [17].

In our results, we observed that the mean of phosphorus was increased in HD patients with/ without diabetes compared with control and diabetic patients the usual cause is a decrease in renal excretion of phosphate. Advanced renal insufficiency reduces excretion sufficiently to increase serum phosphor [18]. At later CKD stages, the hyperphosphatemia occurs either by increasing bone reabsorption and phosphate release or by reducing the bone formation and phosphate uptake[22].
HD patients present with hyperkalemia, which reduces the resting membrane potential, slows the conduction velocity and increases the rate of repolarization [23]. All these changes are the signs of membrane instability and cardiac arrest or ventricular fibrillation may follow and thus this situation usually requires careful and prompt management [24]. During hemodialysis, there is a quick shift of serum K+ which leads to hypokalemia after HD sessions [25]. This study did not show an association between serum Mg++ levels and a risk of incident T2DM in patients with T2DM, compared to controls these slight differences may be supplements drugs or maybe a compensatory state [11]. The young erythrocytes have a higher Mg++ concentration than older cells for this reason in patients undergoing HD have a higher Mg++ concentrations and have been shown to be dependent on residual renal function [26].

**Conclusion**

GFR, urea and creatinine are simple and useful biomarkers which can serve as predictor tests for assessing kidney functions in diabetic patients. The serum Mg, P and K were increased in HD patients, these a worthwhile tool in assessing duration of disease, morbidity and mortality in HD patients. They estimation may help in evaluating conservative treatment and dialysis in CKD. Decreased levels of Na and Ca in HD patients compared with control group.

Submaximal Exercise Task Post Clinical Balance in COPD Patients and its Correlation with Quadriceps Girth, Body Mass Index and Disease Severity

Samana Sayed¹, Waqar M. Naqvi², Pratik Phansopkar³

¹Chief Physiotherapist, Department of Physiotherapy, Krishna Hospital, Mumbai 400703, Maharashtra, India, ²Professor and HOD, Department of Community Health Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India, ³Assistant Professor, Department of Musculoskeletal Physiotherapy, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India

Abstract

Purpose: To study and compare the effect of submaximal exercise on static and dynamic balance in patients with severe and moderate chronic obstructive pulmonary disease (COPD) and correlation of the balance impairments with disease severity, quadriceps girth and body mass index (BMI).

Methods: A sample of convenience of 45 middle aged participants (mean age 53.47 ± SD 4.775), including 15 with severe COPD, 15 with moderate COPD who were not undergoing pulmonary rehabilitation program and 15 healthy controls were included. The subjects performed Timed Up and Go Test (TUG) for dynamic balance and quiet standing to assess postural sway using sway meter with eyes closed and opened in narrow, semi tandem and tandem stance for 30 seconds. The balance variables were then correlated to forced expiratory volume in one second (FEV1), quadriceps girth and body mass index. Significance was set at alpha less than 0.05.

Results: when compared to healthy controls, significant differences were found in postural sway in all the stances in severe COPD patients, and in semi tandem and tandem stances in moderate COPD patients. TUG test significantly differed in both severe and moderate COPD (p=0.0001) and no difference between severe and moderate COPD TUG test was found. Moderate negative correlation was found between FEV1 and postural away in few stances whereas no correlation was found with quadriceps girth and BMI of COPD patients.

Conclusion: Static as well as dynamic balance are affected in COPD patients with postural sway affected more in severe COPD than moderate COPD leading to functional disability and risk of falls which increases with increase in age. Balance alterations can be moderately correlated to FEV1.

Keywords: Chronic Obstructive Pulmonary Disease, submaximal exercise, state and dynamic balance, anteroposterior sway, mediolateral sway, total sway, Timed Up and Go test, Quadriceps girth, Body Mass Index, FEV1.

Introduction

The detriments of peripheral muscle weakness have been noted in chronic obstructive pulmonary disease (COPD) along with hypoxia and hypercapnia, due to systemic manifestations. This extra pulmonary manifestation of has found to be associated with reduced functional mobility and exercise tolerance and deficits in...
simple motor movement\textsuperscript{1,2}. Thus, along with exertional dyspnea being the main factor for functional limitation, peripheral muscle strength also contributes for the same, lower limb being more affected than upper limb\textsuperscript{1}. Quadriceps myopathy is the most recognized characters of COPD coma resulting to two functional dysfunction which is a result of systemic inflammatory response and inactivity\textsuperscript{3,4}. Some studies have shown that myopathy is known to contribute to neurological abnormalities in patient in critical care unit and also that hypoxia effects motor coordination and postural control at high altitude and does they may have a similar effect in patient with hypoxic COPD\textsuperscript{1,5,6}.

Balance is an important component for performing activities of daily life and for being functionally independent. Recent evidences have stated that balance impairment is observed in elder COPD patients. Even balance assessment proved effective in the fallers from non-fallers in elder COPD. Evidence have stated that static balance is affected serious stable COPD following submaximal exercise task. But no studies have been performed to know the differences between moderate and severe COPD and how far quadriceps girth which has found to be reduced in COPD patients due to god resets myopathy is related to balance. Few researchers have studied the effect of body mass index BMI on postal balance but not in BD population. The aim of this study is to compare static and dynamic balance of senior and moderate COPD patients and to correlate it with quadriceps girth, BMI and forced expiratory volume in one second (FEVI) in middle age see OPD so that some of the aging effects on balance can be excluded and balance impairments can be well associated with the disease condition.

**Methods**

45 participants falling in the age group of 45 to 60 years (mean age 53.47± SD 4.775) were recruited including 15 with stable severe COPD (mean FEVI =41.27), 15 stable moderate COPD mean FEVI= 68.33) and 15 healthy controls from the outpatient department of Lala Ram Swaroop TB and Respiratory Medicine Institute. Patients were excluded if they had a history of major exacerbation in past one month. Major orthopedics condition, mobility limiting arthritis, neuromuscular condition\textsuperscript{1,2}, unstable angina, myocardial infarction and hypertension\textsuperscript{8}, any pain (either localized or general) or any conditions affecting low back or lower limb\textsuperscript{7}, cognitive impairment\textsuperscript{1}, vestibular disorders\textsuperscript{1,7}, tuberculosis, other lung diseases other than COPD\textsuperscript{1,7}. A through explanation of the procedure was performed and possible risks and benefits were explained. Written informed consent was obtained from each participant, with ethical clearance from the Research Ethical Committee of Lala Ram Swaroop Institute of TB and Respiratory Care, New Delhi.

**Measurement:**

The pre exercise baseline measurement of breathlessness using Brogs Dyspnoea scale, baseline oxygen saturation and baseline heart rate was measured after enrolling the participant in the study. Quadriceps girth was also measured prior to the test using cloth measuring tape taking lateral joint as a point from which girth was measured at two different levels 10 cm and 20 cm for both the limbs\textsuperscript{9}. Static balance was measured by assessing postural sway in the three validated stances, narrow, semitandem and tandem\textsuperscript{10} i.e. with increasing level of difficulty, with both eyes open and eyes closed using an instrument called “Swaymeter”. It consists of a pair of graduated ruler’s oriented perpendicular to each other and fixed upon a stand. It measures the displacement of the body at the level of the waist in anteroposterior, mediolateral direction and total sway in all the stances with the increasing level of their difficulty through the pen attached to a stand together, which is fixed with a belt\textsuperscript{11}. Patient were asked to stand for 30 seconds in narrow stance with both the feet together, semi tandem stance with the big toe of one foot placed at the side of the heel of the other foot and tandem stance with the big toe of one foot touching the heel of the foot placed ahead of it.

TUG test was performed to assess dynamic balance as well as functional mobility. Subjects were instructed to start by sitting on a chair, which was kept constant (46cm) for all the patients and on the word go to stand up, walk 3m, turn around, walk back to the chair, and sit down. Time was calculated from the time the pelvis was lifted to the time it was placed back on the chair. For older adults, completing the task in 7 to 9 seconds is low risk of hampered dynamic balance which may lead to falls, moderate risk in 10 to 12 seconds, and high risk...
in 13 seconds or more. The order of balance measures was randomized full stop the measurements obtained through the procedure was then correlated to quadriceps girth, FEVI and body mass index of the patients with COPD in order to obtain the relationship between balance and these variables.

**Statistical Analysis**

Analysis was performed using SPSS software version 15.0. the paired t test was applied for within subject dependent variable. As multiple groups were taken, a post hoc analysis was performed using tukey test to compare the difference between each reading. An alpha value of 5% was set for finding the significant difference. Pearson’s r correlation analysis was used to determine the correlation of quadriceps girth, BMI and FEVI with static and dynamic balance.

**Results**

The demographic characteristics of the patients are presented in table 1. All three groups did not differ significantly with respect to age. The Spirometry results showed significant difference in FEV1 among all the three groups. Dyspnea increased on 20 point Borg scale to 10.78 +-2.476 post task as compared to pre task mean rating of 8.84 +- 2.335.

**Eyes open:**

Mean increase in anterior posterior by 1.05, mediolateral (ML) by 2.15cm as well as total sway by 3.22 cm was found in narrow stance in severe COPD patients. Mediolateral as well as total sway was found to be affected in all the remaining stances in COPD patients given in table 2, 3, 4, 5. Mediolateral (p=0.0001) and total sway was found to be affected in moderate COPD patients in tandem stance (p=0.024). Healthy controls also show significant difference in mediolateral sway (p=0.004) and total sway (p=0.02) in tandem stance.

**Eyes closed:**

According to the post hoc tukey analysis, severe COPD patients showed increase anteroposterior sway, mediolateral sway and total sway in all narrow, tandem and semi tandem stances as compared to healthy controls (table 2, 3, 4, 5). However moderate COPD patients showed increased mediolateral sway in semi tandem stance (p=0.003) and anteroposterior sway (p=0.001) and mediolateral sway in tandem stance (p=0.0001) significant difference in total sway in tandem stance (p=0.0001) was also found in moderate COPD patients.

Correlation analysis:

Pearson’s correlation showed moderate negative correlation was obtained FEV1 and postural sway in four stances ML sway in eyes open (r = -0.473, p = 0.008) and closed (r = -0.394, p = 0.03) in narrow stance, semi tandem and tandem stance (r = -0.522, p = 0.003). Correlation analysis was done within 30 COPD patients. No significant correlation was obtained between quadriceps girth, BMI and balance.

Discussion

The purpose of this study was to assess and compare the effects of submaximal exercise task on postural balance, including both static and dynamic balance in COPD patients as compared to healthy controls in the middle aged individuals and to correlate the balance with FEV1, Quadriceps girth and Body Mass Index. The results found significant differences in dynamic balance of severe and moderate as compared to healthy individuals. Total postural sway was found to be affected from normal to challenging stances in severe COPD patients whereas mediolateral sway was only found to be affected in moderate COPD in challenging stances like semi tandem and tandem with more significant differences found in eyes closed stances than eyes open ones. Moderate negative correlation was found between FEV1 and postural sway in four of the total stances indicating inverse relationship between FEV1 and postural sway. This study was design to compare the balance between moderate and severe COPD in middle age population so that some of the effects of aging on
balance which is usually found above 60 years, based on the evidences\textsuperscript{13–16}, can be excluded.

Simple inexpensive, reliable and valid test like TUG test\textsuperscript{7,17–19} for dynamic balance and postural sway through sway meter\textsuperscript{7,11,20} were used to assess balance which can be easily and economically available and used in clinical settings. The alteration in balance as interpreted from the study, can be considered as a consequence of either muscle fatigue which would have occurred due to an exercise task\textsuperscript{7,21,22}. Increase in sway especially mediolateral has been reported in challenging positions in normal individual\textsuperscript{7}, however according to the findings of this study COPD were found to have alterations in balance in even in normal narrow stance and less challenging semi tandem stance as well as showed increased time to complete TUG test. One of the reasons for this may be Quadriceps myopathy since noticeable decreased girth was found in both severe and moderate COPD as compared to healthy controls. Evidence have stated that weak quadriceps muscle is related to postural imbalance and leads to increase postural sway which poses the risk of falls\textsuperscript{13,20}. But since the fatigue and muscle strength was not assessed in this study, and no significant correlation was obtained between girth and balance, it cannot be clearly explained from this point of view.

After contributing factor for an altered balance can be breathlessness since evidences have stated that hypoxia can lead to altered postural balance\textsuperscript{5,6}. According to Killian and Campbell\textsuperscript{23}, as COPD progresses, respiratory muscles have to generate increased pressures to maintain an adequate ventilatory thresh hold resulting in increased dyspnea. Few evidences have shown that myopathy is known to contribute to neurological abnormalities in patient in critical care units and you have stated that hypoxia effects motor coordination and postural control at high altitudes and does they may have a similar effect in patient with hypoxic COPD\textsuperscript{1,5,6}. Even the disease severity it was found to be significantly correlated to postural sway in few variables in this study and evidences signifies the relationship between disease severity and postural balance\textsuperscript{1,24}. More clear results would have obtained if large sample size was taken for correlation. Does the reason for altered postural control in COPD can be thought to be related to disease severity as well as consequences of pulmonary and systemic manifestation in leading to hypoxia and quadriceps myopathy which needs to be further assessed using reliable and accurate measures.

Balance impairment: risk of fall and disability.

Studies have reported that increased CWE is associated with increased fall risk in an individual\textsuperscript{13,25}. Maki and lagoie et al has stated that increased lateral sway is the single best predictor of future following risk in his study on elder population\textsuperscript{16,26}. However peterka et al in his study of subjects ranging from 7 to 81 years stated that patient greater than 55 years shows significant greater and posterior sway which poses them to risk of fall\textsuperscript{14}. Similar findings were found by laughton et al\textsuperscript{26,27} who stated that followers displayed increased a peace way full stop in the study done by Angela at al and Scott et al in COPD patients increased mediolateral and total survey was demonstrated which was considered to hamper the activities of daily life of PD patients and causes them to the risk of falls\textsuperscript{1,7}. Beauchamp et al performed a study to discriminate followers from no followers in using balance measures and found that followers have altered static and dynamic balance the current study supports these findings indicating functional this ability and risk of falls are associated with COPD which increases with CVR 80 of the disease\textsuperscript{25}. Thus the key findings of this study show that severe COPD patients are more affected and have greater balance impairments than moderate COPD patients as compared to healthy controls this can hamper their functional activities and can lead to functional disability. Even moderate see OPD faces balance issues not as significant as severe ones, but are post to risk of falls and functional ability to sense lateral balance is found to be affected during challenging activities. TUG test that assess dynamic or walking balance was found to be significantly affected in both the groups and was falling in the range of high risk of fallers with a mean of greater than 16 seconds for both groups\textsuperscript{28}. This altered dynamic balance reflects a reduced ability while maintaining a standing posture and while performing a potentially destabilizing and challenging activities\textsuperscript{11}.

Limitations:

Use of force plates to record center of pressure excursions or posturography techniques can give more accurate result for the assessment of balance since the
readings obtained from Swaymeter was more manual though it has been validated against force plates. Small sample size and convenient sampling used was another limitation in the study.

Future studies can be done correlating quadriceps strength and endurance in COPD patients with balance. Balance impairment was only assessed in this study, but the time for which these balance alteration remains following an exercise task can be assessed in future research which can help in exercise prescription. Further research can be done to assess the effect of balance training in COPD.

**Conclusion**

Static as well as dynamic balance are affected in COPD patients with postural sway affected from normal to challenging stances in severe COPD patients. Moderate COPD patients also faces balance deficits but in more challenging and destabilizing conditions as compared to severe ones. Thus balance impairments should be assessed while enrolling the COPD patient pulmonary rehabilitation program to control the factors like disability, falls etc. associated with balance deficits. Balance alterations may be inversely related to FEV1.

**Informed patient consent:** Participants recruited in the study signed the informed patient consent forms, and these forms are secured securely at the site of the study.

Evaluation the Effect of Disclusion time Reduction (DTR) in Management Myofacial Pain Syndrome in Iraqi Patients Using the Digital Occlusal Analysis (T-scan)

Sanaa Abdul Hameed Hussein¹, Jamal N. Ahmed²
¹Student, B.D.S Msc. ²Prof. College of Dentistry, University of Baghdad, Iraq

Abstract

The aim of the study is to evaluate the effectiveness of disclusion time reduction in treatment of myofacial pain syndrome using immediate complete anterior guidance development (ICAGD) protocol monitored by digital occlusal analysis (T-scan). Methods and materials: Subjects with full dentition and angle class I relation. DC/TMD criteria were used to diagnose the patients with various MFDS symptoms including mouth opening (assisted and unassisted), excursion movements (mediotrusion and protrusion) and painful masticatory muscles involvement. A visual analog scale was used to assess the pain intensity. Disclusion Time Reduction (DTR) of all molars and premolars to < 0.5 second on all studied locations include: (Centric relation, Maximum intercaspation, Right lateral, left lateral and protrusion) have been made, the patients were recalled tow times at the 7th day and 14th day for the follow up and the subjects were assessed for the symptoms relief. Results: Highly significant difference P≤ 0.001 in period (1st day pretreatment -7th day post treatment) and(1st day pretreatment- 14th day post treatment) related to changes in disclusion time and all symptoms of MFDS but in period (7th day post treatment -14th day post treatment) ,the data outside the comparison limited (OCL) was stated according to the pain intensity, mouth opening (assisted and unassisted)and excursion movements while a non- significant difference P>0.05 were documented related to changes in disclusion time and painful masticatory muscle involvement . Conclusion: The results showed the DTR less than 0.5 seconds reduces musculoskeletal-based symptoms of MFDS patients, and this method can be used clinically with highly success in treatment MPDS.

Keywords: Myofascial pain dysfunction syndrome (MFDS), Disclusion Time Reduction (DTR), Disclusion time (DT), immediate complete anterior guidance, Development (ICAGD).

Introduction

Myofascial pain dysfunction syndrome (MFDS) a common term utilized in dental medicine to depict orofacial chronic pain, is a functional disease related to the masticatory muscles, the neural structures, and the temporomandibular joint (TMJ) structures (1). It is characterized by trigger points affecting more than one muscle group and pain associated with muscle spasm and tenderness caused by touching these points (2). The etiology of TMD, especially muscle pain, is multifactorial and includes parafunctional habits, trauma, stress, heredity and occlusal factors (3). Several treatments have been suggested to control pain and symptoms. These include orthopedic stabilization, intraoral devices, and medications (4).

Good occlusion with symmetric occlusal contacts can influence the stability of orthognathic treatment. The number, location, and size of occlusal contacts, as well as the forces applied, are important for good functioning of the TMJ system (5). So Disclusion time reduction (DTR) is an objective treatment protocol using T-Scan (digital analysis of occlusion) for treating occlusally activated orofacial pains. Chronic occluso-muscle disorder is a myogenous subset of temporomandibular disorder symptoms (6).

Methods and Materials

This study was designed and conducted from April 2019 to February 2020 in the department of oral medicine in the teaching hospital of College of Dentistry/ University
of Baghdad. After obtaining ethical approval from the institutional ethical committee and written informed consent, the participants were selected according to the Diagnostic Criteria for Temporomandibular Disorders (7). The participants completed a self-reported questionnaire, containing information about personal, medical, and dental histories. Subjects with full dentition Angle class I relation included in this study. At each study visit, subjects were asked to answer a questionnaire about the current status of their symptoms according to mouth opening (assisted and unassisted), excursion movements (mediotrusion and protrusion) and painful masticatory muscles involvement. Also the pain intensity was evaluated according the ordinal number scale (VAS) to describe the current status of their condition.Before commencing any treatment occlusal adjustments, the Force Movie mode of the T-Scan was utilized to measure and calculate the pre-treatment Disclusion Times in seconds. After analyzing the pretreatment Disclusion Time data of each subject by digital occlusal analysis T-scan (Novous) Figure (1). The ICAGD enameloplasty (reduction) was performed so established immediate posterior disclusion of 0.5 seconds per each movement figure (2) and figure (4). Additionally, the subject was specifically asked if their new occlusion appeared to feel ‘noticeably lighter’ posteriorly. Each five movements (Centric relation, Maximum intercaspation, Right lateral, left lateral and protrusion) recorded two times in 7th day and 14th day post treatment with (DTR) to obtain a Mean values for each movement per subject. Later compared between the values in 1st day pre-treatment, 7th day post treatment and 14th day post treatment.

Analysis of data was carried out using the available statistical package of SPSS-25. The significance of difference of different means (quantitative data) were tested using Paired-t-test for difference of paired observations (or two dependent means. The significance of difference of different percentages (qualitative data) were tested using Pearson Chi-square test ($c^2$-test) with application of Yate’s correction or Fisher Exact test whenever applicable. Statistical significance was considered whenever the P value was equal or less than 0.05.
Eighty five subjects (68 female and 17 male) with myofacial pain syndrome were included in this study.(25) patients their age range (18-43) years old had full dentition and angle class I have been treated with DTR therapy.

According to the effectiveness of DTR in different locations of movements a highly significant difference $P \leq 0.01$ documented in (1st day pre - 7th day post) treatment , non-significant difference $P > 0.5$ showed in period (7th post -14th day post)treatment and highly significant difference was stated in period (1st day pre -14th day post) treatment.( Table 1) showed Summary statistics concerning studied Measurement of Disclusion time relative to the effectiveness of DTR therapy in different locations of movements.

(*) HS: High Significant at P<0.01; OCL: Outside the comparison limit; ; R: Right; L: Left; DTR: Disclosure Time Reduction; SD: standard deviation; 1st pre: first day pretreatment; 7th post: 7 day post-treatment; 14th post: 14th day post treatment.

Discussion

Depend on the fact that the more time taken for excursive movement (more than 0.4 seconds) leads to longer compression of the periodontal ligament, thereby leading to muscle hyperactivity through the biofeedback system and lactic acid build-up with ischemic changes. The lactic acid then accumulates over time as these prolonged excursive contacts continually hyperactivate the involved musculature, thereby producing the ischemic symptomatology often seen in the MPDS subject (8). Disclosure Time Reduction (DTR) is reduced using a T-Scan guided and measured occlusal adjustment procedure known as Immediate Complete Anterior Guidance Development (ICAGD), where in posterior excursive occlusal interferences are removed selectively from all working and balancing molar and premolar contacts, until the Disclosure Time value becomes < 0.5 seconds per excursion (9). The fact that mentioned above was confirmed by current study when the DTR (ICAGD) therapy appeared an amazing effect on sudden improvement of all signs and symptoms associated with MPDS and this agree with (10, 11).

Many authors have employed computerized occlusal analysis in treating muscular pain (12, 13, 14). In a few controlled clinical occlusal adjustment studies the treated subjects showed dramatic improvements in symptoms (15, 16, 17), while other studies using different occlusal adjustment techniques could not find a correlation between their occlusal corrections and muscular pain symptoms (18, 19, 20).

Interestingly, because the mean values remain constant in subsequent measurements from 7th day post treatment and 14th day post treatment and
registered a highly significant difference between the 1st day pretreatment and 14th day post treatment, so these findings of the current study showed that the effectiveness of this type of therapy was appeared from 1st day and remained constant to 14th day and this agree with Prafulla who concluded Chronic painful muscular TMD symptoms, functional restrictions, and the resultant levels of emotional depression from living with chronic painful symptoms, were all dramatically improved within the treatment group within weeks after they underwent ICAGD. Symptom improvements were maintained over the 6-month period of observation (21). Significantly longer disclusion time, higher posterior frictional contacts, and more TMD symptoms were observed in the post-orthodontic group, suggesting that orthodontic treatment increases posterior tooth friction. Computerized occlusal analysis is an objective diagnostic tool determining the quality of excursive movements following orthodontic treatment (22). The ICAGD enameloplasty significantly reduces excursive muscle contractions after completion of the first ICAGD treatment session (23). The selective grinding showed a statistically significant reduction of action potentials recorded by the surface electromyography of temporal muscle (24). Dudhia et al described that functional interference i.e. clicking and hypermobility occur when remodeling of TMJ achieves sufficient extent and bulk also be explained on the basis that MPDS, although originating as a functional problem, ultimately can lead to organic disease of TMJ (degenerative arthritis) or muscle (contracture) (25).

**Conclusion**

The results showed the DTR less than 0.5 seconds reduces musculoskeletal-based symptoms of MPDS patients, and this method can be used clinically with highly success in treatment MPDS.

Abstract

The present study was aimed to estimate the concentration of selenium Se and toxic metals (mercury Hg and lead Pb) in canned and fresh (meat and fish) from different countries, the results show that the concentrations of Se were above the limits and was ranged between 6.25 ppm to 19.12 ppm in fresh and canned meat and between 0.27 ppm to 9.23 ppm in fresh and canned fish, the concentration of Hg was also above the permitted limits and was ranged between 0.002 ppm to 2.1 ppm in fresh and canned meat and between 0.1 ppm to 3.5 ppm in fresh and canned fish, while the concentration of Pb was within the limits and was ranged between 0.029 ppm to 2.3 ppm in fresh and canned meat and between 0.095 ppm to 1.59 ppm in fresh and canned fish.

Keywords: Fresh meat and fish, Canned meat and fish, Selenium, Heavy metals.

Introduction

The analytical control of heavy metals in food is particularly important, since these pollutants are notably cumulative in nature and, therefore, can be toxic to humans. Their determination in foods of animal origin is, thus, of interest.

Foods contain a wide range of elements such as selenium (Se), sodium (Na), potassium (K), iron (Fe), calcium (Ca), copper (Cu) and zinc (Zn). Many of these metals are essential in living organisms. Metals and other elements can be naturally present in food or can enter food as a result of human activities such as industrial and agricultural processes. Many elements that are present in seafood are essential for human life at low concentrations [¹][²][³].

The metals of particular concern in relation to harmful effects on health are mercury, lead, cadmium, tin and arsenic. Mercury and lead are often referred to as heavy metals [⁴][⁵]. The toxicity of these metals is in part due to the fact that they accumulate in biological tissues, a process known as bioaccumulation. This process of bioaccumulation of metals occurs in all living organisms as a result of exposure to metals in food and the environment, including food animals such as fish and cattle as well as humans.

Toxicological and environmental experts have shown concern for the increasing cases of food contamination with these heavy metals over the years as reported in several literatures [⁶][⁷][⁸][⁹]. Maximum levels for mercury, lead, cadmium and tin in foodstuffs have been set by Commission Regulation No 1881/2006, the framework EU legislation which sets maximum levels for chemical contaminants in foodstuffs.

In the current study the concentration of Se, Hg and Pb were investigated of fresh and canned (meat and fish).
Material and Methods

The study was carried out during 2018. The aim was to identify and quantify the content of Se and heavy metals Hg and Pb) in Twenty-eight type of meat and fish. Apart of sample was fresh and another part was canned from different country.

Apparatus:

All glassware was soaked overnight in 10% (v/v) nitric acid, followed by washing with 10% (v/v) hydrochloric acid, and rinsed with deionized distilled water and dried before using. A Shimadzu Model 12-630-AA Atomic Absorption/flame Emission equipped was used to determine Selenium, Mercury and Lead.

Sample preparation and digestion:

Twenty-eight fresh and cans of fish and meat samples dried in oven at 1050C for 24h, then this sample transferred to desiccators, to remove moisture, then samples leaved to matching with room temperature. The tissue crush by ceramic mortar, then 1g weight from tissue powder and put it in 25 ml glass volumetric flasks and vent closed by a glass plug during digestion. The sample is then taken and digested promptly as follows, the 1gm was weighed into a 25ml glass volumetric flask, and 4.5ml of concentrate HNO3 and 1.5ml of concentrate HClO4 were slowly added, the flask was then shaken well to blend between powder of tissue and acids, the flask was covered by watch glass and left for 24h under the exhaust fan to complete the digestion process. After that, samples were warm at 700C for 2-3h in block digestion, the flasks take out block the digestion, 2-3ml of deionized distilled water was added. Then the opening flasks warmed again in block digestion at 700C until the volume of solution reduced to 2ml. The samples transferred to a flask (50 ml) and complete the volume of deionized distilled water. The solution put in clean plastic tube and centrifuge was used with 3500r/m to 30m, the filtered solution put again in flask (50 ml) and this solution was ready for measurement by atomic absorption spectrophotometer [10].

Results and Discussion

The concentrations of Se, Hg and Pb in fresh and canned (meat and fish) were analyzed to assess the amounts of these metals.
