Aims: To comparing maternal anxiety levels for infants in the NICU and mother in the postnatal care-service (PCS) for stable newborns. Methodology This descriptive study was carried out in Al-Hilla Children’s and Birth Hospital, Al-Hilla City. The 1st 200 families, counting pregnant mother in personal care services (n=100) and pregnant women in neonatal intensive care unit (n=100), backed up by participant as of May, 2018. As data gathering tools, including the STAI TX-1-STAI TX-2 inventory, questionnaires were used to detect the characteristic of mother and newborn. Results Characteristic rates of anxiety were not substantially different between NICU neonate mothers and PCS neonate mothers (t = 0.588, p = 0.557), while status level of anxiety varied greatly among the 2 classes (t = -5.109, p = < 0.001). Motherland anxiety level were determined to be higher for mother whose children in the NICU compared with those of mother whose children were on personal care-services. Conclusion It can boost anxiety and lead to mothers being a mother to a newborn sick. During this difficult time, nursing care may rise mothers’ ability to deal with the sick stresses of the newborn

Keywords: Maternal, Anxiety, Newborn

Introduction

NICU conceded as a frightening place for parent because it’s loud, humid and crowded; however, sophisticated surgical technology and complicated medical terminology are obstacles for parent and newborn (1). Parent, particularly newborn mother living at NICU, may have a psychological problem with having a sick child and may think of losing their child and failing. Achieving conventional positions in parenting. (2-4) Lack of an appropriate environment in which mother can meet their children’s physiological needs (nutrition, drinking, sleep, etc.), In addition to their child’s illness, lack of detail on therapies and medical operations, poor communication with healthcare workers and not taking part in childcare, poor social support to high levels of anxiety (5,6)

Techniques

This descriptive study was carried out in hospitals of Maternity and Childbirth situated in Babylon, Iraq. Energy analysis was used to decide the size of sample; as a result of an energy investigation established on an earlier Yurdakul et al study. For each group of 95 mothers, this study identified 85 per cent of power (7). By assessing the 1st 100 mothers inside every group (PCS or NICU) who decided to take part in this research, this study reached 86 percent energy.

Tools of data-collection

Tool for data-collection involved a concise questionnaire model developed by Literature 5-7-10 and the General Status Anxiety Inventory (STAI TX 1 – STAI TX 2) to assess level of maternal anxiety. Hospitals had obtained the requisite permits for this report. Participants received informed consent. The descriptive questionnaire helps to evaluate mothers’ social and ethnic characteristics, as well as certain newborn characteristics. The additional descriptive questionnaire focused on maternal beliefs about the NICU and their child’s condition within the NICU. General Status Anxiety Inventory (STAI TX 1 –STAI TX 2)
Case Anxiety Inventory: such a measure defines whether a person feels in a given location or situation.

The Inventory of Trait Anxiety: such a standard analytical methods how a person feels regardless of facts of the case.

A type Likert scale, established through Spielberger et al. It is composed of forty items: twenty items measured by state anxiety, and twenty items measured by anxiety apps. On each measure the cumulative score obtained was measured separately. To this value was added a predefined and unfixed number; this number was fifty for country anxiety, and 35 for anxiety attribute. The consequence was the individual degree of anxiety. (11) Orener and Lumbeti adapted that meter to Arabic in 1983. (12).

Analysis and Data collection

Hospital and unit where this research was carried out obtained written permission and approval. Samples were knowledgeable of the purpose of the study and their oral informed consent was attained prior to the beginning of the study. During personal interviews, the researchers were given instruments for the data collection to participants. IBM SPSS 2 assessed the data obtained from the study.

Results

Table 1: Socio demographical Characteristics of sample.

There’s a significant dissimilarity in the State anxiety rating level for 2 classes of mothers. State anxiety level were determined to be higher for mother whose children were in neonatal natal intensive care unit related to those were in PCS.

*p<0.05

There’s no significant association among socio demographical-characteristic (age, level of educational, employment status and level of income), trend and state level of anxiety between mother whose children were in NICU and PCS. There was an important link between the involvement of help networks in the NICU and the state rates of mothers with children. By many mothers who had newborn babies in the NICU there have been significantly higher levels of public anxiety reported by those without a support system than those with the aid systems.

There’s no significant relation seen amongst baby’s gender and birth weight with the NICU mothers’ state-trait anxiety rates (Table-IV). There’s also no correlation between both the NICU mothers’ trait anxiety levels and the duration of hospitalization, The status of the child’s situation and the participation status in child care (p>0.05); there was a positive correlation seen concerning mothers’ state anxiety levels and those character traits.

**Discussion**

Going to maternity is a difficult task and raising a child with a health condition can be more complicated and challenging.\(^{(13)}\) Levels of anxiety in mothers whose babies were in the intensive care unit were higher related to mothers with PCS, while anxiety rates in features were no different in the two classifications (second table). There have also been other studies which have close findings to our research.\(^{5.7-9.14}\)

During this period, mothers need psychological and social help to support the emotional equilibrium of mothers and reduce negative feelings that may clue to adverse health results.\(^{(15)}\) In our research, there was no link among the typical PCS status and anxiety levels and the availability of support systems; further, the level of state concern was low for mothers with strong support systems (Table II). There have been studies which have defended our results.\(^{7, 9, 15, 16}\) Comparing mothers with children in NICU and PCS, there was no significant relationship between the social, obstetric and demographic characteristics of mothers (age, educational status, income level) and anxiety levels (Table 3). Similar to other tests,\(^{7,8}\) Parents whose children have been admitted into NICU need details, especially from nurses, and communicate easily with nurses.

With the current study, the level of state anxiety was higher for mothers whose children were in the intensive care unit and who did not get sufficient information about their child care compared to the aspiring mothers (Table 4). Several studies have shown that having adequate information about an infant and successful interactions with health providers has led to a decrease in levels of maternal anxiety.\(^{8,10,18}\) Mummies will engage in tasks such as holding, transporting and eating. By developing competency and parenting roles, anxiety levels can be reduced in this way.\(^{21}\) In our study, statistical results are statistically significant in terms of the level of state concern for mothers who have not been involved in caring for their children (Table 4). In some other studies similar results were reported\(^{19-21}\)

There was no significant correlation between the anxiety levels typical of mothers and the form of children in either group, according to our findings. Erdem (2010
reported elevated rates of anxiety among mothers who had their male children at NICU. (8) In this study, the level of extreme concern among mothers with male children was believed to be a guarantee in the future due to gender and religious gender, and cultural, economic and mental understanding in Turkey. In our study, an important outcome was the unimportant relationship between maternal anxiety levels and children’s gender in terms of showing that sex did not contribute to maternal anxiety.

**Conclusion**

There was a high level of anxiety amongst mother whose newborn were admitted at NICU. There were certain causes that contributed to maternal anxiety such as lengthy stays in the NICU, the failure of the mothers to care for the infant and the lack of child health knowledge. Previous have shown that mothers need to know the nurse status of their child and to freely interact with the nurses.

Pathological Study of Reproductive Tracts of Awassi Ewes in Fallujah, Iraq

Ahmed Sami Jarad1, Abdul Sattar Faraj Majeed2, Qusay Mohammed Aboud3, Mustafa Salah Hasan3, Waleed Hamid Farhan1 Ahmed Emad Aboud2

1Department of Pathology and Poultry Disease, College of Veterinary Medicine, University of Fallujah, Iraq, 2Department of Veterinary Surgery and Obstetrics, College of Veterinary Medicine, University of Fallujah, 3Department of Internal and Preventive Veterinary Medicine, College of Veterinary Medicine, University of Fallujah

Abstract

A total of forty female genital tracts of local sheep, collected from Al-Fallujah abattoir, were utilized for this study during the period from October 2018 to March 2019. Among these 20% of the samples were pregnant with out any abnormality, and 80% were non pregnant (55% without any problem and 25% showed abnormal macroscopically lesion. The main type of abnormalities were, ovarian adhesion, uterus unicornis, inactive ovaries, cystic ovaries, ovarian germ cell tumor and cervical tumor, metritis, salpingitis and hydrosalpinx with an incidence of 10%, 10%, 10%, 20%, 10%, 10%, 10%, 10% and 10% respectively. The histopathological study revealed that there were a histopathological changes in the previous cases, the ovarian giant cell tumor reported at first in this study in Iraq.

Keywords: genitalia, Awassi ewes, abnormalities

Introduction

Ewes sheep were a chief farm animals, it play an important roles in Iraq economy through provided meat, milk and wool. Unfortunately the number of sheep weakening by 42 per cent in Iraq (1). The fundamental driver of this diminishing was breakdown of the veterinary framework, including disease determination, observation and indicative administrations (2). A significant factor that affects a population’s growth rate is the fertility of its females; genital tract diseases significantly reduce flock productivity and may mean that rearing these animals is uneconomical. Several breeds of sheep were distributed all over the world. The most common breed managed and domesticated in Iraq was the Awassi breed (3,4)

Reproductive tract abnormalities of ewes resulting in infertility, subfertility or sterility cannot diagnosed by routine clinical examination so little information in ewes about the etiology of reproductive failure. Butcher house overviews of the genitalia of ewes in various parts of the world give a decent data on the sorts and frequency or pervasiveness of obsessive (inborn or obtained abnormalities (5,6).

The data on prevalence of ewes genital tract may propose the job of conceptive illnesses in constraint to sheep generation. Anyway the satisfactory learning is missing on the incidence of etiology and nature of pathological conditions in the ewe genitalia.

The present work was designed to determination the pathological change (macroscopic and microscopic) lesion of ewes genital tract abnormalities in ewes slaughtered at the slaughter house of Fallujah- Anbar province, Iraq.

Materials and Methods

This study was achieved on forty sheep female genitalia were calm one day each week in Fallujah butchery house that situated in Fallujah district, AL-Anbar province. specimens were gathered during the period from the October 2018 to March 2019. No information about the all history of the animals incorporated into this investigation. The reproductive
tract were separated after evisceration at the abattoir, the samples were transported with cool box contained normal saline to the pathology lab, college of Vet. Med. university of Fallujah, the connective tissue and the fat surrounding genitalia were evacuated beyond what many would consider possible to clear the genital organs for good examination.

Gross examination of different parts of the genitalia were done, including; ovaries, uterine horn, uterine tubes, body of the uterus, cervix, vaginal and vulva (7).

The abnormalities in different parts of the genitalia were recorded. A tissue test from ordinary and influenced some portion of genitalia (area of around one cubic centimeter) were taken and fixed in plastic compartment contained 10% formalin buffered for histopathological examination. The wax box contain biopsy were catted in 7µm in microtome, the handled and recolored done by Luna (8).

Examination of slides and the observation of changes in the abnormalities were reported.

**Results and Discussion**

Reviewed congenital and acquired pathology of the ewe reproductive system by collection extensive data from abattoir surveys. Out of forty female sheep genitalia examined, 8 (20%) were pregnant and the remain 32 (80%) were nonpregnant genitalia. The stages of pregnancy and the genitalia were appeared normal in all samples. Non pregnant ewes genitalia that give abnormal reproductive tract lesion were (10) (25%) as showed in table (1). Macroscopic lesion were includes; salpingitis, hydrosalpinx, follicular cystic ovary, ovarian fusion, luteal cystic ovary, metritis, uterus unicornis as showed in table (2) and figure (1) respectively, inactive ovaries, cervicitis also reported. These results of abnormality were higher than reported by (9,10,12,15,). Palmieri and his college in (6), they reported a similarly results; cystic structures, hypoplasia or aplasia in apart or in all genital system, our results were in disagreement with data what founded by (16). in ewes cystic ovaries isn't totally comprehended and has not gotten as much consideration as in dairy cattle, it is a typical finding in various breeds of sheep (6).

The cystic ovaries emerge because of anovulation whereby, rather than relapse, follicles continue on expanding in size and persist (17). The main cause of cystic ovaries are insufficient of LH prior or at the time ovulation (18). The incidence of inactive ovaries might be due nutrition deficiency that leads to hormonal dysfunction such as insufficient FSH, which is the primary cause of inactive ovaries (19). Ovarian tumor were observed in one case 10% from abnormalities, an histopathologic picture showed giant cell ovarian tumor figure (2E) in has been observed presence of giant cell in the ovarian stroma. It is area case and there is a little information about the occurrence of ovarian giant cell tumor. It might be due to genetic factors or other environmental cause.

Histopathological examination of fallopian tube as in Figure 2 (F,G,H) showed pus formation with in the fallopian tube mainly contained neutrophils (pyosalpingitis) arrow. high magnification showed ulcerative formation of uterine tube (ulcerative salpingitis). The obtainable study recommended that the occurrence of salpinx inflammation and hydrosalpingitis in sheep comparatively little frequency with prevalence (10% and 10%) receptivity as showed in Table (2). These discoveries are in arrangement with the result recorded bySaberivand and Haghighi (25). Adams(13) documented slight inflammation of salpinx in sheep (7%) and Ansari(20) originate 15 cases of hydrosalpingitis in 3,590 genital system of sheep which affected with our study. The low rate in ewes could be because of the valve-like move which makes impact in ewes at the utero-tubal intersection through and 3 days after estrus which assumes a role in keeping the augmentation of irresistible specialists from the uterus to the tube(22).
The histopathology exam of uterus showed that the endometrium with cystic endometrial hyperplasia (adenomyosis) figure (2I). dilation of cystic glands with preiglandular fibrosis. The available study also suggested that the incidence of metritis were (10%) which in disagreement with the results approved by (16, 26) endometritis were the greatest common outcome of uterine irregularity demonstrating that this condition theatres a more significant role in infertility. Endometritis in sheep, like in cattle, is most common in luteal phase or post-delivery and persuades embryonic harm as a result of uterine tissue disruption or through embryo cytolysis (16, 21, 27).

The histopathology exam of cervix as showed in figure (2K) (A&B), cervix with excessive formation of new glands and congestion of the blood vessels with edema and inflammatory cells in the cervical lumen and interstitial tissue. The prevalence of uterus unicornis was 10%, which might be due to genetic factors as mentioned by (28). Similar observation have been made by Vojgani(10) and Amin (12).

Finally these outcomes uncover a significant zones of reproduction cost in sheep even the nutrition are best over the time and in the nonappearance of reproductive infections and it might be credited to numerous issues like breed, organization an area specification. Such wounded are complete up of female sheep that fail to reproduct for the reason that of irregularities of the genital region (14).

It was concluded from this study that pregnant animal were slaughter in abattoir 20% while non pregnant were 80% with incidence of abnormality 25% of total sample were collected, this reflect that reproductive status of Awassi ewes in Al-Fallujah city.

Incidence Rate and Risk Factors of Ectopic Pregnancy at Maternity Wards in Baghdad City’s Hospitals for the Year 2019

Heba Samir Naje1, Hala Saadi Abdul Wahid 2, Ekhas Ali Hussein 3
1MSC, Ministry of Health student at Maternal and Neonate nursing University of Baghdad, 2 Professors, Community Health Nursing College of Nursing, University of Baghdad, 3 Assistant professor, Department of Obstetrics and Gynecology, College of Medicine, Al-Iraqia University

Abstract

Background: Ectopic pregnancy is a condition of immense gynecological importance, particularly in the developing world, because of the high morbidity and mortality associated with it and the enormous threat to life.

Objectives: To assess the incidence rate and the risk factors of ectopic pregnancy at Maternity Wards in Baghdad City’s Hospitals for the year 2019.

Methods: The study included a non-probability (convenient) sample consisted of (90) pregnant women who have ectopic pregnancies. The study subjects are recruited from 10 teaching hospitals in Baghdad, in their first trimester of gestation age. The study data is collected from pregnant women’ edical records in the Department of Statistics, data are analyzed using descriptive and inferential data analysis process.

Results: the results of the current study indicate that the incidence rate of ectopic pregnancy is (2.217) per 1000 of population at risk for the year 2019. Smoking is accounted as the most predominant risk factor for ectopic pregnancy (55.6%). Most of these pregnant women are between the ages of (15-24) years old (40.0%), college graduates (26.7%), government employees (52.2%), and have a monthly income (901.000-1.200.000) ID (32.2%).

Conclusion: Incidence rate of ectopic pregnancy at the maternity wards in Baghdad City’s hospitals is (2.217) per 1000 of population at risk for the year of 2019. The incidence rate of ectopic pregnancy has not been affected by the risk factors of infertility, previous ectopic pregnancies, IUCD, assisted reproductive techniques and smoking of ectopic pregnancy and the incidence rate of ectopic pregnancy has not been affected by pregnant demographic characteristics of age, education, occupation and monthly income.

Keywords: Incidence Rate, Ectopic pregnancy, Risk factors.

Introduction

An ectopic pregnancy occurs when a fertilized egg grows outside the uterus [1]. Ectopic pregnancy is a life threatening emergency, and if not treated, it can produce adverse effect. It remains the leading cause of pregnancy related death during the first trimester, where it is responsible for 9 – 10 % of all maternal deaths [2]. The incidence of EP has doubled or trebled over the last 20 years and has become a major public health problem. EP accounts for approximately 2% of reported pregnancy. Approximately 1/100 pregnancies are ectopic, with the concepts usually implanting in the fallopian tube. Some ectopic pregnancies resolve spontaneously, but others continue to grow and lead to rupture of the tube [3]. Important etiological factors for EP are pelvic inflammatory disease (PID), post-aborted sepsis, puerperal sepsis, previous EP, previous pelvic surgery and the uses of contraceptive device.

Presence of history of infertility and congenital defects of fallopian tubes consider also as other risk
The present study aims to estimate the incidence of ectopic pregnancy among Iraqi women in Baghdad City as it is one of the Ministry of Health research plans priorities, in order to provide data that can assist in the health strategies planning of control.

**Methodology**

A descriptive analytic element design was conducted throughout the present study among pregnant women at Maternity department attend hospitals in Baghdad City. Department of Statistics (Medical records), in ten hospitals at Baghdad city. Determined validity through panel of experts and reliability of questionnaire(Alpha Correlation Coefficient) is (0.83) which considered significant through of pilot study, they are measured as (2) for Yes and (1) for no.

a. Dependent Variable: Incidence Rate

Result, out of this table, indicates that there is no significant relationship between incidence rate of ectopic pregnancy and risk factors of ectopic pregnancy.
Discussion of the Study Results

Part I: Discussion of Pregnant Socio-demographic Characteristics

Analysis of such characteristics has depicted that these pregnant women are mostly teenagers (15-24) year old and they are accounted for (40.0%) of the total sample (Table 4-1). This finding presents an evidence that such pregnant in this age can develops ectopic pregnancy than others and they are presenting the nature of pregnant women in our culture of getting marriage at earlier age.

The current study finding agrees with a hospital based unmatched case control study results, of (99) cases with ectopic pregnancy and (200) controls who have been selected with a simple random sampling method, the study has identified that the average (± SD) of pregnant age is 27 (± 5) years [4].

Information about maternal demographic characteristics is obtained from the Pregnancy Risk Assessment Monitoring System by (CDC, 2009) has agreed with the study finding and presented evidence that the age distribution of respondents is as follows: (10.5%) are (19) years of age and younger, (76.2%) are (20–34) years of age, and (13.3%) are (35) years old and older.

With respect to their education, the study findings indicate that most of these pregnant are well educated as being college graduates (26.7%) (Table1). This can be interpreted in a way that women in our society are fortunate to continue and pursue well education in the recent years.

Such result does not agree with a report has indicated that more than half (53.4%) of pregnant women reported having more than a high school education, followed by (27.9%) with at least a high school education and (18.7%) with less than a high school education [5].

The current study finding is agreed with that of a cross-sectional study, of (300) pregnant woman with ectopic pregnancy who are with only primary/Junior High School education (p=0.048) [6].

With regard to their employment, the study has revealed that more than half of the study sample are government employee (52.2%) and making monthly income of (901.000-1.200.000) Iraqi Dinar (32.2%) (Table1). Such findings can be inferred that these pregnant play the role as breadwinners for their families.

In the contrary with a retrospective study in Urban Nigeria, on (72) case of ectopic pregnancy, shows that the health problem of ectopic pregnancy is exacerbated with social issues leading to financial stress due to palpable poverty[7].

Part II: Discussion of the Incidence Rate of Ectopic Pregnancy

The present study reveals that the incidence rate of ectopic pregnancy is 2.217 per 1000 of population at risk for the year of 2019 in Baghdad City (Figure 1). It is worth to mention that there are other cases of ectopic pregnancy (about 50 cases) which was documented, but the researcher couldn’t reach their files due to the uncooperative administration of the hospitals under the study.

This finding is higher than a finding of retrospective study, six thousand six hundred sixty-two women give birth in the hospital, (88) women are diagnosed with ectopic pregnancy with an incidence of 1.3% [8].

It has been found in the literature that ectopic pregnancy is a potentially life-threatening condition occurring in (1-2 %) of all pregnancies. The most common ectopic implantation site is the fallopian tube, though 10 % of ectopic pregnancies implant in the cervix, ovary, and myometrium, interstitial portion of the fallopian tube, abdominal cavity or within a cesarean section scar [9].

It has been noted that the incidence rate is (0.5%-1.5%) of all pregnancies. Even though its incidence rate is drop off when compared with earlier decades, it is still the foremost causes of maternal morbidity and mortality in the first trimester of pregnancy, especially in developing countries. In Pakistan, it varies from 1:1 124 to 1:130 pregnancies [10].

Furthermore, the current study is more far lower than a worldwide view presents that incidence rate is (12.4/1000) reported pregnancy in England-Wales, (0.52/1000) women of reproductive age in Beijing-China, (1.68/100) total births in Nigeria and (4%) in
Part III: Discussion of Risk Factors for Ectopic Pregnancy

Analysis of risk factors results for ectopic pregnancy reveals that smoking is accounted as the most risk factor for ectopic pregnancy (55.6%) and then comes the risk factor of infertility (43.3%), and the least risk factors are IUCD (26.7%) and assisted reproductive techniques (26.7%) and previous ectopic pregnancies (13.3%) (Table 4-7). The findings of the study have presented evidence about these factors as being considered as risk factors for ectopic pregnancy among the study sample.

Such findings agrees with a matched case-control study, of (88) cases and (176) controls, has explored that of the fifteen identified risk factors, four are independently associated with increased odds of ectopic pregnancy: prior pelvic inflammatory disease (PID) (adjusted odds ratio [AOR] 13.18; 95% CI 6.19–27.42), followed by current use of levonorgestrel-only pills for emergency contraception (LNG-EC) (AOR 10.15; 95% CI 2.21–46.56), previous use of depot medroxy progesterone acetate (DMPA) (AOR 3.01; 95% CI 1.04–8.69) and smoking at the time of conception (AOR 2.68; 95% CI 1.12–6.40) [12].

A case-control study, of women who are diagnosed with ectopic pregnancy (n = 2411) and women with intrauterine pregnancies (n = 2416) are recruited from five hospitals in Shanghai, China reveals that the risk of ectopic pregnancy is associated with the traditional risk factors including previous EP (Adjusted odds ratio [AOR] = 2.72, 95% CI: 1.83–4.05), previous Chlamydia trachomatis infection (Adjusted OR = 3.18, 95% CI: 1.66–2.88), previous infertility (AOR = 2.18, 95% CI: 1.66–2.88), previous adnexal surgery (AOR = 2.09, 95% CI: 1.49–2.93), previous appendectomy (AOR = 1.64, 95% CI: 1.13–2.37), and previous use of intrauterine devices (IUDs) (AOR = 1.72, 95% CI: 1.39–2.13). Additionally, EP risk is increased following the failure of most contraceptives used in the current cycle including IUDs (AOR = 16.43, 95% CI: 10.42–25.89), oral contraceptive pills (AOR = 3.02, 95% CI: 1.16–7.86), levonorgestrel emergency contraception (AOR = 4.75, 95% CI: 3.79–5.96), and female sterilization (AOR = 4.73, 95% CI: 1.04–21.52). Stratified analysis shows that in vitro fertilization and embryo transfer (IVF-ET) is the main risk factor for EP in women with tubal infertility (AOR = 8.99, 95% CI: 1.98–40.84), although IVF-ET shows no association with EP in women with non-tubal infertility (AOR = 2.52, 95% CI: 0.14–44.67) [13].

In a mini-review study, it has been reported that risk factors associated to ectopic pregnancy are pelvic inflammatory disease, past history of miscarriages, age, parity, infertility, previous ectopic pregnancy, induction of ovulation and intrauterine device usage [10].

A cross-sectional study, of (900) pregnant woman diagnosed with ectopic pregnancy, has depicted that the risk of EP is associated with previous adnexal surgery (adjusted OR = 3.99, 95% CI: 2.40–6.63), uncertainty of previous pelvic inflammatory disease (adjusted OR = 6.89, 95% CI: 3.29–14.41), and positive CT IgG serology (adjusted OR = 5.26, 95% CI: 3.94–7.04). A history of infertility including tubal infertility (adjusted OR = 3.62, 95% CI: 1.52–8.63), non-tubal infertility (adjusted OR = 3.34, 95% CI: 1.60–6.93), and in vitro fertilization (IVF) treatment (adjusted OR = 5.96, 95% CI: 1.68–21.21) are correlated with the risk of ectopic pregnancy [14].

A case-control study, of (150) cases and (300) controls, has found that the risk of ectopic pregnancy has increased with the use of intrauterine device and tubal ligation, whereas decreased with use of oral contraception [15].

A five year retrospective study, of (72) case of ectopic pregnancy, reveals that related risk factors include pelvic inflammatory disease, previous history of abortions, infertility and a previous history of ectopic pregnancy [7].

A hospital based unmatched case control study, of (99) cases with ectopic pregnancy and (200) controls have been selected with simple random sampling method, has indicated that the risk factors identified are marital status and history of contraception use. Accordingly, women with single marital status are (10.81) times (95% CI AOR (3.601, 32.465) more likely to develop ectopic pregnancy than married once. Those who use contraception are (2.27) times (95% CI, AOR (0.214, 24.02) more likely to develop ectopic pregnancy than who do not use contraception (Kebede and Dessiein 2018) [4]. This study is not compatible with current study.
Part V: Discussion of the Relationship between Incidence Rate of Ectopic Pregnancy and Risk Factors of Ectopic Pregnancy

The study findings indicate that the incidence rate of ectopic pregnancy has not been affected by the risk factors of infertility, previous ectopic pregnancies, IUCD, assisted reproductive techniques and smoking of ectopic pregnancy (Table 4-10).

Contrary findings have been reported in the literature that risk factors of surgical, gynecological, obstetrics, sexual, contraceptive, and infectious histories; demographic characteristics; smoking habits; and fertility markers are initiated to be associated with the incidence of ectopic pregnancy.[16]

Conclusion

Incidence rate of ectopic pregnancy at the maternity wards in Baghdad City’s hospitals is (2.217) per 1000 of population at risk for the year of 2019, The incidence rate of ectopic pregnancy has not been affected by the risk factors of infertility, previous ectopic pregnancies, IUCD, assisted reproductive techniques and smoking of ectopic pregnancy and the incidence rate of ectopic pregnancy has not been affected by pregnant demographic characteristics of age, education, occupation and monthly income.

Recommendations:

Measures for early diagnosis of ectopic pregnancy, Annual measurements for the incidence of ectopic pregnancy and accurate follow up for registration and documentation of the cases.

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq

Conflict of Interest: The authors declare that they have no conflict of interest.

Lip Thickness with Tongue Space Area Assessment By Cephalometric Analysis for Iraqi Adult Sample with Class II Dental and Skeletal Pattern

Laith Hamood AL-Salmany1, Zena Hekmat Altaee1, Ahmed Jassam Al-Naqeeb 2

1Assist. Lect. 2Ass. Prof. Department of Orthodontics, College of Dentistry/ University of Anbar, Iraq, 3 Lect. Department of Oral and Maxillofacial Surgery, College of Dentistry/ University of Anbar, Iraq

Abstract

Background: With different skeletal classes, there may be some variability among the lip thickness and tongue space area that could be the causative factor for skeletal malrelationship so that this study was aimed to determine the tongue and the available boundary space area with lip thickness and correlate them together in sample with class II skeletal pattern.

Methods: Seventy Iraqi adult subjects (32 males and 38 females) with cl II skeletal pattern who have increased over jet and ANB angle greater than four degrees. The cephalometric measurements include upper and lower lip thicknesses with height and length of tongue and position of tongue base and hyoid bone from the cervical line. The cephalograms were analyzed using AutoCAD program to measure demanded areas.

Results: This study revealed that a significant gender difference was found between T-Area, V-TT, TH, V-FP, AH-CL, AH-FP, and upper and lower lip thickness in which higher mean value in males than females. The correlation between all the measured variables of present sample with SNA, SNB and ANB angles a non-significant difference was found except for V-CL which shows significant difference. Strong correlation was found among the T-Area with V-TT, TH, V-FP, AH-CL, AHFP, upper lip thickness and lower lip thickness.

Conclusions: In skeletal class II, the associated cranial base angles shows independent association from the boundary soft tissues so that these variations not always contribute to be the causative factor for skeletal disharmony.

Keywords: class II, Cephalometric, lip thickness, tongue space.

Introduction

Evaluation of soft tissue considered the integral part in diagnosis and treatment planning. As the tongue size influence the development of dentoalveolar structures (1), in class II skeletal relationships the small size of the tongue may influence the size of mandible or the positioning of dentoalveolar structures.

The skeletal mal-relationship in craniofacial growth and development may be caused and controlled by both genomic and epigenetic effects. According to Moss theory of growth, the soft tissues grow, and both bone and cartilage react (2,3). The airway form intraorally is influenced by the tongue form and size (4). The major part of upper airway is formed by the tongue which has both extrinsic and intrinsic muscles (5)(6).

Some previous studies have assessed the measurements of the tongue space area in skeletal class I and others measure the tongue size and airway space in patients with obstructive sleep apnea in various malocclusions (7,8,9). Other studies have assessed measurements of soft tissue norm as lip thickness in skeletal class I pattern (10,11,12). The aim of this study was to determine the tongue and the available boundary...
space area with lip thickness in patients with skeletal class II and correlate them together as by understanding these correlations among hard and soft tissues we can predict the final outcome and stability of orthodontic treatment.

**Materials and Methods**

The sample of this retrospective study was carried out at department of orthodontics/ college of dentistry/ Baghdad University, and included seventy Iraqi adult participants (32 males and 38 females) who seeking orthodontic treatment with an age range between 18-28 years to exclude the effect of growth. A true lateral cephalogram were taken for each subject in this sample.

The sample were selected according to the following criteria:

14. Full permanent teeth except 3rd molars.
15. Class II skeletal relationship with increased over jet and ANB angle greater than four degrees.
18. Absence of acquired or congenital abnormalities to the face.

Each radiograph was taken with Frankfort horizontal parallel to the floor with the teeth in centric occlusion and the eyes straight look ahead.

The x-ray Machine used for this study was DIMAX3 Planmeca radiographic machine (digital x-ray unit system) and the digital cephalograms obtained were analyzed with AutoCAD 2015 in which the magnification of the images obtained was corrected by measuring the magnification factor of the cephalometric machine involving the nasal rod ruler graduation and then the measurements were gained.

The measurements of hard and soft tissues include evaluation of the tongue and boundary space region with lip thicknesses according to the landmarks, planes, linear and area measurements used in this study summarized in table 1 and described in figures 1,2 and 3.

Statistical Analysis

By the using of the Statistical Package for Social Sciences (SPSS) version 20, the 76 statistical analysis was done in which all data of sample were calculated.

The statistical analysis included:

1- Descriptive Statistics: including mean, standard deviation, minimum and maximum values.

2- Inferential Statistics: including

- Independent sample t-test: for the genders difference comparison.
- Sig. (2-tailed) or P value.
- Pearson’s Correlation Coefficient:

In order to quantify the strength of the association between angles, linear and area measurements; Pearson’s correlation coefficients were used.

For the statistical evaluation of the results, the following levels of significance are used: p≥0.05 Non-significant (NS)
0.05>p≥0.01 * Significant (S)

Results

The descriptive statistics with gender difference of the present sample was described in table 2, in which a non-significant difference was found among SNA, SNB, ANB and V-CL. However, for the other variables the T-Area, V-TT, TH, V-FP, AH-CL, AH-FP, upper and lower lip thickness a significant difference was found between both genders in which higher mean was shown in males in all measured variables except for ANB angle.

Table 2: Gender difference of the present sample (Male N= 32 and Female N= 38).

The correlation between tongue area, upper and lower lip thickness and related linear measurements with the others was described in table 3 as the following:

- strong correlation was found among the **T-Area**, V-TT, TH, V-FP, AH-CL, AH107 FP, upper lip thickness and lower lip thickness.

- strong correlation was found among the **ANB angle with SNA, SNB and V-CL.** 109, strong correlation was found among the **V-CL with ANB, AH-CL, upper lip 110 thickness and lower lip thickness.**

Discussion

The Harmony of soft tissue profile in some conditions difficult to obtain which may be 121 due to soft tissue covering the teeth and bones is highly variable in their thickness. The 122 thickness and tension of facial soft tissues in addition to the imbalance of dental and 123 skeletal structures could lead to these variations among soft tissue profile (14). Some 124 authors have suggested that the using of cephalograms is easier than the other methods 125 for airway patency measurement (15). Parkkinen et al also confirm that the lateral 126 cephalogram is a reliable method for measuring the dimensions of the nasopharyngeal 127 and retropalatal areas (16,17).

128 In this study, the tongue space area for males and related linear measurements in class 129 II pattern showed higher mean values than females for most measured variables. A 130 significant gender difference was found among the T-Area, V-TT, TH, V-FP, AH-CL, 131 AH-FP,
which is in coincidence with class 1 sample (for the same ethnic population) 132 by other study (7).

133 For the lip thickness, a significant gender difference was found in which higher mean 134 values was in males than females for both upper and lower lips which agrees with class

1 sample (for the same ethnic population) by Al-Janabi MF and Kadhom Z (11) as described in table 4. The upper lip is thinner than the lower lip which differs from class 1 sample by Al-Janabi MF and Kadhom Z who found thicker upper lips especially for females with the same age group. This may be related to the angulation of incisors in class 2 subjects as it is considered the most important determinants to the related soft tissues (6,18). Tatjana Perović ans Zorica Blažej use Burstone lines to compare facial soft tissue thickness among class 2 skeletal pattern (19); they presented that in class 2 skeletal relation the soft tissue thickness at the upper lip is thinner than the lower for both genders which agrees with class 2 sample of this study. However, the gender difference reveals a non-significant difference for class 2 skeletal pattern which disagrees with this study as it could be related to ethnic variation. Kristina Lopatienė et al reveal that the upper lip thickness in skeletal class 2 the females have higher mean value than males 148 (20). The gender difference; however, reveal a non-significant difference among the class 149 2 subjects (tab. 5).

**Table 4: comparative data of class II sample of present study with normative data (class I) of the same ethnic population by other studies.**

</table>
of the association between tongue area, upper and lower lip thickness and related linear measurements with the others was described in table 3 as the following:

- The strong correlation of the T-Area, V-TT, TH, V-FP, AH-CL, AH-FP with each other, this may be related to their representation to the tongue extensions as it lies within the same region.

By meaning of soft tissue area of the tongue influences the boundary hard tissues.

- The strong correlation among the AH-CL with T-Area, TH, V-TT, V-FP, V-CL and AH-FP could be explained by their regional relation with the tongue base in this region.

- The strong correlation among the V-CL with ANB, AH-CL, upper and lower lip thickness may be related to their association to the hard tissues skeletal bases.

- The strong correlation among the upper and lower lip thickness with each other as the lips usually follows the teeth and skeletal base at the associated region which is in agreement with Manal AShamlan and Abdullah M Aldrees (21) who suggest that is due to variation in the upper incisors location with the alveolar bone on the dental base region and the sagittal inclination and position of the lower incisors.

- The strong correlation among the upper and lower lip thickness with T-Area, TH, VFP, V-CL, AH-CL and AH-FP suggest this relation due to the compensatory balance of hard tissue in skeletal class 2 between the tongue and associated inner structures from one side and the upper and lower lips from other side.

However, the correlation among SNA, SNB and ANB angles were strong among each other but weak correlation with the other variables. This suggests that these associated cranial base angles may have independent association from the boundary soft tissue area like the tongue. This could be due to variability of muscular activity and soft tissue tension to the nearby dentoskeletal structures.

**Conclusion**

The tongue space area with lip thickness and related linear measurements in skeletal class II pattern for males showed higher mean values than females for most measured variables and the associated cranial base angles shows independent association from the boundary soft tissue of tongue area and this may be related to variations of thickness and tonicity of facial muscles so that these variations may not always contribute to be the causative factor for skeletal disharmony.

Synthesis, Characterization and Anti-Inflammatory Study of New Heterocyclic Coumarin Derivatives

Muthanna S. Farhan¹, Maadh H. Ahmed¹

¹Lecturer, ²Post Graduate Department of Pharmaceutical Chemistry, College of Pharmacy, University of Baghdad, Iraq

Abstract

The inflammation is one of the most central processes in animal cells defense versus certain injuries or infections of microbes. The most essential metabolic precursor for many inflammatory pathways is PGH2 (prostaglandin), which catalytic synthesis from the AA (arachidonic acid) by COX enzymes. COX can be divided into three isomer COX-1 has important role in many physiological function like hemostasis, platelet aggregation, and protection of gastric mucosa, COX-2 when stimulate cause formation of PGE2 excessively, with other prostaglandin then decrease the pain threshold and nerve ending sensitization, which induce pain, increase permeability of vascular and then enhance the inflammatory associated diseases pathway, and COX-3 has special characteristic, its higher sensitivity to acetaminophen and present in brain. The NSAIDs are therapeutic agents used for the treatment of inflammation, pain, and fever, they work by decreasing the production of prostaglandins due to inhibiting the function of the cyclooxygenase (COX) enzyme, we have two types nonselective and selective COX-2 inhibitors. In order to design new agents with no or low side effect, the COX-2 selectivity should be increased, this achieved by design molecule structurally similar to approved selective COX-2 inhibitors. The synthetic compound in this study contain three pharmacophores, a nucleus of coumarin and substituted oxazole moiety, separated by a hydrazonoethyl spacer, which have structural similarity properties to selective COX-2 inhibitors.

Keywords: Heterocyclic coumarin derivatives, anti-inflammatory, selective COX-2 inhibitor

Introduction

Inflammation is one of the most central processes desired in defense of animal cells versus certain injuries or infections of microbes. Though, inflammation orderly progresses to acute and chronic. Chronic inflammation is caused by a set of diseases like cardiovascular diseases, cancer, and neurodegenerative disorders (¹). The driving force for accumulation of fluid may rise only from the actual tissue metabolic activity, the final being a balance between anabolic and catabolic processes in physiological conditions (²). Main proceedings occur through the inflammatory process contain alteration of vascular permeability, recruitment of leukocyte and accumulation, and liberation inflammatory mediator release (³). Inflammation is a popular pathogenesis of numerous chronic diseases, such as cardiovascular diseases, arthritis, diabetes, bowel disease and cancer (⁴). The most essential metabolic precursor for many inflammatory pathways is the AA (arachidonic acid). many internal and external factor can activate the PLA2 (phospholipase A2). This activation split bounded AA from the membrane phospholipids and makes it ready for the major three inflammatory pathways, which are lipoxygenase, COX pathway, and cytochrome P-450 monooxygenase (⁵). COX can be divided into, COX-1 has important role in many physiological function like hemostasis, platelet aggregation, and protection of gastric mucosa (⁶). The stimulation of COX-2 cause formation of PGE2 (major metabolic product) excessively, with other prostaglandin then decrease the pain threshold and nerve ending sensitization, which induce pain, increase permeability of vascular and then enhance the inflammatory associated diseases pathway (⁷). COX-
3 has special characteristic, its higher sensitivity to acetaminophen, and it has been reported in brain and heart (7). NSAIDs are remarkable therapeutic agents used for the treatment of inflammation, pain, and fever. They work by decreasing the production of prostaglandins due to inhibiting the function of the cyclooxygenase (COX) enzyme (8). The traditional types are correlated with side effects like ulceration of gastrointestinal (GI) and renal toxicity because of their inhibition of COX-1 pathway (nonselective) (9). coumarins consisting of a benzene ring connect to a pyrone ring, figure (1), so they are classified as a type of the benzopyrone family (10,11).

**Figure (1) Chemical structure of Coumarin**

Both natural and synthetic origin compounds of coumarins have an important. Several compounds which containing the coumarin nucleus show useful and varied biological and pharmaceutical activities, Some of these compounds useful in antitumor, photochemotherapy, anti-HIV therapy, antibacterial, antifungal, anticoagulants, antioxidant agents, as CNS-stimulants, and as dyes. The synthetic, semi-synthetic and natural coumarins are beneficial substances in drug designs and studies (12,13). This work is focus on Synthesis and anti-inflammatory evaluation of coumarins derivatives containing three pharmacophores a nucleus of coumarin and substituted oxazole moiety, separated by a hydrazonoethyl spacer.

**Materials and methods**

3-acetyl coumarin bought from SRCT company (Shanghai). Solvent and other reagent that used through reaction were bought from the chemicals store of college of the pharmacy. The monitoring of the reactions was done by thin layer chromatography (TLC), the mobile phase solvent systems used are A: toluene:ethyl (2:1) and B: chloroform:methanol (9.5:0.5). Electronic melting point apparatus (Stuart SMP30) was used to determine all melting points in this study. FTIR spectrophotometer (Schemadzu, Japan), were done by thin film technique. 1HNMR spectra were obtained on BRUKER model Ultra shield 500 MHz spectrophotometer, using Dimethyl sulfoxide (DMSO) as a solvent.

The pathway of synthesis for final compounds was illustrated below in scheme (1)

**Scheme (1) the overall pathway of synthesis for final compounds**
Synthesis of (E)-2-(1-(2-oxo-2H-chromen-3-yl) ethylidene) hydrazine-1-carboxamide compound (I)

A mixture of 3-acetyl coumarin (1.88 g, 0.01 mol), hydrazine-carboxamide.HCl (1.11 g, 0.01 mol), and anhydrous sodium acetate (0.82 g, 0.01 mol) in (25 mL) absolute ethanol was refluxed for 3–4 hrs. The obtained solid was filtered, dried, and recrystallized from ethanol to give compounds (I) (14, 15, 16).

Yield = 89%, Rf = 0.42(B), IR: (3483 & 3147 cm\(^{-1}\)) N-H stretching of 1º & 2º amine, (3074 cm\(^{-1}\)) C-H stretching of Ar ring, (2974 cm\(^{-1}\)) C-H stretching of alkene, (1747 cm\(^{-1}\)) C=O stretching of lactone ring, (1705 cm\(^{-1}\)) C=O stretching of amid, (1585 cm\(^{-1}\)) C=N stretching, (1608, 1492 & 1435 cm\(^{-1}\)) C=C stretching of Ar ring (1238 & 1265 cm\(^{-1}\)) C-O-C stretching of cyclic ether, (1118 & 740 cm\(^{-1}\)) in and out of plane of Ar ring.

1HNMR: 2.13 (3H, s, -CH\(_3\)), 6.53 (2H, s, -NH\(_2\)), 7.38 (2H, m, Ar C-H), 7.61 (1H, m, Ar C-H), 7.76 (1H, m, Ar C-H), 8.32 (1H, m, Ar C-H), 9.53 (1H, s, -NH-NH\(_2\)).

Synthesis of final compounds (II a- II d)

A mixture of compounds I (2.45 g, 0.01 mol), one of following phenacyl bromide or its derivatives: phenacyl bromide (1.99 g, 0.01 mol) for compound (II a), p-bromo phenacyl bromide (2.79 g, 0.01 mol) for compound (II b), p-chloro phenacyl bromid (2.33 g, 0.01 mol) for compound (II c), p-nitro phenacyl bromid (2.44 g, 0.01 mol) for compound (II d), and anhydrous sodium acetate (0.82 g, 0.01 mol) in (30 mL) absolute ethanol, was refluxed for 6–10 hrs. The mixture was filtered after cooling, the filtrate was evaporated, the remaining powder washed with water, and dried. The final compounds were isolated and purified by column chromatography by using (silica gel) as stationary phase and (n-hexane with ethyl acetate 2:1) as mobile phase.

Then crystallized from ethanol to give compounds (III a-d) (14, 17).

(II a) 3-((E)-1-(((E)-4-phenyloxazol-2(3H)-ylidene)hydrazineylidene)ethyl)-2H-chromen-2-one yellow powder, yield = 50%, M.P. = (40-43) ºC, Rf = 0.73 (A), IR: (3066 cm\(^{-1}\)) N-H stretching of 2º amine, (3016 cm\(^{-1}\)) C-H stretching of Ar ring, (2981 & 2939 cm\(^{-1}\)) C-H stretching of alkane, (1735 cm\(^{-1}\)) C-O stretching of lactone ring, (1693 cm\(^{-1}\)) C=N stretching, (1597 & 1423 cm\(^{-1}\)) C=C stretching of Ar ring (1222, 1242 & 1280 cm\(^{-1}\)) C-O-C stretching of cyclic ether, (1076 & 752 cm\(^{-1}\)) in and out of plane of Ar ring.

Anti-inflammatory Study

The inflammatory model that used to evaluate final compounds (II a-d) for the in vivo acute anti-inflammatory effects exploited egg-white induced rat paw edema, for comparison with the anti-inflammatory activity of celecoxib. The decrease of paw thickness is the basis of screening of the newly synthesized compounds for their anti-inflammatory activity.

Methods of Anti-inflammatory study

Both sex albino rats (200 ± 10) were provided by Iraqi Center for Cancer & Medical Genetic Research / Al-Mustansiriyah University, and housed under standardized conditions in animal house. Animals were divided into six groups (six rats per group) as follow: Group 1: injected with the vehicle (in DMSO) with a dose of 2 ml/kg and served as a control group. Group 2: injected with celebrax with a dose of 5mg/kg (18), dissolved in DMSO, and served as a reference group. Group 3-6: each group of six rats injected with the tested compounds (III a-d) respectively, in doses (4.5 mg/kg for comp II a, 5.5 mg/kg for comp II b, 5 mg/kg for comp II c, and 5.1 mg/kg for comp II d), dissolved in DMSO. The reference substance celecoxib was administered both with the tested compounds by the intra-peritoneal route (i.p.). Egg albumin was used to induce rat paw edema as an acute inflammatory model for studying the activity of the final compounds. 0.05mL of undiluted ovalbumin was subcutaneously injected into the left hand paw of the rats; preceded by a half hour of intraperitoneal injection of the drugs or their vehicle (19). Digital vernier used for measuring paw thickness at 7 periods (0, 30, 60, 120, 180, 240, and 300 minutes) and these measurements were taken after the intra-peritoneal administration of the tested compounds or DMSO (control), considered as time zero (20).

In this study there was no significant difference among the tested compounds compared to celecoxib and control at baseline, after 30 and 60 minutes. However, after 120 to 300 minutes, compounds (II b, II c, and II d) showed more activities to reduce paw thickness compared to celecoxib, in which (III d) showed best reduction in paw thickness compared to the other compounds. Compounds (II a) showed less activities to reduce paw thickness when compared to the standard celecoxib after. Among them, compounds (II b, II c, and II d) was found to exhibit the best reduction in paw
thickness relative to the other compounds as illustrated in Figure (2) and Table (1).

edema in rats.

**Conclusion**

The proposed compounds were successfully synthesized, and their chemical structures and purity were determined using IR spectroscopy and ^1^HNMR. The anti-inflammatory was tested using control (solvent DMSO) and standards (celecoxib). The compounds (II b, II c, and II d) showed good anti-inflammatory activity, when compared with standard compound.

The Sensitivity of some Types of Citrus Fruits, the role of the Propolis and the Color of Storage Bags in the Development of Green Mold Caused by Fungi *Penicillium Digitatum*

Hiba Hashim Younes¹, Wa’ad Hamoudi Awad¹, Theyab A. F .Al- Esawee²

¹Assistant Lecturer, ²Lecturer College of Agriculture/ University of Anbar/Iraq

Abstract

The results of the study indicated that green mold caused by *Penicillium digitatum* was noticed in all types of citrus fruits (orange, mandarin, bitter orange, lemon). The most sensitive among these fruits was the mandarin with 56.12% infection, followed by orange with 40.18%. On the other hand, the bitter orange and the lemon showed more resistant to the disease, and the their infection percentages were (32.14% and 30.55% respectively. The results indicated that the color of the bags had a great effect on the development of the disease where the infection percentages when using light green bags and light yellow bags were (19.68%, 17.24%) respectively. While for the dark black bags, the infection percentage was 13.73%. The use of porpolis in all concentrations (6, 8, 10, 12) g/l did not lessen the size of the infected area compared with contaminated treatment by pathogen.

**Keywords:** food; nutrition; toxicity; disease; humidity

**Introduction**

Citrus crops suffer from many diseases, whether before or after the harvest, which cause losses in the quantity and quality of production. Perhaps the most important of these diseases are fungal diseases, especially the green mold disease, as the losses resulting from this disease in 2017 were estimated at 50 million metric tons in cultivation areas of all citrus fruits (15). This disease is spread in most citrus cultivation areas in the world, especially in warm areas with high humidity (1,2,3). The risk this disease can cause increases when appropriate conditions are available such as a temperature ranging between 5 - 25 ° C and relative humidity of more than 80% with the availability of lighting required for the production of spores (4,5). Scratches formed during harvesting and the presence of insects also help in the development of the disease. Moreover, *P. digitatium* has the ability of producing some cellulose and pectin enzymes that increase the risk of this disease (6). Several methods were used to fight this disease, such as the use of paraffin wax, evaporation inhibitors (7) and chemical pesticides (8). In order to know the importance causes of the disease, its severity on citrus fruits and how to reduce it, the study was conducted according to the following axes:

1- Investigating the sensitivity of several citrus to the infection of the green mold disease.

2-The role of storage bags and role of propolis in the development of the disease.

**Materials and Methods**

This experiment was carried out at the University Of Anbar/ College of Agriculture/ Plant Protection Department/ Plant Pathology Laboratory for the winter season 2017-2018. Fruits of different types of citrus were collected (orange, bitter orange, lemon, and mandarine) from the orchards of the district of Heet, Ramadi and Fallujah. These fruits showed symptoms of infection with the disease (9). These infected fruits were placed in sterile polyethylene bags and brought to the laboratory, then pieces from the infected area were extracted from the fruits located in the collection areas. The pieces
taken were 1 cm in length. They were later placed in petri dishes containing PDA media. They were later transferred to the incubator at a temperature of 25 °C for a period of 7 days. After that, the Pathogenic fungus were identified according to the species key (10), and the pathogen was diagnosed to the type level depending on the type key (11).

**Sporophobia Preparation**

Sporophytes were prepared according to (12), 1 ml sterile distilled water was added to each growing petri dish in which the *Penicillium digitatum* was observed, and the water was moved stirred the plate by using a sterile L-shaped glass rod. Then the water containing the sporophyte of the fungus was extracted and put into a test tube A 9 ml container of sterile distilled water. After that, a series of dilutions were added until the concentration reached is 10-7 spores/ml. This concentration is determined using a Haemocytometer slice.

**The sensitivity of some Citrus Fruits to Green Mold Caused by the Fungus Penicillium digitatum**

This experiment was carried out according to the randomized complete block design (RCBD). The treatments were divided as follows

1. T1 = treatment of orange fruit
2. T2 = treatment of mandarin fruits
3. T3 = treatment of (bitter orange ) fruits
4. T4 = treatment of lemon fruits
5. T5 = contaminated pathogen treatment
6. T6 = sound comparison treatment

Each treatment included 4 replicates. In each iteration, there were 3 healthy homogeneous fruits from all types of citrus used. Then all fruits were scratched with superficial scratches orthogonally by a sterile knife of 1 cm length, then all treatments were contaminated, except for the T6 treatment, with the pathogenic fungus of the concentration of 10-7 spores/ml, and then the fruits of each iteration were placed in a sterile polyethylene bag perforated by a cork drill 5 ml. Then, it was left under the natural conditions of the laboratory. Measurements were taken after (10) days by measuring the rate of fungal growth of the infected spot, and then calculating the percentage of the infected area according to the formula:

\[
\% \text{ infected area} = \frac{\text{Fung growth rate}}{\text{The peripheral growth rate of the fruit}} \times 100.
\]

The effect of Citrus Storage Bags Color on the Development of Green Mold Caused by Fungus Penicillium Digitatum

In this experiment, orange fruits, bitter orange, lemon, and local mandarin were used as homogeneous healthy fruits were selected. The treatments were distributed according to RCBD design. The treatments were conducted as follows:

1. T1 = dark black storage bags
2. T2 = Transparent green storage bags
3. T3 = transparent yellow storage bags
4. T4 = exposed orange fruits contaminated with the pathogen
5. T5 = healthy exposed orange fruits

Four replicates were used for each treatment at the rate of 3 orange fruits per replicate. These fruits were scratched superficially, as explained in the previous paragraph. After that all the treatments were contaminated, except for the T5 treatment, by spore concentration at 10-7 spores/ ml, then the bags were sealed tightly and left under laboratory conditions for 10 days. Then the fungal growth of the infected area caused by the fungus was measured. The Effect of Different Propolis Concentrations on % of the *P. digitatum* Infection Area

Propolis was obtained from the apiary section of the Plant Protection Department/ College of Agriculture/ University Of Anbar, then (6, 8, 10, 12) grams of propolis were weighed. Then each weight was placed in a glass beaker containing 1000 mL sterile distilled water. Then the water was heated to a temperature of 60-70 °C with constant stirring for 5 minutes. The resulting solution was later sprayed on the scratched orange fruits, and then the fungus *P. digitatum* was sprayed at a concentration of 10-7 spores/ ml. The same process was repeated for all weights of the propolis In the same
way. Three replications were used for each treatment and three oranges for each iteration. The contaminated comparison treatment was treated with the same fungus solution on the scratched fruits. The treated fruits were left for 10 days under laboratory conditions, after which the fungal growth rate of the infected area was measured for each treatment, and the percentage of the infected area was calculated according to the following formula:

\[
\text{% for the infected area} = \frac{\text{Fung growth rate}}{\text{The peripheral growth rate of the orange}} \times 100
\]

Results and Discussion

Table (1) shows that green mold disease caused by \textit{P. digitatum} is spread in all citrus cultivation areas and in all types of citrus fruits used in this study, and this confirms what is reported in \textsuperscript{(13, 14)}, that this disease is spread in most areas of citrus cultivation in the world. The table also shows that the severity of the disease increases on the fruits of these citrus after the harvest \textsuperscript{(15, 16)}. The risk of this disease is found to be due to the ability of the pathogen (\textit{P. digitatum}) to grow in a temperature range of 5-25 °C when moisture is available at a rate ranging from 75 - 80% \textsuperscript{(1)}.

Table (2) shows that the fruits of the citrus fruits used (orange, bitter orange, lemon, mandarin) varied in their sensitivity to green mold disease, as mandarin fruits recorded the highest levels of sensitivity, and the percentage of infection area reached 56.12%, followed by orange fruits with a percentage of 40.18%, while the fruits of lemon and bitter orange were less sensitive to green mold, as the percentage of the infection area was (30.55%, 32.14%) respectively. This difference in the sensitivity of the citrus fruits used may be due to the difference in the thickness of the outer wall of the fruits and the difference in the cellular composition of the cell wall of these fruits, especially in the difference in the concentration of ethylene gas of the most important means of defense in citrus fruits \textsuperscript{(17,18)}.

Table (3) shows that the color of the storage bags used in preserving citrus fruits had an effect on the development of infection with green mold caused by the fungus \textit{P. digitatum}. Particularly, transparent colors such as transparent yellow and transparent green recorded an infection rate of 17.24% and 19.68%, respectively, while the dark black color was the least affected in the development of the disease, as the percentage of the infected area was 13.73%. This effect is ascribed to the color of the storage bags which affects the amount of light passing through them, which is a key factor in the formation of the pathogen spores. The table also shows that the overlap between the fruits of different types of citrus fruits and the color of the storage bags has a significant impact on the development of the disease. As for the fruits of bitter orange placed in dark bags, it was the lowest in the infection rate with 2.38%. As illustrated in Table (4), the use of the propolis did not lead to any significant reduction in the infected area, and the reason may be attributed to the fact that the heat used led to the decomposition of the substances has a role in resisting the disease.

The response of Brahimi apple’s Cultivar to Foliar Application of Glycyrrhizin Extract (GLE) and Humic Acid (HA)

Duaa Flaih Hasan Al-Mehemdi¹, Ali Ammar Ismaeel Al-Ani²
¹Post Graduate, ²Associate Professor, College of Agriculture, University of Anbar, Horticulture & Gardening Department, 31001, Anbar, Iraq

Abstract

The research team had conducted this work at a private orchard in Saqlawiya – Falluja district in 2019 to investigate the influence of foliar application of liquorice (glycyrrhizin) extract (GLE) and humic acid (HA) on some vegetative growth traits and yield of Al-Ibrahimi apple cultivar. The factorial experiment consisted of 2 factors; the first one was GLE which consisted of 3 levels (L0, L1, L2) of (0, 3, and 6 g.L⁻¹) respectively; while the second one was HA with 4 levels (0, 2, 4, and 6 g.L⁻¹) had symbols of (H0, H1, H2, and H3) successively. Thus, the total number of treatments was 12 of 3 replications. Every apple tree considered as an experimental unit. The HA treatments were applied 7 times to soil every 20 days starting from 20th February 2019 while the foliar applications of GLE were 5 times starting from the 1st April in the same year.

A significant improvement in vegetative growth, quantity, and quality of yield due to GLE and HA applications has been shown in increasing individual leaf area (LA), length of branches (LOB), number of leaves (NOL), total chlorophyll content in leaves (TCL), and total carbohydrates content in leaves (TCCL), average weight of fruits (AWF), and number of fruits per tree (NFT) that reflected positively on increasing yield per individual tree (YPT), total percentage of soluble solids (PSS), vitamin C content in fruits (CC), and decreasing acidity of fruits (TPA). The interaction between factors had significant influence in most of studied traits. Thus the L1H3, L2H2, and L2H3 treatment had the best results.

Keywords: Liquorice; Humic acid; Foliar application; Fruits; Apple; toxicity

Introduction

The apple (Malus pumila L.) is one of Rosaceae family which is the most worldwide spread type of deciduous fruit trees in temperate regions in the globe, the global production of apples is estimated at 83139326 tons, and Iraq’s production of apples is estimated at 626,470 tons(1). Many scientific manuscripts had indicated that the foliar spraying of many herbal extracts had a great effect in improving the vegetative and flowering growth and yield of many plants(2). Among these plant extracts is the extract of licorice plant roots, Glycyrrhiza glabrag, which has been proven in many studies to enhance the productivity of many plants (3), (4) and (5). Found that in spraying of pear seedlings with licorice root extract, had significant increase in plant height, stem diameter, dry weight of leaves and leaf content of chlorophyll. Found that spraying of pear seedlings with licorice root extract has led to significant increase in the leaf area and its total chlorophyll content. (6) Stated an increase in the yield of pomegranate trees when spraying leaves with licorice root extract. The use of organic products has received a lot of attention in the recent period, furthermore, this new system of agricultural production that contain Humic acid has become one of the most important organic compounds used in this field, if it is found that the addition of humic acid to soil leads to increase the cation exchange capacity of soil and increases its pH and thus increases the availability of nutrients and increases

Corresponding author:
Ali Ammar Ismaeel Al-Ani
ag.ali.ammar@uoanbar.edu.iq
the growth of roots and their branches (7), (8) found in their study on Anna cultivar apples that the addition of humic acid to soil by 30 cm\(^3\).tree\(^{-1}\) has led to significant increase in the number of leaves per branch\(^{-1}\) and the area of the leaf increased with an increase in yield by 25.6% in addition to an increase in the average weight of the fruit and the percentage of total soluble solids, (9) also obtained similar results when studying Anna-cultivar apple trees, and (10) stated an increase in tree yield, fruit count per tree, and average of fruit weight of pear (Leconte cultivar) when adding 100 ml per tree of humate-NPK combination (10% humate ratio) to the soil. (11) Had gained the same results on apricot trees (Canino cultivar).

**Materials and Methods**

The effect of foliar spraying with glycyrrhizin root extract (GLE) and the addition of humic acid (HA) to the soil has been studied on some of the vegetative growth characteristics and yield of apple trees (Brahimi cultivar). The factorial experiment of randomized completely block design (RCBD) has been conducted where the GLE was the 1\(^{st}\) factor with levels of 0, 3, 6 g.L\(^{-1}\) have symbols of L0, L1, and L2 respectively, whereas the 2\(^{nd}\) factor were HA levels of 0, 2, 4, 6 g. L\(^{-1}\) have the symbols of H0, H1, H2, H3 for the Humibest product from Meristem Spanish company (have 55% Humic acid, 5% Fulvic acid, and 7% K\(_2\)O) as a humic source. The required quantity of HA was dissolved in 15 liters of water and added circularly around each tree on 50 cm distance and 20 cm depth from main stem, then the HA was applied to soil starting from 20\(^{th}\) February for every 20 days at 7 times. The trees were sprayed with GLE five times every 20 days starting from 1\(^{st}\) April 2019, the results were analyzed using GenStat and then, averages were compared using the least significant difference test (L.S.D) at a probability level of 5%. The following traits have been studied:

1- Individual leaf area (cm\(^2\)) (LA):

The results of table 1. Showed that the individual LA had significantly affected by the increased levels of foliar sprayed GLE. The highest LA average was 21.23 cm\(^2\) for L2 level compared to 19.47 cm\(^2\) in control treatment. The same table revealed that H3 level of HA led to significant increase in individual LA, where it was 21.02 cm\(^2\) compared to insignificant difference of H1 and H2 levels that reached 20.35 and 20.05 cm\(^2\) respectively as well as that H0 had less value of 19.40 cm\(^2\). On other hand, the interaction between GLE and HA had insignificant effect on individual LA.
Table 1. The effect of foliar GLE, soil applied HA, and their interaction on individual LA (cm²) for Brahimi apple in spring season of 2019

2. Increase average of branch length (LOB) (cm):

Table 2 had shown a significant increase in average LOB for every single increase in foliar GLE levels. The highest LOB value of 30.98 cm was found in L2 compared to 24.04 cm in control treatment.

The same table had revealed significant differences among HA levels that affected LOB average. The highest LOB value was 30.33 cm found in H3 compared to 24.22 cm in control treatment H0 which was the least.

The interactions between GLE and HA treatments were significant in increasing LOB values where the highest averages of 33.33, 30.5, 31.33, and 32.42 cm were found in L1H3, L2H1, L2H2, and L2H3 interactions respectively compared to 19.25 cm in control treatment.

L.S.D %5 | HA GLE interactions
---------|---------------------
1.85     | 1.61                3.21
3. Increase average of number of leaves per branch NOL (leaf per branch LPB):

The results of table 3 revealed significant differences among levels of foliar GLE in increasing average NOL. The second level L2 had the highest NOL of 22.51 LPB and insignificant NOL difference of 21.50 LPB in L1 compared to control treatment which had the least average of 16.16 LPB. The results of the same table showed that NOL was significantly increased with HA levels where the highest was 25.28 LPB in H3 compared to the least NOL in H0 which was 15.56LPB.

There was a significant effect of interactions between GLE and HA on increasing NOL values where the highest of them found in L1H3, L2H2, and L2H3 treatments of (30.17, 28.63, and 25.92 LPB) respectively with insignificant differences among them compared to the least of 14.25 LPB in control treatment.

Table 3. The effect of foliar GLE, soil applied HA, and their interaction on NOL (LPB) for Brahimi apple in spring season of 2019.

The increase in vegetative growth traits, consisting of LA, LOB, and NOL when spraying with GLE may be due to the fact that this extract contains a good amount of nutrients necessary for plant growth such as potassium, phosphorus, calcium, other elements, various amino acids, salts and carbohydrates (appendix 1) which are included in the synthesis of many enzymes, especially in the enzymes contained in photosynthesis, as well as the providing of nitrogen plant directly at the spraying (14). The role of GL extract in improving the growth of the plant may be due to its role similar to the work of gibberellin, since it contains mevalonic acid, the bio-initiator of the formation of gibberellin. It is known that the gibberellins work to increase the softness of the cellular walls of the top and sub-top symbiotic, which increases from its permeability and allowing the entry of larger amounts of water and nutrients, which increases the growth and expansion of cells and this is reflected in the elongation of plant branches and increase the leaf area and the gibberellins also work to stimulate the production of auxins and reduce their degradation (15).

(16) Got a significant increase on branches’ length, leaves number, and leaf area of Canino cultivar apricot trees.

4. Total content of chlorophyll in leaves (mg.100 g⁻¹ fresh weight) TCL:

The results of table 4 referred to significant increase of TCL with increasing levels of foliar GLE. The second level L2 has the highest value of 114.0 mg.100 g⁻¹ fresh weight in comparison with least value of 107.6 mg.100 g⁻¹ fresh weight in control treatment. A significant increase of TCL noticed from the same table as a result of increasing HA levels in soil where the highest value of 118.6 mg.100 g⁻¹ fresh weight was shown in H3 treatment compared to control treatment which had the least TCL of 104.7 mg.100 g⁻¹ fresh weight. The interaction between GLE and HA treatments had a powerful effect in increasing TCL where the treatment
L2H3 had the highest value of 122.7 mg.100 g\(^{-1}\) fresh and the lowest value of 102.3 mg.100 g\(^{-1}\) fresh weight was recorded in L0H0 treatment.

The increase in TCL leaves when spraying leaves with GLE may be due to the growth stimulators like macro and micro nutrients that this extract contains, especially nitrogen, which is included in the porphyrin ring, which is the basis for the synthesis of chlorophyll, since 70% of the leaf nitrogen, is included in the formulation of this formula.

**Conclusions**

1- The 6 of GLE and the addition of HA to the soil with levels of 4 and 6 gram per liter had a significant effect in most of the studied traits.

2- The interaction between the two study factors had a significant effect on most of the studied traits, and the best results were in the L2H2 and L2H3 interaction treatments.

A Comparative Study of Cognitive Achievement in Football Among Students who Have Different Learning Styles

Mohammed Saad Jebur¹, Jasim Saleh Majon², Hayder Abdulhafdh Shehab¹
¹ Lec. ² Assist.Prof., College Of Physical Education and Sport Sciences, University of Samarra, Iraq

Abstract
The study aims at identifying the differences in cognitive achievement in football among students with different learning styles. The researchers used the descriptive approach with a comparative study method for its suitability for the nature of the problem, and the sample of the examined students who are the fourth stage students in the Faculty of Physical Education and Sports Science - Samarra University for the academic year 2018-2019. The number of students is (108), and the researchers used the Learning Styles Scale (VAK) that was developed at the Qattan Center for Educational Research and Development and a measure of cognitive achievement in football. The main experiment was carried out on Sunday 5/5/2019 to statistically manipulate data, the researchers used the Statistical Package (SPSS) to find: (mean, standard deviation, simple correlation coefficient Pearson, F test for variance analysis, and L.S.D test). The researchers concluded that there were significant differences in cognitive achievement in football among students with different learning styles. students who preferred visual learning style over students who preferred auditory and kinesthetic learning styles, and students who preferred auditory learning style superior to students who preferred learning style Sens - kinesthetic.

Keywords: Cognitive achievement, football, learning styles (VAK).

Introduction
The learners at any school grade have a set of characteristics, characteristics, and criteria that make him different from other students, and he has the independent personality that leads to a clear difference between him and his colleagues in his view of learning, and the acquisition of different concepts and skills. that helps him to meet his needs, desires, and needs. his motivation to learn increased and his knowledge acquisition increased. Moreover, from the premise that the learning and teaching process is a very complicated issue in terms of the process of its occurrence, especially if we realize that each learner has his method of learning and acquiring concepts through the experiences that he is going through and how he deals with it, i.e. the preferred educational style through which the learner learns. The need to understand the Styles of learning (VAK) is increasing according to the need of group learning within heterogeneous classes and educational literature has given this aspect attention, as the basis of research, in general, must be the learner with all his dimensions as the basic learning unit (1).

The learning style of a particular student includes his preferred method of receiving information and how to process it. Some learners prefer to hear the educational material with the method of lecture, and the other section prefers displaying the educational material by pictures, slides, and video. There is another section that prefers movement during the learning process and direct participation in it to learn (2). Some people prefer to learn in a group while others prefer to work alone, as some prefer to know the subject in a general way first and then the details and some favor the opposite. (3)

Procedures and measurements
Participants
The examined students were chosen from the fourth...
stage students in the Faculty of Physical Education and Sports Science - Samarra University for the academic year 2019-2020 and they are (115) students, by defining the learning style using the scale of preferred learning styles. It was found that the sample prefers three modes of learning which are the learning style Sense, kinesthetic and visual learning style, and auditory learning style. Accordingly, the sample of (108) students was divided into three groups, the first group that preferred the kinesthetic style consisted of (32) students and the second group that preferred the visual learning style consisted of (40) students. The third group that avoids the auditory learning pattern is composed of (36) students, whose percentage is (93.9%) of the total research community.

**Procedures:**

**Learning Style Scale (VAK):** To achieve the aims of the research, the researchers used the preferred Learning Styles Scale (VAK) which was developed at the Qattan Center for Educational Research and Development (1), which is consisted of (80) A paragraph divided into three dimensions:

- The first dimension (20) Items which represent the kinetic learning style, which is from (1-20).

  The second dimension (40) items represent the visual-verbal and non-verbal learning style, which is from (21-60).

  The third dimension (20) is an item that represents the auditory learning style, and it is from (61-80).

The results of the feedback to the scale are calculated to determine the preferred pattern by giving (4) degrees to the answer (always), (3) degrees to the answer (often), two degrees to the answer (sometimes), and one degree to the answer (never), and if you get a high degree in one of the three styles (sensation - kinesthetic, visual, auditory), this indicates that you prefer this style in learning situations.

The used scale gained validity after presenting it in its initial form to a group of experts in the field of educational psychology, physical education, and sports science.

Then stability of the scale was found using the Retest method (4) (5) (6), as the test was applied to a sample of students outside the final application sample and within community research, and then re-application of the scale after two weeks from the first application. Then, after collecting the scale forms were statistically processed using the simple correlation coefficient (Pearson) between the degrees of the first and second application, so the coefficient of stability of the sense-kinematic style (0.82), and the visual style (0.76), it has high stability that can be used in the application of the instrument. The higher the stability coefficient value (0.71), the better. (7)

**Football Cognitive Achievement Scale:**

To measure cognitive achievement of basic football skills, the two researchers adopted the test designed by (4) and is specifically designed to measure cognitive achievement of basic football skills. This test uses objective questions based on multiple-choice, as it contains (40) patterns and each pattern contains (4) alternatives that achieve the goals related to the educational content of basic skills in football. one score is calculated for each correct answer. To find the scientific foundations of the scale, the researchers followed the same previous procedures where the validity of the scale was extracted by presenting it in its initial form. Also, it included (40) patterns on the experience and specialization in the field of football, and the opinions of the arbitrators were taken as (5) patterns (5, 9, 17, 22, 34) were deleted. Thus, in its final form, it contains (35) paragraphs. According to the arbitrators, it is suitable for students of the fourth stage in the College of Physical Education and Sports Science, and thus the scale has obtained apparent honesty.

To ensure the appropriateness of the scale, and to find consistency for it, a survey which is consisted of (4) students is applied. This correlation has reached (0.87) and this stability is valid for the study.

The participants of the survey answered the cognitive achievement scale in football on Sunday (5/5/2019), and the number (108) students were divided into three groups according to their preferred educational items, and without specifying a time to answer the scale, and the correct answer method was explained on the scale, and that By putting a circle around the correct answer that the student thinks appropriate, and after completing the answer to all the items, the scale questionnaires were
collected from them, and thus the final exam score is the sum of his correct answers on the scale.

**Data analysis:**

The data is prepared, organized, and entered into the computer as an XL file; Various statistical methods were used to analyze and process statistical data using SPSS V27, then the standard deviation, then the simple correlation coefficient Pearson, the F test for variance analysis as well as the least significant mean difference of L.S.D were used.

**Results**

**Table 1: Shows the statistical variables related to cognitive achievement according to preferred learning styles used in this study**

* Significant because Sig is less than (0.05)

- The significance of the differences between the visual learning style and the auditory learning style in the cognitive achievement test in football and the favor of the visual learning style.

- The significance of the differences between the visual learning style and the kinetic learning style in the cognitive achievement test in football and the favor of the visual learning style.

- The significance of the differences between the auditory learning style and the kinetic learning style in the cognitive achievement test in football and the favor of the auditory learning style.

Discussion

Table (2) showed significant differences between the three learning styles in the cognitive achievement test in football. In favor of the visual learning style, the researchers attribute these differences to the advantages enjoyed by the group of visual students because they see the teacher’s body language and facial expressions, as this leads to a full understanding of the content of the lesson. Also, the owners of this style tend to sit in the front rows to avoid visual obstacles, they learn better than during visual presentations (such as illustrations, maps, data, digital videos, and slides), they also take notes on the skill or concept which leads to the assimilation of information. The visual student’s group learn better through seeing the educational material and the movements of the teacher and how to perform the skill, it is important that they see what the teacher is doing, as they have high skills in receiving, preparing, and processing visual experiences, which makes their awareness of educational experiences better through the media Video. (8)

The various visual aids used by the teacher in lessons such as educational devices make learning easier and interesting and are an effective tool to attract the attention of learners and help them understand different phenomena (9) and the use of visual aids in teaching are one of the ways to improve course progress and give students additional ways to process information and acquire it in an organized way (10) The great scientist Comenius said: The basis of all learning is to reasonably represent the senses so that knowledge can be easily acquired and preserved (11). Visual students can process the largest amount of information more efficiently because the visual representations supported by half of the human brain make students able to integrate ideas, facts, and concepts and save them in an organized way, especially when paired with an educational environment controlled by students, where it enables them to obtain deeper learning and gain different concepts and skills.

As can be seen from Table (3), there are significant differences between the audio students and the kinetic students for the benefit of the audio students, and the researchers attribute this to the fact that the audio students benefit from the valuable information that teachers give in their lectures, in addition to the talk and discussions...
that take place between the students themselves on the one hand, and between the students and the subject teacher on the other hand, where students interpret the meanings behind the teacher’s speech and focus on the tone of his voice and rhythm during the explanation, which reflects positively on their cognitive and skill achievement, and this is unlike the kinetic students who do not find their goal in the curriculum of the subject teacher. Auditory students are described as enjoying speaking and listening, making sounds when reading such as moving lips and whispering, and tending to use phonemes.\(^{(12)}\)

The auditory students listen to the teacher’s explanation and prefer discussion and work in groups. This is common during lessons related to teaching football skills, as the teacher of the subject before each skill allocates a time when he explains that skill in detail while giving time to interact between him and the students such as asking questions and inquiries and answering them. Many students prefer auditory learning style and love to sit in a quiet classroom and listen to the teacher, so they do not use as much of their energy and economize it.\(^{(13)}\)

In the past, the teacher was seen as the core of the educational process, and recent trends seek for looking at the learner and his needs and taking into account his methods of obtaining the information. Therefore the need to understand student learning patterns is increasing in accord with asking for learning within heterogeneous classes.\(^{(1)}\)

\(^{(14)}\)\(^{(15)}\)\(^{(16)}\) see preferred learning styles (VAK) as a side Among the aspects of individual differences that ask for all educational organizations of the need to consider them and deal with students in a way that considers them.

We can consider understanding students’ favorite learning styles as can improve the planning, production, and implementation of educational programs and the development of experiences, and therefore are more beneficial for students’ desires, improve learning, retain information, and speed of retrieval. The effect of students’ learning styles on their achievement, knowledge, or acquisition of concepts with study\(^{(17)}\) all of which dealt with learning styles as independent variables and their impact on acquiring attitudes, skills, and concepts in different subjects.

## Conclusion

The researchers found, through presenting, analyzing, and discussing the results, that there are different educational patterns among the examined students, and that there are significant differences in cognitive achievement in football between students who prefer the visual style and among students who prefer the auditory style and in favor of the visual style. Moreover, there are significant differences in cognitive achievement in football among students who prefer the visual style and among students who prefer the sensory-kinetic and in favor of the visual style, there are also significant differences in cognitive achievement in football between students who prefer the auditory style and among students who prefer the sensory-kinetic and in favor of the auditory style; The researchers recommend that learning Styles should be taken into consideration when developing curricula for physical education, as it is an aspect of individual differences that must be taken into consideration, and teachers should vary in the use of teaching strategies and methods to suit the different learning styles of their students.

Guggulsterone Suppresses Ovalbumin- Induced Inflammation in Rat Asthmatic Model

Zainab H. Ahmed1, Munaf H. Zalzala2, Manal A. Ibrahim1

1Lecturer, Department of Pharmacology and Toxicology, College of Pharmacy, University of Basra, Basra, Iraq,
2 Assist of Professor, Department of Pharmacology and Toxicology, College of Pharmacy, University of Baghdad, Baghdad, Iraq

Abstract

Background: Asthma is an inflammatory airway disease, which is characteristic by wheezing, chest tightness, dyspnea and cough, all symptoms that are occupied with obstruction of respiratory airway. Aim: investigate guggulsterone activity on improve inflammatory events that associated with asthma. Method: 48 healthy rats (albino, male) divided to 6 groups, rats were sensitized with OVA and preparation lung tissue homogenate for measurement of inflammatory parameters by ELISA and RT-PCR. Also, preparation of lung tissue for histopathological examination. Results: All parameters are significant reduction in treated group with guggulsterone than sensitized group. Also, gugglsterone-treated group’s slides with less inflammatory signs compared to sensitized group slide. Conclusion: Guggulsterone improve inflammatory events that associated with asthma.

Key words: gugglsterone, asthma, anti-inflammatory activity , NF-kappaB.

Introduction

Asthma is an inflammatory airway disease, which is characteristic by wheezing, chest tightness, dyspnea and cough, all symptoms that are occupied with obstruction of respiratory airway. The etiology of disease may be many factors. It is believed to be a combination of environmental and genetic factors. On the other hand, other an important inflammatory cytokine is IL-5, that plays a major role in eosinophil differentiation, proliferation, maturation, and migration to tissue sites with survival. Recently, many studies were suggested that IL-33 is present with asthma. After the injury of the lung epithelial cell, IL-33 produces as an alarm signal and stimulates other immune cells to release of IL-5 and 13. In addition, TNF is a majority inflammatory mediator, which is a chemoattractant for eosinophils and neutrophils, and raises the eosinophils cytotoxic activity on endothelial cells. One of most important transcription factor is NF-κB, which plays major roles in the production of pro-inflammatory cytokine.

Guggulsterone (GS) is a bioactive steroid plant, GS is potent ligands to steroid receptor, specifically glucocorticoid receptor. GS has potent anti-inflammatory effects through inhibiting the stimulation of NF-κB (transcription factor) in response to TNF-α and a direct inhibiting the activation of IKK. Also, GS has antioxidant activity, it is inhibited xanthine oxidase and superoxide dismutase. Both enzymes that enhance the production of ROS (reactive oxygen species) that contributed in pathophysiologic with asthma.

Methodology

Chemicals:

Chemicals and drugs used in recent study including ovalbumin (OVA) (Chadwll Heath ESSEX, England), guggulsterone (Xi’an geekee biotech, China), Prednisolone (Pioneer, Iraq), Formaldehyde (37%) (Naturel, Turkey) and AL(OH)₃ (MERK Darmstadt, Germany).
Animals:
Forty healthy rats (albino, male), that weighing (150-300 gm), were taken from animal house of the University of Baghdad/ College of Pharmacy. Rats were put under photoperiods (12:12-hrs dark/light cycle) and controlled temperatures.

Experimental design:

Group I: Rats were administrated distal water orally without sensitization as control group. Group II: Rats were administrated distal water orally with sensitization as positive control group. Group III: Rats were administrated (25 mg/kg) guggulsterone orally with sensitization. Group IV: Rats were administrated (50 mg/kg) guggulsterone orally with sensitization. Group V: Rats were administrated prednisolone (4.12mg/kg) orally with sensitization.

OVA induced-rats by modified protocol of Manal et al (2013), Tong et al (2008), and Michael et al (1999) studies. Rats were sensitization by IP injection of 1mg OVA, 100mg of Al(OH)₃ in 1ml of PBS (phosphate buffer saline) at (1-3) days, then 100mg OVA , 100mg Al(OH)₃ in 1ml of PBS at 6th day, after that animal were challenged at 9th day by glass chamber with the nebulizer with 1% OVA (1gm OVA in 100ml PBS) for 30 minutes daily for 6 days (7), (8) & (9).

Lung tissue preparation:
The left lung was removed. Then, lung tissue was divided for three parts for histopathologic examination, PCR analysis and homogenate samples.

Measurement of gene expression of TNFα and NF-κB by RT-PCR:
Total RNAs were extracted using Trizol (Bioneer, South Korea). Thirty gram of lung tissue was used to extract total RNA for the complementary DNA synthesis using random primers. Reverse transcriptase-PCR was performed following standard procedures. The primer pairs of the expected products were as follows (forward and reverse, respectively): TNF-alpha, 5′- CTTCTCATTCTGCTGTTG-3′ and 5′- TGATCTGAGTGAGGCTG-3′, NF-κB 5′- CTACGAGACCTTCAAGAGCATC -3′ and 5′- GATGTTGAAAAAGGCATAGGCC -3′, and GAPDH, 5′- TCCAGTATGACTCTACCAGG -3′ and 5′- CACGACATACTCACGACCAG -3′. Amplification products were resolved by 1.0% agarose gel electrophoresis, stained with ethidium bromide and photographed under ultraviolet light. Primers were purchased from Bioneer, South Korea. Real-Time PCR was performed using AccuPower GreenStar qPCR PreMix according to the manufacturer’s instructions (Bioneer, Cat No: K-6210).

Histopathological examination of lung tissue:
The left lung is removed from all the experimental rats. Then it was washed with normal saline solution for preparation tissue to histopathological examination. Then, the washed lung tissues were fixed with formaldehyde (10% of formaldehyde in water). The sample was dried from water by Xylene. This process is done overnight and automated. Finally, molten wax was surrounded the specimen in the container and solidification by cooling and embedding in the wax block. Then, the thin section slide was stained and mounted by the protective cover slip.

Statistical Analysis
Statistical Package for the Social Sciences (Spss, version 25) statistic program was used in the present study for data analyzing. An unpaired Student t-test and one-way ANOVA test used for comparison between groups for finding significant statistic different.

Results
Effect of guggulsterone on IL-4, IL-5 and IL-33 levels in lung tissue homogenate:
IL-4, IL-5 & IL-33 are inflammatory cytokines. IL-4, IL-5 & IL-33 levels (mean ± Std. Error) for rats of group II (positive control) (78.3 ± 5.2, 97 ± 19.7 & 82.4 ± 4.7, respectively) were significantly elevation (p<0.001) than group I (control group) (19.5 ± 5.1, 26.8 ± 1.6 & 35.9 ± 4, respectively) as showed in figure 1. The other significant different in IL-4, IL-5 & IL-33 levels for rats of treated groups III (25 mg/kg guggulsterone) (19.2 ± 2.8, 43.5 ± 11 & 41.4 ± 3.9), IV (50 mg/kg guggulsterone) (16.6 ± 2.4, 32 ± 13.4 & 37.8 ± 3.1) & V (4.12 mg/kg predinsoline) (27.6 ± 2.4, 50.7 ± 6.2 & 46.8 ± 5.4, respectively) were significant reduction (p<0.001) as compared to senitized group II (positive control group) (78.3 ± 5.2, 97 ± 19.7). Also, IL-4 levels for rats of group IV (16.6 ± 2.4) than other treated group V (27.6 ± 2.4).

Values are indicated as means ± Std. Error (n=8) for each group. Group I: Control group, Group II: Positive control group (with sensitization), Group III: Guggulsterone (25 mg/kg) with sensitization, Group IV: Guggulsterone (50 mg/kg) with sensitization, Group V: Predinsoline (4.12 mg/kg) with sensitization. *** symbol referred to significant different (p<0.001) compared to control group, unpaired test student t-test. Groups with non-identical letters are significantly different (p<0.05).

Effect of guggulsterone on TNFα levels in lung tissue homogenate:

TNF levels (means ± Std. Error) in tissue homogenate for rats of sensitized group II (positive control group) (210.9 ± 26) was significantly elevated (p<0.01) than group I (control group) (94.1 ± 21.1) as showed in figure 2. Furthermore, TNF levels in tissue homogenate for rats of treated groups (III, IV & V) (124.2 ± 23.3, 113.1 ± 20.1 & 115.4 ± 10.4) were significantly reduction (p<0.05) than IL-33 levels in tissue homogenate for rats of sensitized group II (positive control group) (210.9 ± 26).
Figure 2: Inhibitory effect of guggulsterone on OVA-induced TNF-alpha expression in lung tissue homogenate.

Values are indicated as means ± Std. Error (n=8) for each group. ** symbol referred to significant different (p<0.01) compared to control group, unpaired test student t-test. Groups with non-identical letters are significantly different (p<0.05).

Effect of guggulsterone on IgE levels in lung tissue homogenate:

IgE is immune marker appeared with an asthmatic pathway. IgE levels in lung tissue homogenate (means ± Std. Error) for rats of group II (sensitized, positive control group) (176.7 ± 7.5) was significantly increased (p<0.001) than group I (control group) (52.8 ± 5.7) as noted in figure 3. Besides, there were significant reduction (p<0.001) in IgE levels in tissue homogenate (means ± Std. Error) for rats of treated groups (III, IV & V) (44.9 ± 8.1, 58.7 ± 2.1, & 47.6 ± 7.3, respectively) compared to sensitized group II (positive control group) (176.7 ± 7.5).

Figure 3: Inhibitory effect of guggulsterone on OVA-induced IgE in lung tissue homogenate.
Values are indicated as means ± Std. Error (n=8) for each group.*** symbol referred to significant different (p<0.001) compared to control group, unpaired test student t-test. Groups with non-identical letters are significantly different (p<0.05).

**Effect of guggulsterone on gene expression of TNFα and NF-κB:**

Gene expression of TNFα and NF-κB (means ± Std. Error) for rats of group II (positive control group) (1.94 ± 0.21, 3.33 ± 0.43) were significantly raised (p<0.001) than group I (control group) (0.41 ± 0.22, 0.7 ± 0.16) as appeared in figure 4. Also, gene expression of TNFα for treated rats of group V was significantly elevation (p<0.05) in compared to group I (control group). There were significant reduction (p<0.001) between gene expression of TNFα and NF-κB (means ± Std. Error) for rats of treated groups (III (0.52 ± 0.23, 0.94 ± 0.08), IV (0.74 ± 0.17, 0.98 ± 0.11) & group V (1.07 ± 0.21, 1.11 ± 0.16) than sensitized group II (positive control group) (1.94 ± 0.21).

**Figure 4: Effect of gugglsterone on gene expression of TNFα & NF-Kβ in lung tissue.**

Values are indicated as means ± Std. Error (n=8) for each group. *** & * symbols referred to significant different (p<<0.05) compared to control group, unpaired test student t-test. Groups with non-identical letters are significantly different (p<0.05).

**Histological assessment of rats’ lung tissue for all studied groups:**

**Figure 5** showed that (D) the cross section of lung tissue for rats group I (control group) and noted that alveolar sac was cleared. Inflammatory cells were not agglomerate in the interstitial tissue. While, (E) group II (positive control group) manifested inflammatory cells were agglomerated in interstitial tissue. Also, Alveolar sac was filled with inflammatory cells. On other hand, (F), (G) & (H) treated groups (III (25 mg/kg guggulsterone), IV (50 mg/kg guggulsterone) & V (4.12 mg/kg predinsoline)) appeared that very less number of inflammatory cells agglomerated in interstitial tissue and alveolar sac was cleared.
Discussion

Asthma is one of the inflammatory and chronic airways disorders, which is manifested that an adaptive and innate immune systems with each other with epithelial cells to produce BHR, overproduction of mucus and airway wall narrowing and remodeling. Predinsoline is traditional ant-inflammatory drug, which is used in this study for comparison pharmacological activity with gugglsterone.

In the current study, IL-4 and IL-5 are proinflammatory mediators, which are higher for rats of sensitized group than control group. Bagnasco et al (2016) study revealed that IL-4 & IL-5 levels in lung tissue are significantly higher in asthmatic group compared to control group. On other hand, IL-4 & IL-5 are significantly reduction with treated groups with guggulsterone due to guggulsterone has anti-inflammatory activity due to its steroid structure and its ability to bind with glucocorticoid receptor in target nucleus and inhibit the pro-inflammatory transcription factors, AP-1 and NFkB and reduced the gene expression of IL-4& IL-5. The other inflammatory mediators is IL-33and it’s level in tissue homogenate for rats of sensitized group is significantly more than control group I. This results in line with the other previous study, Allinne et al (2019). IL-33 levels reduce in treated groups because guggulsterone is occupied with nuclear GR in target cells that lead to increase of DUSP1 expression lead to induce of feedback inhibition of MAPKs and reduce of IL-33 inflammatory signaling pathway.

TNF-α is a powerful proinflammatory cytokine that mediated to inflammatory response of asthma. Kumar et al (2017) study appeared that TNF is higher with asthmatic group in compared to normal group. Similarly, Al-Quraishi (2013), & Froidure et al (2016) revealed that higher level of IgE in asthmatic group than control group. While, Treated groups with guggulsterone that showed significant reduction in TNFα & IgE levels due to guggulsterone has anti-inflammatory activity mediated by glucocorticoid receptor.

Furthermore, TNFα and NF-kB could be measured gene expression in mRNA through RT-PCR technician. In this study, Gene expression of TNFα and NF-kB
are significantly elevation with sensitized group than control group. Busse et al (2005) & Ather et al (2011) studies appeared that quantitative expression of TNFα and NF-κB are higher in asthmatic group in compared to normal subjects. On other hand, guggulsterone has anti-inflammatory activity lead to suppress the gene expression of proinflammatory cytokines including IL-1β, IL-6, IL-8, and TNF-α. Consequently.

Histopathologic results in the recent study appeared inflammatory cells were agglomerated in interstitial tissue of asthmatic lung tissue for rats of sensitized group. Furthermore, Alveolar sac was filled with inflammatory cells and the wall thickness of bronchiole was increased due to pathogenesis pathway of asthma. Guggulsterone with anti-inflammatory activity appeared that lung tissue returned to the normal state with very less number of inflammatory cells agglomerated in interstitial tissue.

Conclusion

Guggulsterone is natural material that has many anti-inflammatory activities through several mechanisms that mediated by steroid receptors and affected on many inflammatory mediators. In future, further many studies that performed guggulsterone could be used for treatment of airway and other inflammatory diseases.

Study the Role of Helicobacter Pylori Infection in a Group of Iraqi Patients with Colorectal Cancer

Walaa Talal Abdul-Lateef1, Essam Mohammed Abdullah2, Jassim Mohsen Ghadhban3

1Post graduate; 2Asst Prof. University of Anbar, College of Pharmacy / Iraq, 3Consultant in Gastroenterology and Hepatology/ Teaching Hospital Gastroenterology and Hepatology /Medical City/ Baghdad/ Iraq

Abstract

Background: Increased developed of colorectal tumor may be linked with Helicobacter pylori. However, the underlying mechanisms were still uncertain.

Objective: Helicobacter pylori infection in the world, in particular in developing countries, is one of most common chronic bacterial infections, This bacterium is responsible for many diseases such as gastritis, peptic ulcer, lymphoma and in some patients may lead to gastric cancer, it is in the world has known 2nd major cause of death from cancer. H.pylori infection may likely raise the risk of colorectal cancer, according to recently published studies. The aimed of this study to detected the role of H. pylori in colorectal cancer.

Methods: Serum of 50 colorectal cancer and colorectal normal with positive H. pylori infection patients were estimated by 14Urea breath test and 25 subjects with no any inflammatory disease as the control group. from each patient were collected Blood samples to investigated of H. pylori specific immunoglobulin G (IgG) and CagA IgG antibodies by using enzyme-linked immunosorbent assay (ELISA).

Results: A total of 50 patients in this study 25 had colorectal cancer and 25 had colorectal normal with H. pylori infection (immunoglobulin G (IgG) P ˂ 0.01 and CagA IgG antibodies P < 0.01) were significantly more prevalent in the patients with colorectal cancer and colorectal normal with Helicobacter pylori infection compared with the healthy controls (P= 0.00019, P= 0.00022 respectively) The relation was statistically non-significant between the antibody seropositivity and gender but Highly significant with age.

Conclusion: The findings indicate that Helicobacter pylori infection can be regarded as a contributing influence for progressive tumor in colorectal.

Key Words: colorectal cancer, Helicobacter pylori-Infection, Serum, Immunoglobulins

Introduction

Colorectal cancer (CRC): One of the world’s most common cancers and the third-largest cause of death from cancer. As shown in 2018 accordingly to epidemiological survey, 1,800,977 new cases with colorectal cancer and 861,663 mortality related to colorectal cancer were registered (1). The International Cancer Research Agency has listed H.pylori as Group I carcinogenic in gastric cancer (2). It’s generally exists in the stomach and that is microaerophilic gram negative (-ve) bacterium (3). Warren and Marshall first cultivated it in 1981 (4). than half of the population are infected with this pathogens and It was most common infection in the world (5). H.pylori transmitted by contaminated water and food It acquired mainly in early childhood and may remain untreated for life, but it also can be acquired in adults (6). Infection prevalence varies in worldwide depending on socioeconomic factors and hygiene rates (7). Most people will not have any problems with the infection but in some H.pylori long-lasting inflammation in the stomach may cause with peptic ulcer disease and mucosa associated lymphoma (8). A major risk for stomach adenocarcinoma occurrences is Helicobacter pylori (9).

dressamalfhad@gmail.com
The cytoxin-associated gene (CagA) may also contribute to cause inflammation and carcinogenic effect (10). The region of CagPAI approximately 40-kb of H. pylori chromosome. The disease of H. pylori can be enhanced by cagA pathogenicity genes in West countries, around 50–70% of H.pylori strains carry it (11). Persons with H.pylori CagA-positive strains infection produce CagA protein circulating antibodies, which are used as diagnostic markers (12). In extra gastric diseases has been also proposed that play an important role, the colorectal was the major extra-gastric organ with H.pylori that expressed of CagA tumor formation and increase developing of colorectal cancer (13).

Colorectal tissue infection with H. pylori may doesn’t contribute in order to elevated the threat of colorectal cancer directly (14). One hypothesis is that gastric Cytotoxin-linked gene A Protein in Helicobacter pylori infection triggers a rise in serum gastrin levels by overproduction of IL8 that high level of gastrin may lead to hypergastrinemia; (15). That is expected to be Intestinal mucosal proliferative consequence carcinogenesis involves cell inflammation and deregulation cycle (16). H.pylori carcinogenesis involves inflammation and the deregulation of the cell cycle by means of the Cytotoxin-associated gene A (CagA) H.pylori protein, binding SHP2 (a human), and acting on it the oncoprotein-based phosphatase which can produce tumor cell growth (17). Links between H.pylori and colorectal tumor either indirect such as correlating increased CagA+ levels and these lesions (18) or increased gastrin levels (19).

The aim of present study to examine the correlation between H. pylori and progressive tumor in colorectal.

### Material and Method

The present study included 50 patients which divided in to (25 were colorectal cancer, 25 were colorectal normal with H. pylori infection) and 25 subjects without any pathological findings as a healthy control group. The current case-control study was attending the gastroenterology & hepatology teaching Hospital/medical city, the endoscopy unit of Ramadi teaching Hospital, and endoscopy unit of Fallujah general Hospital unit from a period September 2019 to February 2020. Arabian patients of Iraq in the Middle East. Patients were chosen with the assistance of surgeons in hospitals. Information has been registered for every patient. Used H2 antagonist or proton-pump inhibitors treatment, former stomach operation and malignancy at another site was exclusion from current study criteria. There are various H. pylori diagnostic tests including invasive tests (endoscopy, biopsy, histopathology, rapid urease, and PCR) and noninvasive tests (respiratory urease, ELISA and stool antigen). Due to their high sensitivity, specificity and simplicity, the current research used the ELISA system. To detected the presence of anti-Helicobacter pylori antibodies. Five ml blood was obtained, from 75 for each group subjects their sera has been tested for Anti-Helicobacter pylori IgG, IgG (CagA) by using enzyme-linked immunosorbent assay (ELISA). Chi-square analyses were conducted for statistical analysis. P values below 0.05 were statistically significant and greater than 0.05 were non-significant.

### Results and Discussion

The distribution of patients according to gender was higher in the male patients with colorectal cancer and colorectal normal with Helicobacter pylori infection than female but no significant differences (P= 0.64), In Table (1)

\( C^2 = 33.084 \ P. value = 0.0005 \) Highly Significant (HS)

Colorectal cancer that combine with \textit{H. pylori} infection in our study appeared significantly higher in the old age people that agrees with previous studies like Zhao Y, et al (22). In colorectal normal with \textit{H. pylori} positive patients this study in agreement with Al-Jubori et al. (23), which demonstrated the same range of \textit{H. pylori} infection at age between (48-58) in Duhok province while not match with study(24), who recorded the highest infected group ranged between (20 - 39) years old. Highest rate of infection in old age may be due to low immunity state. In Table (3). The anti-helicobacter pylori IgG antibodies was highly significantly higher in patients with colorectal cancer and colorectal normal with \textit{Helicobacter pylori} infection compared with the healthy controls (\( P = 0.00019 \)).

C2 = 26.351  P= 0.00019  P < 0.01 Highly Significant

Our study in agreement with study by (Fireman et al., 2000), that’s reported the highest rate of anti-helicobacter pylori IgG in the colorectal cancer than in healthy control, but different with Buso et al. (25), which reported H. pylori IgG antibodies was (71%) in the colorectal cancer group and patients in the control group (65%), the difference having non-statistical significance.

H. pylori have been found in the whole world repeatedly most people diagnosed with H. pylori are asymptomatic, the infection acquired for lifespan(26). It is rarely spontaneously eradicated with any therapy. According to Table (4) CagA IgG antibodies was significantly higher in the patients with colorectal cancer and colorectal normal with Helicobacter pylori infection compared with the healthy controls (P= 0.00022).

C2 =26.04  P= 0.00022  P < 0.01 highly Significant

Current study agrees with Shmuely et al, (27), which showed that in patients with colorectal cancer, seropositive CagA rate was about twice higher than in control and statistically significant, but different study with Zumkeller
et al\(^{(28)}\) who has been investigated no link between \textit{Helicobacter pylori} CagA seropositivity and incident colorectal adenocarcinoma.

There is still little understanding of the mechanism by which \textit{H. pylori} elevated the risk of colorectal cancer. CagA has a pathogenic function in increased risk of gastric cancer \(^{(29)}\). CagA toxin induces serum gastrin secretion, which can serve as a growth hormone in colonic cells \(^{(30)}\) and can cause hypergastrinemia, suggesting an appropriate mechanism for the carcinogenicity of that organism. Moreover, infected with CagA-positive \textit{Helicobacter pylori} strains are correlated with the increased risk of atrophic gastritis developing \(^{(31)}\). Secondary a tropical gastritis to \textit{Helicobacter pylori} infection is associated with decreased acid production which makes the intestinal tract more common to a large number and variety of microbial species, which are associated with tumor in colonic growth \(^{(32)},^{(33)}\). A number of observational studies have investigated the correlation between \textit{H.pylori} serum positive and colorectal cancer risk \(^{(21)},^{(34)}\) and other found no relationships at all between this infection and the cancer \(^{(35)}\).

Another study by PCR The incidence of \textit{Helicobacter pylori} in colorectal adenocarcinoma tissue was significantly higher in contrast with the normal colorectal tissue \(^{(36)}\) in particular CagA positive strains the gastric colonized mucus trigger D gastric antrum cell deficiencies. Lead to elevated of gastrin that act as mitogen proliferative of tumor in colorectal tissue\(^{(37)}\).

Conclusion

The research indicated that a significant link between CagA-positive \textit{Helicobacter pylori} and colorectal cancer; development by different mechanism. Nevertheless, Much farther studies with larger samples are required to accurately evaluate the role of \textit{H. pylori} in these pathologies. Shed further bright on their probable role in colorectal carcinogenesis with \textit{Helicobacter pylori} infection by study other virulence factor VacA cytotoxin and BabA adhesion.

A Reliable Quantification Method for Trimethoprim in Pharmaceutical Samples by HILIC-HPLC

Zahraa Muhsen Hussein¹, Ashraf Saad Rasheed²

¹Post Graduate, ²Assist Prof., Department of Chemistry, College of Science, University of Baghdad, Al-Jadriya campus, 10071 Baghdad, Iraq

Abstract

Trimethoprim is sometimes used in conjunction with sulfonamides for drug therapies. A practicable method has been developed to determine trimethoprim in pharmaceutical formulations by hydrophilic interaction liquid chromatography coupled with an ultraviolet detector. The development and investigation of a new HLIC assay of trimethoprim. The separation was made in the HALO-HILIC column using a NaOAc/HAc buffer (40 mM-pH 4.75) with acetonitrile (10:90) (v/v) as mobile phase and was quantified by UV detection at 280 nm. The limit of quantification was about 0.0242 ppm and the limit of detection 0.008 ppm. The calibration curves were linear in the investigated range (0.01-3 ppm). The recovery of trimethoprim was 99-102.5%. The method was applied in pharmaceutical formulations.

Keywords: Trimethoprim, HILIC, Tablet, syrup, UV-detection; toxicity

Introduction

Trimethoprim is an antibiotic used exclusively in bladder therapy. For the middle ear and traveler’s diarrhoea, there are other uses. In people with HIV/AIDS, pneumocyst pneumonia can be treated with sulfamethoxazole or dapsone (1, 2). Trimethoprim class of compounds is diaminopyrimidine. It has an inhibitor of sulfonamide dihydrofolate reductase, commonly prescribed synergistic antimicrobial agents mainly used in the prevention and treatment of urinary tract infections (3). And used to treatment Pneumocystis carinii pneumonia, otitis media, shigellosis, salmonellosis, and chronic bronchitis (4). Trimethoprim was available from 1969 Sulphametboxazol combined (Co-trimoxazole) but has been marketed in the US, Scandinavia since 1980 (5, 6).

For the determination of trimethoprim in pharmaceutical or biological samples, several HPLC procedures were identified (4, 7-16). Hydrophilic interaction liquid chromatography (HILIC) was a variant of normal stage liquid chromatography, but the separation mechanism employed in HILIC was more complex than that in NP-LC. Alpert proposed the abbreviation HILIC for the first time in 1990 (17). Since 2003, the number of HILIC publications has significantly increased (18). HILIC, like NP-LC, employs traditional stationary polar phases like silica, amino, or cyano (19-23). However, the mobile phase used in the mode RP-LC is identical (18, 22, 23). HILIC technology has thus recently begun to growing dramatically in the determination of pharmaceuticals, nucleosides, carboxylic acids, inorganic ions, dansyl-amino acids, and flavonoids by Rasheed and its co-workers (24-38). The goal of this study was therefore to develop and validate a simple, rapid, and sensitive HILIC method in pharmaceutical samples to determine trimethoprim.

Materials and Methods

Chemicals and reagents:

In purifying solutions, Millipore filters (0.22 μm) were used. From Sigma-Aldrich obtained trimethoprim, acetonitrile (ACN) and sodium acetate as far as the chemicals are concerned. 0.1 μs/cm (System-US Millipore) of Millipore water conductivity was used. Tablets and syrups of six different commercial companies, as follows: tablets (Supreme 500 mg-Ajanta-India, Septrin 500 mg-Aspen-Germany, Methyprin 500 mg-SDI-Iraq), syrups (Septrin Paediatric Suspension
100 ml-Aspen-Germany, Bactrim 100 ml-ASIA Pharmaceutical Industries-Syrian, Bactrim 100 ml-Pioneer-Iraq).

**Instrumentation and chromatography**

Chromatography was performed on the Merck-Hitachi HPLC System consisting of an L-6200 gradient pump; the Rheodyne valve allows injection 20 μL and UV-visible L-4200. A HILIC HALO® 2.7 column (100 mm-2.1 mm) was used. The data were collected using N2000 workstation software to empower chromatography manager. The mobile phase composed of acetonitrile with acetate buffer (40 mM-pH 4.75) (90:10) (v/v). The mobile phase was filtered through 0.2 μm Nylon filter membranes. The analysis was carried out under gradient conditions using a flow rate of 0.5 ml/min at room temperature. The chromatogram of separation and determination trimethoprim was detection at 280 nm.

**Results and Discussion**

**Optimizing the separation of trimethoprim:**

As a pharmaceutical model, trimethoprim has been selected to test the HILIC retention mechanism using HALO 2.7 column by applying the acetate buffer with ACN content as eluent. At 90% ACN and 40 mM-pH 4.75 of acetate buffer, the chromatogram was obtained (Figure 1). The systemic variability of the contents of the ACN is increasing in mobile phase compounds between 50% and 95%; the concentration of eluent between 10 mM and 80 mM with a pH between 3 and 5.5.

![Figure 1: Chromatogram for the separations of trimethoprim using Halo column](image)

Separation of trimethoprim with varying ACN content

Eluent ACN effect on trimethoprim retention was observed at 40 mM-pH 4.75 acetate buffer. Trimethoprim hydrophilic interaction behavior appears to increase by 50% to 95% in the eluent ACN ratio, with the trimethoprim retention factor increasing. Trimethoprim hydrophilicity is the explanation for this behavior; trimethoprim’s HILIC behavior is shown (Figure 2a), which was attributed to the trimethoprim log P_{OW} (-0.16) (39).

Separation of trimethoprim with varying buffer concentration
In 10-80 mM (pH 4.75) of eluent, the effect of the acetate buffer is recorded at an eluent ACN of 90 percent. The findings appear in (Figure 2b). The trimethoprim retention factor in the column should increase the rising buffer concentration in the acetate eluent. The hydrophilicity of trimethoprim is the explanation for trimethoprim behavior. The stationary process of the HILIC material is closely related.

Separation of trimethoprim with varying eluent pH

A shift in eluent pH can be used to boost the next composition of the mobile phase. The eluent pH must be modified to completely distinguish the trimethoprim in HILIC mode. At a constant buffer of 40 mM and ACN of 90%, the pH was improved from 3 to 5.5. The retention time decreases as shown in Figure 2c. This is because the amino group in trimethoprim is deprotonated.

**Figure 2:** Study separation mechanism of trimethoprim (a) Effect of ACN content (b) Effect of buffer concentration (c) Effect of pH (d) The calibration curve.

**Calibration graph:**

The calibration trimethoprim curve is developed by plotting the trimethoprim concentration against the peak area and showing the concentration range (0.01-3 ppm) as Figure 2d shows.

Statistical data information:

A detailed evaluation under HILIC conditions and a monitor of statistics in Table 1 were used for the corresponding calibration curve of trimethoprim. Precision and accuracy were evaluated on the same day and different days with RSD% and Rec.% were evaluated. The relatively small defaults and high recuperation values indicate that the proposed method is successful (Table 2).

Such findings have been compared to the results produced about those obtained in the United States Pharmacopeia protocol \(^{(40)}\) to determine the competence and efficiency of the HILIC approach. The results of the t-test and F-test variance-ratio (Table 4) which were confidential to 95% were used for data analysis. The measured values of t and F did not surpass the theoretical values so that the accuracy of the determination of trimethoprim in six pharmaceutical types does not substantially vary in both methods.

**Conclusions**

A new validated HILIC method was developed to determine trimethoprim in syrups and tablets. The HILIC method has demonstrated compliance with the ICH Harmonized Tripartite Guideline. To evaluate low ppm trimethoprim ranges, a HILIC method was developed. The suggested method was simple, fast, and sensitive enough. HILIC interaction with trimethoprim is seen in the stationary HALO phase. It is due to the Octanol-water partition coefficient value of trimethoprim.

Assessment of Serum Concentration of Ghrelin and Obestatin in *Giardia lamblia* Infected Patients: A Case Control-Study

Rana Talib Al-Nafakh¹, Hawraa Ameer Mubark¹, Raad Abdul-Ameer Al-Asady²

¹Lect. ²Assist. Prof., Department of Medical Microbiology, Faculty of Medicine, University of Kufa, Najaf, Iraq.

Abstract

Background: Globally, *Giardia lamblia* is one of the major causes of diarrhea in humans and it is the commonest reported gastrointestinal parasite. Thus, the present research work aims to investigate the serum concentration of ghrelin and obestatin in patients with giardiasis. **Objective:** The current study was designed to determine of *G. lamblia* infection effects on some biomarkers such as ghrelin and obestatin. **Methods:** The study was conducted on 48 patients infected with *G. lamblia* and 48 healthy persons, who attended the general hospital of AL-Hakeem in Najaf city from September to December 2018. **The results:** The results showed a highly significant decrease (P<0.0001) in serum concentration of ghrelin and a highly significant increase (P<0.0001) in serum concentration of obestatin in *G. lamblia* infected patients (28.85ng/ml ±3.2) and (186.53ng/ml ± 1.56) respectively, in comparison to the control group (81.39ng/ml ± 3.8) and (92.89ng/ml ±2.9) respectively, with a significant positive association between the concentrations of ghrelin and obestatin (r = 0.0954). **Conclusion:** Ghrelin and obestatin are important physiological biomarkers that can support the diagnosis of *Giardia lamblia* parasite.

Keywords: *Giardia lamblia*, giardiasis, ghrelin, obestatin, Diarrhea, Patients.

Introduction

Giardiasis is a gastrointestinal infection caused by a zoonotic flagellated protozoan parasite *Giardia lamblia*. This parasite replicates in a luminal non-invasive extracellular way into the small intestine of humans and other vertebrates, that may cause a diarrheal disease [¹]. Worldwide, *G. lamblia* is the third major infectious cause of diarrheal disease with more than 300 million detected cases annually [²].

Giardiasis in humans may be asymptomatic or associated with diarrhea, flatulence, abdominal cramp, malabsorption, bloating, and weight loss. Severe infection leads to malabsorptive diarrhea with bulky and greasy stools [³].

Because the gastrointestinal tract parasitic infection produces injurious and harmful effects on the tissues and the physiology of the host, various mechanisms that lead partially or completely to the loss of appetite, the loss weight, the malabsorptive diarrhea or afebrile status should be assessed [⁴].

Although many studies regarding intestinal protozoa as *G. lamblia* concentrate on the anorexia; to date, an appetite peptide level, ghrelin, and its derivative obestatin in the parasitic infections of the GIT have not been investigated completely.

Ghrelin is a 28-amino acid peptide, and is produced and released mainly by the stomach. Ghrelin is a main appetite regulator through initiation of meal after sensing of nutrient [⁵]. In addition, ghrelin control homeostasis of glucose by inhibition the secretion of insulin and control the hepatic output of glucose. Ghrelin signaling controls homeostasis of energy by reducing thermogenesis to decrease expenditure of energy. [⁶].

Obestatin is a 23-amino acid peptide hormone released from the stomach. Apposite to ghrelin, that causes an increase in appetite and weight (obesity), obestatin appears to act as an appetite decreasing hormone (anorectic hormone), reducing intake of food and decreasing weight gain. Obestatin also participated in ameliorating memory, controlling sleep, affecting the proliferation of cell, elevating the pancreatic juice enzyme secretion and preventing glucose-induced
insulin secretion.

Regarding the orexigenic function (appetite stimulant) of ghrelin and the anorectic effect (appetite reducer) of obestatin [7], this study hypothesized there was a reduction in the level of serum ghrelin and an increase in the serum level of obestatin in patients with giardiasis. Ghrelin is termed the ‘hunger hormone’ because it stimulates appetite, while Obestatin is an anorectic peptide.

In addition, the above functions of ghrelin and obestatin may be affected by the change in the serum levels of these two hormones which may explain many aspects in the pathophysiology of some of the giardiasis clinical features as loss of appetite, loss of weight, absence of fever, failure to thrive in children and other signs and symptoms. Therefore, the aim of the present study was to evaluate the serum concentration of ghrelin and obestatin.

The results of the current study may supply an important information regarding the effects of ghrelin and obestatin in giardiasis.

**Materials and Methods**

During the period from September to December 2018, a case-control study was designed for 48 patients (28 males and 20 females) with giardiasis and 48 healthy persons, who had no clinical evidence of any type of diseases (26 males and 22 females) as a control group.

The patients were randomly selected from patients who attended AL-Hakeem hospital, Najaf Province.

Patients have included if the general stool examination was positive for *Giardia lamblia* parasite, from both genders male or female of any age.

Any patient with giardiasis on treatment, the patient with chronic loss of appetite and/or weight for any cause rather than giardiasis, febrile patient, a diabetic patient, obese patient, and/or patient with mixed intestinal parasitic infection were excluded.

The Kufa Medical College Ethical Committee approved the protocol of this study.

**Stool Samples Collection:** Each stool sample was collected in a clean screw cap stool containers, labeled with the number and date of collection.

**Detection of *Giardia lamblia* Parasite:** Microscopic diagnosis of *Giardia lamblia* was performed immediately after the collection of the stool sample. A small amount of stool specimen was processed and for each stool specimen, normal saline and Lugol’s iodine direct wet preparations were performed at the same time, one slide by using normal saline (0.85%) for demonstrating the trophozoites motility and a slide with Lugol’s iodine 5% for identification of internal protozoal structures [8].

**Blood Specimens Collection:** Five ml of blood was collected from each patient infected with *G. lamblia* and healthy person. Blood samples were drawn in sterile plain tubes and were left for 30 minutes at room temperature. Then the tubes were centrifuged for 5 minutes at 3000 rpm. Serum was collected and kept in sterile tubes in deep freeze (-20) until use.

**Detection of Serological Markers:** Two human biomarkers (hormones) were measured in this study. The serum concentration of the two markers; ghrelin and obestatin (Elabscience Company, Bulgaria) was determined by using ELISA technique according to the manufacturer procedure.

**Statistical analysis:** Data was collected, summarized, analyzed and presented using and Microsoft Office Excel 2010 and statistical package for social sciences (SPSS) version 23. The comparisons between the difference in mean concentrations of ghrelin or obestatin of the giardiasis patients and the healthy control persons were analyzed by T-test. And Spearman correlation was used to evaluate the correlation between the concentrations of ghrelin and obestatin and the results were expressed as the correlation coefficient (r). P-value less than 0.05 was considered statistically significant.

**Results**

The current study enrolled a total of 48 patients (28 males and 20 females) with *Giardia lamblia* infection and 48 healthy persons (26 males and 22 females). Overall, the age range was from 2 years up to 71 years and 2 years up to 70 years for patients and healthy persons (control group) respectively.

The obestatin serum level of patients with giardiasis and healthy persons
The serum concentration of obestatin, in terms of mean ± standard deviation, were 186.53 ±1.56 ng/ml and 92.88 ±2.9 ng/ml in all patients with giardiasis and healthy persons respectively; with a highly significant difference (p = < 0.0001), 186.71 ±1.6 ng/ml and 93.307 ±3.1ng/ml in male patients with giardiasis and male healthy persons respectively; with a high significant difference (p = < 0.0001) and 186.28 ±1.5 ng/ml and 92.157 ±2.6 ng/ml in female patients with giardiasis and female healthy persons respectively; with a high significant difference (p = < 0.0001) as shown in figure 1.

The ghrelin serum level of patients with giardiasis and healthy persons

The serum concentration of ghrelin, in terms of mean ± standard deviation, were 28.848 ±3.2 ng/ml and 81.387 ±3.8 ng/ml in all patients with giardiasis and healthy persons respectively; with a highly significant difference (p = < 0.0001), 28.885 ±3.2 ng/ml and 82.521 ±3.7ng/ml in male patients with giardiasis and male healthy persons respectively; with a highly significant difference (p = < 0.0001); and 28.796 ±3.2 ng/ml and 79.800 ±3.9 ng/ml in female patients with giardiasis and female healthy persons respectively; with a high significant difference (p = < 0.0001) as shown in figure 2.
3.3. The relationship between Serum concentration of Ghrelin and Obestatin

The present study revealed a significant positive association between the serum levels of ghrelin and obestatin in *G. lamblia* infected persons \( r = 0.0954 \) (Figure 3).

![Graph showing the association between ghrelin and obestatin serum levels in *Giardia lamblia* infected persons.](image)

\[ y = 0.6296x - 88.582 \]
\[ R^2 = 0.0954 \]

**Fig. (3). The association between ghrelin and obestatin serum levels in *Giardia lamblia* infected persons.**

**Discussion**

*Giardia lamblia* is an intestinal protozoan and distributes throughout the world. In 2013, the infectivity rate of giardiasis in Iraq was 1.77% and the highest rate was reported in Najaf province which was 7.9% \[^9\]. So, *G. lamblia* infection is considered as a significant health problem in Najaf province.

The current study revealed a significantly lower serum level of ghrelin in patients with giardiasis in comparison with the healthy persons. The results of this study agree with the study of Al-Hadraawy *et al.* \[^5\] Which proved the decrease of serum ghrelin level patients with giardiasis. In addition, the current study agrees with most studies which proved the decrease of ghrelin concentration with parasitic disease, as in the study of Ernsoy *et al.* \[^4\].

Ghrelin level reduced in patients with *G. lamblia* infection and other protozoal and helminthic infections are suspected to recompense for a raise in the serum sugar level in these infections; explained by the association between ghrelin and insulin \[^10\]. The reduced ghrelin level in these patients recorded in the current study is consistent with the suggestion that this may be the important cause of the anorexia in patients with giardiasis \[^11\], also the loss of appetite could be the main cause that leads to loss of weight in giardiasis patients.

This decrease of the ghrelin may be due to the intestinal hypermotility in patients with giardiasis \[^11\] because the protozoan *G. lamblia* colonizes in the duodenum and jejunum by attaching to the intestinal epithelium but without any mucosal invasion \[^12\]. The mechanism of pathogenesis is summarized by the destruction of the small intestine mucosal barrier, resulting in inflammation with malabsorption of fats \[^13\].

Another probable reason which can interpret, at least partially, the low serum ghrelin concentrations in persons with giardiasis might be to reduce the peroxidation of lipid that elevated as a consequence of this protozoal infection \[^6\].

The results of the current study revealed a significantly higher serum levels of obestatin in patients with giardiasis in comparison to the healthy persons, this increase could be due to parasitic damage to mucosa of intestinal in the acute period of infection such as inflammatory, ulcerative, and pathological changes in the epithelial cells villi \[^14\]. Indeed, none of the reviewed articles study the correlation between giardiasis and serum concentration of obestatin.
This high level of obestatin is suspected to be one of the important causes beside the low level of ghrelin (as above) for the appetite loss in *G. lamblia* infected persons. The increased level of obestatin and decrease level of ghrelin reported in the current study supports what is reported by Lacquaniti et al., [7] Who stated that: opposite to ghrelin, obestatin reveals as an appetite stimulant (anorectic) hormone, reducing intake of food, decreasing the emptying of the stomach and motility of jejunum, and decreasing gain of weight, and the study of Pan et al., [15] who reported that the effect of obestatin on food intake is in contrast to ghrelin.

This difference in ghrelin and obestatin levels may be due to the gastric infection that associated with the severity of chronic inflammation and glandular atrophy in the corpus of the stomach [16].

The present study disagrees with the study of Tschöp et al., Which showed that the circulating levels of ghrelin are increased in anorexia, but obestatin is low as well as the giardia trophozoites causes an increase in the host disruption and intestinal motility [17].

In the current study, in spite of the rise in the obestatin serum concentration and the reduce in the ghrelin serum concentration in persons infected with giardiasis, the serum level of ghrelin correlated positively and significantly with the serum obestatin level. This may be explained by the fact that obestatin is a 23-amino acid peptide hormone that is derived from post-translational cleavage of preproghrelin, the same peptide precursor as ghrelin, which is a 28-amino acid peptide released from the stomach [7]. Ghrelin, a polypeptide hormone which increases appetite, and the results of this research revealed decreased levels in giardiasis. Obestatin, as an anorexigenic hormone is an important factor to fit into the complexity of the pathophysiological scenario of the protein energy wasting [18].

Beside loss of appetite and nausea, loss of weight and failure to thrive in children may be caused by the inhibition action of obestatin on ghrelin stimulation of growth hormone levels [19], where the ghrelin is able to promote adipogenesis in the adipose tissue by directly stimulating the growth hormone secretion in the pituitary and on energy-regulating centers in the hypothalamus [20] and by making a communication between the brain and the gastrointestinal tract [21].

**CONCLUSIONS**

This study concluded that ghrelin and obestatin are important physiological biomarkers can support the diagnosis of *Giardia lamblia* parasitic infection. In addition, the elevation in the serum level of obestatin, and the decrease in the level of ghrelin may be the important cause of the anorexia, loss of weight and failure to grow in patients with giardiasis.

**ETHICS APPROVAL AND CONSENT TO PARTICIPATE**

All procedures were performed in compliance with The Code of Ethics of the World Medical Association (Declaration of Helsinki). The Kufa Medical College Ethical Committee approved the protocol of this study. Informed consent was obtained for each patient and healthy person. Evaluation of the Efficacy of Beauveria bassiana in Controlling the Periplaneta Americana in Iraq

Qutebh Ahmed Hajm1, Hushm Naje Hmed2
1 MSC Insects / Lecturer, 2 PHD Insects / Assistant Professor, Department of Biology, College of Education, University of Samarra, Iraq

Abstract

The current study was conducted from the ninth month of the year 2019 to the end of the sixth month of 2020 aiming and evaluating the effectiveness of the fungus Beauveria bassiana in controlling the Periplaneta americana.

More than 250 samples were collected, and the most of them were collected for the purpose of studying Biology control. The fungus Beauveria bassiana was used in the control, where the fungus was used in four different concentrations and kneaded by mixing with water and dilution, where the concentrations were used (0.25 × 107, 0.5 × 107, 0.75 × 107, 1 × 107) and all recorded death rates of 100% in nymphs after the passage of (244,168,120,96) respectively, and in adults, a murder rate was recorded after (244,192,144,120) hours respectively, and there were significant differences in the percentage of homicide between adults and nymphs.

Keywords: Periplaneta americana, Beauveria bassiana, Cockroaches

Introduction

Cockroaches have survived on Earth for more than 300 million years, almost without change. There are approximately 3,500 species of cockroaches around the world, 50 of them are considered household pests, and the remains of their food secrete foul-smelling secretions in their places, but they are not pests. Therefore, it is dangerous, it is found in abundance near areas where there is often stagnant water or areas where there is usually constant humidity such as toilets, kitchens and sewage, and cockroaches often feed on human faeces, garbage and sewage. Cockroaches cause allergies in children and transmit pathogens such as asthma, diarrhea, leprosy and polio (1,2,3).

The cockroach is one of the most common pests in city environments which is closely related to food that carries and spreads highly antimicrobial bacteria and can act as a vector for many microorganisms that affect public health (4). Although the cockroach is not the most important vector of disease, but it has a role in transmitting some diseases such as allergies as well as the spread of diseases such as: cholera, leprosy, dysentery, diarrheal diseases and plague, cockroaches carry filth and pathogens on their legs and bodies and contamination of food upon contact (5,6).

The control of cockroach groups depends on the control of insecticides, which are among the oldest methods, such as the use of pyrethroids, organophosphates, organic chlorine, carbamates, and stomach toxins, such as hydramethlonone and sulfuramide (7).

Entomopathogenic fungi has been in use for several years as a biological control tool for many insect pests as alternatives or supplements to chemical pesticides (8). Among these species is Buveara bassiana, as commercial preparations of this fungus have proven successful in controlling many pests, as insects infect a disease known as White muscardin (9).

The aims of the current study:

1- Evaluation of the efficiency of Buveara bassiana in controlling cockroaches.

3- Evaluation of the efficiency of Buveara bassiana in controlling the Periplaneta Americana in Iraq.
Materials and working Methods

Cockroach collection and breeding

Male and female cockroaches were collected from three different areas of the city of Samarra, namely Al-Mu’tasim sub-district, Al-Huwaish district, and the city center of Samarra. 300 cockroaches were collected through the net and hand traps, and by using chemicals to push the cockroach out of the sewage streams, insects were raised and multiplied in plastic containers with dimensions 25 x 40 A poison in which wood structures were placed to accommodate the cockroach in the form of tunnels were covered with a layer of dull cloth (10).

It was placed inside a room in a dark place with the provision of appropriate conditions, from a temperature ranging between 25-45 °C and a relative humidity of 65-70%. The appropriate note is to change the water and food every ten days to avoid rotting the bread (11).

The source of the fungus B. bassiana: -

The fungus was obtained from the Ministry of Agriculture / Plant Protection Department, the biotechnology project as a commercial product, and it was used according to the instructions issued by the Department of Prevention by dissolving (5) grams of the powder in a liter of distilled water, after which the dilution process was carried out to concentration by adding distilled water to Main focus (Department of Plant Protection, 2019).

Control of Periplaneta americana and nymphs:

The mushrooms were cultivated on an agricultural medium to ensure the effectiveness of the fungus. Potato agar was used as an agricultural medium for the fungus. Five adult insects were placed in transparent plastic containers and three replications were made. The insects were sprayed with different mushroom concentrations for each container and the concentrations were 0.25 x \(7^{10}\), 0.5 x \(7^{10}\) x 0.75 x \(7^{10}\), 1 x \(7^{10}\) and with three replicates for each concentration. The control repeater was sprayed with distilled water only. The containers were placed in an incubator on a temperature of 2 ± 28 °C and a relative humidity of 5 ± 70% to maintain the water content of the cockroaches and mushrooms. The insects were monitored for a period of ten days, and the results were recorded every 12 hours.

Microbial control with B. bassiana of adults and nymphs Periplaneta americana.

The results of Table (1) show that the highest concentration of killing is the concentration 1 x \(7^{10}\), and the lowest concentration in terms of the killing rate is the concentration of 0.25 x \(7^{10}\). The concentration of 1 x \(7^{10}\) gave the highest percentage of killing after passing 48 hours, at a rate of 0 6%, followed by a concentration of 0.75 x \(7^{10}\) spore / ml, at a rate of killing 40%, then a concentration of 0.5 x \(7^{10}\) spore / ml, and the concentrations were recorded at 0.5 x \(7^{10}\), 0.75 x \(7^{10}\), 1 x \(7^{10}\) spore / ml, the rate of killing after The passage of 72 hours (80,60,40)%, respectively. After the passage of 96 hours, the concentrations were recorded (0.25 x \(7^{10}\), 0.5 x \(7^{10}\), 0.75 x \(7^{10}\), 1 x \(7^{10}\)) spore / ml killing rate (100,80,40,20)%. Respectively, after 120 hours, the two concentrations (0.25 x \(7^{10}\), 0.5 x \(7^{10}\)) were recorded as a spore / ml killing percentage (80.60)%, respectively, and the concentration reached 0.5 x \(7^{10}\) to a 100 killed percentage after 168 hours and the concentration reached 0.25 x \(7^{10}\) spore / ml to 100% killing after 240 hours.

Table (2) shows the effect of the fungus on Periplaneta americana adults in all concentrations, where the highest concentration of 1 × 710 spore / ml was recorded, a 40% killing rate after 48 hours, and a concentration of 0.25 × 710 spore / ml, a 20% killing rate, after 72 hours. The concentrations recorded (0.25 × 710, 0.5 × 710, 0.75 × 710, 1 × 710) spore / ml killed a percentage of (60,60,20,20)%, respectively, but after 96 hours the concentration was recorded (0.5 × 710, 0.75 × 710, 1 × 710) spore / ml killing rate 80,80,60%, respectively, but after 120 hours the concentrations were recorded (0.5 × 710, 0.75 × 710, 1 × 710) spore / ml killing percentage) 100, (80.40)%, respectively, and after 144 hours, the two concentrations (0.25 × 710, 0.5 × 710) recorded a spore / ml killing percentage (100,80) respectively, and the concentration reached...

(0.5 x 10^7) spore / ml to 100% killing after 192 hours. As for the concentration (0.25 x 10^7) spore / ml, it reached a 100% killing rate after 240 hours. It was found through the results of the study that the nymphs were more susceptible than the whole insects to the fungus, and this is due to the frequent shedding that causes the nymph to undergo periods of weakness in the Q-layer in the initial stages after molting, which facilitates the process of penetration by the hepatitis of B. bassiana. It was also found that the effect of reducing the concentration of the fungal suspension was significant on the severity of the infection, and that the correlation was positive between the percentage of killing and the concentration of the sporophyte suspensions of the fungus, and the dilution could be considered an important factor in the efficiency of the fungus in eliminating the *Periplaneta americana*.

(12)

The study showed that increasing the duration of exposure is another determinant factor for increasing the efficiency of the fungus so that the spores can grow and begin to penetrate the cockroach’s qi and penetrate into the internal tissues of the cockroach, as well as making holes in the q-layer and thus increasing the chance of the cockroach being exposed to water loss, and the direct influence of environmental conditions as a result of exposure to the body wall. To the damage caused by the penetration of the hyacinths of the fungus to the wall of the body. (13)

The results of this study gave clear evidence of the possibility of using the fungus B. bassiana in controlling and eliminating the *Periplaneta americana* under specific conditions and times that depend on moderate temperatures and suitable humidity, which is a prerequisite for the control procedure, because the fungus needs specific conditions of temperature and humidity to enable it to activate its efficiency in infestation. The insect and its elimination. (14)
pointed out about the effect of fungi on the life roles of mosquitoes, as the fungus succeeded in controlling mosquitoes as well as succeeding in controlling the spread of malaria.

Conclusions

The possibility of using microbial control to reduce the spread Periplaneta Americana.

Fung B. bassiana can be used to control the spread of the *Periplaneta Americana*.

Recommendations

Conducting further studies using microbial control to reduce cockroach spread

The Effect of Biomarker (IL-8) on the Tissue of Colorectal Cancer Patients by using IHC Technique

Zinah Saad Madhloom¹, Aqeel Shakir Mahmood², Alice Krikor Melconian³
¹Senior biologist/Ministry of Science and Technology/Iraq, ²Assistant Professor/Department of Surgery/College of Medicine/University of Baghdad/Iraq, ³Professor/Biotechnology Department/College of Science/University of Baghdad/Iraq

Abstract

Aim: The search to evidence a link between the molecular markers (IL-8) with colorectal cancer. The aim of the presented work is examining the relation regarding the biomarker (IL-8) in colorectal cancer (CRC) tissues as well as its relation with the other clinic pathological variables.

Methods: The detection of IL-8 was confirmed using histopathological examination of colonic biopsy of tissue section fixed on slides previously coated and analyzed by immunohistochemistry method (IHC), hence to detect the variable regarding IL-8 expression in normal as well as CRC tissues including (adjacent normal tissue and healthy controls tissues); in addition to its association with other clinic-pathological variables (intensity, gender and age).

The results of the study specified the enrichment regarding IL-8 expression in the samples of CRC with the use of IHC approach. No considerable relation has been indicated between the expression of IL-8 with the other clinical-pathological variables (gender and age), yet there has been considerable relation between the expression of IL-8 and the stain’s intensity (grade), while it has been increased in tissues of CRC; this might be specified as one of the risk factors with regard to the CRC’s development and the metastasis in the samples of CRC, also it might be significant marker to predict insignificant prognosis in patients experiencing CRC, also it can be utilized as possible therapeutic target in the CRC.

Keywords: Immunohistochemistry technique, Biomarker, Colorectal cancer, Metastasis.

Introduction

The cancer’s incidence is increased yearly. CRC can be considered as the second most general cause regarding mortality from cancer in Western world ¹. A lot of factors (genetic and environmental) have been involved in mortality as well as propagation resulted from CRC. From the many trophic factors, chemokines were of major role.

IL-8 can be defined as chemokine that is created through a lot of tumor in addition to normal cells, also its major role is in the amplification and initiation regarding acute inflammatory reactions. Furthermore, IL-8 was involved in the chronic inflammatory process in addition to the diseases with the chronic inflammatory component including cancer (colorectal), the level has been increased with the progression and metastasis of disease ²,³.

Interleukin-8 (IL8), belong to neutrophil-specific CXC sub-family of chemokine (ELR) with defining CXC amino acid motif including (Leu, Arg, and Glu), which might not only be acting on Leukocyte chemotaxis, infectious diseases and inflammatory responses ⁴. IL8 is generated by many different normal cells and tumor cells and its main goal is initiating and amplifying acute inflammatory reactions. IL8 was implicated as well in the chronic inflammatory diseases and procedures with chronic inflammatory components like the cancer ³. It has been known to be possessing pro-angiogenic and tumorigenic characteristics. IL8 over-expression was discovered in numerous human tumours, inclusive the CRC, and is related to insufficient prognoses ⁵. The cells of the tumor generate IL8 as an autocrine factor.
of growth that promotes the growing of the tumor, metastatic spread, and invasion of tissues. Ning and coworkers reveal that the use of a xenograft model of the tumor, cells that express IL8 produced considerably larger tumors compared to control cells with enhanced density of the micro-vessels.

Whereas the applications related to the immunological approaches to the histopathology caused marked improvement in microscopic diagnosis that is related to the neoplasm. Even through that the histological analysis regarding Haematoxylin & Eosin (H&E) stained tissue section remain the core related to practice of neck and head surgical pathology, due to the fact that immunohistochemistry (IHC) remains the major applied and provided approach in pathology for determining the expression status regarding tumor-associated proteins, also for studying the clinical prognostic relevance related to the biomarkers.

This work has been developed for examining the differences in the expression of IL-8 between the tissues of CRC in addition to the matched adjacent normal mucosa tissues, as well as the relation between expressions of IL-8 as well as the clinic pathological features in the CRC.

Materials and Methods

Surgical specimens

Fresh specimens (80) of colorectal tissues were collected from patients with CRC (n=42) beside healthy control individuals (n=10). Likewise; (n=28) CRC samples from (n=42) were matched with adjacent normal tissue (n=28). All these specimens were obtained from patients underwent colonoscopy and segmental colonic resections, those that were diagnosed as having colorectal cancer with different grades or healthy tissues were considered as a control group.

All these tissue samples were collected from patients; admitted maintained in different hospitals in Baghdad city, during the period of 2018 -2019.

All sought after datum on demographic and clinical histopathological parameters which was gained from the patient’s medical records and designed information sheet. The exclusion criteria were on patients for CRC patients including chemotherapy or radiation treatments prior surgery, also excluded the patients who had another malignancies or polyps in another organs. All participants received conventional bowel preparation without preoperative antibiotic administration.

Histopathological Examination

It was performed according to the method. The histopathological examination of the colon tissues which were selected from the patients of CRC were determined after fixing, and sectioning the organs, then staining them as well as Immunohistostaining. All these were performed in the Educational Laboratories in the City of Medicine as follows:

1- Preparation of Histological Sections:

At the moment of eradication the part of Colon tissue or Rectum was removed and then washed with PBS, preserved and fixed in 10% formalin for (24-48) hr. Then the section was washed up with tap water and processed with a set of increasing ethanol concentrations for 2hr at each concentration. After that, the tissue was clarified in xylene for 2hr, then it was impregnated in melting paraffin at 60-70°C for 1hr. The tissue was embedded in paraffin blocks and waited to be solidified, finally it was sectioned using a microtome at slices of (5-6μm) and they were mounted on the slides. The sections of tissue have been stained with the eosin stains and hematoxylin, after that the cell morphology has been identified within light microscopy.

2- Immunohistochemical examination:

Specimen preparation for IHC staining:

The tissue sections of human cancer subjected to immunohistochemistry analysis with the use of GenTex System (Gen Tex / USA) as well as PolyExcel HRP/DAB Detection System (Pathinsitu / USA) on the basis of the instructions of manufacturer. Put briefly, the tumor blocks have been formalin-fixed, paraffin-embedded and cut into 4-μm-thick sections.

Antibody dilutions:

IL-8 is concentrated antibodies, hence diluted them with antibodies diluent according to company (Pathinsitu and Gen Tex) sheet enclosed with them:

IL-8 was diluted by ratio of 1:100-1:1000 (according
to the sheet between 100-1000), by taking 1xPBS, 20%Glycerol(pH7), 0.025% ProClin 300 which was added as a preservative.

Controls of marker:

Tissues of Gastric Ca known to express the antigens of interest have been utilized as positive controls. Whereas for negative control, omitting primary antibody and after that has been replaced with PBS.

Immunohistostaining steps:

This was accomplished according to 10.

The slide’s evaluation has been made through the pathologists which is blinded for the characteristics of patients. Slides have been scored in the following way on the basis of an approach suggested via 11: Intensity related to staining has been classified from 0 to 3, as 0(-) negative, 1(+) low or weak, 2(++) moderate, and 3(+++) high or strong. The staining’s extent has been indicated as the percentage regarding positive cells with regard to the whole tumor area, has been classified from 0 to 3, as 0(0%), 1(10-20%), 2(20-50%), 3(>50%). The final staining score has been evaluated through adding staining intensity as well as the staining’s extent.

Statistical Analysis

Data analysis has been conducted with the use of available statistical package of SPSS-25. The data have been provided in simple frequency measure, percentage, standard deviation, mean, in addition to range (minimum-maximum values).

The significance of difference regarding various percentages (qualitative data) has been tested with the use of Pearson Chi-square test ($c^2$-test) with application regarding Yate’s correction or Fisher Exact test when appropriate. Statistical significance has been specified when the P value has been equal or not more than 0.05.

Results

H&E stained

The results of intensity of the stains (grade of differentiation) was classified from 0 to 3, as 0(-) negative, 1(+) poorly, 2(++) moderate, and 3(+++) well differentiated.

The expression of IL-8 in CRC

The results regarding cytokine IL-8 illustrated an increased in IL-8 expression [from score (+1, +2, +3)] as seen in (Figures 1A,1B, and1C) respectively, as well as positive stained cells in cancer cells of patient compared with healthy control, and adjacent normal tissue. The results of statistical analysis indicated a significantly increased in IL-8 expression in CRC tissue in comparison to adjacent controls as well as healthy control individuals as showed in (Tables 1, and 2); while no significant association appeared between adjacent normal tissue compared with healthy control tissue (Table 3). As well as no considerable relation has been indicated between IL-8 expression and other clinic pathological variables (age, gender) (Table 4).

Figure 1: IL-8 IHC Scores expression (400x): A- Score +1 expression; B- Score +2 expressions; and C- Score +3 expressions.
Table 1: The data regarding the significant expression of IL-8 scoring and intensity of stain in patient’s cancer tissue compared to healthy control individual’s tissue.

Discussion

The over-expression regarding IL-8 was recognized in various human tumors, such as CRC, also it is related with the poor prognosis.5

With regard to colonic mucosa, the upregulation that is related to IL-8 happen in relation to the inflammation’s degree in ulcerative colitis and the Crohn’s disease.12,13 With regard to the human colon cancer cell lines, constitutive expression related to IL-8 was associated to the metastatic potential,14 also was indicated to be of high importance in the progression of distant metastases. Some researches indicated that the induction related to the IL-8 signaling elevated the NF-κB transcriptional activity.15,16 A study conducted via 17 examined the patterns related to the gene’s expression in colon cancer cells in addition to the corresponding normal mucous cells through DNA microarray analysis, indicating an elevation in the IL-8 expression in cancer cells in comparison to adjacent normal mucosa. Furthermore, a study by 18 indicated that increased levels of IL-8 mRNA in tumor tissue in comparison to corresponding normal mucous tissue, more often positive staining with regard to IL-8 protein specified in poorly and moderately differentiated tumors in comparison to excellently differentiated tumors (P=0.024). A research carried out via 14 assumed that IL-8 expression in colon carcinoma cells is of high importance in metastasis and growth, also such data in accordance with the results of 19. Results specified no considerable relation between IL-8 expression scoring a gender or age related to the patients.

While another supported that CXCL8 expression has been considerably upregulated in the tumoral samples in comparison with the normal tissue, and such upregulation elevated with the age of patients.2 The results suggested that IL-8 staining has been more common in well-differential and moderate tumors in comparison to adjacent and healthy controls which were stained poorly or mildly and negative differentiated. While Čačev et al.18 showed that the positive immunohistochemically IL-8 staining has been more common in poorly and moderately differentiated tumors in comparison to excellently differentiated ones.

Conclusion

The highly elevated expression of IL-8 in CRC tissues; may be specified as risk factor with regard to the CRC’s development and metastasis in CRC samples and may be of high importance marker to predict poor prognosis in the patients experiencing CRC that might be applied as possible therapeutic target in CRC.

Prevalence and Risk of Leukemia Reported Cases, Observational Descriptive Statistic from Iraqi Center for Hematology in Baghdad Province

Ruaa Hameed Abdulridha¹, Nada Kadum Jawad², Ahmed Tariq Numan²

¹Assistant. Instructor, Department of Biotechnology, College of Science, University of Baghdad, Baghdad, Iraq,
²Assist. prof. Department of Medical Laboratory Technology, Al-Mustafa University College, Baghdad, Iraq

Abstract

Background: Leukemia is one type of blood cancer developed in the bone marrow and other blood-forming organs. Based on a combination of onset speed and cell origin, leukemia can generally be divided into four subtypes: acute lymphoblastic leukemia (ALL), acute myeloid leukemia (AML), (chronic lymphocytic leukemia (CLL), and chronic myelogenous leukemia (CML).

Methods: A total of 3102 eligible leukemia cases were documented in the Iraqi Center for Hematology in the City of Medicine in Baghdad between January 2018 and December 2019. 1402 documented in 2018 and 1700 in 2019 for all types of cancer. Patients ages were between 1 year and 90 years, among all leukemia cases, the mostly 36% (n = 730) were aged ≤15 years. Results In our study males accounted for a higher proportion of leukemia patients, 58% compared to 42% females, ALL was the more prevalent type among the studied group for both years; contribute% 55.17 din male %53.45 in female, followed by AML 36.87% vs 40.27%, CLL 5.23% vs 2.22% and CML 2.73% vs 4.06% in male and female respectively. Conclusion It was observed that the prevalence of leukemia in Baghdad increased between (2018-2019) from 1402 to 1700, the youngest age 15 registered most of leukemia cases. Males were mostly victim of the disease as compared to females which were less frequent. It was observed that acute lymphoblastic leukemia (ALL) was most common type of leukemia.

Key Words: Leukemia; Prevalence; acute myeloid leukemia; chronic lymphocytic leukemia; and chronic myelogenous leukemia.

Introduction

Leukemia is type of blood cancer originally developed in the bone marrow and other blood-forming organs. Based on a combination of onset speed and cell origin, leukemia can generally be divided into four subtypes (1).

(I) Acute lymphocytic leukemia (ALL) is a malignant transformation and proliferation of lymphoid progenitor cells in the bone marrow, blood and extramedullary sites; While 80% of ALL occurs in children, it represents a devastating disease when it occurs in adults. Within the United States, the incidence of ALL is estimated at 1.6 per 100,000 population. In 2016 alone, an estimated 6590 new cases were diagnosed, with over 1400 deaths due to ALL (American Cancer Society). The incidence of ALL follows a bimodal distribution, with the first peak occurring in childhood and a second peak occurring around the age of 50 (2).

(II) Acute myelogenous leukemia (AML) is the second most common pediatric leukemia with poor outcomes indicated by 5-year survival rates of 50-60% (3). The difficulty of obtaining bone marrow samples and the in vitro cytarabine chemo sensitivity in primary AML cells is probably the reason for the lack of such studies, especially in pediatric patients (4).
(III) Chronic lymphocytic leukemia (CLL) is characterized by a clonal expansion of mature CD5 CD23+ B-lymphocytes that accumulate in the bone marrow and infiltrate lymphoid tissues such as the spleen and lymph nodes (5). CLL is the most common leukemia in the Western world, is a heterogeneous disease remains incurable in virtually all cases. CLL predominates in the elderly, and the incidence of the disease increases exponentially with age (6). Thus, the number of CLL patients is expected to rise in the future, given the increase in the aging population, bringing to light new clinical challenges and public health issues. Patients with CLL show a tremendously variable clinical course ranging from excellent prognosis with no treatment to short-term survival, despite early initiation of therapy (7).

(IV) Chronic myelogenous leukemia (CML) Chronic myeloid leukemia (CML) is a myeloproliferative neoplasm with an incidence of 1–2 cases per 100 000 adults. It accounts for approximately 15% of newly diagnosed cases of leukemia in adults. In 2017, it is estimated about 9000 new CML cases will be diagnosed in the United States, and about 1000 patients will die of CML. Since the introduction of imatinib in 2000, the annual mortality in CML has decreased from 10%-20% down to 1%-2%. Consequently, the prevalence of CML in the United States, estimated at about 25–30 000 in 2000, has increased to an estimated 80–100 000 in 2017, and will reach a plateau of about 180 000 cases by 2030 (8).

Finally cancer is one of the leading causes of mortality in developed and developing countries. It is expected that the Incidence and burden of cancer will increase throughout the World due to the population growth and aging especially in less developed countries which account for about 82% of the world’s population (9).

Material and Methods
We conducted a retrospective, descriptive, epidemiological study of leukemia cases for both gender in the Iraqi population diagnosed between January 2018 and December 2019. The data of this study that include the gender, clinical history, age, type of leukemia were managed and registered by Iraqi Center for Hematology, which is a clinical center in the City of Medicine in Baghdad, that diagnose and registry hematology disease in the Iraq except Basra and Kurdistan regions. The variables calculated were for example patient’s age, gender, type of leukemia and their residence addresses. Controls have been chosen by keeping the patients’ detail in consideration. Diagnoses were including peripheral blood films and morphology of bone marrow which involved cytochemical staining and immunophenotyping. Selected topic was accepted by scientific committee; official acceptance was taken from health authorities to conduct this study. Collected information was kept confidential.

Statistical Analysis
All statistical analysis was carried out by using statistical package for social sciences (SPSS) 16.0 version. Odds ratios with 95% confidence intervals were calculated to determine the strength of the associations.

Results
A total of 3102 eligible leukemia cases were documented in the Iraqi Center for Hematology between January 2018 and December 2019. 1402 documented in 2018, 900 were males (64.2%) and 502 were females (35.8%) and 1700 in 2019, 898 were males (52.8%) and 802 were females (47.2%). The percentage of cases with leukemia in male was more than female (Table 1). Patients ages were between 1 year and 90 years, among all leukemia cases, the mostly 36% (n = 730) were aged ≤15 years.

The commonly morphological distribution of leukemia in 2018 was acute lymphoblastic leukemia (ALL) by 498 cases (65%) for males and 273 cases (35%) for females followed by acute myeloid leukemia (AML) by 335 cases (63%) for males and 198 cases (37%) for females then chronic lymphocytic leukemia (CLL) by 59 cases (84.3%) for males and 11 cases (15.7%) for females and finally chronic myeloid leukemia (CML) by
8 cases (29%) for males and 20 cases (71%) for females (Table 2).

The commonly morphological distribution of leukemia in 2019 was acute lymphoblastic leukemia (ALL) by 494 cases (55%) for males and 424 cases (52.9%) for females followed by acute myeloid leukemia (AML) by 328 cases (36.5%) for males and 327 cases (40.8%) for females then chronic lymphocytic leukemia (CLL) by 35 cases (3.9%) for males and 11 cases (15.7%) for females and finally chronic myeloid leukemia (CML) by 8 cases (29%) for males and 20 cases (71%) for females (Table 3).

Regarding the distribution of types of leukemia in our study as a total, ALL was the more prevalent type among the studied group, contributed (55.17% male versus 53.45% female), followed by AML (36.87% male versus 40.27% female), CLL (5.23% male versus 2.22% female) and the less frequent type was CML which contributed only (2.73% male versus 4.06% female). The results show a significant difference in number of cases between male and female in all types. ALL, AML and CLL more incidence in male than female while CML more incidence in female than male. (Table 4).

Discussion:

The present study demonstrated increasing in the leukemia cases from 2018 to 2019. This is logical due to the large number of wars and crises that occur in Iraq. In the last 31 years (1980-2010), Iraq has seen three wars, (Iran-Iraq war, 1980-88), (Gulf War, 1990-91), and (Iraq War, 2003) as well as Economic sanctions (1990-2003), Sectarian war (2006-2007) and American occupation (2003-2010). These varieties of wars and crises have a negative impact on the people’s health. (10). Similarly (Alghamdi et al.’(2014) and Ghojogh et al.’ (2015) reported increasing in the incidence of leukemia cases in Saudi Arabia and Iran patients respectively (11, 12).

The present local study demonstrating that the percentage of cases with leukemia in male (58%) was more than in female (42%). Iraqi population in other region of Iraq, Karbala Province also reported a similar finding that accounted 58.2% for males and 41.8% for females between November 2011 to May 2018 (13), in Brazil, it is estimated the prevalence of leukemia in male more than female also (14). Saudi study performed in 2001-2008 also confirmed the result (15).

The most prevalence aged were ≤15 years was clearly obtained (15), while another Iraqi study in Karbala Province, showed the most prevalence aged were ≤10 years (13). As well as 60% of patients in United States were under 20 years of age (16).

In our study ALL was the more prevalent type among the studied group; contributed 54.31% (% 55.17 in male %53.45 in female, followed by AML 38.57% (36.87% vs 40.27%), CLL 3.73% (5.23% vs 2.22%) and the less frequent type was CML which contributed only 3.4% (2.73% vs 4.06%). This result was in similar with the data from studies in other region of Iraq, Karbala Province that ALL is the more prevalent type with 41% followed by CML 24.1%, AML 19.2% and CLL 15.7% (13) and Sulaymaniyah province ALL was the most common type of leukemia with 44% in all cases, CML was the second type with 20% of cases followed by CLL, 18% and AML, 17% (17).

In Croatia, the most common type of leukemia was CLL, which accounted for 42% of leukemia, followed by AML with 27%, ALL with 17% and CML with 14% (18). In Bangladesh, on the other hand, AML was the most prevalent hematological malignancy 28.3% followed by CML 18.2 %, ALL 14.1 % and CLL 3.7 % was the least common (19). In addition, Indian study seem to reinforce the result that ALL is the most prevalent type...
in leukemia (20).

**Conclusion**

It was observed that the prevalence of leukemia in Iraqi Center for Hematology in Baghdad Province increased between (2018 - 2019) from 1402 to 1700, the youngest age ≤ 15 registered most of leukemia cases. Males were mostly victim of the disease as compared to females which were less frequent. It was observed that acute lymphoblastic leukemia (ALL) was most common type of leukemia. Epidemiological study can play a vital role in understanding the occurrence and outcome of the disease.

Detection of Fungal Toxins Produced by Dermatophytes by using Thin Layer Chromatography

Abeer Mohammed Ali Al-garawyi1, Adnan H. Al-Hamadani2, Adnan waheed Al-Bederi3
1Post graduate Biology Department, Education for Pure Science College, Al-Muthanna University, Iraq, 2 Prof. Department Microbiology/ College of Medicine / Al-Qadisiyah University, 3Prof. Department Anatomy/ College of Medicine / Al-Qadisiyah University

Abstract
Dermatophyte fungi include a wide range of filamentous fungi that are pathogenic to humans including three superficial cutaneous genera such as ; Epidermophyton, Microsporum and Trichophyton. However, the aim of this study isolation and identification of fungi responsible of dermatophytosis and detection of the dermatophyte ability to produce mycotoxins. The results of this study showed that 49(69.01%) out of 71 specimens were gave positive results , while 22 (30.98%) were gave negative results by examination on 10%KOH and cultured on Sabouraud dextrose agar with cyclohexmaide. Out of 49 culture positive isolates, 31(63.3%) T. rubrum isolates was the most frequent etiological agent followed by 11( 22.4%) T. mentagrophytes ; 5(14.3%) M. canis and 2 (4.1%) Epidermophyton floccosum isolates. The use of the TLC method to detect of mycotoxins in chloroform extracts for 49 dermatophyte mycelia. It was found all dermatophyte isolates are able to produce fluorescent stains with different colors under UV light at 365 nm , also these stains may be act as a non-enzymatic virulence indicator (mycotoxins).

Keywords: E. floccosum , Dermatophytosis, TLC , Mycotoxins.

Introduction
Dermatophytes are anamorphic genera which includes Epidermophyton, Microsporum and Trichophyton , all of these genera cause superficial fungal infection called dermatophytosis. Dermatophytes are also characterized as keratinophilic fungi, as they infect the skin, hair, and nails of humans and animals. Usually, dermatophyte infections are limited only to the outer layer of the epidermis and also unable to penetrate the deep tissues of a healthy individual (1) . Dermatophytes are included Anthropophiles ( infect human) , zoophiles ( infect animals) and geophiles (soil dwelling), all of these subdivisions according to their natural habitat. Dermatophytes are characterized by the secretion of large quantities of analyzed enzymes such as lipase , elastase, keratinase, phospholipase and protease depending on the specificity of the different substrate , the pathogenicity of host tissues occurs (2) . Keratinase enzyme produced by Bacillus species (3),(4) Streptomyces (5) and also dermatophytes fungi (6) . The outer layer of the epidermis characterized by being rich in keratinous substance such as the skin, hair and nails , which is considered a favorite for the dermatophytes fungi. In addition to keratinase, protease is also regarded one of the most important enzymes produced by dermatophytes as a virulence factor(7). There are non-enzymatic virulence factor that are produced by dermatophytes fungi such as ; xanthomegnin is mycotoxin produced by T. rubrum, which is also produced from Penicillium and Aspergillus , whether in vitro or in vivo causing nephropathy and death in animals. The T. rubrum culture characterized by red pigmentation on the reverse side , this is explained by the production of xanthomegnin which is also noted in infected skin and nail specimens (8). There are limited species of dermatophytes that have the ability to produce
 materials or melanin-like compounds, whether in vitro or in vivo, which play a similar role in pathogenesis of dermatophytic diseases (9). Aim of this study; isolation and identification of fungi responsible of dermatophytosis and detection of dermatophyte ability to produce mycotoxins such as Aflatoxin-like compounds chemically and separation of these mycotoxins by Thin Layer Chromatography (TLC).

**Materials and Methods**

**Isolation and Identification of fungal isolates:**
71 samples were collected from patients with dermatomycosis infections during period from February 2018 to January 2019. All the specimens were divided into two portions, one portion for direct examination under light microscope and other was cultured on sabouraud dextrose agar.

**Detection of dermatophytes ability to produce mycotoxins:**

**Isolation and purification of mycotoxins:**
We used nutrient broth (NB) to detection of mycotoxins produced by dermatophyte fungi. Subsequently, prepared 25 flask with volume 500ml then each flask added to it 250 ml NB, after sterilization and cooling, the culture media was inoculated with agar blocks of 5 mm of pure isolates grown on sabouraud dextrose agar SDA for 7 days at a rate of one disk per flask, except one flask left without inoculation as a control for comparison, and incubated at 28 °C for three weeks. After incubation, the entire contents were filtered with a sterile, clean gauze and then chloroform was added to the broth (1:1) in a separation funnel. The mixture was shaken for a few minutes then separated an upper layer containing spores and mycelia, and a lower layer containing chloroform and mycotoxins. The bottom layer filtered through a Whatman No. 1 filter paper then concentrated by using reflective condenser to approximately 1 ml in dark bottles (10).

**Detection of mycotoxin by using Thin Layer Chromatography technique (TLC):**

This experiment was carried out in a toxicology laboratory at the College of Applied Medical Sciences/ Karbala University, where used Thin Layer Chromatography plates (TLC) with dimensions of 20 * 20 cm, after activated in the electric oven at a temperature of 105 °C for an hour before use (11). The separation system used consists of chloroform : methanol 98:2 and 15μl of standard mycotoxin was taken by capillary tube, and put on the line a distance of 2 cm from left edge of the plate and at a distance of 2 cm between the spot of standard mycotoxin put an amount equal to the standard mycotoxin from the first fungal isolate extract and thus to the rest isolates extract. After that, the plate was placed in the separation tank containing the separation system consisting of a mixture of chloroform and methanol, at a ratio of 98: 2 v/v. The separation solution was monitored until it reached a distance of approximately 2 cm from the top end of the plate, then plates removed and dried under laboratory conditions for a period of 5min (12). Then compare the RF value and color for the mycotoxins spots with standard.

**Determination of UV absorbance:**

The partially purified mycotoxin compounds which produced by dermatophytes fungi subjected to UV radiation at a wavelength of 365 nm absorption spectrum on TLC to distinguish the absorption bands in the sample (12).

**Results and Discussion**

The result of this study showed 49(69.01%) out of 71 specimens were gave positive results, while 22 (30.98%) were gave negative results by examination on 10%KOH and cultured on Sabouraud dextrose agar with cyclohexmaide (SDAC) (Fig-1).
The results of this study showed that there is a statistical significant (P<0.05). This result is identical to the results of Lafta [13]; Maluki and Alaa [14]. Out of 49 culture positive isolates, 31(63.3%) T. rubrum isolates was the most frequent etiological agent followed by 11(22.4%) T. mentagrophytes; 5(14.3%) M. canis and 2(4.1%) Epidermophyton floccosum isolates (Fig-2).

The results of this study showed that there is a statistical significant (P<0.05). However, this result is matching with the results of Al-Shamei [15] but not compatible with results of Hindy and Abiess [16] who found Trichophyton species was most frequent etiological agent followed by Microsporum species. Anupama, [17] who found 33/63(52.4%) T. rubrum isolates were most predominant followed by T. mentagrophytes 20/63(31.7%) and M. gypseum 2/63(3.2%). This study showed that 49(100%) culture positive isolates possess the ability to produce fluorescent spots with different colors when chemically analyzed by using TLC technique. As well as, the fungal isolates varied in their production for these stains, depending on comparison of spots size and fluorescent intensity under UV light with standard mycotoxin as shown in (Fig-3).
The results of current study also showed that some of these spots had Rf. an identical to the standard Rf., while the other spots had Rf. different from the standard Rf. Although there are no previous studies and scarcity of references about this topic for the purpose of comparison, the precise diagnosis for these compounds is focus of the current studies, in our lab.

**Conclusion**

The use of the TLC method to detect of mycotoxins in chloroform extracts for 49 dermatophyte mycelia. It was found all dermatophyte isolates are able to produce fluorescent stains with different colors under UV light at 365 nm, also these stains may be act as a non-enzymatic virulence indicator (mycotoxins).

Possible Protective Effects of high- versus low- dose of lutein in combination with irinotecan on Liver of Rats: Role of Oxidative Stress and Apoptosis

Alaa Radhi K1, Nada N. Al-Shawi
1Assist Lecturer, 2Prof. Department of Pharmacology and Toxicology, College of Pharmacy, University of Baghdad, Iraq

Abstract

Objectives: The current study was designed to describe roles of oxidative stress via the measurement of malondialdehyde and total antioxidant markers, and apoptosis through the measurement of caspase 3 marker, as mechanisms of liver toxicity induced by irinotecan; and to explore the possible protective effects of high- and low- doses of lutein against irinotecan induced toxicity in the liver of rats.

Methods: Thirty six (36) Sprague-Dawley rats were randomly divided into six groups: Groups I, rats received single oral daily dose of dimethyl sulfoxide (4 ml/kg); Group II (irinotecan-treated), received single oral daily dose of dimethyl sulfoxide (4ml/kg) for 25 days by oral gavage and subsequently received irinotecan (50mg/kg) on days: 5, 10, 15 (total dose=150 mg/kg) by intraperitoneal injection; Groups III and IV, received oral dose of lutein (6mg/kg/day) and (24mg/kg/day), respectively by oral gavage for 25 successive days (lutein-treated); Groups V and VI (lutein+ irinotecan), received oral dose of lutein (6mg/kg/day) and (24mg/kg/day), respectively by oral gavage for 25 successive days, and subsequently received irinotecan (50mg/kg body weight) on days: 5, 10, 15 (total dose=150 mg/kg) by intraperitoneal injection.

Results: Orally-administered lutein with total cumulative dose of irinotecan (Groups V and VI), resulted in significant reduction (P<0.05) of serum aspartate aminotransferase and alanine aminotransferase, and significant reduction (P<0.05) of malondialdehyde; but, significant elevation (P<0.05) of serum total antioxidant capacity; and there was significant reduction in caspase 3 in liver tissues homogenates compared to the corresponding levels in the group of rats administered irinotecan (Group II).

Conclusion: Results of the current finding suggested that administration of lutein may be a useful compound that alleviated irinotecan induced toxicity to the liver.

Keywords: Lutein, Irinotecan, AST, ALT, Malondialdehyde (MDA), TAOC, Caspase 3 (Casp-3).

Introduction

The DNA topoisomerase enzymes are fundamental to cell function and abundantly found in all fields of life; and different topoisomerase enzymes precede a vast range of functions regarding to the maintenance of DNA topology within DNA transcription and replication; and are targets of a broad range of anti-microbial and cancer chemotherapeutic agents (1).

Irinotecan (CPT-11), a semisynthetic drug that was derived from the natural alkaloid plant camptothecin which was clinically introduced in the late of 1980s (2). Such drug is vastly used in the treatment of pancreatic, colorectal, and lung cancer; furthermore, irinotecan is a prodrug for the active metabolite SN-38, which is 100- to 1000-fold further cytotoxic more than irinotecan (3).

Authors reported that, the mechanism of the antitumor action of irinotecan is through the inhibition of DNA topoisomerase I that it can cause DNA damage
which consequently may lead to cell death in fast-proliferating natural cells such as intestinal basal cells and BM cells (4); the interaction of irinotecan with topoisomerase type I (Topo I)–DNA cellular complexes has cytotoxicity in S-phase-specific. Irinotecan also kill the non-S-phase cells at greater concentrations through mechanism related to DNA damage by transcriptionally induced and other mechanism of apoptosis (5); thus, treatment with irinotecan can be associated with gastrointestinal (GI) and hematologic toxicities; where, the main dose-limiting toxicities are sever delayed diarrhea and neutropenia, respectively (4).

Lutein is a carotenoid pigment; and it is a compound of xanthophyll group that found abundantly in kale, corn, animal fat, spinach, etc. (6). It cannot be synthesized by human body but can be provided only by diet or supplementation (7). Moreover, lutein can selectively be taken up into the macula of the eye where it thought to protect against the development of age-related macular degeneration (8). Also, It has been reported that lutein exhibited antioxidant, anti-genotoxic property, reduces inflammation and immunosuppression induced by ultraviolet radiation in mouse models and may have protective activity against macular degeneration due to age effect (6).

**Objectives**

The current study was designed to describe roles of oxidative stress and apoptosis as mechanisms of liver toxicity induced by irinotecan; and to explore the possible protective effects of high- and low- dose of lutein against irinotecan induced toxicity in the liver of rats.

**Materials and Methods**

**Reagents:** Rat’s kits Standards were obtained from SUNLONG BIOTECH CO., LTD, China.

**Drugs:** Irinotecan 100mg vials obtained from Fresenius Kabi, India and the pure powder of lutein was obtained from Xi’an Rongsheng Biotechnology Co., Ltd. China.

**Animals and experimental design**

Thirty six (36) adult Sprague-Dawley rats, each weighing 150-200gm were taken from The Animal House of the College of Pharmacy/ University of Baghdad, under controlled and conventional laboratory conditions; rats were housed in cages of stainless steel, of temperature (25°C), relative humidity and natural light/dark cycle. Standard laboratory rodent tap water and chow were supplied ad libitum, and the animals adapted for a one week period prior of the experiment. The animals were divided into six groups of six rats each as follows:

- **Group I (Control):** received single oral daily dose of dimethyl sulfoxide (DMSO) (4 ml/kg) for 25 consecutive days by oral gavage. This group served as control.
- **Group II (irinotecan-treated):** received single daily oral dose of dimethyl sulfoxide (DMSO) (4 ml/kg body weight/day) for 25 days, and subsequently received irinotecan (50mg per kg body weight) on days: 5, 10, 15 (total dose=150 mg/kg) by IP injection.
- **Group III (6mg lutein/kg/day) (lutein-treated):** received oral dose of lutein (6mg/kg/day) daily by oral gavage for 25 consecutive days.
- **Group IV (24mg lutein/kg/day) (lutein-treated):** received oral dose of lutein (24mg/kg/day) daily by oral gavage for 25 consecutive days.
- **Group V (6mg lutein /kg/day + irinotecan):** received oral dose of lutein (6mg/kg/day) daily by oral gavage for 25 consecutive days, and subsequently received irinotecan (50mg per kg body weight) on days: 5, 10, 15 (total dose=150 mg/kg) by IP injection.
- **Group VI (24mg lutein /kg/day+ irinotecan):** received oral dose of lutein (24mg/kg/day) daily by oral gavage for 25 consecutive days, and subsequently received irinotecan (50mg per kg body weight) on days: 5, 10, 15 (total dose=150 mg/kg) by intraperitoneal injection.

Twenty-four (24) hours after the end of treatment, all rats were euthanized by diethyl ether anesthesia and from each rat blood sample were withdrawn from the carotid artery at the neck and collected into the labeled centrifuging tubes and leaved to clot for 20 min at room temperature to obtain serum, which was separated by centrifugation at 3000 rpm for 20 min, and is utilized for the assessments of biochemical parameters [Aspartate
aminotransferase (AST), alanine aminotransferase (ALT), and total antioxidant capacity (T-AOC), levels.

Furthermore, rats’ liver were quickly excised, placed in chilled phosphate buffer solution (PBS) (pH 7.4) at 4°C, blotted with filter paper and weighed. For the preparation of 10% tissues homogenates, 9ml of PBS (pH 7.4) was added to 1gram of the liver, then the tissue was homogenized by tissue homogenizer that set at 3 for 1 minute at 4°C. All preparations were freshly prepared and kept frozen at (-180°C) unless worked immediately for the measurement of MDA and Casp-3 in liver tissue homogenates.

**Statistical Analysis**

Data was expressed as the values of mean±standard deviation (SD). Data were analyzed by utilizing computerized Statistical Package for the Social Sciences (SPSS) program. The statistical significance of the differences among various groups is determined by one-way analysis of variance (ANOVA). The statistically significant differences were considered when P value less than 0.05 (P<0.05).

**Results**

Irinotecan (Group II) cause significant (P<0.05) elevations in serum levels of AST (Fig. 1), and ALT (Fig. 2) each compared to the corresponding levels in control (Group I) rats; and, there were significant (P<0.05) reduction in serum levels of TAOC (Fig. 3); furthermore, there were significant (P<0.05) elevations in MDA contents (Fig. 4) in liver tissue homogenates compared to control (Group I) rats; similarly, there were significant (P<0.05) elevations in Casp-3 level in liver tissues homogenates of rats (Fig 5) compared to control (Group I) rats.

Groups III and IV rats that orally received lutein 6mg/kg and 24mg/kg, respectively each produced non-significant differences (P>0.05) in serum AST, ALT, and TAOC; also, there were non-significant differences (P>0.05) in MDA and Casp-3 in liver tissues homogenates with respect to corresponding levels in Group I rats (Figures 1-5, respectively).

Administration of lutein at a dose of 6mg/kg body weight, and 24mg/kg each in association with irinotecan (Groups V and VI respectively) significantly (P<0.05) reduced serum enzymes AST (Fig. 1), ALT (Fig. 2) and significantly (P<0.05) elevated serum TAOC (Fig. 3) levels with respect to Group II; Moreover, significant (P<0.05) reduction in MDA contents in liver tissues homogenates (Fig. 4) and significantly (P<0.05) reduced Casp-3 in liver tissues homogenates (Fig. 5) with respect to Group II.

By comparing various markers measured in groups of rats that received low versus high doses of lutein in association with irinotecan (Groups V and VI), there were significant (P<0.05) reduction in serum levels of AST (Fig 1), and ALT (Fig 2) in Group VI rats compared to the corresponding serum level in Group V rats. Furthermore, there were non-significant elevation (P<0.05) in serum TAOC (Fig. 3), non-significant (P<0.05) differences in MDA contents (Fig. 4) and in Casp-3 (Fig 5) in liver tissue homogenate of Group VI rats compared to the corresponding levels in Group V rats.

Additionally, by comparing various markers measured in groups of rats that received low and high dose of lutein in association with irinotecan (Groups V and VI) compared to control (Group I) rats, there were non-significant (P>0.05) differences in serum level of AST and ALT (Fig. 1 and 2) of Group VI compared to the corresponding levels in Group I rats; there were non-significant (P>0.05) differences in serum level of TAOC (Fig. 3); MDA contents (Fig. 4) and in Casp-3 (Fig. 5) in liver tissue homogenate of each of Group V and Group VI rats compared to the corresponding levels in Group I rats.
Fig. 1: Effects of lutein (6mg and 24mg) on irinotecan induced liver toxicity on serum aspartate aminotransferase (AST) in rats. Data are expressed as Mean±SD, n = 6. Values with non-identical small letters (a, b, and c) are significantly different (P< 0.05). Values with non-identical capital letters (A and B) are significantly different (P< 0.05).

Fig. 2: Effects of lutein (6mg and 24mg) on irinotecan induced liver toxicity on Serum Alanine Aminotransferase (ALT) levels in rats. Data are expressed as Mean±SD, n = 6.
Values with non-identical small letters (a, b and c) are significantly different (P< 0.05).

Values with non-identical capital letters (A and B) are significantly different (P< 0.05).

Fig. 3: Effects of lutein (6mg and 24mg) on irinotecan induced liver toxicity on serum Total antioxidant capacity (T-AOC) in rats.

Data are expressed as Mean±SD, n =6.

Values with non-identical small letters (a, and b) are significantly different (P< 0.05).

Values with non-identical capital letters (A) are significantly different (P< 0.05).

Fig. 4: Effects of lutein (6mg and 24mg) on irinotecan induced toxicity on MDA in liver tissues homogenates of rats.

Data are expressed as Mean±SD, n =6.
Discussion

Severe adverse effects of the clinical use of irinotecan including myelosuppression and diarrhea can limit the using of such drug in the aggressive therapy; where, myelosuppression, especially the neutropenia, was frequently-observed in patients received irinotecan chemotherapy (9). Moreover, authors mentioned that there was a link between irinotecan therapy and the development of steatohepatitis that pathologically characterized by inflammation, accumulation of fat (steatosis), hepatocytes ballooning, and fibrosis (4). Although exact mechanisms by which irinotecan caused steatohepatitis are not entirely understood, oxidative stress (OS) and mitochondrial dysfunction seems to play a main role (10).

The current study confirms that irinotecan caused liver toxicities, as was evidenced through the significant (P<0.05) elevations in MDA content (figure 4) in liver tissue homogenates; in addition, there were reduction in serum TAOC (figure 3) and elevation in serum AST, and ALT (figures 1 and 2, respectively).

The role of apoptosis as a mechanism provoked by irinotecan on its toxicity on liver was not previously described; but in this study, irinotecan caused significant elevation in Casp-3 level in liver tissue homogenate (Figure 5); and thus, the current study is considered the first that demonstrate the role of apoptosis in liver toxicity-induced by irinotecan. Thus, we did not have a chance to compare the results of this study with other reports concerning this respect.

Lutein was extensively studied for its anti-inflammatory and antioxidant neuro-protectant activity in various disease models like uveitis, diabetic retinopathy, ischemia/reperfusion injury, and light induced retinopathy (11). Furthermore, it has been reported that lutein exhibited anti-genotoxic property,
and may attenuate the immunosuppression induced by ultraviolet radiation in mouse models and may have protective activity against macular degeneration due to age effect; and it has activity in chemopreventive and can protect from macular degeneration due to age effect (6).

The current study showed that lutein (6mg and 24mg/kg/day) attenuates irinotecan -induced reduction in serum TAOC level and also attenuates irinotecan -induced elevation in serum AST, and ALT levels, and MDA contents and Casp-3 levels in liver tissues homogenates of rats (figures 1, 2, 3, 4 and 5).

**Conclusion**

Results of this study suggested that oxidative stress and apoptosis have roles in mechanisms of liver toxicity induced by irinotecan; besides, the utilized doses of lutein has protective effect on irinotecan-induced toxicity to the liver during the DNA topoisomerase enzymes inhibitor (irinotecan) chemotherapy.

The Association between Severity of Dental Caries and Salivary Immunoglobulins in Asthmatic Adult Patients

Ahmed AbdulRazzaq Hammoodi Al-Anbari,1 Maha Adel Mahmmod AL-Ani2

1Post Graduate in Oral Microbiology, Department of Basic Science, College of dentistry, University of Baghdad / Iraq, 2Assistant Professor, Department of Oral Microbiology, University of Baghdad, Iraq

Abstract

The salivary samples were collected adequately from 80 subjects distributed equally (40 asthmatic subjects and 40 control subjects) of ages range between 20-60 years. This comparative survey was determining the caries index (DMFT), Streptococcus mutans, Streptococcus sobrinus, salivary IgA and IgE. So this study have shown highly significant difference P ≤ (0.01) found in effect of age on salivary IgA in control adult subjects and non-significant difference (P > 0.05) displayed in influence of age on salivary IgA. So this comparative investigation have demonstrated that non-significant difference (P > 0.05) found in influence of age on salivary IgE to both groups of study. However, the correlation between age and salivary IgE is a weak negative relationship.

Key words: Asthma, dental caries, salivary IgA, salivary IgE

Introduction

Asthma is a chronic disease causing airway inflammation in the lungs involving many cells and cellular elements. Worldwide, roughly 300 million people are affected by this disease irrespective of the age ¹. During the last few decades, disease has been elevated in some countries but has stabilized in other countries ²³. The asthma in period of adulthood is more frequent in females than in males ³. Today, the most active available therapy for asthma is anti-inflammatory inhalers (glucocorticosteroids) and, if necessary, the addition of ß2 agonists (bronchodilatory agents) ⁴.

It’s attributed to hyper-responsiveness of airways to triggers that impacts the sensitivity of the nerve endings in the air passages of lungs and so they become easily excited, for example exercise as well as allergens, which causes recurrent symptoms e.g. dyspnea (shortness of breath), coughing, chest tightness and wheezing ⁵. This disease can be considered as the most common in childhood and is also a major problem of public health in adult populations. In an attack, the lining of the pathways swell resulting the narrowing of the airways and decreasing the passage of air in and out of the lungs ⁶. The basic mechanism of asthma is an inflammatory process in the airways. The highest prevalences of asthma were recorded in Peru, Australia, New Zealand and the lowest recorded prevalence was documented in Albania and Russia ⁷.

The asthmatic patients have many problems in oral health. One of these problems is dental caries (DMFT index) which characterized by an irreversible contagious disease of multi-factorial etiology resulting demineralization of inorganic elements and destruction of an organic part of tooth structure ⁸. Several surveys have been shown an elevated incidence of dental caries in asthmatic patients ⁹. The increased incidence of caries is attributed to: low salivary PH (reduced buffering capacity), low salivary flow rate, raised consumption of carbonating drinks and sweets and magnified desiccating effect due to mouth breathing. Mutans streptococci (MS) is dominant cariogenic bacteria considered to be high in asthmatic subjects as compared to non-asthmatic subjects due to decreased salivary flow rate ¹⁰.

Materials and Method

Sugar Bacitracin-20M (Sugar bacitracin -20 modified)agar (which is obtained from Bulgaria), Human IgE ELISA kit(that we got from Al-shkairate
establishment for medical supply, Jordan) and Salivary IgA ELISA kit (which is got from LDN, Germany)

**Method**

This comparative study involved the salivary samples of 40 control subjects and 40 asthmatic patients of ages between 20-60 years according to the birthday. Collecting the saliva was made in early morning between 8am to 9 am. Prior to collecting the saliva, subjects were advised not to drink or eat for 3 hours before this step. Around 1 to 3 ml of total unstimulated saliva was assembled easily by drooling into sterilized cups that possess graduations, with the forward tilted head or by permitting the accumulation of saliva in the mouth and then expectorate into a cup (to avoid any possible contamination), while the determination of salivary flow rate (ml/min) must be done by using the graduated cup as (volume of saliva sample collected is divided on time needed for collecting the saliva) ml/min. Then taking 0.5 ml by micropipette for serial dilution tube, and the resulting saliva should be centrifuged for 3000 rpm for 10 min., and the clear supernatant saliva was collected and stored in a freezer at -20°C. The use of Vortex mixer for two minutes so that salivary samples be homogenous. Tenfold steps of serial dilution were prepared, 0.1 ml was withdrawn from each dilution (10⁻¹, 10⁻², 10⁻³, 10⁻⁴, 10⁻⁵) and spreading by use of sterile microbiological spreaders on the petri dish plates of SB-20M agar.

These plates were incubated anaerobically by using a gas pack provided in an anaerobic jar for 24 hours at 37°C followed by aerobic incubation for 24 hours at 37°C. such experiment was accomplished in duplicate.

**Results and Discussion**

The caries index (DMFT), microbial counts, salivary IgA and salivary IgE in two study groups are demonstrated in table 1 and table 2. The results displayed the mean rank of DMFT in control group is higher in males as compared with females. Also the mean rank of microbial counts represented with Streptococcus mutans, Streptococcus sobrinus and total streptococci counts in males is higher than that of females. As related to the salivary IgA and salivary IgE, there is non-significant differences (P > 0.05) between the gender and both salivary immunoglobulins (IgE and IgA) as shown in table 1.

As for asthma group, table 2 demonstrates non-significant differences (P > 0.05) between influence of gender on DMFT index, microbial counts and salivary immunoglobulins represented with salivary IgE and IgA.

In this comparative study, results display there is a weak positive relationship of DMFT with age in both groups of study with non-significant differences (P > 0.05) between DMFT and age in control group and asthma group. Also results indicate highly significant (P ≤ 0.01) difference between DMFT and S. mutans count in both groups. Also there is highly significant difference (P ≤ 0.01) between DMFT and S.sobrinus in both groups. Subsequently, the difference is highly significant (P ≤ 0.01) between DMFT and total Streptococci count in both groups of study. Low salivary PH (reduced buffering capacity), low salivary flow rate and other parameters
are increasing severity of caries and subsequently elevation of MS levels in asthmatic patients. However, there is non-significant differences (P > 0.05) between DMFT index and both salivary immunoglobulins (IgA and IgE) in control group and asthma group. At the same time, the correlation is a weak negative relationship between DMFT and salivary IgA in both groups, but the correlation between DMFT and salivary IgE is a weak positive relationship in control group and weak negative relationship in asthma group. Relative there is an increase in mean values of IgE in asthma group as compared with control group. Increased Th2 levels in the airways liberate specific cytokines which stimulate inflammation of eosinophils and generation of IgE(immunoglobulin E) by mast cells.

In regards to salivary IgA, results illustrates the mean value in control group is higher than that of asthma group and this is may be due to taking β2 agonists that aggravate the severity of caries by decrease the salivary flow rate and reduce levels of salivary IgA in asthmatic patients. So the correlation this salivary parameter with age in control group is a strong positive relationship and the difference is highly significant (P ≤ 0.01), but in asthma group, there is non-significant difference (P > 0.05) between salivary IgA and age with taking in consideration that there is a weak negative relationship. So the results demonstrated that there is a weak negative relationship between salivary IgA and S. mutans count as well as the correlation between salivary IgA and S. sobrinus count is also a weak negative relationship.

As for the correlation between both salivary immunoglobulins (IgA and IgE) is a weak negative relationship whether in control group or till in asthma group. So the statistical difference between salivary IgA and IgE is non-significant (P > 0.05).

Results displayed that in both groups of study there is a weak negative relationship between IgE and age as well as non-significant statistical difference (P > 0.05). So the correlation in both groups is a weak positive relationship between IgE and S. mutans count with non-significant statistical difference (P > 0.05), but the correlation is a weak positive relationship between IgE and S. sobrinus count in control group and a weak negative relationship between them in asthma group. So statistically there is non-significant difference (P > 0.05) between IgE and S. sobrinus in control group and asthma group.

Conclusion

As related to the low salivary flow rate and low PH in asthmatic adult patients, the levels of dental caries index (DMFT), S. mutans and S. sobrinus are higher in asthma group than that in control group.

So the mean value of IgA is higher in control subjects than that in asthmatic adult patients. So the mean value of IgE in asthmatic subjects is higher than that in control subjects.

Phenotypic and Molecular Characteristics of Biofilm and other Virulence Genes in *E. coli* and *K. pneumoniae* Isolates from Healthy Dairy Cow, Human and Environmental Sources

Ali A. Kadhum¹, Mohammed H. Khudor²

¹Biologist, ²Prof. Department of Microbiology, College of Veterinary Medicine, University of Basrah, Iraq

Abstract

*Escherichia coli* and *Klebsiella pneumoniae* for ones role in opportunistic infections and pathogenic methods in veterinary and human medicine, including the formation of biofilms. 33 *E. coli* and 8 *K. pneumoniae* isolates of these micro-organisms isolated from cow’s milk, stools and utensils. Identification were done by biochemical reaction and confirmed by Polymerase Chain (PCR). These isolates exhibit biofilms formation, as strong, moderate, weak capacities. The expression of the *fimA* gene. The percentage (84.8%) 28/33 of *E. coli* was able to produce biofilm while (100%) 8/8 in *K. pneumoniae*. The virulence factors of all bacterial isolates were also studied to determine *hylA* and *bla-CTX-M* genes in *E. coli* and, *magA* and *bla-CTX-M* genes in *K. pneumoniae*. were results presence extended spectrum β- lactamases (ESBLs). *bla-CTX-M* gene in *E. coli* and *K. pneumoniae* (78.7%, 87.5%) It also emerged that not all isolates carry other virulence genes for this study.

**Key words :** biofilm, virulence genes, *E. coli*, *K. pneumoniae*

Introduction

Microbial adhesion onto, surfaces and therefore the biofilm formation are considered serious, regarding their economical and public health consequences in many sectors for humans. The presence of pathogenic microorganisms on food sector facilities represents a severe potential health risk to consumers. Contaminated food contact with surfaces promotes contamination of food products which leads to foodborne disease³. With this pathogen contamination, of bulk tank milk by Shiga toxin-producing *E. coli*. therefore, milk is at risk for contamination by any pathogen that is present in feces or farm environment². Grass-fed cattle are the main reservoir of such *E. coli* strains. Some *E. coli* strains can produce toxins that induce serious human infections. cross-contamination of milk can occur in utensils contamination and during subsequent handling and preparation. Their feces might contaminate and thus act like a microbial carrier which might end up contaminating other foods such as milk, outbreaks due to *E. coli* 0157: H7 and *klebsiella* spp. have been associated primarily¹. The ability to adhere to different materials and formed biofilms have been an important factor associated with *E. coli* and *klebsiella* spp. virulence additionally, resistance to antimicrobials in biofilm-forming isolates contributes to bacterial persistence which may lead to chronic infections and treatment problem⁴. *Escherichia coli* and *Klebsiella pneumoniae* are not only constituents of the commensal gut flora but also common opportunistic pathogens in intestinal infection and implicated in the urinary tract and bloodstream infections. They frequently harbor ESBL- encoding genes. Broad-spectrum beta-lactamase production is associated with increased infections and mortality⁴ virulence *E. Coli* capsule with polysaccharide. More than 80 different types of capsules, *E. Coli* capsules are categorized into four major classes according to the genetic organization of the capsule gene cluster and its biosynthesis and assembly mechanism⁵. To *K. Pneumoniae* usually expresses on its surface a smooth lipopolysaccharide (LPS with O antigen) and capsule polysaccharide (K antigen) both leading to the pathogenesis of microorganism diseases caused by this species⁶,⁷
Material and Methods

Samples (190) were collected from different locations (60 cows milk, 60 stool human and 70 utensils samples). The collected samples were immediately, delivered to the laboratory in a cool box and tested within 24 h.

All E.coli and Klebsiella pneumoniae isolates grow readily on MacConkey agar and colonies typically appear large and pink, with pink pigment usually, diffusing into the surrounding agar indicating, fermentation of lactose. Klebsiella pneumoniae show the colonies mucoid on MacConkey agar. However E. coli colonies have a characteristic green metallic sheen on EMB agar. The API-20 E kit (bioMérieux – France), was used for confirmation the identification of isolates.

The method of DNA, extraction was done by using (Geneaid extraction Kit). The concentration of DNA, was estimated by using the nanodrop system 8.

Biofilm formation was assayed phenotypically by the ability of cells to adhere to the wells of 96-well microtiter plate 9. Two hundred microliters of this bacterial culture were used to inoculate pre-sterilized 96-well polystyrene microtiter plates and later incubated for 48 hrs. at 37°C, all wells were washed with sterile physiological saline for the elimination of unattached cells. Afterward, 200 µl of 1% crystal violet was added to each well. After 15 min. at room temperature, each well was washed with 200 µl sterile physiological saline. This process was repeated three times. The crystal violet bound to the biofilm was extracted later with 200µl of ethyl alcohol, and then absorbance was determined at 540 nm in an ELISA reader 10.

Specific primer sequences in PCR assays, and the predicted size of the amplified products, for the different pathogenic gene, coding regions were employed (Table 1). The reaction volume for magA, hylA, fimA and bla-CTX-M genes was 20 µl, while the amplification program was 3 at 95 C for denaturation, 30 cycles for denaturation 95 C (45 Sec.) ,annealing 60 C (45 Sec.) and extension 72 C for 50 Sec. with final extension 72 for 10 Min.

Results

The raw milk, stool and utensils samples displayed the presence of *E.coli* and *klebsiella pneumonia* contamination. The raw milk samples were polluted with the fecal coliform according to the results of fermentative growth in MacConky. Out of 190 samples (milk, stool and utensils) were collected from different sources, 33 samples (17.36%) were contaminated by *E.coli* isolates. While eight samples (4.21%) *Klebsiella pneumoniae* were confirmed. All *E. coli* 33 isolates were produce biofilm (100%). Out of 33 isolates 14 (42.42%), were strong biofilm producer. The high percentage of isolates with strong biofilm produce were in stool isolates 10/19 (52.63%). The moderate biofilm produce isolates were 8/33 (24.24%), While the weak biofilm produce isolates were 11/33 (33.33%). Also all *K. pneumoniae* isolates were able to produce biofilm (100%). Out of a 8 tested *Klebsiella pneumoniae* isolates by using pre-sterilized 96-well polystyrene microtiter plates (Fig.1) 5/8 (62.5%) of isolates were moderate biofilm producers and the remaining isolates 3/8 (37.5%) were weak biofilm, producer.

![Figure 1: Pre-sterilized 96-well polystyrene microtiter plates biofilm production.](image)

From 33 *E.coli* isolates, 28 (84.8%) were carried the genes responsible on biofilm formation *E. coli* and 8 (100%) *k. pneumoniae* were had fimA gene responsible for biofilm formation (Table 2, Fig 2). The detection of hylA gene in *E.coli* and magA gene in *k. pneumoniae* while bla-CTX-M in both. The results showed that hylA gene and magA gene were not found an all *E. coli* and *K. pneumoniae* isolates respectively, while *CTX-M* gene was found in 26/33 (78.7%) of *E. coli* isolates, while in *K. pneumoniae* isolates was found in percentage 7/8 (87.5%), table 3, Fig 3.

Discussion

In this study, a high percentage of agreement, was observed for the phenotypes of isolates, determined by microtiter plate applicability, reliability and high reproducibility of the microtiter plate were previously verified for bacterial biofilm\textsuperscript{15}. The isolated \textit{E. coli} and \textit{K. pneumoniae} were evaluated for biofilm formation, by using phenotypic microtiter plate screening as well as molecular detection of genes. Microtiter plate (MTP) showed that 33 isolates of \textit{E. coli} were biofilm producers, 42.2\% of isolates were strong, 24.2\% were moderate and 33.3\% were weak biofilm producers. This study consistent with results of previous study by\textsuperscript{32}. While eight isolates of \textit{K. pneumoniae}, were able to form biofilm percent 62.5\% moderate and 37.5 weak. These data are in accordance with those reported by\textsuperscript{17}.

\textit{E.coli} tends to be the most important cause of infections associated with mastitis. However, more precise investigation of individual farms revealed a farm-specific infection pattern where a single Gram-negative bacterial species, perhaps there is subclinical mastitis or intra mammary infection\textsuperscript{18}.

The \textit{fimA} gene is responsible for the formation of biofilms. Type 1 fimbriae are encoded by \textit{fimA} gene, which can facilitate bacterial adhesion and biofilm formation\textsuperscript{26}. This study was detected production of \textit{fimA} gene in 84.8\% of \textit{Escherichia coli} isolated from stool, milk and utensils where as found in Table (4). Result in this study is an agreement with a result of a study done by\textsuperscript{20}. Another study had been noticed less percentage in study done by\textsuperscript{21}. Who founded 76\%. This study was revealed that all \textit{K. pneumoniae} isolates wich was all have been positive for the presence of \textit{fimA} gene in 8/8100\%. This result agreement with result of\textsuperscript{21}. who showed the presence of \textit{fimA} and \textit{fimH} genes in 100\%.

The investigation and detection of \textit{blaCTX-M} gene in \textit{E.coli} isolates revealed in this study the presence of this gene in percentage 78.7\% (26/33) this result near from study done by\textsuperscript{22}.

In \textit{K. pneumoniae} the result presence of a \textit{blaCTX-M} gene was found in percentage 80\%. But this result was less than the result by\textsuperscript{25} in China who mentioned the percentage was 87.62\%. But it was higher than the result reported by\textsuperscript{24}, who reported 30\%, the other hand the \textit{hylA} gene was not detected in all \textit{E.coli} that similar to studies findings were obtained by\textsuperscript{20}. While disagree with the result reported by\textsuperscript{20}. while was \textit{magA} gene in all were negative for \textit{K. pneumoniae} isolates this result agreement with result reported \textsuperscript{27} but was differ from the result reported in AL-diwaniyah city, Iraq who recorded \textit{magA} gene in percentage 92\% by\textsuperscript{22}. Variations in the geographical distribution of Serotypes of \textit{K. pneumoniae}, were identified by\textsuperscript{28}. 

The presence of multiple genotypes and a high degree of genetic variation in *K. pneumoniae* isolates has also been confirmed by\(^2\). A study reported by\(^3\) that there are plasmid-carried genes that can express capsular polysaccharide synthesis (cps) genes.

Abstract

The importance of the research is that it is a research attempt that is concerned with consolidating the idea of a pressing play style in the reality of Iraqi clubs and teams training through this defensive method to achieve the desired goal, as well as experimenting with the use of defensive exercises characterized by rapid application and high accuracy together, and to know the extent of the impact of exercises in a pressing style of play in developing defense man to man for young football players in a step aimed at strengthening the sports field with practical experiments and service to researchers in the sports field. The research objectives to prepare pressing play style exercises to develop defense, man to man, for young football players. To identify the effect of exercises in a pressing play style in developing defense, man to man for young football players. The researchers used the experimental method to design the two equivalent groups (experimental and control) with a pre and post-test that is consistent with the nature of the research problem. The research sample was chosen by a simple random method (lottery), where the experimental group was represented by the Al Shuohda youth sports club, whose number was (22) players, and the control group was represented in the Nahrain youth sports club, whose number is (21), (10) players were chosen from each group, experimental and control group by the deliberate method, and the research variables included the defense man to man (Close defense - flexible defense - cutting and acquisition - cutting and farthest). The researchers used statistical methods (mean, standard deviation, coefficient of torsion, Levin’s coefficient, t-test for correlated and non-correlated samples), and after presenting, analyzing and discussing the results, the researchers reached the following conclusions: pressing play style exercises developed man-to-man defense with two types of close defense and flexible defense for the experimental group under study. pressing play developed cutting, possession, cutting and farthest.

Keywords: exercises, pressing-style, defense, young, football players

Introduction

The offensive and defensive side in football is considered as complementary to the other, as the attack enables the team to achieve goals and win ¹. As for the defense, its mission is to keep dangerous attacks away from the goal and cover the nearby and most important areas that may cause problems for the team if they are not properly monitored. Continuous pressure on the players of the opposing team, each according to his position and the type of defense assigned to him, as each player has duties on the field of defense and offensive. From the above, we see the necessity of using modern methods and techniques in the process of sports training, as well as playing with modern methods that can serve the method that the coach deems appropriate during the competition, especially with the diversity of methods used by competitors, and from here lies the importance of research as it is a research attempt concerned with establishing the idea of pressing play ² style in the reality of Iraqi clubs and national team training through this defensive method to achieve the desired goal, as well as experimenting with the use of defensive exercises characterized by rapid application and high accuracy together, and knowing the impact of exercises in the pressing play style to developing defense man to man for young football players in a step aimed at strengthening the sports field practical experiments and service for

DOI Number: 10.37506/ijfmt.v15i1.13770
researchers in the field of sports. The football game is in constant development and this development came as a result of modern methods based on scientific foundations through studies, research, analysis and correct planning and did not come in vain or random. These methods have significantly and remarkably developed the performance of the teams, some of which focus on attack, some of which focus on defense, including what focuses on attack and defense, according to what each team has, and among the methods that have emerged in recent times is the compressive style of play, which made a clear shift for the teams that used it in terms of results in the local league or external participations, and from the teams that used this method is the English club Liverpool, led by the German coach (Jürgen Klopp), who was known for this style in the 2015 season in the English premier league.

And through the experience of the two researchers, being former players in the Iraqi premier league and holders of the (C and B) Asian football tournament, and through their follow-up to the Iraqi premier league and the Iraqi teams, the compressive style of play was not used as a style famous for in local or foreign competitions, but rather is used poorly during competitions and matches as well. The researcher noticed weakness in the performance of defensive duties, including man-to-man defense, who is characterized by close control of competitors, especially in areas close to the goal and scoring areas, which are the areas from which most goals are scored, as well as a weakness in the process of retrieving the ball through cutting, possession or cutting and farthest.

**Methodology**

The researchers used the experimental method to design the two equivalent groups (experimental and control) with pre and post criteria that are compatible with the nature of the research problem, and to achieve the desired goals.

The research community included Wasit governorate clubs for youth participating in the first-class Iraqi football league of (10) clubs, and the research sample was chosen by a simple random method (lottery), where the experimental group was represented by the Al Shuohda sports club for youth of (22) players, and the control group was represented by the Nahain sports club For youth, their number is (21), and (10) players have been identified from each experimental and control group by deliberate method. The researchers conducted homogenization of the sample members in terms of length, mass, and training age.

The table shows the homogeneity of the variables, as the values are confined to (± 1) in the torsion coefficient, and the coefficient of levene was greater than the level of significance (0.05).

**Field research procedures:**

To measure man-to-man defense, the two researchers made a tournament for four clubs (Al-Shuhada, Al-Nahrain,
Al-Kut and Wasit), including the club that represented the experimental group and the club that represented the control group, where the researcher made a draw in a simple random way to choose the two clubs in the competition prepared by the researchers, in order to avoid bias for any of the research community clubs and to ensure that the experimental research variables are preserved. The first half was filmed only in order to involve the research sample for the two clubs and not to switch them during the first half of the competition, these matches were presented to the expert (Abdul Amir Naji) former captain of Al-Zawra Club and an analyst for Al-Iraqiya sport channel, who analyzed the matches through the (Dart Fish) analytical program through which defense data are given a man to a man and this procedure was done in the pre and post-tests of the subject of study without any change in circumstances.

Pre-tests:

The researchers held a four-way tournament that started on Wednesday 8/1/2020 at three o’clock in the afternoon at the Al-Shuhada club stadium, which represents the experimental group, and the Al-Nahrain club stadium, which represents the control group, with two matches every day and a two-day break between one match and another, and the championship lasted for a week until 14/1 / 2020.

Equivalence was performed on the two research groups by conducting tests for the research variables, as the researchers conducted a parity process for the two groups (the experimental group that applied the pressing play style and the control group that applied the coach’s style), and to find parity between the two groups, the researcher used the variables to be developed by conducting the tests and measurements used In the search represented in table (2).

Significant at a significance level (0.05) if the confidence level is ≤ or = (0.05)

The main experience:

The researchers, after reviewing the scientific sources and previous studies, prepared exercises by pressing play style, which aim to develop man-to-man defense, and these exercises are in line with the nature and conditions of football matches, and they are distributed in the training units appropriately taking into account the components of pregnancy training (intensity, size and rest) during three days a week (Sunday, Tuesday and Thursday) in order for these exercises to be able to achieve development in man-to-man defense in football. These exercises will be applied during the start of the main experiment.
Post-tests:

After completing the main experiment, post-tests were conducted for the research sample, a quadruple championship was held for the same clubs participating in the pre-test, namely (Al-Shuhada, Al-Nahrain, Al-Kut and Wasit), where the championship was held on Tuesday 17/3/2020 at three o’clock afternoon, with two matches a day, a match at the Al-Shuhada club stadium, a match at Al-Nahrain club, and a two-day break between one match and another, and the tournament continued until Monday 23/3/2020, as the tournament lasted for seven days.

Statistical methods used:

The researchers used the statistical bag (spss) to analyze the research results, including:

- Mean.
- STD.EV.
- Skew ness.
- leven coefficients.

Presentation, analysis and discussion of results:

Discussion of the post-test results of the experimental and control group in man-to-man defense.

The researchers attribute the reason for the development of the experimental group to the use of the stress playing style that had an effective role in the development of performance for a man-to-man defense and the ratio of possession, by increasing the desire and motivation towards training and highlighting the potential capabilities of the players, as (1) indicates that the style of play one of the methods that have a clear impact and are used by coaches frequently in different periods of preparation, because they seem easy-leaning and this is evident in football by giving duties towards the goal to be achieved during the course of playing in various forms, and this method is characterized by the development of physical, skill and planning elements 6. The researchers also see that the use of these exercises within specific areas in the training units was a clear goal, which facilitated the work of the players, and that the repetition of performance was for the purpose of ensuring accuracy and speed in performance and avoiding errors during the performance of the players, and this was confirmed (2). That the repetition of exercises in the training unit makes the players less wrong in the implementation of duties and more control over performance, whether with the ball or without the ball, which makes the player take the correct position to perform the skillful or planned duty and then avoid the mistakes that occur in it as it gains the player good compatibility for performance.

Also the researchers see that group training within the specified spaces has an effective effect in spreading the spirit of cooperation and continuous work among the members of the same group and works to raise the player's skill and planning capabilities, both defensive and offensive, as (3), indicates that group training is the point The basic exercises in the exercise and that at the same time it develops the movement and planning skills of the players.
Conclusions

Based on the research results reached within the limits of the research community, the following conclusions have been reached:

1- Pressing style play exercises developed man-to-man defense, with both types of close and flexible defense for the experimental group under study.

2- The experimental group surpassed the control group in the post test and in all research variables.

3- Pressing play exercises performed a great role in strengthening the bonds of teamwork among the players in terms of bearing some of the mistakes received and covering them up.

Recommendations:

1- Teaching and training novices and juniors the style of stress playing, in a way that suits each stage, as a basis for them in the future.

2- The use of a stress playing style in the development of other types of individual or team defense.

3- Training the style of pressing play according to different playing areas.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Faculty of Physical Education and Sports Sciences and all experiments were carried out in accordance with approved guidelines.

Assessment of Mothers' Knowledge about Febrile Convulsions of Children at Ibn- Albalady Hospital in Baghdad City

Ali Obaed Shneshil
Lecturer, Pediatric Nursing Unit, College of Nursing, Al-Bayan University, Baghdad / Iraq

Abstract

Background: In terms of occurrence, about of children in the age group of one to five years have at least one episode of febrile convulsion. These, have recurrent seizures and many get admitted to the hospital.

Aims: This study was conducted to assess the level of mother's knowledge about Febrile Convulsions

Methodology: A descriptive study design has been conducted with pediatric emergency unit at the Ibn-Albalady Hospital in Baghdad City during the period from the 3rd March 2020 up to the 13th 2020. A purposive non probability sample of (100) mother were selected from emergency pediatric unit. Out of the women questioned, febrile convulsion was reported by 100 mothers. Table (2) summarizes that the mothers knowledge items concerning child with febrile convulsion. In general, their knowledge were poor to fair in all items, and they are accounted for 2(18.1%), 9(81.9%) respectively, and overall mothers knowledge about febrile convulsion were fair. The results illustrate that (48%) of the study sample represent fair knowledge, (39%) were having poor information and (13%) were having good information about child with febrile convulsion at emergency ward of Ibn- Albalady hospital. The data were collected by using constructed questionnaire, which consisted of 11 items self-administrated method used and filled by using the questionnaire. Been described of data analyzed through using of two statistical approaches. Descriptive statistical analysis and inferential statistical analysis.

Results: The study results revealed that (48%) of the mothers under study were having fair knowledge. Mothers' knowledge regarding febrile seizures was non-significantly associated with positive history of febrile seizures, urban residence, higher parental education, and working mothers.

Conclusions: Generally, mothers’ knowledge regarding their children with febrile convulsions was poor to fair.

Keywords: Mothers’ Knowledge, Febrile Convulsions, Children

Introduction

A febrile convulsions, or febrile seizures, are frequently encountered in pediatrics, and despite often being self limiting, these seizures strike fear in the hearts of patients' careers. Febrile seizure is the most common type of convulsive disorder and one of the most recorded causes of emergency hospital admission in children under 5 years of age In spite of having a good prognosis, FS is extremely frightening, emotionally traumatic, and anxiety provoking when witnessed by parents, which make it a very difficult condition for them to deal with. Concerns about the future health of the child are the most common causes of fear among the parents. Sources of concern include fear of recurrence, physical disabilities, mental retardation, and even death. During seizure, the parents may think that their child is dying, but fortunately, most of febrile convulsions are benign rarely have FSs caused brain damage and except developing countries, there are no documented cases of febrile convulsions-related deaths on record. A febrile convulsion was defined as an event in infancy or childhood, usually occurring between three months and five years of age, associated with fever but without evidence of intracranial infection or a defined cause. Many parents think that their child is dying when he or she has a febrile convulsion, and they are concerned that epilepsy or mental retardation may result.
Febrile convulsions are common, occurring in 2 to 4 percent of children at least once before five years of age. Mental retardation has been reported in up to 22 percent of children with febrile convulsions who were hospitalized or seen in specialized clinics., found that children who had febrile convulsions did not differ in intelligence from their normal seizure-free siblings at seven years of age.

Febrile seizure (FS) is a benign convulsive disorder in under 5-year-old children, but at the same time, it is an alarming event in the lives of both child and parents. Lack of parent's knowledge about the nature of FS and how they should deal with it can lead to poor management.

The fever is one of the most common presenting complaints, is being the reason for health visits in about 70% of pediatric age group. Parents frequently perceive fever as a disease rather than a symptom or sign of illness.

Studies found that parents are not correctly informed or well educated about the definition, measurement, and diagnosis of fever.

**Objectives:** To assess the knowledge of mothers regarding febrile seizure in their children under five years

**Methodology:** A descriptive study design was conducted with pediatric emergency unit at Ibn-Albalady Hospital in Baghdad City from the 3rd March 2020 up to the 13th 2020. A purposive non probability sample of (100) mother were selected from emergency pediatric unit. The study instrument consisted of two parts: First part related to characteristics of studied mothers and children seizure. Second part related to mothers knowledge data about their children with febrile seizure. The scoring system for the questionnaire was dichotomous, with the correct answer scoring (1) and the incorrect answer scored zero (0). The data were collected by using the constructed questionnaire, which consisted of 11 items self-administrated method used and filled by using the questionnaire. Been described of data analyzed through using of two statistical approaches. Descriptive statistical analysis and inferential statistical analysis.

Grande mean of score = 0.41

$F$: frequency, $%$: percentage, $SD$: Standard Deviation, $MS$: mean of score, $Ass.$: Assessment by $MS$: (0.00 – 0.33) Poor; (0.34 – 0.66) Fair; (0.67– 1) Good.
Table (2) summarizes the mothers knowledge concerning items of febrile convulsions, in general, their responses were poor to fair in all items, and they are accounted for 2(18.1%), 9(81.9%) respectively, and overall mothers knowledge about febrile convulsion were fair.

The experiences of mothers whose children suffered from FC were complicated. The findings indicated that the experiences of these mothers were reflected in three themes, namely perceived threat, seeking solution, and difference in adaptation ⁹.

In terms of perceived threat, mothers believed that although FC often had a good prognosis and usually had no serious complications, the disease was still a threat to the child. Observing children during convulsion was reported as a scary event by mothers. They talked about their concerns about growth and development disruptions in the future life of their child. Studies have shown that seizures in children created serious concerns and fear in parents.² Fear of death, repeated seizures, low IQ, mental retardation, learning disabilities, paralysis, physical disability and an uncertain future for the child were some sources of fear for parents ¹⁰.

The results showed that mothers tried to find the best treatment and care for their child in order to restore her/his health. They also constantly searched for information in order to learn how to care for their child, so as to prevent relapsing convulsions and their complications. It was found that fever and FC were particularly worrisome for parents, causing them to frequently seek medical advice. They often required information which could enable them to manage their child’s illness ¹¹.

The results in figure (1) illustrate that (48%) of the study sample represent fair knowledge.

This table shows (48.%) of the sample was fair,(39%) were poor information and (13%) were good information of mothers about child with febrile convulsion at emergency ward of the non-teaching hospital.

Figure (1): Distribution of the mothers’ knowledge about febrile convulsion according to levels of assessment.
One of the necessary supports for parents was informational support. Such support includes the information delivered by healthcare personnel and the individuals in close contact with the child. Overprotecting the child was seen in some mothers. They felt that they have to monitor the child frequently to protect her/him. Several studies have shown that some sick children were under excessive control and monitoring.  

Also, a study found that the parents of children who suffered from chronic sicknesses not only accepted their children’s condition and its concomitant limitations, but also tried to remain optimistic about the future and hoped for the emergence of future effective medical treatments for the disease.  

Was found. Mothers who have a background with FS tended to be employed, have a higher education, and have urban residence compared to their non-working, rural, poorly educated counterparts. Regarding the attitude of the mothers towards FS, it was seen that although mothers can recognize a FS, a much lower percentage showed the ability to see the signs that precede the convulsions such as (only 38.3% knew that FS could reoccur.  

A large percentage knew about reducing the temperature, putting the child in safe place, placing the child in a lateral position. However, many mothers showed that they were doing incorrect practices such as opening the mouth and placing something inside, shaking the child, suction of secretions from the child’s nose and mouth, doing cardiac massage, and stimulation of the child. While earlier it was apparent that 91.6% of mothers knew that it was important to constantly monitor a child’s temperature, This goes to show that while these mothers may have good understanding of the condition; short, consistent reminders via the media or the public health sector (posters, advertisements) can raise the needed awareness to allow for a better understanding and attitude towards FS.  

All these items revealed bad knowledge which mearf bad quality of care provided to child with febrile convulsion. These results need an important gain steps to improve the care which help the major areas of advancement in child care include fever resuscitation protocols, early care to prevented of the febrile econvulsion, nutritional support regimens, topical antimicrobials and infection control, treatment of sepsis, thermally-neutral environments, and pharmacological modulation of the hyper-metabolic response. These factors have contributed to improved of child health care, reduced inflammation and energy demands, attenuated hyper-metabolism and muscle catabolism, and consequently decreased morbidity and mortality following and complicatio of high fever.  

This result of the study indicated that most of mothers have fair of knowledge toward information care of child with febrile convulsion. They worked routine for child with FC at home. The knowledge of standard care is not performed by large number of mothers which is due to many causes: the different level of education of mothers may affect their checking and readings of the vital signs, the preparation and using equipments that is used in Providing care as measurement of vital signs which is not enough lack of interventions related to inadequate structural continues education Programs as a result of hospitals’ policy and policy of Ministry of Health for continuing of education, insufficient nursing resources like library, online resources, reading of journals and lack of mothers documentation.  

A mother who has witnessed her child’s seizure and hospitalization is emotionally under a lot of pressure. She is always afraid of complications and recurrence of the event. Nurses in a family-centered profession are in such an excellent place to support mothers and families in coping with the situation and providing them with sufficient information in order to help them to gain a better understanding of the disease and also prevent its possible recurrence.  

Conclusions  

Generally, mothers’ knowledge regarding their children with febrile convulsions was poor to fair.  

Recommendations: Health education activities need to be focused on increasing mothers’ knowledge through various channels and assuring on double activities whether individually or in groups and further research can be carried out on large sample size of mothers with focus on variety of related variables that may influence their knowledge concerning child with febrile convulsion.

Is there an Impact of PAI-1 on the Thrombotic Episode in Iraqi Obese Patients with Corona Virus -19

Elham Abed Mahdi
Assist. Prof., Chemistry Department/ Faculty of Education for Girl / Kufa University

Abstract

Objective: firstly To assess the incidence of Corona Virus -19 covid-19 as risk factors in obese individuals leading to thrombotic episode, and secondly to compare the effects Plasminogen activator inhibitor-1 (PAI-1) on the occurrence of this thrombotic status in obese and normal body weight individuals. The pathogenesis of Coronavirus disease 2019 (COVID-19) is gradually demonstrated and explained around the world A high and a great number of thrombotic episodes are reported, in present study can be consider the COVID-19 as a prothrombotic disease.

Design and Methods: The experiments comparing the PAI-1 in 90 obese and 30 normal body weight participants aged 32-62 years. The obese patients subdivided to three groups: first group consisted from 30 over weight individuals and the second group comprised from 30 obese patients, while third group consisted from 30 morbid obesity patients. All participants underwent to the medical examinations to make sure they were infected with covid-19. The activity of PAI-1 and tissue plasminogen activator (t-PA) was determined by applied ELISA method by certain kit in all study groups individuals.

Results: Three study groups (overweight, obese, and morbid obesity) elicited significant (p< 0.05) elevation in metabolic characteristics such as fasting blood glucose (FBG), fasting insulin and lipids variables, as well as increasing in insulin resistance (HOMA-IR) and D-dimer fractions, in addition to there were significant augmentation in PAI-1 and t-PA in three study groups when comparing with those of normal or healthy body weight

The present results show a positive relationship between PAI-1 and body mass index, t-PA, D-dimer and metabolic characteristics which include fasting blood glucose, fasting insulin and lipids fractions, also HOMA-IR.

Key Words: Covid-19, Obesity, PAI-1, t-PA, thrombosis

Introduction

Coronaviruses are a great family of viruses which cause diseases in animals and humans. Seven coronaviruses can leading to infection in people around the world but commonly people have infected with these four human coronaviruses 1. The main organ which affected is a respiratory system, the infection ranging from the common cold to more severe comorbidities such as Middle East Respiratory Syndrome (MERS) and Severe Acute Respiratory Syndrome (SARS) and the most recently discovered coronavirus (COVID-19) causes infectious disease 1. The virus is spread rapidly between individuals through respiratory droplets during coughing. As of 13 September 2020, 210 Countries and Territories around the world have reported over 28,946,628 confirmed cases and 924,610 deaths of COVID-19, only in Iraq show 286,778 coronavirus cases and 7,941 deaths.

There are very few available data on impact of (body mass index) BMI for patients with COVID-19 infections, the obesity in the COVID-19 epidemic plays a major role in the pathogenesis of COVID-19 infection. It is believed the immune system, which is an essential player in the pathogenesis of COVID-19, also plays an substantial role in obesity which enhanced inflammation.
in adipose tissue. The metabolic dysfunction is a main cause of inflammation in adipose tissue which potentially leading to dyslipidaemia, insulin resistance, diabetes mellitus, hypertension, and cardiovascular disease CVD . In previous research the case of influenza A, was the obesity increases the duration of virus and severity ; the complication of having virus in patients with obesity was 42% longer than persons who do not have obesity . Another study indicated that in H1N1 influenza, obesity is consider as risk factor for hospitalization and death .

Several investigators revealed that BMI was significantly higher in patients with a severe form of COVID-19 infection . The published of retrospective analysis on 112 patients with COVID-19 infection demonstrated that BMI of the critical group with range (23.0-27.5 kg/m²) was significantly higher than that of the general group with range( 20.0-24.0 kg/m²), then critical group were subdivided into two groups, survivors (84.8%) and non-survivors (15.18%). Among the non-survivors, 88.2% of patients had a BMI > 25 kg/m² . Thrombotic events were an aggravating cause of death. Thromboembolic risk is known to be higher in patients with obesity than in the general population. It logically follows that obesity can be an aggravating risk factor for death from COVID-19 infection .

Plasminogen activator inhibitor-1 (PAI-1) play an important role in inhibition of plasminogen activators which included tissue-type plasminogen activator (t-PA) and urokinase-type plasminogen activator (u-PA), additionally, it regulates the fibrinolytic system as well as PAI-1 have a pivotal role in acute thrombotic phenomenon such as deep vein thrombosis (DVT) and myocardial infarction (MI). PAI-1 have more biological effects beside to the role in thrombosis including its central role in fibrotic disorders, atherosclerosis, renal and pulmonary fibrosis, diabetes mellitus, and cancer .

PAI-1 is produce in adipose tissue, and its levels in plasma are increased in obesity and reduced with weight loss . In a great epidemiological studies, the high level of PAI-1 has been established as a predictor of myocardial infarction . It is important to mention that effect of PAI-1 eliminates after adjustment metabolic syndrome components .

Abnormalities in coagulation factors and imbalance illustrated the link between obesity and thrombosis which occur in both arterial and venous . Several studies have shown that patients with BMI higher than 30 kg/m² have higher concentrations of all pro-thrombotic factors (fibrinogen, vonWillebrand factor (vWF), and factor VII), when compared to normal BMI controls, with a positive correlation with central obesity, in the same way, the concentrations of plasminogen activator inhibitor-1 (PAI-1) have been elevated levels in obese patients when compared with non-obese controls, as well as, it is correlated directly with visceral fat. Likewise , patients with obesity are characterized by higher plasma levels of anti-thrombotic factors, which include, tissue-type plasminogen activator (t-PA) and protein C, when compared with non-obese individuals, the enhancing these factors may be represent a protective role to counteract the increase in pro-thrombotic factors . Just as mentioned earlier the adipose tissue participate directly in product of plasma PAI-1, then stimulating other cells to produce PAI-1. In addition to, the adipose tissues secreted interleukin-6 (IL-6) which linked with the actions to produce tumor necrosis factor-α (TNF-α) in obesity, these findings could explain the association of insulin resistance with endothelial dysfunction, coagulopathy, and coronary heart disease. Recent studies mentioned the role of leptin in impairing balance and enhancing thrombosis, so the abnormalities value of some hormones such as (androgen, catecholamines) likely to combined with the accumulation of body fat may be leading to the impairment of coagulative pathway in obesity . Some investigators demonstrated to be efficient method to improving the obesity combined with pro-thrombotic risk profile .

![Figure (1): The role of PAI-1 in inhibition of fibrinolysis](image-url)
Systemic inflammation, endothelial dysfunction, disturbances of lipid and glucose metabolism, and IR contribute to the hypercoagulable state and the impaired fibrinolysis found in obesity. However, obesity is characterized by the elevation of several clotting factors and PAI-1 directly affecting coagulation and fibrinolysis independent of genetic factors. Moreover, a recent study has reported that subcutaneous adipose tissue shows a stronger relationship with functional measures of hypercoagulability as compared to visceral adipose tissue, suggesting that the anatomic location of adipose deposition may influence the type of thrombotic event, with visceral adipose tissue being associated with arterial thrombosis whereas subcutaneous adipose tissue predisposing to venous thrombosis.

Materials and Methods

Study Design

In this study, 120 hospitalized individuals with covid-19 infection aged 32-62 years were recruited during the period April–May 2020. The 90 obese patients subdivided to three groups: first group consisted from 30 overweight individuals (BMI 25.0-29.9 kg/m²) and the second group comprised from 30 obese patients(BMI 30.0-39.9 kg/m²), while third group consisted of 30 extreme obesity patients(BMI >40 kg/m²) while the fourth group comprised from 30 covid-19 patients with healthy body weight (BMI 18.5-24.9 kg/m²). The questionnaire in the present study was prepared in accurately depending on the opinion of the specialist, including medical swap, D-dimers analysis and CT-scan in addition to the demographic characteristics such as height, weight, and vital signs such as systolic and diastolic blood pressure, all this information was provided through oral interviews with patients and supervising physicians.

Blood Biochemistry Analysis:

All blood sampling was carried out under sterile conditions. Blood glucose measurements which included fasting blood glucose, post prandial blood glucose using certain kits from Spinract, Spain, fasting insulin levels using ELISA kit from Calbiotech, USA then determined HOMA-IR by certain equation. In addition to the measurement of blood lipid profiles were carried out, that included total cholesterol, HDL-cholesterol and triglycerides were obtained between 8 and 10 am following a 10-h fast, using kits from Biolabo, France. Estimates of LDL-cholesterol were calculated using the Friedewald equation. Plasminogen activator inhibitor 1 (PAI-1), tissue-type plasminogen activator (t-PA), and D-dimers were measured using ELISA method by Elabscience, China kit.

Statistical Analysis

The statistical analysis was achieved by the statistical package for the social science (SPSS) software for windows, version 20.0. the result were represented as mean ± standard deviation (Mean ± SD). Two - way Analysis of variance was used to compare variables in different studied groups. Pearson’s correlation was applied to determine the relation among the measurable factors of the present study, significant was determined regression. The confidence interval was set at 95%, thus p values less than 5% (p<0.05) were considered statistically significant.

Result and Discussion

A total of 120 patients (77 males and 43 females) were participate in current study with a mean age of 51.2 ± 16.4. sixty -two patients were entered to intensive care unit ( ICU) ; most of them were obese or they have extreme obesity. Table (1) illustrated patient characteristics and laboratory data.

18 (29%) of ICU patients developed thrombosis (10 pulmonary embolisms, 6 deep vein thromboses, and 2 acute aortic thrombosis) diagnosed with computational tomography scan (CT scan) and other laboratory tests such as (D-dimers analysis). D-dimers were increased in 80% of overweight, obese, and extreme obesity patients when compared with healthy weight individuals, most of them were admitted to (ICU) in hospital. ICU patients from three groups (overweight, obese, and extreme obesity) presenting with an aggressive form of Covid-19 disease who had significantly higher levels of t-PA, PAI-1 (p=0.000) of each other when compared with ICU patients who had healthy weight.

Plasminogen activator inhibitor PAI-1 is the primary inhibitor of both tissue-type (t-PA) and urokinase-type (u-PA) plasminogen activators, which inhibits fibrinolysis and has causative relationship with various vascular complications.
In addition to PAI-1 is the dominant inhibitor of the fibrinolytic system. Increased concentration of PAI-1 in the circulation enhanced hypofibrinolysis which is a state of impairment of removal the thrombi from the vascular system, by degradation cellular matrix, migration of smooth muscle cell and angiogenesis, as well as PAI-1 may affect in the development of atherosclerotic lesions.

High PAI-1 levels are correlated with an cardiovascular risk of atherothrombosis, dyslipidemia, hyperinsulinemia, and hypertension. PAI-1 has important role in acute thrombotic events such as fibrotic disorders including atherosclerosis and renal and pulmonary fibrosis. Tissue plasminogen activator (t-PA) and plasminogen activator inhibitor-1 (PAI-1) directly effect thrombus formation and degradation leading to risk for arterial thrombosis. PAI-1 is a procoagulant, proinflammatory, and profibrotic molecule. The PAI-1/tissue plasminogen activator (tPA) ratio uses as a tool of a patient’s fibrinolytic balance which can indicate thrombus and stroke risk.

The present study finding agreed with the study which mentioned that levels of (t-PA) are increased in obese diabetic patients and the major episode behind atherosclerosis is inhibition of fibrinolysis due to enhanced plasminogen activator inhibitor-1 (PAI-1) levels, marker of ineffective fibrinolysis leading to increased thrombus formation and produce the unstable plaque. Additionally high serum glucose concentration also has been shown to be associated with elevated PAI-1 levels. Increased PAI-1 levels have been encountered in many disease conditions, including metabolic syndrome, diabetes, and obesity. The results of the prospective cardiovascular study indicated that PAI-1 play important role in adipose tissue development and insulin signaling in adipocytes. PAI-1 is the primary inhibitor of both tissue-type and urokinase-type plasminogen activators, which inhibits fibrinolysis and has causal relationship with various vascular complications.

The outcomes showed a significant increase in blood sugar levels and insulin concentration in overweight, obese and extreme obesity patients comparing with healthy weight patients, the aim of evaluate fasting blood sugar and fasting insulin was to determine the insulin resistance by certain equation by HOMA-IR formula, table (1) shows highly significant increase in HOMA-IR values in obese and extreme obesity groups, while did not show significant differences between obesity and extreme obesity.

The study reported a significant increase in the levels of triglycerides, and very low density lipoprotein binding cholesterol (vLDL-c) of patients with overweight, obesity and morbid obesity comparison to healthy weight individuals group. In addition to the present study shows that high density lipoprotein binding cholesterol (HDL-C) in serum of obese and extreme obesity groups is significantly decreased (p<0.05) compared with that of healthy weight group show Table (1).

1: Healthy weight 2: Over weight 3: Obese 4: Extreme obesity

As shown in Table (2), serum (PAI-1) concentration were positively correlated with BMI, fasting blood glucose, fasting insulin, HOMA-IR, triglyceride, VLDL, t-PA, and D-dimers, while inversely correlated with HDL, these correlation indicated (PAI-1) levels effecting on the independent risk factors which proved that (PAI-1) might be participated in thrombosis occurrence.

Previous studies provides more evidences that PAI-1-dependent mechanisms may attribute to the pathogenesis of insulin resistance and type 2 diabetes mellitus. For example, in the IRAS study (Insulin Resistance Atherosclerosis Study, a longitudinal cohort of 1047 subjects followed for 5 years), PAI-1 was a mainly predictor for the evolvement of diabetes mellitus, even after adjusting for adipose tissue distribution, and insulin sensitivity. Another study revealed that visceral and subcutaneous adipose tissue PAI-1 mRNA expression were positively correlated with BMI in severe obesity (r=0.043/0.56, respectively). Moreover, there are more information for that weight reduction virtually reduces plasma PAI-1 in obese humans. These previous findings are in line with present results which correlating serum PAI-1 with adipose tissue BMI. Furthermore, another study demonstrated that PAI-1 which secreted from omental adipose tissue is greater than that from subcutaneous adipocytes. Thus, increased omental fat secretion of PAI-1 may be contribute to the enhanced atherothrombotic risk of human central obesity.

In epidemiological studies, there are a direct link between PAI-1 and lipid parameters (e.g., triglyceride and HDL-C levels) in healthy young adults. Also, recent studies supposed that very low density lipoprotein (VLDL) was responsible for increasing the PAI-1 level by increasing a VLDL response element localized to the promoter region of the PAI-1 gene and mediating VLDL which induced PAI-1 transcription in endothelial cells.

A previous in vitro research also showed that small-sized HDL, but not large-sized HDL, enhanced PAI-1 release in the murine 3T3 adipocyte cell line; however, to date, there are limited data on the association of PAI-1 with the functional and structural properties of the different lipoprotein fractions.

The pathophysiology of Covid-19-related thrombosis is incompletely understood. In Covid 19 the Inflammation status promotes releasing tPA and PAI-1 from endothelial cells. In addition, the ctivation of platelets in covid-19, also release large amounts of PAI-1 because the platelets are the major circulating pool of PAI-1 that can contribute to a high local concentration of PAI-1 at the location of a growing fibrin clot. Increased PAI-1 is responsible for hypofibrinolysis and fibrin persistence. Interestingly, increased PAI-1 plasma levels were observed in patients during the SARS-CoV epidemic in 2002. Persistent fibrin deposition in lung parenchyma and alveolar spaces of Covid-19 patients strongly suggests that despite increased levels of tPA, high PAI-1 levels can overcome local tPA release. In addition, plasma hypofibrinolysis from elevated levels of PAI-1 and TAFI is a risk factor for venous thrombosis.

**Conclusion**

There are much evidences about the impact of PAI-1 on thrombosis formation in covid-19 patients who suffered from three types of obesity and the sever of disease associated with increment of BMI. In addition to the analysis of our data established that the homeostasis between coagulation and fibrinolysis is not found in patients with Covid-19 infection, who suffered from hypercoagulability and hypofibrinolysis at the same time which correlated with high PAI-1 and increased t-PA levels. Additionally, in present study concluded this severity of covid-19 increase with increase the number of metabolic syndrome components such as hyperglycemia, hyperinsulinemia and dyslipidemia.

Molecular, Biochemical, and Phenotypic Identification of Phenol and Cresol Degrading Acinetobacter baumannii Strain Selected from Al-Rumaila Oil Well

Noor Mohammad Ali¹, Aamal Ghazi Mahdi Al-Saadi¹

¹M.Sc., Ecology Department/ College of science, University of Al -Qadisiyah, Diwaniyah 58001, Iraq.

Abstract

Background: phenol and cresol are dangerous compounds that have harmful effects on aquatic life, plants and, many other organisms. Therefore, it is necessary to effectively eliminate these compounds to protect the environment.

Aim: The aim of this study is to select and characterize bacterial strain(s) from oil contaminated soils and testing its ability for biodegrading phenol and cresol.

Methods: Biochemical tests were performed in addition to morphological and molecular detection through 16S rRNA analysis to identify the selected strain after growing on Mineral salts medium (MM) containing phenol or cresol. The residual concentration of phenol and cresol was analyzed over the time period by means of the 4-aminoantipyrine assay.

Results: the selected strain was identified as Acinetobacter baumannii strain HILLA-1, and it was able to remove 100% of the phenol at all the used concentrations after 48 h. This strain was also able to degrade 100% of cresol at concentrations (25,50,75,100,200 ppm /L) and 99.37%, 88.69%, and 94.73% at concentrations (300,400,500 ppm /L) respectively after 48 h.

Conclusion: The selected and identified Acinetobacter baumannii strain HILLA-1 can provide a putative source for bioremediation of phenol and cresol contaminated environments.

Keywords: Acinetobacter baumanni, phenol, cresol, Biodegradation, 16S rRNA

Introduction

A large number of organic compounds have been released to the environment since the beginning of the industrial revolution. These compounds are chemically manufactured and many of them are discarded as waste. Phenol is one of the most common toxic environmental pollutants, and it is classified as a dangerous substance to human health and other organisms (EPA, 2003) because many of phenolic compounds possess the ability to survive and not disintegrate in the environment. They also have the ability to move, biotransform, and bioaccumulate in human and animal tissues as well as increasing their concentration in the food chain.
and waste. Phenolic compounds have harmful effects on aquatic life, plants and many other organisms. The natural sources of phenol that were formed as a result of forest fires and the natural emission of phenol when asphalt was used as an adhesive in cities. On the other hand, cresol is a colorless viscous liquid that is used as an intermediate in the production of other chemicals. Its chemical formula is C7H8O. Methyl phenol is an aromatic organic compound that has a variable melting point that is determined by ambient temperatures. It is involved in various fields in the manufacture of pesticides, petroleum products, dyes, and also in the pharmaceutical industries. It is very toxic to humans if inhaled or swallowed, even in very low concentrations. It often results in problems such as eye, mouth, throat and skin irritation, vomiting, liver and heart damage, paralysis, coma, and sometimes death. Residues of phenol and its derivatives can be removed from the environment through a combination of physical and chemical treatments such as adsorption, osmosis, adsorption, photo catalysis, and electrolyte oxidation, but these treatments are impractical due to the high cost and formation of other toxic compounds. Therefore, biological methods have received more attention than physical and chemical methods because many different bacteria are known to use phenolic compounds as the only sources of carbon and energy. The degradation of phenol and its derivatives has been studied by bacteria. A large number of different bacterial species have been found to have the ability to biodegrade phenolic compounds such as Acinetobacter spp. In the current study, an Acinetobacter baumannii strain that has the ability to biodegrade phenol and cresol at high concentrations was selected from oil contaminated soil of Al-Rumaila oil well and identified based on phenotypic, biochemical, and molecular approaches. The Biodegradation rates of phenol and cresol by the selected strain were also reported in this study.

Materials and Methods

Sample collection

(20 samples) collected from soil contaminated with petroleum products from various places. Samples were collected in sterile glass bottles and transferred to the laboratory for the required tests.

Growth media

Mineral salts medium (MM) was used for selection. It consists of the following g/L materials, according to

<table>
<thead>
<tr>
<th>Material</th>
<th>Concentration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mgso 4.7H2O</td>

</tr>
</tbody>
</table>

The materials were dissolved in a liter of distilled water and mixed well to ensure that all the materials were dissolved and sterilized for 20 minutes at 121 °C and the pH was adjusted (7).

Selection of phenol and cresol tolerant bacterial strains

A weigh of 5 g of each soil sample was added to 50 ml of liquid mineral salts medium (MM). Phenol or cresol was added at a concentration of (25 mg/L) and (25 ppm/L), respectively as the sole source of carbon and energy. The flasks then were incubated for 5 days at 30 °C. 0.1 ml of the bacterial suspension was transferred to MM agar medium containing the same concentrations of phenol and cresol and incubated for 5 days at 30 °C. This step was repeated two times to obtain pure colonies and to ensure that the isolated bacterial species are capable of degrading phenol and cresol.

The ability of the bacterial isolates to degrade phenol and cresol compounds

Standard titration curves were prepared for both compounds by preparing standard solutions for each of them. The assay of testing the ability of the isolated strain to degrade phenol (25, 50, 75, 100, 200, 300, 400, 500 mg/L) and cresol (25, 50, 75, 100, 200, 300, 400, 500 ppm/L) was performed as mentioned in (Barwick & Vicki 2003). Then using the absorption values on length 460nm to build a calibration curve for the two compounds using an Excel program to obtain the mathematical equation in order to calculate the concentrations of the remaining phenol and cresol compounds. After the growing of bacteria to assess their efficiency on length 600nm in the biodegradation process This assay was performed twice to confirm the degradation ability of the isolated strain to phenol and cresol twice to confirm the degradation of the isolate to phenol and cresol by 4-aminoantipyrine assay. Identification of the Phenol-cresol degrading Bacterium

The isolated bacterial strains was identified based on morphological characteristics on MacConkeyagar, Vitek 2 compact system biochemical tests (which was
used according to the manufacturer’s instructions), and sequence analysis of the 16S rRNA gene. DNA extraction and 16S rRNA sequencing. Genomic DNA was extracted from the selected Acinetobacter baumannii bacterial isolate using the PrepTM Genomic DNA MiniKit provided by Macrogen / Korea according to the manufacturer’s instructions. DNA amplification was performed by a PCR master mix containing 3 μl forward and reverse primers, 14 μl nuclease-free water, 5 μl Template DNA, 25 μl Master Mix. 16S rRNA gene was amplified from the DNA genome by PCR using the following forward and reverse primers for 16S rRNA respectively: 5’AGAGTTTGATCCTGGCTCA - 3’ and 5’GGTTACCTTGATTACGACTT -3. The polymerase chain reaction was carried out under the following conditions: Initial denaturation at 95 °C for 120 seconds followed by denaturation at 95 °C for 30 seconds, followed by annealing at 53 °C for 30 seconds, followed by elongation at a temperature of 72 °C for 150 seconds and the final elongation score of 72 for 300 seconds, respectively.

DNA sequencing analysis

The 16S rRNA PCR product of Acinetobacter baumannii strain HILLA-1 was extracted and sent to Bioneer (Korea) to perform nitrogenous base sequencing. The base sequence of the selected strain was registered in the NCBI GenBank records, and its accession number is MT032339.1. Using the BLASTn tool, Homologous sequences were attained from the NCBI database. Homology to Acinetobacter baumannii strain HILLA-1 were chosen with accession numbers: MK027249.1, MN636473.1, MN623687.1, MN175924.1, MN175925.1, MN175923.1, MN175922.1, MN175921.1, MN175920.1, MN173945.1. Sequences alignment and phylogenetic tree analysis were done using Mega X software. The phylogenetic tree was drawn based on neighbor-joining method.

Results

Characterization of the selected phenol/Cresol strain

An Acinetobacter baumannii strain, obtained in the current study, was isolated from oil contaminated soil of Al-Rumaila oil well. The strain was selected using a MM medium containing phenol or cresol then characterized after culturing on MacConkey agar plates. The colonies appeared small, round, convex and mucous, with a light cream color as shown in Figure 1. The colonies were purified and identified using Gram’s stain which showed Gram-negative bacterium in a form of semi-spherical bacilli. The selected strain was further subjected to biochemical identification using Vitek 2 compact system as shown in table 1.

Analysis of 16S rRNA gene sequence

16S rRNA fragment was amplified from the gDNA of the *Acinetobacter baumannii* isolate and detected with about 1498bp as shown in Figure 2. The sequence of 16S rRNA gene of the isolated strain of the current study can be found under the accession number MT032339.1 at NCBI–GenBank with the name of *Acinetobacter baumannii* strain HILLA-1. The BLAST results showed that the base sequence of the 16S rRNA of *Acinetobacter baumannii* strain HILLA-1 was 98.94% identical to *Acinetobacter baumannii* strain B18 (Accession number MK027249.1) and 98.82% identical to *Acinetobacter baumannii* strains with Accession numbers: MN636473.1, MN623687.1, MN175924.1, MN175925.1, MN175923.1, MN175922.1, MN175921.1, MN175920.1, MN173945.1 (Table 2).

The ability of *Acinetobacter baumannii* strain HILLA-1 to degrade phenol and cresol in different concentrations

Results showed that *Acinetobacter baumannii* strain HILLA was capable of degrading phenol completely by 100% for all concentrations (25, 50, 75, 100, 200, 300, 400, 500 mg/L) after 48 hours of incubation, as shown in Table (3), with an increase in the rate of bacterial growth during the incubation period, as shown in Figure 4. Furthermore, the results revealed that the biodegradation ability of *Acinetobacter baumannii* strain HILLA to cresol for concentrations (25, 50, 75, 100, 200 ppm/L) was 100% while the concentrations (300, 400, 500 ppm/L) are 99.37%, 88.69%, and 94.73% respectively after 48 hrs as shown in Table (4) with an increase in the vital growth rate of isolate as in Figure 5.

Discussion

Petroleum compounds and its derivatives polluting the environment threaten human health and many other living organisms present in land and marine systems, so getting rid of pollution by oil vehicles is very important at various levels. Biological treatment is one of the most important techniques available in removing pollution as it is less dangerous than other types of treatments. It is a physical and chemical purification of the environment from pollutants by using microorganisms naturally present in such environments because of their ability...
to break down dangerous compounds into less toxic compounds.

**Conclusion**

We have selected and identified a local *Acinetobacterbaumannii* strain, which degrades phenol and cresol as the only carbon sources. Our strain showed a high efficiency in breaking down even high concentrations of phenol (500 mg/L) and cresol (500 ppm/L). Therefore, *Acinetobacterbaumannii* strain HILLA-1 may be taken into consideration as a helpful biotechnological means for the treatment of diverse environments contaminated with phenol or cresol.

Evaluating Growth Charts Use among Children Less Than Five Years of Age at Primary Health Care Centers in Al-Hillah City

Muna Abdulwahab Khaleel
Prof., Nursing College / Al-Bayan University / Baghdad / Iraq

Abstract

The study was conducted at two primary health care centers in Al Hilla city which covered Al Gameyah primary health care center and Al Kawthar primary health care center for the purpose of evaluating the use of growth chart and to determine mothers understanding toward the meaning of the weight chart in terms of growth. All registered children aged 0-5 years who were living in areas served by the above two mentioned primary health centers were included. The following results may be drawn on the objectives of the study. The proportion of registered children who possessed a chart was very high (99.8%). The proportion of registered children who acquired a chart at birth was high too (99.6%). It is of interest to find that the date of birth of (99.6%) of children was registered and the weight at birth of (99.2%) of them was known too. It was found that only (90%) of study population had their weight charted on the curve of growth charts. The study showed that no children of both sexes were attending regularly to have their weight charted in most months of the year. The study generally depicted that the level of immunization of the children in study area was remarkable and high.

Keywords: Growth Charts, Children, Age, Primary Health Care Centers

Introduction

Growth and development of children has fundamental importance in a country’s overall progress. Growth monitoring is widely accepted and strongly supported by health professionals, and is a standard component of community pediatric services throughout the world. The WHO has recommended use of growth chart (GC) for close monitoring of children’s growth. However, the availability of this tool does not automatically translate to its use. Knowledge of its meaning, usefulness and acceptance by the health professionals who are directly in charge of childcare is necessary. Many conferences were held in the world to discuss the health of children in general with special emphasis on growth monitoring; this was voiced loudly in Alma-Ata, USSR, 1978. Since eighties till now researchers devoted much time and efforts to child health and emphasized that growth monitoring is an important technique for identifying individuals, groups, communities whose growth is not keeping up with the expected pattern. Many Pediatricians believe that the two of the most important things about a healthy child are that he should be growing and that he should be about the right weight for his age. Laraway and others reported that growth standards have been developed in most countries of Europe and North America by measuring normal healthy children both cross-section ally and also by following their growth longitudinally over a period of time. Ben-Joseph and others stated that in developing countries where failure of growth is a common phenomenon, the need for suitable growth charts has been acutely felt, but the lack of appropriate local standards and absence of well-planned longitudinal studies of children are major obstacles. World Health Organization (WHO) pointed out that, growth charts provided three channels of growth in weight based on internationally acceptable optimum and it was adopted by many different countries. Moreover, the WHO (1978) organized all efforts to promote the more widespread use of growth chart in primary health care and recommended a prototype of growth chart with guidelines for chart’s use in health services.
other concerned organizations have shown their deep concern on the benefits of using the growth chart and they stated that it can offer a simple and inexpensive means of monitoring child health and nutritional status and can be used by community health workers with very little instructions and supervision. Researchers have emphasized that, regular monitoring of weights of children on a weight chart is helpful for the promotion of optimum growth in children and also they stated that, such diagnostic, curative and promotive / preventive uses of the growth chart have needed clarification in order to achieve full acceptance of their use in clinical as well field conditions. This study was conducted for the purpose of evaluating the growth charts use and to estimate the proportion of mothers understand the meaning of the weight chart in terms of growth.

Methodology

All registered children aged (0-5) years who were living in areas served by Al Gameyah primary health care center and Al Kawthar primary health care center at the time of the study were included. Interviewing of (400) mothers was conducted at the above two mentioned primary health centers and a question was asked whether they understood the meaning of the weight chart in terms of growth. The data were gathered from growth charts and health records available at the above two mentioned primary health care centers. The data described by using simple statistical analysis such as: frequencies, percentages to assess the results of the study.

Table No (1) shows that children who registered in both primary health care centers aged from (0-5) years were 12380. The proportion of children who possessed a chart was very high (99.8%). Here the mothers considered the chart as a sort of passport to health care, and they were proud to possess it. It is of interest to report that the children who acquired a chart at birth were very high too (99.6%).

From table (2) it can be seen that between the ages of (0-5), of 12380 children registered in both PHC centers, the date of birth of 12380 (99.6%) was known, and the weight at birth of 12380 (99.2%) of them was known too while they were recorded in growth charts as normal ranged from 2.5kg-3.5kg (90%) of them only. This information will be valuable to the child as he grows up, as well as being important in assessing his health. In a study of the relationship between birth weight and child growth in Guatemala over a period of 9 years (1965-1974), the study showed that infants born with deficient weight tend to remain in lower growth tracks whether the variable measured was weight, height or head and chest circumferences through the entire length of the study. But here in this study the problem is the absence of a suitable method of monitoring and recording the weight of children regularly on a simple growth char. That means recording is in adequate, and this is because of the fact that health workers have little or no training in the symbolism involved in such charts, therefore it is difficult in assessing child’s health.

The research was done to discover how often the weight of children was charted in each year of their life. From table (3) it is clear that no children of both sexes, boys and girls in primary health care centers were attending regularly, therefore their weight was not charted in most months of the year. From the researcher’s observation, it was found that most of their attendances
were consistent with the time of receiving their vaccines and when they were sick.

Studies conducted on the evaluation of the use of growth chart in in Northeast District of Delhi, India and in Isfahan found inconsistent results in that a high proportion of children both sexes were attending regularly enough to have their weights charted in most months of the year $^{17,18}$. This difference in the results may be because the majority of mothers were not advised about the importance of weight chart in terms of growth. The study also showed how frequently children attended the clinic. The attendances for all children of the studied population were analyzed. From table (4) it was clear that mothers brought their children to the primary health care centers during their first three years of life especially the second year, this might due to the fact that mothers attended the clinic for the purpose of vaccination, while the numbers of attendances dropped during the fourth and fifth years of the children life. Besides that, the table shows that mothers brought their girls more than boys, and this finding is contradicting with most of Iraqi women’s customs because male are always more protective than female. Therefore, this result could be due to small sample size studied which represented (1.6%) of study population only.

Estimation was made for the level of immunizations of children in the area, and the results are shown in table (5). The study generally indicated that the level of coverage in the study area is remarkable and high as compared to some other developing countries $^{14}$.

The high level of immunization in the area is partly due to many important points, first is the coordination and cooperation between health authorities and other organizations. Second is the experience gained by health staff from different aspects of preventive programs in encouraging women to bring their children. Similarly, the campaigns and the mass media has an important role contributed to the knowledge of the public about health and prevention of diseases by immunization. So by using these approaches it was possible to contact defaulters.

A question was asked for (400) mothers in the primary health centers during the time of the study whether they understood the meaning of the weight chart in terms of growth, and those involved concluded that a very small proportion (26%) only had some awareness and understanding.

Finally, the investigator recommended that the responsible authorities should follow the best use of growth charts in all primary health care centers, and conducting training courses for nurses and other health care providers who are working with growth charts units.

Complications of Kalazzer among Children in Hilla-city

Ibtesam Khalid Kamil
Assistant Prof., Al-Bayan University, College of Nursing, Pediatric Nursing, Iraq

Abstract

Objective: This study aimed to detect the types of complications of children suffering from kalazar; also to identify the reason of these complications.

Methodology: A descriptive study carried out from Feb15th to June 15th of the academic year 2017. The sample consisted (109) children from general maternal and children hospital in Hilla/Babylon. The study designed and data was collected using structural questionnaire which was prepared by consulting panel research expertise, also by assessment approach and interview was done with parents of children. The collected data were analyzed through descriptive statistics by frecuency and percentage.

Results: The results of the present study indicated that most of the children age were (13-18) yrs.(40.4%); male gender more involved (67%) and (27%) were from Mesaib city. The education level of parents were within secondary school, mothers (52%) fathers (43%). The income of affected children families involved in the study were (51%) poor, which isn’t enough to maintain healthy well being status and medical requirements. Complications revealed that children suffers from bleeding tendency (13.5%) sever animea were (20%) hepato spleenomegaly were (14.0%) , finally death occurs because of septicemia (37%).

Conclusion: Complications accurs because of poor and inappropriate medical diagnosis, also infective medical treatment during hospitalization and lake of medical follow up to children suffering from kalazar by the health team after hospital discharge.

Keywords: Complications, Kalazar, Children, Hilla-city

Introduction

Kalazar is a parasitic disease caused by the visceral leishmaniasis. This parasite lives in infected dogs transfer to sand flies to human, then humans can also transmit the parasite between each other through a blood transfusion or shared needles. Different species of the parasite cause each form, cutaneous leishmaniasis affects the skin and usually not serious; visceral leishmaniasis damage the interior organs and can be life-threatening; mucocutaneous leishmaniasis can lead to partial or complete destruction of the mucous membranes found in the nose, throat, and mouth 1. The parasite common in tropical and subtropical environments, affected region are often remote and unstable, with limited resources for treating this disease. According to the (WHO), environmental and climate factors heavily influences the spread of disease; 350 million people all over the world are consedered at risk, and 2 million of new cases occur yearly. (90%) of cases occur in Mediterrean; Central West Asia; Middle East; North and East Africa; South and Latin America 2. In Iraq kalazar disease increased from 5% of people with visceral leishmaniasis in (1999-2000) to 9% in (2016-2017) 3. Socioeconomic conditions; poverty is a determining factorfor the disease, malnutrition, illiteracy, large migrations caused urbanization emergency situations and changes; infections and people who have weakened immune systems are also at increased risk of this conditions 4. The incidence rate of kalazar is from (1-14) yrs. of age, the disease occurs from 2-8 months after being bitten by a sand fly; typically lead to fever, malaise, skin ulcer and dark ashen color, shivering, loss of weight, anemia, digestive disorder, dyspnea, edema in the lower limbs,
lymphadenopathy, jaundice and hepatosplenomegaly and some patients progress with heavy bleeding, finally sepsis and renal failure leads to death. For diagnosis, skin biopsy by scraping one of the ulcers to identify the parasite, also physical and blood exam is required. Treatment include medication that contains antimony (e.g. meglumine and sodium stibogluconate). Ulcers on the face that cause disfigurement may require plastic surgery. The potential complication include bleeding and weakened immune system which can be life threatening and fatal. Death occurs due to complications of the disease and not to the disease itself.

Methodology

Design: A descriptive study was conducted, purposive sample of (109) children were suffering from kalaazar in Hilla-city. Questionnaire has been used as a tool of data collection, for the period of Feb. 15/2017 to June 15/2017 and consist of socio-demographic data; pts complains from the disease types of complications and causes of death. Data were analyzed using the descriptive statistical data analysis which include (frequencies and percentage).

<td>34</td>
</tr>
<tr>
<td>Septicemia</td>
<td>14</td>
<td>37</td>
</tr>
</tbody>
</table>

Table (6) shows the causes of death among the sample, (37%) because of septicemia, (34%) had died because of renal failure and finally (29%) had died because of respiratory failure.

**Discussion**

This research study had been reported that the highest percentage (40.4%) of the sample was at age group (13-18) yrs. as shown in table (1), this finding was consistent with study[3] done in Iraq, they found the relation of kalazar with this age group, also male gender shows (67%) more than female (33%) because the increase risk factor of exposure to the infection. Parent education shows that father had secondary school level while mothers counted (43%) this means, they got the education for understanding the nature of kalazar 2; in term of providing health maintenance to their children. The highest percentage of the sample residency was presented in rural area(51%); from (Mesaib 27%, Haswa field 24%); while 49% from urban part in Hilla city and Mahaweel region. Concerning the economic status of children families income were (47%) low and not enough that means they couldn’t tolerate the cost of medications which were needed for their sick children, besides the requirements of their living status and health issues 8. Children with kalazar in the study shows a complications because of bleeding tendency (13.5%); while (20%) of the sample suffer from anemia; (14%) from hepatosplenomegaly 9. Children stay (1-2 wks) mostly (71.5%) of them; this period of time is not enough for better prognosis 10,11. Only (34%) of the children got complete recovery while (35%) of them gets worse condition. The main complications are septicemia(16%), Nephritis (15%) and pneumonia (12.5%). These complications lead’s the children with kalazar to death. Also respiratory failure (29%); renal failure (34%); and (37%) because of septicemia. Children becomes resistant to treatment due to their weak prevention to disease and poor immunity system 12.

**Recommendations:**

1- Encourage more experimental studies and educational programs concerning kalazar disease in terms of planning and implementing high standard of medical and nursing therapy, through organizing scientific efforts by the Iraqi Ministry of Health and the Academic work within the Iraqi Universities for better control of the disease and personal protection in the community.

2- Provide safety methods and environmental management especially in rural area in order to reduce epidemiological problems, also to interrupt the transmission of the disease in the community and decrease the mortality rate.

3- Apply effective network of communication through Broadcasting; Social Media to increase public information concerning kalazar disease in terms of
prevention and early detection of sick children, and to provide and maintain healthy approach of medical treatment and nursing care within the society.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved and all experiments were carried out in accordance with approved guidelines.

Assessment of Diabetes Patient Adherence to Dietary Recommendation in Diabetics Center in Al-Najaf city

Iman Qasim Kteo Al-hussein 1, Zahraa Abdull Abbass Taher Al-Khafajy 1, Haider Mohammed Halooob AL-Abedi 1, Athraa Abbas Al-Zeyadi 2

1 M.Sc. Adults Nursing, Faculty of Nursing, University of Kufa, 2 M.Sc. Maternal and Newborn Health Nursing

Abstract

Objective: This study aimed to assess of diabetes patient adherence to dietary recommendation in Diabetics center in Al-Najaf city and to find out the relationship between the diabetic patient adherence to dietary recommendation and their demographic and clinical data. Methodology: Descriptive analytic design was carried out to assess of diabetics patient adherence to dietary recommendation in Al-Najaf City/ Health Directorate of Al-Najaf Al-Ashraf / Al-Sadder Medical City / Al-Najaf Center for Diabetes and Endocrine. The study was carried out from February 1st, 2018 up to March 28th, 2018. A non-probability (accidental) sampling technique was used consisting of (100) female and male those who visit Al-Najaf Center for Diabetes and Endocrine. Data collected through using of a well-designed questionnaire consist of three parts: Part I: Socio-demographic Characteristics, Part II: Clinical Data: consists of (6) items and Part 11: Patient adherence to dietary recommendation. This part of the questionnaire consists of (16) items.

Conclusion: It is concluded that the Majority of the stay sample have fair adherence to diabetics dietary recommendations.

Recommendation: Based on study conclusion, its need for a good relationship between the patient and health-care provider in order to provide more understanding and knowledge about the disease and its non-medical management and diabetic’s patients need dietary recommendations with means of education, such as published materials with regard to dietary regimen.

Keywords: Diabetes, Patient, Diabetics Center in Al-Najaf city

Introduction

Diabetes mellitus (DM) consist an enormous public health problem globally, associated with high morbidity and mortality 1. Normally, a certain amount of glucose circulates in the blood. The major sources of this glucose are absorption of ingested food in the gastrointestinal tract and formation of glucose by the liver from food substances. Diabetes mellitus (DM) is a chronic progressive metabolic disorder characterized by hyperglycemia mainly due to absolute (Type 1 DM) or relative (Type 2 DM) deficiency of insulin hormone 2. The exact mechanisms that lead to insulin resistance and impaired insulin secretion in type 2 diabetes are unknown, although genetic factors are thought to play a role. Regardless of the specific cause, the destruction of the beta cells results in decreased insulin production, unchecked glucose production by the liver and fasting beta cells cannot keep up with the increased demand for insulin, the glucose level rises and type 2 diabetes develops Despite the impaired insulin secretion that is characteristic of type 2 diabetes, there is enough insulin present to prevent the breakdown of fat and the accompanying production of ketone bodies 3. The treatment of diabetes should start with non-pharmacological therapies such as lifestyle interventions. Diet plays a major role in the therapeutic strategy to keep patients with diabetes in good glycemic control and prevent micro and macro vascular complications 4. According to the American Diabetes Association (ADA) and the European Association for the study of Diabetes (EASD) prescribed dietary recommendations for the
treatment of this disease since many years. Type 2 Diabetes is defined as chronic hyperglycemia resulting from either decreased insulin secretion, impaired insulin action or both in the absence of autoimmune destruction of the pancreatic beta cell. Classically, type 2 diabetes occurs in the older, obese patients in the setting of strong family histories of diabetes and in association with other components of the metabolic syndrome. Unhealthy practices and perception for diabetic patients can lead to increase the effect of the disease and complications which can be prevented. The diabetic complications such as nephropathy and retinopathy and neuropathy can affect the quality of life of the patients and can lead to a significant effect on patient’s quality of life and productivity. Healthy dietary habits and lifestyle modifications the cornerstones of type 2 diabetes prevention and management. Adherence to lifestyle modification recommendations lessens the disease burden and reduces the morbidity and mortality associated with type 2 diabetic complications.

Methodology

Design of the study: Descriptive analytic design was carried out to assess of diabetics patient adherence to dietary recommendation in Al-Najaf City/ Health Directorate of Al-Najaf Al-Ashraf / Al-Sadder Medical City / Al-Najaf Center for Diabetes and Endocrine.

Study objectives: This study aimed to assess of diabetics patient adherence to dietary recommendation in Diabetics center in Al-Najaf city and to find out the relationship between the diabetic patient adherence to dietary recommendation and their demographic and clinical

Duration of the study: The study was carried out from February 1st, 2018 up to March 28th, 2018.

Sample of the Study: A non-probability (accidental) sampling technique was used consisting of (100) female and male those who visit Al-Najaf Center for Diabetes and Endocrine. The Study Instrument: Data collected through using of a well-designed questionnaire consist of three parts: Part I: Socio-demographic Characteristics: This part consists of (7) items, including (gender, age, and marital status, level of education, occupational status, residency and socio-economic status) and Part II: Clinical Data: consists of (6) items, including (duration of disease since diagnosis, treatment, health education regarding self-care activities, complications, smoking and body mass index). Part III: Patient adherence to dietary recommendation. This part of the questionnaire consists of (16) items, the items include assessing patients’ adherence to dietary recommendation.

Ethical consideration: This is essential value and should be obtained before collecting the information, to respect the patient’s dignity and values. The investigator can achieve this permission from the moral committee at the Nursing Department in the faculty of Nursing / University of Kufa. Also another agreement from Al-Najaf Al-Ashraf Health Directorate / Al-Sadder medical city / Al-Najaf Center for Diabetes and Endocrine. In addition to above, the researcher told each participant that this is an involuntary work, and they can leave any time even the interview process uncompleted.

Questionnaire Validity: The questionnaire validity faces validity for the initial developed instrument which is specified through panel of (5) experts (4) Experts from faculty of Nursing/University of Kufa (with experience of > 5 yrs at their jobs field). Who were asked to review the instrument, and to inspect relevancy, clarity, and sufficiency of the questionnaire to measure the concept of interest. The data was collected through the applying of the developed questionnaire with aid of structured interview technique with the subjects as they are individually interviewed. The data collection process started from March 1st, 2018 to March, 20th, 2018.

Statistical Analysis: In this study, the data were analyzed by using of (SPSS) program version 19 (Statistical Package for Science Service), and the statistical package (Excel 2013).

Related to table (4) there were good relationships between the patient (occupation, type of treatment and complications) with their adherence to dietary recommendations.

Discussion

According to (Table 1) in the results, the study shows that the entire study sample (54%) are male. The finding is consistent with results of [9] which mentioned in their study result that majority of the study subject were male. Regarding their age, the majority (86%) of the research samples are at age group of (50) yrs and more. This result is in agreement with other study [10] in their study found that a third of the participants, (26.9%) aged 50 to 59 years. Concerning the marital status the majority (86%) of the study subjects are married. This finding reinforced with the study result of [11] which mentioned majority of the study sample were married.

In related to the level of education the most of the study samples (31%) are illiterate while regarding the diabetic patient occupational status, about (45.0%) are house wife. These results matching with the study result of [8]. Concerning socio-economic status, about half of the sample (47%) reveals their economic status that is barely sufficient, while concerning the residency the study result show that highest percentage (84%) of the study sample are lived in urban area. These result reinforced with the study of [2] which mentioned that 80% of people with diabetes live in low- and middle-income countries.

Concerning duration of disease in the (table 2), the higher percentage (56%) is for those who are suffering from the diabetic for period from 10 years and more. This result comes along with the findings of other study which is carried out by [12].

Regarding the type of treatment, the results of the study display that the highest percentage (34%) of the study subjects are with oral hypoglycemia treatment. This result matching with the study result of [9] which mentioned the majority of participants were taking oral hypoglycemic medications. The present study shows that in regards to the education related to self-care, the most of the study subject (72%) are not received education related to self-care. This finding may related to the lack of nursing education and instruction to the patient about the dietary and exercise recommendation for the management of the diabetic disease and to reduce the complications related to disease. Related to the smoking, the majority of the study samples (84%) are not smoker. These findings matching with the study done by [13] who represents the majority of their study sample were not smoker. In regard to the study subject body mass index, the most of the study subject (38%) are overweight. These result agreements with the study finding done by [14] that represent the majority of their sample were overweight. Concerning the complications related to disease, the highest percentage of the study sample suffers from Neuropathy & Eye problems.

According to the above (table 3) in the result, the overall assessment of diabetic’s patient adherence to dietary recommendation is fair. This outcome is reinforced by a study done by [12] who concluded in their study results that the level of adherence to dietary recommendations in the study group was moderate.

Table (4) in the result shows that there are high significant relationship between two items (occupation and treatment ) and patient’s adherence to dietary recommendation at p-value less than 0.05, in addition there were significant relationship between the complication related to the disease and patients adherence to dietary recommendation at p-value less than 0.05. While there are non-significant relationship between the other items of diabetic patients demographic and clinical data and their adherence to dietary recommendation at p-value more than 0.05.

Conclusions

1- It is concluded that the most of the research sample are male and their dominant age are within 50 years and more, the most of them are illiterate. It was summaries that the most of the study sample taking oral-hypoglycemia medication, most of them not received education related to the disease and their dietary recommendation and in regard to their BMI it’s concluded that most of them are overweight. It is concluded that the Majority of the stay sample have fair adherence to diabetics dietary recommendations. It is concluded that there are significant relationship between the patient (type of treatment, occupation and complication related to disease) and their adherence to dietary recommendations.
Recommendations:

1. Based on study conclusion, its need for a good relationship between the patient and health-care provider in order to provide more understanding and knowledge about the disease and its non-medical management. Encourage the diabetic patients who visit the diabetic center to follow the healthy dietary recommendations. Diabetic’s patients need dietary recommendations with means of education, such as published materials with regard to dietary regimen. It is recommended to design proper booklet by the diabetic’s center to guide the visitors about the non-medical management of diabetic’s disease.

Impact of Adolescents’ Life Style and Reasons of Skipping Essential Meals upon their BMI at Secondary Schools in Baghdad City

Buthainah Basheer Saleh1, Eqbal Ghanim Ma’ala2
1Lecturer- Collage of Nursing- Al-Bayan University, 2 Prof., The Dean Collage of Nursing, University of Baghdad

Abstract

Background: Excessive harmful and unhealthy weight-control behaviors have potential serious consequences due to impact on their life style. Specifically dieting is considered a major risk factor for eating disorders. Unhealthy dieting can also decrease intake of energy and essential nutrients.

Objective: The study aimed to identify the adolescents’ lifestyle, and reasons of skipping essential meals and find out the relationship between adolescents’ lifestyle and reasons of skipping essential meals and their demographic data (gender and Body Mass Index).

Methodology: A descriptive study design was conducted on impact of lifestyle and reasons of skipping essential meals upon adolescents’ Body Mass Index in secondary schools at Baghdad city, starting from 20th of April 2013 to the end of October 2014. Non-probability (purposive) sample of 1254 adolescents were chosen from secondary schools of both sides of Al-Karkh and Al-Russafa sectors. Data was collected through a specially constructed questionnaire format include (20) items multiple choice questions. The validity of the questionnaire was determined through a panel of experts related to the field of the study, and the reliability through a pilot study. The data were analyzed through the application of descriptive statistical analysis frequency, & percentages, and inferential statistical analysis, chi-square, are used.

Results: Regarding the gender, finding indicates that males and females (48.7, and 51.3%) respectively, were approximately equal, and the result study samples find more than one forth BMI were almost equal in under and normal weight percentile (27.8%, and 27.8%) respectively, they spent mostly time (5 hours and more) in watching TV, and use the computer for playing games, and sometimes eat during watching TV or playing computer games. Adolescents’ gender has highly significant association with times sharing with physical activity per week but the other items have no significant association. Adolescents’ Body Mass Index has highly significant association with their lifestyle. Adolescents’ gender has highly significant association with the reasons of skipping breakfast meal and the adolescents’ Body Mass Index have no significant association with the reasons of skipping meals

Key wards: Lifestyle, skipping essential meals, Body Mass Index.

Introduction

Adolescents’ media exposure is one of important factors for accessibility of fast food and snack food through advertisement messages. This factor is representing external environmental factors from adolescent development theory and can shape youth’s eating behavior according to specific situation differentials. Logically, number of media in the family can be addressed in eating habits clearly as when youth had exposed too many kinds of media frequently. Youth can follow and imitate according to famous stars from media and advertisements. In addition, when youth were accessed to many shops selling variety of fast food and snacks, they will be tried to buy and got these with reasons of modernization as well as busy schedules of businesses. (1) In regard to mass media, teenage group is the main target group of consumer product that is all luxury goods or malnutrition food such as high
sugar, high fat, high calorie, high sodium food, snack in attractive package candies, or chewing gum and so on. Especially teenagers always regard consumption as fashion by following frequent commercial advertisement such as televisions, radios, magazines, movies, and imitation from celebrities or favorite persons such as movie stars, singers, actors, actresses, sportsmen as well as copying friends in the group. Moreover, a number of studies in other countries such as Australia and the United Kingdom have found that television advertising to children for high sugar and high fat foods is prevalent \(^{(1)}\). In Thailand, advertising of all forms, but particularly television advertising, encourages children to eat unhealthy foods. Many children spend several hours a day in front of the television and computer play games. It can perhaps be said that families and advertisements together create sugar addiction among children. Some companies even promote their products for children inside school and other free samples to create brand loyalty. Children who watch a lot of television are less physically fit and more likely to eat high fat and high energy snack foods and some candies, because television takes time away from play and exercise activities. \(^{(2, 3)}\) Commercials for healthy food make up only 4% of the food advertisements shown during children’s viewing time. The number of hours of television viewing also corresponds with an increased relative risk of higher cholesterol levels in children. Television and computer using can also contribute to eating disorders in teenage girls, who may emulate the thin role models seen on television. Eating meals while watching television should be discouraged because it may lead to less meaningful communication and, arguably, poorer eating habits. \(^{(4, 5)}\)

Parents may also influence not only on adolescents but also on their child’s behaviors, and ultimately weight, through the social-emotional climate in the home, particularly given evidence suggesting that overweight in adolescence is associated with greater family conflict less family cohesion. The family social-emotional climate in the context of pediatric health studies includes variables, such as level of cohesion, adaptability and connectedness, as well as family meal environment. There has been limited focus on associations between family climate and specific weight-control behaviors and body image among adolescents, it has been suggested in some reasons is significantly associated with disordered eating and weight-control behaviors among adolescents, with lower family cohesion and adaptability predictive of binge eating, and use of extreme weight loss behaviors, such as vomiting and crash dieting among adolescent females. \(^{(6)}\)

Family connectedness, prioritizing of family meals, and a positive family mealtime environment have been found to be more inversely associated with unhealthy weight-control behaviors (UWCB), self-esteem, and body satisfaction among at-risk for overweight and youth overweight, suggesting that the family social-emotional climate dose not only affect on behavior of adolescents, but also on their cognitions. Family meal structure (e.g., fewer family meals), and more than familial expression of weight concerns. More evidence is needed to assess the effect of parent and family variables on weight-control behaviors, overeating and body image, particularly in an overweight population of adolescents, given that this population appears to be at greater risk for use of extreme weight-control behaviors and binge eating. \(^{(7, 8)}\)

There are weight control strategies which may include healthy behaviors such as moderate dieting and exercise, and can provide potential health benefits to adolescents to unhealthy eating practices including skipping meals, fasting, restricting intake of certain foods, and chronic dieting behaviors as well as potentially harmful behaviors such as self-induced vomiting laxatives, and diet pills, and adolescents smokers. \(^{(9)}\)

Excessive harmful and unhealthy weight-control behaviors have potential serious consequences due to their impact on physical emotional and psychosocial health. Specifically dieting is considered a major risk factor for eating disorders. Unhealthy dieting can also decrease intake of energy and essential nutrients and may be associated with a variety of symptoms including fatigue anxiety, and constipation and irregular menstrual cycles among girls. \(^{(10)}\)

**Methodology**

A descriptive study design was conducted on impact of lifestyle and reasons of skipping meals upon adolescents’ Body Mass Index in secondary schools at Baghdad city, starting from 20\(^{th}\) of April 2013 to the end of October 2014. Non-probability (purposive) sample of
1254 adolescents were chosen from secondary schools of both sides of Al-Karkh and Al-Russafa sectors. Data was collected through a specially constructed questionnaire format include (20) items multiple choice questions. The validity of the questionnaire was determined through a panel of experts related to the field of the study, and the reliability through a pilot study. The data were analyzed through the application of descriptive statistical analysis frequency, & percentages, and inferential statistical analysis, chi-square, are used.

</tr>
</tbody>
</table>

χ² = Chi-square, sig. = significant, p-value ≤ 0.05

This table shows that adolescents’ gender has highly significant association with the reasons of skipping breakfast meal but the other item have no significant association.

**Discussion**

In the present study as shown in table (1) refers to statistically distribution of the observed frequencies, percentages of all studied sample demographical characteristics variables. Regarding to the gender, the finding indicates that males and females (48.7, and 51.3%) respectively, were approximately equal. This study was nearly agrees with Romanian high schools study sample (43.1%, and 56.9%) for male and female respectively. The result study samples find that more than one forth BMI were almost equal in under and normal weight percentile (27.8%, and 27.8%) respectively, that indicate they did not have good nutrients for developing their physically and psychologically performance and this result supported with Romanian study because most of the study is indicated about under and normal weight for both genders (16.5% and 73.4%) respectively. (11)

New Mexico middle school students recently surveyed, 20% reported watching two hours of TV on an average school day, and 16% watch five or more hours per day. Half of all high school students watch from one to three hours of TV on an average day, while 20% watch four or more hours. (12) Regarding to adolescents’ lifestyle in table (2and 3) this result agrees with the finding of Romanian study most of the sample spent mostly times eating when watching TV and computer games. (1)

Adolescents’ gender has highly significant association with times sharing with physical activity per week but the other items have no significant association shows that in table (4), this results agrees with adolescents Damascus, Syria study . (13)

Adolescents’ Body Mass Index has highly significant association with their lifestyle shows that in table (5), this results was disagrees with adolescents Saudi study shown that no significant association BMI with Saudi adolescents’ lifestyles . (14)

In tables (6)(7) there are many reasons lead adolescents always and sometimes skipping the breakfast meal like, no appetite at early morning when they want to go to school, or no time to prepare their meal or no anyone to prepare it, and some of them self-esteem overweight. While the study samples’ reasons of
skipping lunch and dinner meal by mostly not eating the favorite food, or they have a conflict with their family, always eating snacks when they go to school, did not fasting to keep their weight, or because of the schools time the adolescents ate their lunch late, sometimes eating more at watching TV and playing by computer games, and eating at midnight, while they did not sleep after eating at night. This result agrees with the Turkish study. (15)

Abstract

Objectives: The objective of this study was to assess the short term effect of relaxation exercise on vital signs measured at baseline.

Method: A quasi-experimental design with pre and post-intervention with a group control method. Sixty subjects, divided to study and coronal group measurement of vital signs (Temperature, pulse, respiration and blood pressure) done by researchers, by using a calibrated sphygmomanometer, mercury thermometer, and done of four relaxation exercises include (deep breathing, leg relaxation exercise, arm relaxation exercise, and face muscles relaxation exercise).

Results: The findings of research appear there is a significant difference between the study and control sample in vital signs after applied relaxation techniques, and This table reveals the statistical significance and high significance between study and control study for the physical parameter (vital signs) after applied the relaxation technique.

Conclusions: The currents study concludes, some relaxation exercises such as (deep breathing, leg relaxation exercise, arm relaxation exercise, and face muscle relaxation exercise) after application for a study group, make a slight alteration in vital signs. And there is no significant association among the control group. The authors recommend the training of the office employees about some relaxation exercises.

Keywords: Effect, Nurse, Relaxation Exercise, Vital Signs, Measurement.

Introduction

The application of relaxation exercise in reduce anxiety and pain relief mentioned in several works of literature and have well resulted in reducing pain, anxiety, and lowering vital signs 1-3. Regarding surgical intervention, were the highest levels of anxiety and fear, the nurse can play a pivotal role in lowering a patient’s vital signs related to anxiety from surgery 4. Also, Nurses play a role in the adaptive response and rise patient experience to emotional problems before the surgical procedures which affect blood pressure, pulse, and respiratory rate to be near baseline 2. On the other hand, patients with maladaptive responses to pain and anxiety can play a negative role not only in need of sedative or opioids drugs but in the length of hospital stay 2,5. According to literature, there are several unpleasant feelings and discomfort associated with the stressed and anxious patient include muscles tight up such as headache, backache, neck and shoulder pain, instability of breathing, panic, palpitation, tremor, numbness in the hand and the face, as a result, relaxation is the most effective way of how to control the physical and feeling. There are many hormones such as cortisol, glucagon, adrenaline, epinephrine, and norepinephrine are connected with stress as well as there are many
physiological indicators including blood pressure, heart rate, respiratory rate, and body temperature. According to Kim et al. (2016) progressive muscle relaxation exercise creates a positive impression, to reduce the level of stress that evidenced by low blood pressure, slow breathing and decrease heart rate. The ability of people to be relaxed is required to learn, it is skilled more than natural ability. Moreover, relaxation exercise is safe, cost-effective, availability, and easy to nurse to teach the patients in multi health care setting. The current study measures the effects of some relaxation exercise in making a slight alteration in vital signs for persons in the workplace, the use of the inexpensive method is available can make positive effects regarding physiological body changes and can increase productivity.

Methodology

Research Hypothesis: the author hypothesized the most study subjects, have slight changes in vital signs after relaxation exercise practice.

Design: Descriptive design study was conducted using a questionnaire to collect data.

Setting and Data Collection: Twenty subjects in the college of nursing university of Al-Muthanna who met the inclusion criteria were vital signs measured and intervention of relaxation exercise and after that vital signs were measured.

Ethical Approval: This study was approved and permitted by the ethical committee in the college of the Nursing University of Al-Muthanna. The purpose of the study was explained to the participants. Informed consent was reviewed and permitted by the ethical committee in the college of the Nursing University of Al-Muthanna.

Study sample: the researchers applied this research on (60) employer office, Instructor, and worker are the population in this study. The target population that provided the sample data is a group of subjects who met the sampling criteria. All subjects with different educational levels were included in this study.

Instrument: study instrument includes

This tool consisted of two parts:

Part I: Subjects demographics characteristics include: age, gender, level of education, occupation.

Part II: Vital signs measurement before and after relaxation exercise intervention.

Data Analysis: The statistics done by the Statistical Package for the Social Sciences (SPSS) version 22 software was used to perform the statistical analysis. By use frequency, percentage, mean, slandered deviation, and dependent and independent t-test.

Findings

The current findings of 60 clients who participate in this study, were their mean age of the study group 37.90, and the control group was 38.06 mean of age and the majority (30%) was 29-35 years old. Regarding gender distribution, the majority of the study sample was female in the study group (66.7%) and the control group(73%). The quarter 26.7% of the study group was a bachelor’s degree and one-third (33.3%) of the control group also bachelor’s degree. According to marital status, the most (86.6%) of the study group was married in the same manner the most (93.3%) of the control group also married. Finally, according to the residence, the majority of 66% of the study group was urban, and near two-third (73%) of the control group also residence in the urban area see table (1).

In comparison between study and control groups of vital signs measurement, the study group systolic blood pressure SBP was 114.63 mean of scores and the control group was record 118.63 mean of score SBP readings and have a significant association between study and control groups(t=-2.379,p = 0.020). The diastolic blood pressure DBP reading for the study group recorded 62.13 mean of the score, and 65.00 mean of scores for the control group, and The single most marked observation to emerge from the data comparison was the significant association between study and control group (t=-3.627,p = 0.001). The findings also show the body temperature record 37.06 mean of the score for the study group, and body temperature record 36.13 mean of scores, and there is a significant association between the study and control group post applying relaxation exercise (t=-5.470,p= 0.000). It is interesting to note the pulse rate for the study group was 72.90 mean of the score and the pulse rate for the control group was 70.40 mean of the score, and there is a significant association between study and control group (t=-2.232, p = 0.001. Finally, the respiratory rate was 14.70 mean of the score for the study group, and
15.83 mean of scores for the control group, and there is a significant association between the study and control group \((t=-3.554, p=0.001)\) after relaxation exercise applied to see table (2).

The comparison significance of vital signs means of score between pre-application and post-application period for the study group. Current findings show the SBP reading has a significant association between pre/post-test for the study group were \((t=4.054, p=0.000)\). Regarding DBP, the findings show a significant association between before applied period and after an applied period of relaxation exercise were \((t=2.948, p=0.000)\). Also, body temperature had a significant association between both pre/post applied relaxation exercises were \((t=11.366, p=0.000)\). According to pulse rate, there is a significance relationship pre/post applied relaxation exercise \((t=15.031, p=0.000)\). Regarding the respiratory rate, there is a significant association between pre/post applied relaxation exercise was \((t=16.858, p=0.000)\) see table (3).

Discussion

The current findings of 60 participants showed, according to SBP, there is a significant association 0.02 between the study group were the mean of score 114.6, and the standard deviation was 7.88. These results agree with the study done on preeclampsia primiparous women, the authors implement two types of exercise on two groups of preeclampsia woman and the found a significant association between the systolic and diastolic blood pressure reading in pre-intervention and post-intervention and there is no significant association in the control group [7]. These reflect the importance of relaxation exercise in reducing blood pressure (see table 2,3) This result of the study is similar with the article explained most people seeking medical attention for decreased blood pressure with muscle relaxation in various age group [8] and Maria et al. (2016) indicated that Simple yoga exercises (as relaxation exercises) may be useful as a supplementary hypertension therapy in addition to medical treatment [9]. Regarding temperature reading, the findings show the significance association
0.000, of body temperature, reading between pre-relaxation exercise intervention 37.066 ±0.583, and post-intervention 36.133 ±0.730, in comparison with pre-application of relaxation exercise for both study and control groups. These results come along with Ismansyah et al. they found the muscles relaxation have greatest effects on the body temperature in contrast with slow breathing intervention [10]. According to the pulse rate record, the results of the study show the significance association 0.030 between study group 72.900 ± 4.389 and the control group 70.400 ± 4.287, and the authors notice a slight alteration in pulse rate nearly two beats. On the other hand, there is no significant association between the study and control group before the application of relaxation exercise. These results are supported by Sahin & Basak were they found that can intervene progressive relaxation exercise as nursing interventions to increase patients’ satisfaction and positively affect vital signs in patients who undergo surgery with spinal anesthesia there is a significant association between study and control groups post- applied of progressive relaxation exercise. The importance of Sahin and Basak is evidence of the effects of relaxation exercise not only in reality but also in the virtual environment, so the current authors ensure the application of the relaxation exercise in a real environment. Finally, the respiratory rate also has light alteration after application of relaxation exercise where the p-value was 0.001 and the study group 14.700 ± 1.235 and the control group was 15.833 ± 1.234 and there is no significant association between study and control groups before relaxation exercise application [11]. These results come in the line with Hameed et al, and Chatterjee, & Mukherjee, they found the significant differences in the experimental group after they applied muscle relaxation exercise and music therapy [12&13]. The authors found the role of relaxation exercise to make a slight alteration in vital signs and especially in respiratory rate. Music as relaxation technique used to patients hospitalized in a hospice environment, they found this relaxation technique effect on vital parameters such as blood pressure, heart rate and oxygen saturation [14]. The result of this study similar the research done by Sarıtaş and Araç, (2016) explained the effectiveness of some relaxation therapy on vital signs (decrease in pulse values, systolic blood pressure value and diastolic blood pressure) and pointed the effectiveness of some relaxation therapy increase the oxygen saturation rate of patients in surgical intensive care unit [15].

Conclusions

The currents study concludes, some relaxation exercises such as (deep breathing, leg relaxation exercise, arm relaxation exercise, and face muscle relaxation exercise) after application for a study group, make a slight alteration in vital signs. And there is no significant association among the control group. The authors recommend the training of the office employees about some relaxation exercises.

Effect of Diabetes and Hypertension on Right Carotid Artery Intima Media Thickness and Variable Spectral Waveform Indices And Parameters in Relation To Age for Iraqi Patients

Samar I. Essa¹, Ahmed Abduljabar Al-Sabbagh², Satar M. Kadam³
¹Assist. Prof. Dr., Department of Physics, College of Science, University of Baghdad, Baghdad, Iraq, ²Lecturer Dr., National Diabetes Center (NDC), AL-Mustansiriyah University, Baghdad, Iraq, ³Lecturer Dr., Surgery Department, College of Medicine, University of Baghdad, Baghdad, Iraq

Abstract

Background: Arterial stiffness is related with atherosclerosis and cardiovascular disease events. Patients with atherosclerotic disease show to have larger diameters, reduced arterial compliance and lower flow velocities.

Aim of study: To compare between patients of two age groups with concomitant diseases diabetes and hypertension in regard to intima media thickness and blood flow characteristics in order to estimate the blood perfusion to the brain via the common and internal carotid arteries.

Subject and Methods: 40 patients with (diabetic and hypertension) diseases were enrolled, they were classified according to age. Color Doppler and B mode ultrasound was used to determine lumen Diameter (D), Intima – media thickness (IMT), end diastolic velocity (EDV), peak systolic velocity (PSV), Resistive Index (RI), Pulsatility Index (PI), and the flow rate indices were calibrated and calculated.

Results:- Results show that the change in the lumen diameter between the old patients group and the younger group were (2.02%) with insignificant (p value >0.05), and the difference in the in intima-media (IMT) thickness between the two age groups (35- 55) and (56-75) are (33.8%) with significant (p value <0.05). The change difference in peak systolic velocity was (-13.29%) with insignificant (p value >0.05), while the difference in the (EDV) between both age groups was (-38.02%), with significant p value <0.05. Pressure gradient and flow rate have given insignificant difference between both age groups.

Conclusion: The intima media is significantly thicker for the old age group than in the younger group. The increased thickness of intima media did not influence the lumen diameter significantly. A clear change in PSV, EDV, RI, and PI was observed which have influenced blood perfusion to the brain.

Keywords: Diabetic and hypertension, Blood flow velocity, Right common carotid artery.

Introduction

Several studies have shown that arterial stiffening occurs with age, and is associated with the increase of cardiovascular disease ¹,². Increased intima media thickness of the common carotid artery is a good marker of atherosclerotic and predictor incidence of stroke ³. Age effect on the particular smooth muscle (which found within and consist the majority of the wall of blood vessels, arteries have more bulk smooth muscle within their wall than vein, thus their greater wall thickness) can reduce elasticity and compliance, also increase in wall thickness, mainly affecting the media and intima, blood velocity also decreases, aged vessels show reduced collagen fiber and calcium are accumulated in the artery causing calcification and thus increase endothelial permeability.⁴

Diabetes and hypertension are a major risk factor for coronary heart disease and stroke and is the major
B-mode ultrasound high resolution which is non-invasive method was used to evaluated intima-media thickness of the common carotid artery can serve indicator for carotid atherosclerosis 6.

Internal carotid artery stenosis is estimated by parameters (end-diastolic velocity, peak systolic velocity, and resistive index) are used to measure the pulsatile blood flow that related to vascular resistance and vascular compliance caused by microvascular bed distal and reflects wall extensibility 7.

Pulsatility index can be calculated by (peak systolic velocity - end diastolic velocity) / mean flow velocity 8; increase pulsatility index may be indicate that severity of small vessel disease, contribute to vascular injury and progression of atherosclerosis in cerebral vasculature 9.

Doppler ultrasound was used to evaluate blood flow velocity in a cardiac cycle including end diastolic velocity (EDV), peak systolic velocity (PSV), pulsatility index (PI), and resistance index (RI) 10.

subject and methods

The study enrolled 40 patients with type 2 diabetes Mellitus and hypertension (21 females and 19 males, with a mean age of 56.17± 9.74 years). The consent of the patients were obtained for the purpose of conducting the study after being informed of the aim of the study and Medical Ethics Committee of hospital approved the study.

The present work was performed in National Diabetic center/ AL-Mustansyriah University, during the period May 2020 until July 2020.

Mindray (DC-60) Ultrasound and Doppler machine with a linear probe (7 L4A) at 6.6 – 13.5 MHz was used in this work.

All patients participating in the study suffering from hypertension and diabetes only.

The patient was lying in the supine position with aid of a pillow below the shoulder and neck to extend the neck and enable the examination of common and internal carotid arteries.

Intima-media thickness on the near and far wall (and mainly for far wall) of common carotid artery at both sides were selected and about 1 cm proximal to the bifurcation of the common carotid artery was measured. Lumen diameter was measured by placed a transducer at the lateral side of the neck correspond to the course of carotid artery.

Peak systolic velocity, End diastolic velocity, and Flow velocity were measured from both internal arteries, (1–2) cm distal to the bifurcation, the continuous tracing of the intimal-luminal interface of the near and far walls of the common carotid artery with at least three – five cardiac cycles to obtain optimum and clearest view for the wall and also for blood flow velocity and indices measurement.

Resistive index (RI) and Pulsatility index (PI) were measured and recorded.

Statistical analysis

Statistical data analyses performed using Microsoft Office Excel 2007.

Normally distributed continuous variables were presented as mean values ± standard deviation (SD). Differences between both age were analyzed with the unpaired t test. P value less than 0.05 was considered statistically significant.

Results

The study included 40 patients with hypertension and type 2 diabetes (21 females and 19 males), they have been divided into two age groups, the younger group age was 35-55 year old, mean age (47.7± 7.47 year) and the older group age was 56-75 year with mean age (62.43 ± 5.60 years). Table 1: shows the change difference between the two age groups 56-75 year old and young age group 35-55 year old for right common carotid and internal carotid arteries.

There was insignificant change in lumen diameter between the two age groups (2.02%), p value > 0.05. While the change in (IMT) between both age groups was (33.8%) with significant p value <0.05. The change in (PSV) was (-13.29%) was insignificant p value > 0.05. On the other hand the (EDV) change for younger and old
group (-38.02%) with significant value. The change in (RI) and (PI) between both age groups was (7.93%), (29.41%) respectively with significant p value < 0.05, and the change in pressure gradient and Flow rate for both age groups were insignificant p value > 0.05.

**Discussion**

In the present study show that the change difference in intima media thickness for both age groups was (33.8%). It is expected that this increase in the thickness of intima media reduces the lumen diameter significantly which, in turn, reduce the blood flow but the overall change in the lumen diameter is very small between both groups, no more than (2.02%) in spite of change in the IMT thickness. This may be due to the arterial compliance decreases or increased arterial stiffness caused by aging, hypertension and diabetes is the result of changes in the artery wall, and also associated with increased collagen deposition due to increased wall thickness and elastin content of the intima declines, these changes in elastin and collagen content are important effects on the arteries stiffness; on the other hand age causes increase endothelial cell, and hypertrophy of vascular smooth muscle. The result show that the small change in the lumen diameter with a large change in the peak systolic velocity may indicate that the slower velocity did not relate to the change in the diameter of the lumen but it may be mainly linked with the increase in the flow resistance, this conclusion is reflected on the resistive index as it is higher in the elderly than younger group by 7.93% this index is an indicator of an increased resistance in the distal vessels. For this reason the reduction in peak systolic velocity in elderly is more than in the younger group by (-13.29%), table (1). In our study, the higher resistive index and lower end diastolic velocity for elderly group in patients with large artery atherosclerosis due to a greater resistance in intracranial
vessels that also associated with an increased risk of stroke and significantly increases the prediction of cardiovascular events.\textsuperscript{15,16}

We have observed a contralateral PSV and volume flow rate (VFR) in these cases gave a higher PSV and VFR for the young group than the old group, VFR is also higher for the younger group indicating less blood perfusion for the elderly.\textsuperscript{17} Result in the present study show that pulsatility index which is higher in elderly than younger group. This increase is related to increased distal vascular resistance, and a peaked waveform causes of blood flow to be more pulsatile (increased systolic flow and decrement diastolic flow), which induce fibrosis, calcification, hypertrophy of endothelium and smooth muscle cells in cerebral circulation, this led to marker of small vessel disease and microangiopathic changes in brain with subsequent of stroke events.\textsuperscript{18,19}

The Effect of Using Competitive and Traditional Methods in Learning Some Basic Gymnastics Skills

Zaid Sami yasir¹, Diaa Fadel Abbas¹, Hayder Naji Habash Alshawi²

¹ Assistant lecturer, Ministry of education/ Najaf Education Directorate/ IRAQ. ² Prof. Dr., University of Kufa/ Faculty of Education for Girls / Department of Physical Education and Sports Sciences / IRAQ, Haydarn.

Abstract

The research aims to identify the effect of using competitive and traditional methods on learning some basic skills in gymnastics. The research sample was selected from third stage students in the College of Physical Education and Sports Sciences at the University of Kufa. The research aims to identify the effect of using competitive and traditional methods on learning some basic skills in gymnastics. The researchers assumed that there were statistically significant differences between the pre and post-tests in favor of the post-test between the two methods separately, as well as the existence of statistically significant differences between the two methods in favor of the competitive method. In learning some basic skills in gymnastics, among the most important conclusions and recommendations made by the researchers are:

1- The group that learned the competitive method achieved an improvement in learning most skills in gymnastics than the group that learned the restrictive method.

2- Directing the attention of teachers and trainers in the sports field by using the competition method as a means of learning basic gymnastics skills.

Keywords: competitive style, learning basic gymnastics skills

Introduction

The effect of the teacher’s style on his students is the degree of their academic achievement, so teaching methods in the field of physical education should guide their teachers to the goals ¹, contents and methods that help in their success in teaching and educating students on scientific grounds because successful teaching includes a mature and useful scientific material for students. It is to be alive and fruitful so that the student interacts with it and benefits from it. It is not placed in the textbooks and methodology for the purpose of the student to read it or memorize it automatically and then return it in his theoretical and scientific tests. Rather, the scientific material studied by the student to think, contemplate, experiment, conclude and evaluate the results of his experience in it and in this way may become The scientific material is a culture in the student’s ² life and not just static information stuck in his memory, and the style of competition is one of the common and necessary methods of teaching, and the effectiveness of gymnastics is one of the activities that depend on achieving achievement on individual work and has received great attention to raising the level of artistic performance, and that this level is a result The process of motor learning is imperative ³. Much research has been conducted on the importance of competition methods in student education. Competition (self and between group members and groups) is an effective and powerful teaching method for influencing his working life.

Based on the above, Researchers decided to study one of the methods of competition, which is the method of competition and compare it with the traditional method of learning some basic skills in gymnastics, and the research problem was that the effectiveness of gymnastics is one of the individual sports activities included in the sports curriculum for the third stage in the Faculties of Physical Education and it includes a group One of the basic skills requires the student to learn them, and the researchers noted through their readings
and field observations that most of the methods used in teaching basic skills in gymnastics is the traditional method, which consists of the teacher’s self-views and ideas, directing the student’s work. From here the research problem emerged in the study of any of the two teaching styles, it is able to achieve the educational goals in a balanced manner and works to raise the level of students’ performance of basic skills in gymnastics in a better way. The objectives of the research were to identify the effect of using the competitive style and the traditional method in learning some basic skills in gymnastics and to identify the differences between the competitive and traditional styles in learning some basic gymnastics skills.

### Practical part

Researchers used the experimental method for its suitability in solving the research problem on students of the third stage in the College of Physical Education and Sports Sciences at the University of Kufa for the academic year 2019-2020 and the research sample consisted of students of the two divisions (B-C), which students (20 students) were randomly selected. As (10 students) from Division (B) were selected to represent the experimental group and (10 students) from Division (C) to represent the control group, and for the purpose of homogeneity, (2 students) were excluded from the research group due to absence and injury, and thus the research sample became (18 Student) and as indicated in Table (1).

#### Table (1). Shows the number of members of the two research groups and the teaching method used

</tbody>
</table>

For the purposes of homogeneity and parity between the two research groups in the age, weight and height variables, and in order for the researchers to return the difference to the experimental factor, the two research groups must be equivalent and homogeneous in the variables that are related to the research and which have an effect on the variable under study, so the process of parity and homogeneity between the research group was done to control the weight variables And age and height.

For the purpose of achieving parity between the two groups, research some basic gymnastics skills that have been identified, as shown in Table (3):
Table (2). shows the arithmetic mean, standard deviations and the value (calculated t) for the two research groups in some basic gymnastics skills that were covered by the research.

</table>

Note that the value of (tabular t) is (1.74) with a degree of freedom (17) and a level of significance (0.05) greater than the value of (calculated t), and this indicates that there are no statistically significant differences between the two research groups, which indicates the parity of the two research groups,

**Tests used in the research**

Several basic motor skills have been selected in artistic gymnastics that are part of the gymnastics curriculum for third-stage students in the College of Physical Education and Sports Sciences. The most important of these skills are:

1- **Roll forward:**

It is the rotation of the body around its transverse axis so that its parts touch the ground from the shoulders to the pelvis and then the feet and lead in front of the body in a state of ball or curve and from stability or movement and that the centre of gravity of the body is close to the ground, which helps in the speed and ease of rolling.

2- **Roll back:**

It is the rotation of the body back around the axis of width and it is more difficult than rolling in front of the movement backwards and the presence of the head as an obstacle in this rolling and the movement leads backwards and the body is rounded or with the legs and they are extended and from different initial positions.

3- **Standing on the hands:**

Standing on the hands is one of the difficult movements because of the small base of support and the distance of the centre of gravity from the ground and the movement leads to either individual or doubles rise.

**Motor skills evaluation:**

Researchers relied on the opinions of experts specialized in artistic gymnastics on how to evaluate or give the final grade to students when they perform the motor skills assigned within the educational program, as it was agreed to take the degree of the subject’s professor (i.e. the final score that students obtain in the final exam when performing the motor skills).

On this basis, basic motor skills were evaluated in the students’ gymnastics hall.

**Exploratory Experience**

Researchers intended to conduct the exploratory experiment on a group of students from the same research community, but they did not enter the basic
experiment and the number reached (10) students. The experiment aimed to identify the obstacles and errors that could occur during the application of the program to avoid them, as well as the time taken for the tests.

**The main part of conducting research**

**The pretest**

Researchers intended to conduct the pre-test on the research sample in the gymnastics hall of the College of Physical Education and Sports Sciences at the University of Kufa, and Researchers intended to establish the conditions for testing from place and time and the assistant work team to achieve the same conditions or similar as possible when making the post-selection.

**Main experience (tutorial)**

The program included (12) educational units distributed into (3) basic skills in gymnastics, and each skill was allocated (4) lessons. Thus, the educational time for each skill reached (360) minutes, thus the total time for each group of the two research groups reached (1080 minutes), i.e. Equivalent to (18) hours, and the main experience (the educational program) lasted (45) days from (10/15 - 1/12/2019) and in the two teaching methods (competitive and traditional) knowing that the physical education study time takes (90) minutes in this program (The 90 minutes) broken down into:

- 25 minutes prep (warm-up)
- 45 minutes main part (tutorial application)
- 20 minutes closing part (calming down)

This division is applied to the two research groups and the implementation of the program was supervised by the assistant working group.

**Post-test**

After completing the application of the main experiment (the educational program), the post-test was conducted on the research sample on Thursday 3/12/2019 and under the same conditions or similar as possible for the test.

**Statistical means**

Researchers used statistical methods in the (SPSS) program

Results

Table (3). shows the arithmetic mean, standard deviations, and the value of (t) calculated in the pre and post-tests of the control group in some basic skills in gymnastics.

<table>
<thead>
<tr>

</tbody>
</table>

Note that the tabular value of (T) at the degree of freedom (8) with a level of significance (0.05) is evident from the results that appeared in Table (4) that the statistical differences were in favour of the dimensional test since all the calculated (t) values were greater than the values of (T) Tabular, which indicates the existence of a significant difference between the pre and post-test for the control group, which fulfils the first research hypothesis.
Table (4). shows the arithmetic mean, standard deviations, and the value of \( t \) calculated in the pre and post-tests of the experimental group in some basic gymnastics’ skills.

<table>
<thead>
<tr>

<td>4.56</td>
</tr>
</tbody>
</table>

Note that the tabular value of \( t \) is at a degree of freedom (8) and with a level of significance (0.05) = (1.83). It is clear from the results that appeared in Table (5) that the statistical differences were in favour of the post-test since all the calculated \( t \) values were greater than Table (v) values, which indicates the presence of significant differences between the pre and post-tests of the experimental group, which fulfils the first research hypothesis.

Table (5). shows the arithmetic mean, standard deviations, and \( t \) value of the two research groups in the post-tests of some basic gymnastics’ skills.

<table>
<thead>
<tr>

<td>Sig.</td>
</tr>
</tbody>
</table>

Note that the tabular value of \( t \) is at the degree of freedom (17) and the level of significance (0.05) = (2.11). It is clear from the results that appeared in Table (6) that the calculated value of \( t \) was greater than the tabular value of \( t \), which indicates the existence of significant differences between the two groups in favour of the experimental group that used the competitive method, which fulfils the second research hypothesis.

Results

It is evident from the two tables (5 and 4) that there are significant differences between the pre and post-tests and in favour of the post-test, and the reasons for the differences between the two groups are attributed to the effect of the educational program. A proper understanding of the factors and principles that are relevant to the topic to prove their impact and value in certain educational situations. The results showed that there are significant differences in the level of students ’performance in all the basic skills chosen and in favour of the experimental group, which was trained and learned according to the competitive method among the group members. The
researchers attribute that to teaching The basic skill under the excitement and motives commensurate with the situations required by the basic skills during their practice in real competition and contribute to raising the level of skill performance which is included in the educational goal, and this is confirmed by (Lotfi Abdel Fattah) (The principle of kinetic learning calls that the practice and training must take place as much as possible. The way you will practice the skill (helping learners acquire skills more quickly). And that an atmosphere that is absolutely devoid of competition is unable to consult learners to learn and achieve, and that the atmosphere in which learners compete in friendship and sportsmanship is the best educational procedure, and (Barakat) confirms who mentions (that competition with a colleague in learning affects because it is a motivating factor and forces the learner to fully use his personality Notifying him of the results of his work, comparing him with his colleagues, and his notice of the extent of his progress or delay is one of the strongest motivations for learning and that the learner’s negligence and not notifying him of his position will lead the learner to boredom and slow learning).

**Conclusion**

There are significant differences between the pre and post-tests for the two teaching methods and in favor of the post-tests. The group that learned the competitive style achieved an improvement in learning most of the skills from the group that learned the traditional method. Every skill has a peculiarity in learning by imposing the kinetic style of the skill to be learned.

Evaluation of Antioxidants Capacity of Non-Enzymatic Antioxidants and Its Effect in Glucose Level in Diabetic Patients

Rana Fadhil Mousa
Assistant Prof., College of Veterinary Medicine / University of Kerbala

Abstract

Background: Oxidative stress might participate in the pathophysiology of diabetes type 2. Systems of non-enzymatic antioxidants are made up of scavenging molecules that are formed endogenously.

The Study Objective: This study’s aims were evaluation of the non-enzymatic antioxidants and their effect in levels of glucose among diabetic patients.

Methodology: A total of eighty patients with DM type 2 and forty healthy persons (control) were enrolled within this study. Serum and plasma were obtained from collected blood samples. The Ferric Reducing Ability of Plasma (FRAP) method was used for detection of the total antioxidant capacity (TAC). Ellman’s method was used to determine the level of reduced glutathione. The serum CAT activity was detected by the technique explained by Sinha.

Results: The findings revealed that, among diabetic groups, there was a significant elevation in glycosylated hemoglobin and glucose levels; HbA1c and FBG levels were significantly higher; MDA, NO, LPI, TAC and GSH showed significant greater values. The activity of SOD showed significantly greater mean value among the control group.

Conclusion: The results suggest that antioxidants defense might be decreased in T2DM, as TAC levels were decreased. The increased levels of MDA, NO, LPI, TAC and GSH were associated with oxidative stress. Assessment of GSH could help in recognition of the extent of oxidative stress in diabetes as well as prevention and control of diabetic complications.

Keywords: Antioxidant, total antioxidant capacity, non-enzymatic antioxidants, diabetes

Introduction

Hyperglycemia that results from insulin dysfunction leads to interruption in the glucose homeostasis, one of these disorders is type 2 diabetes mellitus (T2DM). Diabetes is a chronic disorder that is, today, considered a common disease globally, and it is also widely spread among Arab countries 1. Recently, there are evidences suggesting that oxidative stress might participate in the pathophysiology of DM type 2 via rising the insulin resistance or making impairments in the secretion of insulin hormone 2. Regarding the fact that DM type 2 has an association with cardiovascular complications, oxidative stress was found to likely have a role in the diabetes pathogenesis as well as cardiovascular disease 3. Systems of non-enzymatic antioxidants are made up of scavenging molecules that are formed endogenously like glutathione, vitamin E, vitamin C, selenium, carotenoids, etc. 4. The imbalance amongst radical-generating and radical-scavenging systems is what causes oxidative stress which means more production of free radical or decrease in the antioxidant defense activity or both 5. It was reported that diabetes mellitus disease is along with an increase in the free radicals’ formation in addition to a decrease in the antioxidant defense capacity, resulting in an oxidative damage for cell elements 6. On the other hand, antioxidants are the line of defense that protects the body cells from the free radicals’ attack. The function...
of antioxidants is adding a large number of electrons into the blood vessels to be given to the monovalent free oxygen radicals that search for the lost electron, provided by antioxidants, so they become divalent, and hence, they settle and make no damage to the body cells. In diabetes, it was found that the levels of certain antioxidants like vitamin E as well as vitamin C were lowered. Additionally, among diabetic patients, the actions of antioxidant enzymes catalase, superoxide dismutase, as well as glutathione peroxidase was found to be diminished. Previously, numerous researches have been performed for studying the biomarkers of oxidative stress. In the early 1990s, a new total antioxidant capacity assay has been developed by Miller et al., and it was termed “total antioxidant capacity” (TAC).

**Methodology**

A total of 80 patients with DM type 2 and 40 healthy persons (control) were enrolled within the present study. Basic data such as age, gender, habits, lifestyle and previous medications were collected.

**Samples collection:**

Venous blood samples were collected from every fasted participant, within 2 various tubes, a plain tube contains sodium fluoride and another one EDTA coated. Samples that were collected in the plain tubes were centrifuged for obtaining the serum samples which were used for determination of antioxidant markers. Samples which were collected in EDTA coated tubes were utilized for determination of the glycated hemoglobin (HbA1c ≥ 6.2 0%) as well as levels of glucose in plasma.

**Measurement of the antioxidant markers:**

The Ferric Reducing Ability of Plasma (FRAP) method was used for determination of the total antioxidant capacity (TAC), where a ferric tripyridyltriazine complex of no color is reduced into a ferrous complex of blue color by the antioxidants present in serum. The findings were described in μmol per mg of protein. The Ellman’s method used to determine the level of reduced glutathione, via developing of a yellowish color which was read in the spectrophotometer at 412 nm. The results were expressed as μmol/mg protein. The serum CAT activity was detected by the technique explained by Sinha. The findings were described as U/mg of protein.

**Statistical Analysis**

Statistical analysis was done using SPSS (Statistical Packages for Social Sciences- version18). Data were analyzed via using One Way Analysis of Variance (ANOVA) for calculation of the p-value for healthy and other patients’ groups. Software Graph Pad Instat 3 was applied for testing the relation amongst the groups of the study. The results were presented as mean ± standard error. Statistical significant difference was considered at the level of (p ≤ 0.05).

**Results**

The basic data of the study participants were shown in Table 1. Among the study groups, males appeared to be more than females, where the sex ratio was [1.09]. The patients had an age ranged from thirty to ninety years with mean of [54 ± 3] years. The age represented was mostly from forty to sixty among healthy people as well as the diabetic patients, resembling (75%) and (60%) respectively.

**Variation of clinical parameters:**

Fasting blood glucose (FBG) and Glycated hemoglobin levels were detected for evaluation of the glycemic state among diabetic cases, they were shown in Table 2.

and FBG mean ± SD=(2.12 ± 0.14, and 1.14 ± 0.04, respectively). The body mass index (BMI) values had no significant change among patients and control groups.

| Table 2: Clinical parameters variation between control and diabetic groups: |
|-----------------------------|-----------------------------|-----------------------------|
|                            | Diabetic patients (mean ± SD) N = 80 | Control (mean ± SD) N = 40 | P value   |
| BMI (kg m²)                | 27.21 ± 5.27                 | 29.03 ± 5.32                | P > 0.05  |
| HbA1C (%)                  | 8.21 ± 0.45                  | 4.57 ± 0.11                 | P < 0.05  |
| FBG (g/l)                  | 2.12 ± 0.14                  |                             |           |

**Variation of markers of oxidative stress:**

The current study also reveals that there were modifications within both oxidant and antioxidant conditions of patients compared to controls.

The activity of superoxide dismutase (SOD) showed significantly greater mean value among the control group (0.42 ± 0.04) compared to the diabetic patients (0.37 ± 0.03) (P < 0.05). Malondialdehyde (MDA) is an aldehyde of low molecular weight which could be resulted from the attack of free radical on polyunsaturated fatty acids of biological membranes and its detection is useful in examining lipoperoxidation. The levels of serum MDA, nitrite oxide (NO) and lipid peroxidation index (LPI) showed greater values among diabetic patients (0.28 ± 0.02, 216.06 ± 8.95, and 0.182, respectively) than control group (0.29 ± 0.03, 191.40 ± 11.54, and 0.181, respectively) which indicate the oxidative damage of lipids mediated by free radicals.

The values of TAC showed a significant increase (P < 0.05) among diabetic patients (160.45 ± 7.64) than control group (210.47). In addition, the reduced glutathione (GSH) had significantly higher values (P < 0.05) in diabetic patients (9.79 ± 0.59) than control group (6.76 ± 0.58), Figure 1.
Figure 1: Levels of oxidant and antioxidant markers.

(MDA malondialdehyde, NO nitrite oxide, TAC total antioxidant capacity, SOD superoxide dismutase, GSH reduced glutathione, LPI lipid peroxidation index. * significant at P < 0.05)

Also, a significant negative relation between FBG and glutathione were detected in diabetic patients (P < 0.05), while HbA1 showed a significant positive correlation with NO among diabetic patients (P < 0.05) indicating that oxidative stress might influence HbA1c, Table 3.

Discussion

Oxidative stress might participate in the pathophysiology of diabetes type 2 via rising the insulin resistance or making impairments in the secretion of insulin hormone [2]. In T2DM, the oxidative stress had an association with massive alterations on the systems of antioxidant enzyme (SOD, CAT, GPx, GSH) as well as total antioxidant capacity (TAC) that result in peroxidative damage for proteins, lipids, carbohydrates, and the nucleic acids, as well that could be used as biomarkers for diabetes [3].

The current study assessed the oxidant status, HbA1c as well as FBG in a group of patients with T2DM. The age group which was represented mostly was between
[forty to sixty] for healthy persons as well as the diabetic patients.

HbA1c and FBG levels of diabetic patients were significantly higher than healthy people. These results were in agreement with Abudawood et al. 14 who has performed a study on the association between oxidative stress, DNA damage and cancer risk in T2DM in Riyadh, KSA, and higher levels were found of HbA1c and FBG in diabetic patients compared to controls. HbA1c and FBG are the indicators of type2 diabetes mellitus where the elevated glucose levels interfere with the metabolism of the free radicals and this is associated with increasing in the lipid and protein oxidation leading to more tissue damage 15,16.

The current study showed that diabetes mellitus disease, hypertension as well as smoking increases the oxidative stress which is represented by the significantly lower mean value of the activity of SOD among the diabetic patients, and significantly higher levels of MDA, and NO that were shown among diabetic patients, (P < 0.05). These findings were in agreement with the findings of Pieme et al. 17 study. MDA is the most essential marker of oxidative stress 18.

Raddam et al. 18 also revealed that the levels of MDA had significant high values and lower SOD levels in all diabetic patients. Also, Evereklioglu 19 found that patients with diabetes with macular degeneration showed a lesser SOD activity and greater of MDA and NO levels compared to healthy persons.

Additionally, this study revealed a significant reduction in the total antioxidant capacity (TAC) with a higher lipid peroxidation index (LPI) (but it was non-significant) in diabetic group.

A study by Sohrab et al. [20] on men with T2DM showed similar findings; where it was found that higher levels of markers of oxidative stress were observed with lower TAC. McCracken et al. 21 also found that the TAC levels were reduced among diabetic patients without glycemic control, and this was partially improved with suitable glycemic control. Similarly, Čolak et al. 22 revealed that the total antioxidant capacity were significantly lower among diabetic patients. It was mentioned that the decrease in the levels of the total antioxidant capacity is correlated to a higher occurrence of diabetes disease as well as its complications 23.

Reduced GSH, is a non-enzymatic antioxidant that has a significant role via making protection of the cells from the oxidative damage and, consequently, maintain the levels of the active state of vitamins E and C within cells throughout making neutralization to the free radicals 4. There is a possibility that the elevation in the GSH levels among diabetic patients is correlated to increasing the glutathione peroxidase activity by neutralizing free radicals that were created in the disease complications. It was found that the reduced GSH, an extracellular non-enzymatic antioxidant, makes inhibitions to the oxidative activity via several ways 27. The increased levels of NO in addition to the positive correlation between NO and HbA1 observed in diabetic patients could be described by the theory of the effect of hyperglycemia on the endothelium of blood vessels and the related vascular tone through influencing levels of NO 28. This study revealed that the oxidative stress markers were increased in diabetic patients with decreased SOD. In an experimental study, the kidney and heart SOD levels as well as liver GPx were increased 29.

**Conclusion**

This study aimed to evaluate the non-enzymatic antioxidants and its effect on levels of glucose among diabetic patients. From the findings of this study, it is suggested that there is some of evidence that antioxidants defense might be decreased in T2DM, as serum TAC was decreased. In addition, the activities of SOD were found to be reduced in diabetic patients while MDA, NO, LPI, TAC and GSH showed higher values among diabetics. The increased NO levels identifies the effect of hyperglycemia on the vascular endothelium and increasing the risk of cardiovascular complications of T2DM due to decreasing the vascular antioxidant defense. In addition, the increased levels of GSH in T2DM support that fact that oxidative stress might participate in the pathophysiology of diabetes type 2. Therefore, it is recommended that assessment of GSH could help in recognition of the extent of oxidative stress in diabetes as well as prevention and control of diabetic complications.

Abstract

Antioxidants are a line of defense that protects the cells of the body. Attacking the stray oxygen molecules. The function of these antioxidant is to add a group of electrons to the blood vessels to give them to electrolytes or monovalent free radicals so that they stabilize and calm down and do not destroy cells. Thus, antioxidants work to achieve a balance between free radicals and antioxidants In the cell and keeps the cell from being damaged. Increased electrolytes or free radicals work To weaken the ability of antioxidants’ and enzymes secreted by cells despite the fact that the cell has a self-protection and a defensive line to secrete self-antioxidants, and here the importance of antioxidants arises. These metabolic changes increase the oxidative effort and affect the ability to achieve and the efficiency of athletes, as well as the body contains a lot of antioxidant systems Oxidative stress that includes enzymes such as GSH) Glutathione Dos) Super oxide D ismutses. Exercise can produce an imbalance between ROS and antioxidants, which is referred to as oxidative stress. Dietary antioxidant supplements are marketed to and used by athletes as a means to counteract the oxidative stress of exercise. Whether strenuous exercise does, in fact, increase the need for additional antioxidants in the diet is not clear. This research showed the role of free radicals in causing oxidative stress during exercise. The results showed significant increased in malondialdehyde (MDA) level (as an index of lipid peroxidation) glutathione (GSH) superoxide dismuatse activity (SOD) in subjects after efforts of exercise in comparison with the control group.

Key Word : SOD, antioxidant , MAD, Athletes, Sport

Introduction

The cells in our body continuously produce free radicals and reactive oxygen species (ROS) as part of metabolic processes. Free radicals are molecules or part of molecules which have one or more unpaired electrons in external electronic shell. Main characteristics of these molecules are very short life span and extremely high reactivity. Injurious effects of free radicals are induced by necessity to establish electronic stability and therefore they react with next stable molecule, taking its electron and creating new free radical. The at way this molecules also becomes unstable and further interferes with other molecules from its surrounding which leads to impairments of cellular components. Free radicals are created during the process of oxidative phosphorylation in mitochondria 14. Oxidative stress occurs as a result of ROS activity and reduced protective mechanisms that lead to impairments in cells and tissues functions. It causes secondary damage through late cell death and inflammation 15. Various studies have shown that oxidative stress represents pathogenetic foundation of many diseases 16. ROS are normally neutralized by complex system of antioxidant defence 17. The system of antioxidant defence can be divided into two groups: enzymes including superoxid dismutase (SOD), catalase (CAT), glutathione preoxidase (GPX); and non-enzymes including vitamins C and E, retinol, bilirubin, uric acid, redox glutathione, thiols, coenzyme Q₁₀, stress proteins, albumins, as well as transport proteins and storage proteins for Fe²⁺ i Cu²⁺ which disable potentially harmful metal ions and their involvement in
production of free radicals. Nevertheless, low levels of ROS appear to be necessary for important physiological functions such as cell signaling, immune response, and apoptosis. Many studies have shown that exercise induces oxidative stress and causes adaptations in antioxidant defenses. Training can have positive or negative effects on oxidative stress depending on training load, training specificity and the basal level of training. Data suggest that regular long term training can induce antioxidant response to the oxidative stress. The results of a study which investigated the relationship between oxidative stress and exercise overtraining/overreaching support the possibility that the beneficial effect of physical exercise on oxidative stress might be associated with increased antioxidant defences. It is also well known that active and non-active skeletal muscles produce reactive oxygen and nitrogen species although it is not quite clear where oxidants originate during physical activity. The degree of oxidative damage, as well as the time course for elevation in oxidative stress markers has varied across studies, and appears to be dependent, among all, on the type, intensity, volume and duration of exercise. This leads to differences in oxidative status between athletes in different sport disciplines, but the results of the previous studies are inconsistent.

**Subjects and Exercise Programmed:**

12 male student volunteers as Control from education college– from Almustaqbal university college, were recruited to participate in the study. And 45 male volunteers athletes from different gym sport in Babylon province, ages between (20-40) years. All subjects were The questionnaire taken from the case and control sheets involved: types of food, occupation, age, type exercise, gender, Supplements, smoking habit, alcohol intake type Sport. All tests took place in human performance laboratory of Almustaqbal university college. The temperature ranged from 14°C to 20°C. Athletes performed all testing in the same equipment conditions and drank the same energy beverage.

**Blood Sampling Procedures**

About (5 ml.) Blood samples were collected by puncture from an antecubital vein in resting after Exercise conditions The blood samples were centrifuged (at 3000 rpm for 300 sec), and serum was divided into aliquots and frozen in dry ice prior to storage at –20°C until assayed for glutathione, MDA, and superoxide dismutase.

**Antioxidant Analysis**

**Determination of Reduced Glutathione(GSH) in Blood Serum**

GSH level was determined in blood serum using a modified method dependant by Sedlack and Lindsay, (1968). The method depends on Ellman’s reagent which contains [5,5-dithiobis(2-nitrobenzoic acid)] or known as DTNB which reacts with the thiol group of reduced glutathione to form a coloured solution absorbed at (412) nm.

**Determination of Lipid Peroxidation in Blood Serum (Malondialdehyde, MDA)**

MDA level was determined in blood serum through the measurement of MDA concentration. The method depends on the reaction between MDA and thiobarbituric acid or (Beruge and Aust, 1978) to form a coloured solution absorbed at (532) nm.

**Determination of Superoxide Dismutase (SOD) Activity in Blood Serum**

(SOD) activity level in blood serum was determined using photochemical method. The method included using sodium cyanide as peroxidase inhibitor. This methods depends on an indirect approach to determine the SOD activity through the change in formazene absorbance formed from the reduction of O2 • (which is produced by radiating the sample of serum with light) for nitroblue tetrazolum (NBT) dye (Brown and Goldstein, 1983). Decreased difference in formazene absorbance means increased SOD activity.

**Data Analysis**

All values are presented as means ± SD. Between-group, differences for selected variables were determined by SPSS Statistic Analysis.

The increase in energy consumed during exercise increases the oxygen demands of the active tissues, increasing up to 20 times in comparison with basal state. The oxygen flow in the peripheral skeletal muscle tissue can increase up to 200 times, increasing 30 times the blood flow, and the oxygen difference in the arteriovenous blow increases 3 times. As a result, the oxidative metabolism is increased, maximizing the energy produced by unit of substrate and avoiding lactate accumulation. Dillard et al. (1978) first described that extenuant exercise induced lipid damage in tissues. After that, many other investigations focused on the effects of exercise and training in oxygen toxicity and the body defense response. It is accepted that oxygen toxicity can be implicated in some pathologic situations. The understanding of the mechanisms associated with physiological responses that explain how exercise increases the oxygen toxicity and the design of appropriate measures to minimize toxicity are indispensable to: 1. Increase exercise efficacy as a preventive and therapeutic instrument in clinical practice. 2. Control the damaged tissue induced by exercise. Oxidative stress induced by extenuant exercise is a situation by which cells are exposed to a prooxidant environment and defense mechanisms are not enough, affecting the redox state of the cells. Due to this, nutritional supplements of antioxidants such as vitamin C, vitamin E, carotenids, and polyphenols in the diet are important.

Further research is required to support these hypotheses. Where the hypotheses said the Malondialdehyde (MDA) is one of the most frequently used indicators or biomarkers of lipid peroxidation. It was significantly increased as a result of exercise in the present study. Two theories support the concept that resistance exercise could lead to an increase in the production of oxygen free radicals in active muscle sites. A widely held hypothesis involves the ischemia-reperfusion injury. Intense muscle contractions can result in a temporary decrease in blood flow and oxygen availability and subsequent ischemia. The following reperfusion period (muscle relaxation) produces an abundant reintroduction of O2 and results in the formation of the O2- radical. Mechanical stress is another hypothesis used to explain an increase in free radicals. In particular, eccentric exercise causes high levels of force that has been shown to initiate muscle tissue damage. This initiates the inflammation process that eventually produces oxygen free radicals and lipid peroxidation. The significant increase in MDA agrees with other investigators. They reported that moderate intensive treadmill running exercise was sufficient to result in muscle damage and increases in the susceptibility of erythrocytes to in vitro peroxidation represented by MDA. Similar result was reported by others where they suggested an increase in plasma MDA immediately after exercise. It was also recorded a significant increase in MDA at 6 hours post exercise. Glutathione (GSH) oxidation in different tissues is a valid parameter to appreciate oxidative stress. In this situation, intracellular GSH rapidly oxidizes to GSSG. Intracellular GSSG can be reduced to GSH in the presence of a reductase glutathione and NADPH as cofactor. When the oxidative stress is high, the relation between GSSG/GSH can be higher than the reduction ability of the cells. In this situation, the heart and skeletal muscle cells pour GSSG out of the cells. In extenuant exercise, an increase of GSSG and a decrease of total glutation (GSSG + GSH) in the skeletal muscle tissues such as the liver and heart has been observed. This increasing production of GSSG exceeds the reductase glutathione’s ability to reduce disulfide group, thus explaining that the GSSG spill from the tissue to the plasma. The increasing oxidized glutathione plasma concentration as a result of the exercise has been demonstrated in many studies.

The glutathione synthesis ability in the liver is high and exercise induces a decrease of glutathione, promoting a protective response of the liver. Up to now, the work has been focused in the damaging effect of exhaustive exercise. However, moderate exercise results in a healthy and beneficial practice that prevents diseases, due to its ability to prevent oxidative stress. Oxidative stress induced by exercise depends on the type, intensity, and the length of the exercise. However, interindividual variability is attributed to the level of training, sex, nutrition, and genetic factors.

In biological tissues, the superoxide anion can be converted into the nonradical species hydrogen peroxide and singlet oxygen by the aid of SOD enzyme. Thus, SOD provide the primary defense against ROS generated during exercise. The activity of this enzyme is known to increase in response to exercise in both animal and human studies. Like to the present study in which SOD activity was increase significantly (p<0.001) in training athletes.
Therefore, athletic performance increases the production of free radicals that lead to cell damage, and then it has been observed that physical performance leads to an increase in the blood level as well as an increase in the expiratory air content of the lungs, both of which are indirect signs of metabolic oxidation, even if they differ in different people. Take an anti-oxidant Oxidation during food or through preparations before training reduces muscle fibers resulting from athletic training. A decrease in the level of fat in the blood was observed as a result of an increase Training time due to increased adaptation, Also, an increase in the blood content of the reduced GSH image was observed. In another hand, it was found that running training for athletes improves the anti-oxidant amount of blood compared to non-athletes in terms of the red blood cell content of Vitamin E for Glutatione and the activity of the catalase enzyme. So this research show the Regular exercise increases the efficiency of the antioxidant defense system Reduced amount of oxidative stress in the absence of regular exercise.

Health Consequence of Gas Filling on the Workers’ Health of Two Cities in Iraq (Comparative Study)

Hussein Ali Mohammed¹, Wijdan Abdulameer Kamel², Abid Salih Kumait³

¹Lecturer, Department of Adult Nursing, University of Kirkuk, College of Nursing, ²Assistant Lecture, Department of Basic Nursing Science, University of Kirkuk, College of Nursing, ³Ph.D. Assistant Professor, Department of Adult Nursing, University of Kirkuk, College of Nursing

Abstract

A gas is a sample of matter that conforms to the shape of a container in which it is held and acquires a uniform density inside the container, even in the presence of gravity and regardless of the amount of substance in the container. If not confined to a container, gaseous matter, also known as vapor, will disperse into space. The term gas is also used in reference to the state, or condition, of matter having this property.

Aims: To identify the demographic data of the worker and to comparative beteen kirkuk gas filling company and Tikrit gas filling company among work hazards like health, physical, chemical, physiological, mechanical hazards.

Methodology: Quantitative design (comparative study) was conducted for worker in company gas filling in Tikrit (Salah aldin) and Kirkuk city the study was carried out from the 10th February 2020 to 13th August 2020. This study was conducted in Kirkuk city and Tikrit (Salah aldin). The present study was conducted in two company of gas filling: Company gas filling / branch Kirkuk and Company gas filling / branch salah Eldin. The data was prepared, organized and coded into the computer file; Statistical Package for Social Science (SPSS) version (24) was used for data analysis

Results the result of demographic data for both kirkuk and Tikrit city shows that the age group (20-29 years) represents a high percentage in the Kirkuk gas and Tikrit city and represent (40.0%) and (38.0%) respectively, with regard to the gender the results shows high percentage from gender were male in kirkuk and tikrit and represent (95.0%) and (98.0%) respectively, also the result shows the kirkuk workers were more less effected than tikrit workers also the results shows the chemical, mechanical and psychosocial hazard was effect in tikrit workers more than kirkuk workers.

Key word: Health consequence, Gas Filling, workers health

Introduction

A gas is characterized as a detail of issue comprising of particles that have neither a characterized volume nor characterized shape. It is one of the four essential conditions of issue, alongside solids, fluids, and plasma. Under customary conditions, the gas state is between the fluid and plasma states. A gas may comprise of molecules of one component (e.g., H₂, Ar) or of mixes (e.g., HCl, CO₂) or blends (e.g., air, characteristic gas) (1) Flammable gas is utilized in numerous homes for warming and cooking. Lamentably, petroleum gas holes may happen without the mortgage holder in any event, acknowledging there is a gas spill. A few people’s feeling of smell is extremely delicate to gaseous petrol, while others can’t smell it by any means. Seeing a portion of the notice indications of a petroleum gas spill in the home might just spare a daily existence (2) Cerebral pains and Dizziness, for some people, the primary indication of a gas break might be a migraine. While huge numbers of us experience migraines every day, unexpected or unexplainable cerebral pains ought to never be disregarded. On the off chance that the migraine doesn’t disappear after you go outside for
some time, or while you’re grinding away, consider the possibility that you may have a flammable gas spill. People may encounter episodes of dazedness alongside a cerebral pain. Ask other relatives or flat mates in the event that they’re encountering episodes of cerebral pains and dazedness also (3) Queasiness, Along with migraines and wooziness, people presented to a gaseous petrol hole may likewise encounter sickness. Such manifestations might be exacerbated if the house is quit for the day winter, or if the carport or storm cellar isn’t appropriately ventilated. Sporadic Breathing, A flammable gas hole may cause trouble or unpredictable taking in a few, particularly the youthful and older. note that a gaseous petrol break may suck oxygen from the air and produce substantial measures of carbon dioxide, which can prompt trouble breathing that may diminish the measure of oxygen in your lungs and blood and cause obviousness. Weariness, Some people presented to a petroleum gas spill additionally feel a mind-boggling feeling of exhaustion or dormancy. As a rule, this is brought about by absence of sufficient oxygen stream in the body. An individual ought to recuperate rapidly whenever moved to an alternate area. (4)

Methodology

Quantitative design (comparative study) was conducted for worker in company gas filling in Tikrit (Salah aldin) and Kirkuk city the study was carried out from the 10th February 2020 to 13th Augst 2020

This study was conducted in Kirkuk city and Tikrit (Salah aldin ). The present study was conducted in two company of gas filling: Company gas filling / branch Kirkuk and Company gas filling / branch salah Eldin.

The Sample of the study consist of from a non-probability (purposive) sample was selected. It consisted of (200) workers .(100) workers of sample was collected from mechanical Company gas of Kirkuk City and (100) manual company gas of mechanical Company gas of Salah Eldin City.

The study instrument (questionnaire) was consisted of three major parts to meet the purposes of study. The first part is related to workers demographical characteristics such as (age, gender, residence, marital status, department, educational attainment, monthly income, years of service, time of work per day, training, and number of training), the second part is related to Health Hazards these part include Physical health hazards: They consist of (9)items ,chemical health hazards, they consist of (8) items ,mechanical health hazards: they consist of (7) items ,Psychological health hazards: They consist of (5) items and biological health hazards: They consist of (5) items and the third part is related to precautionary measures They consist of (11) items . The overall items were ( 56) items, by using the scale (Agree=3), (Neutral =2), (Disagreement =1). Content validity was determined by presenting the questionnaire to a panel of (11) experts in different specializations, six in medical surgical nursing, three in community health nursing, and two in maternity and child health .The data collection was carried out for the period from the 10th February 2020 to 10th April 2020

The data was prepared, organized and coded into the computer file; Statistical Package for Social Science (SPSS) version (24) was used for data analysis

Result of the study :-

**Discussion of the Results**

The Results shows in Table (1) had revealed that an age group was high at (30-39) yrs in both kirkuk company gas filling and tikrit company gas filling and constitute 26.0% and 29.0 respectively

Explanation of this result because the system in our country most of the graduates students from the Institute of oil and gas direct work in the Kirkuk and tikrit gas company there for we find high percentage from the workers at age (30-39) yrs in both kirkuk and tikrit gas company

Our reslut is agreement with other study conducted by Achalu 2016 found that the staff of age group greater percent within (30-40 years) and constitute 30.0%

Also the result of the present study indicate The staff were male is high percentage in company gas filling / branch Kirkuk and branch tikrit ,and constitute 95.0% and 98.0% in both kirkuk and tikrit company respectively

Interpret of this result Because of the work at company need heavy work and dangerous and carrying heavy things there for we find great percentage from workers was male.

The current investigation is concurrence with Heymann (2016) discovered Sample included 90.5% (n=200) guys and 9.5% (n=21) females in Because of substantial work and perilous and conveying overwhelming things to be the most male laborers due to the working environment

Likewise the outcomes shows the high rate 78.0% and 82.0% were immediate contact to the gas from kirkuk and tikrit respectively

The decipher of this outcome identified with the kind of work at gas organization and the organization gas filling is more requirement for physically laborers there for we discover high rate were immediate contact.

With regard to the time of work per day the results of the present study show that the highest percentage is 78.0% and 73.0% were work (6-8) hours at kirkuk and tikrit respectively .the explanation of this result related to the system work at gas filling company need for long time working there for we find high percentage from workers work for at lest 6-8 hours

Table (2) Comparative about awareness of gas station workers regarding physical hazard at at Kirkuk city and Tikrit city the reult of this table shows that mean of scores of workers staff of kirkuk and tikrit city was high Awareness in all items

Physical dangers that influence wellbeing laborers incorporate introduction to commotion, vibration, ionizing and no ionizing radiation, and power. With the exception of very noisy commotion of a hazardous or effect nature where some measure of hearing misfortune and additionally auxiliary harm happens (acoustic injury), uproarious clamor at first uniform the sensitive hair cells in the inward ear causing a move in hearing limit. This is known as a transitory limit move (TTS) (6).

A basic test can be led by laborers to survey the impacts of word related introduction to clamor and its effect on hearing sharpness a few substances might be basically innocuous in certain structures, (for example, a square of metal, a bit of wood or granulated strong synthetic compounds) however might be perilous in another structure, (for example, fine residue particles or smoke that can be promptly breathed in or arrangements that might be sprinkled and promptly consumed through skin). This is additionally a significant thought in surveying dangers from physicochemical risks. The grouping of risky fixings is likewise a significant factor in the general hazard. Concentrates or unadulterated substances might be amazingly dangerous, while weaken arrangements of a similar concoction may not be risky at all. The extraordinary warmth of welding and starts can cause consumes. Eye wounds have come about because of contact with hot slag, metal chips, sparkles, and hot terminals. Furthermore, over the top presentation to warmth can bring about warmth stress or warmth stroke. Welders ought to know about the side effects, for example, exhaustion, unsteadiness, loss of hunger, sickness, stomach torment, and fractiousness. Ventilation, protecting, rest breaks, and remaining hydrated will ensure against heat

Table (3):comparative about Awareness of gas station workers regarding Chemical Health Hazards at
Kirkuk city and Tikrit city. This table shows that mean of scores of Workers Staff of Tikrit city was high Awareness in all items in comparative of Kirkuk city which was was moderate Awareness.

The explanation of this result related to safety measure at Kirkuk gas company more than Tikrit gas company.

Exposure standards are based on the airborne concentrations of individual substances that, according to current knowledge, should neither impair the health of, nor cause undue discomfort to, nearly all workers. They do not represent a fine dividing line between a healthy and unhealthy work environment. Chemicals with workplace exposure standards are listed in the *Workplace Exposure Standards for Airborne Contaminants*. These exposure standards are also available from the Hazardous Substances Information System (HSIS) on the Safe Work Australia website. The HSIS database contains additional information and guidance for many substances. Although exposure standards may also be listed in Section 8 of the SDS, you should always check the *Workplace Exposure Standards for Airborne Contaminants* Some substances give off distinctive odours which can alert workers to the presence of a hazardous chemical. For example, hydrogen cyanide has a smell of bitter almonds. However, not everyone can smell hydrogen cyanide and higher concentrations of hydrogen cyanide can also overload nasal receptors resulting in workers being unable to detect it. Hazardous chemicals can also have no odour. Thus, odour should not be relied on as a means of detecting the presence of hazardous chemical.

Table (4): comparative about Awareness of gas station workers regarding Mechanical Health Hazards at Kirkuk city and Tikrit city, this table shows that mean of scores of Workers Staff of Tikrit city was high Awareness in all items in comparative of Kirkuk city which was was moderate Awareness.

Interpret of this result refers to the types of work at Tikrit gas company more hard than Kirkuk gas company.

Table (5): comparative about Awareness of gas station workers regarding Psychosocial Health Hazards at Kirkuk city and Tikrit city, this table shows that mean of scores of Workers Staff of Tikrit city was high Awareness in all items in comparative of Kirkuk city which was was moderate and low Awareness.

Absence of inspiration and regard, prompting low degrees of efficiency. Factors, for example, quality client support, group attachment and group building are influenced because of representative truancy and absence of interest. Significant levels of representative turnover are additionally experienced. While trying to decrease representatives being exhausted and feeling less enthused while at work, it is significant that those at the top, for example, supervisors perceive the pressure and weights felt by representatives when they are given such a large number of duties. Administrators must devise approaches to draw out the best in representatives to propel them and lift their regard to guarantee an occupation all around done. This can be as straightforward as regarding representatives as a greater amount of a resource for the association by demonstrating gratefulness for their difficult work and commitment. Notwithstanding how extreme, solid and versatile you think you are, toward the day’s end, we are for the most part people, and as such bosses should avoid seeing them as machines. There’s a cutoff to the amount we can propel ourselves truly, yet our enthusiastic perseverance can be driven much further. It’s essential to know your cutoff points by methods for working SMART. You’re nothing but bad to anybody, in particular yourself in case you’re not in top mental and physical condition.

Table (6): comparative about Awareness of gas station workers regarding Biological Health Hazards at Kirkuk city and Tikrit city, this table shows that mean of scores of Workers Staff of Tikrit city was high and moderate Awareness in all items in comparative of Kirkuk city which was was moderate Awareness.

Eduardodias health (2016) report that the Gasoline, a straightforward, fluid got from oil contains two fundamental synthetics: benzene (C₆H₆) and other known cancer-causing agents. Cancer-causing agents don’t straightforwardly influence DNA, however lead to malignant growth in different manners. For instance, they may make cells isolate at a quicker than ordinary rate, which could build the odds of changes to DNA. Note that not all cancer-causing agents bring about malignancy. Numerous variables must be contemplated length and power of the exposure.

Wluk (2018) report that the natural and irresistible
specialists might be sent to an individual through inward breath, infusion, or by skin contact. Sources incorporate patients, asymptomatic transporters, or vectors, for example, rodents, cockroaches, and mosquitoes. The quantity of living beings in nature, combined with their destructiveness and an individual’s protection from them, decide if the individual will get the infection or not. A contamination control program ought to characterize the fundamental strategies, methodology, and practices so as to limit the danger of malady event and transmission at a human services office. This necessitates laborers be counseled and that the exertion is bolstered by the entirety of the executives and staff(11).

Conclusions

The demographic data for both kirkuk and Tikrit city the result aso shows that the age group (20-29 years) represents a high percentage in the Kirkuk gas and Tikrit city and represent (40.0%) and (38.0%) respectively. With regard to the gender the results shows high percentage from gender were male in kirkuk and tikrit and represent (95.0%) and (98.0%) respectively. also the result shows high percentage from workers was worked at direct department contact in kirkuk and tikrit and represent (78.0%) and (82.0%) respectively. The physical hazard were same level in both Tikrit and Kirkuk workers. The results Shows the psychological, biological and psychological hazards most common at Tikrit workers than Kirkuk.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Department of Adult Nursing and all experiments were carried out in accordance with approved guidelines.

Non COVID Symptoms and its Impact on Quality of Life among the Professionals Residing at Pune City

Sharadha Ramesh¹, Poonam Yadav²

¹Director cum Professor, Symbiosis College of Nursing, Symbiosis International University, Pune, Maharashtra, India, ²Tutor, Symbiosis College of Nursing, Symbiosis International University, Pune, Maharashtra, India

Abstract

Introduction: COVID-19 has made all of us understandably too much cautious to visit the physician’s. We have rescheduled the appointments and trying to manage our care viva virtual visits, Also trying to stay safe by restricting movements. It’s important to keep taking precautions like handwashing, avoid touching face area and also wearing the masks in public. Hence it’s very important for all of us to know when to seek medical help.

Objectives of the study: 1. To assess the Non COVID Symptoms among working professionals in Pune City 2. To assess the impact of Non Covid symptoms on quality of life among working professionals in Pune City 3. To associate the selected Demographic variable with the Non COVID Symptoms among working professionals in Pune City

Methodology: Survey study was conducted among 265 working professionals in Pune City. Non probability convenience sampling technique was used to select the samples. Informed consent was obtained from all participants, and made them aware that the information gathered is used only for research purpose. Structured questionnaires were prepared to elicit information from the participants.

Result: The study result says that are various Non Covid symptoms which the general population is facing in the current scenario which are being identified in the study result and also the Non Covid symptoms are being associated with the various selected demographic variable the result pertaining to that shows that there is significant association between working profession and monthly family income with Non COVID Symptoms as the P value is less than 0.05. In this current situation the investigator wanted to recommended further studies to find out the various other Non covid symptoms faced by the general population an should be paid attention and treated on time.

Key Words: Non COVID, Symptoms, Impact, Quality of life, Professionals.

Introduction

COVID-19 has made us prudent to visit the hospital in any means. Individuals are trying hard to manage their care at home by avoiding visits to the clinics so as to avoid getting exposed to Covid virus. This has made everyone to take measures that promotes health and wellbeing of ourselves. Certain hygienic measures needs to be taken by each and every one to avoid falling prey to Covid. This includes washing hands thoroughly for 20 seconds, maintaining respiratory hygiene, following social distancing practice. Recently all are following the guidelines given by WHO but it is important for all of us to know when to seek medical help. It is necessary for us to know and understand the non covid symptoms so as to deal with it optimist. The non covid symptoms include headache, eye irritation, fatigue, loss of tired, irregularity of bowel, weight alteration, mood swings, fear, skin irritation, body ache. (1,2,3)

Statement of the Problem

An exploratory study to assess the Non COVID Symptoms its impact on quality of life among the professionals residing at Pune City
Objectives:

1. To assess the Non COVID Symptoms among working professionals in Pune City
2. To assess the impact of Non Covid symptoms on quality of life among working professionals in Pune City
3. To associate the selected Demographic variable with the Non COVID Symptoms among working professionals in Pune City

Methodology

RESEARCH APPROACH

Quantitative research approach was adopted for this study to accomplish the objectives of the study.

RESEARCH DESIGN

In this study, Non-experimental Exploratory survey design was used.

VARIABLES

Independent Variables:

The independent variable for the study was Non COVID Symptoms.

Dependent Variables:

The dependent variables of the study was Quality of life.

SETTING OF THE STUDY

The investigator conducted the study in urban area of Pune City.

POPULATION OF THE STUDY

SAMPLE AND SAMPLE SIZE

In the present study, the professionals residing in the selected area of Pune City. Who fulfilled the inclusive criteria were the samples.

SAMPLE SIZE

The sample size was 265.

SAMPLING TECHNIQUES

Non probability convenience sampling technique was used to select the samples.

DEVELOPMENT AND DESCRIPTION OF THE TOOL

The instrument was developed and complied by the investigator with the guidance of experts and review of literature. The data collection questionnaire used in the present study had the following components:

Section A: Assessment of background variables

- Demographic variables of the mother:

This included study participants age, religion, type of family, monthly income in rupees, educational status

Section B: Structured Question on Non Covid Symptoms.

Section C: Structured Checklist on Impact on Quality of Life.

CONTENT VALIDITY

Content validity of instrument was done by the panel of experts in the fields of Nursing Research and Statistics. The experts’ suggestions were incorporated in designing the final tool for this study.

RELIABILITY

Reliability of the tool was measured using Karl’s Pearson coefficient of correlation’ test retest method for Non Covid symptoms structured questionnaires and inter rater method for perceived practice.

The reliability r value were 0.78. These values were very high thus making it a reliable tool for assessing the “Non COVID Symptoms and its impact on quality of life among the professionals residing at Pune City”.

Above table no 2 Describes the Non Covid symptoms in selected professionals of Pune City.

The various symptoms which were identified in the current study are headache, eyes irritation, fatigue and tired, loss of appetite, bowel irregularity, sleep disturbance, weight alteration, mood swings, fear of uncertainty, panic, skin irritation, body ache. The results regarding headache includes 52.83% professionals experience headache more frequently whereas 32.08% professionals experience it less frequently and 15.09% professionals never experienced headache. The eyes irritation and discharge results suggests that 49.057% experience it more frequently whereas 39.62% professionals experience it less frequently and 11.32% professionals have never experienced it. The results regarding feeling tired and fatigue includes 45.283% professionals experience it more frequently whereas 43.40% professionals experience it less frequently and 7.55% professionals have never experienced tiredness and fatigue. The loss of appetite results include 49.057% professionals experience it more frequently whereas 43.40% professionals experience it less frequently and 7.55% professionals have never experienced it. The results regarding the irregularity of bowel include
33.962% professionals experience it more frequently whereas 62.26% professionals experience bowel irregularity less frequently and 5.66% professionals have never experienced bowel irregularity. The sleep disturbance results include 41.509% professionals experience sleep disturbance more frequently; whereas 49.06% professionals experience it less frequently and 9.43% professionals have never experienced sleep disturbances. The weight alteration result includes 49.057% professionals experience it more frequently; whereas 37.74% professionals experience it less frequently and 13.21% professionals have never experienced it. The mood swing results exhibits 52.83% professionals experience mood swings more frequently; whereas 32.08% professionals experience mood swings less frequently and 15.09% never experienced mood swings. The results regarding feeling fear of uncertainty revealed that 37.736% professionals experience it more frequently whereas 52.45% professionals experience it less frequently and very few 9.81% have never experienced fear of uncertainty. The panic experience includes 30.189% get panic more frequently; whereas 60% professionals experience panic less frequently and 10.94% professionals never feel panic. The Skin irritation changes results interpret that 18.868% professionals have more frequently experienced skin irritation, majority 47.55% professionals have experienced it less frequently whereas 33.58% professionals have never experienced skin irritation and changes. The result regarding the feel of bodyache on regular basis showed that 52.83% of the professionals had more frequently; whereas 58.87% of the professionals had less frequently experienced bodyache and 6.04% professionals have never experienced bodyache.

</table>
Considering the physical factor, 46.88% professionals more frequently experience that the non covid symptoms have affected their physical wellbeing whereas 29.69% professional has experienced less frequent effect of non covid symptoms on their physical wellbeing and 23.44% professionals never experienced any impact on their physical wellbeing.

The mental/psychological factor suggests, 58.5938% professionals more frequently experience that the non covid symptoms have affected their mental wellbeing whereas 33.20313% professional has experienced less frequent effect of non covid symptoms on their mental wellbeing and 7.42188% professionals never experienced any impact on their mental wellbeing.

The social factor reveals, 50.7813% professionals more frequently experience that the non covid symptoms have affected their social wellbeing whereas 27.3438% professional has experienced less frequent effect of non covid symptoms on their social wellbeing and 21.875% professionals never experienced any impact on their social wellbeing.

The financial factor displays, 43.3594% professionals more frequently experience that the non covid symptoms have affected their financial wellbeing whereas 15.625% professional has experienced less frequent effect of non covid symptoms on their financial wellbeing and 10.1563% professionals never experienced any impact on their financial wellbeing.

The level of independence mounts that, 74.2188% professionals more frequently experience that the non covid symptoms have affected their level of independence whereas 27.3438% professional has experienced less frequent effect of non covid symptoms on their level of independence and 29.2969% professionals never experienced any impact on their level of independence.

Considering the environmental factor, 31.25% professionals more frequently experience that the non covid symptoms have affected their level of independence whereas 39.0625% professional has experienced less
frequent effect of non covid symptoms on their level of independence and 29.6875% professionals never experienced any impact on their level of independence.

Description of the association of selected demographic variables with Non COVID Symptoms among the selected professionals.

In proceeding To find out the association of demographic data with Non COVID Symptoms data was analyzed and found that there is significant association between working profession and monthly family income with Non COVID Symptoms as the P value is less than 0.05.

Conclusion

The above study result says that are various Non Covid symptoms which the general population is facing in the current scenario which are being identified in the study result and also the Non Covid symptoms are being associated with the various selected demographic variable the result pertaining to that shows that there is significant association between working profession and monthly family income with Non COVID Symptoms as the P value is less than 0.05. In this current situation the investigator wanted to recommended further studies to find out the various other Non covid symptoms faced by the general population an should be paid attention and treated on time.

Implications

The findings of the study has implications in different branches of nursing profession, i.e. ursing practice, nursing service, nursing education, nursing administration and nursing research.

Nursing practice.

- The nurse role is to care for the patients according to their health condition to improve their quality of life.

- The nurse practitioners can utilize the assessment toll and identify the symptoms are related to COVID or Non Covid in the client to improve their quality of life.

- The nurse can educate the population to reduce their anxiety raised due to Non Covid symptoms and to improve their quality of life.

Nursing education

- Conference, workshops and seminars can be planned and executed for nurses to impart update their knowledge and positive practice towards care of Non Covid Symptoms and quality of life.

- Nursing educator to update their knowledge and skills of providing care for patients with Non Covid symptoms and quality of life.

Nursing administration

- Nursing personal should be prepared to take a leadership role in educating the population around her to take care and differentiate the Covid, Non Covid Symptoms and points to improve quality of life.

- The administrator can encourage the nurse for conducting research in various aspects regarding the Non Covid Symptoms and quality of life in the general population.

- The administrator can organize conference, workshop and seminar for nurses regarding the Non Covid Symptoms and quality of life in the general population.

- The administrator should support the staff to conduct programme on various Non Covid Symptoms and quality of life.

Nursing Research

- There should be more scope for the research in this area to improve the care for clients having Non Covid Symptoms and to improve their quality of life.

- Knowledge on importance quality of life and Non Covid symptoms is important for the general population to know. There is a need for extensive research regarding education on Non Covid Symptoms and to improve their quality of life.

- The study will be useful for further reference.

- The results of the study encourage the nursing personnel’s for conducting research in various aspects regarding importance to know various Non Covid Symptoms and quality of life.

Recommendations

The study recommends the following...
• A similar study may be conducted with large number of sample and population in various settings.

• A similar study may be conducted with large number of sample and population in various settings.

• A comparative study can be conducted between rural and urban population.

• A true experimental study with experimental and control group can be conducted.

Conflict of Interest – Nil

Source of Funding - Authors have no financial support to this project. The study was fully funded by authors.

Ethical Clearance – Ethical approval of the study taken from Symbiosis College of nursing ethical committee. Informed consent was taken from the professional included in the study. Informed the responders regarding the data collection procedure. The collected data was used only for research purpose and kept confidential

Impact of Years’ Experience upon Nurses’ Knowledge and Practice concerning Infection Control at Critical Care Units in Baghdad City

Wafaa Abd Ali Hattab¹, Alaa Jawad Kadhim², Musaab Majid Abdulwahhab¹
¹Ph.D. (University of Baghdad-College of Nursing-Adult Nursing Department), ²M.Sc. (University of Baghdad-College of Nursing-Adult Nursing Department)

Abstract

Introduction: Infection control or hospital-acquired infections are the major concern of the health care system and agencies. Critical care nurses are on the first-line contact with the patients, so on, they are most vulnerable to acquired infections. It is really important to regularly check their knowledge and practices concerning infection control. Objectives: The study aims to identify the impact of years’ experience on nurses’ knowledge and practices concerning infection control in three hospitals and center (Baghdad teaching hospital, Ibn Al-Nafees hospital, and Ibn al-Bitar center) Methodology: Cross-sectional study was conducted, the study starting from 4th of July 2020 to 13th of November 2020. Non-probability (purposive) sample was used to select 110 nurses who work at critical care units in three hospitals and center (Baghdad teaching hospital, Ibn Al-Nafees hospital, and Ibn al-Bitar center). The years of experience should no less than one year. The instrument was composed of two parts. Firstly, covers the nurses’ demographic characteristics. Secondly, included self-report questions about nurses’ knowledge and an evaluation sheet concerning nurses’ practices of infection control with 24 questions for knowledge and 12 questions for practices checklist. Results: The study revealed that the nurses’ knowledge toward infection control record 38%, 41%, and 21% for low, moderate, and high knowledge respectively. In comparison, nurses practices record 47%, 42%, and 11% for low, moderate, and high practices respectively. Most of the study sample 62% was females while 38 % of the subject was males. The age group (20-29) takes the highest percentage (38%). In addition, about (27.3%) of the nurses who works in critical care units have 1-5 years of experience. Significant statistical associations were found between nurses knowledge and practice from one hand and years’ experience on the other hands p ≤ 0.05. Recommendation: Based on this finding, the researcher recommended further studies involve more nurses and other health professionals regarding infection control and highlight the importance of infection control to nurses with (1-5) years’ experience by symposium or teaching programs.

Keywords: Impact, Years’ Experience, Nurses’ Knowledge & Practice, Infection Control, Critical Care Units

Introduction

Hospital-acquired infections are significantly high, especially in critical care units. Both nurses and patients are vulnerable to get those infections, patients in critical care units have low immunity as a result of their health status and can easily be infected with viruses and bacteria [1, 2, 3]. In comparison, nurses are in direct contact with patients for a long time [4, 5]. Nurses’ knowledge and practices about precautions and infection prevention strategies are the cornerstones to minimize the burden of hospital-acquired infections [6]. Accordingly, Information about nosocomial diseases is imperative to improve infection control strategies and to create successful preventive and therapeutic methodologies which, thus, will help us in diminishing the prevalence, and mortality rate [7, 8]. The infection control is a key part of training for all health services personnel, for their health as well as to minimize nosocomial infection and along these lines improve nurses and patients safety [9, 10].
Methodology and Materials

Design of the study:

A cross-sectional research design was conducted from the period 4th of July 2020 to 13th of November 2020 to find out the impact of years’ experience on nurses knowledge and practices concerning infection control. Hospitals and center (Baghdad teaching hospital, Ibn Al-Nafees hospital, and Ibn al-Bitar center) in Baghdad city were included. Non probability (purposive) sample was used to select 110 nurses who worked in critical care units and have at least one year experience.

Tools of the study:

It was consisted of two parts, first part: composed of nurses’ demographic characteristics include age, gender, and years of experience in the critical care units. Second part: consist of (24) self-reported questions for nurses’ knowledge and (12) questions as a checklist evaluation for practices concerning infection control.

Validity and Reliability

The content validity of the knowledge and practices sheet was checked by ten experts in College of Nursing / University of Baghdad with different specialty and modifications done accordingly. Reliability was done to determine the stability of the questionnaire by using test-retest method (correlation coefficient 0.89).

df: degree of freedom, F: frequency, sig: significant

Table (3) reveals significant statistical association between years’ experience and nurses’ practices in critical care units concerning infection control.

**Discussion**

Results in figure (1) shows that the moderate level of knowledge takes highest percentage (43%) concerning infection control while (47%) of the nurses records the high level practices. Most of the study (62%) sample was females, and the age group (20-29 years) takes the highest percentage (38%). The years’ experience (1-5) years records (27.3%) of the study sample.

This finding approximately similar with the study in Baghdad Teaching Hospital done by Abdel-latif, 56.6 were females, and 43.3% of them at age 20-29 years old, it is agree with the results of at eight hospitals in Saudia Arabia. Another study has been found that females were more Informationable than males toward infection control [11, 12].

The study results demonstrate that years’ of experience associate with nurses’ knowledge. In addition, there is a statistical significant association with nurses’ practices, the nurses have affected their compliances to standard precautions, thus more years of employment lead to more experiences which finally influences on nurses’ practices. This result agrees with study done by Eskander who find that there is a significant association between the Nurses’ Information and the years of employment [13]. Hassan, A. and Fatima were indicating positive relation between the skills and the years of experience as a nurse.

**Conclusions**

According to the results, the study conclude that years’ experience associate with the nurses knowledge and practices toward infection control in critical care units, the more years’ experience lead to more knowledge and skills toward infection control.

**Acknowledgements**

The authors feel privileged to thanks College of Nursing/ University of Baghdad for their cooperation to complete the official request for conducting the research.

Detection of Biochemical Causes the Diabetic Retinopathy in Diabetes (Type II) Patients in Al-Muthanna Province

Yusra Ali Hameed¹, Jawad Kadhum Muraih²

¹M.Sc., ²Prof., Dr., Department of Chemistry, College of Science, Al-Muthanna University, Iraq

Abstract

Background: Accumulating evidence indicates that oxidative stress, imbalance between reactive oxygen species production and antioxidant scavenging that may play a role in the etiology of type 2 diabetes mellitus and occurrence diabetic retinopathy as a result from increasing activity of free radicals and accumulation of lipid peroxidation products.

Aim: To investigate the association between glycemic control, lipid peroxidation and antioxidant status.

Methodology: A descriptive cross-sectional study on non-probability was conducted (sample collection) of (232) type 2 diabetes mellitus patients. Plain tubes, the tools and instruments that were used to collect data.

Results: The results of the study revealed that dyslipidemia and hypertension were found to be more prevalent in the diabetic retinopathy subjects than the regular diabetic subjects. Plasma antioxidant levels were higher in the diabetic subjects than the diabetic retinopathy subjects while malondialdehyde levels were found to be higher in the diabetic retinopathy subjects.

Conclusion: Duration of diabetes has very important effect on both MDA and uric acid levels for diabetic patients with/without retinopathy. Oxidative parameters value not influence by residence as well as body mass index not has any effect on uric acid level.

Keywords: Antioxidant Status, Oxidative Stress, Diabetic Retinopathy, Lipid Profile.

Introduction

Diabetic retinopathy (DR) is the most common disease that caused by micro-vascular complication of diabetes, occurs in both T1, T2 DM and is secondary to prolonged uncontrolled hyperglycemia and other risk factors. In adolescents and young adults with type 1 diabetes, over 80% have some form of DR when the duration of diabetes is over 15 years. It is estimated that 90% of the blindness due to DR is preventable (1) (2). Long term of high blood glucose levels in uncontrolled diabetes can be the cause of glucose auto-oxidation, nonenzymatic protein glycation and activation of the polyol pathway with increase oxidative stress.

The global number of individuals with diabetes in 2000 was estimated to be 171 million (2.8% of the world’s population). The number of people with DM worldwide is projected to increase to 366 million by 2030, 298 million of whom will live in developing countries (3) (4). There is a relationship between chronic hyperglycemia and long-term complications in diabetes. The long-term effects of diabetes include progressive evolution of micro-vascular complications, particularly in the eye and the kidney, and an increased frequency of macro-vascular disease such as peripheral vascular and coronary heart disease (3) (5). Complications of micro-vascular and macro-vascular are the leading cause of
morbidity and mortality in diabetics. However, diabetic patients often die from macro-vascular disease and main mortality is the coronary heart disease (CHD). Long-term complications of DM include retinopathy with potential vision loss (6) (7) (8) (9).

Diabetic retinopathy (DR) is the most common disease that caused by micro-vascular complication of diabetes, occurs in both T1, T2 DM and is secondary to prolonged uncontrolled hyperglycemia and other risk factors. In adolescents and young adults with type 1 diabetes, over 80% have some form of DR when the duration of diabetes is over 15 years. It is estimated that 90% of the blindness due to DR is preventable (1) (2). Long term of high blood glucose levels in uncontrolled diabetes can be the cause of glucose auto-oxidation, nonenzymatic protein glycation and activation of the polyol pathway with increase oxidative stress.

Oxidative stress is the result of an imbalance in the pro-oxidant/antioxidant ratio in favor of the former, potentially leading to form macromolecules and dysfunction in the cell. Oxidative stress is the result of an imbalance in the pro-oxidant/antioxidant ratio in favor of the former, potentially leading to form macromolecules and dysfunction in the cell (10). Improved oxidative stress contributes to the damage of pancreatic β-cell progressively due to glucose toxicity, which leads to severe weakness of glucose-stimulated insulin secretion (11).

In normal physiological conditions, there is a balance in the generation of reactive oxygen and nitrogen species (ROS, RNS) and antioxidant defense system to protects organisms against ROS, RNS toxicity. In diabetes, imbalance in the pro-oxidant/antioxidant can damage cellular macromolecules, leading to protein modification and lipid peroxidation (12). Lipid peroxidation is an autocatalytic free radical mediated destructive process where poly unsaturated fatty acids in cell membranes degraded to form lipid hydro peroxides. Through lipid peroxide products such as conjugated dienes and malondialdehyde (MDA) are increased in patients with T2DM. MDA is produced as a relatively stable end product from the oxidative degradation of polyunsaturated fatty acids (PUFA), and this free radical-driven lipid peroxidation has been causatively implicated in the aging process atherosclerosis, Alzheimer’s disease, and cancer (13) (14). Serum MDA used as a bio-marker of lipid peroxidation and served as an indicator of free radical damage (15).

The study of the oxidative stress status may be the knowledge base for understanding of the pathogenic mechanisms of complications in diabetes and may have important implications for antioxidant supplements in order to slow progress, choose optimal treatments and prevent complications and their consequences.

**Materials and Methods**

232 subjects as three groups, 58 patients (24 male and 34 female) have diabetic retinopathy, 78 patients (26 male and 52 female) have type 2 diabetes mellitus without retinopathy cases and 96 subjects (52 male and 44 female) as healthy control groups. For the purpose of this study, 232 subjects and age and gender-matched control subjects were recruited. Plain tubes, the tools and instruments that were used in the study.

**Metabolic biochemical markers for investigation**

1. Estimation of fasting plasma sugar by glucose oxidase/peroxidase method Trinder’s method.
2. Measurement of total cholesterol by Cholesterol esterase peroxidase or CHOD-POD method
3. Measurement of triglycerides by Lipoprotein lipase, Glycerol phosphate oxidase and Peroxidase. The method for the analysis is a modification of that of Trinder.
4. Measurement of malondialdehyde; MDA is determined as Thiobarbituric acid reactive substances.
5. Measurement of superoxide dismutase; Superoxide dismutase was measured by the method of Kuthan H, et al., (1986).
6. Measurement of total antioxidant capacity; Measures total antioxidant capacity in which Cu$$^{2+}$$ is reduced by antioxidant to Cu$^{+}$. The resulting Cu$^{+}$ specifically forms a colored complex with a dye reagent. The color intensity at 570 nm is proportional to TAC in the sample.

**Statistical Analysis**

Completely randomized design (CRD) was used
for this study in the analysis of variance for the means of studied parameters (sugar, lipid, oxidative stress, and antioxidants parameters) by using one-way ANOVA test, t-test, and Dennett’s test at a 5% level of significance. Moreover, data were processed and analysis by using statistical program social science (SPSS 22) and the results were expressed as Mean ± SD.

Results and Discussion

The study showed that T2DM and DR subjects had significantly higher FPS and HbA1c levels compared with control subjects according to reports of the American Diabetes Association (ADA) and the World Health Organization (WHO). Furthermore, increased HbA1c level was observed in DR more than T2DM. The results of the study under hand go along with study entitled (Total Antioxidant Status in Type 2 Diabetic Patients in Palestine) that carried out in Palestine found that there is a significant relationship between HbA1c and different group at ($\square = 0.002$) ($^{16}$). Also, in other study that carried out in African stated that the FPG and HbA1c levels were respectively 2.05 and 2.32 times higher in the group of patients with diabetes and complications compared to those of healthy persons ($^{17}$). HbA1c is a product of non-enzymatic addition of glucose to hemoglobin and the rate of this conjugation is directly proportional to the level of blood glucose. So, the high % of HbA1c level observed in our study denotes that the type 2 diabetic subjects are under poor glycemic control.

Figure (1): Comparison of HbA1c and FBS means among study groups.
This figure shows that significantly high levels of total cholesterol, triglyceride, LDL and VLDL in patients with T2DM than control. However, no significant difference in the level of HDL were identified between the three groups. These findings not harmonizing with study that conducted in Turkey stated that mean total cholesterol, triglyceride, LDL, HDL and VLDL levels were not significantly different between the groups ( =0.693, =0.774, =0.644, = 0.910 and =0.967 respectively (18)). However, it is going along with study that carried out in South Africa found that serum triglyceride (TG) ( = 0.004) and high-density lipoprotein cholesterol (HDL-C) ( = 0.007) showed significant differences among group (19). Moreover, study the proportions of lipid profile disorders were higher in DM patients compared to apparently healthy controls Moreover, study the proportions of lipid profile disorders were higher in DM patients compared to apparently healthy controls (20) (21).

The result of current study goes along with study that conducted in Nigeria to investigate some oxidative stress related parameters in T2DM. Who found that significant differences of oxidative stress between patients and control groups (22). While, in regarding to uric acid the current study shows no significant difference in the level of uric acid between T2DP and healthy controls, and that inconsistent with study that carried out in India found that there is a significant difference between uric acid and three different group of study at $P<0.001$ (23). Glucose intake may affect both the production and excretion of uric acid by several mechanisms. An increased flux of glucose is thought to increase purine generation, while increased anaerobic glycolysis generates increased circulating lactate which leads to a reduction in renal excretion of uric acid (24).

Moreover, in other study that carried out in Africa reported that a statistically higher level of malondialdehyde (MDA) was observed in a group of patients with diabetes and complications compared to those without complications this finding compatible with study under hand (17). The high concentration of serum lipids in the type 2 diabetic subjects is mainly as a results of increased mobilization of free fatty acids from peripheral depots, due to loss of the inhibitory action of hormone sensitive lipase. Peroxidation of polyunsaturated fatty acids in blood produces malondialdehyde (MDA) that leads to oxidative damage. T2DP has reported an increased levels of lipid peroxidation (MDA) and reduced antioxidant status may play a major role in diabetic complications (25). Pavithra et al. reported higher levels of MDA in patients with DM compared with controls and in patients with DR versus those without DR, also suggesting that oxidative stress may play a significant role in the development of DR. As a result, levels of MDA are used as an index of LPO and in consequence of oxidative stress (2). Hyperglycaemia leads to overproduction of ROS through several pathways that may lead to destruction of various macromolecules in the body including lipids through the mechanism of oxidative stress (26).

Abstract

Aim: The objective of the present study was to evaluate the microleakage of composite restorations alone or with amalgam base in proximal box of class II cavity preparation.

Method: Eighty proximal cavities (Mesio-occlusal and disto-occlusal) were prepared in 40 premolars with carbide bur and randomly divided into four groups. Group A restored with composite resin; the other three groups restored with combined amalgam-composite restoration as follows. Group B the composite inserted immediately after insertion of amalgam, group C the composite inserted after 5 minutes of amalgam insertion while in group D the composite inserted after two days of amalgam insertion. Marginal adaptation was evaluated at the following interfaces: tooth-amalgam(T-A), tooth-composite resin (T-C) and amalgam-composite (A-C). Microleakage was evaluated by means of methylene blue infiltration after 21 days water storage and thermocycling aging. Microleakage was assessed by measuring the depth of horizontal dye penetration. Image J analysis software was used to measure the penetration of dye in the tooth- filling interface and in the amalgam-composite interface. One-way ANOVA and post-hoc Tukey HSD tests (α =0.05) were used statistically for analyzing gather data.

Results: There were a significant statically showed by ANOVA test between teeth -fillings interface, according to Tukey’s test there were a significant difference between teeth-composite interface and teeth-amalgam interface (p<0.05), while between composite- amalgam interface, ANOVA test showed a significant difference between groups and Tukey’s test showed a significant difference between groups according to time of placement of composite on amalgam filling (p<0.05).

Conclusion: Using of amalgam at the cervical base of the box in Class II combined amalgam-composite restoration has better result than using of composite from marginal leakage view.

Keywords: microleakage, marginal adaptation, Class II cavity, amalgam-composite restoration.

Introduction

The restorations of amalgam have good mechanical properties and many advantages such as relatively easy of insertion, resistance to fracture are adequate reasonably, after a period of time it allows good marginal sealing in the mouth, relatively economical and its less sensitive technique than direct tooth colored composite restorative materials (¹). Historically, it was used for long time clinically with proven longevity (²). In spite of initial marginal adaptation of composite resin restoration is better than amalgam (³), amalgam restorations occasionally fail because of secondary caries (⁴) and this due to deposition of oxides by surface corrosion which leads to enhance marginal self-sealing over time (⁵). The chief complaint of amalgam restorations is the darkness of color of these restorations which presents an unpleasant aesthetically (⁶). On the other hand, tooth colored composite resin material represents an aesthetically pleasant materials for restorations which have many advantages such as
requiring less sacrificing of sound tooth structure and enhance fracture resistance of teeth (7). In spite of the failure rate of composites is similar to amalgam (8) but there are many shortcomings such as; it’s technique sensitive, it’s survival rate in larger cavities is less when compared to smaller cavities (9). It’s bonding in the gingival margins of proximal restorations are critical because of little enamel in this area or even diminished of it (10) and it’s failure may occurs due to marginal gaps that results due to polymerization shrinkage which leads to breakdown of adhesive bonding (11). This shortcoming of composite fillings in the gingival margin of proximal boxes are opposite to the good marginal seal of amalgam fillings in this area because of gradual oxide deposition (12). To benefits from the advantages of composite resin restorations and amalgam restorations and to minimize their shortcomings, a combined of composite and amalgam restorations can be an alternative for them separately (13). The advantage of this combination restorations; the amalgam ensures the cervical marginal auto-sealing with aging while composite strengthen residual dental structures in addition to it’s esthetically acceptance (14,15). Another advantage of this possible combination is the repair of fractured of old amalgam restoration without the need for removing the remaining intact amalgam (16).

Materials and Methods

Forty readily available intact human caries-free maxillary premolars were collected and stored in distilled water. All teeth were cleaned and polished using pumice and rubber cups. The teeth were mounted in the acrylic resin to within 2 mm apical to the cemento-enamel junction to facilitate the handling and control of the samples. on these teeth eighty standardized mesio-occlusal (MO) and disto-occlusal (DO) Class II box cavities were prepared with gingival margins located 1 mm above the CEJ. Each tooth received two proximal cavities using a high-speed handpiece with air/water spray. A new bur was used for each four teeth. The bucco-lingual width of the cavities was approximately one-third of the intercuspal distance, and the depth were 2.5 millimeters.

The samples were randomly divided into four groups (n=10 (20 proximal cavities) /group) to receive the following treatment:

Group A: Restored with Composite resin.

Group B: Restored with combined amalgam-composite (composite placed immediately after insertion of amalgam).

Group C: Restored with combined amalgam-composite (composite placed after 5 minutes of insertion of amalgam).

Group D: Restored with combined amalgam-composite (composite placed after 2 days of insertion of amalgam).

The Composite resin used in treatment was (SonicFill 2, Kerr A2), the amalgam was (F-400, SDI), the Bonding agent was (Scotchbond™ Universal Adhesive, 3M-ESPE), the light cure used for polymerization of composite was (SDI Radii-Plus), the amalgamator used for trituration of amalgam was (SDI Ultradent 2, Victoria, Australia) and the matrix bands used were (SuperMat Adapt SuperCap Matrix, Kerr) which were used for all teeth before starting treatment.

In group A: the cavities were etched using phosphoric acid 37% for 15 seconds then thoroughly rinsed with water and dried then bonding applied as recommended by manufacturer’s instruction then SonicFill 2 composite resin were applied in two increments to fill the hole cavity and each increment was light cured as manufacturer’s instruction recommendation.

In group B: after etching the cavities, the alloys were mixed according to manufacturer instructions using an amalgamator. A standardized technique was used to transfer the amalgam to cavities using amalgam carrier until reaching the height of pulpal floor. Bonding agent was applied and cured immediately after insertion of amalgam and then composite resin was applied to the remaining cavity in one increment and cured as recommended by manufacturer’s instruction.

In group C: after etching of cavities, the alloys were mixed, transferred to cavities until reaching the height of pulpal floor. After 5 minutes of amalgam insertion, bonding agent was applied and cured and then composite resin was applied to the remaining cavity in one increment and cured as recommended by manufacturer’s instruction.
In group D: after etching of cavities, the alloys were mixed, transferred to entire cavities with minimal carving and after setting of amalgam the samples were stored in distilled water. After two days of amalgam insertion, 1.5 mm of amalgam filling was removed then bonding agent was applied and cured and then composite resin was applied to the new remaining cavity in one increment and cured as recommended by manufacturer’s instruction.

All the samples were stored in distilled water after restorations for 21 days, then thermocycling were performed at 5 ± 1°C to 55 ± 1°C for 500 cycles, with 30 seconds dwell time. The teeth were coated with two layers of nail varnish except for the restoration and 1 mm of peripheral area, then stored in container containing 2% Methylene Blue for 24 hours at room temperature. After removal from the dye solution, teeth were rinsed under running tap water and left at room temperature for 2 hours for dryness and dye fixation then embedded in clear resin. The specimens were sectioned in mesio-distal direction at the middle of the restorations with special diamond sectioning bur (Renfert, Germany) mounted in dental engine (Marathon 3, Korea) with water cooling. Microleakage was evaluated using Image analysis (Image J) software by measuring the linear penetration of the dye in micrometer from the external surface of interfaces using a stereomicroscope with a reflected light under magnification of 45x. Marginal adaptation was evaluated at the following interfaces: tooth-composite resin interface (T-C), tooth-amalgam interface(T-A) and amalgam-composite resin interface(A-C). Descriptive statistics including means and standard deviations were calculated for the microleakage analysis. The obtained data were subjected to one-way analysis of variance (ANOVA) and Tukey HSD test to determine significant differences among the three interfaces. The level of significance was set at p =0.05. All statistical analyses were performed using SPSS 15.0 (SPSS Inc., Chicago, IL, USA).

**Results**

A total of 80 sections were examined for evaluation of the dye penetration quantitatively at the tooth-filling interface and amalgam-composite interface with different periods of placement of composite. All the groups exhibited microleakage between the tooth-filling interface and amalgam-composite interface.

In the tooth-filling interface; The descriptive statistic (mean, standard deviation and standard error) are represented in (table 1). One-way ANOVA showed that the difference between the experimental groups was statistically significant (p<0.05) (Table 2). The post hoc Tukey multiple comparison tests showed the following results: tooth-composite interface exhibited statistically significant results compared with the three others amalgam-tooth interfaces(p<0.05), There was no statistically significant difference between groups of amalgam-tooth interfaces (p>0.05) (Table 3).

In the amalgam-composite interface; the descriptive statistic (mean, standard deviation and standard errors) are represented in (table 4). One-way ANOVA showed that the difference between the experimental groups was statistically significant (p<0.05) (Table 5). The post hoc Tukey multiple comparison tests showed the following results: the microleakage between fillings when composite inserted after two days of amalgam insertion exhibited statistically significant results compared with the others two groups (p<0.05), There was no statistically significant difference in microleakage between fillings whether the insertion of composite immediately or after 5 minutes of amalgam insertion (p>0.05) (Table 6).

Silver amalgam was widely used for restorations of posterior teeth due to their unique properties but with the improvement of tooth colored restorations, the drawback of amalgam fillings mostly due to their unpleasant color. In spite of composite bind micro-mechanically to enamel and dentin but unfortunately, its inherent polymerization shrinkage leads to leakage of oral fluids and toxins of bacteria leading to secondary caries especially in proximal cavities at cervical areas (17). One of the methods to overcome this shortcoming of composite is the combined amalgam composite restoration in which the amalgam inserted in the base especially in the cervical area under the composite (18), in order to combining the aesthetic properties of composite and required properties of amalgam cervically.

In the present study, the interfaces between tooth-composite, tooth-amalgam and composite-amalgam were evaluated using dye penetration test which considered one of the most commonly employed test used in microleakage studies. The linear penetrated dye was measured using Image J analysis software to have quantitative outcomes rather than subjective scoring.

Eighty interfaces between teeth and fillings were investigated to measure dye penetration, analyzed data showed that the composite have more leakage than amalgam and this may be due to the presence of little

</table>
or even no enamel in the cervical area which is the main cause of decreasing bond strength in this area. In spite of the advancement in composite and bonding system which may be the cause of not extending the dye more than 1 mm in the interface between tooth and composite but still this may leads to caries which subsequently jeopardize the longevity of tooth integrity; in contrast, the gap sealing between tooth and amalgam restoration may be time dependent.

On the other hand, the extent of microleakage in the amalgam-composite interfaces in the present study showed that the leakage when insertion of composite immediately after insertion of amalgam was less than leakage when insertion of composite on set amalgam or even less than waiting five minutes, and this may be due to penetration of bonding agent into the freshly placed amalgam inside the irregularities and porosities of it’s surface and as a consequence decreasing of microleakage in the interface by creating bonding with composite resin filling and this in agreement with Mertz-Fairhurst & Newcomer 1988 (19) and Sharafeddin & Moradian 2008 (20).

The maximum amount of dye penetration in the amalgam-composite interface in the present study was 179 micron which may be considered as an acceptable value especially in a freshly placed amalgam because there is a possibility of sealing of this gap by oxide layer with time. The result of this study indicates that the repairing of existing amalgam filling restoration by composite resin materials would be more advantageous from the view of conservative dental treatment and from the view of esthetic consideration and this in agreement with Çehreli et al. (21).

Conclusions

Although all interfaces of restored specimens in the present study showed some degree of microleakage but the findings may be clinically acceptable especially in placement of composite on freshly placed amalgam in class II combined amalgam-composite restoration which also may indicate a reliable method for restoring defective amalgam restoration.

Brain habits, Accuracy and Its Relationship to Self-Confidence for Handball Players

Ali Hussein Ali1, Muntadhar Saheb Mahdi2, Ahmed Khudhair Abbas3, Wissam Salah Abdul Hussein4

1Assist. Prof. Dr., Faculty of Physical Education and Sports Sciences/ University of Kerbala, Iraq, 2Lecturer Dr., Faculty of Physical Education and Sports Sciences/ University of Kerbala, Iraq, 3Lecturer, Faculty of Physical Education and Sports Sciences/ University of Kerbala, Iraq, 4Prof. Dr., Faculty of Physical Education and Sports Sciences/ University of Kerbala, Iraq

Abstract

The current research aims to identify the struggle for accuracy and its relationship with self-confidence among players of the Baghdad and Middle Euphrates clubs with handball, to achieve this goal, two tools have been prepared, one of which is to measure the struggle for accuracy and the other to measure self-confidence after finding their psychometric characteristics represented in honesty and constancy, the two tools were applied on the research sample of (152) players from the clubs of Baghdad and the Middle Euphrates with youth handball and after analyzing the data using statistical means the research resulted in the research sample enjoying the struggle for accuracy and self-confidence in them, as well as the existence of a statistically significant correlation between the struggle for accuracy and self-confidence of the players of Baghdad and Euphrates clubs with handball.

Keywords: Brain habits, self-confidence, handball players

Introduction

Athletes generally try to achieve their own goals and they differ in their responses to different alerts and situations according to individual differences, the situation that includes a challenge to the player may be threatening to another player, and this is why he encourages 1 the first to deal with this situation and tries to solve the problem he is exposed to and sees in it an opportunity to enhance himself and his appreciation and increase his sense of self-confidence and confront the opponent with high spirit and ability as a result of the size of the stadiums, especially the handball court, due to the approach of the opponent and the continuous increase in pressure along the competition, the psychological 2 aspect plays an important, prominent and direct role, and the lack of interest in it leads to a lack of fulfillment of the duties, technical and planning skills, and adaptation to the opponent’s reactions, through which the behavior of the players on the field can be determined with high and accurate performance, and this requires a continuous physical, 3 skill and psychological struggle. One of the habits of the mind is (the struggle for accuracy). When a player matures in possessing this trait, he increases the care and focus of his work at the required level in the stadium this trait is related to what the player possesses in terms of cognitive, skill and psychological characteristics and characteristics, and it may have one of these traits, which is the subject of this research, which is self-confidence, and in that, given that a person’s confidence in his abilities, skills and attributes is a catalyst factor to improve his performance, whether that performance is technical, physical or mental 4. Hence, the problem of the current research is summarized in the answer to the following question: What is the strength and direction of the correlation between the struggle for accuracy and self-confidence of the players of the Baghdad clubs and the Middle Euphrates with hand reel?

Research objectives:

- The struggle for accuracy among the players of the Baghdad and Euphrates clubs with handball.
- Self-confidence of the players of the clubs of Baghdad and the Euphrates through handball.
Relationship the correlation between the struggle for accuracy and self-confidence of the players of the Baghdad clubs and the Middle Euphrates handball.

Research fields:

The human field: Includes players from Baghdad clubs middle Euphrates youth.

Time field: from 15/7/2020 to 22/10/2020.

Spatial field: Club halls in Baghdad and the middle Euphrates.

Terminology used:

- The struggle for accuracy:

Definition (Kallick & Costa, 2000): Individuals who value accuracy and perfection and take the time to check their products and to make sure that what they do is accurate and flawless in order to reach the highest possible standards and this makes them proud of their achievements that are characterized by perfection, craftsmanship and perfection(1).

Procedural definition: The total score that the respondent obtains when answering the paragraphs of the Struggle for Accuracy scale adopted in the current research.

- Self-confidence:

The researchers definition it: It is a personality trait of a strong and balanced individual and his ability to deal with different situations and the direction of others by knowing himself as a result of continuous evaluation and appreciation.

Procedural definition: The total degree obtained by the respondent when answering the paragraphs of the self-confidence scale adopted in the current research.

Research methodology and field procedures:

Research Methodology:

The researcher used the descriptive approach in the survey method and correlational studies as a better way to solve the research problem due to its relevance and the nature of the current study.

Community and sample research:

The research community included (250) young handball players from clubs in Baghdad and the Middle Euphrates. The research sample included (*). By applying the (Stephen) equation (*) to (152) youth players from Baghdad’s clubs with handball, it was withdrawn by a simple random method, as shown in table (1) below.

\[ n = \frac{N \times p (1 - p)}{\left[ N - 1 \times \left( \frac{d^2}{z^2} + \frac{2}{N} \right) \right] + p (1 - p)} \]

Table (1) shows the numbers of community members and the research sample and the percentages for each club:

Research tools:

In order to achieve the goals of the current induction, two tools were required, one to measure the struggle for accuracy and the other to measure self-confidence, through reviewing the literature and previous studies, a scale (Struggle for Accuracy) prepared by (Asaad Abdul Hassan: 2019), In building this scale, it was based on the theory (Costa and Calic: 2000) of the habits of the mind with its (71) paragraphs and its (five) dimensions, and the measure of self-confidence prepared by (Marwa Abdul-Jabbar: 2014) with its (60) paragraphs and its (three) dimensions.

For the purpose of applying the two scales, it was necessary to verify their psychometric properties represented in validity and consistency, as follows:

Validity: Means that the test measures what it was set for, meaning that the honest test measures the job that it claims to measure and does not measure anything else in place of it or in addition to it (3). Therefore, the two scales were presented to a group of specialized arbitrators, the results have resulted through (deleting, amending and merging) the paragraphs of the two main scales, as shown in table (2) below.

Table (2) shows the opinions of specialists in the paragraphs of the scale of struggle for accuracy, the Scale of self-confidence, and the Chi-square for agree and disagree.

<tr>
<td>32.36.42.43.44.61.62.63.64.71</td>
<td>5</td>
</tr>
</tbody>
</table>

Chi-tabular value = 3.84 , degree of freedom = 1, significance level = 0.05

It is noted from table (2) above that the number of remaining paragraphs of the scale of (Struggle for accuracy) reached (25), because the value of the Chi calculated ranged between (10 - 6.4) which is greater than the tabular value (3.84) at the level of significance (0.05), and the degree of freedom (1) while (46) paragraphs were deleted because the value of chi calculated for it ranged between (0 _ 3.6), which is less than the tabular value of chi (3.84) at a level of significance (0.05) and a degree of freedom (1). As for the measure of self-confidence, (20) items were kept because the value of
Kai which was calculated for it ranged between (6.4-10), which is higher than the value of Kai of (3.84), While (40) paragraphs were deleted, the value of chi ranged between (0 _3.6), which is less than the tabular value of (Ki) of (3.84) at the level of significance (0.05) and the degree of freedom (1).

Reliability: A static test is a test that has a high degree of accuracy, proficiency, consistency, and objectivity in relation to its measurement (4), to achieve this, the two measures were applied to a sample of the youth group of (25) players, and after a two-week period, the two scales were re-applied to the same sample. according to the (Pearson) correlation coefficient, its value appeared (0.86), which is a good indication of the reliability of the Struggle for accuracy scale, and (0.80) for the self-confidence scale.

Statistical means: The statistical data were processed using the following laws:

1. The arithmetic mean
2. Standard deviation
3. T test for a sample and the community
4. Pearson Correlation Coefficient
5. The chi-square test for good matching

The final application: After the psychometric characteristics were found, represented by validity and reliability in the scale of the struggle for accuracy and self-confidence, they were applied to the research sample of (152) players from the clubs of Baghdad and the Middle Euphrates with handball.

Presentation, analysis and discussion of results:

This chapter includes a presentation, explanation and discussion of the findings of the researchers after analyzing the answers and performance of the sample members and treating them with appropriate statistical means as follows:

In order to achieve the first objective of the research, which is to identify the level of struggle for accuracy of the clubs of Baghdad and the Middle Euphrates with handball, the answers of the individuals of the research sample (152) were analyzed, and it appeared that the arithmetic mean reached (93) with a standard deviation (8.6), which is higher than the hypothesis mean of (62.5) to verify the differences between the arithmetic mean achieved and the hypothesis, a t-test was used for one sample, and the results appeared in table (3) below.

<table>
<thead>
<tr>
<th>Sample</th>
<th>mean</th>
<th>Std. deviation</th>
<th>hypothesis mean</th>
<th>T value</th>
<th>Sig type</th>
</tr>
</thead>
<tbody>
<tr>
<td>152</td>
<td>93</td>
<td>8.6</td>
<td>62.5</td>
<td>43.36</td>
<td>Sig</td>
</tr>
</tbody>
</table>

It appears from table (3) above that the calculated value of (t) of (43.36) is higher than the tabular value of (t) of (1.96) at the level of significance (0.05) and the degree of freedom (151), this means that the research sample represented by (youth handball players for Baghdad and Euphrates clubs) have a high level of struggle for accuracy, this may be attributed to the nature of the game practiced by these players and the high ability to focus on performance to achieve achievement, and this high ability stems from the fact that the members of the sample are in most of them students of the Faculties of Physical Education and Sports Sciences, which was positively reflected on their performance considering that the vocabulary of the school curriculum and the information it contains were reflected in their motivation and desire for the better.

And to achieve the second goal of the research, which is to identify the level of self-confidence of (players of Baghdad and Euphrates clubs with handball), after analyzing their answers, it was found that the arithmetic mean (83) with a standard deviation (6.02), which is higher than the hypothesis mean (60), and
for the purpose of identifying the statistical significance of the apparent differences between the arithmetic and hypothetical mean, test (T) was used for one sample, the results appeared as shown in table (4) below:

**Table (4) Shows the arithmetic and hypothetical average and the calculated T-value for the sample of Baghdad and Euphrates clubs for the measure of accuracy and self-confidence**

<table>
<thead>
<tr>
<th>Sample</th>
<th>mean</th>
<th>Std. deviation</th>
<th>hypothesis mean</th>
<th>T value</th>
<th>Sig type</th>
</tr>
</thead>
<tbody>
<tr>
<td>152</td>
<td>83</td>
<td>6.2</td>
<td>60</td>
<td>11.5</td>
<td>Sig</td>
</tr>
</tbody>
</table>

It emerged from table (4) above that the calculated value of (t) amounted to (11.5), which is higher than the tabular value of (t) of (1.96) at the level of significance (0.05) and the degree of freedom (151), this means that the research sample represented by (youth handball players for Baghdad and Euphrates clubs) have self-confidence, as previously mentioned, it comes from two sources, one of which is represented by the psychological and cognitive culture that the players possess, since most of them are students of the Faculties of Physical Education, so they kept their practice of this game and their mastery of its skills, which was positively reflected in raising their self-confidence.

To achieve the third goal of identifying the correlation between (the struggle for accuracy and its relationship to self-confidence), a Pearson correlation coefficient was used that reached (0.72), for the purpose of identifying the statistical significance of the correlation coefficient, the (t-t) test was used, as shown in table (5) below.

**Table (5) Shows the correlation coefficient of the research sample.**

<table>
<thead>
<tr>
<th>Sample</th>
<th>correlation coefficient</th>
<th>T .R</th>
<th>T value</th>
<th>Sig type</th>
</tr>
</thead>
<tbody>
<tr>
<td>152</td>
<td>0.72</td>
<td>12.87</td>
<td>1.96</td>
<td>Sig</td>
</tr>
</tbody>
</table>

It appears from table (5) above that the calculated value (T .R) of (12.87) is higher than the tabular value of (T) of (1.96) at a level of significance (0.05) and a degree of freedom (150). The more keen and eager to achieve accuracy in performance and this is what appeared through this result.

Chronic Myeloid Leukemia and Associated Oral Manifestations

Suha Abdulhussein Hindy1, Ali M. H. Alyassiri2, Ali Q.L. Lilo3

1Assistant Prof. Dr. Oral Pathology, Department of Oral Surgery and Oral Diagnosis, College of Dentistry, University of Babylon, 2Assistant Prof. Dr. Oral Medicine, Department of Oral Surgery and Oral Diagnosis, College of Dentistry, University of Babylon, 3Lecturer Dr. Oral and Maxillofacial Surgery, Department of Oral Surgery and Oral Diagnosis, College of Dentistry, University of Babylon

Abstract

Background: Leukemia defined as a hematological disorder associated with proliferating white blood cell-forming tissues as resultant increasing of circulating immature white blood cells or abnormal cells.

Aims of the Study: To investigate clinically the oral manifestations or discomfort oral features in patients with chronic myeloid leukemia.

Subjects, Materials and Methods: Thirty- three patients participated (17 males and 16 females) in the current study with chronic myeloid leukemia already.

Results: Total numbers of cases were (33). (17 males and 16 females), the percentages of these results showed gingival bleeding (87%), fungal infection (84%), oral petechiae (72%), gingival overgrow (63%), and then finally painless oral ulceration (60%), The early diagnosis of this disease knowing that the first clinical symptoms of leukemia happen in the oral cavity with normal or show challenging changes in initial laboratory tests.

Conclusions: Because of their clinical importance for early diagnosis, all such lesions or pathological status deserves the full attention of the doctors (like oral physician and general physician).

Keywords: Leukemia, oral signs, complications.

Introduction

Lymphoma, leukemia and finally plasma cell tumors; are the most common groups of hematologic malignancies. Leukemia is defined hematological disorder associated with proliferating white blood cell-forming tissues as resultant increasing of circulating immature white blood cells or abnormal cells. Leukemic disease characterized by a disordered proliferation and differentiation of neoplastic cells. Leukemia, arises from the clonal proliferation of abnormal hematopoietic cells with impairment in regulation, differentiation, and finally in programmed cell death “apoptosis”. The multiplication of leukemic cell at the expense of normal hematopoietic cell lines results failure in marrow area, depressing in the count of blood cell “cytopenia” and bleeding then finally death due to infection, or both outcomes 1,2. The exact cause of leukemic disorder is unknown. Certain chemicals (benzene), large doses of ionizing radiation, then finally infection with specific viruses (e.g., Epstein-Barr virus “EPV”, human lymphotropic virus) these factors associated with increasing causes of leukemia. Exposure to electromagnetic fields and cigarette smoking also have been proposed to be causative conditions 3. Depending on clinical behavior; leukemia classified into acute or chronic, also can be characterized based on hematopoietic cell line affected myeloid or lymphoid. Clinically four diagnostic categories of this disorder can be clarify as fallow 4,5:

1. “acute myelogenous leukemia AML”,
2. “acute lymphocytic leukemia ALL”.
3. “chronic myelogenous leukemia CML”. and
finally

4. **“chronic lymphocytic leukemia CLL.”**

Seventy percent of leukemia patients revealed in the line of their disease oral symptoms or signs. The most obvious oral features or manifestations in patients with leukemia are petechiae due to thrombocytopenia, ecchymosis, and gingival hemorrhage or finally gingival bleeding.

Ecchymosis is involved in the differential diagnosis, a coagulation disorder or hemorrhagic diathesis. Certainly, patients taking anticoagulant drugs may have associated with oral ecchymosis, especially on the buccal mucosa area or tongue sided; either of which can be traumatized while chewing process. Appearing of ecchymosis in the oral mucosa may also related with liver cirrhosis patients finally end-stage renal disease exposing dialysis technique or also called patients with chronic renal failure (CRF).

Gingival overgrowth or enlargement is usually associated with local inflammatory conditions such as food impaction, poor oral hygiene, or mouth breathing. Systematic events like drug therapy, hormonal changes, or infiltration by tumor may also cause or predispose to the severity of gingival enlargement. The gingival overgrowth or hyperplasia can be noted in von Recklinghausen’s neurofibromatosis “neurofibromatosis 1”, sarcoidosis, Wegener’s granulomatosis, primary amyloidosis, Crohn’s disease, acromegaly, Kaposi’s sarcoma, and then finally lymphoma and patients with leukemia.

The development or clinical appearance of gingival infiltration is unpredictable in any individual patient. As general talking, gingival hyperplasia or overgrowth resolves completely or partially with effective type of treatment in patients with leukemia; as chemotherapeutic type.

Oral signs and symptoms or clinical features, in patients with leukemia may include; painless mucosal ulceration, also the oral infections a typically present, as dental abscesses may clinically appear as necrotizing area in oral soft tissue without swelling, and recrudescent herpes simplex virus, may present with wide extending lesions affecting both the keratinized mucosa and non-keratinized mucosal area, also oral soft tissue colonize with oral Candida albicans.

**Aims of the study**

To investigate clinically the oral manifestations or discomfort oral features in patients with chronic myeloid leukemia.

**Subjects, Materials and Methods**

Thirty three subjects participated (17 males and 16 female patients) in the current study with chronic myeloid leukemia already diagnosed by hematologist specialists in Merjan medical city / Babylon – Iraq, this research was done between December 2016 - April 2017. These subjects without signs and symptoms for any other medical history. The intra-oral examination of patients were done during the first two to four weeks of diagnosis.

Intra-oral photographic pictures were taken for each patient; dental mirror, tweezer and pieces of gauze were used during examination and diagnosis of these oral lesions.

**Results**

The results of the current study as shown in the table (1).

<table>
<thead>
<tr>
<th>No. of patients</th>
<th>Oral petechiae, hemorrhage</th>
<th>Gingival bleeding</th>
<th>Gingival overgrowth</th>
<th>Painless Oral ulceration</th>
<th>Candidal infection</th>
</tr>
</thead>
<tbody>
<tr>
<td>33 (100%)</td>
<td>24 (72%)</td>
<td>29 (87%)</td>
<td>21 (63%)</td>
<td>20 (60%)</td>
<td>28 (84%)</td>
</tr>
</tbody>
</table>

To clarify purpose, these results showed in the following, figure (1).
That means. Higher percentage of patients (87%) present with gingival bleeding (fig. 2), followed by candidal infection (84%), (fig. 3), then oral petechiae (72%), then gingival overgrowth (63%), (fig. 4, a &b) and the least one is painless oral ulceration (60%), (fig. 5). That means the most common and first sign of chronic myeloid leukemia is gingival bleeding which considered as triggered sign in this disease, due infiltration of tumor cells in the gingival tissue.

Figure (1): Oral features in Patients with chronic myeloid leukemia.

Figure 2: Gingival bleeding  Figure 3: Fungal infection

Figure 4 (a): Gingival swelling  Figure 4 (b): gingival overgrowth
Discussion

As general talking, the appearance of oral features or manifestations in patients with leukemia according to general conditions of the patients. Before treatments begin for these patients, large numbers of leukemic cells infiltrates extending of wide area of oral tissues. 

Silva et al., 2012 revealed that the typical oral features of patients with leukemia in acute status or stage involving: oral ulceration, gingival swelling, petechiae, mucosal pallor, spontaneous gingival bleeding, then finally herpetic infections and candidiasis. Advanced cases of leukemia may include cervical lymphadenopathy, malaise, also include laryngeal pain and fever.

Clinical appearance of oral infection like fungal, herpetic and bacterial due to immunocompromised in health status in acute stage of disease in addition to the appearance of these opportunistic infections because of neutropenia during chemotherapy or radiotherapy.

Leukemia cells infiltrate tissues like oral soft tissues and membrane in addition to multiple functional organs (as lung, bones, testis, lymph nodes and so on… etc) that will become centaury sites or also called sites of infections (reservoirs).

Albuquerque et al., 2005 stated that the leukemia may resulted in destructive radiolucencies with losing of lamina dura around the teeth and erosion of the dental or crestal alveolar bone.

Finally, patients with leukemia may clinically associated with petechial patches, points, ecchymosis and bleeding tendencies due to blood vessels; larges and smalls infiltrates by leukemic cells also this disease including functionless and immature of blood cells therefore can be concluded the oral health considering as mirror images of general health.

The present study confirmed the same oral manifestations that manifested in previous studies, and the main manifestation is gingival bleeding.

Conclusions

The dentist, and mainly the periodontics and oral medicine specialists (oral physician), oral pathologist, plays an important fundamental role in the early diagnosis of this disease knowing that the first clinical symptoms of leukemia happen in the oral cavity, which mainly starts as spontaneous gingival bleeding with normal or show challenging changes in initial laboratory tests.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Department of Oral Surgery and Oral Diagnosis and all experiments were carried out in accordance with approved guidelines.

Legalizing speed Endurance Training According to Some Physiological Indicators for 800-Meter Runners for Youth

Mohammed Amanah Kaittan1, Emad Amanah Kaittan2, Ahmed Abdulrazzaq Fadhil3

Abstract

The importance of research lies in the preparation and codification of speed endurance exercises according to some physiological indicators for 800-meter runners for youth and to identify the effect of codifying speed endurance training according to some physiological indicators of 800 meters for youth, as the researcher adopted the experimental approach in designing the two equivalent groups (control and experimental) to suit the nature of the research, where the research sample was determined by deliberate selection of young runners in athletics at the age of (18-19 years) according to the classification of the international athletics federation, as the research sample included (10) runners representing Baghdad clubs who were distributed randomly (by lot) into two groups control and experimental group each consisting of (5) runners, physiological tests were performed, including the maximum consumption of oxygen and lactic acid, and the physical tests included (1000) meter endurance test and (800) meter achievement test on the research sample, and the researcher came to the following conclusions that the speed endurance training gave progress in the level of the (800) meter running in this test, and they need to be stable and avoid fluctuation in the variation in the values of this test, the results showed that the experimental group members outperformed the control in the physiological indicators (lactic acid concentration, the maximum oxygen consumption (VO_{2max}) in the post-tests. The researcher recommended the necessity of conducting physiological tests to legalize training loads because of their effective role in the training process, focusing on developing and rationing the speed bearing capacity because of its direct impact on the development of achievement in the activities of middle-distance athletics.

Keywords: Legalizing speed, training, physiological indicators

Introduction

The development of the level of sports performance in order to achieve high levels of achievement in different sports depends on the diversity in the use of training methods that have a great impact in improving the sports figures and their different effects stimulate those interested in the field of sports training to the continuous diversity in the use of the most effective training methods, and a contribution to developing achievement. Therefore, the 800m game is one of the fast medium runs that is performed with sub-extreme intensity and due to this feature there is a specificity when training it in terms of the energy system prevailing in it and the method and training method that affects the physical abilities used and the physiological variables that characterize this game, and as a result of this peculiarity, the chosen physical capabilities and physiological indicators should be in this direction, because this event is viewed as a fast running race, and this gives an idea of the general trend in thinking about developing achievement in this competition it should focus on special physical abilities and some physiological variables affecting this competition and the common characteristics between it and the fast running and developing the \(^{3-5}\) time of this activity that needs compatibility and harmony, and because the runner possesses the capabilities that are in harmony with the requirements imposed by the performance stages of this event from the special physical abilities that have a positive effect in maintaining the speed throughout the race distance and the intensity required by the activity.
by taking advantage of improving neuromuscular work and adapting body systems in order to reach high achievement, hence the importance of research in codifying speed endurance training exercises according to some physiological indicators for 800-meter runners.

Research problem:

Run 800 Olympic competitions that require the athlete who specializes in this event to have special physical and physiological abilities in addition to patience, challenge, and willpower all combined in order to achieve achievement, the researcher noticed, through looking at the results and participation of the Iraqi runners, the achievement of the (800)m run, that the level of achievement in this event does not develop among Iraqi players compared to the international record that was recorded in the Brazilian Rio Janeiro olympics, as the scientific research and experiments that have been reached in this activity, which is not bearing large energy waste, the researcher was called upon to address this problem by codifying speed endurance exercises for the effectiveness of (800)m jogging according to physiological indicators, including the accumulation of lactic acid and the maximum oxygen consumption.

Research objectives:

1. Preparing and codifying speed endurance training according to some physiological indicators for 800-meter runners for youth.

2. Identify the effect of codifying speed endurance training exercises according to some physiological indicators of (800)m for youth

Research hypothec:

There are statistically significant differences between the pretest and the post test in (physical and physiological tests for 800-meter young runners and in favor of the post-test.

Research fields:

The human field: Baghdad youth runners clubs.

Spatial field: College of Physical Education and Sports Sciences Stadium for Athletics / University of Baghdad.

Methodology

The researcher chose the experimental approach in designing the two equivalent groups (control and experimental) for its suitability with the nature of the research.

Community and sample research:

The research sample was determined by intentional selection of young runners in athletics at the age of (18-19 years) according to the classification of the International Athletics Federation, as the research sample included (10) runners representing Baghdad clubs, who were distributed randomly (by lot) into two control groups. Each experimental group consisted of (5) runners, as the control group implemented the training curriculum followed by the trainer, either the experimental group adopted the same approach except for the speed-endurance exercises prepared by the researcher and it is implemented.

Devices, tools and methods used in the research:

Methods of data collection:

- Arab and foreign sources.
- The International Information Network The Internet.
- Personal interviews for experts.
- Exploratory experience.
- Tests and measurements.
- Results registration form.
- Data dump form.
- Auxiliary work team
- Statistical methods.

Tools and devices used:

To obtain data and reveal facts, the researcher will use the following tools:

- Lactic acid device measurement in the blood (Lactate Pro) number 2.
- Maximum oxygen consumption measuring device (VO2Max).

Field research procedures:

Determine the physical and physiological tests used in the research:

Test ran 1,000 meters:

**Objective**: To measure the speed endurance for running a distance of (800) meters.

**Tools used**: track and field stadium, (12) stopwatches, and registration forms.

**Scientific conditions**: (Shaker Muhammad Al-Sheikly) prepared by the British Olympic coaches (Watts and Wilson) as a speed endurance test for running 800 meters (1), experts and trainers agreed that it is suitable for measuring the endurance of speed for running a distance of (800) meters.

**Performance description**: All five players were selected together to ensure the element of competition, as each player stood in his field, then the test began by giving players a directive to go behind the starting line to take the starting position from standing, upon hearing the start signal, the players set out to run and cover two and a half laps (1000 meters), and upon reaching the finish line the timing clocks were stopped, and the time spent by each player was read, and recorded in the scoring form.

Achievement test ran 800 meters:

**The purpose of the test**: to measure the effectiveness of 800 meters.

**Tools used**: track and field stadium, stopwatches that can measure more than one time during the test, assistants, registration form.

**Performance description**: The test was conducted in accordance with the conditions and regulations of the International Federation of Athletics, as were all tested together for the purpose of runners compete, and every runner in the field of dedicated running, after that, the test begins by instructing runners to go behind the starting line to take the starting position from standing, when the start signal is heard, the runners start running two laps on the track for a distance of 800 meters.

Register: The registrar records the completion time in the form prepared for this purpose in the minute and the second to the nearest fraction of a second.

**Blood lactic acid concentration test before and after physical effort** (2):

**Test name**: Measurement of lactic acid concentration in the blood before and after physical effort.

**Objective**: Find out the percentage of lactic acid concentration in the blood.

**Tools used**: A lactate pro2 LT-1710 device, needle drill, test strip, graduated tape, medical cotton, sterile materials and registration form.

**How to use it**: Blood samples will be taken every two weeks during the special endurance period before and after the effort.

Register: The reading shown by the device for each player is recorded in the registration form.

**Maximum oxygen consumption (VO2max) test** (3):

**Test objective**: Measurement of maximum oxygen consumption (VO2max).

**Device and tool**: Maximum oxygen consumption measuring device (VO2max).

**Procedures and performance specifications**: Before starting the test, the test performer cleans the VO2max respirator with an antiseptic solution, ties the Fitmate Pro system parts together, attaches the pulse belt to the tester’s chest, and attaches the Bluetooth pulse receiver to the Fitmate pro, after entering the player information into the device, which includes name, date of birth, gender, height, weight, and choosing the type of test to be performed (VO2mx), and then fixing the respirator tightly with its belts and making sure that breathing air does not leak from the mask, then the tester climbs onto the treadmills and runs gradually with increasing speed, as the tester begins to control the increase in running speed on the device with the speed gradient from the special button for that in the treadmills starting from (4.5) to (13-) 14) km / hour, the Fitmate Pro device contains a small screen with a graph box showing the pulse and maximum oxygen consumption (VO2max)
with the ratios for each of them, which is monitored by the rectifier.

**Register:** the device gives a comprehensive reading tape for measurements of maximum oxygen consumption (VO₂max), the image of which is shown.

**Measuring unit:** Milliliter / kg / minute.

**Exploratory experience:**

The exploratory experiment was conducted at nine o’clock in the morning on 1/9/2020 by three players from the research sample, in order for the players to get used to the testing procedures to understand them and not to be afraid of the procedures.

**Pre-tests:**

After completing the exploratory experiment and avoiding the difficulties and obstacles that appeared in it, the researcher conducted the pre-tests for the functional variables of the individuals of the research sample consisting of distance runners (800 meters).

The main experience:

The researcher prepared a training curriculum with endurance of speed for the effectiveness of (800 meters) based on his experience and field training experience and drawing on the opinions of specialists in the field of sports training science and scientific and Arab training and physiological sources. (Muhammad Reda Al-Madaghmi) confirms that most of the changes resulting from training occur during the first period of the curriculum Training within (8-12 weeks) (⁴). The duration of the implementation of the training curriculum lasted (8) weeks, at the rate of (2) two training units per week, and the number of training units reached (16) units that were applied in the period from 4/9/2020 to 3/11/2020.

**Post-test:**

The assistant work team, under the supervision of the researcher, conducted the post tests of the individuals, the research sample, and under the same circumstances, to give equal opportunity to the individuals of the research sample in recording the results.

The statistical means used:

- SPSS.
- (V20) (Virgin).
- Mean.
- Standard deviation.
- Coefficient of torsion.
- T-test for correlated samples.
- T-test for non-correlated samples.

Presentation, analysis and discussion of results:

**Table (1) Shows the results of the arithmetic mean and the standard deviations of the two research groups (experimental and control) in the pre and post- tests in the speed endurance test (1000 m) and the achievement test (800 m).**

N = 5 for each group
Table (1) shows that the arithmetic mean of the experimental group in the speed endurance test of running speed (1000) meters preceding was (160.625) and the standard deviation (2.9649), in the post test, the mean became (153.26) and the standard deviation (1.15877), while the mean of the control experimental group was (163.755) and the standard deviation (3.51759), and in the post test the mean became (160.989) and the standard deviation (3.04025). As for the achievement test, it shows that the mean of the experimental group in the pre-test was (125.034) and the standard deviation (1.749). In the post-test, the mean became (118.153) and the standard deviation (2.686), while the mean of the control group in the pretest was (126.249) and the standard deviation (1.214), and in the post test the mean became (123.383) and the standard deviation (2.359).

In order to identify the difference between the pre and post-tests in the results of the speed endurance test, the achievement test, the researcher used a (T-test) test for correlated samples for each of the two research groups, as shown in table (2):

Table (2) shows the mean of the differences, the deviations of the differences, the value of the test (T) and the significant significance of the two research groups (experimental and control) in the pre and post-tests in the speed endurance test (1000 m) and the achievement test (800 m).

Degree of freedom (n -2) $5 + 5 - 2 = 8$ and the level of significance (0.05)

Table (3) shows that the mean of the experimental group in the endurance test of running velocity was (1000) meters (153.26) and the standard deviation (1.15888). As for the control group, its mean was (160.986) and the standard deviation (3.04029). The calculated T-test value was (5.310) at the significance level (0.05) and the degree of freedom (8). (Sig) (0.001) which is smaller than (0.05). This means that there is a statistically significant difference with regard to the two research groups and in favor of the experimental group. As for the achievement test, it shows that the mean of the experimental group in the post test was (118.155) and the standard deviation (2.686), while the control group had its mean (123.384) and the standard deviation (2.359), after calculating the value of (T) calculated using the law of (T)-test for non-correlated samples that were (3.274) at a level of significance (0.05) and a degree of freedom (8), the value of (Sig) (0.014) is less than (0.05), which means that there is a statistically significant difference, while the two research groups in the achievement test ran (800) meters in favor of the experimental group.

**Discuss the Results**

Discussing the results of the difference between the pre and post tests for the two research groups and the (t) values for the post tests between the experimental and control groups in the speed endurance test (1000 m) and the achievement test (800 m).

From reviewing the two tables of statistical significance (2 and 3) for testing physical abilities, he ran (1000) meters between the pre and post-tests, the two research groups and the post-tests between them showed improvement in each of them in the tests and the superiority of the experimental group over the control group, and the researcher attributes this result to the proposed exercises that were done they applied them to an experimental group of young runners, which led to the occurrence of adaptations that had an effective impact on the development and development of speed endurance, and this is certainly due to the privacy of the proposed approach to developing special endurance, which is an important principle of sports training principles that must be taken into account, especially for running coaches (800
meters), Mufti Ibrahim Hammad believes that “one of the conditions for enduring special speed training as one of the physical abilities of anaerobic prolongation requires the use of exercises characterized by high intensity using the method of high-intensity interval training for specific periods of time interspersed with positive (incomplete) rest between repetitions, provided that these are The exercises are characterized by a gradual increase in velocity at a time when the distance also decreases gradually, which will improve the ability of velocity stretching. “(5) , Shakir Al-Dara’a states, “The results are better the more the intensity is close to the maximum intensity” (6). The researcher attributes this development in the dimensional tests and for the benefit of the experimental group in a test running (1000 meters) more than the racing distance to the effectiveness of special endurance exercises that contributed to the development of this test time, as the distance of this test is greater than the completion distance (800 meters), the test distance (1000 meters) needs both aerobic and anaerobic energy sources, therefore, the special endurance exercises used by the researcher tended towards the development of anaerobic capabilities and as a result of the repetitions and intensity specified for each distance, which led to the body carrying physical burdens as a result of its fatigue in order to create special adaptations for the functional organs that were reflected in the development of the performance level of this group in performing the maximum possible degree from the intensity of jogging and for the longest possible period of time, (Ibrahim Al-Basri) confirms, “Experiences have proven that endurance and stress in the body during exercise, especially special endurance exercises, lead to gradual normalization of the body on effort and thus affect the ability of the heart and circulation system (7), and the researcher believes that the exercises that have been implemented have contributed to creating functional changes and upgrading the level of group members, which enabled them to travel the test distance in the least possible time. Although the control group had obtained a percentage of development at the time of this test, the difference was in favor of the experimental group in the significance of the differences, as the regularity of the experimental group sample in performing the exercises and the commitment to the specified rest times without interruption and the seriousness that they enjoyed in performing the exercises of different distances, intensity and time contributed to raising the efficiency of the functional devices, modifies the vital functions of body systems and this effect appears in their responses to loads of different intensity (8).

As for the achievement of running (800 meters), the researcher attributes that this development that appeared on the members of the experimental group is due to the effectiveness of the proposed training approach adopted by the researcher, where he focused mainly on developing special endurance (endurance of speed) by the method of low and high interval training. The intensity is from the real competition time, which reflects the mutual relationship between endurance and speed in the term endurance speed as complex abilities that contribute to determining achievement during the race, (Raisan Khuraibet 1998) asserts that “structured and programmed training and the use of types of standardized stresses in training and the use of optimal rest types between repetitions lead to an improvement in the level of achievement (9), and this is what distinguished the experimental group from the control, which led to the development of the level of performance the experimental group, which was reflected in the performance of the maximum possible degree of racing speed and for the longest possible period of time, as the use of balanced and comprehensive training leads to avoiding a drop in running speed because special training works to improve endurance (10) , it must be noted that the proposed training curriculum that the experimental group underwent contributed to the development of achievement more than the control group, as it was characterized by endurance exercises for medium and short distances that are directed towards developing oxygen and non-oxygen energy, distances that range between 2 minutes and more are used to improve oxygen endurance, while short distances that range from 15 to 120 seconds are used to develop non-oxygenic endurance. "This is one of the special endurance requirements that an 800-meter running event needs, as it needs both sources of oxygen energy and non-oxygenic, therefore, enduring speed is one of the abilities that may decide the race in the 800-meter event (11), on (Miles, T1992) “and this shows the effectiveness of the exercises included in the curriculum, as it came in line with what happened in terms of achievement, considering that the special endurance is the main factor in the repetition of similar movements such as running
movements according to the endurance of speed and which were included in this achievement test, which was reflected in the results of this group in the post-test as well as the development of the traits included in the program the contestant for this event needs it (12), (Atheer Sabri 1983), citing Yonath, Hack and Carmel, confirms, “The physical qualities of a middle-distance runner are endurance, speed and strength, and these qualities are important and are required to be developed to raise the level of achievement, (Less and more than the racing distance) continuously will inevitably increase the rate of speed over the course of the race and that the development of the speed endurance capacity of the members of the experimental group had the cut-off point in determining the completion time between the two groups as a result of the correlation of the completion time in the 800-meter running event and the variables related to this activity with the development special speed endurance capacity (13).

Table (4) Shows the results of the arithmetic means and the standard deviations of the two research groups in the pre and post-tests in the functional indicators tests.

\( N = 10 \) degree of freedom \((n - 2) 5 + 5-2 = 8\) and level of significance \((0.05)\).

Table (6) shows that the arithmetic mean of the experimental group in the post-lactic acid measurement test was \(14.840\) and the standard deviation \(0.7021\), while the control group had its mean \(13\) and the standard deviation \(0.249\), the value of \((T\)-test\) calculated for non-correlated samples was \(4.262\) at a level of significance \(0.05\) and a degree of freedom \(8\), and the value of \((\text{Sig})\) was \(0.003\), which is less than \(0.05\), this means that there is a statistically significant difference with regard to the two research groups and in favor of the experimental group.

Discussing the difference between the results of the pre and post-tests for the two research groups and the \( T \) values of the post-tests between the two experimental and control groups in functional indicators:

From a review of the statistical significance tables \((5 \text{ and } 6)\), physiological indicators (heart rate, lactic acid concentration, and maximum oxygen consumption \(\text{VO}_{2}\max\)) between the pre and post-tests of the two research groups and the post-tests between them, it is evident that there has been an improvement in each of them in the tests and the superiority of the experimental group on control group, the researcher attributes this
result to the proposed exercises that were applied to the experimental group of youth runners, in which repetitions, training stresses and rest periods were codified based on the physical and physiological capabilities of the runners, which were codified through the trainer’s knowledge of the responses firsthand through the time of cutting distances during training. “That a person who has the ability to metabolically adapt is characterized by the ability to work for long periods with low rates of consumption of sources of energy production in the body, that is, the availability of what is known as the economy in the consumption of energy stocks (14), Imad al-Din Abbas states, “The pregnancy given to a player causes excitement and change in the vital organs and systems of the body in terms of function and chemistry, and this appears in the form of improvement in the adequacy of the various organs and systems”, in addition to the distinction of performance, economy by effort, as a result of continuing to perform pregnancy despite the onset of feeling tired and then begins to adapt to this pregnancy (15) and Bastwissi Ahmed mentioned that “the efficiency of muscular work is related to the presence of a large proportion of oxygen in the muscles or its transfer from the lungs to the muscles for movement by means of aerobic and anaerobic reactions (16).

Conclusions

Based on the research results reached within the limits of the research community, the following conclusions have been reached:

4- Speed endurance training have given progress in the level of the (800) meter runners in this test, and they need to be steady and avoid fluctuation in the variations in the values of this test.

5- The results showed the superiority of the experimental group over the control in the physiological indicators (lactic acid concentration, the maximum oxygen consumption (VO_{2max})) in the post-tests.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the General Directorate of Education in Babylon and all experiments were carried out in accordance with approved guidelines.

Salivary Changes with the Age and their Effect on Plaque Related Disease

Haider Adnan¹, Suha Abdulhussein Hindy², Ali Zaki Naji³

¹ MSc Oral Microbiology, College of Dentistry, Jabir Ibn Hayyan Medical University, ² Assistant Prof. Dr., PhD Oral Pathology, Department of Oral Surgery and Oral Diagnosis, College of Dentistry, University of Babylon, ³ Assistant Prof. Dr., Board General Pathology, Department of Basic Science, College of Dentistry, University of Babylon

Abstract

Background: Saliva is an exocrine clear oral fluid predominantly secreted by salivary glands both major and minor. It consists of many constituents, mainly water and others are electrolytes, enzymes, immunoglobulins and other antimicrobial factors.

Saliva plays an important role in the oral health, the level of its components change with age, and that has direct effect on teeth and periodontal tissue, because saliva plays a critical role in the development of dental caries and periodontal diseases.

The objective of this study to estimate salivary changes by investigation the level of alpha-amylase and MMP-8 enzymes, sIgA, and salivary minerals (Calcium, Magnesium and Phosphorus) in relation to age.

Materials and Methods: Ninety persons were chosen from different age groups (60) males and (30) females, the age ranged between 20 up to 50, and divided into three subgroups.

ELISA technique was used to evaluate the level of salivary alpha-amylase, MMP-8, and sIgA. Salivary electrolytes were evaluated according to their kits.

Results: Results showed that the level of sIgA significantly decreased with the age, salivary alpha–amylase decreased with the age but not significant statistically, and MMP-8 increased with age but not significant statistically. Regarding salivary minerals (Ca, P, and Mg) results showed that calcium and magnesium levels significantly increased with age, while phosphorus level increased with age also but not significant statistically.

Conclusion: Decrease in the level of sIgA and alpha-amylase with age, while increase in the level of MMP-8 and salivary minerals (Ca, P and Mg) with age, may indicate decrease in the incidence of dental caries and increase in the incidence of periodontal disease with age.

Key words: sIgA; salivary immunoglobulin A, MMP-8; matrix metalloproteinase-8, Alpha amylase enzyme.

Introduction

Saliva is a clear, slightly acidic oral fluid, mostly produced by parotid, submandibular, and sublingual glands and the minor glands. (1) Saliva is an exocrine secretion containing many constituents. It consists mainly of water about 99%, which contains many electrolytes like; calcium, potassium, sodium, magnesium, chloride, bicarbonate, phosphate, and proteins, characterized by immunoglobulins, enzymes, and other antimicrobial factors, mucosal glycoproteins, traces of albumin and some polypeptides and oligopeptides which are of importance to oral health. (2, 3) Saliva plays an important role in the oral health, the level of its components change with age, and that has direct effect on teeth and periodontal tissue, because saliva plays a critical role in the development of tooth decay and periodontal diseases.
Histological analysis; with the advancing age the parenchyma of the salivary glands is replaced gradually by adipose and fibro-vascular tissue, and the capacity of the acini is reduced. Salivary immunoglobulin A (sIgA) is characterized as a part of the immune system “first line of defense” against pathogenic microbes. Restricting the adhesion of microbes, these antibodies respond to biofilm development and thus interfere with the defense of plaque related diseases; dental caries and periodontal diseases. Alpha amylase enzyme considered as one of the main components of saliva that play a role in oral health. In solution, this enzyme, contributing to the bacterial clearance by binding to bacteria. In comparison, it initiates the digestion of starch in enamel pellicle thus give substrates for colonization of bacteria and enhance their adhesion to tooth surface. MMP-8 (matrix metalloproteinase-8) is the most proficient proteinase to initiate degradation of type I collagen and extracellular matrix that associated with the destruction of periodontal and peri-implant tissue, leading to the loss of tooth and dental implant. MMP-8 act as a central mediator in chronic infection, encouraged inflammatory conditions and can exert, anti-inflammatory and defensive properties in addition to the classical surrogate tissue destructive properties. Calcium contributes about 1.9% of the body weight and considered as the most abundant mineral in the body. About (99%) of this percentage in the skeletal system, and the remaining; in the teeth (0.6%), the extracellular fluid (0.6%), the soft tissues (0.6%), and the plasma (0.3%) Calcium provides a structural role in providing rigidity (structure and strength) to the skeleton. Phosphorus considered as the next most abundant mineral in the body after Calcium. These two minerals work together to form strong teeth and bones. Nearby (85%) of the phosphorus in the body is in the teeth and bones. Magnesium regarded as the fourth more abundant mineral in the body. It act as a cofactor for more than 300 enzymatic reactions, where it is essential for the metabolism of adenosine triphosphate (ATP). Magnesium is necessary for the synthesis of DNA and RNA, with protein synthesis.

**Aim of Study**

To study salivary changes according to age by evaluation the level of Alpha-amylase enzyme, MMP-8 enzyme, salivary IgA, and the level of salivary minerals (Phosphorus, Calcium and Magnesium) according to the aging process.

**Material and Methods**

This study was conducted in the center of Hilla city carried out from December 2017 to January 2018. The samples were collected from different age groups from general population. The data were analyzed in University of Babylon \ College of Dentistry

Ninety persons from different ages were chosen: Males (60) and females (30), the age of the persons ranged from 20- up to 50 years. This group of persons are divided into three different age group, as shown in the table below.

The saliva was allowed to accumulate in patient’s mouth for two minutes, then the patient was asked to spit the accumulated saliva into the receiving vessel. Two ml of un stimulated saliva samples were centrifuged at 4000 rpm for 15 minutes; the clear supernatant was separated by micropipette and pouted in plane tubes then stored at (-20 °C) in a deep freeze for subsequent analysis which was carried out in maximum period of three weeks. The swab was rotated to remove saliva from the oral cavity, inoculated in media then plate incubated
at (37 °C) for 48 hours anaerobic condition.\(^{(18)}\)

ELISA technique used to evaluate salivary IgA, Alpha- amylase and MMP-8.

Phosphorus according to Phosphorus kit (Phosphomolybdate method) by Mindray, Calcium according to Calcium kit (Arsenazo III method) by using Mindray. Magnesium according to Magnesium Kit (Xylidyl Blue Method) by using Mindray

Statistical Analysis

Data were processed and analyzed with independent Anova- test using statistical package of social science SPSS 19 and the results were expressed as (Mean±SD).P-values < 0.05 were considered statistically significant.\(^{(19)}\)

Results

The study group consists of three different age groups; group I (33) person, group II (32) persons and group III (25) persons, as shown in table (1).

Evaluation of salivary IgA

The results showed that Mean ± SD of salivary IgA level for age group I (20-35years) is (492.63±18.30) which is higher than Mean ± SD of age group II (36-50 years) (290.34±22.10) and higher than Mean ± SD of age group III (51 years and above) and the difference among the study groups is significantly decreased with age (P≤0.05). As shown in table (2).

Evaluation of salivary amylase alpha I enzyme and salivary MMP-8:
Results show that Mean±SD of amylase alpha I enzyme of the age group I is (110.35±66.42), while that of age group II is (71.19±58.53) and of age group III is (85.87±56.62). The difference among the three study groups was decreasing with the age, but not significant statistically (P≥0.05). As shown in table (3).

For the level of MMP-8; in age group I is (0.48±0.50), while in age group II is (0.66±0.85) and in age group III is (0.70±0.80), that shows increasing with age, but not significant statistically (P≥0.05). As shown in table (3).

**Evaluation of salivary minerals (Calcium, Phosphorus and Magnesium) among different age group:**

Table (4) shows that Mean±SD of salivary Calcium for age group I is (6.04±1.87), and for age group II is (5.67±0.79), while for age group III is (8.07±0.56), which shows significant increasing with age (P≤0.05).

For salivary Phosphorus, Mean±SD for age group I is (88.38±16.5) and for age group II is (90.38±5.21), while for age group III is (90.56±17.30) that showed increasing with age but not significant statistically (≥0.05). As shown in table (4).

While Mean±SD of salivary Magnesium level in age group I is (1.94±0.26), for age group II is (1.96±0.38) and for age group III is (2.70±0.44), which shows significant increasing with age (P≤0.05), as shown in table (4).

Discussion

Saliva plays an important role in the maintenance of oral health (dental caries and periodontitis). The data of the present study showed that all the participants had dental caries. However, current data expressed a variation in the saliva among different age group. With the age there are some changes occur in salivary flow, amount and composition.

Regarding salivary IgA is a part of the immune system “first-line of defense” against pathogenic microbes, by restricting the adhesion of microorganism.

These antibodies counter to the formation of dental biofilm and therefore interfere with the defense of plaque related pathologies “caries and periodontal diseases” (20, 21, 22). In addition, they act to neutralize enzymes, toxins, and viruses; or by working in cooperation with other factors like lactoferrin and lysozyme. (23)

The results of this study showed that the level of salivary IgA in age group I, is higher than the level of age group II, and higher the level of age group III, and the differences among the study groups show significant decrease with age.

Jafarzadeh, et al., in (2009) and Jafarzadeh, et al., in (2010) found that decline in the salivary IgA levels after the age of sixty years could be attributed to the higher risk of oral infections in the elderly.(24,25)

While Eliasson, et al., in (2006) investigated IgA concentrations in secretions of palatal, buccal, and labial salivary glands in individuals aged 18-72 years. The saliva samples of individuals beyond the age of 65 have shown to have higher salivary IgA levels than other individuals. Increased whole salivary IgA concentrations in older ages have been attributed partly to positive age-related effects on IgA concentrations in the buccal gland secretions. (26)

Childers, et al., in (2003) determined the concentrations of IgA in the parotid saliva of healthy children (age 6-12) and healthy adults (age 22-51) and found that IgA levels increased with the age. (27)

Regarding the concentration of salivary enzyme, the results showed that the concentration of α- amylose I, among different age groups is decreasing with age, but the difference is not significant. These findings are in agreement with that of other studies who establish lesser
α-amylase levels in the elderly (28, 29), while others demonstrated no significant difference, or even

Variations in the results among studies may be due to differences in the methods used, alteration in age groups, and method of saliva collection and saliva used, stimulated or resting type. (30)

There is positive correlation between the level of Ca and α-amylase, because the micro molar levels of Ca2+ are required to stabilize the structure of barley alpha-amyloses in the endoplasmic reticulum of the aleurone layer where these enzymes are synthesized (31). The stabilization mechanism includes an interaction between some negatively charged amino-acid residues and cations. The benefit of this interaction is to keep the three-dimensional structure of protein, which is necessary for the activity of this enzyme. (32, 33)

Elimination of Ca from the genus bacillus, result in reducing thermal stability and enzymatic activity of α-amylase (34), or even increased the susceptibility proteolytic degradation of this enzyme. (35)

Salivary amylase has the ability of metal-binding. Its structure has two sites for metal ion binding, and has one site is selective for Ca binding. It has been found that copper or zinc cannot replace Ca in salivary α-amylase. Therefore, the stability of Ca-amylase binding is a unique interaction. (36)

The presence of Ca in enamel pellicle is necessary for the process of remineralization. While the presence of α-amylase in the enamel pellicle provides the essential substrates for bacterial colonization and enhancing their adhesion to the structure of tooth, and lead to demineralization; therefore, studies about the interaction between Ca and α-amylase in enamel pellicle can provide better explanation for process of remineralization. (36)

Matrix metalloproteinases (MMPs) are family of (24) proteases that play a role in both physiological and pathological conditions. They almost degrade all the components of extracellular matrix and regulate inflammatory processes. They are inhibited by metalloproteinases tissue inhibitors. The main collagenolytic MMP identified in oral fluids is MMP-8, like saliva, oral mouth rinse, gingival crevicular fluid, and peri-implant fluid. MMP-8, that present in oral fluids considered as a strong biomarker that associated with the diagnosis of periodontal disease, their severity, progression, and in fellow-up process. (37)

High level of MMP-8 indicate the loss of supporting periodontal tissues relatively than inflammation. The main collagenolytic MMP detected in the gingival tissue and oral fluids is MMP-8, about (80%) of collagenases found in the gingival crevicular fluid and considered as a periodontal biomarker. (37)

MMP-8 defined as one of the most salivary biomarkers used for detection of alveolar bone destruction that associated with different clinical and radiological parameters, like deepening of periodontal pockets, progression loss of attachment, bleeding on probing and alveolar bone loss. (38)

That explaining the finding of this study, which demonstrated that the level of MMP-8 decreased with age.

Nassar et al., in 2014 found positive correlation between increasing age and salivary MMP-8 levels. These findings were in agreement with the findings of the present study. (39)

A plausible explanation for increased periodontal disease severity with increasing age is prolonged exposure to risk factors over a longer duration and possible influence of undiagnosed concurrent systemic diseases predisposing periodontal breakdown. (39)

Regarding the concentration of salivary minerals, the results showed significant increasing in the level of salivary calcium among different age groups with the age. These findings were in agreement with Sevon et.al, in 2008, who found that salivary Ca levels increased with age (40), while, Salvolini, et al., in 1999 and Chauncey, et al., in 1981, found reduced Ca level in old males. (41, 42)

Phosphorus is the most abundant mineral in the body. Calcium and phosphorus act together to form strong bones and teeth. About (85%) of phosphorus of the body present in the bones and teeth (43). Phosphorus also found in little amounts in tissues and cells all over the body. (43)

The present study showed increasing in the level of salivary Phosphorus with the age. These findings were
in agreement with Sevón, et. al., 2008 who showed that concentration of salivary phosphorus increased with age. (40)

In this study when compared the level of salivary calcium and phosphate in patients with dental caries, periodontitis, and control group, the results showed highly significant statistically, which show high level of calcium and phosphate in patients with periodontitis when compared with controls and dental caries group.

That in agreement with a study done by Sewon et. al., in 1990 who found positive correlation between periodontitis and high level of salivary calcium. (44) Others demonstrated higher concentration of calcium in plaque is associated with low caries incidence. (45, 46)

On the other hand, results showed significant increasing of magnesium level with age.

Both Calcium and Magnesium identified as important elements for the function of different systems in the organisms of human and animal. High level of salivary magnesium, decrease the colonization of streptococcus mutans and therefore, reduced caries possibility. (46)

Gutman and Ben in 1974 demonstrated an elevation in the mean of electrolyte content (Na, K, Ca, and Mg) and a reduction in salivary flow with age; these results indicate probable correlation between the salivary properties and aging process. (47)

The above results explaining the relationship between increased incidence of periodontal disease and decreased incidence of dental caries with the age.

Evaluation of Morphological (Macroscopic and Microscopic) Parameters of Placentas in Pregnancies Complicated by Preeclampsia, Diabetes and Preeclampsia and Diabetes

Malak A. Al-yawer1, Nameer F. AL-Kalifa2

1Prof. University of Baghdad, College of Medicine; Department of Anatomy; 2Lect. University of Diyala, College of Medicine, Department of Anatomy

Abstract

This study was done to compare the morphometric parameters of placentas in well controlled patients with preeclampsia, diabetes, and preeclampsia-diabetes with that of normal uncomplicated placentas.

Patients & Methods: A total of Twenty four placentas were freshly collected. Six placentas for control group and eighteen placentas for complicated group (preeclamptic- diabetic and preeclamptic--diabetic subgroups). The placentas were grossly examined (shape, number of cotyledons, weight, and thickness). After suitable fixation, tissue processing and sectioning, the sections were stained by hematoxylin and eosin to study the general morphology and morphometry of the following parameters: number of terminal villi, number of syncytial knots, number of apoptotic cells and number of fetal capillaries.

Result: The weight of the baby in D- subgroup was significantly increased when compared with control group and with P and P-D subgroups . Microscopical morphometry regarding number of terminal villi, apoptotic cells, syncytial knots and fetal capillaries were increased in complicated subgroups. The thickness of basement membrane was 0.8µm in control group and it was increased in all complicated subgroups. The highest value was reported by D- subgroup (2 µm).

Keywords: Parameters, pregnancies, Preeclampsia, Diabetes

Introduction

The placenta acts as a natural barrier between the maternal and fetal blood circulations and fulfills a wide range of endocrine and transport functions. The location between the two bloodstreams makes the placenta not only a crucial regulator of fetal nutrition, gas exchange, and maternal immune tolerance, but makes this fetomaternal organ also a target for maternal and/or fetal metabolic alterations associated with pregnancy pathologies. One of these pregnancy pathologies is gestational diabetes mellitus (GDM)(1). DM is a common clinical condition that affects approximately 1 to 15% of pregnant women(2). GDM is a metabolic disease defined as progressively impaired glucose intolerance with the onset or first recognition during pregnancy(3). Fetuses with intrauterine exposure to hyperglycemia more often present with macrosomia, birth trauma, neonatal hypoglycemia, and respiratory distress syndrome (4). The second pregnancy pathology that affects the placenta is preeclampsia which is a hypertensive disorder of pregnancy defined by the American College of Obstetrics and Gynecology (ACOG) as 'new onset of hypertension on two separate occasions with proteinuria arising de nova after the 20th weeks of pregnancy in a previously normotensive non-proteinuric woman(5). Pre-eclampsia is a human pregnancy-specific disorder with an incidence of 2-8% worldwide (6). The incidence being 3 to 7 % in nulliparous and 1 to 3 % in multiparous. It is directly associated with 10 to 15 % of maternal deaths(7). The diagnostic criteria for preeclampsia is systolic blood pressure of >140mm Hg or diastolic blood pressure of >90mm Hg measured at rest on two different occasions at least six hours apart accompanied by proteinuria of >0.3 g in a 24-hour urine specimen (8).
The placenta is a mirror which reflects the intrauterine status of the fetus. An adequate knowledge of the morphometric analysis of the placenta proves to be useful in the early assessment of placental sufficiency and also the state of fetal wellbeing. Hence, this study was done to compare the morphometric parameters of placentas in well controlled patients with pre eclampsia, diabetes, and preeclampsia-diabetes with that of normal uncomplicated placentas.

**Materials & Methods**

A total number of 40 freshly delivered placentas were collected from the government hospital for women and children in Diyala. The placentas were collected soon after their expulsion, from normal deliveries. They were divided into two major groups; control group (10 women) and complicated group (30 women). The latter was divided into three subgroups (10 women each), pregnant women with pre eclampsia(P); pregnant women with diabetes(D) and pregnant women complicated by both pre eclipampsia and diabetes(P-D). Clinical criteria for selection of patients were shown in table 1. The collected placentas were washed under running tap water and the membranes were thoroughly examined and trimmed. The umbilical cord was cut, leaving a length of 5cms from its placental site of insertion.

The specimens were then transported in formalin (10%) filled plastic containers to the Department of Anatomy.

In all the collected placentas, the following parameters were studied: weight, shape, placental thickness and the number of cotyledons. From each placenta, tissue pieces measuring 0.25×0.25 cm were taken 2 cm from the attachment of umbilical cord. After 24 hours fixation in 10% formalin (Fluka AG. Chemicals, Buchs), the fixed tissues were processed for routine paraffin- wax embedding. From each paraffin tissue block, 2 sets of sections were prepared. The 1st set was used for routine heamatoxylin - eosin stain; the 2nd set for the Periodic Acid Schiff’s reaction (PAS). In our study microscopic morphometry included the following parameters: number of apoptotic cells, number of terminal villi, number of syncytial knots, number of fetal capillaries and thickness of trophoblastic basement membrane (microns) using 40X objective and 10X ocular at 6 random fields per sections.

The data collected were analyzed using the computer facility with the available software statistical packages of SPSS 17 (Statistical Packages for Social Science, version 17.0). Results were presented in simple measure of mean ± S.D.(standard deviation). The significance of difference among quantitative variables of groups was assessed using one-way analysis of variance (ANOVA).

**Results**

In all groups, the placenta is disk like, and round to oval. The fetal surface appeared congested in P-subgroup, ranged from red-purple to shiny translucent in D- and D-P subgroups. Subchorionic fibrin/fibrinoid deposits and infarcted area were significantly increased in all complicated subgroups (table 2).

- Macroscopic parameters of the placenta (Table 3 and 4):

  - The number of cotyledons were significantly decreased in all complicated subgroups. The weight of the placenta in control group was 510 gm. In P subgroup was significantly decreased (375.8gm) and in D- and D-P subgroups were non significantly increased and they were 550gm and 521.6gm respectively.

  - The weight of the baby in control group was (3191gm). In D- subgroup was significantly increased (4300gm) when compared with control group and with P and P-D subgroups.

  - The thickness of placenta was 2.5 cm in control group while in all complicated subgroups, the thickness of placenta was 2.2cm

- Microscopic Examination of Placenta (Tables 5 & 6):

  - The number of villi in control group was 10.5 and it was significantly increased in P, D and P-D subgroups when compared with control group.

  - The number of apoptotic cells in control group was 11.4 and it was significantly increased in P, D and P-D subgroups when compared with control group.

  - The number of syncytial knots were 12.4 in control group and their number was significantly increased in P, D & P-D.
subgroups when compared with control group.

The thickness of basement membrane was 0.8µm in control group and it was increased in all complicated subgroups. The highest value was reported by D-subgroup (2 µm).

The number of fetal capillaries was 8.3 in control group. It was significantly decreased in P– subgroup when compared with control groups and with D-and P-D subgroups and was significantly increased in D- and P-D subgroups when compared with control and P-groups.

Discussion

Round or oval placentas are the predominant human placental form, but many other shapes exist (Bilobed placenta, Placenta membranacea, Succenturiate placenta, Fenestrated placenta, Ring (zonary) placenta (12). Anomalies may develop from abnormal fetal genes expressed by the placenta, an abnormal maternal environment, or an abnormal fetal-maternal interaction (13). As all the subjects were apparently healthy and there was no evidence of maternal malnutrition. The hemoglobin level was about 10gm/ dl in all subjects included in this study. This may be the reason of normal shape. Only in severe malnutrition, abnormal shape has been reported by previous workers (14,15).

In our study, fibrinoid deposits moderately increased in all complicated groups which mean that focal degeneration of syncytiotrophoblast increased in these groups. This finding is in agreement with older findings by Horman who considered that factors such as hypoxia and acidosis might lead to syncytial degeneration and eventually result in replacement of the syncytiut by fibrinoid(16).

The number of cotyledons, in complicated group, was significantly decreased. This may be explained by an altered distribution of fetal blood in complicated placenta resulting in different modes of arrangement of intracotyledonary vessels of complicated pregnancy(17).

The placental weight was significantly decreased in preeclampsia. This finding corroborate with the study of Fox (18). The placental weight in D and P-D subgroups was non significantly increased as it had been found by Clarson et al. that when diabetes is well controlled during pregnancy, the placental weight does not deviate from that of normal organs (19).

This study reveals that the fetal weight was significantly decreased in P-subgroup. This finding corroborate with the studies of other workers (18,19,20). Rath stated that in hypertension; arrangement of the intracotyledonous vasculature is altered resulting in low birth weight of babies (17). The birth weight in P-D and D subgroups was increased and it was significant in the latter. The weight gain in diabetic’s placentas may be attributed to macrosomia and compensatory hyperplasia. Macrosomia affects the fetus and fetal part of placenta i.e. chorionic plate. The macrosomia may be attributed to fetal hyperinsulinemia in response to hyperglycemia in fetuses of diabetic mothers (21).

Thickness of the placenta depends upon the length of the villi (22). In present study, the thickness of placenta (length of stem villi) in all complicated subgroups was non significantly decreased when compared with control group.

Longitudinal growth of the capillaries within the mature intermediate villi exceeds that of the villi themselves so the capillaries coil and form loops that bulge from the villous surface, forming grape-like outgrowths known as terminal villi (23). The development of this low impedance capillary network parallels the proportional rise in fetal cardiac output entering umbilical arteries to about 40% at term (24). In our study, the number of terminal villi was significantly increased in all complicated subgroups and this means that the capillary growth exceeds the longitudinal villous growth in these groups which may occur secondary to an increase of fetal cardiac output entering umbilical arteries in these groups.

Apoptosis is initiated via the extrinsic or intrinsic pathway. Both pathways rely upon a cascade of protein interactions orchestrated by a family of 14 cysteine proteases, caspsases, which are able to cleave structural proteins producing the morphological appearances typical of apoptosis. In addition, active caspsases potentiate the apoptotic signal by activating a variety of pro-apoptotic proteins (25). The extrinsic pathway is controlled by members of the tumour necrosis factor (TNF) death receptor family (26). The intrinsic pathway is initiated by cellular stress; such as DNA damage, reactive oxygen species, the unfolded protein response,
or removal of growth factor support\textsuperscript{(27)}. In our study, the significant increase in apoptotic cells in P- and D- subgroups may be attributed to an exaggeration of extrinsic and/or intrinsic pathways.

Syncytial knots are consistently present, increasing with increasing gestational age, and can be used to evaluate villous maturity. Increased syncytial knots are associated with conditions of uteroplacental malperfusion and are important in placental examination\textsuperscript{(28)}. Therefore, the significant increase of syncytial knots in P- and D-subgroups was due to fetal malperfusion of placental villi.

It is well known that molecular composition of the basement membrane changes during maturation of villous trophoblastic and endothelial basement membranes, these changes are particularly obvious in area of trophoblast proliferation and villous sprouting\textsuperscript{(29)}. Due to increased incidence of apoptosis, large number of parenchymal cells (trophoblast, endothelial cells) has been observed to be eliminated and replaced by fibrous tissue\textsuperscript{(30)}. This fibrous tissue was synthesized by fibroblasts of villous stroma. Fibroblasts also take part in the synthesis of subtrophoblastic basement membrane\textsuperscript{(31)}. In this way, secondary to increase incidence of apoptosis in all complicated subgroups, large number of parenchymal cells (trophoblast, endothelial cells) had been replaced by fibrous tissue and this may play a role in increase thickness of basement membrane.

Placental angiogenesis can be subdivided regarding its mechanisms and the geometry of the resulting vascular bed\textsuperscript{(32,33,34)} into branching angiogenesis (multiple sprouting of micro vessels produces a complex multiply branched capillary web) and non-branching angiogenesis(Vascular bed expands by elongation of existing capillary loops). In this way, the significant decrease in number of fetal capillaries in P- subgroup may be due to non-branched angiogenesis which may become the only mode of angiogenesis which is suppressed by binding of PI GF to VEGFR-1. The significant increase of fetal capillaries in D-and P-D subgroups has occurred as branched angiogenesis may become the only mode of angiogenesis which may be stimulated by binding of VEGF-A to its receptors.

**Conclusions**

An adequate knowledge of the morphometric analysis of the placenta with its clinical relevance proves to be useful in the early assessment of placental sufficiency and also the state of the fetal wellbeing. In mothers who have had no previous antenatal checkup, a thorough examination of the placenta helps in the early diagnosis of the fetal complications, soon after parturition and thus helps in the early treatment of the baby by neonatologists.

Abstract

The descriptive-correlation study design used to investigate the relation between parenting styles and children’s behavior difficulties by using the Parenting Styles and Dimensions Questionnaire, and Strengths and Difficulties Questionnaire to achieve study objectives. An online questionnaire applied as a method of data collecting on 101 parents (majority of them mothers) and their 4-11 years old children, 58 of them were males and 43 were females. The finding of the current study reveals that the authoritative parenting style was used more than other styles and correlated significantly with good child behaviors while the authoritarian and permissive style used less and correlated negatively with child’s behaviors. In conclusion, when parents use an authoritative or democratic style enhances children’s positive behaviors more than other styles.

Keywords: Parenting styles, behavior’s problems, and behavior’s difficulties

Introduction

Parenting style characterizes as emotional relationship and the quality of parent-child interaction, and this interaction has great importance in the learning, development process, and behaviors of a child(1).

Diana Baumrind at the end of the 20th century categorized parents based on two dimensions; responsiveness and demandingness, and describe three different kinds of parenting styles: (authoritative, authoritarian, and permissive). Authoritative parents have a high level of responsiveness and demandingness to their children but being firm in setting rules and limits. They direct their children’s behaviors and attitudes by emphasizing the reason for rules and by negative reinforcement(2).

Authoritarian parents have low responsiveness and high demandingness for absolute obedience. They try to control their children’s behaviors and attitudes through unquestioned mandates. They establish rules and regulations or standards of conduct that they expect to be followed rigidly and unquestioningly(3).

The permissive parenting style is characterized by high responsiveness and low demandingness. They use little or no control over their children’s actions. They avoid imposing their standards of conduct and allow their children to regulate their activity as much as possible. These parents consider themselves to be resources for the children, not role models.

Many previous studies show that the children’s behaviors earned in the early years shape their personality structure, attitudes, beliefs, and value judgments of individuals. Children acquired most of these behaviors from their parents, which consider the first teacher(4).

The interaction between parents and children have a great effect on their social development and behaviors, and across the years and these interactions diminished because of many factors; one of them was the occupied parents with digital devices or technologies(5,6).

Parents may use one or more than one style or may change the parenting style as the child grow up. In other words, if the parents fall in choosing the proper parenting style or use inappropriate behaviors when dealing with their children this can affect children’s socialization. Therefore, knowing a child’s behaviors, characteristics, and temperament by their parents help them to use or adjust the appropriate parenting style(7).
The present study aimed to investigate child behavior difficulties and to find out the association between parenting style and children’s behavior difficulties.

**Method**

**Design & Setting of the study:** A descriptive correlational study design was used in this study throughout the period 1st of February 2020 to the 3rd of May 2020.

At the beginning of the outbreak of COVID-19 in Iraq, the government took many restrictive measures to decrease the spread of contagion one of them was a curfew; during the period of quarantine, the family members stay at home and avoid crowding to protect themselves from getting a disease (infection). Therefore the researchers used an online questionnaire as a method for data collection in this circumstance; the online questionnaire was answered in March of 2020 by 101 parents of children age (4-11 years old) live in the Babylon governorate. The questionnaire consisted of three parts:

1. Demographical characteristics of parents and their children 4-11 years old (child age, child gender, parent (father or mother), parents’ educational attainment, parents’ occupation, family income, and numbers of family members.

2. The Parenting Styles and Dimensions Questionnaire (PSDQ)\(^8\) was used to identify the preferable parenting style by Babylonian’s parents and it is extracted from (9). PSDQ consisting of 30 items (13 for authoritative style, 13 for authoritarian style, and 4 items for permissive style), each item rated on a scale of 1 (*never*) to 3 (*always*). All three categories of parenting style demonstrated good internal consistency (Cronbach’s alpha was reported 0.77 for authoritative, 0.78 for authoritarian, and 0.72 for permissive).

3. Strengths and Difficulties Questionnaire (SDQ)\(^10\). SDQ is a 25-items parent or teacher-form measure of children’s behaviors from 4-17 years old. This form is a 3-level Likert scale, scored as (0 = doesn’t apply, 1 = apply sometimes and 2 = certainly apply). Some items were reversed for the statistical purpose. The rate of the scale was based on the mean of items’ scores to (0 - 0.66) very poor behaviors, (0.67 - 1.33) poor behaviors, and (1.34 - 2) good behaviors. Good reliability and validity of the SDQ have been reported in a previous study\(^11\).

**Statistical Analysis:** Data was analyzed by using SPSS (statistical package for social sciences) version 20 to find out the associations between parenting styles and child behavior difficulties by use personal correlational coefficient and use the descriptive statistic for demographical variables and to identify the preferable parenting style.

*. Significant at (P<0.05), **. Significant at (P<0.01)

Bivariate (Pearson) correlates analysis was used to identify the association between a child’s behavior difficulties and type of parenting style. The finding showing a positive- significant correlation between children’s behaviors and the authoritative parenting style, which means when the parents use this style their child behaves in a good way. On the contrary, the other parenting style (authoritarian and permissive) showing a significant negative correlation with children’s behaviors. This means when these styles are always used by a parent the child exhibits poor or difficult behaviors.
Discussion and Conclusion

The aim of the current study was to find-out the association between experienced parenting styles and behavior difficulties in preschool and school-age children in the Babylon governorate. The current findings revealed that the Authoritative parenting style was preferred or used more than others. The authoritative or democratic parenting style was most commonly used by Babylonian’s parents and that may due to their benefit in improving the parent-child relationship and enhancing good communication and interaction between them, besides aiding in the proliferation of child’s creativity (1) as well as raising social responsibility and a sense of self-esteem of the child as the previous study has shown (12). Moreover, The result of the current study goes in line with the Jordanian study conducted by and Lo et al., (3) study.

The results in Table (3) showed a positive-significant correlation between children’s behaviors and authoritative parenting style while, the others parenting style (authoritarian and permissive) showing a significant negative correlation with children’s behaviors. This was parallel with (14) study and similar to the (15) study, which mentions that the family whose use authoritative style; their children demonstrate a lower level of problematic behavior, greater academic competence, and a higher level of psychosocial development than children who come from authoritarian, permissive and neglecting families. Furthermore, a parent that practicing authoritarian style was significantly associated with child abuse, and that lead to increase stress and affect negatively on family climate (16,17). In contrast with the parent who used authoritative style was associated with a lower risk of all types of child maltreatment (physical abuse, psychological abuse, and neglect) (3). In conclusion, the Babylonian parents practicing authoritative style more than other styles, and when they use the authoritative or democratic style enhance their children’s positive behaviors more than other styles.

Summary:

This study showed that the authoritative parenting style was used more than authoritarian and permissive styles by Babylonian parents and there is a significant correlation between authoritative parenting style and good child behaviors, while there is a significant correlation between authoritarian and permissive styles and negative child’s behaviors. This means when the parent uses authoritarian and permissive style the children exhibit behavior difficulties more than those children of a parent that use authoritative style.

Assessment of Children with Thumb Sucking Habit in Babylon City

Abdulmahdi A. Hasan
PhD, Ass.proof, Psychiatric & Mental Health Nursing Department, College of Nursing, Babylon University

Abstract

Aims: The purpose of this study is to assess the prevalence of thumb sucking habit between preschoolers and the effect on their occlusion of the habit.

Materials and Methods: 42 of pre-school children aged 4-5 years who were inspected by questioning for the presence or absence of thumb sucking habit, and thumb examination, and the teeth were examined for the presence of decreased over flight and overbite or open bite.

Results: Total number children have thumb sucking habit, and open bite of them.

Conclusion: In this age group (4-5) years, the number of children with thumb sucking habit was considered high and the habit was found to increase the prevalence of malocclusion of deciduous.

Keywords: Thumb, Children, Babylon, school.

Introduction

The incidence of malocclusion is greater in children with sucking habits than in children with no habit at the age of 3-12, but when children avoid sucking their fingers before the age of 6, they do not have a higher rate of malocclusion than children with no history of sucking habits(1,2).

1. Oral habits should be of paramount health interest to orthodontists because they can induce malocclusion and interfere with the advancement of therapy (4). Irregular oral habits work so silently and unintentionally that even the patient is often unaware of their presence. Originally, all these basic habits are performed by deliberate attention, with each occurrence being less and less conscious effort.

Sucking habit is the infant’s fist-coordinated muscle activity and is also considered a natural reflex. There are essentially two forms of sucking; the nutritional form that provides essential nutrients, while non-nutritional sucking provides a feeling of warmth and a sense of safety, and this type of sucking can be considered as an important first step in the child’s self-regulation development.

So that, babies suck to comfort themselves when they are upset, it’s also away for exploring and in some cases, sucking may be just away for babies to pass the time (9,10), but many children recognize that the habit is an infantile mechanism, they find it difficult to leave because it becomes an enjoyable habit by the time (11). Besides, they may use it to get their parents’ attention (12,13).

The sucking habit period is important, a short period of time may have no or little effect (13,14). In some children, the sucking habit is little or more than a passive insertion of the finger into the mouth, with no apparent buccinators activity (14,15), so that children who suck vigorously but intermittently may not displace the incisors much, if at all, while others who produce 6 hours or more may not displace them.

Literature Review

A review of the literature on thumb sucking habit prevalence shows that this varies from one population to another. The aim of this research was: 1) to evaluate the prevalence of sucking habits among Iraqi pre-school
children living in Babylon City; 2) to assess the impact of certain cultural factors on that prevalence; and 3) to study the effect that these habits could have on primary dentition. Cross-sectional

Study was conducted using a survey questionnaire and clinical examination of 42 Iraqi children aged 3-5 using a stratified random sampling technique for clusters. The prevalence of sucking habits with the dummy-sucking being the dominant type was 48.36 per cent. In the first few years of life most dummy suckers had lost their habits while more digit-suckers were still present at age 5. Sucking behaviors were related only to the schooling of the parents and the methods of feeding the infant without any major influence of gender or birth rank or family income. Kids with current digit sucking habits had slightly more distal molar and canine relationships of Class II (P < 0.05), greater over jet, and wider bite than kids without sucking habits.

Such variations became also more important (P < 0.01) when compared dummy-suckers to non-suckers. A more flexible snap was the only observable consequence of past sucking habits. In children with sucking habits the posterior cross bite was no more common than in children without these habits. The concern regarding sucking habits is evident from the number of articles that have appeared in scientific journals over the past 50 years.

Methodology

The sample of this study was consisted of 50 preschool children from districts in Babylon city, with age range of 4-5, the selection of this age group is to reveal the prevalence and effect of thumb sucking habit before the time of eruption of permanent teeth. The children were divided into two groups, first group consisting children with thumb sucking habit and the second consisting children without thumb sucking habit. the children were examined for the presence of thumb sucking habit ;the sucked digit often reveal callous formation and under development (16) in addition to that a history is taken from the teaching staff about the presence of the habit for all children to confirm the clinical findings, the overjet was measured by avernia by measuring the distance between the labial surface of lower central incisors and labial surface of upper central incisors ,while the overbite is measured by considering the amount of vertical coverage of the upper central incisors to the lower central incisors.

Table(1) Show that the (42) examined children (15)of them have thumb sucking habit (9%) of the total

Discussion and Conclusion

Prevalence of thumb sucking habit in preschool children and its effect on deciduous teeth was not adequately dealt with in researches; on the other hand, it may be much easier to manage the habit at early stages than to leave it to become more enjoyable behavior to the child, so that data of prevalence and effect of T.S.H. during this stage of child’s life is beneficial to know how much efforts are needed to assist children to leave the habit at early stages. This study found that the percent
of preschool children having T.S.H. is 9% which is not angelic table percent because part of them may retain the habit causing malocclusion of the permanent teeth. This study also made accompanist of dental occlusion between children with and without T.S.H.

It was found that the percent of children having increased over jet is higher in the group having T.S.H. which may be due to proclanation of maxillary incisors and retroclination of mandibular incisors; and the overbite in the group having T.S.H. is higher which may be due to over eruption of upper incisors due to the increase in the over jet, and the percent of children with open bite in the group with T.S.H. is higher which may be due to a combination of interference with normal eruption of incisors, and excess eruption of posterior teeth, these findings agree with the findings obt the differences between the two groups in all types of changes in occlusion (overjet; overbite) are statistically non-significant which may be due to the small percent of children with increased overjet, overbite and open bite in the control group due to causes other than T.S.H, like; class 2 malocclusion, mouth breathing, tongue thrusting.

It can be concluded that thumb sucking habit effect the deciduous teeth by increasing over jet, overbite and prevalence of open bite; these effects may arise in permanent teeth if the habit was retained, and the percent of children having the habit of thumb sucking at this age range is still considered to be high, so it is suggested that parents should be instructed to consult psychiatrist and orthodontist if the child still having the habit at this age, to stop the habit as soon as possible.

Stakeholders’ Perspectives on Quality of Death Registration
And Possibility of Introducing Verbal Autopsy Into Kurdistan Region of Iraq

Ahmed Mohammed Amin Ahmed1, Tariq Salman Al-Hadithi2

1Assist. Lecturer, 2Prof., Department of Community Medicine, College of Medicine, Hawler Medical University, Erbil – Iraq

Abstract

Aim: To explore stakeholders’ perspectives on the quality of death registration and possibility of introducing verbal autopsy into the Kurdistan Region, Iraq.

Methods: Qualitative interviews conducted with 15 stakeholders from the Ministry of Health, Directorates of Health, and Medico-legal Institutes of Erbil, Sulaymaniyah, and Duhok of the Kurdistan Region of Iraq. Stakeholders were selected through the purposeful sampling method. Responses were analyzed using qualitative content analysis and thematic analysis. Responses were categorized into three main categories: strengths, gaps, and suggestions for improving the death registration in the Kurdistan Region.

Results: The strong points in favor of the current death registration were: easy and good practice, it was easy for people to get a certificate, the existence of laws and regulations related to death registration, having a “standard death certificate,” and follow-up and monitoring of the process of death registration at the Medico-legal Institutes. The gaps were incompleteness and inaccuracy in most of the locations, staff ignorance, no checking of data, missing cases, no use of the data, and no standardized process for compiling data.

The stakeholders emphasized on implementing the existing rules and regulations, building staff capacity, systematic processes for data management, and follow-up and monitoring as strategies for improvement.

All the stakeholders reported that verbal autopsy is appropriate for solving problems related to cause-of-death data. However, the feasibility of verbal autopsy will be a challenge for several reasons, including the current economic crisis.

Keywords: Death registration, Kurdistan Region of Iraq, verbal autopsy.

Introduction

Death registration is a key element for health system planning, evaluating the effectiveness of health services, and epidemiological studies. However, inaccuracies in death registrations are a global problem and many reports on death statistics from countries to the World Health Organization (WHO) have incomplete or inaccurate death registrations. Even in developing countries, a significant proportion of deaths occur without medical information on the cause of death. In order to support policy development, death registration should have all detailed records of the decedents’ ages, sex, and correct causes of death. Death registration in the Kurdistan Region of Iraq is produced through three ways:

• Death that occurs in hospitals: the attending senior physician specifies the cause of death and the
registrar issues a “death certificate.”

- Death from natural causes that occurs at home: the relatives of the deceased person report to the court and get a “legal death certificate” that has no information on the cause of death.

- Death from unnatural causes, e.g., due to accidents: the medico-legal institutes investigate the cause of death and issue a death certificate.

The system for death registration in Iraq is based on records from hospitals and is mainly administrated manually. The study of Zangana et al. in the Kurdistan Region revealed inaccuracies in the cause of death at registration and limited use of death certificates. They added that there was an urgent need for educational efforts to achieve a complete and accurate death registration.

Method

Setting

This study was carried out from July 2017 through May 2018 in three governorates of the Kurdistan Region of Iraq: Erbil, Sulaymaniyah, and Dohok. The study participants were from all the sites that deal with death registration in order to obtain the perspectives from all the jurisdiction levels namely the Ministry of Health (MoH), the Directorates of Health (DoH) and the Medico-legal Institutes (MLI) of all three governorates of Kurdistan region of Iraq. A total 15 stakeholders were interviewed; two were from the MoH (13.3%), seven were from the DoH (46.6%) and six were from the MLI (40%). Participants included males and females. The participants were selected, via the purposeful sampling method, because of their knowledge and familiarity with death registration.

Instruments

The researchers developed a set of semi-structured qualitative interview guides that consisted of open-ended questions with specific follow-up probes. The qualitative data collection tool was in Kurdish language and then translated into English language with adjustments to phrasing.

The qualitative interview explored the participants’ perspectives about the current death registration practice, particularly regarding its strengths and gaps in effectiveness and suggestions for improvement. Moreover, specific thoughts were explored regarding the feasibility and appropriateness of introducing verbal autopsies into the current practice.

Data collection procedures

The interview process was conducted by the main researcher. The interviewer contacted each potential participant by phone to introduce the study and arrange an in-person interview, which could be completed in one or multiple sessions, based on the respondent’s preference. Informed consent was obtained for all participants at the first in-person meeting prior to any data collection. All interviews were conducted in the Kurdish language except one, which was done in Arabic, and all interviews were tape recorded in full. Audio recordings were transcribed and translated into English. The translation was subsequently reviewed and verified by another native Kurdish speaker who was fluent in English.

Analysis

Qualitative data analysis was conducted in two phases. The initial phase was reading the English transcriptions thoroughly and extracting key response points from each participant, which produced a table of responses for each question at each stakeholder level. The researchers then consolidated each table by combining responses that had the same meaning and listing the number of respondents who gave each response, producing a summary table of responses that was sorted by frequency for each question at each stakeholder level.

The second phase of analysis involved the summary tables and coded responses. Each set of relevant responses was combined across all the question tables, resulting in three consolidated lists (strengths, gaps, and suggestions) per stakeholder level. Within each list, the responses were then sorted and grouped according to emergent themes. Responses that appeared to address multiple themes were placed within both themes.

Results

The findings of this study are segregated into three main categories: strengths, gaps, and suggestions for
improving the current death registration practices. The most frequently mentioned strength was easy practice and easy for people to get certificate. Based on the perceptions of all the MoH respondents, the current practice can be done easily by staff, but none of the MLI stakeholders saw it as simple. Regarding the stakeholders’ perception of how people who don’t work with death registrations see the death registration system, 87% of all stakeholders indicated that people see it as easy since “they can get death certificate easily.” Half of the MLI respondents consider it a good practice, but neither the MoH nor the DoH respondents agreed with that assessment.

Only 40% of the overall stakeholders (100% of the MoH respondents) agreed that the existence of the laws and regulations related to death registration is strength of the current practices. Having a “standard death certificate” was raised as a strength point by the stakeholders. Follow-up and monitoring of the process of death registration is vigorous at the MLI (100%), whereas none of the other stakeholders considered this a serious task. Regarding training on the International Statistical Classification of Diseases and Related Health Problems (ICD) codes and employing them, MoH stakeholders reported that some staff had been trained, but they hadn’t confirmed if they were employing it: “some staff from statistic departments of some PHCs have being trained on ICD-10 simplified codes... and it seems that they are using them.” However, the MLI stakeholders indicated that they were not using the ICD – 10 and were not trained on the system. Although the MoH stakeholders stated that the practice is simple and good, the accuracy of death registration process was only confirmed by the MLI; both the MoH and DoH stakeholders indicated that the practice is not accurate.

The gaps that were mentioned by the stakeholders were: 73% of all stakeholders raised concerns about the incompleteness of the data; this was markedly higher among the MoH and DoH stakeholders than those at the MLI. Staff ignorance was reported as a prominent cause of the current gap across all stakeholders. Overall, 53% of the participants (with 100% MoH) shared concerns about accuracy and reported that the death registration is not accurate in most of the locations. MLI stakeholders recognized the shortage of health system as a gap, whereas the MoH stakeholders didn’t mention this. Only 40% of the stakeholders identified problems related to the ICD system as a gap. Other gaps identified across stakeholders were no checking of data, missing cases, no use of data, no standardized process of compiling data, and problems with storing data.

Discussion

Many factors affect the completeness and quality of death registration. Staff experience, familiarity with the deceased person, time allocation for the death registration process, and the perception of the importance of death certificate are among the main factors that affect the completeness and accuracy of the death registration. The United Nations Statistics Division highlighted some activities, among many, that proved useful for countries to improve their death registration systems; these included engaging political people in improving civil registration, periodic training of staff, continuous performance monitoring, and maximal use of information technologies related to the systems.

The present study found that there are rules and regulations in the Kurdistan Region for dealing with death registration, but they are not practiced. This is similar to what was found in some Pacific island countries as there is legislation regarding death registration and the weakness is that there is inadequate implementation of such legislation. On the other end, Mathers et al. found that many countries do not appreciate the value of data for public health development and hence they don’t have sufficient procedures and regulations to ensure that death registration processes are done correctly.

One of the similarities among Kurdistan and Pacific island countries is the compilation of death data by various health settings and the usage of standard international medical death certificates, which was identified as a strength factor. There are also similarities in their weaknesses, such as lack of cause of death data for deaths outside health facilities, limited statistical analysis of the registered data, and insufficient quality assessment and control.

The practice of completing a death certificate in Kurdistan is that senior doctors are responsible for assigning the cause of death to their patients, even if they are not at the hospital when their patients die. This is recommended by Bobbie et al. as of the familiarity
of physicians with their patients. They also addressed inexperience, fatigue, time factors, and the perceived lack of importance of the death certificate as factors that affect the accuracy and completeness of death registration, which were similar to what the stakeholders highlighted in the present study.

The suggestions from the stakeholders were similar to those raised by Rao et al. for African countries. These included addressing training needs, quality control, and examining the feasibility of innovative methods, such as verbal autopsy. Including training on how to accurately identify the cause of death in continuing professional development and in medical teaching curricula as well as the training of administrative personnel were previously highlighted as essential strategies in death registration system: these were also emphasized by the stakeholders in this study. A study conducted in Spain by Villar et al. revealed that an educational session can raise the accuracy rate of mortality data by more than three-fold. The stakeholders highlighted the importance of training on ICD codes and this was also raised by Rao et al.

The perspectives of stakeholders related to hiring more staff and conducting training on new systems for improving the completeness and efficiency of death registration in the present study coincides with similar studies conducted in Jordan and Vietnam. Those studies include suggestions like increasing the number of staff and training physicians and other staff who deal with death registration. The importance of training was raised by others as skilled personnel have a critical role in death registration and training provides the knowledge and skills needed for efficient work and hence a better understanding of what is expected and fewer errors.

Conclusion

This study pointed out the stakeholders’ perspectives regarding death registration in the Kurdistan Region of Iraq. They highlighted the existence of rules and regulations and using the standard death certificate format as strength points, among some others, for the current practices. They also mentioned the gaps of the current death registration, including incomplete and inaccurate data, no systematic process of compiling data, no use of data, and staff ignorance. The main suggestions from stakeholders for improving the death registration were emphasizing and implementing the existing rules and regulations, conducting capacity building for doctors and those who deal with death registration, instituting systematic processes for data management, and follow-up and monitoring.

The Effect of Ultrasonic Activation of Two Different Sealers on the Fracture Resistance of Obturated Root Canals

Hussain Khaleel Mohammed¹, Manal Hussain Abd-alla²

¹M.Sc. Student. (Department of Conservative, College of Dentistry/ Mustansiriyah University. Baghdad-Iraq,
²Ass. Prof. (Department of Conservative, College of Dentistry/ Mustansiriyah University. Baghdad-Iraq

Abstract

The aim of the current study is to evaluate the effect of ultrasonic activation of two sealers: EndoSequence BC and AH Plus on the fracture resistance of obturated roots.

Materials and Method: Forty eight mandibular first premolars were decoronated to a length of 13 mm from the apex. The roots were divided into two groups (24 samples) to be obturated with gutta percha using either EndoSequence BC(Group I) or AH Plus (Group II) sealers. Each group was further subdivided into two subgroups (n=12). Subgroups IA and IIA were obturated without ultrasonic activation of the sealers. Subgroups IB and IIB were obturated with ultrasonic activation of the sealers. The activation of the sealers was performed using size 15 ultrasonic K-file for a total of 20 seconds 2 mm short of the working length. The samples were subjected to fracture resistance test using a universal testing machine at a across head speed of 0.5 mm/min. The data were analyzed using One way ANOVA and Tukey tests at a significant level of 0.05.

Results: The fracture resistance mean values of the EndoSequence BC subgroups with and without activation were significantly higher than those of AH Plus sealer (P<0.05).

Conclusion: The ultrasonic activation of both sealers did not enhance the fracture resistance of obturated roots.

Keywords: Bioceramic, Epoxy resin based sealer, Ultrasonic.

Introduction

During endodontic therapy, the tooth structure can be compromised increasing the possibility of root fracture due to: removal of supporting tooth structure by access opening and instrumentation, pressure during obturation and dehydration of dentin.¹² The standard obturation material that has been used for years in root canal therapy is gutta percha. However, one of the disadvantages of gutta percha as a filling material is that it does not bond or adhere to the dentinal walls of the root canal resulting in an incomplete sealing of the canal space. It has been shown that the use of sealers with an ability to bond to the root canal dentin will strengthen the remaining tooth structure, thus increasing the root resistance to fracture.³⁴ Nowadays, numerous sealers have been introduced into the market that are supposed to adhere to the root canal dentin such as: methacrylate resin-based sealers, epoxy resin-based sealers, mineral trioxide aggregate (MTA) based sealer and calcium silicate-based sealer. The adhesion and the mechanical interlocking of the sealer can strengthen the remaining tooth structure.⁴ Bolles et al., in 2013⁵ and Macedo et al., in 2014⁶ stated that the use of ultrasonic activation to the endodontic sealers during obturation can increase sealer pressure against the root canal walls allowing better penetration into accessory canals, isthmus, and dentinal tubules, with formation of a greater number, density and extension of tags.⁷⁸ Thus, increasing the adhesion and mechanical interlocking of the filling material.⁹,¹⁰

Endosequence BC sealer is a calcium silicate-based endodontic sealer, with a self-adhesive nature. It has nano-particles permit it to flow readily into the canal’s irregularities and dentinal tubules. In addition, no shrinkage occurs on setting, resulting in a gap-free
interface between the gutta-percha, sealer and dentin.\textsuperscript{11} AH Plus sealer, on the other hand, is an epoxy resin-based sealer characterized by very good mechanical properties, easy handling, potential for better wettability of the dentin and gutta-percha surfaces and self-adhesive property.\textsuperscript{12}

Topcuoglu et al., in 2013\textsuperscript{13} and Yendrembam et al., in 2019\textsuperscript{14} evaluated the fracture resistance of teeth filled with AH Plus and Endosequence bioceramic root canal sealers in vitro. They concluded that both sealers were capable of increasing the force to fracture in single-rooted endodontically treated premolars. Guimarães et al., in 2014\textsuperscript{7}; Wiesse et al., in 2018\textsuperscript{8} and Sachin et al., 2018\textsuperscript{15} evaluated the influence of ultrasonic vibrations on the penetration depth of both sealers using confocal microscopy. They concluded that the ultrasonic activation was linked with higher bond strength values, greater intratubular penetration and better interfacial adaptation to root dentin and less existence of gaps and voids than no activation technique. However, the effect of ultrasonic activation to Endosequence BC and AH Plus sealers on fracture resistance of obturated roots has not been cleared yet. Therefore, this study was conducted to evaluate the effect of ultrasonic activation of Endosequence BC and AH Plus sealers in the assessment of fracture resistance of endodontically treated roots.

**Materials and Methods**

Freshly extracted forty eight single rooted mandibular first premolars were collected after extraction for orthodontic reason from patients with age ranged from (20-30) years old.\textsuperscript{16} The teeth were cleaned from calculus and tissues manually using cumine.\textsuperscript{17} Then, the teeth were stored at room temperature in 0.1 % thymol solution for 48 hs to prevent dehydration and bacterial growth. The teeth were decoronated at a length of 13 mm from the anatomical apex for standardization and to achieve a stable reference during working length determination and instrumentation. The working length was established to be 1 placing a K-file size 10 (Dentsply, Switzerland) into the canal until observing it at the apical foramen.\textsuperscript{13}

For root canal instrumentation, the canals were first irrigated with 1 ml of 2.5 % NaOCl for 1 minute. Then, K-file size 15 was introduced to the full working length to obtain a reproducible glide path. The canals were instrumented using ProTaper Next system (Dentsply Maillefer Endodontics, Switzerland) by the following sequence: X1(17/0.04), X2(25/0.06), X3 (30/0.07) and X4 (40/0.06). For standardization, each canal was irrigated with a total amount of 5 ml of 2.5% NaOCl. Then, a 3 ml of EDTA 17% was applied for 1 minute, then a final irrigation was applied with 10 ml of distilled water.\textsuperscript{13,19} Each canal was dried with two paper points size 40/0.06.\textsuperscript{20}

The roots were randomly divided into two groups (n=24) according to the types of root canal sealers: EndoSequence BC Sealer (Group I) and AH Plus sealer (Group II). Each group was subdivided into two subgroups (n=12): Group IA and Group II A were obturated without sealer activation and Group I B and Group II B were obturated with sealer activation.

For Group IA, a master guttapercha cone X4 (40/0.06) (Dentsply Maillefer) was inserted into the canal to full working length (12 mm) with a good tug-back. EndoSequence BC Sealer was introduced into the root canal by its intracanal tip. The tip was placed into the coronal one third of the canal and the sealer was released while slowly withdrawing the tip from the canal.\textsuperscript{13} Then, the master cone was reinserted and the excess of guttapercha was cut off with a guttapercha cutter at the level of canal orifice.\textsuperscript{20}

For Group IB, the samples were treated as in Group IA except that after the application of the sealer, activation of the sealer was performed using an ultrasonic K-file size 15 in a piezoelectric ultrasonic handpiece (SatelecActeon) at 6 mode power.\textsuperscript{15} Then, the file was activated 2 mm short of the working length, with 2-3 mm back and forth movements in a bucco-lingual and in a mesio-distal direction of the root canal for a total of 20 seconds.\textsuperscript{15}

For Group IIA, the roots were obturated in a similar way using AH plus sealer which was manipulated according to the manufacturer’s instructions. The two pastes were mixed to get a homogenous creamy consistency and the master cone was coated with the sealer and slowly inserted into the canal until the working length was reached.\textsuperscript{14,22} According to the manufacturer instructions, the canal walls were coated with AH Plus sealer through a simultaneously rotating movement of
the master cone in a counter clockwise direction four times per a canal. The excess of gutta-percha was cut off with a gutta-percha cutter at the level of canal orifice.20

For Group IIB, the samples were obturated with ultrasonic activation of AH Plus sealer which was performed in a similar way as in Group IB using the ultrasonic handpiece.

After obturation of the roots of each group, the samples were radiographed to ensure the quality of obturation.13 The samples were stored in an incubator for 1 week at 37°C and 100% relative humidity to permit fully set of the sealers.20 All the procedure was performed by one operator for standardization.

In order to assess the fracture resistance test, the roots were fixed in a cylindrical acrylic block (20 mm height and 20 mm diameter) using a cold-cured acrylic resin to simulate the alveolar bone. While a periodontal ligament simulation was performed by coating the root surface with a thin layer of light-body addition silicon. Then, the roots were embedded into the acrylic resin exposing 2 mm of the coronal parts of the roots.14,20 Fracture resistance test was performed for all roots using an Instron testing machine. A spreader-like metal tip (0.8 mm in diameter) was positioned at the center of each canal orifice and a vertical force was exerted at a across head speed of 0.5 mm/min until fracture.20 The fracture force was recorded in Newton.20

All of the analyses were performed using SPSS 21 software (IBM-SPSS Inc., Chicago, IL, USA). One-way analysis of variance (ANOVA) and post hoc Tukey tests were used to determine the significance difference between the subgroups at P<0.05.

Results

The results of the descriptive statistics are shown in Figure 1. One way ANOVA test showed that there was a significant difference between EndoSequence BC sealer and AH Plus sealer with and without activation (P=0.000). However, the results of Tukey’s test for multiple comparisons between the groups (Table 1) showed non-significant differences neither between the subgroups of EndoSequence BC Sealer (Group IA & Group IB), nor between the subgroups of AH Plus sealer (Group IIA &Group IIB) as P > 0.05.

Figure 1. Bar chart graph representing the mean fracture resistance (N) of all subgroups.

**Discussion**

It has been reported that during root canal treatment, there will be a reduction in the fracture resistance of the root which consequently leads to tooth extraction.\(^{23,24}\) Hence, one of the essential features of any root canal filling material is their capability to reinforce and significantly strengthen the endodontically treated roots. Recently, researchers illustrated that the adhesion and the mechanical interlocking of the sealers can strengthen the remaining tooth structure, increasing its resistance.
to fracture.4

In this study, the effect of ultrasonic activation of two dentin bonding capable sealers (EndoSequence BC sealer and AH Plus sealer) on the fracture resistance of obturated root canals was evaluated. The results showed that the mean values of fracture resistance of both subgroups of EndoSequence BC sealer with and without activation were significantly higher than AH Plus sealer subgroups. Significantly higher fracture resistance for bioceramic sealers vs AH Plus sealer were also reported by recent studies using Totall fill biocermic sealer.25,26 Two other studies reported similar results using Endosquence bioceramic sealer.14,27 Reasons for such a result were related to the deeper penetration of the nanoparticles of EndoSequence BC sealer into the dentinal tubules and canal irregularities. EndoSequence BC sealer has a nanoparticle size of an average of 0.2 µm, which could increase the distribution of particles into dentinal tubules particularly within the apical root area.28 AH Plus sealer, on the other hand, and according to the manufacturer, contains calcium tungstate particles with an average size of 8 µm and zirconium oxide particles with a 1.5 µm size. The larger particles could not enter easily into the small tubules and the sealer tags would be weaker than those of bioceramic sealer.20 Additionally, Yendrembam et al., in 201914 showed that EndoSequence BC sealer has a higher adhesiveness to the root dentin than AH Plus sealer. EndoSequence BC sealer create a chemical and micromechanical bonding with dentin by means of the production of hydroxyapatite during setting, in contrast to a limited adhesion of AH Plus sealer to dentin from a mild covalent bond between its open epoxide ring and the amino group in the collagen fiber.29,30 Oltra et al., in 201731 reported that EndoSequence BC sealer had a significantly more residual filling material than AH Plus sealer after removal of the sealers indicating higher interlocking of EndoSequence BC sealer. Another possible reason could be related to polymerization shrinkage of AH Plus sealer associated with the use of large amounts of sealer in the canal when used with a single cone technique.32,33 In contrast, the EndoSequence BC sealer is a hydrophilic in nature and has no shrinkage11,34 and it expands 0.2% on setting producing a self-seal. This expansion together with the chemical and micromechanical bonding could improve the bonding of the root canal sealer to the canal walls.35,36

Topçuoğlu et al., in 201313 reported a higher, however, not significantly different fracture resistance mean value of EndoSequence BC sealer compared with AH Plus sealer. Such a difference could be related to the differences in methodologies. In this study, a spreader-like of 0.8 mm diameter metal tip with a vertical force in 0° angle, resulting in splitting stress exerted along the long axis of the root. Additionally, the roots had only 2 mm exposed above the acrylic block. This resulted in smaller stresses because of decreased bending movements and maximum stresses situated more cervically.20,37

It has been reported by many studies that the activation of endodontic sealers might improve root canal sealing, predominantly in areas of difficult access for example lateral and accessory canals, isthmus, recesses, and apical deltas.7,8 Numerous studies illustrated that the use of ultrasonic activation of these sealers cause greater dentinal sealer penetration and less presence of gaps, and increasing the adherence to the root dentin.7,8,15,21 However, the result of this study showed that the ultrasonic activation to both sealers produced no significant effect on the fracture resistance of obturated roots. This could be explained primarily as higher penetration can be different in different levels of the root. Better penetration due to sealer activation can be seen for both sealers in the apical more constricted areas than the coronal area.7,8 Therefore, further investigations and studies are still needed to verify the effect of sealer activations on its adhesion to root dentin at different root levels.

Conclusions

Under the circumstances of this study, the following conclusions are withdrawn:

1. EndoSequence BC sealer group showed a significantly higher fracture resistance than AH Plus sealer group with and without activation.

2. Ultrasonic activation of both EndoSequence BC and AH Plus sealers produced no significant influence on the fracture resistance of obturated roots.

Hepato-nephroprotective Role of *Lepidium sativum* against Oxidative Stress Induced by Dexamethasone in Rats

Sawsan Agbashee Abraheem Alsadee  
*Assistant Lecturer, Misan University, Department of Basic Sciences, College of Nursing*

**Abstract**

The current research was prepared to explore the hepato-nephroprotective effect of *Lepidium sativum* seed aquatic extract against oxidative stress stimulated by dexamethasone in rats. Animals were classified as follows; group one was used as control while groups 2, 3 and 4 were treated orally with *Lepidium sativum* seed extract (LSSE; 20 mg/kg, daily), interperitoneally with dexamethasone (DEX; 1 mg/kg BW) and LSSE plus DEX for 14 days, respectively. Administration of DEX elevated thiobarbituric acid reactive substances (TBARS), hydrogen peroxide (H$_2$O$_2$), and kidney and liver function biomarkers level, and lactate dehydrogenase activity. While enzymatic (SOD, CAT, GPx, GR, GST) and non-enzymatic (GSH) antioxidants, protein content, and alkaline phosphatase activity were significantly decreased. Otherwise, rats supplemented with LSSE singly declined lipid peroxidation and improved most of the studied parameters. Moreover, rats pretreated with LSSE then received DEX showed significant alleviation in lipid peroxidation, antioxidant status and biochemical indices with respect to DEX treated group. Conclusively, LSSE has beneficial protective effects and has the capability to counteract the harmful influence of DEX. So, *Lepidium sativum* might represent a novel approach in the therapy of dexamethasone because of its antioxidant properties.

**Keywords:** Dexamethasone; *Lepidium sativum*; oxidative stress; antioxidant enzymes; liver and kidney dysfunction.

**Introduction**

Glucocorticoids (GCs), the primary stress hormones secreted by adrenal glands, are essential for life. Several synthetic glucocorticoids such as dexamethasone, prednisone, and betamethasone are more potent than natural cortisol. They are involved in the treatment of disturbances induced by an overactive immune system as allergies, asthma, autoimmune diseases and sepsis. Additionally, GCs are involved in several diseases including obesity, metabolic syndrome, hypertension, and depression. GCs have several side effects including the activation of the mineralocorticoid receptors leading to the growth of renal injury. However, dexamethasone that given in vivo can also induce albuminuria and promote also renal injury. Furthermore, high GCs concentrations result in overproduction of reactive oxygen species (ROS) leading to alteration in mitochondrial permeability, cellular energy and calcium levels followed by apoptosis. The over production of ROS in dexamethasone therapy is predominantly due to increased NADPH oxidase activity. Previous study showed that dexamethasone treatment prompted gluconeogenesis, increased insulin resistance in addition to lipid disturbances. Reactive oxygen species are ordinarily created in a regulated manner in human and animals. Nevertheless, xenobiotics can provoke oxidative stress and consequently hurt the cellular macromolecules. Essentially, the cellular defense mechanism versus ROS toxicity involved non-enzymatic (glutathione (GSH), vitamin E, ascorbic acid, β-carotene, and uric acid) and enzymatic antioxidants (superoxide dismutase, catalase, selenium-dependent glutathione peroxidase, selenium-independent glutathione peroxidase, alkyl hydroperoxide reductase, glutathione S-transferase and glutathione reductase).

Great interest is directed to many plants because of their antioxidant and anti-inflammatory potential, among them *Lepidium sativum* Linn which belongs to...
Cruciferae family. *Lepidium sativum* is known as “El-Rshad” is an edible herb with aroma flavor. In traditional medicine, different parts of this plant have been adopted for several diseases therapy (jaundice, liver problems, spleen diseases, gastrointestinal disorders, menstrual problems, arthritis, asthma, headache, nasal polyps, breast cancer, and other inflammatory conditions)\(^8,9\). *Lepidium sativum* seeds essential oils contains fatty oils, protein, carbohydrate, vitamins, fatty acids, flavonoids, and isothiocynates glycoside\(^10\). Interestingly, experimental evidences showed that *Lepidium sativum* has multiple useful properties as antihypertensive, diuretic\(^38\), anti-asthmatic\(^37\), hypoglycaemic, antioxidant\(^10\) and anti-inflammatory\(^39\). Therefore, the existent study was prepared to evaluate the hepato-renal protective effect of *Lepidium sativum* seed aqueous extract against oxidative stress and biochemical perturbations induced by dexamethasone in rats.

### Materials and Methods

#### Materials

*Lepidium sativum* seeds (LSS) were collected from local market of Baghdad, Iraq and stored in air tight containers. Dexamethasone phosphate (DEX ≥ 98%), was bought from Sigma Chemical Company. All other chemicals were of analytical grade.

**Lepidium sativum seed extract preparation**

*Lepidium sativum* seed aqueous extract was prepared by boiling 1 g of dry seeds powder in 100 ml of distilled water for 10 min and left for 15 min to soak then chilled and filtered. The obtained filtrate was lyophilized and the required dose was prepared and reconstituted in 10 ml of distilled water per kilogram bodyweight prior oral administration directly.

**Experimental design**

Twenty-eight male Wister rats (150–170 g) were bought from the Faculty of Medicine, Alexandria University, Alexandria, Egypt. The protocol was approved by the local University Committee in conformity with the ethics and guidelines of the National Institutes of Health. Rats were distributed in cages seven per each and kept on commercial diet and water *ad libitum* and acclimated (temperature, 21°C; photoperiod, 7 a.m. to 7 p.m.) for two weeks. Animals were classified into four groups: group 1 used as the control, while group 2 was treated orally with *Lepidium sativum* seed aqueous extract (LSSE; 20 mg/kg), group 3 was injected interperitoneally with dexamethasone (DEX; 1 mg/Kg) dissolved in saline and the fourth group received LSSE one hour before DEX treatment, respectively. *Lepidium sativum* and dexamethasone were administered daily for 14 days according to\(^19\). At the experiment termination, rats were anesthetized using isoflurane, and then killed via cervical dislocation and livers and kidneys were immediately removed.

#### Blood and tissue samples

Blood samples were assembled for serum preparation and permitted to stand for 30 min for blood clotting at 25°C then centrifuged at 3000 ×g for 15 min. Serum of each sample was taken and stored at −20°C till utilized in the determination of biochemical parameters. Livers and kidneys were taken away and homogenized in ice-cold 0.01 mol/l sodium-potassium phosphate with 1.15% KCl buffer (pH 7.4) and centrifuged at 10,000 g (4°C) for 20 min then the supernatants were taken and utilized for the determination of different assays.

**Determination of TBARS, H\(_2\)O\(_2\) and glutathione content**

Thiobarbituric acid-reactive substances (TBARS), hydrogen peroxide (H\(_2\)O\(_2\)), and reduced glutathione (GSH) content were measured in liver and kidney homogenates using the methods of Ohkawa et al. (1979), Velikova et al. (2000), and Ellman (1959), respectively.

**Determination of antioxidant enzyme activities**

The activities of superoxide dismutase (SOD; EC 1.15.1.1), catalase (CAT; EC 1.11.1.6) and glutathione S-transferase (GST; EC 2.5.1.18) were assessed by the methods of Misra and Fridovich (1972), Aebi (1984) and Habig et al. (1974), respectively. While the activities of glutathione peroxidase (GPx; EC 1.11.1.9) and glutathione reductase (GR; EC 1.6.4.2) were evaluated according to Hafeman et al. (1974).

**Determination of biochemical parameters**

Alanine aminotransferase (ALT; EC 2.6.1.2) and aspartate aminotransferase (AST; EC 2.6.1.1) activities were assayed using kits from SENTINEL CH.
Lactate dehydrogenase (LDH; EC 1.1.1.27) and alkaline phosphatase (ALP; EC 3.1.3.1) activities, protein content, and total bilirubin were estimated by the methods of Cabaud and Wroblewski (1958), Principato et al. (1985), Bradford (1976) and Walters and Gerade (1970), respectively. Urea and creatinine concentrations were measured according to Patton and Crouch (1977) and Henry et al., (1974), respectively.

**Statistical analysis**

Data from different groups were represented as means ± standard errors (SEM) then analyzed utilizing SPSS software (version 22, IBM Co., Armonk, NY). Comparison between groups was done through one-way ANOVA followed by Tukey’s post-hoc test. P value ≤ 0.05 was approved to be significant.

**Results**

**General health**

None of the dexamethasone treated rats showed signs of morbidity or mortality during the study.

**Lipid peroxidation and reduced glutathione**

The present results revealed significant (P< 0.05) increase in TBARS and H$_2$O$_2$ levels, the indicators of lipid peroxidation, in liver and kidney homogenate after DEX treatment versus control while rats pretreated with LSSE then treated with DEX presented a significant reduction in TBARS and H$_2$O$_2$ levels as compared to DEX- treated rats. On the other hand, GSH content was significantly decreased in DEX -treated rats. While rats treated with both LSSE and DEX, induction in GSH content was observed as compared with DEX- treated rats. Supplementation with LSSE alone reduced the concentrations of TBARS and H$_2$O$_2$ and induced GSH content in liver (Table 1) and kidney (Figure 1) homogenates.

**Antioxidant enzymes**

A significant reduction (P<0.05) in SOD, CAT, GPx, GR, and GST activities was observed in liver (Table 2) and kidney (Figure 2) homogenates of DEX- treated rats. Furthermore, rats taken LSSE + DEX showed significant alleviation in the activities of antioxidant enzymes as compared to DEX - treated ones (P<0.05). Moreover, LSSE supplementation alone improved antioxidant enzyme activities significantly versus the control group.

**Liver and kidney function biomarkers**

Data showed that AST, ALT, and ALP activities and protein content decreased while LDH activity as well as serum urea, creatinine and total bilirubin increased significantly (P < 0.05) in rats received DEX as compared to control. Moreover, a significant modulation in enzyme activities and protein content in rats received LSSE then treated with DEX versus DEX group was observed. LSSE supplementation alone had insignificant alteration on the enzymes and protein contents in (Table 3 and 4).

**Discussion**

In the current investigation, the protective role of LSSE against DEX - induced oxidative injury and biochemical perturbations was studied. To our knowledge there are no findings have been pointed out the efficiency of LSSE as natural products for overcoming DEX harmful effect. Dexamethasone is known to disrupt oxidants/antioxidant balance in tissues, leading to various biochemical and physiological dysfunctions. Rats treated with DEX exhibited an imbalanced oxidant/antioxidant status as apparent in TBARS and H$_2$O$_2$ elevation accompanied by depletion in enzymatic (SOD, CAT, GPx, GR, GST) and non-enzymatic antioxidants (GSH) in the liver and kidney homogenates indicating the failure of antioxidant defense system to overcome the flow of ROS. The current results are in consistent with Kiersztan et al. (2017) and Jatwa and Kar (2010) who demonstrate the generation of hydroxyl free radicals and lipid peroxidation in the kidney of rabbits and mice treated with dexamethasone, respectively. Moreover, several authors showed that dexamethasone induced ROS generation in different tissues and cells via the mitochondrial electron transport chain, vascular endothelial xanthine oxidase and NADPH oxidase (Almeida et al., 2011; Feng and Tang, 2014; Assaf et al., 2012). So, this study showed that administration of DEX impaired antioxidant defense system since it has the capability to induce oxidative stress.

Antioxidant enzymes are so important in the preservation of homeostasis for normal cell function in addition they are used as indicators of oxidative stress (Gutteridge, 1995). Superoxide dismutase, as part of the defense system versus oxidative hurt in aerobic organisms, catalyzes superoxide anion (O$_2^-$) to O$_2$ and H$_2$O$_2$, which then is reduced to H$_2$O by H$_2$O$_2$-scavenging enzyme, catalase. The decrease in both SOD and CAT activities might be related to inhibition of enzyme protein synthesis. Glutathione plays a crucial role in cellular protection versus xenobiotics toxicity because of its thiol group (Halliwell and Gutteridge, 2007). Glutathione acts as a reducing non-enzymatic antioxidant and as a substrate for GPx and GST antioxidant enzymes (Cosso et al., 1997). GPx preserves the lipid-cellular membrane from oxidative injury (Kantola et al., 1988) and spurs hydroperoxide reaction with reduced glutathione to form disulphide glutathione (GSSG) (Kalaiselvi et al.,...
While, glutathione S-transferases (GSTs), play a critical role in the detoxification process of xenobiotic to non-toxic products, protecting against electrophiles and oxidative stress (Ghosh et al., 2012). Moreover, inhibition of GST activity in the liver and kidney of DEX-treated rats might repress the elimination of cellular free radicals leading to renal damage displayed by elevation of lipid peroxidation and creatinine (Kiersztan et al., 2017). DEX may affect the synthesis of GSH through the inhibition of glutathione-synthase and glucose 6-phosphate dehydrogenase activities. Additionally, DEX retards the diversion of oxidized glutathione (GSSG) into its reduced form (GSH) via GR inhibition (Yeh et al., 2005). In consistence with the present results, GCs may also indirectly participate in the induction of oxidative stress through inhibiting antioxidant enzymes activity. So, antioxidant enzymes, which prohibit the chain reaction of free radicals, are so important in alleviating DEX hurtful effect in liver and kidney tissues.

The induction in kidney function biomarkers (urea and creatinine) in DEX-treated rats reflected the renal dysfunction. This may be attributed to the metabolic impairment in liver function, as urea is the end-product of protein breakdown. While, high creatinine concentration is related to muscle creatine catabolism that leads to kidney damage (El-Demerdash and Nasr, 2014). Also, DEX may contributes to disturbances in kidney functions, resulting in development of albuminuria which is considered as an early indicator of renal damage or inflammation (Xu et al., 2010).

Xenobiotics are transformed in the liver into less harmful products leading to hepatocytes damage. In the current study, rats received DEX showed significant variations in AST, ALT, ALP and LDH activities as well as total bilirubin and protein levels. These parameters are important biomarkers for hepatocellular damage (Chen et al. 2019) and its alterations pointed out hepatocytes damage that altered the transport function and membrane permeability as well as leakage of enzymes from the cells to the bloodstream indicating hepatotoxicity (Gokcimen et al., 2007; Chen et al. 2019; Albasher et al., 2020). Also, lipid peroxidation has a fundamental role in the disruption of hepatocellular membrane integrity, leading to the leakage of cytoplasmic enzymes and this confirmed the possible mechanism of oxidative stress in liver lesion induced by DEX (Bhaduria, 2012). Lactate dehydrogenase is known as a potent marker in the toxicity assessment of many xenobiotics. The observed induction in LDH activity in DEX-treated rats may be attributed to cellular decay that leads to impairment in carbohydrate and protein metabolism in addition to energy depletion (Sivakumari et al., 1997). Alkaline phosphatase is an important membrane-bound enzyme used as a biomarker for xenobiotics toxicity and critical enzyme in the biological processes. It is responsible for detoxification, metabolism, and biosynthesis of macromolecules that are required for many biological functions and its inhibition in organs could be attributed to tissue necrosis that leads to seepage of the enzyme into the bloodstream (Yarbrough et al. 1982). The elevation in total bilirubin may be related to diminished liver uptake, conjugation, or prolonged bilirubin output from hemolysis (El-Demerdash, 2004). Protein is an essential cellular component susceptible to damage by free radicals and its depression might be because of exaggerated leakage via nephrosis (Chatterjea and Shinde 2002). Additionally, the decrease in protein may be related to disturbance in protein anabolic and catabolic processes.

Our results inferred that LSSE pre-supplementation significantly repaired the liver and kidney biomarkers induced by DEX confirming its guarding potential and its important role in preventing oxidative stress related liver damage due to its anti-inflammatory effect. Protective and therapeutic use of ethanolic LSSE in rat’s renal failure reduced urea and creatinine concentration significantly indicating excess of glomerular filtration rate. Also, administration of aqueous LSSE for 3 weeks exhibited antihypertensive and diuretic activities and suppress free radical attack in rats. So, this study is a successful attempt that introduces *Lepidium sativum* as a wonderful antioxidant for mitigation of DEX-induced oxidative stress in rats due to its antioxidant properties.

**Conclusion**

In conclusion, the present results pointed out that dexamethasone has the potency to cause hepatorenal dysfunction via oxidative injury, alterations in antioxidant defense system, enzyme activities, and biochemical parameters. Furthermore, *Lepidium sativum* administration in combination with dexamethasone...
attenuates its harmful effect by quenching and chelating free radicals. So, *Lepidium sativum* had a powerful antioxidant role in alleviating dexamethasone side effects by potentiating antioxidant defense system status and depressing free radicals’ generation.

An Updated Review on Some Neurotoxic Pharmacological Agents Along with their Neurotoxic Mechanisms

Muhammad Irfan Bashir¹, Nur Hidayah Kaz Abdul Aziz², Dzul Azri Mohamed Noor³

¹Researcher, ²Scientist, Discipline of Pharmacology, School of Pharmaceutical Sciences, Universiti Sains Malaysia, Minden 11800, Penang, Malaysia, ³Scientist, Discipline of Clinical Pharmacy, School of Pharmaceutical Sciences, Universiti Sains Malaysia, Minden 11800, Penang, Malaysia

Abstract

This review will provide the vital information about some pharmacological agents which are Neurotoxic. Through this update, Anti-cancer, Anti-bacterial, Analgesic, Psychoactive drug and Anabolic steroid medication are reported briefly regarding their neurotoxic mechanisms. In this review all information regarding neurotoxic drugs is collected from 2020 published work by Web of science, Scopus, PubMed and Google Scholar. It is concluded that all these drugs which are part of our study are neurotoxic. There is need to discover some method to reduce their toxicity and to avoid the chronic use of these medications.

Key Words: Neurotoxic, Pharmacological agents, Anti-cancer, Analgesic, Antibacterial

Introduction

Several types of drugs have side effects on brain, some are minimal, and some are toxic. Toxic effects of drug on brain can cause irreversible brain damage sometimes which are very dangerous for mental health, as any living organism can lose its life due severe neurotoxicity ¹. In routine treatments we don’t know about some drugs which we are taking has negative impact on our mental health as well as on our nervous system ².

Neurotoxicity is a major side effect of many chemotherapeutic drugs used for the treatment of many diseases, including tumors. Toxicity can compromise the quality of life of patients. As per previous reports 84.4% of patients which were affected by lymphoma and treated with chemotherapeutic agents developed a serious neuropathy regarding sensory organs and 43.8% showed polyneuropathy, causing a significantly dangerous for the quality of life ³.

Such effects are usually cause spontaneously fade, as doses are high then chances of neurotoxicity are also high ⁴. If these drugs are used at high therapeutic levels for long time, the plasticity of the neurons is affected badly, and the damage becomes irreversible sometimes ⁵.

Neurotoxicity is one of the main reasons of drug withdrawal, and the biological experimental methods of evaluating neurotoxicity are time taking and arduous. Many Anti-biotic, Analgesic are also showed their neurotoxicity due to their cytotoxic and neurochemical disturbing mechanisms ⁶.

In this updated review, adverse effects of some drugs that cause neurotoxicity are explained individually. These updates are collected from recently published work in 2020. Among these drugs, anti-cancer, anti-bacterial, Analgesic, Psychoactive drug and Anabolic steroid medication are reported briefly. Table 1 is showing summarized report regarding some neurotoxic drugs with their mechanism.

**Bortezomib**

Bortezomib is an anti-tumor agent that inhibits 26S proteasome degrading proteins. While apoptotic transcription activation in response to bortezomib has also been observed, mechanisms regarding influence on gene silencing mediated regulation by non-coding RNAs remain not fully explained. Bortezomib showed the severe neurotoxicity through apoptosis in PC12 cells. It imparts neurotoxicity regardless of cell density. Some studies also showed that, highest cytotoxicity in low cell density, bortezomib more frequently cause major peripheral neuropathy, only few of studies have reported the effective strategy to prevent its side effect.

**Doxorubicin**

Doxorubicin is the most potent anthracycline antibiotics used for treatment of multiple cancer types including breast cancer therapy. But its efficacy is limited by fatal toxicities associated with therapy causing damage to normal tissues and organs. It Interacts with nuclear DNA, altering the pair base sequence and preventing the topoisomerase-II-mediated DNA repair mitochondrial DNA, impairing expression of proteins involved in mitochondrial functions.

**Cisplatin**

Cisplatin is an anti-cancer drug it interreacts with DNA, forms crosslinks between chains and induces apoptosis. Central or Peripheral neuropathy. 50–85% score of sensory and sensorimotor neuropathy. Oxidative stress, generation of DNA adducts, apoptosis, mitochondrial dysfunction are also among its neurotoxic mechanisms. Cisplatin also react with RNA but the ration of modified molecules to the total number of the same molecular species in the cell is much higher in the case of DNA molecules, binding of this agent to the DNA is the main cause of its toxicity.

**Carboplatin**

Carboplatin is widely used agent to treat the various types of cancer. However, a number of severe side effects induced by the nonspecific binding of platinum drugs to normal tissues limit their clinical use. This drug is also involved in Inhibition of the DNA repair pathways, generation of DNA adducts and cause severe neurotoxicity.

**Oxaliplatin**

Oxaliplatin is involved in acute neuropathy upon exposure to chronic peripheral neuropathy, in which sensory axonal nerve abnormal generation of DNA adducts is occurred. Mostly due to Alterations in voltage-gated sodium channel kinetics, Calcium chelation and Potassium channel blockade. Peripheral neurotoxicity is a main toxicity that afflicts up to 90% of patients with colorectal cancer which are taking oxaliplatin containing therapy.

**Ifosfamide**

Ifosfamide is an alkylating agent used in the treatment of various solid tumors, including small cell lung cancer, testicular cancer, cervical cancer, and sarcoma. It is Pro-drug, that after bioactivation, inhibits the DNA functions and cause cell death. Chloroacetaldehyde (metabolite responsible for neurotoxicity) inducing many damages to the mitochondrial respiratory chain depletion of glutathione level in central nervous system and also creating oxidative stress.

**5-Fluorouracil**

This drug also reacts with DNA synthesis and inhibits of thymidylate synthase which blocks the thymidine formation. Seldomly sensorimotor polyneuropathy is observed during treatment with 5-Fluorouracil. Maximum doses and combined use of 5-FU with interferon alpha increases the neurotoxicity. It impairs the urea cycle and permits an accumulation of ammonia a transient stagnation of 5-FU catabolites induces neurotoxicity. This drug can increase the cellular thiamine metabolism, inducing a thiamine deficiency.

**Novel Methcathinones**

These are mitochondrial toxicants whose toxicity is increased by transferring the temperature from 37 to 40.5 °C. It can cause apoptosis and necrosis among brain cells. The activation of proper defense mechanisms like autophagy is necessary to prevent the cell dysfunction and cell death. Mitochondrial toxicity, which is accentuated by hyperthermia, represents an important mechanism of the neural toxicity of these compounds.
Methotrexate

Methotrexate is a folic acid antagonist for the treatment of cancer and rheumatoid arthritis because of its high potency and efficacy. It inhibits the enzyme dihydrofolate reductase which interference with DNA synthesis, DNA repair, protein synthesis, cellular replication, lipids and cause autonomic neuropathy. Aseptic meningitis occurs in 10–50% of patients due to influence of this drug. Disturbances of myelin metabolism, inhibition of glucose metabolism, oxidative stress.

Cefepime

Cefepime is an antibacterial drug belongs to cephalosporins, previously its concentrations were determined in 584 individuals. Among 319 individuals with available through concentrations included, the overall incidence of neurotoxicity was 23.2% (74 of 319 individuals). Maximum cefepime plasma trough concentrations were significantly associated with risk of neurotoxicity. Possible adverse neurological effects based on the occurrence of neurological signs (altered mental status, depressed concentration of consciousness, aphasia, myoclonus, asterixis, confusion, seizure, dystonia).

Nandrolone decanoate with Cannabis

These are Psychoactive drugs. Polydruge use among adolescence is a widespread activity and has enhanced in the last some years. Most nandrolone decanoate abusers combine its use with cannabis. Abuse of both drugs conferred larger neurotoxic effects than either drug alone that were at least partially attributed to inflammation, oxidative stress, and apoptosis in the hippocampus and prefrontal cortex of brain in rats.

Tramadol

Tramadol is a synthetic analogue of codeine that is prescribed for the treatment of moderate pains as an analgesic. It has also some side effects including emotional instability and anxiety. It triggers astrogliosis and microgliosis along with neuronal death in the prefrontal cortex. Behavioral problems and cognitive function impairment are other side effects of tramadol. Previous results indicate that tramadol is responsible for neurodegeneration in the prefrontal cortex through activation of neuroinflammatory response.

Cathinones N-Ethylhexedrone and buphedrone

N-Ethylhexedrone and buphedrone are emerging synthetic cathinones. Small information about their negative effects within central nervous system. These drugs showed in vivo/in vitro neurotoxicity’s but enhanced specific N-Ethylhexedrone induced behavioral abnormalities.

Conclusion

Due to reported neurotoxic mechanisms of all discussed drugs in this review, it is concluded that long term use of these medication can cause brain damaged. There is need to find some methods to overcome the neurotoxic effects of all these drugs.

CT scan Findings of COVID-19 in Patients with Fatty Liver

Israa Mohammed Sadiq¹, Kermanj Ismail Bakr¹

¹Lecturer in Kirkuk College of Medicine, MBChB (Tikrit University), FIBMS Radiology (Iraqi Board for Medical Specialization). Department of Surgery/ Radiology, College of Medicine, University of Kirkuk, Kirkuk/Iraq.

Abstract

Purpose: COVID 19) is a respiratory disease caused by a member of the coronaviruses family, named (SARS-CoV-2), discovered in December 2019 in China. This study aims to assess the association of the simple fatty liver disease with the severity of the chest computed tomography (CT) scan findings in COVID 19.

Materials and Methods: It was a cross-sectional study that enrolled 322 patients with positive (RT-PCR) tests and chest CT scan findings. Patients with chronic lung and liver disease, alcoholics, and abnormal liver function tests excluded from the study. The liver CT scan density assessed, accordingly the patients divided into fatty-liver and non-fatty liver groups. The severity of lung CT changes compared between them, using Chi-square test.

Conclusion: COVID patients with fatty liver have more progressive changes in the chest CT scan. They have similar lung lesion distribution to non- fatty liver patients. Crazy paving lesions, septal thickening, Lymphadenopathy and plural effusion in fatty liver patients occurs in the same frequency as non-fatty liver patients

Keywords: CT scan, COVID 19, Fatty Liver.

Introduction

(COVID 19) is a respiratory disease caused by a member of the coronaviruses family, named (SARS-CoV-2), discovered in December 2019 in China. The majority of patients have cough, fever, myalgia, with or without dyspnea. Certain groups of patients developed severe illness. COVID-19 diagnosis depends on the real-time polymerase chain reaction (RT-PCR) test. Chest computed tomography (CT) is used for early detection, assess severity, and for follow-up of the patients. Typical findings appear when lung tissue early reacts to the insult as focal peripheral rounded ground-glass opacities (GGO), which may become more extensive, confluent, and may evolve to dense consolidation . Other less common CT scan findings include linear and curvilinear opacities, vascular enlargement, and bronchial dilation. Pulmonary nodules, lymph node enlargement, cavities, and pleural effusions are rare findings.

Findings associated with high mortality include extensive lung involvement and the presence of consolidations. As published in recent studies, patients with cardiovascular disease, diabetes, chronic kidney disease, and older age are at a higher risk of infection and prone to a graver outcome once infected. Non-alcoholic fatty liver disease (NAFLD) is another comorbidity that affects the severity of COVID-19. It is a chronic disease characterized by the presence of hepatic steatosis (intrahepatic lipid of more than 5% of liver weight) without a history of alcohol intake, with or without abnormal liver tests. It is the liver manifestation of the metabolic syndrome, which is characterized by
the presence of obesity, insulin resistance, hypertension, and hyperlipidemia. NAFLD has a doubtful association with infections; recent studies reported an association with community-acquired pneumonia and a higher risk of evolving to severe disease in COVID-19 patients. (19-23) The study aims to assess the association of the simple fatty liver disease with the severity of the chest CT scan findings in COVID-19.

Materials and Methods

1. Study population: It is a cross-sectional study done for 322 patients with COVID 19 at Azadi Teaching Hospital/Kirkuk city/Iraq, attending the CT scan unit for evaluation of their chests from March 2019- June 2019.

   Inclusion criteria: adult Patients with positive CT scan findings and nasopharyngeal RT-PCR tests were enrolling in the study.

   Exclusion criteria: Include patients with a known history of heart failure, pre-existing lung or liver disease, alcoholic persons, those with positive serology for hepatitis virus, and abnormal liver function tests. We collected the clinical information from the documentation of the clinicians.

2. Imaging: CT examinations without intravenous contrast medium achieved by a multidetector-row scanner (Siemens Brilliance), the energy level of 200-250 mA, and 120 kV. The patients imaged in the supine position. The slice thickness was 5 mm, images taken from the upper neck to the level of the umbilicus. The CT scan examinations in both lung and mediastinal windows evaluated by two radiologists with at least five years’ experience in CT scan imaging. Any differences of opinion resolved with consent. The CT examinations were done at 3-10 days from the onset of the symptoms.

3. CT interpretation: Liver density assessed to confirm the diagnosis of hepatic steatosis as liver attenuation less than 40 HU. (24) (Fig 1a)

   The CT COVID changes attenuation classified as pure GGO, predominantly GGO, or consolidation (Fig 1b), and pure consolidation attenuation, while the degree of lung involvement assessment done as the following: both lungs divided into six regions, three equal zones for each one: upper, middle, and lower zones. Each zone graded into less than 5% involvement, 5-25%, 25-50%, 50-75%, and > 75% lung involvement, then the average percentage is calculated for each patient. (25)

4. Statistical analysis: Continuous variables expressed as mean (± SD) and categorical variables as frequency (percentage). The lung lesion densities and extension compared between two groups differentiated according to their liver involvement by the fatty change. A probability (p) value of less than 0.05 was considered statistically significant. Version 17, SPSS software was used for statistical analyses.

This study approved by the Faculty of Medicine’s Research Ethics Committee/ Kirkuk University - Iraq. The individual data not explored in the study.

The patients gave verbal informed consent to participate in this study.

Figure 1. a, b. A 57-year-old woman with COVID-19, in the fatty liver group. Axial CT image (a) of the upper abdomen in abdominal window, average liver density is 11.9 HU (b) chest CT scan in the lung window, shows predominant consolidation in the both lower lobes.
Findings

Three hundred twenty-two patients (160 males and 162 females) with laboratory diagnosed COVID19 had positive CT scan findings. Their age range was 18-70 years, and the mean was 50.25 (± 13.1), 66 (20.5%) of them had fatty liver and 256 (79.5%) had normal liver density. (Table 1)

In the fatty liver group, the CT scan findings were pure GGO in 24 patients (36.36%), predominantly (more than 50%) GGO in 12 (18.18%), predominantly consolidation in 25 (37.87%), and Pure consolidation in 5 (7.57%). While in the non-fatty liver group, the findings were pure GGO in 75 patients (29.29%), predominantly GGO in 90 (35.15%), consolidation in 69 (26.95%), and Pure consolidation in 22 (8.59%). There is no statistical difference in pure consolidation and GGO between both groups in contrast to mixed density lesions which is predominantly GGO in the non-fatty liver group (P=0.003) and predominantly consolidation in the fatty liver group (P=0.04). Using chi-square test. The result is significant at p < 0.05.

Other CT scan findings in the fatty-liver group were as the following: Crazy paving 24 (36%), Septal thickening 5 (5.57%), Plural effusion 22 (33.33%) and Mediastinal lymphadenopathy 1 (1.51%). While in non-fatty liver were 100 (39%), 10 (3.9%), 86 (33.56%), and 5 (1.95%) respectively. There was no significant difference in the incidence of these findings between the two groups.

There were no pericardial effusion, cavitation, neither nodule incidence in this study.

**Discussion**

In our study, 66 (20.5%) had fatty liver density, which approximates the global prevalence, which is about 25.24% (26). This group of people had a chance to develop more severe and extensive lung changes in COVID 19, as they had predominantly consolidative lesions, in contrast to the non-fatty-liver group who had GGO more. COVID 19 damaged the lungs of the Fatty liver group more extensively (25-50 %) in comparison to the non-fatty-liver group as their lungs involved more in (5-25%). It was consistent with the result of a study done in China by Kenneth I. Zheng et al who stated that (fatty liver patients that were obese had more severe COVID-19 disease) (27) as the fatty-liver group’s weight was significantly more in our study. (fatty-liver disease patients had significantly more recurrent
infections regardless of coexistent metabolic syndrome) a statement proved by William Nseir et al (22) The fatty liver patients had a higher risk of progressive COVID 19, a conclusion made out by Julie Lucifora et al. (28) This relation is probably due to the association of fatty liver change with low vitamin D serum levels, which in turn increases the susceptibility to infection and autoimmunity. (29, 30) In addition to the deficient innate immunity to the coronavirus representing by high M2 blood macrophages, which suppress the response to the infections. (31) In both groups, the distribution of the lung lesions was more frequently peripheral and bilateral, and to a lesser degree had a diffuse behavior, the least distribution pattern was unilateral and central lung involvement. The result was in line with much of the studies. (2, 6, 10, 12)

In both groups, like other papers, other CT scan findings were seen almost in the same percentage. About one-third of the patient had crazy paving lesions and septal thickening. Lymphadenopathy and plural effusion were relatively rare. (6, 10)

Limitation of the study: We did not consider the patients who may have received COVID 19 treatment, which might affect their CT scan findings.

**Conclusion**

COVID patients with fatty liver have more progressive changes in the chest CT scan.

The distribution of the lung lesions in both fatty and non- fatty liver are similar.

Crazy paving lesions, septal thickening, Lymphadenopathy and plural effusion in fatty liver patients occurs in the same frequency as non-fatty liver patients.

Studying the Relationship between the Lund Mackay Score and Response to Medical Treatment in Patients with Chronic Sinusitis

Gholam-Ali Dashti Khavidaki1, Reza Gharibi1

1Associate Professor, Department of ENT Disorder, AL-Zahra Hospital, Zahedan University of Medical Sciences, Zahedan, Iran

Abstract

The present study was conducted to investigate the relationship between the Lund Mackay score and response to medical treatment in patients with chronic sinusitis. The present study was performed cross-sectionally on 150 patients referred to Khatam-ul-Anbia Hospital in Zahedan for whom the diagnosis of chronic sinusitis was confirmed and met the study criteria. Demographic data and clinical signs of patients were recorded for based on CT scan, The Lund Mackay score was evaluated. Patients were treated for 4 to 6 weeks and finally re-evaluated for symptoms and response to treatment. Data were analyzed using SPSS software version 24, McNemar test, Mann-Whitney and other necessary tests for descriptive statistics. A significance level of 0.05 was considered. 3.55% of patients were male (83 patients) and 7.44% were female (67 patients). The mean score of the Lund Mackay in the present study was 92.11 with a standard deviation of 2.3. Symptoms of olfactory dysfunction, sinus pain, nasal obstruction and nasal discharge showed significant improvement after treatment (p <05.0). Based on the results obtained at the end of the study, the presence of nasal polyps (p = 001.0) and nasal obstruction (p = 003.0), after the end of the treatment period, showed a significant relationship with the response to treatment. In general, this study suggested that the mean score of The Lund Mackay had a significant positive relationship with the severity of patients’ clinical symptoms and the severity of sinusitis. Therefore, it can be considered as a suitable criterion in diagnostic and therapeutic evaluations of patients.

Keywords: Chronic Sinusitis, the Lund Mackay Score, Medical Treatment

Introduction

Sinusitis Inflammation of one or more cavities of the paranasal sinuses, most often caused by viral infections of the upper respiratory tract (1). One of the most common reasons for patients to visit a doctor is Sinusitis. About 25 million people in the United States impose nearly $2 million directly to the medical system each year. Failure to correctly diagnose the disease and its causes or not paying attention to the patient’s underlying health problems which can be a contributing factor to this disease and also prescribing inappropriate drugs against sinusitis has led to the chronic type of the disease which means symptoms such as sinus tenderness. Or post-nasal drip for more than 12 weeks (2, 3). In cases of chronic sinusitis, its treatment requires more expensive antibiotics, and in some cases it does not respond to medical treatments and requires more aggressive treatments, such as endoscopic sinus surgery.

Due to the variety of treatment methods and the variable response of chronic sinusitis to treatment, it
seems necessary to follow the treatment process of patients and their response. Despite the centrality of clinical diagnosis in sinusitis, many physicians use CT scans to confirm the diagnosis of chronic sinusitis and determine the severity of the disease. CT scans are also used to determine anatomical abnormalities and to determine the roadmap for surgery. Therefore, CT scan is used as an essential component in the diagnosis and treatment of chronic sinusitis (4, 5).

It is often assumed that the symptoms in patients are related to objective scores obtained from the severity of the disease. However, the relationship between radiological findings and symptoms in sinusitis is discussed. Also in the treatment of chronic sinusitis, the predictive value of radiological scores in the description of symptomatic progression after surgery is still unknown. There are different staging systems in chronic sinusitis. Many studies in these cases have been performed using conventional radiography, CT, MRI, which have disadvantages, including superimposition of maxillary and facial structures on conventional radiography, the high-dose risk of radiation in CT; Lack of cortical bone imaging with MRI, therefore, this modality is not sufficient to show the sinus drainage system alone. In addition, it has disadvantages such as high price and insufficient access (6, 7).

The Lund Mackay scoring system became popular as a simple evaluation tool to facilitate treatment decisions in the mid-1980s (8). Considering the contradictory results of previous studies on the relationship between symptom severity and Lund Mackay radiological score, the present study attempts to find out the exact dimensions of the use of this scoring system in chronic sinusitis by examining this relationship in a significant population of chronic sinusitis patients.

**Material and Method**

**Participants:** The statistical population of this study includes patients who referred to Khatam Al-Anbia Hospital in Zahedan for treatment due to chronic sinusitis during 2016 to 2018 and met the necessary criteria. Ethical principles in accordance with the general guideline of ethics in medical sciences research with human subjects in the Islamic Republic of Iran were observed. Patients who had been treated for chronic sinusitis by an otolaryngologist were included. The patients must had had no structural abnormality in their CT scan such as retention cysts or nasal deviation. Exclusion criteria include patients with clinical symptom of acute sinusitis, patients with CT scans of symptoms such as retention cysts and patients with deviated septum without sinusitis and treatment protocol.

**Data collection:** Before beginning study, a questionnaire was completed that included questions about the patient’s history including age, gender, clinical symptoms of chronic sinusitis, and a history of illnesses. Then, this study was performed on 150 patients with chronic sinusitis who met the criteria of the study. CT scan of the paranasal sinuses was done for all patients. Based on the CT scan findings, The Lund Mackay score was calculated for each patient. In radiological sinusitis examination, considering the Lund Mackay score, a slight and severe increase in the thickness of the anterior and posterior Ethmoid sinuses, sphenoid, frontal, maxillary, and Ostitomeatal complex obstruction or air fluid surface as diagnostic signs and symptoms such as retention cyst and deviated septum without obvious sinusitis is considered as negative CT scan. Then, according to the Lund Mackay score, each scan with a score = 0 is normal and each scan with a score> 0 is abnormal (9). Also, at the beginning of the study, in addition to CT scan, DOTS score, which is a valid criterion for evaluating clinical symptoms, was calculated for patients. Then, patients were treated for 4 to 6 weeks, and re-examined for response to treatment and DOTS criteria. Ultimately, based on the treatment results, patients who did not respond well to treatment were recommended to do surgery.

**Statistical Analysis:** All statistical analyzes were performed using SPSS software version 24. Shapiro-Wilk test was used to examine the normal distribution of data. Considering the abnormal distribution, appropriate non-parametric tests were used in the relevant results. Patients were divided into three age groups: 1 (8 to 18), 2 (18 to 40) and 3 (over 40) years, and the Lund Mackay scoring was divided into 5 categories: 1 (8-5), category 2 (9-12), category 3 (13-16), group 4 (17-20) and group 5 (21-24) were divided.

**Findings**

**Patient baseline features:** The frequency distribution of age, gender and score of The Lund
Mackay is shown in Table 1. As shown in the table, 3.55% of patients were male (83 patients) and 7.44% were female (67 patients). 3.51% (77 people) were in the age group of 8 to 18 years, 30% (45 people) were in the age group of 18 to 40 years and 7.18% (28 people) were over 40 years old. Finally, the highest frequency distribution in terms of The Lund Mackay score is related to the score range 9 to 12 and includes 3.45% (68 patients) of patients. In this study, no cases of Wegener, immunodeficiency and migraine were found. Patients were divided into two groups: people with a history of allergies (67 people) and people with a negative history of the disease (83 people).

**The effect of treatment on DOTS clinical criteria:** The frequency of clinical criteria (DOTS criteria) before and after treatment is shown in Table 2. Changes in studied clinical variables, except nasal polyps, before and after treatment, showed a statistically significant difference (p < 0.05). Considering the information mentioned in the table, this difference in all these variables was a significant decrease in the frequency of the relevant symptom, but in the case of nasal polyps, the changes before and after treatment were not significant (p = 0.005).

The relationship between The Lund Mackay score and response to drug therapy in different age groups:

According to the findings shown in Table 3, in the age group of 18 to 40 years, the relationship between response to drug therapy and The Lund Mackay score was statistically significant (p = 0.002). Therefore, the average score of The Lund Mackay, in Patients who did not respond well to medication (requiring surgical treatment) (13.29±3.40) were significantly more likely than patients who responded well to medication (10.05±2.50). No significant relationship was found in the other 2 age groups.

The relationship between The Lund Mackay score and response to drug therapy in different genders:
According to the findings shown in Table 4, the relationship between drug response and The Lund Mackay score in men was statistically significant (p =0.006). Therefore, the mean score of The Lund Mackay, in those patients who did not respond well to medication (requiring surgical treatment) (13.25 ± 3.09) were significantly higher than patients who responded well to medication (11.26±2.64). As can be seen in Table 4, the difference in scores in terms of response to treatment among women was not significant (p =0.109).

Relationship between The Lund Mackay score and response to drug therapy based on considering allergies: According to the findings shown in Table 5, in patients who did not report a specific disease history, unlike patients with allergies, the relationship between drug response and The Lund Mackay score was statistically significant (p = 0.026). Therefore, the mean score of The Lund Mackay was significantly higher in those patients who did not respond well to medication (requiring surgical treatment) (12.93±3.18) than in patients who responded well to medication (11.30±2.86).

**Relationship between The Lund Mackay score and response to drug therapy based on medical history:** Patients who did not report previous treatment, the relationship between response to drug therapy and the Lund Mackay score was statistically significant (p = 0.010), with the mean score of The Lund Mackay was significantly higher in patients who did not respond well to medication (requiring surgical treatment) (13.41 ±3.42) than in patients who responded well to medication (11.10 ±2.95). Therefore, in patients with a history of drug therapy (p = 0.163) or surgical treatment (p = 0.281), the difference in The Lund Mackay score with response to treatment was not statistically significant.

**The relationship between The Lund Mackay score and disease outcome status after the treatment:** All remaining symptoms at the end of the study are significantly correlated with the average score of The Lund Mackay. So, for all outcomes, the mean score of The Lund Mackay showed a significant increase in proportion to the severity of the clinical symptom (from high to low: permanent symptom, occasional symptom and no symptom, respectively) (P<0.05).

**Discussion**

Almost all studied clinical variables, before and after treatment, show a statistically significant difference. Symptoms of olfactory dysfunction, sinus pain, nasal obstruction and nasal discharge showed significant improvement after treatment, although in the case of nasal polyps, the changes before and after treatment were not significant. Patients who experienced outcomes such as sinus pain, nasal polyps, nasal obstruction, nasal discharge, and olfactory dysfunction had a higher mean, according to The Lund Mackay score, resulting in more severe sinusitis.

Also, all the remaining symptoms at the end of the study showed a significant relationship with the average score of The Lund Mackay. For all outcomes, the mean score of The Lund Mackay showed a significant increase in proportion to the increase in clinical symptom severity. For all outcomes the mean score of The Lund Mackay showed a significant increase in proportion to the increase in severity of clinical symptom.

Limited studies have been performed on the relationship between clinical findings and the Lund Mackay score. For instance, a study conducted by Safavi Naeini et al. on the diagnostic value of clinical signs and symptoms in the sinusitis diagnosis of 198 patients. This study was done according to the results of CT scan and considering the Lund Mackay system. In this study, it was found that patients suffering from nasal congestion and recurrent coughs had more severe sinusitis based on Lund Mackay score than those who did not (10). This finding is consistent with the results of the present study, which suggests the value of The Lund Mackay score in assessing the severity of sinusitis in patients. In a study by Hopkins et al. (2007), The Lund Mackay score was assessed in patients with chronic rhinosinusitis. In this...
multicenter study, it was suggested that those patients who had a higher mean score based on The Lund Mackay system were more likely to be candidates for surgery, and the higher the score, the more invasive surgery was used \(^{(11)}\). Also in the above study, patients were divided into two groups based on the status of nasal polyps: sinusitis patients with polyps and patients who had only sinusitis. In sinusitis patients without polyps, this CT scan score was significantly lower. According to a recent study that confirms our previous results and findings, The Lund Mackay score can be a good predictor of the severity of clinical symptoms and patients’ quality of life \(^{(12)}\).

However, studies have reported the results of the weakness of The Lund Mackay criterion in CT scan and also reported the Lund Mackay criterion’s weakness in predicting the patients’ clinical status with chronic rhinosinusitis, which highlights the importance of further studies for a more accurate view. For instance, in a study by Peter H. Hwang et al. on the association between the symptoms of chronic rhinosinusitis and the results of CT scans using the Lund Mackay, we found that out of 125 patients in the study, 115 patients had symptom criteria for CRS. However, 40 out of 115 patients had negative scans (Lund-Mackay = 0) despite having diagnostic criteria for rhinosinusitis. Out of 115 people, 75 had positive scans (Lund-Mackay > 1). Indicating poor convergence between chronic positive rhinosinusitis and CT positive \(^{(13)}\).

Limitations of this study are: Similar studies should be performed at longer time periods and with larger sample sizes for greater results certainty of evaluating changes in the Lund Mackay score in sinusitis patients. Second, it seems useful to evaluate the outcomes after surgery and compare it with the remaining outcomes after medical treatment. Third, the use of the Lund Mackay score classification in order to predict the response to treatment in patients and determine the appropriate treatment method in future studies seems necessary.

**Conclusion**

In summary, our study showed that there is a significant relationship between the Lund Mackay score based on CT scan findings and patients’ clinical status and treatment response. Therefore, this evaluation system can be used as an effective way to predict the prognosis of patients with chronic rhinosinusitis. However, current findings in this area are limited and further studies’ approval is needed. Another finding of this study, which seems to be new and important in its kind, is the great power of predicting clinical status with the help of CT scan in the age group of 18-40 years, male patients without a history of allergies, and without prior treatment.

Impact of Meningitis on Cognitive Skills and Development in Children

Seyedeh Mahsa Mahmoudinezhad Dezfooli1, Shaqayeq Khosravi2

1Associate Professor, Emergency Medicine Management Research Center, Iran University of Medical Sciences, Aliasghar Children Hospital, Tehran, Iran, 2Emergency Medicine Management Research Center, Iran University of Medical Sciences, Aliasghar children Hospital, Tehran, Iran

Abstract

The present systematic review aims to investigate the impact of meningitis on the cognitive skills and development of children. In this systematic review, relevant studies were identified via searches through medical information databases of MEDLINE, PubMed, ISI, EMBASE, Cochrane with the keywords of Meningitis, Meningitis and Complications, Meningitis and Children, Meningitis and Intelligence Quotient (IQ), Meningitis and Development, and their derivatives. In this study, amongst 198 articles reviewed, 11 articles met the inclusion criteria. All studies, except one case, reported a decrease in growth and IQ in children who experienced meningitis. Based on the results of the present study, children who have experienced meningitis at a younger age are more prone to disability, growth retardation, and lower IQ than other children throughout the later years of their life.

Keywords: Meningitis, intelligence quotient (IQ), development, Children, Systematic Review

Introduction

Meningitis is the inflammation of the meninges or protective membranes that surround the brain and spinal cord (1, 2). The disease is usually caused by a bacterial or viral infection or, rarely, a fungal infection (1, 3). In the bacterial type, the three main pathogens are Streptococcus pneumoniae, Haemophilus influenzae and Neisseria meningitidis (4) and in the viral type, enteroviruses, human parechoviruses and Chikungunya viruses are the causative agents of the disease (5). Mortality rate in viral meningitis is very low and most patients recover, but in bacterial meningitis, depending on the type of bacterium, it could kill 10% to 25% if left without appropriate treatment. Also, depending on the patient’s age, underlying disease, and surgery on the nervous system, different bacteria cause different symptoms in the patient. Bacterial meningitis is contagious and is caused by a specific bacterial infection that could be fatal if left untreated the number of leukocytes, cognitive impairment and infection with Streptococcus pneumonia were collected as prognostic factors in adults with bacterial meningitis. Meningitis, if left untreated, can lead to serious complications and even death. Therefore, early and accurate diagnosis is one of the research priorities of this disease. There are many methods available, such as examining the patient’s clinical symptoms, performing MRI and CT scans, biochemical blood tests, and examining the cerebrospinal fluid (6). Meningitis is a serious and dangerous disease that usually occurs quickly and unexpectedly. Although the disease affects different ages, the highest risk is for infants and young children (1). In children, the peak age of meningitis is 6 to 12 months, and 90% of cases occur in children under 5 years (7). The mortality rate of this disease is 2% in children and 20 to 30% in infants (8, 9). Symptoms of meningitis include fever, headache, refusal to eat or vomit, skin blemishes, drowsiness, photosensitivity, and neck spasms (10, 11). Pediatric imaging is one of the most indication of procedural sedation and analgesia. In the

pediatric patient, performing CT scan is stressful and leads to increased mental stress, absence of cooperation with the staff, restlessness, and anxiety in the patient (12). However, any child with suspected meningitis and seizures should have an LP. All suspected children with meningitis must be closely monitored, whether LP or experimental treatment (6). Many pharmacologic and non-pharmacologic strategies to manage pain exist for pediatric pain treatment. Pharmacological and integrative non-pharmacological therapies has been indicated in acute and chronic pain treatment (13). The results showed that both pharmacological and non-pharmacological treatment methods in relieving and reducing pain and anxiety in a wide range of pediatric diseases (such as respiratory tract infections, burns, surgery, dental restorations) are effective (14). Although the clinical symptoms of most children who survive meningitis subside within a few weeks, some can lead to severe disorders such as cranial nerve dysfunction, hemiplegia, ataxia, hydrocephalus, physical disability, mental retardation, seizures, and visual and hearing impairments (15, 16). Overall intelligence, measured by IQ, is one of the most powerful predictors of a person’s future life, material well-being, and mental health. Even small deficiencies in intelligence affected by meningitis could impair a person’s chances of survival and academic achievement (17). Christie et al., In a systematic review of the effect of meningitis on children’s IQ and growth, reported that survival from bacterial meningitis had an adverse effect on children’s IQ and growth, while viral meningitis had no significant cognitive effects (17). The present systematic review also tries to investigate the effect of meningitis on IQ and development of children.

Materials and Methods

In this systematic review, relevant studies were identified via searches through medical information databases of MEDLINE, PubMed, ISI, EMBASE, Cochrane with the keywords of Meningitis, Meningitis and Complications, Meningitis and Children, Meningitis and Intelligence Quotient (IQ), Meningitis and Development, and their derivatives. The references in all articles found during the search process were evaluated, in order to include other possible sources in the study. Then, by studying the abstracts, the studies that were completely unrelated to the objective of this research were removed and the studies that were completely relevant or possibly related were recorded; also, by examining the full text of the articles, the articles that were completely relevant to the purpose of this research were selected. In the last stage, among the selected articles and based on the criteria of critical evaluation, the articles that had the inclusion criteria of the study were selected. It should be noted that all stages of evaluating the quality of articles were performed by two independent researchers.

Inclusion criteria: Laboratory meningitis proven to be caused by any infection (bacterial, viral or fungal), studies in which the results and consequences or complications of meningitis other than death or acute complications were evaluated, Time scale: Results or follow-ups reported 1 month after meningitis, Type of studies used: Prospective, retrospective, and case-control studies or cross-sectional studies on the consequences of meningitis, which were written in English, were used. Also, the articles in which the IQ or growth age or stage of development of the infant were evaluated using valid tools, were included in the present study; In this regard, Intelligence was considered as the average of full-scale IQ, Performance IQ (PIQ) or Verbal IQ (VIQ) as standard scores (mean = 100, SD = 15) or Ratios with low IQ (less than 70, i.e. 2 standard deviations (SD) below average), and Infant development was also considered as the desired result in growth performance in movements, language, or cognitive domains compared to standard data and DD measurements. Exclusion criteria: Studies in which acute complications were evaluated only 1 month after the onset of disease, were excluded. Articles published before 1955; Articles published in languages other than English; Articles about meningitis in people with the suppressed or weakened immune system. Screening and Data Extraction: Two trained authors performed search strategies. In the first stage, the titles and abstracts were reviewed for the selection of articles; in the next stage, the two authors independently reviewed the full text of the articles. Differences in findings were resolved through the criterion method of general conclusion of articles and were organized in this study.

Findings

In this study, 198 articles were reviewed. After removing 41 duplicates, 157 titles and abstracts were reviewed for content validity. After excluding 84 articles
due to content mismatch and differences in variables, 73 articles were registered (Figure 1).

![Diagram of the process of review and selection of articles]

Finally, 11 articles that met the inclusion criteria were selected, of which 4 articles were prospective cohort, 1 article was prospective, 1 article was a cohort study, 2 articles were retrospective cohort study, and in 3 articles the type of experiment was not specified.

All studies, except one case, reported a decrease in growth and IQ in children who experienced meningitis. Also, hearing loss or impairment in 36%, visual problems and blindness in 18% of cases, reduced ability to read and write in 18%, speech and language problems in 18%, neurological complications in 36%, seizures in 27%, Hydrocephalus in 9%, decreased mobility in 18%, cranial nerve palsy in 27%, and disability in 36% of these articles was reported.

**Discussion**

Meningitis affects different aspects of children’s development. Taylor et al. have reported that these children have poorer reading skills and need special supportive training; They also stated that the outcome of the disease is affected by the age and sex of the child and the socio-economic status of the family (18). In general, children with meningitis are at higher risk for disability, and these disabilities could include mild to moderate hearing loss and neurological or central auditory impairment, which adversely affects a child’s learning, academic performance, and behavior (19). Compared to control groups, these children showed significantly poorer results in the evaluations of intelligence and high-level neuropsychological skills and had more behavioral differences at home and at school. In addition, the risk of complications is higher in people who have experienced acute neurological complications during their illness (4). Grimwood et al. Reported that some low-level skills, such as attention, processing speed, and instant memory capacity, improve in 7- and 12-year assessments. However, high-level...
cognitive skills such as organizational skills, problem-solving, verbal fluency, and mental flexibility are still impaired in 12-year assessment. This may reflect a delay in the process of developing executive functions. According to Anderson et al., even 12 years after the illness, children with a history of meningitis experience neurobehavioral consequences. Although the risk of side effects is higher for children with acute neurological complications in bacterial meningitis, people with uncomplicated disease are also at risk, and they also have fewer functions than control children in a number of tasks and show a greater degree of disability. The data also show that the apparently normal survivors of meningitis are at a lower level of skill than their peers for a number of their intellectual, educational, and cognitive tasks.

Children with meningitis had a significant decrease compared to control children in terms of verbal intelligence, functional intelligence, and full-scale IQ. These children could not perform better than control children in tests of educational ability, visual skills, memory, learning, and executive skills. These differences between the children with meningitis and control children were approximately one-third of SD for each score. Although the mean IQ scores were close to the test standard, the results indicated a slight overall defect in meningitis survivors compared with control children. Infants with viral meningitis under 1 year, 1 to 6 years after the infection have smaller head circumference, lower IQ, and delayed language skills compared to control children. In a study by Christie et al., the results showed that survival from bacterial meningitis had a detrimental effect on IQ and growth, but there was no evidence that reports the efficacy of viral meningitis on IQ. The decrease in IQ in survivors of bacterial meningitis was approximately 5 degrees compared to the healthy control group and was equivalent to a 0.33% decrease in SD in IQ. Survivors of bacterial meningitis are five times more likely to develop mental disorders (IQ <70) than controls.

Briand et al. argued that a standard follow-up protocol could help create better rehabilitation protocols for children and parents. Neurological and neurophysiological follow-ups on a larger scale could be useful for the initial follow-up of children with learning disabilities. These follow-up tips may also be helpful for parents since they could help them understand the consequences of long-term complications.

## Conclusion

According to the results of the present study, children who have experienced meningitis at a younger age are more prone to disability, growth retardation, and lower IQ in later life than other children. Even the children who are apparently healthy survivors of the disease have shown developmental delays and problems in cognitive functions compared to healthy people. Families, school teachers, and health professionals play an important role in identifying or assisting people with learning and behavioral problems. Because the children without identifiable risk factors may have significant functional disabilities after meningitis, families and school teachers should be aware of possible language deficiencies and problems in understanding language-based content.

The present study aimed to determine the relationship between subclinical hypothyroidism and diabetic retinopathy in patients with type 2 diabetes mellitus. In this cross-sectional analytical study, 150 patients with type 2 diabetes mellitus were assessed. The eye fundus examination was performed using fundoscopy to confirm or rule out retinopathy. Thyroid hormones were also measured by special kits to diagnose subclinical hypothyroidism. The criteria for diagnosis of this disorder include the high serum thyrotropin concentration (≥ 4mIU/L) plus normal serum free thyroxin levels. Statistical analyses were done using IBM-SPSS. In the study, 34.66% suffered retinopathy. A total of 24.0% suffered subclinical hypothyroidism with higher prevalence rate in those with retinopathy as compared with the group without retinopathy (p = 0.001). Those with diabetic retinopathy also experienced longer duration of diabetes than those without this event (p = 0.006). Analysis show a significant role for type 2 diabetes mellitus (OR = 1.121, P = 0.003), and high TSH level (OR = 1.342, P = 0.006) to predict diabetic retinopathy. This study showed an association between hypothyroidism, diabetes and increased TSH with retinopathy. Retinopathy is significantly predictable with the presence of subclinical hypothyroidism and longer duration of diabetes.

Keywords: Diabetes mellitus, Subclinical hypothyroidism, Retinopathy

Introduction

Type 2 diabetes mellitus is a major group of disorders characterized by varying degrees of insulin resistance, reduced insulin secretion and increased glucose production that affects around 285 million people worldwide in 2010, with a rapidly increasing prevalence around the world (1). The prevalence of this phenomenon is 0.2% in people under age 20, 11.3% in people over the age of 20 and 26.9% in people over 65 years of age. Meanwhile, due to an increase in the prevalence of obesity and a decrease in physical activity, the increase in the prevalence of type 2 diabetes mellitus has been higher than imagined (2). In diabetic patients, there are many acute and chronic complications that can be attributed to cardiovascular, renal, neurological, infectious and ocular complications (1, 3). Diabetic retinopathy is an ophthalmologic complication of diabetes mellitus and one of the causes of blindness in people with this disease (1, 4). Prolonged diabetes, poorly controlled blood glucose, advanced age, male gender, increased systolic blood pressure, consuming antihypertensive medications can increase the likelihood of diabetic retinopathy (5). Given that the prevalence of diabetes is increasing, the progression of diabetic retinopathy is also rising as one of the microvascular complications of diabetes mellitus (6). The prevalence of retinopathy, non-proliferative retinopathy and proliferative retinopathy was 3.1%, 1.1% and 0.1% in the general population and 23%, 19.1% and 8.2% in the diabetic population, respectively. Since the most effective treatment for diabetic retinopathy is to prevent it, the importance of identifying risk factors and the
causes of increased prevalence of diabetic retinopathy is clarified (2, 4). The thyroid plays an important role in the body’s metabolism (7) and recently suggested that the prevalence of people with thyroid disorders, especially subclinical hypothyroidism, was significantly higher in people with type 2 diabetes mellitus. Subclinical hypothyroidism is an asymptomatic stage of hypothyroidism characterized by elevated serum thyrotropin levels and serum free thyroxine levels (8). Patients with subclinical hypothyroidism have an endothelial dysfunction, which may lead to dysfunction of the small veins as the main fundament of retinopathy (8, 9). Some Studies demonstrated association between high thyroid stimulating hormone (TSH) levels and an increased risk of diabetic (10, 11) and some studies do not show this relationship (12). For this reason, in many studies, it is recommended that people with thyroid disorders, especially subclinical hypothyroidism, should be screened for retinopathy so that the condition can be given to health authorities in a controlled manner. Therefore, due to the high prevalence of diabetes and hypothyroidism and various complications due to the lack of control of diabetes, especially retinopathy, and the possible association of these two diseases with diabetic retinopathy, the present study aimed to determine the relationship between subclinical hypothyroidism and diabetic retinopathy in patients with type 2 diabetes mellitus.

Materials and Methods

Study design: In this cross-sectional analytical study, 150 patients with type 2 diabetes mellitus who referred to the internal clinic of Kowsar Hospital of Semnan between 2013 and 2014, with the preservation of inclusion and exclusion criteria were assessed. The sampling method was convenience sampling. Furthermore, data were collected through a questionnaire and Para clinical results.

Inclusion and exclusion criteria: The inclusion criteria were having type II diabetes mellitus, disease duration ranged 2 to 5 years, serum hemoglobin A1C 6.5% or higher, lack of clinical manifestations of thyroid disorders including fatigue, malaise, skin dryness, puffiness of face and hands, lack of laboratory findings related to thyroid disorders including raised TSH level along with reduced free T4, and conscious consent to participate in the study. In this regard, those with the history of cancer, liver or kidney disorders, chronic infections, using the drugs affecting thyroid functions (such as glucocorticoids, oral contraceptives, or NSAIDS) were all excluded from the study.

Study protocol and Biologic samples: After taking the medical records including demographics, medical history and medications, a clinical examination was performed to determine height, weight and blood pressure. Also, thyroid stimulating hormone (TSH), free thyroxine (free T4), hemoglobin A1C (HBA1C) and fasting blood glucose (FBS) were measured at the hospital laboratory using the special kits. TSH and T4 levels were measured by radioimmunoassay technique. HBA1C was measured by high-performance liquid chromatography (HPLC). FBS Fasting blood glucose was also measured by a glucose oxidase method. The eye fundus examination was performed using fundoscopy. The information was included in the data collection forms, which was previously prepared by the researcher for this purpose. This work continued until the sample volume was completed.

Data collection: Venous blood samples were collected in test tubes containing clot activator, immediately stored on ice, and—one hour after collection—centrifuged at 4000 rpm for 10 minutes. Plasma were separated and stored at −80°C through the hour to be analyzed. Those with normal free thyroxine (FT4) and an increased TSH (≥4 μIU/ml) level were diagnosed with SCH. Digital retinal photographs (two eyes × two fields), taken using a TRC-NW7SF (Topcon, Tokyo, Japan) non-mydriatic camera at 45°, were examined independently by two qualified retinal photography graders following quality assurance protocols. The severity of diabetic retinopathy was graded based on the international clinical diabetic retinopathy severity scale. data of patients and laboratory results were recorded in a pre-designed information form and finally entered for statistical analysis.

Statistical analysis: Descriptive analysis was used to describe the data, including mean ± standard deviation (SD) for quantitative variables and frequency for categorical variables. Chi square test, independent t test were used for comparison of variables. The correlation between quantitative variables was tested by the Pearson’s correlation test. For the statistical analysis, the
statistical software IBM SPSS Statistics for Windows version 25.0 was used. P values <0.05 were considered statistically significant.

**Findings**

In this study, 150 patients with type 2 diabetes mellitus were analyzed. The mean age of patients was 57.94 ± 9.68 years including 93 men (62.0%) and 57 females (38.0%). Of the participants in the study, 52 (34.66%) suffered retinopathy. None of the patients has overt or clinical hypothyroidism. Comparing baseline characteristics between the patients with and without retinopathy showed no difference in patients’ age (p = 0.232), gender (p = 0.329), body mass index (p = 0.431) (Table 1).

A total of 36 patients (24.0%) suffered subclinical hypothyroidism with higher prevalence rate in those with retinopathy as compared with the group without retinopathy (42.3% versus 14.3%). However, there was no difference in the level of T4 between the patients with and without diabetic retinopathy (1.10 ± 0.04 ng/dL versus 1.20 ± 0.02 ng/dL, p = 0.222). In order to investigate the relationship between the mentioned variables on retinopathy, logistic regression analysis showed that type 2 diabetes mellitus was significantly associated with retinopathy (OR = 1.121, 95%CI: 1.041 – 1.208, P = 0.003), and high TSH level (OR = 1.342, 95%CI: 1.086 – 1.657, P = 0.006) to predict diabetic retinopathy (Table 3).

Discussion

In our study, it was found that subclinical hypothyroidism is directly and significantly associated with retinopathy. Also, retinopathy was directly and significantly associated with Type 2 diabetes mellitus and TSH levels. Coherent research has shown patients with subclinical hypothyroidism have an endothelial dysfunction, which may lead to inappropriate operation of small veins increasing the likelihood of retinopathy \(^8,^9\). The association between thyroid hormone levels and retinopathy has been observed in other studies \(^10,^11,^13\). For this reason, in many studies, it is recommended that people with thyroid disorders, especially subclinical hypothyroidism should be screened for retinopathy. In study on 1581 subjects with normal thyroid function, the results showed that TSH levels had a positive correlation with insulin resistance and, as a result, with diabetic retinopathy \(^14\). In another study conducted on the Beijing Tongren Hospital of China on 1,117 patients with type 2 diabetes mellitus, it was found that the prevalence of diabetic retinopathy in people with subclinical hypothyroidism was higher than those with normal thyroid \(^9\). Also, although the level of fasting blood glucose and hypertension are known to be two factors affecting diabetes \(^15-17\), Yuedong Hu (2015) noted that these two factors had no meaningful relationship with diabetic retinopathy \(^18\). Moreover, in a study of 11140 patients with type 2 diabetes mellitus, the results showed that control of blood pressure below the normal level, even for 5 years, had no significant effect on the prevalence of diabetic retinopathy \(^19\), which was similar to our findings. In a study conducted by Javadi et al. (2009) in Saudi Arabia, more than 50% of people with diabetic retinopathy were older than 60 years of age \(^20\), which was also similar to our study results. Similarly, in a study by Khalid Al-Rubeaan et al. (2015), unlike our study, the prevalence of diabetic retinopathy in males was more than females \(^21\). The reason for this was the lower number of males in our study than the similar studies, which reduced the likelihood of diabetic retinopathy in men. Additionally, obesity is a problem because of the direct relationship with diabetes \(^22,^23\). In this regard, Studies noted that the BMI of diabetic individuals had a meaningful relationship with diabetic retinopathy \(^21,^24,^25\), but in our study, there was no significant relationship between BMI and risk for retinopathy.

One of the most important limitations of this study was its cross-sectional nature that limited the outcome analysis. Another limitation in this study was the relatively small number of statistical samples that should be cautious about generalizing its outcomes to other individuals and populations. Also, in this study, the definition and division of obesity has been done based on the BMI of individuals; while this index does not differentiate between muscle distribution and fat distribution. Even the distribution of fat in different parts of the body could have changed the risk of developing diabetes in different individuals, as the results of various studies indicate that the distribution of fat levels in the upper and lower abdomen, the risk of Metabolic diseases, especially diabetes, are increased more than those who have a fat mass in the lower parts of the body \(^26-29\).

One of the other limitations of this study was the lack of examination of a number of diabetes-related factors mentioned in other studies, including smoking, as well as exercise and physical activity, which, of course, due to the limited means of measuring this study. Also, the treatment of diabetics (insulin or oral medication) was another issue that could not be verified due to the limitations of this study.

Conclusion

Subclinical hypothyroidism is associated with diabetic retinopathy in type 2 diabetic patients. There is a positive correlation between level of TSH and intensity of diabetic retinopathy in type 2 diabetics with subclinical hypothyroidism. Also, subclinical hypothyroidism was one factor that significantly increased the risk of diabetic retinopathy. Therefore, considering the high prevalence of diabetic retinopathy and its relation to the subclinical hypothyroidism, planning for the education of patients at risk for diabetes or diabetic patients regarding long-term complications of diabetes, especially retinopathy is essential.

A Survey of Knowledge Level about Pediatric oral/dental Health among Pediatricians

Masoud Haghighikian¹, Mohsen Khaleghian¹, Ali Saberi¹, Mohammad Nasiri¹
¹Associate Professor, Department of Surgery, Rasool-e-Akram Hospital, Iran University of Medical Sciences, Tehran, Iran

Abstract
Pediatricians play a central role in children’s health care and are the first line of care for oral/dental conditions. The level of pediatrician knowledge about oral/dental health is not accurately determined. In this cross-sectional study, a previously adapted questionnaire was used to evaluate the level of oral/dental health knowledge among pediatricians affiliated with medical universities in Tehran, Iran. The data were summarized through descriptive statistics and central index tests. In this study, 263 pediatricians (49.4% male) completed the questionnaire. The mean age was 43.9 years. Only 17 individuals (6.5%) had completed a course of oral/dental health during their residency. The mean score was 5.9 ± 1.7. Questionnaire scores were similar between male and female pediatricians. Time from graduation and completion of an oral/dental health course was not associated with better performance according to the questionnaire. The level of knowledge about oral/dental health among pediatricians is inadequate. Most pediatricians have not completed a training course on this matter. These findings highlight the need for integrated training programs to improve pediatrician knowledge about oral/dental health.

Keywords: Knowledge Level, Pediatric oral/dental Health, Pediatricians, Medical Universities.

Introduction
Oral/dental diseases such as dental carries and periodontal conditions are among the most common chronic conditions in children, which begin during the first few years of life and could be best avoided in infancy and childhood (¹). Negligence of such disorders could lead to dental and gingival complications, tooth loss, distorted self-image, and decreased quality of life (²). Prevention is considered as the most effective method to avoid such complications and to improve oral health. The increasing prevalence of dental carries and gingivitis among children in developing countries makes them important subjects in health-care policy (³,⁴). Children are an important target for oral health preventive interventions; hence, providing consistent measures of prevention and education in this age group is of paramount importance (⁵,⁶).

Pediatricians are the first-line in children’s health-care, meaning their familiarity with oral/dental health subjects in providing evidence-based care and education to families can promote prevention of oral/dental diseases (⁷). A few studies in this field have demonstrated inadequate levels of oral/dental health training among pediatricians (⁸). Previous studies were conducted among Iranian medical interns and pediatric residents, which revealed substandard oral/dental knowledge level among these groups (⁹,¹⁰). There is limited evidence concerning the sufficiency of pediatricians’ oral/dental knowledge. In the present study, we sought to determine the level of oral/dental health knowledge among pediatricians in Tehran.

Material and Methods
Study design and participants: In this cross-
sectional descriptive study, between 2018 and 2019, a group of pediatricians who practiced in Tehran and other Iran city were asked to complete a questionnaire regarding oral and dental hygiene among children. Participant selection was done through convenience sampling.

**The questionnaire:** The questionnaire used in this work was adopted from previous studies, previously conducted pilot surveys, and was approved by dentistry professors in all universities involved (9,10). There were four initial questions about the participant’s age, sex, the number of years passed since their pediatrics residency program graduation, and whether they have taken part in any specific course on oral/dental hygiene during their residency. These were followed by 15 multiple-choice questions covering pediatric oral and dental hygiene, tooth-brushing, routine dentistry evaluations, fluoride use, and tooth development. Each question was assigned a score of 1 if the provided answer was correct, and 0 in case of an incorrect answer. The performance of each individual was evaluated according to the sum of the scores and was designated as “weak” for a score of 1-5, “moderate” for 6-10, and “good” for 11-15.

**Data analysis:** Sex and participation in an oral / dental course are demonstrated as number (percentage). Age, years since graduation, and questionnaire scores are demonstrated as mean ± standard deviation. Comparison of categorical and continuous variables was made between males and females using Chi-Squared test and independent samples T test, respectively. An association between two continuous variables was tested by Pearson correlation.

**Findings**

Overall, 263 participants who completed the questionnaire were included in the study. Among the participants, 130 (49.4%) were males, and the mean age was 43.9 ± 7.3 years. The mean time from residency graduation was 8.2 ± 4.1 years and 17 individuals (6.5%) stated that they had completed a course of oral/dental hygiene during their residency.

The mean score was 5.9 ± 1.7 among the studied population. Frequency of correct responses are demonstrated in Table 1 and visualized. The minimum score was 1 and the maximum score was 11. The classification of pediatricians according to questionnaire scores are shown in Table 2.

</tr>
</tbody>
</table>

Questionnaire scores were not different between male and female pediatricians (5.7 in males versus 6.0 in females; p = 0.19). Older pediatricians had higher scores but the association of time from graduation with oral/dental hygiene knowledge nearly missed signficancy (p = 0.051). The scores were similar between those who had completed a course on oral/dental hygiene during their residency and those who had not. (p = 0.168)

Discussion

According to these results, the level of pediatricians’ knowledge about oral/dental health is far from sufficient. Furthermore, only a small fraction of pediatricians reported participation in a course on oral/dental hygiene during their training. Gender and time of graduation had no significant association with the questionnaire score. Importantly, pediatricians are generally the first-line in the care of children who may have oral/dental conditions. Pediatricians are the physicians who refer children to dentists and lack of knowledge and confidence to perform a directed oral/dental exam can lead to under-appreciation of such conditions in the pediatrics practice.

A previous study of medical interns in Tehran with the same questionnaire showed that oral/dental health knowledge is inadequate among trainees and concluded that new training programs should be incorporated in the medical curriculum to address this issue. The mean score of participants was 4.87 and age, sex, and duration of training did not show any association with the score (9). Another study with a similar questionnaire was conducted among pediatrics residents of Tehran which demonstrated an insufficient level of oral/dental health knowledge in residents. Moreover, none of the participating pediatric residents had been through a course focusing on oral/dental health. The mean score 6.43 and only 27.3% had a high enough score to be considered as good dental knowledge (10).

Various reports from other studies point to the suboptimal attention towards oral/dental health of children. In a Canadian study, the authors reported that only 1.8% of pediatricians could answer all the oral health-related questions correctly, and 73.9% of them reported regularly inspecting patients’ teeth. The study concluded that lack of appropriate knowledge impedes high-quality dental care for children (12). A study from Belgium reported that pediatricians’ knowledge about oral health was insufficient and highlighted the need to improve this knowledge among physicians involved in preventive care of children. In this study, 71% of pediatricians reported to have taken part in some sort of training course for oral/dental health, and most relied on information brochures (13).

Herndon et al. studied the level of oral health knowledge in pediatricians and general practitioner and concluded that pediatricians performed better in this regard; however, both groups had suboptimal knowledge and improvement was needed. They found no direct association between training for oral/dental disease prevention and performing the recommended practices. Nevertheless, training was associated with increased confidence relating to dental issues (14). A study from India reported that while 58% of general dental practitioners were aware of early childhood caries, only 2% of medical practitioners had knowledge about this condition. Among medical professionals, older age was associated with better dental health knowledge (15).

In a study from Shiraz, the knowledge, attitude, and practice regarding dental health was assessed among general practitioners and pediatricians. A self-completed questionnaire was used for this study. There was not a significant difference between general practitioners and pediatricians in knowledge, attitude, and practice. Physicians with higher working hours, and those who worked in government-administered centers with high workloads demonstrated a higher level of knowledge and better practice. On the other hand, there was no
association between the time passed from graduation and their performance (16). These data point out that overall, pediatrician knowledge about oral/dental conditions can be improved, which could in turn lead to more focused prevention strategies with reduction in the burden of pediatric and adult oral/dental diseases and conditions. Such improvement in pediatrician knowledge is specifically important in the developing countries. It should be noted that our findings are limited by the small sample size, which was due the reluctance of specialists to complete the questionnaire.

Conclusion

According to the present study, the level of pediatricians’ knowledge about oral/dental health in children is far from appropriate. Most pediatricians in this study did not receive any oral/dental health training during their residency. Due to their central role in children’s care and the importance of oral/dental conditions in this age group, providing focused training in this subject for pediatricians seems necessary.

Clinical Characteristics and Short-Term Outcomes of Patients with Severe COVID-19

Morteza Mousavi-Hasanzadeh¹, Alireza Kamali², Fatemeh Safi³, Hossein Sarmadian⁴, Amir Almasi-Hashiani⁵

¹Researcher, Student Research Committee, Faculty of Medicine, Arak University of Medical Sciences, Arak, Iran, ²Associate Professor, Departments of Anesthesiology and Critical Care, Arak University of Medical Sciences, Arak, Iran, ³Associate Professor, Department of Radiology, School of Medicine, Arak University of Medical Sciences, Arak, IR Iran, ⁴Associate Professor, Department of Infectious Diseases, Faculty of Medicine, Arak University of Medical Sciences, Arak, Iran, ⁵Associate Professor, Department of Epidemiology, School of Health, Arak University of Medical Sciences, Arak, Iran

Abstract

We report the demographic characteristics, laboratory findings, vital signs and outcomes of 19 laboratory-confirmed COVID-19 patients who admitted to ICU; from 15 Feb to 15 March 2020 in Arak, Markazi Province, Iran. Data showed that the most common laboratory findings on first day of ICU admission, were leukocytosis (52.6%), neutrophilia (73.6%), lymphopenia (100%), anemia (100%), hyperglycemia (78.95), increased levels of INR (100%); AST (66.66%), ALT (50%) and LDH (100%). 36.36% and 45.45% of patients had elevated total and direct bilirubin, respectively but all of patients had normal range of ALK-p (Table 1). In term of vital signs (3 first days); SBP, DBP and PR did not have significant changes but O₂ saturation increased from 82.9 % to 93 % and the number of mechanical ventilated patients increased from 36.8% to 73.3%

Keywords: COVID-19, Arak, Laboratory findings, Vital signs

Introduction

Corona virus can damage the respiratory system and about 26% of patients with Covid-19 need intensive care unit (ICU) care (¹). At presents, Covid-19 has a substantial morbidity and mortality and is known as a global threat (²). Due to the lack of information, we report the demographic characteristics, laboratory findings, vital signs and outcomes of 19 laboratory-confirmed COVID-19 patients who admitted to ICU; from 15 Feb to 15 March 2020 in Arak, Markazi Province, Iran.

Materials and Method

Our data were obtained from two hospitals affiliated to Arak University of Medical Sciences in the center on Iran. Oropharyngeal samples were collected and tested by COVID-19 RT-PCR at Arak laboratory for symptomatic cases. RT-PCR was done according to the same protocol described by National Institute for Viral Disease Control and Prevention (China). Data were analyzed using Stata software version 13.

Findings

The mean age was 71.53 (S.D: 10.87, range: 52-92) years that 52.63% of them were male, 78.95% of individuals have past medical history (DM; 56.25%, HTN=IHD= HLP; 15.78%). The most common clinical and computed tomography (CT) manifestations were shortness of breath 76.92%, fever 69.23%, cough 61.54%, myalgia 30.77% and bilateral mixed ground glass opacities with consolidations 57.89%. The most common laboratory findings on first day of ICU admission, were leukocytosis (52.6%), neutrophilia (73.6%), lymphopenia (100%), anemia (100%), hyperglycemia (78.95), increased levels of INR (100%); AST (66.66%), ALT (50%) and LDH (100%). 36.36%
and 45.45% of patients had elevated total and direct bilirubin, respectively but all of patients had normal range of ALK-p (Table 1). In term of vital signs (3 first days); SBP, DBP and PR did not have significant changes but O2 saturation increased from 82.9 % to 93 % and the number of mechanical ventilated patients increased from 36.8% to 73.3% (Table 2).

The mean of Hospitalization, ICU stay, time from hospital to ICU admission and intubation period were 8.36 (S.D; 4.70, range; 1-17), 5.73 (S.D; 4.66, range; 1-16), 2.57 (S.D; 3.0, range; 0-10 days) and 4.52 (S.D; 5.48, range; 0-17) respectively. Besides, only one patient extubated from mechanical ventilation (intubation period; 6 days) and discharged from ICU. Among died patients, super infection (e.g. bacterial, fungal and etc) weren’t seeing in any patients. Of these patients, 1 patient (5.26%) has been discharged and eight patients (42.1%) are active patients and case fatality rate (CFR) was estimated 52.63% (95%CI: 29.2-74.9%).

**Discussion**

Most of the COVID-19 patients who admitted to ICU were old and male and had liver injury (hepatocellular form), and also like available studies on COVID-19 patients (3-5), presented with leukocytosis, neutrophilia, lymphopeni and high level of AST, ALT and bilirubin. Liver injury in sever patients with COVID-19 is higher than mild one (6) and it seems this virus affected liver and maybe through this way induces sever or lethal condition. That’s why, above factors which can consider as prognostic factors in COVID-19 patients. Besides, the most common initial symptoms and CT findings of them were shortness of breath, fever, cough and bilateral mixed GGO with consolidation which confirmed by available studies. CFR in COVID-19 ICU patients was estimated 52.63% and the number of mechanical ventilated patients increased that maybe indicate an exacerbation of pulmonary involvement and can be a cause of high mortality in ICU. In the end, according to past evidences that have showed the SARS-Cov is naturally neuroinvasive (7-9) and induces neuron death in animal model (10), also according to limitation in data about neurological problems in COVID-19 patients, the sudden cardiac arrest of these patients and no responsivenes of them to cardiopulmonary resuscitation (CPR) can because of central nerves system involvement. This our hypothesis needs to future wide investigation in COVID-19 patients.

**Conclusion**

The mortality rate is too high in ICU admitted patients and the results suggested that past medical history has an important role on COVID-19 mortality rate.

**Ethical Clearance:** Ethical approval for the study was provided by the Ethical Committee of Arak University of Medical Sciences (IR.ARAKMU.REC.1398.333).

**Source of Funding:** Vice chancellor of research and technology of the Arak University of Medical Sciences was funded the study. The funder has no role in data collection, analysis, interpretation and manuscript drafting

Assessment of Diabetes Patient Adherence to Dietary Recommendation in Diabetics Center in Al-Najaf City

Iman Qasim Kteo Al-hussein1, Zahraa Abdull Abbass Taher Al-Khafajy1, Haider Mohammed Haloob AL-Abedi 1, Athraa Abbas Al-Zeyadi2

1M.Sc. Adults Nursing, Faculty of Nursing, University of Kufa, 2M.Sc. Maternal and Newborn Health Nursing

Abstract

Objective: This study aimed to assess of diabetes patient adherence to dietary recommendation in Diabetics center in Al-Najaf city and to find out the relationship between the diabetic patient adherence to dietary recommendation and their demographic and clinical data.

Methodology: Descriptive analytic design was carried out to assess of diabetics patient adherence to dietary recommendation in Al-Najaf City/ Health Directorate of Al-Najaf Al-Ashraf / Al-Sadder Medical City / Al-Najaf Center for Diabetes and Endocrine. The study was carried out from February 1st, 2018 up to March 28th, 2018. A non-probability (accidental) sampling technique was used consisting of (100) female and male those who visit Al-Najaf Center for Diabetes and Endocrine. Data collected through using of a well-designed questionnaire consist of three parts: Part I: Socio-demographic Characteristics, Part II: Clinical Data: consists of (6) items and Part 111: Patient adherence to dietary recommendation. This part of the questionnaire consists of (16) items.

Conclusion: It is concluded that the Majority of the stay sample have fair adherence to diabetics dietary recommendations.

Recommendation: Based on study conclusion, its need for a good relationship between the patient and health-care provider in order to provide more understanding and knowledge about the disease and its non-medical management and diabetic’s patients need dietary recommendations with means of education, such as published materials with regard to dietary regimen.

Keywords: Diabetes, Patient, Dietary Recommendation, Diabetics Center

Introduction

Diabetes mellitus (DM) consist an enormous public health problem globally, associated with high morbidity and mortality [1]. Normally, a certain amount of glucose circulates in the blood. The major sources of this glucose are absorption of ingested food in the gastrointestinal tract and formation of glucose by the liver from food substances. Diabetes mellitus (DM) is a chronic progressive metabolic disorder characterized by hyperglycemia mainly due to absolute (Type 1 DM) or relative (Type 2 DM) deficiency of insulin hormone [2]. The exact mechanisms that lead to insulin resistance and impaired insulin secretion in type 2 diabetes are unknown, although genetic factors are thought to play a role. Regardless of the specific cause, the destruction of the beta cells results in decreased insulin production, unchecked glucose production by the liver and fasting beta cells cannot keep up with the increased demand for insulin, the glucose level rises and type 2 diabetes develops. Despite the impaired insulin secretion that is characteristic of type 2 diabetes, there is enough insulin present to prevent the breakdown of fat and the accompanying production of ketone bodies [3]. The treatment of diabetes should start with non-pharmacological therapies such as lifestyle interventions. Diet plays a major role in the therapeutic strategy to keep patients with diabetes in good glycemic control and prevent micro and macro vascular complications [4]. According to the American Diabetes Association (ADA) and the European Association for the study of Diabetes
(EASD) prescribed dietary recommendations for the treatment of this disease since many years [4]. Type 2 Diabetes is defined as chronic hyperglycemia resulting from either decreased insulin secretion, impaired insulin action or both in the absence of autoimmune destruction of the pancreatic beta cell. Classically, type 2 diabetes occurs in the older, obese patients in the setting of strong family histories of diabetes and in association with other components of the metabolic syndrome [5]. Unhealthy practices and perception for diabetic patients can lead to increase the effect of the disease and complications which can be prevented. The diabetic complications such as nephropathy and retinopathy and neuropathy can affect the quality of life of the patients and can lead to a significant effect on patient’s quality of life and productivity [6]. Healthy dietary habits and lifestyle modifications the cornerstones of type 2 diabetes prevention and management [7]. Adherence to lifestyle modification recommendations lessens the disease burden and reduces the morbidity and mortality associated with type 2 diabetic complications [8].

Methodology

Design of the study: Descriptive analytic design was carried out to assess of diabetics patient adherence to dietary recommendation in Al-Najaf City/ Health Directorate of Al-Najaf Al-Ashraf / Al-Sadder Medical City / Al-Najaf Center for Diabetes and Endocrine.

Study objectives: This study aimed to assess of diabetics patient adherence to dietary recommendation in Diabetics center in Al-Najaf city and to find out the relationship between the diabetic patient adherence to dietary recommendation and their demographic and clinical

Duration of the study: The study was carried out from February 1st, 2018 up to March 28th, 2018.

Sample of the Study: A non-probability (accidental) sampling technique was used consisting of (100) female and male those who visit Al-Najaf Center for Diabetes and Endocrine. The Study Instrument: Data collected through using of a well-designed questionnaire consist of three parts: Part I: Socio-demographic Characteristics: This part consists of (7) items, including (gender, age, and marital status, level of education, occupational status, residency and socio-economic status) and Part II: Clinical Data: consists of (6) items, including (duration of disease since diagnosis, treatment, health education regarding self-care activities, complications, smoking and body mass index). Part 111: Patient adherence to dietary recommendation. This part of the questionnaire consists of (16) items, the items include assessing patients’ adherence to dietary recommendation.

Ethical consideration: This is essential value and should be obtained before collecting the information, to respect the patient’s dignity and values. The investigator can achieve this permission from the moral committee at the Nursing Department in the faculty of Nursing / University of Kufa. Also another agreement from Al-Najaf Al-Ashraf Health Directorate / Al-Sadder medical city / Al-Najaf Center for Diabetes and Endocrine. In addition to above, the researcher told each participant that this is an involuntary work, and they can leave any time even the interview process uncompleted.

Questionnaire Validity: The questionnaire validity faces validity for the initial developed instrument which is specified through panel of (5) experts (4) Experts from faculty of Nursing/University of Kufa (with experience of > 5 yrs at their jobs field). Who were asked to review the instrument, and to inspect relevancy, clarity, and sufficiency of the questionnaire to measure the concept of interest. The data was collected through the applying of the developed questionnaire with aid of structured interview technique with the subjects as they are individually interviewed. The data collection process started from March 1st, 2018 to March, 20th, 2018.

Statistical Analysis: In this study, the data were analyzed by using of (SPSS) program version 19 (Statistical Package for Science Service), and the statistical package (Excel 2013).

Related to table (4) there were good relationships between the patient (occupation, type of treatment and complications) with their adherence to dietary recommendations.
Discussion

According to (Table 1) in the results, the study shows that the entire study sample (54%) are male. The finding is consistent with results of [9] which mentioned in their study result that majority of the study subject were male. Regarding their age, the majority (86%) of the research samples are at age group of (50) yrs and more. This result is in agreement with other study [10] in their study found that a third of the participants, (26.9%) aged 50 to 59 years. Concerning the marital status the majority (86%) of the study subjects are married. This finding reinforced with the study result of [11] which mentioned majority of the study sample were married. In related to the level of education the most of the study samples (31%) are illiterate while regarding the diabetic patient occupational status, about (45.0%) are house wife. These results matching with the study result of [8]. Concerning socio-economic status, about half of the sample (47%) reveals their economic status that is barely sufficient, while concerning the residency the study result show that highest percentage (84%) of the study sample are lived in urban area. These result reinforced with the study of [2] which mentioned that 80% of people with diabetes live in low- and middle-income countries

Concerning duration of disease in the (table 2), the higher percentage (56%) is for those who are suffering from the diabetic for period from 10 years and more. This result comes along with the findings of other study which is carried out by [12].

Regarding the type of treatment, the results of the study display that the highest percentage (34%) of the study subjects are with oral hypoglycemia treatment. This result matching with the study result of [9] which mentioned the majority of participants were taking oral hypoglycemic medications. The present study shows that in regards to the education related to self-care, the most of the study subject (72%) are not received education related to self-care. This finding may related to the lack of nursing education and instruction to the patient about the dietary and exercise recommendation for the management of the diabetic disease and to reduce the complications related to disease. Related to the smoking, the majority of the study samples (84%) are not smoker. These findings matching with the study done by [13] who represents the majority of their study sample were not smoker. In regard to the study subject body mass index, the most of the study subject (38%) are overweight. These result agreements with the study finding done by [14] that represent the majority of their sample were overweight. Concerning the complications related to disease, the highest percentage of the study sample suffers from Neuropathy & Eye problems.

According to the above (table 3) in the result, the overall assessment of diabetic’s patient adherence to dietary recommendation is fair. This outcome is reinforced by a study done by [12] who concluded in their study results that the level of adherence to dietary recommendations in the study group was moderate

Table (4) in the result shows that there are high significant relationship between two items (occupation and treatment ) and patient’s adherence to dietary recommendation at p-value less than 0.05, in addition there were significant relationship between the complication related to the disease and patients adherence to dietary recommendation at p-value less than 0.05. While there are non-significant relationship between the other items of diabetic patients demographic and clinical data and their adherence to dietary recommendation at p-value more than 0.05

Conclusions:

It is concluded that the most of the research sample are male and their dominant age are within 50 years and more, the most of them are illiterate. It was summaries that the most of the study sample taking oral-hypoglycemia medication, most of them not received education related to the disease and their dietary recommendation and in regard to their BMI it’s concluded that most of them are overweight. It is concluded that the Majority of the stay sample have fair adherence to diabetics dietary recommendations. It is concluded that there are significant relationship between the patient (type of treatment, occupation and complication related to disease) and their adherence to dietary recommendations.

Recommendations:

Based on study conclusion, its need for a good relationship between the patient and health- care provider in order to provide more understanding and knowledge
about the disease and its non-medical management. Encourage the diabetic patients who visit the diabetic center to follow the healthy dietary recommendations. Diabetic’s patients need dietary recommendations with means of education, such as published materials with regard to dietary regimen. It is recommended to design proper booklet by the diabetic’s center to guide the visitors about the non-medical management of diabetic’s disease.

The Application of an Indigenous Polymer for the Plastination of Teaching Anatomical and Biological Specimens

Alaa A. Sawad

Prof., Department of Anatomy, College of Veterinary Anatomy, University of Basrah, Basrah, Iraq

Abstract

Plastination was fabricated in 1978 by Dr. Gunther Von Hagens at the University of Heidelberg, Germany, which kept for the good conservation of anatomical and biological material. The present goal was to utilize a cost-effective plastination polymer as compared to the standard S10 technique using silicone polymers. The S10 is the original silicone polymer used for the preparation of plastinated specimens and whole dissecting body.

Specimens were fixed in formalin 10%, dehydrated and decreasing in acetone, and at last, impregnated by local commercial unsaturated polyester resin and ultimately hardening at 50 °C temperature.

The plastinated specimens were clean, durable, odorless, portable and non-toxic, it can be kept for long durations without any changes. The usage of widespread S10 silicon method is high costs so with the aid of using indigenous chemicals it is possible to produced low costs anatomical models for education and for studying anatomy.

Keywords: polyester resin, education, impregnation, formalin, plastination.

Introduction

In the plastination technique, the water and lipids in biological and anatomical tissues are substituted by a curable polymer. The hardener polymer give, dry, odorless, durable, and devoid of noxious effects of formalin specimens. The first innovate of the plastination at the Anatomical Institute of Heidelberg university, Germany by Dr. Gunther Von Hagens in 1979.

In the last years plastination a large evolution take place in which gross anatomical and biological educations.

The plastination laboratory was designed and established at the College of Veterinary Medicine, University of Basra since 2013 and has produced good quality plastinated specimens.

Generally the polymers that used are the silicone, epoxy or polyester resins which hold the specimens in a dry, odorless state with minimal aftercare.

The main disadvantage of using formalin for fixation and preservation of tissues are that they are fripper when its handled, with difficulty transportation and troubles of spillage. In addition to its toxicity. However, formalin is still the main preservative of tissues due to its low costs, the plastination technique applied polymers which are forcefully impregnated into the tissues to get stable and free from deterioration specimens. They can easy handled and not brittle like the formalin preserved tissues.

The methods in plastination includes of four steps – fixation, dehydration, forced impregnation in a vacuum and hardening, many curable polymers used in this process.

An indigenous polyester resin was used in this procedure was cheaper, with the same efficiency in comparison with standard silicon S10, and it was a motivating materials when compared to other teaching aids like wet specimens, glass and wood models. The plastination is being used as a method of preserving specimens and anatomical organs at the College of...
Materials and Methods

In the college of veterinary Medicine, University of Basrah, Indigenous polymer has been convenient for preservation of anatomical specimens and organs since 2013.

The procedure includes, Fixation, Dehydration, Forced impregnation, and hardening

Fixation

Anatomical specimens were fixed before plastination to avoid corruption and prevention the action of other enzymes. Whole fixation of the sample were very important to the final quality of a plastinated organ, the plastinated specimens that have been fixed in 10% formalin for several days according to its size, this gave the tissues steadiness and stops autolysis. The fixed organs were washed in clean water to rub from excessive fixative.

Dehydration

After formalin fixation the specimens were put in acetone for dehydration. There were three changes of acetone, each for three weeks, In this step, the acetone displaced gradually instead the water in the tissues. The volume of acetone should was 5-10 times than the volume of the specimens. Acetonometer (Fig1) was used every day to monitor the specific gravity of acetone and the level of dehydration. When the concentration stabilized at 98% the dehydration became complete.

Forced Impregnation

Acetone saturated specimens were transfer into a large vacuumed chamber (Fig2) and submerged in locally obtained polyester resin (Fig3) at freezer temperature 10-25°C (Fig3) gradually the vacuum raised till reached 5 mm Hg using vacuum pump and vacuum gauge (Fig4). Pressure can be controlled by adjustment of a shutoff valve in the line between the pump and chamber to stabilized the level pressure at the chamber. Impregnation checking by showing the acetone bubbles released from the polymer surface due to its lower boiling point +56°C, the indication to be complete when the acetone bubbles stopped liberation the specimens are taken out of the vacuum chamber. The excess resin is exsiccating.

Heat hardening

After complete impregnation the specimens cured in a heat treatment at 50°C temperature for curing, final curing in an oven take about 7-10 days depending at the size of the specimens.

Results

The plastination method can be used for whole body or organs, in human and animals, for Anatomical, pathological and surgical specimens in addition to biological samples such as parasites and insects (Fig:5). The advantage of this methods to obtained odorless dry and sturdy actual biological specimens (Fig:6), Non-toxic and can handles easy without gloves, preservation anatomical specimens without the usual problems such as moistened specimens, mold and not required special storage climate. By this method the students conceived to use of Plastination specimens in the dissection room to be helpful to anatomical education and it’s a good and enjoyable method improved to understanding the anatomy for students and provides an additional tool for long-term maintenance for anatomical education.

Fig. 4: vacuum pump for dehydration and forced impregnation
Discussion

The first foundation of plastination laboratory in Iraq and production of resin specimens at the college of veterinary medicine, University of Basrah. These characteristics are similar to 9 which mentioned that the plastination laboratory in the College of Veterinary Medicine at the University of Basra, Iraq, was designed and built to use the standard S10 method of plastination.

Plastination technique can be applied for whole body or organs, in human and animals, for anatomical, pathological and surgical specimens in addition to biological samples such as parasites and insects, that in comparable with plastination has become an important means of preservation of organs, for well dissected specimens 8. The specimens obtained in our methods were dry, odorless and non-toxic that can handled easy without gloves, its in agreement with 11 plastination technique has yielded dry, odorless and durable plastinates which are useful as an adjunct for demonstration at museums. Plastication was good and enjoyable method improved to understanding the anatomy for students and museums 6 explained that the specimens serves as a great aid for understanding anatomy of different organs.
in their original form with any disturbance of smell.

Abstract

Introduction: - Chronic inflammation is a basic feature of end stage kidney disease and is associated with increasing risk of mortality and morbidity in patients undergoing dialysis. The aim: - the study amid to evaluate white blood cells and IL-6 in patients undergoing hemodialysis and without hemodialysis. Methods and Subjects: - The study was designed on 106 patients with chronic renal failure age range (20-69 years). The patients divided in two groups according to treatment, 40 patients with conservative treatment and 66 patients with hemodialysis treatment. IL-6 were determined by using a commercially available ELISA Micro wells kit. Total white blood cells count and differential count were determined by using an automated hematology autoanalyzer XT2000i. Results: - showed a significant (p<0.05) decrease of total white blood cells count, neutrophils, lymphocytes, monocytes, eosinophils and basophils in hemodialytic group when compared with conservative group. But IL-6 levels was higher significantly (p<0.01) in hemodialytic group when compared with conservative group. Conclusion: - hemodialysis session impaired immune system and activated anti-inflammatory factors.

Keywords: - Hemodialysis, Conservative treatment, Chronic inflammation

Introduction

Chronic kidney disease (CKD) is a life-threatening disorder often related with hypertension, kidney dysfunction, progression to kidney fibrosis, and eventual chronic renal failure [1,2]. Chronic inflammation is a basic feature of end stage kidney disease and is associated to an increasing risk of mortality and morbidity in patients under hemodialysis [3, 4, 5]. Patients with hemodialysis treatment, have an increased susceptibility to infectious diseases compared with healthy subjects [6, 7]. White blood cells play important function in host defense mechanism against infectious diseases [8].

The three mechanisms stimulation of the pro-inflammatory system may be occurs in hemodialytic patients: inflammatory response stimulated by bio-incompatible dialysis membranes, contact to local fistula and graft infections and contact to contaminated dialysate containing cytokine-inducing substances such as endotoxins [5] On the other hand, membrane adsorption of cytokines and clearance through HD session may be change circulating cytokine levels [9]. Some of inflammatory marker could be used in medical practice that include interleukin-6 secreted from activated endothelial cells, monocytes, adipocytes, fibroblasts and macrophages as a result to several stimuli, such as bacterial endotoxins, IL-1b, tumor necrosis factor (TNF-a), oxidative stress and physical exercises. The main effects of IL-6 are result of its level in the circulation and take place at distinct positions and far from its origin [10]. The possible causes of raised IL-6 levels in ESRD diseased people may be belong to the losing of renal function and some factors are related with hemodialysis [11].
The aim: The aim of this study was to evaluate white blood cells and IL-6 in patients undergoing hemodialysis and without hemodialysis.

Subjects and Methods

The study was conducted on 106 patients with chronic renal failure age range (20-69 years).

The patients were divided into two groups according to treatment, 40 patients with conservative treatment (12 Males and 29 Females) and 66 patients with hemodialysis treatment (44 Males and 22 Females). IL-6 were determined in serum of all patients by using a commercially available ELISA Micro wells kit from Diaclone France. Total with blood cells count and differential count in whole blood of all patients were determined by using an automated hematology autoanalyzers XT2000i (from sysmex, Japan).

Statistical Analysis

SPSS version 20 was used as Statistical analysis. The results comparison assessed by student t-test.

Results

The results illustrated total white blood cells count, neutrophils, lymphocytes, monocytes, eosinophils, and basophils showed the normal range (4-10 x 10^9 / L, 2-7 x 10^9 / L, 1-3 x 10^9 / L, 0.2-1 x 10^9 / L, 0.0-0.5 x 10^9 / L and 0.0-0.1 x 10^9 / L) respectively in conservative group (7.7±0.3 x 10^9 / L, 4.8±0.3 x 10^9 / L, 1.9±0.1 x 10^9 / L, 0.5±0.0 x 10^9 / L, 0.2±0.0 x 10^9 / L, 0±0.0 x 10^9 / L) and in hemodialytic group (5.7±0.2 x 10^9 / L, 3.6±0.1 x 10^9 / L, 1.4±0.0 x 10^9 / L, 0.4±0.0 x 10^9 / L, 0.1±0.0 x 10^9 / L, 0.0±0.0 x 10^9 / L) respectively. However total white blood cells count, neutrophils, lymphocytes, monocytes, eosinophil and basophil decrease significantly (p<0.05) in hemodialytic group when compared with conservative group. IL-6 levels were in conservative group (16.4±3.4 pg/ml) and in hemodialytic group (26.0±5.96pg/ml), rise than the upper limit of the normal rang (5-15pg/ml), The IL-6 level was higher significantly (p<0.01) in hemodialytic group when compared with conservative group. As showed in table below.

Discussion

Our current study shows white blood cells count and differential count decreased significantly in hemodialytic patients, but they were within normal ranges. That uremia related to immune dysfunction has been seen in some researches. However, abnormal immune dysfunction are recorded because of uremic toxins [12]. Prevalence of the studies focused on the abnormal dysfunction of WBC. Minnaqanti and Cunha pointed that subjects showed renal disorders impair defense of host [13]. Baqdasarian et al showed subjects with kidney disease on dialysis counter with infection which is a major cause of mortality and morbidity [14]. The studies revealed that there is a relationship between renal disorder and infection. Hayder et al., reported that total WBCs were decreased significantly at the ages 40-60 years of 111 CRF on dialysis, while total WBCs reduced statically in 50 CRF of HD patients [15]. Suresh et al., has been perceived that the total white blood cells are decreased in HD patients than the control. The specific mechanism by which chronic renal disease leads to a slight decrease in total white blood cells count is not clear. The possible hypothesis is as follows in chronic kidney failure patients undergoing dialysis, in the dialyzer, exposure of blood to artificial membranes may result in complement activation in vivo [16]. Agrawal et al., have recorded that antigen presentation dendritic cells decreased in uremia [17]. Decreasing number of B lymphocytes capacity for producing antibody have been recorded in uremic subjects by Pahl et al., [18]. Depleting of naïve and memory T cells in uremic cases has been recorded by Moser et al [19]. The total and differential count showed significant differences but values were within limit of the normal ranges that normal total and differential WBC count in one study was seen in majority of cases (28 cases 87.5%). Four cases (12.5%) revealed increased WBC count and neutrophilia, that the etiology of chronic renal failure was included type-II diabetes mellitus 8 cases (25%) obstructive uropathy 5 cases (15.62%), hypertension 3 cases (9.37%) and renal tuberculosis 1 case each (3.125%) and in remaining 14 cases etiology was not known [20]. While Agarwal and Light had reported that Patients with CKD had more eosinophils and granulocytes and less lymphocytes. Over time, granulocytes rise and lymphocytes reduced in those with and without CRD. In addition, in those with CRD, over time monocytes increased and eosinophils decreased [21].

IL-6 were as an immunological Parameters that cytokines are released in the course of HD session mainly by monocytes, and factors responsible for monocytes activation include endotoxins that may be present in dialysate fluid, activated complement and dialyzer membrane itself [22]. The physical interaction between artificial dialyzer membrane and some compounds in dialysate fluid leads to activation of alternative pathway of complement. The type of dialyzer membrane is critical in this course [23]. Our results of study showed serum concentrations of IL-6 are increased in hemodialysis patients. Several studies reported unchanged serum IL-6 during HD concurrent with increased clearance or membrane adsorption of these cytokines [24]. The reasons for this phenomenon maybe depend on cytokine kinetics. The half-life of IL-6 (3-7 min), are seem to be short..Plasma cytokines are quickly bound to cell surface receptors, this suggests that stable plasma concentrations are achieved by a continuously high production rate. As a consequence, the entire amount of cytokines potentially removed via hemodialysis is maybe significantly lower when compared with the endogenous production [25]. It is not unlikely that the serum concentrations of cytokines serve as target of feedback mechanisms, since their endocrine function has been displayed, apart from paracrine functions [26]. Thinking that adsorption of cytokines happens mainly in the first minutes of HD and may not reflect a substantial amount of cytokine elimination [25]. HD membranes may rise cytokine production by activating mononuclear cells [27].

Conclusion - hemodialysis session impaired immune system and activation anti-inflammatory factors.

Medical Induction of First Trimester abortion by Misoprostol or Misoprostol with Letrozole

Myasar Jasim Mohammed AL-taie¹, Enas Jaleel Alobaidy², Hayder Abdulhafedh Kurji ³
¹Lecturer, Department of Anesthesia Bilad AL-Rafidein University College, Iraq, ²Assist. Prof., Department of Obstetrics and Gynecology, College of medicine, University of Al-Diyala, Iraq, ³Lecturer, Department of Pharmacy, Bilad AL-Rafidein University College, Iraq

Abstract

Background: Managing of abortion is an important subject in gynecology. Millions of patients had suffered from spontaneous abortions that occur per year.

Objectives: The aim of this study was to compare the effect of misoprostol alone and misoprostol with letrozole in the induction of abortion in the first trimester of pregnancy.

Patients and Methods: In a single –blind clinical trial, 128 female applicants for legal abortion within the first trimester of pregnancy that referred to AL-Batool hospital, were divided in to two groups: intervention (misoprostol with letrozole) and control groups (misoprostol alone). The complete abortion, drug-induced side effects of misoprostol and letazole were noted and evaluated.

Results: The complete abortion rate was 93.2% in intervention group and in 68.7% in the control group (misoprostol) only, which was significantly higher in intervention group (p = 0.001).

Abdominal pain in the intervention group is also significantly lower than that of the control group (p = 0.013). Intervention group also had significantly lower duration of bleeding rather than control group (p = 0.006).

Conclusions: Based on our results, pretreatment with letrozole plus Misoprostol was more effective for prompting abortion in the first trimester of pregnancy without increasing side effect compared to misoprostol alone.

Keywords: Letrozole; Abortion, Induced; Misoprostol, Pregnancy, First rimester;

Introduction

Regarding the national center of vital statistics, centers for disease control and prevention and the world health organization definition, abortion is the termination of a pregnancy before the 20th week of pregnancy or termination of pregnancy before the fetus weighing 500 g (¹, ²).

Abortion managing is an important subject in gynecology. Millions of spontaneous abortions happen, and more than a million of induced abortions are occur yearly either by drugs or surgical techniques. Definitive treatment for abortion is a surgical practice yet it is invasive and costly, is not required for all females.

According to the American college of obstetricians and gynecologists (2005), medical abortion is an suitable alternative for surgical techniques in pregnant women with gestational age of less than 49days founded on the last menstrual period (LMP) (³).Spontaneous abortion happens in 10% - 20% of whole pregnancies, while, 80% of abortions occur earlier the 12th week of pregnancy. (⁴)

In medical therapy, abortion done by various drugs, considering mifepristone drugs has limited access, its high cost, it is not available in most of the countries and alternative drugs are used to induce abortion (⁵). One
of these drugs which used both vaginally and orally is prostaglandin E1 analogue, misoprostol, which is Known as Cytotec trade mark. Misoprostol is a cheap drug which could be kept in room temperature and usually used as vaginally and orally \((6)\). Misoprostol is widely used for induce of labor, softening of the cervix, curettage, hysteroscopy, therapeutic abortion, endometrial biopsy, early termination of pregnancy, treatment of incomplete abortion or missed abortion and treatment of postpartum hemorrhage \((3)\). Use of 800 mcg of vaginal misoprostol results in abortion by exciting the myometrium \((7)\). Oral or vaginal rout of administration of misoprostol cause complete abortion in nearly 85% of cases within seven days before the 12th week \((6,7)\).

Letrozole is a non-steroidal aromatase inhibitor for the treatment of estrogen-dependent breast cancer. Estrogens are required for continuation of the pregnancy. Letrozole is competitive reversibly bonds with cytochrome P450 and inhibits the production of estrogen by the enzyme aromatase. Aromatase inhibitors are commonly used to treat patients with breast cancer \((8-9)\).

Aromatase inhibitors have no androgenic, progesterone and estrogenic effects. It seems that aromatase inhibitors, such as letrozole, can open a new path and be a significant therapeutic option in the treatment of females. Letrozole is an aromatase inhibitor that can amplify the effect of misoprostol in first trimester abortions. Aromatase is an enzyme that is secreted from the placenta, ovarian granulosa cells and other tissues, such as fat, muscle, brain and breast tissue. Letrozole has been used in the treatment of estrogen-dependent breast cancers \((7)\).

**Materials and Methods**

In a single-blind randomized, A 128 women were included in our study, study protocol was approved by the Ethics Committee of Diayla university, Diayla medical college, during June 2016 to April 2018, Considered as two groups of intervention and control after consent of patient and her spouse to participate in the study, who age above 18 years old were referred to AL Batool Teaching hospital .

Inclusion criteria were involved:

1. Age of patient over 18 years old.
2. Gestational age less than 64 days gestation, missed abortion. (<9 wks).
3. Hemoglobin >10 g/dL.
4. Absence of any maternal illnesses such as: heart disease, asthma, past history of thromboembolism, cancer, renal failure, and liver illnesses.

Where exclusion criteria as followed: any medical problematic in patient which necessity to interfere and emergency management, history of allergy to misoprostol or letrozole drugs or Coagulopathy problem.

A 128 patient divided into two equal group, Sixty-four patients in intervention group and 64 patients in control group. In intervention group to encourage drug abortion, patients first received 10 mg letrozole per day orally for 3 days, then they received 600 microgram oral misoprostol as single dose. While in control group patients first daily established placebo of letrozole similar intervention group and then 600 microgram single dose oral misoprostol was used. In both groups, patient who had spontaneous abortion before starting treatment of misoprostol in the first three days of study, were excluded from the study.

Patients in both groups hemoglobin levels were examined at the beginning and end of the study. Serum estradiol levels were measured at the beginning in control group and measured at the beginning and before taking misoprostol in intervention group.

Both groups were checked for 4 hours after receiving single dose of misoprostol and were observed for probable side effects such as abdominal cramp or possible bleeding, and in terms of absence of abdominal cramp or severe bleeding, were released after explanation risk and threatening signs such as bleeding more than normal menstruation.

Subsequent visit and monitoring of patients in both groups was showed 15 days later and response to treatment and complete abortion, amount and period of bleeding, drug side effects such as nausea, vomiting, diarrhea, headache, dizziness, pain in the lower parts of the abdomen, and ague all were detected and ultrasound to perform in both groups to check uterine cavity and measuring the hemoglobin level. If remnants of pregnancy or failure in termination of pregnancy,
repeated doses of misoprostol or curettage can be done. In both groups of control and intervention were put in two categories of response to treatment and failure in response to treatment.

Statistical analysis was done by SPSS, software package version 16.0 for windows (SPSS Quantitative data were accessible as mean ± standard deviation (SD), while qualitative data were established as frequency and percent (%). To compare qualitative variables chisquare statistical test was used and to relate quantitative variables between two considered groups independent T-test was implemented. Also to associate intra-group quantitative variables such as hemoglobin, paired T-test was applied. Significance level was considered as p < 0.05.

Generally comparing both groups in expressions of duration of bleeding, intervention group had significantly lower duration of bleeding rather than control group (p = 0.006)

Discussion

Medical abortion reduce side effects such as bleeding and infection, and also stress in patients, relating with surgery. In medical abortion technique it is possible to use several drug regimens to induce abortion. Misoprostol is a prostaglandin analog and a benign and cheap drug which is used for inducing medical abortion and frequent studies have shown its efficiency\(^{10, 11}\).

In a pilot study, in persuading abortion in 40 legal below r-63-day abortion cases, 7.5 mg letrozole for 2 days, and then usage of vaginal misoprostol leads to preform abortion in 80% of patients and comparing with Mifepristone, using of letrozole with misoprostol together was more efficient than combination of letrozole and mifepristone\(^{12}\). In the present study also success rate of complete abortion was higher in using misoprostol and letrozole comparing with using misoprostol alone (p = 0.001).\(^{11, 12}\)
In a prospective study success rate in prompting abortion for 56-day or less pregnancies using single dose misoprostol vaginally, was informed 72%. Also this study claimed that in case of failure in access to mifepristone, using misoprostol only clinically could lead to suitable outcomes (13). Also a evaluation of this study has revealed that in treatment of missed abortion in the first trimester of pregnancy by misoprostol, 800 microgram misoprostol as single dose per vagina or 600 microgram single dose sublingual misoprostol are good substitutes for surgery. This study also expressed that after advising misoprostol there was no necessity for hospitalization and patients would refer in case of severe bleeding or infection (14). In the current study also frequency of complete misoprostol for using misoprostol alone was 68.75%, and in case of lack of admission to another drug, using this drug had suitable outcomes similar other studies (13,14).

In a pilot study, up to the ninth week of pregnancy in 50 person, a single dose of 200 mg mifepristone and 10 mg letrozole per day for 3 days, and lastly 800 microgram single dose 1 misoprostol per vagina, were used to persuade abortion rate of complete abortion in this study was 98%, and also no significant side effects were informed (15).

Similar to recent study, in a clinical trial, on 168 women below -63-day pregnancy age, letrozole treatment before misoprostol was examined. Success rate in complete abortion in letrozole getting group was significantly higher than that of group getting misoprostol alone. Between side effects, vomiting was significantly more in letrozole group than in control group (16). In current study using letrozole did not lead to rise in side effects and even abdominal pain and bleeding time in intervention group was significantly lower than that of control group. Also abdominal pain in letrozole receiving group was lower than that of control group. Finally numerous new studies express that, implementing effective drug regimens for inducing abortion is more affordable and risk free than methods such as vacuum aspiration (19, 20), which should be paid attention by physicians.

Abstract

Current study was happened in Bâqubah province for kidney failure patients (in Ibn Sina Center) for dialysis in Bâqubah teaching hospital and started from September (2016) to March (2017). (100) samples of blood collected from patients of renal failure, males number (61) and females (39) with age range (10–88) years and collected (50) samples of blood from healthy individual have been accredited as group control, males number (25) and females (25) with age range (10–88) years. Result of current study appeared that the ratio of disease rate among males (61%) than females (39%) with no significant different between groups (P>0.05). Result of biochemical parameters expressed increased levels of B.urea, and S.creatinine For patients when compared with control with significant different between groups (P<0.05), so uric acid was raised For patients when compared with control but with no significance different between groups (P>0.05), either albumin and total protein parameters were lowest For patients when compared with control with significance different between groups (P<0.05). The hematological parameters (HB, PCV, WBC and PLT) result were noticed decreased For patients when compared with control with significance different between groups (P<0.05). The conclusions of our study showed the percentage of male patients are more than female, age periods (31-50 and 51-70) years have high percentage of patients, low levels of all hematological parameters (HB, PCV, PLT and WBCs) in patients than controls, high levels of biochemical parameters (B.urea, S.creatinine, Uric acid) in patients than controlsm, while (Albumin and protein) were low in patients than controls. The aim of current study is detecting hematological and biochemical parameters changes in patients with Renal failure in Bâqubah province.

Key words: renal failure, biochemical parameters, hematological parameters.

Introduction

Acute renal failure appear a rapid losing in renal function leading to kidney function loss resulting and increased nitrogenous waste in blood and fluid balance. Is a common threat to people with serious illnesses in intensive care units, in addition to the mortality rate of 42% to 88% [1].

Renal failure is the kidney’s inability to remove metabolic end products from blood and dysregulation on fluid, electrolytes, and pH balance of fluids. It may be the cause of kidney disease, urinary tract defects of a non-ethnic origin, or systemic diseases and kidney failure is divided into acute or chronic. Acute renal failure is reversible damage of kidney that may be treated [1][2].

Millions People are affected by non-fatal kidney disease, urinary tract infection, blockage and kidney stones are considered to be the most important diseases observed in the kidneys. Up to 20% of all women have urinary tract infections at some time in their lives and at least 1% of patients develop kidney stones [3]. Chronic kidney disease (CKD) is a syndrome characterized by gradual and irreversible deterioration of kidney function due to the slow destruction of the kidney weft and consists of a wide range of different physiological pathological processes, which are associated with chronic renal failure, and eventually ends in death when adequate numbers of the Nephrons. Acidosis is the main problem in CRF with the development of biochemical asymptomatic and clinical uremia syndrome. Normal
renal function and progressive reduction of glomerular filtration rate (GFR)\textsuperscript{4,5}

Ki In kidney disease is associated with many hematological changes. Anemia is similar to the degree of renal insufficiency and the most important reason is the failure of renal erythropoietin secretion. In addition to chronic blood loss, blood dissolution and bone marrow fracture through retained uremic factors\textsuperscript{6}

The aim of current study is detecting hematological and biochemical parameters changes in patients with Renal failure in Baqubah province.

**Material and Methods**

Current study was happened in Baqubah province for kidney failure patients (In Ibn Sina Centr) for dialysis in Baqubah teaching hospital and started from September (2016) to march (2017). (100) samples of blood collected from patients of renal failure, males number (61) and females (39) with age range (10–88) years and collected (50) samples of blood from healthy individuals have been accredited as group control , males number (25) and females (25) with age range (10–88) years. Collected 5 ml of blood and it was left at room temperature 20-25°C to allow it to clot, then the sera was separated by centrifugation for (5-10) minutes, and sera divided into three tubes (250 µl) and stored at -20°C still examination.

**Parameters of current study**

1- Hematological parameters

The hematological parameters (HB, PCV, PLTs and WBCs) were measured by Complete Blood Count (CBC) system.

2- Biochemical parameters

The Biochemical parameters (B. urea, S. creatinine, Uric acid. Albumin and protein) were measured by Cobas 400.

**Statistical Analysis**

Chi-squared and T test are method used to analysis of current data, a level of significance of P<0.05 was applied to test, the statistics software used to process the data analysis were the (SPSS v.22)\textsuperscript{7}.

**Results and Discussion**

Results of current study showed the percentage of males more than females with non-significant difference between sex as well as two groups p>0.05 and shown as in table (1).

| Table (1) Distribution of study groups according to sex. |
|----------------------------------|---|---|
| **Study group** | **Control** | **Patients** |
| Male | 25 | 61 |
| % | 50 % | 61 % |
| Female | 25 | 39 |
| % | 50 % | 39 % |
| Total | 50 | 100 |
| p value | No Sig. (p>0.05) |
Results of current study show that the percentage of males with renal failure more than females and reasons of it may be due largely to the daily effort after exposed then women, large number of protein consume by men than women, in addition to that muscle mass in men than women leads to increase concentration of creatinine in men \[8\]. In addition, result of current study were compatible with results conducted by \[9\].

In current study the age range of renal failure patients were 10-88 years as shown in table (2). Also the current study results showed that the age periods 10-30 and >70 years recorded lowest rate of disease, while the age period 31-50 and 51-70 years recorded highest rate of disease. The age of control group range between 10-88 year and divided into groups, and found significant different between groups P<0.05 as shown in table (2).

In current study WBCs was low in patients than controls and this low was agree with study [21]. Low causes of WBCs in patients with renal failure includes:-

1- Leukocytopenia is related to inflammation.
2- High concentration of pro-inflammatory cytokines and specially TNF-α which lead to inhibition leukocytosis [21].

In addition, PLTs levels were low in current study and our study was agree with study [22] that refer two decreases levels of PLTs in patients with renal failure.

Platelets circulate in the blood of mammals and participate in blood clotting which leads to the formation of blood clots. Thrombocytopenia plays a major role in blood clot events, especially in the identification of heart disease and atherosclerosis in patients with end-stage renal failure [23].

In current study we measured the biochemical parameters in patients and control. Notice increase some biochemical parameters (B. sugar, B. Urea, Creatinine , Uric acid) in patients than control, and decrease protein, Albumin . The concentrations of B. Urea were high in patients (102.65 ± 42.98 mg /dl ) than to control (31.48±9.73 mg /dl) respectively with high different significant (P<0.05). so The concentrations of Creatinine was high in patients (5.75±2.09 mg /dl) than to control (5.31 ± 1.64 mg /dl) respectively with no different significant (P>0.05), while the protein and Albumin were low in patients (63.62±8.71 g /dl and 36.16±6.28 g /dl) than to control (70.92±5.92 g /dl and 44.52 g /dl ± 6.36 g /dl) with high different significant (P<0.05). as shown in table (4).
This study is agreed with the researches [24] which are includes high levels (Uric acid and S.urea) in patients with renal failure when compared with control group. the hemodialysis which diabetic dialysis patients ,they are more likely to develop cardiovascular disease compared with non-diabetic dialysis patients.

The results show that an increase urea level in in serum blood for patient with hemodialysis when compared with control group ,may be due to the urea is the first organic solute detected in the blood of Patients with renal failure had the most significant quantified melanin secreted by kidneys in patients. However, however, we need many research showing signs and symptoms of uremic recurrence by raising levels of soluble in patients with polina [25].

On other side result of study Urinary symptoms in patients were found to be alleviated by initiation of renal dialysis, even when urea was added to the aura to maintain the level of nitrogen in the blood at about 90 mg per deciliter [26].

The result show high level in serum creatinine for patient with renal failure when compared with control group. creatinin is an excreting substance that is produced in creatin metabolism in a nonenzymatic pathway. High level in creatinine and urea may be due to pre renal or post renal disorders [27].

Our study had several important limitations. Glomerular filtration rate (GFR)is of dises which are based on serum creatinine however, they can potentially lead to over diagnosis of chronic kidney disease [28].

In dialysis patients low serum creatinine is a marker for protein-energy wasting, which is a strong predictor of anemia and mortality in renal transplant recipients [29]. A diagnostic test to assess kidney function is used to Determination of serum creatinine. [30] show The doctors rely on plasma concentrations of waste materials from creatinine and urea. These tests are sufficient to determine whether a patient is suffering from kidney disease and help to measure the efficiency of the kidneys in filtering the blood. It also gets the amount of nitrogen and creatinine in the blood increase.

GFR is used to show how determine the stage of renal disease and guide decisions about treatment and the renal function of the patient still has. [31] Renal renal failure is caused by conditions that damage structures within the kidney - glomerular, interstitial or tubular. More common injury than common tubes is toxic in origin or ischemia. That ischemia associated with clinical failure and obstruction within the nucleus. The toxic abuse of tubular structures, acute glomerulonephritis,
acute erythema and kidney disease are the major causes of kidney failure [31].

On other hand high level in serum uric acid may be to development of renal dysfunction, a potential mechanism by U.A. Kidney disease may be exacerbated by activation of the renin angiotensin system (RAS). Research has found that RAS plays a role in worsening kidney disease by increasing the level of glomerular and systemic pressure, in addition to its direct cause of cirrhosis and damage to blood vessels and renal cells. In the early stages of hypertension that causes an increase in U.A leads to a decrease in renal blood flow which in turn causes a change in the balance between the turnover of the spinal cord and the cortical cycle, which may lead to a decrease in urate secretion [23].

A new approach toward the prophylaxis and treatment of uric acid nephropathy is the enzyme uricase, which catalyze station of uric acid causing mechanical obstruction, direct toxicity to endothelial cells and epithelial, and potentially activation of the innate immune system [27].

In this study the results show decreased signification in albumin level in patients with renal failure. This result is a gree with [34] and [33]. The effects of nutritional status and inflammatory association with the number of deaths in dialysis patients [20] and some studies show albumin level relationship increased 47% in the risk of death. The increase in death risk was partially explained by the inflammatory pathway. The albumin is negative in the acute negative phase, and the level of albumin in the serum is strongly affected by the presence of inflammatory, serum albumin measurements in patients with dialysis patients can not accurately assess dialysis patients [34] show Decrease in serum albumin levels may be associated with increased blood viscosity and hypercoagulable states [28]. The albumin plays an important role as a free radical activator, a carrier of a wide range of drugs, hormone and binding agent for toxic compounds. The mucosal pressure may negatively affect fluid transfer between interstitial space and intracellular vacuum. [29]. On other hand the results show the total serum protein decreased signification in patients renal failure when compared with control group ,the concentration in total protein because of ultrafiltration, which leads to is low protein binding which tend to decrease further during dialysis and peculiar behavior of hip uric acid [30][31].

Conclusions

The conclusions of our study showed:-

1- The percentage of male patients are more than female.

2- Age periods (31-50 and 51-70) years have high percentage of patients.

3- Low levels of all hematological parameters (HB, PCV, PLT and WBCs) For patients when compared with control.

4- High levels of biochemical parameters (B. urea, S.creatinine, Uric acid) For patients when compared with control , while (Albumin and protein) were low For patients when compared with control.

Abstract

Worldwide, the most common cancer-related deaths and poses one of the top ten most risk cancers globally in many countries, is the thyroid carcinoma. In human cancers, there are important factor associated with it. The viral agent is one of them which is involved in the spread of tumors, including thyroid cancers. So, the present study was designed to determine the relationship between Cytomegalovirus infection with some Iraqi patients who suffer from the thyroid carcinoma in tissue cancer from different site (papillary, follicular and lymph node) by using In Situ Hybridization Technique, related to their age, gender, site distribution, histological grade and the tumor stage. The sixty biopsies were randomly collected during the period between June 2017 until October 2018, CMV was detected in (28.3%) (17 out of 60 patients, the mean age was 39 years old, ranged between (27-72) years old, female to male ratio was (1.3 : 1) with 34 women and 26 men. The most of these cases were papillary carcinoma 39, followed by follicular 13 and the rest 8 cases were at the lymph node. Histological grades that involved were 37 well differentiated, 18 were poorly differentiated, and 5 were moderately differentiated. Tumor staging included 43 patients who fall in stage I and II, while the rest 17 patients fall in stage III and IV. Regarding to the positive results, CMV correlates in a highly significant association with each of (age, gender, grading, tumor stage, and site distribution at p<0.01).

It could be concluded from that the in situ hybridization is useful in the clinical evaluation of patients with thyroid carcinoma. And suggested that the viral agent cytomegalovirus is involved in thyroid carcinogenesis and may play an important role in the malignant transformation of thyroid cancer.

Keyword: Thyroid cancer, cytomegalovirus, Insitu hybridization.

Introduction

Thyroid cancer is the most common cancer in the head and neck and the major tumor malignant of the endocrine gland(1). thyroid cancer types which including the well differentiated papillary (80% of the cases), and follicular (15% of the cases),while the latter being divided into conventional and oncocytic type (Hürthle cell), anaplastic carcinoma as well as poorly differentiated carcinoma(2), poorly differentiated and anaplastic carcinoma are both can arise de novo, or secondarily from papillary thyroid cancer and follicular thyroid cancer (3).

The early stage well differentiated papillary patients as well as the follicular carcinoma patients usually have an excellent prognosis, whereas, the patients with either aggressive tumors or distant metastases, have a 5-years survival rate of 40% (4). Unlike the thyroid cancer three aforementioned types, medullary cancer, which derives from the neural crest, more specifically, parafollicular, or C cells (5). It accounts for about 3–4% of all cases of thyroid cancer(6), its clinical course varies from the indolent to rather aggressive, with high mortality rates association (5). Primary thyroid lymphoma represents the rare non-Hodgkin lymphoma (7) which derives predominantly from the B-lymphocytes (8).

From 2000 until 2014, the thyroid cancer incidence for both individuals of both genders has significantly increased, particularly for females aged between 55 to 64 years (9). The increase rates refers to tumors in all stages. The reasons for this increase have not been completely
Many risk factors associated with thyroid cancers, for instance, viral agents are considered as a carcinogenic risk factor in more than 20% of human cancers \cite{10,11,12}. Human Cytomegalovirus have been implicated in the etiology of many human malignancies like breast cancers, cervical cancers, prostate cancers, colon cancer and thyroid cancer \cite{13,14}.

Many molecular methods can be used to identify the nucleic acid of viruses like HCMV, the one of these is InSitu Hybridization (ISH) method which can be used the frozen tissues and preparation of cytology as well as the tissue fixing by using radioactive labeled probes and also with non-radioactive labels as fluorescent moieties, biotin and enzyme conjugated probe \cite{15}.

**Materials and Methods**

This study was designed as a retrospective study, involved thyroid tissue samples which were collected as archival tissue blocks, during the period from June 2017 until October 2018, the series of sixty formalin fixed paraffin embedded tissue samples which were enrolled in the current study had been biopsied with patients data age, gender and diagnosis of histopathology and the site distribution. sixty patients with thyroid cancer (mean age 39 years) ranged between (27-72) years, female to male ratio 1.3 :1 with 34 women and 26 men. They have collected randomly from Teaching laboratories/ Medical city in Baghdad. Whom already diagnosed as a (papillary, follicular and lymph node ) of thyroid cancer by a specialist, They are compared with 10 healthy control where their data of ages and sex were matched to patients group.

preparation technique of the slides and tissue sectioning was done in the teaching laboratories/ Department of Histology/ Medical City/ Baghdad. The first tissue section mounted in ordinary slide to be stained with Hematoxylin and eosin, and the two subsequent tissue sections were mounted in the charged slides to be used for In Situ Hybridization for detection of DNA of the HCMV. In Situ Hybridization technique for molecular detection of CMV DNA in these tissues were performed by high sensitivity generation ISH as steps follow:

1- Pre-hybridization step : All the samples were deparaffinized and dewaxed by Xylene and with series of ethanol 100, 90 and 70% then in D.W. after that immersing in citrate buffer (pH: 6), deproteinization by placing in the proteins K solution, then dehydration by immersing these slides in D.W. and 70, 90 and 100% ethanol.

2- Hybridization step: By adding CMV probe to each slide, and placing them in an oven at 98 C° to denaturation of the DNA probe, then removing and incubation for overnight at room temperature to allow hybridization of the probe with the target nucleic acid.

3- Post hybridization step: By using protein block buffer to falling off all coverslips then conjugating onto all sections, using substrate, and counterstained with ethanol, xylene and mounted with DPX.

**Statistical Analysis**

The statistical analysis system – SAS \cite{16} was used to effect of differences factors in study parameters. The chi-square $\chi^2$ test at the comparative between percentage in this study.

**Results and Discussion**

The differentiated thyroid carcinoma arising from a follicular epithelial is the commonest endocrine malignancy, while papillary thyroid carcinoma accounts for the majority of the differentiated thyroid cancer \cite{17}. That given the fact in which the prevalence of non-medullary familial thyroid cancer in about only 5% \cite{18}, differentiated thyroid carcinoma is mostly sporadic and the only established epidemiological factor is associated with thyroid cancer are ionizing radiation as well as iodine deficiency \cite{19}.

The sixty paraffin embedded tissue blocks of thyroid carcinoma patients were enrolled and studied in the current study by using In Situ Hybridization method for detection of Cytomegalovirus infection and as shown in table(1). Cytomegalovirus detected in 17 out of 60 (28.3%)of patients and this disagreed with other finding research \cite{20} who reported no relation between CMV and thyroid cancer by using PCR technique for CMV DNA. There is no longer research for thyroid cancer with HCMV in Iraq. But the virus cytomegalo is detected in many cancers type by using the InSitu hybridization
method like with head and neck OSCC in (36.6 %) of patients (21). Mean age of the patients was (39 years old), 38 out of 60 were under 40 years of age and 22 were above 40 years (figure 1) and there is a highly significant correlation between CMV and the age of patients at P<0.01. Some previous studies have shown that thyroid cancer percentage was noticed to increase by age, and the likely recurrence of cancer is lower in young patients. Also besides, age played a significant role in the survival disparity, and the mortality rate is starting to climb at age of 45, and the rate of recurrence starting at age 60 years (22). The mortality risk was 5.4 times higher in aged >45 years versus <45 years (23), and the presence of distant metastases, the age remains as a strong prognostic indicator (24). It could be suggested there is a correlation between age and cancer development, because the prolonged exposure to lots of factors that may promote cancers, same as viruses and radiation and some chemicals (25). According to the thyroid carcinoma site distribution, the most affected site was the papillary 39 out of 60 (65%), followed by the follicular 13 out of 60 (21.6%) then the lymph node 8 out of 60 (13.3%) as in (figure 2). Statically there is a significant association between CMV and the site distribution at P<0.01. The present study, in agreement with (26) who found that papillary carcinoma accounts for 71% of the total thyroid malignancies in that studied. Even though confirmed with (27) and (28) who also observed the incidence of papillary carcinoma to be 76.6% and 78.56%, respectively. The major type of malignant tumor among all thyroid carcinomas worldwide, comprising an estimated 80% of thyroid cancers (29). As in (Figure 3) shows the female: male ratio is 1.3:1 and the gender distribution is 1.3:1 with 34 females and 26 male and statically there is a significant association at P<0.01. Our findings confirmed with other studies (26,30) which observed that female predominance in their studies with the female: male ratio of 5:1 and 2.6:1, respectively. It suggested that thyroid cancer and thyroid disease have more incidence rates in females than in male, because the females is more exposure to hormonal changes than males. Regarding the grade of the tumor and as shown in (figure 4), the well differentiated is the most predominant type, it was 37 out of 60 cases followed by poorly differentiated 18, then 5 cases were moderately differentiated with the significantly statistic association at P<0.01. In many previous studies of thyroid cancer related viruses the major samples were well differentiated because the main type which derives from follicular epithelial cells is well-differentiated papillary followed by well differentiated follicular carcinoma then the poorly and moderately differentiated. (3,30,31). In (figure 5) the predominant stage of the tumor is I, II 43 out of 60, whereas, 17 out of 60 were fell in stage III, IV, statically there is a significant correlation at P<0.01. This finding was disagreed with (20) who found and reported that is More than one-third of their patients fell in stage III and IV and thyroiditis did not correlate with tumor stage.

In our study, it recognized some of the limitations, the patients number that studied was small, So as the results obtained from selected population maybe not extrapolated to the other population. Some previous study has shown that CMV could widely distribute in other organs (21,32).

Prevention and First Aid of Mechanical Airway Obstruction among Children: Supportive Stratiges for Mothers

Nadia Abdel-Latif Ali¹, Huda Shawky Mahmud²

¹Lecturer, Community Health Nursing, Faculty of Nursing, Cairo University, Cairo, Egypt,
²Lecturer, Pediatric Nursing, Faculty of Nursing, Helwan University, Cairo, Egypt

Abstract

Children considered as one third of today’s population and the whole future for us. For raising society being healthy, it is vital of having children being healthy. Mechanical airway obstruction is a communal and fatal fortune in group of pediatric age. It needs prompt treatment and recognition for avoiding outcomes as fatal. Despite aspiration of foreign body (FBA) could be event as threatening of life, it can be still preventable. The mostly significant risk factor for FBA is caregivers knowledge lacking. A pre/post quasi design of experimental was implemented in the outgoing study. Three hundred mothers as purposive were included in the current study. The study aim was to assess the supportive strategies influence for mothers in respect to prevention and first aid of mechanical airway obstruction among children. The work was performed in the outpatient pediatric department of El Sayed Galal University hospital. Tool I: data sheet as socio-demographic for children and their mothers, Tool II and Tool III: sheet of questionnaire in respect to knowledge of mothers besides reported practices of mothers. Results showed that the mean age of the studied mothers was (34.13±8.97), and more than three quarters of them (%76.7) were didn’t receive previous training program. Differences of significant were detected between post and pre supportive strategy in knowledge of mothers and reporting practices in prevention and first aid of choking that wasn’t affected by their socio-demographic characteristics (P value >0.05).

Keywords: first aid, mechanical airway obstruction, children, mothers, Supportive Strategy.

Introduction

“The children of today are the adults of tomorrow. Every child has right to grow up in a healthy environment. They deserve to inherit a safer, fairer and healthier world. There is no task more important than safeguarding their environment” 18. Choking is the introduction of a foreign object into a child’s airway that come to be blocked and minimizes or obstructs completely the flow of air to lungs. Obstructions mostly are clean through child coughing but in certain circumstances airflow is blocked completely, it might be no sounds for alerting others and a person might die in few minutes. Choking episode signs might including the person can’t speak (which ordinarily can), they are not able breathe, sounds wheezy breathing, silent attempts at coughing, decreasing consciousness levels, silent or quiet cough, cyanosis 10,4. Mechanical airway obstruction is a communal and fatal fortune in group of pediatric age. It needs prompt treatment and recognition for avoiding outcomes as fatal. Foreign body (FB) aspiration/inhalation is still death cause, usually in early childhood ⁴. Choking is respiration interruption via internal airway obstruction, typically via small toys or food in children being young. Such inhibits O₂ from passing to brain and lungs that causes damage to brain or death within 4 minutes. Children below 3 years age are particularly choking-vulnerable due to small airways. Parents must remember maintaining balance of constant between child overprotecting and freedom giving to him in his learning process environment hazards 12,8. Despite aspiration of foreign body (FBA) could be event as threatening of life, it can be still preventable. It might minimize via risk factors identifying and applying strategies for managing accordingly the factors of risk. The mostly significant risk factor for FBA is caregivers knowledge lacking. Strategies for choking prevention include education the prevention and the first aid for choking. It is clear that
nurse being pediatric has significant function in respect to education which delivered to parents for reduction and prevention chocking among children

**Study aim**

The study aims are:

- To identify the mothers’ knowledge level and reported practices regarding prevention and first aid of mechanical airway obstruction among children.

- To assess the supportive strategies influence for mothers in respect to first aid and mechanical airway obstruction prevention among children.

**Design of research:**

Time series quasi research experimental design (pretest-posttest) was used for the study.

**Sampling and sampling size**

At the current work, 300 mothers as appropriate sample along their children of age below 5 years was enrolled to examine the supportive strategies influence for avoidance and first aid of mechanical airway obstruction among children were selected from the pediatric outpatient department of El Sayed Galal University hospital. Randomized sample was selected by using a SPSS, for sample size determining; analysis of power was performed utilizing 0.05 as significance level, 0.95 as the power and affect 0.25 sizes. The needed size of sample gotten was 300 mothers along children below 5 years old.

**Considerations of ethics**

For ethical considerations before collection of data, approval was gained from the research scientific hospitals board, outpatient departments head and nursing faculty and University of Helwan. Informed verbal consent was given by mother before study participation.

**Setting:**

This work was performed in the department of pediatric outpatient hospital of El Sayed Galal University.

**Instruments:**

Three information collection tools:

**Tool I:** Characteristics as Socio-demographic for mothers including; education level, age, state of working …etc. and. Socio-demographic characteristics of children include: gender, and age…etc.

**Tool II:** Mothers’ knowledge about chocking. It comprised 6 questions of 12 as total score for knowledge of mothers.

**Tool III:**

**Part I:** reported mothers practice in respect to prevention of chocking, that including measurers checklist utilized in chocking prevention, 18 items which mothers should know to prevent chocking,

**Part II:** Mothers’ reported practice regarding first aid for chocking child, adapted checklist include standardized steps for first aid used in reliving of chocking.

**Part III: Strategies as supportive for prevention of chocking**

This part included booklet guide for mothers to avoid chocking among children less than 5 years.

2.7 Study as pilot

pilot was performed on 10% of sample size for clarity ensuring, tools applicability, and sample estimation size and the needed time for collecting data. The pilot sample study was omitted from size of total sample.

2.8 Reliability and validity

Tools were given in to 5 expert’s panel in different fields of nursing to test validity content. Reliability test was performed utilizing test of Cronbach to be reliable accepted on (Cronbach alpha was 0.82).

**Technique**

This current work performed on 3 phases:

1- **Phase of pre-paratory:** A review of previous and current, international, and national literature being related was done in several problems aspects utilizing articles, books, magazines, and periodicals.

2- **Planning phase:** the supportive strategy was developed, after an extensive literature review
considering mothers and their levels of understanding. After that, the training was conducted.

3- Implementation phase:

Before collection of data and conducting the study, official consent was gained from the research scientific hospital board, the pediatric outpatient head of the department of El Sayed Galal University hospital.

- Informed oral approval by mothers was given before study participation.

- At the opening interview, the researcher introduced herself to initiate communication line explaining supportive strategies purpose and nature. The study was performed in the morning from 9 Am to 2Pm.

- Developing session of training according to obtaining information from initial evaluation the researchers developing training sessions for improving knowledge of mothers and practice regarding prevention and first aid of mechanical air way obstruction among children.

- Every mother along her child was individually interviewed following study method and purpose explaining. Each interview approximately took 30 to 40 minutes to finish filling in tool of study, based on mother’s response and understanding.

- Collected data were started at Oct., 2018 till end of Apr., 2019.

4- Evaluation phase:

In the out patients, mothers met with researchers for evaluating the test of strategy as post supportive

Table (1) illustrated that, more than one third (35%) of the studied mothers were aged 25 < 30 years old while only (5%) aged ≤ 40 years, with the mean age = 34.13 ± 8.97, according to education level, extra than one third (36%) of them were of high level of education. nearly three quarters were working, while more than three quarters of them (76.7) were didn’t receive previous training program related to prevention and first aid of mechanical airway obstruction among children, and about two thirds of them (%65.67, %65.3) were male and had history of child choking at home respectively. Additional than $\frac{2}{3}$ of enrolled children (%69.67) were less than three years of age where mean age = 2.92 ± 1.19.

Figure 1: Knowledge source of the studied mothers regarding first aid and prevention of mechanical airway obstruction among children, before and after supportive strategy (n= 300).

Figure (1) represented over half (53.33) of mothers studied their source of knowledge regarding prevention and first aid of mechanical airway obstruction among children from relatives, neighbors, and friends while only (14.67) from health care workers (doctors and nurses).
Figure (2) revealed that nearly hundred percent (90.3%) of the studied mothers had unsatisfactory knowledge score regarding prevention and first aid of mechanical airway obstruction while only (2.0%) of them had good knowledge before supportive strategy compared to more than half (55.7) after supportive strategy. It was found that there was highly differences of significant between mothers’ total mean knowledge score before and after supportive strategy at p. value < 0.001**

Figure (3) revealed more than 3 quarters (75.67%) of the mothers studied had unsatisfactory score of practices regarding prevention and first aid of mechanical airway obstruction while only (3.67%) of them had good practices before supportive strategy compared to nearly half had fair and good practices (45.67 and 47.33) respectively after supportive strategy. It was found that there was highly significant of differences between mothers’ total mean practices score before and after supportive strategy at P. Value < 0.001
Discussion

Currently, safety of child stays significant parent’s anxiety. Exposed children to risk of injury as they raise, children have a very limited capability to react rapidly and correctly in situation of emergency, that elevate chocking and death risk.

Results exposed that studied mothers mean age was 34.13± 8.97 years old. According to education level, extra than one third of them were had high level of education. Nearly three quarters were working, while more than three quarters of them were didn’t receive previous training program related to prevention and first aid of mechanical airway obstruction among children.

These findings go in the same line with Nour et al., (2017) who assess attitude, knowledge, and mother’s practices towards accidents of home among children at KSA reported which about 35.16% of the studied mothers had age ranged from 20 – 30 years. While dis agree with More than half of them were not working (58.59%), had University education (57.81%) and having more than 2 children aged 2 – 6 years (54.69%) and one fourth had previous training on first aid but dis agree related working as More than half of them were not working (58.59%).

The findings of the current study reinforced by El-Sabely et al (2014), who studied Education of mothers and their knowledge regarding prevention of home accident among pre-school children in rural areas in Governorate of Sharkia, revealed mothers age means of (34.1±9.6) years. In respect to level of education, 33.3% finished university level where more than 1/2 injured children (59.3%) were of 3years or lower, more than 1/2 of them (58.7%) were males. But dis agree related to status of occupation revealed that over 1/2 of mothers (58%) with no work.

The current results represented that over 1/2 half mothers their source of knowledge from relatives, neighbors, and friends while only (%14.67) from health care workers(doctors and nurses). This result supported by 13 who revealed that, Nearly two third of participants depend on social media as a source of knowledge about home accidents followed by doctor/nurse and the least sources were books and newspapers (17.97%). As well as agree with child El-Sably et al (2014), who revealed that over 3/4 of them gained their data from relatives, and radio and TV, then “doctors and nurses” (15.3%) , “part of curriculum” approximately (14%) whereas source being lowest was from “books” (6.7%).

The current results illustrated there was difference of significant between mothers’ total mean knowledge and reported practice regarding prevention and first aid of mechanical airway obstruction among children, before and after supportive strategy. Such results are in accordance with the proposed hypothesis and reinforced with Alazab,(2012) and Eldosoky,(2012) who concluded that in the pretest, mothers of deficit knowledge.

The current study illustrated that nearly hundred percent of the studied mothers had unsatisfactory knowledge score regarding prevention and first aid of mechanical airway obstruction while only (2.0%) of them had good knowledge before supportive strategy compered to more than half after supportive strategy. it was found that there was highly differences of significant between mothers’ total mean knowledge score before and after supportive strategy at p. value<0.001. This goes in the same line with Karyś , et al., (2016) who investigated knowledge of mothers of first aid administration to pre-schoolers in incidents of choking, in Poland revealed that 58% evaluated their knowledge being poor while 18% were disable to self-evaluate their skills as they were not sure that their knowledge was accurate.

This result supported by 18 who assessed the structured teaching programme effectiveness on mothers knowledge in respect to accidents prevention among pre-schoolers in designated Anganwadi , revealed that pre-test majority of mothers 75 (75%) had knowledge as average, 14 (14%) had knowledge as good and 11 (11%) had knowledge as poor, whereas in post-test indicated a marked increase in knowledge level, that all the mothers 100(100%) had good knowledge regarding prevention of accidents among preschooler’s. This findings are comparable with the study findings of 9 post-test mean knowledge score (24.14±2.01) was upper than the pre-test mean knowledge score (10.33±2.06) (11). Another study by 17 conducted in mothers (155) in Brazil where results showed a significant surge in knowledge regarding accidents prevention in children in all questions self-applied (p<0.05).
Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Faculty of Nursing and all experiments were carried out in accordance with approved guidelines.

Abstract

Purpose: COVID 19) is a respiratory disease caused by a member of the coronaviruses family, named (SARS-CoV-2), discovered in December 2019 in China. This study aims to assess the association of the simple fatty liver disease with the severity of the chest computed tomography (CT) scan findings in COVID 19.

Materials and Methods: It was a cross-sectional study that enrolled 322 patients with positive (RT-PCR) tests and chest CT scan findings. Patients with chronic lung and liver disease, alcoholics, and abnormal liver function tests excluded from the study. The liver CT scan density assessed, accordingly the patients divided into fatty-liver and non-fatty liver groups. The severity of lung CT changes compared between them, using Chi-square test.

Conclusion: COVID patients with fatty liver have more progressive changes in the chest CT scan. They have similar lung lesion distribution to non- fatty liver patients. Crazy paving lesions, septal thickening, Lymphadenopathy and plural effusion in fatty liver patients occurs in the same frequency as non-fatty liver patients

Keywords: CT scan, COVID 19, Fatty Liver.

Introduction

(COVID 19) is a respiratory disease caused by a member of the coronaviruses family, named (SARS-CoV-2), discovered in December 2019 in China. (¹, ²) The majority of patients have cough, fever, myalgia, with or without dyspnea. Certain groups of patients developed severe illness. (³) COVID-19 diagnosis depends on the real-time polymerase chain reaction (RT-PCR) test. (⁴) Chest computed tomography (CT) is used for early detection, assess severity, and for follow-up of the patients. (⁴-⁸) Typical findings appear when lung tissue early reacts to the insult as focal peripheral rounded ground-glass opacities (GGO), which may become more extensive, confluent, and may evolve to dense consolidation . (⁹) Other less common CT scan findings include linear and curvilinear opacities, vascular enlargement, and bronchial dilation. Pulmonary nodules, lymph node enlargement, cavities, and pleural effusions are rare findings. (⁶,¹⁰)

Findings associated with high mortality include extensive lung involvement and the presence of consolidations. (¹¹-¹⁵) As published in recent studies, patients with cardiovascular disease, diabetes, chronic kidney disease, and older age are at a higher risk of infection and prone to a graver outcome once infected. (¹⁶-
Non-alcoholic fatty liver disease (NAFLD) is another comorbidity that affects the severity of COVID-19. It is a chronic disease characterized by the presence of hepatic steatosis (intrahepatic lipid of more than 5% of liver weight) without a history of alcohol intake, with or without abnormal liver tests. It is the liver manifestation of the metabolic syndrome, which is characterized by the presence of obesity, insulin resistance, hypertension, and hyperlipidemia. NAFLD has a doubtful association with infections; recent studies reported an association with community-acquired pneumonia and a higher risk of evolving to severe disease in COVID-19 patients.

The study aims to assess the association of the simple fatty liver disease with the severity of the chest CT scan findings in COVID-19.

Materials and Methods

1. Study population: It is a cross sectional study done for 322 patients with COVID 19 at Azadi Teaching Hospital/Kirkuk city/Iraq, attending the CT scan unit for evaluation of their chests from march 2019- June 2019.

Inclusion criteria: adult Patients with positive CT scan findings and nasopharyngeal RT-PCR tests were enrolling in the study.

Exclusion criteria: Include patients with a known history of heart failure, pre-existing lung or liver disease, alcoholic persons, those with positive serology for hepatitis virus, and abnormal liver function tests. We collected the clinical information from the documentation of the clinicians.

2. Imaging: CT examinations without intravenous contrast medium achieved by a multidetector-row scanner (Siemens Brilliance), the energy level of 200–250 mA, and 120 kV. The patients imaged in the supine position. The slice thickness was 5 mm, images taken from the upper neck to the level of the umbilicus. The CT scan examinations in both lung and mediastinal windows evaluated by two radiologists with at least five years’ experience in CT scan imaging. Any differences of opinion resolved with consent. The CT examinations were done at 3-10 days from the onset of the symptoms.

3. CT interpretation: Liver density assessed to confirm the diagnosis of hepatic steatosis as liver attenuation less than 40 HU. The CT COVID changes attenuation classified as pure GGO, predominantly GGO), or consolidation (Fig 1b), and pure consolidation attenuation, while the degree of lung involvement assessment done as the following: both lungs divided into six regions, three equal zones for each one: upper, middle, and lower zones. Each zone graded into less than 5% involvement, 5-25%, 25–50%, 50–75%, and > 75% lung involvement, then the average percentage is calculated for each patient.

4. Statistical analysis: Continuous variables expressed as mean (± SD) and categorical variables as frequency (percentage). The lung lesion densities and extension compared between two groups differentiated according to their liver involvement by the fatty change. A probability (p) value of less than 0.05 was considered statistically significant. Version 17, SPSS software was used for statistical analyses.

This study approved by the Faculty of Medicine’s Research Ethics Committee/ Kirkuk University - Iraq. The individual data not explored in the study.

The patients gave verbal informed consent to participate in this study.

Figure 1. a, b. A 57-year-old woman with COVID-19, in the fatty liver group. Axial CT image (a) of the upper abdomen in abdominal window, average liver density is 11.9 HU (b) chest CT scan in the lung window, shows predominant consolidation in the both lower lobes.
Findings

Three hundred twenty-two patients (160 males and 162 females) with laboratory diagnosed COVID-19 had positive CT scan findings. Their age range was 18-70 years, and the mean was 50.25 (±13.1), 66 (20.5%) of them had fatty liver and 256 (79.5%) had normal liver density. (Table 1)

1Using student t test, 2using chi-square test. The result is significant at p < 0.05. 3Number.

In the fatty liver group, the CT scan findings were pure GGO in 24 patients (36.36%), predominantly (more than 50%) GGO in 12 (18.18%), predominantly consolidation in 25 (37.87%), and Pure consolidation in 5 (7.57%). While in the non-fatty liver group, the findings were pure GGO in 75 patients (29.29%), predominantly GGO in 90 (35.15%), consolidation in 69 (26.95%), and Pure consolidation in 22 (8.59%). There is no statistical difference in pure consolidation and GGO between both groups in contrast to mixed density lesions which is predominantly GGO in the non-fatty liver group (P=0.003) and predominantly consolidation in the fatty liver group (P=0.04). (Table 2)

</tbody>
</table>

Using chi-square test. The result is significant at p < 0.05.

Other CT scan findings in the fatty-liver group were as the following: Crazy paving 24 (36%), Septal thickening 5 (5.57%), Plural effusion 22 (33.33%) and Mediastinal lymphadenopathy 1 (1.51%). While in non-fatty liver were 100 (39%), 10 (3.9%), 86 (33.56), and 5 (1.95%) respectively. There was no significant difference in the incidence of these findings between the two groups.

There were no pericardial effusion, cavitation, neither nodule incidence in this study.

Discussion

In our study, 66 (20.5%) had fatty liver density, which approximates the global prevalence, which is about 25.24%. This group of people had a chance to develop more severe and extensive lung changes in COVID 19, as they had predominantly consolidative lesions, in contrast to the non-fatty-liver group who had GGO more. COVID 19 damaged the lungs of the Fatty liver group more extensively (25-50 %) in comparison to the non-fatty-liver group as their lungs involved more in (5-25%). It was consistent with the result of a study done in China by Kenneth I. Zheng et al who stated that (fatty liver patients that were obese had more severe COVID-19 disease) as the fatty-liver group’s weight was significantly more in our study. (fatty-liver disease patients had significantly more recurrent infections regardless of coexistent metabolic syndrome) a statement proved by William Nseir et al. The fatty
liver patients had a higher risk of progressive COVID 19, a conclusion made out by Julie Lucifora et al. (28) This relation is probably due to the association of fatty liver change with low vitamin D serum levels, which in turn increases the susceptibility to infection and autoimmunity. (29, 30) In addition to the deficient innate immunity to the coronavirus representing by high M2 blood macrophages, which suppress the response to the infections. In both groups, the distribution of the lung lesions was more frequently peripheral and bilateral, and to a lesser degree had a diffuse behavior, the least distribution pattern was unilateral and central lung involvement. The result was in line with much of the studies. (2, 6, 10,12)

In both groups, like other papers, other CT scan findings were seen almost in the same percentage. About one-third of the patient had crazy paving lesions and septal thickening. Lymphadenopathy and pleural effusion were relatively rare. (6, 10)

Limitation of the study: We did not consider the patients who may have received COVID 19 treatment, which might affect their CT scan findings.

**Conclusion**

COVID patients with fatty liver have more progressive changes in the chest CT scan.

The distribution of the lung lesions in both fatty and non-fatty liver are similar.

Crazy paving lesions, septal thickening, Lymphadenopathy and plural effusion in fatty liver patients occurs in the same frequency as non-fatty liver patients.

Impact of Work Environment upon Respiratory Tract Health Problems among Workers at Textile Industries in Baghdad City

Wissam Jabbar Qassim1, Rajaa Ibraheem Abed2
1Assist Prof, Community Health Nursing Department, Nursing College, University of Baghdad,
2Assist Prof, Fundamental of Nursing Department, Nursing College, University of Baghdad

Abstract

Objective: To evaluate the effect of the work environment on the respiratory health problem of workers in the textile labs in Baghdad city.

Methodology: The sample consisted of 100 workers working in the wool and cotton fabrics in the General Company for Textile Industries in Baghdad for the period from 3 Jan of 2017 to 20 of May 2018. A randomized structured sample of (100) workers was selected using the probabilistic selection method. The questionnaire was built for the purpose of the study and the reliability of the questionnaire was verified through a pilot study and then it was presented to (10) experts to establish its credibility. (20) Items in the questionnaire divided into three sections, namely demographic information, symptoms and signs, and finally diseases that affect the respiratory system. The data were collected using the questionnaire method and analyzed the data by applying statistical descriptive analysis, which includes frequency, the mean and the computational mean, and the deductive statistical analysis, which included the Kay square test.

Results: Results of the study show that the results of the study indicated that most of the workers suffer from frequent coughs due to allergies to cotton and wool (68%) with persistent respiratory infections. The study concluded that most of the workers suffer from persistent cough due to the sensitivity of the raw material that enters the textile industries namely cotton and wool. Recommendation: The study recommended that further studies be carried out with the possibility of carrying out an educational program for workers to reduce the occupational hazards of the respiratory system in textile factories.

Key words: Impact, Work environment; Respiratory tract Health Problems

Introduction

The occupational health initiatives were started in collaboration with WHO in 1950, first of them was the formulation of an official definition of “Occupational Health”. Accordingly Occupational Health was defined as “Promotion and maintenance of the highest degree of physical, mental and social well-being of workers in all occupations; the prevention among workers of departures from health caused by their working conditions; the protection of workers in their employment from risks resulting from factors adverse to health; the placing and maintenance of workers in an occupational environment adopted to his physiological and psychological capabilities and to summarize: the adaption of work to man and of each man to his job “. In simple words, it is concerned with health problems in relation to man & his general social, biological, chemical & physical environment[1]. The occupational risks are estimated to be the tenth leading cause of morbidity and mortality among the global risk factors. The cost of occupational disease burden is estimated to be 2-14 percent of the gross national product for various countries. The work-related risks were estimated to cause 7,75,000 deaths globally in 2000. Of this the leading causes were unintentional injuries (41 percent) followed by COPD (40 percent), and cancer of the trachea, bronchus or lung (13 percent) being the major contributors of deaths. The injuries causing 3,10, 000 deaths, the dust-related...
The number of deaths related to carcinogens is 2,43,000 and the work-related carcinogens account for 1,46,000 deaths. The textile industry is the second largest industry in the world after agriculture. In India, the textile industry significantly contributes to the foreign exchange earned by the country [2].

Respiratory diseases and illnesses, such as asthma, bronchitis, pneumonia, allergic rhinitis, and sinusitis, can greatly impair a child’s ability to function and are an important cause of missed school days and limitations of activities. Symptoms associated with both mild and severe manifestations of these respiratory conditions, such as cough, wheeze, congestion, chest pain, shortness of breath, respiratory distress, and death in the most extreme cases, are responsible for substantial morbidity and a large cost burden to families and society [3].

Methodology

A descriptive assessment design is carried throughout the study to assess the work environment among textile industry workers in Baghdad City from January 3rd 2017 to May 20th 2017. The permissions have been obtained from Baghdad (Textile Industry, Cotton and Woof Textile) to carry out the study. The study is conducted at two groups (General Company for Cotton Textile Industry and General Company for Woof Textile Industry) in Baghdad City. A non-probability (purposive) sample of 100 workers is selected from the general company for cotton textile industry and general company for woof textile industry in Baghdad City. A question has been constructed to achieve the aims of the study, which comprises three parts: the first part contains the demographic characteristics sheet which consists of 7 items and the second part contains 10 items and the third part contains 10 items. A pilot study is carried out from January 3rd 2017 to May 20th 2017 to determine the content validity and internal consistency split – half reliability of the study instrument. Reliability of the questionnaire is used to determine the accuracy of the questionnaire since the results showed very high level of the stability and internal consistency of the main study domains at the level of items of the questionnaire.

Spearman rank correlation coefficient

Content validity of the instrument is determined through panel of 9 experts. The experts are asked to review the instrument, and their responses indicate that all of the experts agree that 20 items of the instrument are clear and adequate for the measurement of the phenomenon underlying the study. Data collection through the use of the study instruments and the interview technique as means for data collection from February 4th 2017 to 20th March. Data are analyzed through the application of descriptive data analysis approach which includes frequency, percent, and total score and inferential analysis such as chi-square.

Results of the Study

With respect to subject of “Textile Type”, the studied sample is distributed similarly between Cotton and Wool sectors, and for each sector, they are accounted for 50(50%). Relative to subject of “Age Groups”, the studied sample is distributed similarly among the sex groups with no significant difference at P>0.05. On subject of “Educational level for fathers and mothers”, the results illustrated that most of the studied sample had good graduated levels, such that “Secondary, and Intermediate” degree, and they are accounted for 37(37%) and 24(24%) respectively, and statistically reported high significant differences at P<0.01. “Type of work”, the results that most of machine operators are the more half of the sample officers, and they are accounted for 56(56%), while most of workers are married they are accounted for 89(89%), and statistically reported high significant differences at P<0.01. Income, and socio-economic status illustrated that most of the studied sample had a moderate level, and accounted for 78(78%) with no significant difference at P>0.05 compared with different groups.

The results of this table shows all of items were non-significant except item (5,6) are significant and highly significant item 2.

**Discussion of the Results**

Analysis of such characteristics reveals that the respects to subject of “Textile Type”, the studied sample are distributed similarly between Cotton, and Wool sectors, and for each sector are accounted 50(50%). Relative to subject of “Age Groups”, studied sample are Less than half the sample is slightly age-restricted between (41-45) years old, distributed similarly among the sex groups with no significant different at P>0.05. This is within the factory policy of making equality between men and women. On subject of “Educational level for workers”, results illustrated that most of studied sample had good graduated levels, such that “Secondary, and Intermediate” degree, and they are accounted 37(37%), and 24(24%) respectively, and statistically reported high significant differences at P<0.01. This category of workers who carry this certificate is the most class of workers working in this factory for low wages and carrying hard work. That most of machine operator the more half of sample officers, and they are accounted 56(56%), while most of workers are married they are accounted 89(89%), and statistically reported high significant differences at P<0.01.

Income, and socio-economic status illustrated that most of studied sample had a moderate level, and accounted 78(78%) with no significant different at P>0.05 compared with different groups. The study findings depict that most of these worker’s demographical characteristics, that the All pairwise correlations between education, income, and occupation were positive and were stronger for men than for women. The lowest correlation was between education and income, indicating that education is not a primary determinant of wage. Higher correlations were shown for education and occupation, suggesting that skills acquired during education may help determine occupation. Although correlations ranged from .23 to .67, their relatively low magnitude (highest adjusted R2 = 45%) indicates that the three dimensions are not redundant measures of SES.

2. **Discussion of the Subjects’ Sign and symptoms:**

This domain the all items were non – significant except I suffer from persistent cough (0.05) I suffer from secretion of respiratory system (ulcer) (0.02). One of the greatest risks to workers working in textile factories is respiratory infections and allergies in the airway and lung [5], Because it more exposure to dust and or other pollution in dust and or other pollution industries make if danger on the worker to developed respiratory health problem among worker.

3. **Discussion of the Subjects’ pulmonary diseases:**

Result of this table shows all items were non – significant except I suffer from sore throat (0.41) suffer from pulmonary Congestion (0.34) are significant and high significant item bronchitis (0.00). Because of the worker’s don’t wear the protective Cloth or PPE that protect them from the sore threat and pulmonary Congestion so they more exposure to it. The values, or for employees who show a decrease in pulmonary function on the after-exposure test. If the physician feels significant changes have occurred from year to year, or if the worker has complaints about breathing, six-month test will also be done. Employees who are below 60 percent of the predicted value on their breathing test will be sent to a physician for an evaluation. Employees will be furnished written information on the results of their examination.

4. **Discussion of the Relationship between Workers’ Knowledge and Their Demographic characteristics of the Study:**

Analysis out of this table indicated that significant relationship were reported between the subjects age and worker’s knowledge. Because of the more age in textile worker is (41-45) years and young additional too Long shift of work and direct exposure to cotton and wood this make these a going more have Vern ability to disease. Age differences account for between 0-5 percent to %2 of the overall explained Variation in the data when no other Variable are controlled, (the relation of age to workplace injuries). Table 4 shows that the significant relationship was reported out of these between the subjects gender and worker’s Know at textile work. This table focuses on productivity and earning for tow reason. Frist, a focus exclusively on labor force participation provide only a partial picture of women and men’s experience in the labor market. Second, despite significant progress in female labor force participation over past 25 years,
prevised and persistent gender differences remain in productivity and earning across different sectors and jobs. Men’s and women’s jobs differ greatly, whether across sector, industries, occupation, type of jobs. Or type of firms. Compared in other studies female have about 40 over world in 2007-2008. [6].

Non- significant relationship was reported out of this between the marital status and worker’s knowledge (table 4). Because of the socioeconomic state play important role in worker’s life. Spicily in young to make family or who or how have family and children to cover costs of education or other responsibilities. The significant relationship between educational level and worker’s knowledge. Because the women’s stay how educational level than men’s. The women’s more closed to machines of productive cotton and wood so the women have more Vern ability to disease. The significant relationship between type of work and worker’s knowledge. Because of worker’s have direct contact to machines so they have direct contact or exposure to wood and cotton dust and other factor, noise. more than those who work in office job mean not closed to machines. So the worker has high risk or Vern ability to disease dependent on type of work or type of machines. Also the duration of exposure to dust or there factor make worker’s develop health problem among respiratory system.

**Conclusion**

The study showed that the majority of workers who deal with cotton and wool suffer from persistent cough, and the study showed that the work environment has a direct impact on the respiratory system of workers especially that most suffer from bronchitis. The study found that older workers in the 41-45 age group are more likely to suffer from respiratory infections. Environmental factor of physical, biological, chemical, psychological, and social ones had critical impact upon the worker’s health status.

Effects of Addition of Melatonin and L-Arginine on Cooled Semen Parameter of Iraqi Local Breed Rams in Vitro

1Assist. Prof., Coll. of Veterinary Medicine, University of Fallujah, Anbar, Iraq, 2Assist Prof. Coll. of Applied Science, University of Fallujah, Anbar, Iraq, 3Assist Prof. Assist Prof. Coll. of Agriculture, University of Anbar, Anbar, Iraq, 4Prof., 5Researcher, Coll. of Veterinary Medicine, University of Fallujah, Anbar, Iraq

Abstract

The current study was carried out on six Iraqi breed rams, aged between 2 to 4 years, during the period from Nov. 2018 to the Mar. 2019. Semen samples were collected from each ram with electro ejaculator at the morning, one ejaculate per week over a time of 16 weeks. Pooled semen for all rams were used to evaluate the characteristics of semen to avoid individual variation between the animals. The volume and the color of fresh semen was recorded directly, then semen was evaluated for mass and individual motility, live/dead percentage and sperm abnormalities. Semen samples were diluted 1:10 with a Tris-based extender, and divided into seven parts (each part 2ml), 0.1µmol, 1.0µmol & 3.0µmol concentration of melatonin were added to the T1, T2 and T3 respectively, L-arginine were added to the T4, T5 and T6 in 0.001µmol, 0.1µmol and 1.0µmol concentration respectively while T7 serve as a control without any addition. All treatments cooled at 4°C. Then semen parameters evaluated. It was concluded from this study that addition of 0.1 µmol melatonin significantly protected ram sperm cell from cold storage that induced negative effects on sperm function. However the addition of L-arginine have no beneficial effect on cooled ram semen.

Keywords: semen characteristics, melatonin, L-arginine, anti-oxidants materials.

Introduction

Artificial insemination (A.I) plays an important role in sheep industry. It participates in distribution of Superior genetic materials from a little numbers of rams to a large numbers of ewes (32). These distribution of genetic materials leads to improvement of pure bred ewes (5) via increase meat, milk and wool production (45). Mammalian and ram semen seems to be more susceptible and sensitive to oxidative stress resulting from reactive oxygen species (ROS) produced from metabolic activity of cellular components of semen during storage due to a high content of sperm cell membrane of unsaturated fatty acids phosphor lipid (4, 16, 20, 34). Although the oxidation is important for life, but it may cause a harmful effect due to the formation of free radicals that cause a damage to sperm cells (20). The oxidative stress may cause a reduction in reproductive performance of ram through its effect on characteristics of seminal fluid, due to production of ROS, which have a great role in lipid peroxidation in the sperm membranes with production of fatty acids peroxides that leads to a decrease in sperm motility and reduced their ability of fertilization (11). In order to reduce the effect of these free radicals or prevent their action, antioxidant either natural or synthetic were used (39, 44) Arginine is an amino acids of alkaline groups having a positive charge which includes; Lysine and Histadine, acts as antioxidant through its stimulation of Glutathione peroxidase which acts on Hydrogen peroxide (H2O2) and organic peroxide which is a site compounds resulted from metabolic activity of the body to water and oxygen ions. This peroxide when left to react with iron or copper ions it produced free radical of Hydroxyl that have a strong reaction (49). Arginine metabolism in the body resulted from the effect Arginase enzyme that leads to production of nitric oxide (No), ornithine and urea (47). It has been reported by many authors that treatment with arginine effect the male and female reproductive system.

Corresponding author:
A. A. Omar
Email: dr.aliabd@uoffallujah.edu.iq
through the increase blood supply of genital organ and increase sexual desire (5, 31). Kaya et al. (25) observed that injection of arginine intramuscular increase sperm motility, sexual desire and accelerate ejaculation in the ram. The mechanism of arginine action act to increase sperm motility might be due to increase synthesis of ATP that supplied sperm with energy (33). Melatonin (N-acetyl-5-methoxytryptamine) or it may called dark hormone, secreted mainly from pineal gland, but it has been recognized to be synthesized in many other sites (36). It consists mainly from the amino acid tryptophane, and its receptors present in a numbers of tissues and organs of the body. It control or regulates daily and seasonal harmony of the biological activities in the body and increase sensitivity of leydig cells to interstitial-cell stimulating hormone (ICSH) (9). Also it controls many serious physiological events, including metabolism, sleeping, circadian rhythms and body temperature stability (12, 28, 43). Furthermore, it acts as anti-oxidant and anti-apoptotic substance (48) through its ability to remove different types of free radicals such as ROS, H₂O₂, OH⁻ and activate the production and catalyze of enzymatic antioxidant like; superoxide dismutase (SOD), Glutathione peroxidase (GOX) and Catalase (CAT) (27, 37, 39). Melatonin have the ability of enhancing body immunity (19). And has been used to boost the maturation of ova and to improve embryo development in many species, sheep, cattle and buffalo (2, 30, 46). Deng et al. (13) reported that treatment of Rams with melatonin increase the testosterone levels in the interstitial cells of the testes through increase Insulin like growth factor from sertoli cells which regulates synthesis and secretion of testosterone due to presence of melatonin receptors on sertoli cells membranes (15). It has been observed that addition of antioxidant such as melatonin or L-arginine protect sperm cells form harmful effect of ROS and improve sperm activity during its storage in unfrozen state (1, 6, 29). The objective of the Current study was to investigate the effect of addition melatonin and L-arginine Tris extender on cooled ram Semen in vitro.

Materials and Methods

The current study was carried out on six Iraqi local breed rams aged between 2-4 years, Presented in the farm of college of veterinary medicine, University of Fallujah Al-Anbar province during the period from November 2018 to the March 2019. The animals were fed alfalfa and hay the water was given in a free choice. All animals were healthy and treated for internal and external parasite and vaccinated with Co-Baghdad and Pox. Semen samples were collected from each ram with electro ejaculator (Electro jac5/a neogen company, U.S.A.) at the morning one ejaculate per week over a time of 16 weeks (sixteen samples program). Samples were taken and put it in a water bath at 38°C. Pooled semen for all rams were used to evaluate the characteristics of semen to avoid individual variation between the animals. 1ml of semen sample was taken to determine its parameters. Volume of the semen was directly measured by reading of graduated marks of collecting tubes. Color of semen has been visually evaluated according to Salisbury et al. (40). Mass motility has been done by putting a drop of fresh undiluted semen on a warm slide at 36°C and examined under light microscope supplied with heat stage at 100× magnification. Estimate the swirl grade according to Chenoveth et al. (10), the grades include Rapid swirl (very good), slower swirl (good), general oscillation (fair), sporadic oscillation (poor). One drop of fresh semen plus one drop of sodium citrate were taken to estimate the individual motility. Two smears of semen stained with eosin-nigrosin, were prepared (8) and used to determine the percent of dead/ alive and morphological abnormal spermatozoa (primary and secondary) according to Bielański et al. (7). Sperm concentration was calculated with hemocytometer chamber (40). Semen samples were diluted 1:10 with a Tris-based extender according to concentration of spermatozoa (Tris: 24.2gm, citric acid: 13.4gm, fructose: 10gm, glycerin: 64ml, egg yolk: 192ml, distal water up to one liter) described by Eidan et al. (17). Diluted semen was taken and divided into seven parts (each part 2ml), 0.1µmol, 1.0µmol & 3.0µmol concentration of melatonin were added to the T1, T2, T3 respectively, L-arginine were added to the T4, T5 and T6 in 0.001µmol, 0.1µmol and 1.0µmol concentration respectively while T7 serve as a control without any addition. All treatments cooled gradually via addition a piece of ice until it reaches 4°C within 2h. Semen parameters evaluated after dilution and cooling. Statistical analysis was applied using Tuckey’s - W procedure and chi-square test according to Steel and Torrie (42).

Resultand Discussion

The Characteristics of fresh semen of local Iraqi
rams in non-breeding season are shown in table:1. There were no statistical difference (P≤0.05) in semen parameters between rams in different ejaculates of the same ram. These results indicates that the semen is of good quality even when it collected in non-breed.

Table: 2 show semen parameters after diluted with Tris based extender with addition of melatonin and L-arginine in different concentration (0.1, 1.0, 3.0) μmol and (0.001, 0.1, 1.0) μmol respectively. There were a statistical differences (P≤0.05) in individual motility %, dead/ alive% and sperm abnormalities between 0.1μmol melatonin concentrations as compared with L-arginine or control treated semen. Similar observation has been reported by many investigators (6, 23, 26). The addition of antioxidant such as melatonin to ram semen (6) has been shown to protect sperm against harmful effects of reactive oxygen species (ROS) and improve sperm motility during sperm liquid storage or in unfrozen state.

Table: 3 showed the effect of addition of melatonin and L-arginine after cooling on the percentage of dead/ alive sperm, which showed a statistical difference (P≤0.05) between different treated semen. In the current study it observed that melatonin addition to the diluent in vitro enhanced the cooled preservation capacity of ram sperm in a dose of 0.1μmol and efficiently maintained sperm motility and other parameters over 48h of cooled storage. Melatonin is an indole derivative secreted rhythmically from pineal gland, plays an important role in the reproductive functions in mammals (37). Melatonin presents in seminal plasma, having multiple actions on different physiological process, as its metabolites are indirect anti-oxidants and powerful direct scavangers that protected sperm cells from free radicals raised by their metabolism (3, 24). Melatonin also modulating the glutathione activity to improve mitochondrial health state and functions (18). L-arginine is found to effect the reproductive process. O’Flaherty et al. (35) determined that L-arginine has a protective effect on spermatozoa against the sperm plasma membrane lipid peroxidation and enhances the cell metabolism. It has been reported that low concentration of L-arginine increase sperm motility, whereas high L-arginine concentration decreases sperm motility (21, 22). In addition, it has been found that nitric oxide synthesized from L-arginine might help or assist to induce acrosome reaction, sperm chemotaxis, and sperm egg interaction (22, 38). In current study the ineffectiveness of L-arginine on ram semen in vitro might be due to the high dose usage as explained by (21, 22, 29).

Different letter show statistical difference at (P≤0.05).

The results of table-4 showed that there was a statistical difference (P≤0.05) between different treatments and doses as compared with the control one. The lower percentage of sperm abnormalities were observed in melatonin treatment with different doses especially at 0.1Mmol. Similar observations have been made by (13, 14, 15). It has been reported that melatonin promotes development of haploid germ cells from early developing spermatogenic cells of sheep under in vitro environment (13). It has been found that melatonin acts as anti-oxidant through their ability to remove various types of free radicals such as ROS, H₂O₂, OH⁻ and superoxide dismutase (SOD), glutathione peroxidase (GPX) and catalase (CAT) (37). The result of L-arginine treatments were disagreed with several authors (25, 33, 49). The ineffective results of L-arginine might be due the concentration applied or used that decrease sperm motility and increase abnormalities (21, 22).

**Conclusion**

It was concluded from this study that addition of 0.1µmol melatonin significantly protected ram sperm cell from cold storage that induced negative effects on sperm function. However the addition of L-arginine have no beneficial effect on ram semen.
Table: 4 show the percentage of abnormalities of cooled ram semen after dilution and addition of L-Arginine and Melatonin

The Role of IL-25 and IL-35 in Amoebiasis

Adnan S. Khalaf Al-Majid1, Alyaa A. Hafez2

1MSc College of Science, Department of pathological analysis, University of Thi-Qar; 2Assist. Prof. College of science, Department of Pathological Analysis, University of Thi-Qar

Abstract

Background: Amoebiasis is a protozoon infection of the human intestine spread through the world, the most prevalent form of the disease is amebic dysentery which characterizes acute diarrhoea with observable blood and mucus in stools.

Aims: This article aimed to detects the role of IL-25 and IL-35 in the immune response against amebic dysentery.

Methods: This study was conducted in Thi-Qar province-Al-Nasiriyah city in Muhammad Al-Mousawi Hospital for Children, the study included collection of (60) blood samples from amoebiasis patients and (30) apparently healthy children at a period from September 2019 to March 2020 with the age less than one year to 15 years that divides to four age groups, the levels of IL-25 and IL-35 were determined by ELISA technique.

Results: The results indicate that the IL-25 and IL-35 concentrations in serum samples from amoebiasis patients were significantly higher when compared with that from healthy controls. The highest level of IL-25 was recorded in the third age group of patients with level 1677.2 ± 867.2ng /ml, compared with the high level in the third age group of control with level 450.40 ± 97.31ng /ml. Also, the findings indicates the highest level of IL-35 recorded in the second age group of patients with level 291.0 ± 62.3ng /ml, while the high level recorded in the first age group of control with level 8.246 ± 0.60 ng /ml.

Keywords: IL-25, IL-35, Amoebiasis, cytokine

Introduction

Amoebiasis is an infection of the human intestine by E. histolytica protzoen, also called amoebic dysentery is acute diarrhoea with observable blood and mucus in stools and the existence of haematophagous trophozoites in stools or tissues. Non-dysenteric amoebic colitis presents as recurring seizures of diarrhoea with or without mucus and no visible blood with the presence of E. histolytica cysts or non-haematophagoustrophozoites (1). E. histolytica stimulate both the innate and adaptive immunity such as the resistance of the mucosal barrier and lymphocytes of the class Cluster of differentiation 4 (CD4), Cluster of differentiation 8 (CD8) and the presence of amoeba antibodies such as immunoglobulin Class A secretory (SIgA) (2).

The cells in the intestine adhere to and distinguish the Gal/GalNAc lectin of parasites by (TLR)-2/4, as these cells work to send pro-inflammatory signals and leads to the formation of inflammatory cytokines, including IL-1β, IL-6, IL-8, IL-12, IFN-γ and TNF-α, these signals lead to attraction of the defending cells like: neutrophils and macrophages to the position of amoeba infection (3). IL-25 belongs to the IL-17 family; the name for the alternative is IL-17E. The protein contains 177 amino acids, which are secreted by many human cells, such as T cells, macrophages, masts, epithelium, dendritic and other (4). A study by (5) treating infected mice with intestinal IL-25 showed that it stimulates the immune response against Trichinella spiralis infection.

Also, observed that intestine IL-25 would be inhibited during CDI infection in humans and mice.
Therefore they concluded that an IL-25 induces eosinophil to defend against *Clostridium difficile* colitis CDI \(^{(6)}\). IL-35 was first known in 2007, has been added in the IL-12 family for similarity in the unique heterodimeric structure. It is mainly provided by CD4 Treg as well as by stimulated B cell and a smaller extent by motivated endothelial cells and monocyte cells \(^{(7)}\). Li and his colleagues enrolled in an interleukins study that IL-35 and IL-37 ratio are higher in inflammatory bowel disease (IBD) patients, while serum IL-35 and IL-37 level were suggestively low in the ulcerative colitis (UC) patients compared with healthy controls (HC) \(^{(8)}\).

**Material and Methods**

The study involved collection of 3 ml of blood for each samples from 60 children suffering from amebic dysenteriae and 30 samples from apparently healthy children as control with the age ranging from less than 1 year to 15 years during the period from September 2019 to march 2020 in Al-Musawe Hospital for children in Al-Nasiriyah city-Thi-Qar province-Iraq. Serum cytokine concentrations of IL-25 and IL-35 were determined in the serum samples by using enzyme linked immunosorbsent assay (ELISA) technique according to manufacturer’s instructions (BIO-TEC-China) using microplate spectrophotometric reader.

**Statistical Analysis**

All data of the present study were statistically analyzed by using Microsoft windows 10 Excel (version2010) and SPSS version 24 (ANOVA for Leas Significant Difference LSD and Independent T. test).

**Results**

The study showed higher level of IL-25 and IL-35 concentrations in patients who infected with amoebiasis in comparison to health control and recorded statistically significant difference in levels of IL-25 and IL-35 between all age groups of patients compared with corresponding age groups of health control at P. value < 0.05 (Tables 1 & 2)

Discussion

Level of IL-25 for Patient and Control According to Age Groups

The current study showed rising levels of IL-25 in all age groups and differences between them, significant differences were observed. These results indicate the impact of IL-25 with E. histolytica infection. In the present study, it is possible to find a role for IL-25 with amoebiasis by noting several things. High levels of IL-25 when we examined and compare patients of
amoebiasis with healthy control serum of all ages. This means that interleukins concentration does not affect with the patient’s age, but rather depends on increasing the number and concentration of parasites, also the immune status of patients, and the evidence is that the interleukin concentration increased in triple infections more than double and single infections.

This compatible with study by (9) pointed out that epithelial cells in the human intestine have the ability to produce IL-25, which has an important role in balancing defensive barriers in the intestine, as well as commensal bacteria in the intestine, which have the ability to stimulate intestinal epithelial cells to produce IL-25. The increase levels of IL-25 in this study may due to the ability of many types of cells to produce this cytokines such as T. cells, dendritic, macrophage, eosinophil and epithelial cells (4). IL-25 levels associated with increase the inflammation during intestinal infection because its ability to stimulate the production of some immunological mediators like: IL-8, chemotactic factors for neutrophil and induced inflammation also that IL-25 has been proved to enhance mucus production in intestinal (10), and production of Th2 cytokines such as: IL-4 which help in humeral defense mechanism against pathogens including parasite infection (11)(12).

So, IL-25 plays an important role in implicating immune response against amebiasis. As (13) mentioned that IL-25 provided protection from *E. histolytica* in an eosinophil-dependent, as demonstrated by abrogation of protection by depletion of eosinophils.

A role for eosinophil’s in amebiasis is show that decline eosinophil products (Charcot-Leiden crystals) exist along with trophozoites in the stool of patients with amebiasis (14). In addition (11) was also shown IFN-γ, IL-17(IL-25) contribute to vaccine-induced protection in murine studies, these findings suggest an important role for cell-mediated cytokine production in protection from amebiasis. Camelo and his colleagues found that IL-25-induced inflammation is typically characterized by elevated levels of type-2 cytokines which lead to pathological changes in the lungs and digestive tract, such as elevated serum IgE and IgG1, increased mucus secretion, and epithelial cell hyperplasia (15).

**Level of IL-35 for Patient and Control According to Age Groups and Statues of Infection**

The present study recorded the higher level of IL-35 in all age groups and statistically significant difference in levels of IL-35 between all age groups of patients compared with corresponding groups of health control. We showed distinctly the high level of IL-35 concentration with infection more than one parasite, where the highest infections were triple, double and single infections respectively. Also, the high level of IL-35 concentration does not depend on a specific age group, and we also recorded a rise in both sexes, as there are no statistical differences between them. This means that interleukins concentration does not affect by the patient’s age, but rather depends on the patients’ immune status.

The presence study agree with Cao and his colleagues in Chongqing, China, they found that IL-35 levels in serum samples from adult or child patients with sepsis was significantly higher compared with healthy controls and progressively increased according to sepsis severity (16). Also our study agree with study by Fonseca (17) in Mexico City recorded results suggest that down-regulation of inflammation in active Inflammatory Bowel Disease (IBD) patients might be based on the increased expression of IL-35 and IL-37. As in a study by (18) they found T cells that secrete IL-35 and have suppressive functions can be induced in the intestines of mice infected with the intestinal parasite Trichuris muris. Also agree with Choi found that IL-35 has an immunosuppressive effect on inflammation through induction of Treg cells and suppression of Th1 and Th17 (7). These results agree with (19) has been shown IL-35 in other chronic inflammatory diseases and parasitic/bacterial infections, where the inhibitory cytokines.

Depending on the results achieved in our study of patient’s children with amebiasis and comparing them with healthy children, and according to published research, we saw that the level of IL-35 rises in gastrointestinal infections, as it is considered an immune suppressant.

**Conclusion**

The cytokines under this study produces in high levels during the course of intestinal amoebic infections and they play important role in the development severity of the symptomatic form of amoebic dysentery.

Appropriate Antibiotic Use for Community-Acquired Pneumonia in Inpatient Settings and Its Impact on 30-days Readmission and Mortality Rate

Rafida Sofi Kamila¹, Maftuchah Rochmanti², Arief Bakhtiar³

¹Student, Faculty of Medicine, Universitas Airlangga, Surabaya – Indonesia 60131, ²Lecturer, Department of Pharmacology and Therapeutics, Faculty of Medicine, Universitas Airlangga, Surabaya 60131 - Indonesia, ³Lecturer, Department of Pulmonology and Respiratory Medicine, Faculty of Medicine, Universitas Airlangga, Surabaya 60131 – Indonesia

Abstract

Background: Community-Acquired Pneumonia (CAP) is a lower respiratory tract infection with bacteria as the most frequent causative agent. Therapy for pneumonia includes appropriate antibiotic usage. Inappropriate antibiotic use supposedly increase 30-days readmission and mortality rate.

Objective: To evaluate the antibiotic use and the impact of appropriate antibiotic use on the 30-days readmission and mortality of CAP patients in inpatient non-ICU settings.

Method: A cross-sectional, analytic study was conducted. We collected data from Universitas Airlangga hospital’s medical record to obtain the details of antibiotic usage. Result were evaluated using the Gyssens algorithm. A chi-square test was used to identify the impact of appropriate antibiotic use on the 30-days readmission and mortality.

Result: A total of 90 patients with CAP fulfilled the inclusion criteria. One gram of ceftriaxone IV was the most prescribed antibiotic for therapy of CAP. The amount of appropriate antibiotic use is 85.6%. Five patients (5.6%) went through the 30-days readmission. There was no death reported. The statistical test between antibiotic use and 30-days readmission obtained \( p \) value=0.894 (\( p > 0.05 \)).

Conclusion: There was no significant impact of appropriate antibiotic use on the 30-days readmission rate and the mortality rate could not be assessed.

Keywords: 30-days readmission, antibiotic use, community-acquired pneumonia, Gyssens algorithm, mortality

Introduction

Antibiotic resistance can occur due to inappropriate antibiotic use. This unabating phenomenon increasingly becomes a problem in public health issues. Antibiotic resistance will rapidly increase along with inappropriate antibiotic use ¹⁻³. As methicillin was widely used in the 1960s, Staphylococcus aureus soon becomes resistant to the drug, treatment decision for MRSA infection can be challenging due to a change in its Penicillin Binding Protein (PBP) so that it is resistant to beta-lactam class antibiotics⁴⁻⁶. WHO stated that in 2013, at least 700.000 people died due to antimicrobial resistance to bacterial infection, malaria, HIV/AIDS, and tuberculosis. WHO also predicted that there will be approximately 10 million death due to antimicrobial resistance in 2050 ⁷. Appropriate antibiotic usage is substantial to the success of therapy. Inappropriate Empirical Therapy (IET) is said to be associated with a potentially worse outcome such as higher 30-day readmission rates and mortality rate⁸.

Lower respiratory tract infections, such as CAP, are the most common infection cause of death in the world and are the third cause of global death in 2008 ⁹. The mortality rate among CAP patients in non-ICU general
ward setting is reported to be around 2%. This rate increases in the ICU setting, >65 years, male, and patient with co-morbid diseases. This study was conducted to identify the appropriate antibiotic use in CAP patients and also to evaluate the impact of appropriate antibiotic use on the 30-days readmission and mortality of CAP patients.

Methods

This was a cross-sectional study that included all CAP patients (ICD code J18.9) admitted in inpatient non-ICU settings and were diagnosed with pneumonia in their first assessment examination. Patients were over 18 years old and hospitalized in the general ward of Universitas Airlangga hospital, Surabaya, East Java, from 1 January 2018 to 31 December 2018. We observed the antibiotic use in CAP patients through their medical records and collected data on patients’ characteristics, i.e., sex, age, admission date, and length of stay. We also collected data on patients’ antibiotic prescriptions, i.e., type of antibiotic, duration of therapy, dosage, route, timing, and interval time of prescription. Later we also observed the patients’ outcomes; 30-days readmission and mortality. The independent variable in this study was the antibiotic usage in CAP patients and the dependent variables will be 30-days readmission and mortality. We excluded those with incomplete medical records, patients with other infections, and patients who had been discharged against medical advice (DAMA). Total sampling was used in this study. Antibiotic usage was evaluated using the Gyssens algorithm and on the clinical practice guideline of the ATS/IDSA 2019 as well as the local guideline from Perhimpunan Dokter Paru Indonesia (PDPI) 2014. The Gyssens algorithm is a qualitative measurement to assess antibiotic usage and has been widely used in worldwide studies. The Gyssens algorithm will show the rationality of antibiotic usage based on grouping of 0—VI categories. A chi-square test was used to identify the impact of appropriate antibiotic use on the 30-days readmission and mortality.

Result

We collected 90 patients’ medical records who fulfil the inclusion and exclusion criteria of the study. Patients characteristic is shown in Table 1. The majority of the patient was female (57.8%), aged 45—64 years old (50%), and with the length of stay for 4 days (37.8%). Ceftriaxone (56.7%) was the most prescribed antibiotic for CAP, followed by levofloxacin (28.9%), ceftazidime (7.8%), meropenem (3.3%), cefixime (1.1%), cefotaxime (1.1%), and azithromycin (1.1%). Evaluation of antibiotic usage using the Gyssens algorithm will be expressed as ‘appropriate’ and ‘inappropriate’ and is shown in Table 2. Antibiotic use in 77 prescriptions were considered as appropriate (85.6%) while in 13 prescriptions were inappropriate (14.4%), according to Gyssens algorithm. The most common type of error was category IIIB (shortened duration) (11.1%). One prescription (1.1%) was classified as category IVA (alternating agent is more effective) and two prescriptions (2.2%) were classified as category VI (incomplete medical record), one of them showed no data of the interval time and the other contained no data regarding the timing of the prescription. It is reported that 5 of 90 patients (5.6%) underwent the 30-days readmission (Table 3), in which 3 of them were more than 65 years old and 4 of 5 them had co-morbid diseases (Table 4). All five patients who underwent the 30-days readmission had already been given the appropriate antibiotic prescriptions in their initial treatment (p=0.894) (Table 5). No mortality is reported in this study (Table 6).

Discussion

Types of Antibiotic

According to the 2019 ATS/IDSA Guideline for adults with CAP, two regimens are strongly recommended for CAP therapy in an inpatient setting; monotherapy of levofloxacin and combination therapy of beta-lactam and macrolide. Alternative for adults with both macrolide and fluoroquinolone contraindications is the combination therapy of beta-lactam and doxycycline.

Monotherapy of levofloxacin was prescribed in 26 patients (29.3%). A systemic review from 16 randomized control study reported that monotherapy of levofloxacin significantly caused less clinical failure, withdrawal, and diarrhea compared to the combination therapy of beta-lactam and macrolide.

Monotherapy of beta-lactam was prescribed in 63 patients (70%) and is the most prescribed antibiotic regimen for adults with CAP. Aside from combination therapy, monotherapy of beta-lactam can also be considered as an alternative for inpatients with non-severe CAP. A randomized controlled trial in 580 patients reported that monotherapy of beta-lactam failed to show noninferiority to combination therapy of beta-lactam and macrolide in moderately severe community-acquired pneumonia.

Another randomized controlled trial study also reported that there is no difference in mortality, complication, and length of stay between monotherapy and combination therapy in CAP patients.

One patient (1.1%) was prescribed with macrolide azithromycin as their empirical CAP therapy. Macrolide monotherapy is an antibiotic option for adults with CAP in outpatient settings, and is not recommended in inpatient settings. Macrolide works effective intracellularly and covers pathogens such as Gram-positive bacteria, Legionella, Mycoplasma pneumoniae, and Chlamydia pneumoniae. However, macrolide monotherapy should be given based on the resistance level and that is based on studies of macrolide failures in patients with macrolide-resistant S. pneumoniae. The rate of macrolide resistance among Streptococcus pneumoniae isolates in the United States is reported for >30%, a high level of resistance.

Duration of Therapy

It is reported that 79 out of 90 prescriptions (87.8%) were given for no less than 5 days, while 11 prescriptions (12.2%) were given for <5 days. According to the guideline by ATS/IDSA 2019, the duration of therapy should be guided by clinical stability (resolution of vital sign abnormalities), ability to eat, and normal mentation. Antibiotics should be given until clinical improvement
is achieved and is strongly recommended to be given for no less than a total of 5 days. Recent data supported that administering antibiotics for less than 5 days is barely sufficient. As most patients will achieve clinical stability in the first 48—72 hours of therapy, the total duration of therapy for 5 days will be sufficient for most patients and 7 days for CAP due to suspected or proven MRSA or *Pseudomonas aeruginosa* \(^{11,21}\).

**Appropriate Antibiotic Use**

There were 77 prescriptions (85.6%) classified as Gyssens 0, which means that the antibiotic use is appropriate. The result also shows that 10 prescriptions (11.1%) were classified as Gyssens IIIB, which means that the total duration of antibiotic therapy is too short (less than 5 days). Gyssens IIIB is the most common error found in this study. Another type of error is Gyssens IVA, which is found in 1 prescription (1.1%). Gyssens IVA implies that the antibiotic prescription is not appropriate because other antibiotics are more effective. One prescription in this category received azithromycin monotherapy. Azithromycin, which is a macrolide class of antibiotics, should be used together with beta-lactam antibiotics in empirical therapy for CAP in non-ICU inpatients \(^{11,12}\). The combination of beta-lactam and macrolide antibiotic therapy is said to provide better results than monotherapy which associated with a reduction in mortality and / or a shorter length of stay compared to the monotherapy with beta-lactam \(^{22}\).

The use of antibiotics as empirical therapy for CAP in this study can be concluded to have a rate of 85.6% of appropriate antibiotic use and 14.4% in other categories (Gyssens I-VI).

**30-days Readmission**

Five patients (5.6%) underwent readmission with the same diagnosis within 30 days after the patient was discharged. Early hospital readmission is a common and costly occurrence in elderly and high-risk patients. To improve the quality of care and to reduce unnecessary health expense, policymakers have made reducing 30-days readmission as a priority \(^{23}\). The incidence of 30-days readmission is often found in patients with CAP \(^{24}\). Zillberg *et al* stated that the 30-days readmission rate would increase if patients received inappropriate empirical therapy \(^{8}\). However, all five patients who underwent the 30-days readmission in this study had received appropriate therapy (Gyssens 0) on their initial CAP treatment. The statistical test between the 30-days readmission and the appropriate antibiotic use with chi-square test method obtained \(p\)-value = 0.894 (\(p > 0.05\)), suggesting that the incidence of 30-days readmission is not influenced by the appropriate antibiotic use and it can be concluded that the appropriate antibiotic use in this study has no significant impact on the 30-days readmission.

Undergoing the 30-days readmission while receiving appropriate therapy in the patients’ initial infection can occur due to some considerations. Factors such as age, immunodeficiency, malignancy, heart failure, and chronic conditions can increase the proportion of pneumonia cases that fail to have complete resolution. In other words, readmission for pneumonia may occur due to unavoidable causes. Patients with COPD, heart failure, diabetes, and malignancy will increase the proportion of readmission for pneumonia cases \(^{25}\).

In this study, 3 patients who underwent readmission were> 65 years old. Old age is related to a decrease in the general condition of the functional organ so individuals are more at risk of developing pneumonia \(^{26}\). Meanwhile, 4 patients had medical conditions other than CAP itself, such as malignancy, COPD, and heart failure. Those are known factors that cannot be avoided in readmission of CAP cases \(^{25}\).

**Mortality**

No mortality was found in this study. According to the guideline by PDPI in 2014, the mortality rate of CAP in inpatient settings is 5—20% and it will greatly increase in intensive care unit by more than 50%. However, it is also stated that the prognosis for CAP is generally good depending on several factors such as patient factors, causative bacteria, and the use of appropriate antibiotics \(^{12}\). We could not assess the impact of the appropriate use of antibiotics on mortality rate as there is zero mortality in both appropriate and inappropriate antibiotic use in this study.

**Conclusion**

Appropriate antibiotic use in adults with CAP in inpatient non-ICU settings of Universitas Airlangga
Hospital is 85.6%. The most common error in antibiotic usage is shortened duration (Gyssens IVA). The 30-days readmission rate is 5.6% and the mortality rate is zero. There was no significant impact of appropriate antibiotic use on the 30-days readmission and the impact of appropriate antibiotic use on mortality rate could not be assessed as there was no death in this study.

Ethical Clearance: This original research study had been approved by the Universitas Airlangga hospital Surabaya ethical committee in health research (3594/UN3.9.1/PPd/2019).

Conflict of Interest: The authors declare that they have no conflict of interest.

Source of Funding: Self funding.

Assessment of Knowledge and Perceived Practice on Using Eco-Friendly Toys among Mothers of Under Five Children

Sharadha Ramesh1, M.Vatchala Devi2

1Director cum Professor, Symbiosis College of Nursing, Symbiosis College of Nursing, Symbiosis International University, Pune, Maharashtra, India, 2Vice principal cum Professor, HOD-Child Health Nursing, Indira College of Nursing, Pandur, Thiruvallur, Tamilnadu, India

Abstract

Introduction: Plastic is one of the most toxic substances in the world and there are several hazards of plastic usage. Plastic is a non-biodegradable product and do not decompose by biological actions of microbes. It takes about 1,000 years for plastic products to break down. They remain in the same state in the environment as we throw them whereas e-friendly are environmentally safe because the materials used to create the toys are natural, biodegradable and also recyclable.

Objectives of the Study: 1. To assess the level of knowledge on using eco-friendly toys among mothers of under five children. 2. To assess the perceived practice on using eco-friendly toys among mothers of under five children. 3. To determine the correlation between knowledge and perceived practice on using eco-friendly toys among mothers of under five children. 4. To find the association between socio-demographic variables and the level of knowledge and perceived practice on using eco-friendly toys among mothers of under five children.

Methodology: Survey study was conducted among 60 mothers with under five children at MK Pet, Tiruttani. Non probability convenience sampling technique was used to select the samples. Informed consent was obtained from all mothers, and made them be aware that information used only for research purpose. Structured interview schedule was conducted to elicit information from the participants.

Result: The inferences made are: Majority 40 (67%) had inadequate knowledge, 19 (31%) had moderate knowledge whereas least number 1 (2%) had adequate knowledge on using eco-friendly toys whereas 24 (40%) had fair perceived practice, 23 (38%) had poor perceived practice and only 13 (22%) had good perceived practice on using eco-friendly toys. There was a significant positive correlation between the mean score of knowledge 381 with S.D 6.35 and the mean score of perceived practice 724 with S.D 12. The calculated Karl Pearson’s coefficient of correlation r=0.07 was positively significant with low correlation at p < 0.05* level. there was significant association established with the type of family and mothers educational status at the level of P < 0.05* level. There was no statistically significant association found with the demographic variables of age of the mother, religion, education, number of children, occupation, monthly income with P < 0.05* level. The analysis revealed that there was significant association established with the religion and number of children variable at the level of P < 0.05* level. There was no statistically significant association found with the demographic variables of age, education, monthly income, type of family, number of children with P<0.05* level.

Key Words: Assessment, Knowledge, Perceived Practice, Eco-friendly toys, Mothers of Under Five Children

Introduction

Play is a child’s business and way of life. It is a legitimate right of childhood, representing a crucial aspect of children’s physical, intellectual and social development. All experts agree that children learn by playing and toys are the instruments that allow them to discover the world they live in. Ever since they are born,
toys motivate babies to use their feet and hands in order to discover forms, colours and sounds. Once babies know how to sit and crawl, toys incite them to be on the move. If their favourite toy is out of reach, the baby will use its muscles to try and grab it. Toys boost children’s creativity and they help them express their emotions (internal and external). Toys also motivate kids to take initiative, learn to negotiate and teaches them how to get better organized. Toys also promote children’s cognitive development by stimulating their concentration and memory skills (board games) and giving them the ability to solve problems creatively, which is key to their future autonomy (playing with building blocks). The Indian toy industry has shown tremendous growth and expansion potential in the domestic market that is estimated at about US $850 million and it generated 0.5 percent of the global market. Only 20% of the Indian market is served by Indian toy manufacturers while the rest is served by imported toys from different countries mainly from China and Italy.\(^\text{1,2,3}\)

We are living in a plastic planet. Plastics participate in human life from birth to death, and from waking to sleep, in objects of daily and specialised use alike. Plastic is a non-biodegradable product and do not decompose by biological actions of microbes. It takes about 1,000 years for plastic products to break down. They remain in the same state in the environment as we throw them. This, in turn, pollutes the land, sea and the atmosphere and one among them is plastic.

Here comes the question of safety. Toy safety is the practice of ensuring that toys, especially those made for children, are safe, usually through the application of set safety standards. In India also there is a move to make toys that meet global standards. But a large population lives in rural areas where toys which are sold are health hazard and injure the child in one way or the other. Choking is the number one reason for accidents, but chemicals such as lead can also cause developmental problems like behavioural disorders and sickness. Exposure to lead can affect almost every organ and system in the human body, especially the central nervous system. Lead is especially toxic to the brains of young children.\(^\text{2}\)

Indian markets are today flooded with Chinese toys which do not conform to any quality standards. Who and how should this be regulated? In many countries, commercial toys must be able to pass safety tests in order to be sold. It is time that we have a framework to protect the children and ensure that the toys available in the market are safe.

Eco-friendly products may seem to be more expensive, but long-term they are actually more cost efficient. Eco-friendly products tend to last much longer. These products are typically made from recycled materials and are sturdy, withstanding most drops, kicks, and dishwashers. Eco-friendly products may have a larger sticker price, but since they last longer, it is an investment that will pay off.

Plastics, for example, are known to have BPA, lead, and other harmful chemicals that can cause many different illnesses and diseases in both children and adults. For children, it can cause premature puberty, diabetes, stunted growth, and autoimmune disorders. Using eco-friendly products improves quality of life in terms of mortality, age, diseases, and illnesses. They ensure the safety of families and the planet.\(^\text{5}\)

Most of the children play with low-quality plastic toys which are highly dangerous. Plastic toys contain chemicals such as polyvinylchloride, phthalates, polystyrene, polyester and acrylic which are absorbed by the human body. They also alter hormone secretion. Hence, plastics are found to be highly carcinogenic and can be blamed for the growing incidence of childhood cancers as well as attention deficit hyperactivity disorder and learning disability. As health care providers, it is our prime responsibility to educate parents on the dangers associated with the use of plastic toys. So the researcher felt there is a need to conduct study on knowledge and perceived practice on using ecofriendly toys among mothers who is considered as primary care providers.\(^\text{7}\)

**Statement of the Problem**

“A descriptive study to assess the knowledge and perceived practice on using ecofriendly toys among mothers of under five children at MK Pet, Tiruttani”.

**Objectives of the Study**

- To assess the level of knowledge on using ecofriendly toys among mothers of under five children.
- To assess the perceived practice on using ecofriendly toys among mothers of under five children.
- To determine the correlation between knowledge and perceived practice on using ecofriendly toys among mothers of under five children.
To find the association between socio-demographic variables and the level of knowledge and perceived practice on using ecofriendly toys among mothers of under five children.

Null Hypotheses

- **NH₁**: There is no significant relationship between level of knowledge and perceived practice on using ecofriendly toys among mothers of under five children.

- **NH₂**: There is no significant association between socio-demographic variables and the levels of knowledge on using ecofriendly toys among mothers of under five children.

- **NH₃**: There is no significant association between socio-demographic variables and the levels of perceived practice on using ecofriendly toys among mothers of under five children.

Assumptions

- Mothers of under five children may have inadequate knowledge on importance of providing ecofriendly toys to their wards.
- Mothers of under five children may have poor perceived practice in buying ecofriendly toys in day to day life.
- Mothers of under five children may not have adequate understanding on impact of using plastics on the child as well as soil.
- Plastic toys impair child’s IQ level and it is a potent carcinogen.
- Indian parents and toy sellers have very less awareness about all types of toys and brands.
- It is difficult for the parents to differentiate among Indian and foreign toys for buyers.
- Money is not playing the major factor, choice of parent and child matters more. Many places, especially in rural areas, it is seriously difficult because they are not even aware of what is toxic and what is brand.
- Very less people were concerned about the toxics. Foreign Toy Industry is technology focused but toxics and attracts parents as well as children.

Delimitations

- The study was delimited to 1 weeks only.
- The study was delimited to under five mothers who were residing in MK Pet, Tiruttani.
- The study was delimited to under five mothers who are available at the time of data collection.
- The study focused only on perceived practice and the actual practice was not measured directly using observational check list in the mothers’ natural settings.

Projected Outcome

- This study will help the under five mothers to gain adequate knowledge and awareness on importance of ecofriendly toys.
- This study helps to alarm the mothers on ill-effects of buying plastic toys.
- This study help for the future reference for generating evidence based instructions on current scenario in using ecofriendly toys.
- This study may stimulate mothers converting from perceived practice into actual practice i.e., motivate them to go green (buying ecofriendly toys).
- Specific R&D for development of innovative and novelty toys and games will be set up to offer new green products as per fast changing needs/requirements of the domestic as well as export markets for toys.
- There will be a need to have a check over toxics available in toys.
- Advertisements will be telecasted to create awareness about toxics in toys and its ill effect.
- Strict laws will be formulated and executed if any toxic is found in toys.

Methodology

Research Approach

Quantitative research approach was adopted for this study to accomplish the objectives of the study.

Research Design

In this study, Non-experimental descriptive survey design was used.
Variables

Background Variables:
Mothers age in year, religion, type of family, monthly income in rupees, educational status of the mother, occupation of the mother, age of the child, number of child, number of plastic toys purchased in last one year, number of eco-friendly toys purchased in last one year, and how much spent for the toy.

Independent Variables:
The independent variable for the study was using eco-friendly toys

Dependent Variables:
The independent variables of the study were knowledge and perceived practice on eco-friendly toys.

SETTING OF THE STUDY
The investigator conducted the study in MK Pet urban area adopted by GRT College of Nursing, Tiruttani.

POPULATION OF THE STUDY

Target population
This is the population that the investigator had chosen to study and make generalization. The target population for the study was all the mothers with under five age children.

Accessible Population
The accessible population was all the mothers of under five age children who were living in in MK Pet, Tiruttani.

SAMPLE AND SAMPLE SIZE
In the present study, the mothers of under five aged who fulfilled the inclusive criteria were the samples.

SAMPLE SIZE
The sample size was 60.

CRITERIA FOR SAMPLE SELECTION

Inclusive criteria:
• The mothers who were willing to participate.
• The mothers who were residing in the selected urban area.

Exclusive criteria:
• The mothers who were not co-operative
• The mothers who were underwent educational programme on eco-friendly toys.

SAMPLING TECHNIQUES
Non probability convenience sampling technique was used to select the samples.

DEVELOPMENT AND DESCRIPTION OF THE TOOL
The instrument was developed and complied by the investigator with the guidance of experts and review of literature. The data collection questionnaire used in the present study had the following components:

Section A: Assessment of background variables
• Demographic variables of the mother: This included study participants age, religion, type of family, monthly income in rupees, educational status of the mother, and occupation of the mother.
• Demographic variable of the child: This included age of the child, and number of child
• Ecofriendly toys related factor variables: This included number of plastic toys purchased in last one year, number of eco-friendly toys purchased in last one year, and how much spent for the toy.

Section B: Structured Questions on Knowledge of Using Ecofriendly Toys

Section C: Structured Checklist on Perceived Practice of Using Ecofriendly Toys

CONTENT VALIDITY
Content validity of instrument was done by the panel of experts in the fields of Child Health Nursing, Nursing Research and Statistics. The experts’ suggestions were incorporated in designing the final tool for this study.

PILOT STUDY
Formal permission was obtained from the Head
of the Research Chairperson and Research Advisory Committee at GRT College of Nursing, Tiruttani. Individual permission was obtained from the mothers of under-five children. Pilot study was conducted in urban area at Tiruttani which was excluded from the main study. Brief introduction about the investigators and study was given. The confidentiality of the responses and the identity was assured. Pilot study was done on 6 samples. The pilot study aided the investigators to check the feasibility of conducting the main study in order to determine the statistical analysis and to assess the time required for data collection.

Reliability

Reliability of the tool was measured during pilot study using Karls Pearson coefficient of correlation’ test retest method for knowledge and inter rater method for perceived practice. The reliability r value were 0.78 for knowledge and 0.86 for practice. These values were very high thus making it a reliable tool for assessing the knowledge and perceived practice on ecofriendly toys among mothers of under five age children.

Data Collection Procedure:

A descriptive survey study was conducted among mothers of under-five children at MK Pet, Tiruttani after obtaining written permission from the head of the institution and Research Advisory Committee in GRT College of Nursing and Health Centre at MK Pet. The subjects were selected using convenience sampling technique. The data collection period was month. Data was collected from the mothers who were available in the time of study and accepted to participate in the study. Informed consent was obtained from all mothers, and made them be aware that information used only for research purpose. Structured interview schedule was conducted to elicit information from the participants. Explained the study participant’s rights to withdraw or withhold the information. Participants are provided with investigators contact information.

Data Analysis and Interpretation

Demographic Data

I. Frequency and percentage distribution of demographic of mothers of under five children

- With respect to the age of 27 (45%) were in the age group of 21-25 years, 26 (33%) were in the age group of 26-30 Years, 7 (12) were in the age group of 18-20 years and rest 6 (10%) were in the age group of 31 Years and above.

- In related to the religion dominantly 46 (77%) were Hindu, 10 (17%) were Muslim, 4 (6%) were Christians and none of them belonged to other community.

- In accordance with the educational status, secondary school education 20 (33%), primary education 17 (28%), graduate 14 (23%) and illiterate 9 (16%).

- In concern with occupational data most of them were home maker 40 (67%), 9 (15%) were private employee, 6 (10%) were daily wages and rest 5 (8%) were Government employee.

- Regarding the monthly income 22 (37%) were between 10001-15000, 6(27%) were getting below Rs.5000; 14 (23%) were Rs.50001-10,000; 8 (13%) were getting monthly income of above Rs.15000.

In related to type of family 35 (58%) were lives in nuclear family and rest 22 (37%) were belongs to joint family and only 3(5%) of the samples lives in an extended family.

In related to number of the children 27 (45%) were having one child, 24 (40) were having two children, 06 (10%) were having 3 children and 3 (5%) were having more than 4 children at home.

II. Frequency and percentage distribution of demographic of under five children

No=60

frequency percentage distribution of demographic and clinical variables of under five children. With regard to age of the child, majority of them 25(42%) belong to 1-2 years; 17(28%) are between 3-4 years; 12(20%) of them are above 5 years and 6(10%) are infants.

With regard to number of toys purchased in last one year, 21(34%) of the parents purchased only one toy of their wards; 19(32%) of them purchased 3 toys; 10(17%) of the parent purchased 4 toys and only 10(17%) of them purchased 5 and above toys for their children.

In concerned with the number of ecofriendly toys purchased in last one year, 25(42%) of them purchased 2 toys; 19(32%) were purchased 3 toys; 7 (11%) were purchased 4 toys; and only 9 (15%) were purchased 5 and above toys for their children.
In accordance with the amount spent on toys, majority of the parents 22(36%) were spend Rs.50-100; 14(23%) were spend between 10-50 rupees; 15(25%) were spend between 100-300 rupees and only 8(13%) spend Rs.300 and above.

III. Frequency and percentage distribution of Mothers of under five children based on their level of knowledge on using ecofriendly toys

The above figure 1 illustrates level of knowledge on using ecofriendly toys among mothers of under-five children.

The mothers of underfive children distributed as majority 40 (67%) had inadequate knowledge, 19 (31%) had moderate knowledge whereas least number 1 (2%) had adequate knowledge on using on ecofriendly toys.

IV. Frequency and percentage distribution of Mothers of under five children based on their level of perceived practice on using ecofriendly toys
The inferences made are, the mothers of under five children distributed as 24 (40%) had fair perceived practice, 23 (38%) had poor perceived practice and only 13 (22%) had good perceived practice on using ecofriendly toys.

V. Distribution of mothers based on their correlation between level of knowledge and perceived practice on using ecofriendly toys

<table>
<thead>
<tr>
<th>Variables</th>
<th>Mean</th>
<th>Standard Deviation</th>
<th>r-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Knowledge</td>
<td>381</td>
<td>6.35</td>
<td>r=0.07</td>
</tr>
<tr>
<td>Perceived Practice</td>
<td>724</td>
<td>12</td>
<td>p = 0.05</td>
</tr>
</tbody>
</table>

Significant at p<0.05*

The inferences made are

There was a significant positive correlation between the mean score of knowledge 381 with S.D 6.35 and the mean score of perceived practice 724 with S.D 12. The calculated Karl Pearson’s coefficient of correlation r=0.07 was positively significant with low correlation at p < 0.05* level.

VI. Distribution of mothers based on their association between socio-demographic variables and the level of knowledge on using ecofriendly toys

Association of level of knowledge regarding importance of play needs among parents of under five children with their selected demographic variables.

The analysis revealed that there was significant association established with the type of family and mothers educational status at the level of P < 0.05* level. There was no statistically significant association found with the demographic variables of age of the mother, religion, education, number of children, occupation, monthly income with P < 0.05 *level.
VII. Distribution of mothers based on their association between socio-demographic variables and the level of perceived practice on using eco-friendly toys

Depicts association between the levels of perceived practice regarding importance

Of using eco-friendly toys among mothers of under five children with their selected demographic variables.

The analysis revealed that there was significant association established with the religion and number of children variable at the level of P < 0.05* level. There was no statistically significant association found with the demographic variables of age, education, monthly income, type of family, number of children with P<0.05* level.

Conclusion

Play and childhood is inseparable. Play is any child’s business and it is their way of life which brings comprehensive development. Age-specific toys are used to comfort the child from the time of birth. Most of the children play with low-quality plastic toys which are highly dangerous. Young infants with too thin stage bite and suck on a lead-painted toy put them at risk of lead poisoning. Plastic toys contain chemicals such as polyvinylchloride, phthalates, polystyrene, polyester and acrylic are absorbed by human bodies and also alter hormones secretion. Hence, plastics are found to be highly carcinogen and it is evident that growing incidence of childhood cancers as well as attention deficit hyperactivity disorder and learning disability. As health care providers, it is our prime responsibility to educate parents on dangers associated with the usage of plastic toys. Eco friendly toys are environmentally safe because the materials used to create the toys are natural, biodegradable and also recyclable. We should create an awareness and make sure that every toy used by the children are eco-friendly, chemical free and safe.

Implications

The findings of the study has implications in different branches of nursing profession, i.e. nursing practice, nursing service, nursing education, nursing administration and nursing research.

Nursing practice

- The nurse role is to select the play materials according to age group of children with safety measures.
- The nurse practitioners can utilize ecofriendly play therapy to assist children in enhancing intellectual development and problem solving skills.
- The nurse can educate the children as well as their family regarding hazards of using plastic toys and its later effect on the child.

Nursing education

- Conference, workshops and seminars can be held for nurses to impart update their knowledge and positive practice towards using ecofriendly play articles.
- Nursing educator to update their knowledge and skills of providing ecofriendly play needs in various healthcare settings such as pediatric ward, ICDS and Centres should be given.

Nursing administration

- Nursing personal should be prepared to take a leadership role in educating parents regarding importance of play needs as well as ecofriendly toys. They should include their interest in educating parents during disseminate information about importance of play needs.
- The administrator can encourage the nurse for conducting research in various aspects regarding importance of ecofriendly toys
- The administrator can organize conference, workshop and seminar for nurses working in the pediatric ward
- The administrator should support the staff to conduct programmes on importance of ecofriendly toys.

Nursing research

- There should be more scope for research in this area to improve parents knowledge on importance of ecofriendly play needs. There is a need for extensive research regarding education techniques in order to improve the parents knowledge and in turn help bringing in positive and good practice regarding importance of using ecofriendly toys among mothers of under five children.
- The study will be useful for further reference.
- The results of the study encourage the parents to select suitable play materials according to age group of the children.
Encourage the nurses for conducting research in various aspects regarding importance of ecofriendly toys.

**Recommendations**

The study recommends the following

- A similar study may be conducted with large number of sample in different settings
- A comparative study can be conducted between rural and urban parents.
- A true experimental study with experimental and control group can be conducted.
- A similar study can be conducted through video teaching.
- A similar study can conducted to assess practice on important of ecofriendly toys in their daily life.

**Limitations**

The study has the following limitations

- Sample taken was only 60 mothers of under five children.
- Study was limited to assess the knowledge and perceived practice regarding importance of ecofriendly toys need among mothers of under five children.
- Duration of data collection was 1 week.
- The study assessed only parents of under five children.

**Conflict of Interest** – Nil

**Source of Funding** - Authors have no financial support to this project. The study was fully funded by authors.

**Ethical Clearance** – Ethical approval of the study taken from Symbiosis College of nursing ethical committee. Informed consent was taken from the participants. Informed the responders regarding the data collection procedure. The collected data was used only for research purpose and kept confidential.

Canine-premolar Transposition, Family Pedigree and Related Dental Anomalies

Mushriq Abid1, Samher A. Al-Shaham2, Zaynab MR. Al-Chalabi3
1Assistant Professor at the Department of Orthodontics/College of Dentistry/University of Baghdad, 2Lecturer at the Department of Orthodontics/College of Dentistry/University of Baghdad, 3Orthodontists Specialist at the Ministry of Health-Iraq

Abstract

Maxillary canine-premolar transposition is a rare and complicated dental anomaly that needs special consideration by the orthodontist. The aim of the present study was to investigate the clinical features of maxillary canine-premolar transposition and report the family pedigree to determine the mode of inheritance. A cross-sectional study was performed on 39 patients having maxillary canine-premolar transposition in which both clinical and radiographic examination were performed. Moreover, 112 family members were clinically examined looking for canine transposition. Variables such as location, sex and the presence of hypodontia and peg-shaped lateral incisors were investigated. The study found that unilateral transposition (89.7%) was more common than bilateral occurrence (10.2%) affecting the left side (64.1%) more than the right side (35.9%). Females were affected more than males (74.4% and 25.6% respectively). Congenitally missing teeth were reported in 12.8% and lower second premolar was the most commonly missing tooth. Peg-shaped maxillary lateral incisor was reported in 7.7% of the sample. Family pedigree confirmed the presence of a history of transposition or ectopically positioned canine in 15.3% of the sample suggesting an autosomal dominant inheritance of the trait. In conclusion this study suggested an association between genetic factors and maxillary canine-premolar transposition. Further studies are required using genetic testing to confirm the findings of the present study.

Keywords: Canine, Transposition, genetic, dental anomaly, peg-shaped, hypodontia

Introduction

Transposition of teeth is a rare condition which has a serious impact on the occlusion and is defined as a positional interchange between two adjacent teeth. Previously research provided important information on the prevalence of this anomaly which varies depending on the population featuring very low incidence (0.2-0.5%) 2-5.

Gender differences have been reported in different studies and are still unclear. Some research reported no gender difference 6, while others reported female predominance over males 4, though conversely some studies reported more affected males than females 7. Transposition is more frequently observed in the maxilla than the mandible 8, moreover canine-premolar transposition is the most frequent type 4, and unilateral presentation is more frequent than bilateral 9.

To date several theories have been proposed to be the causative factor of transposition such as trauma 10, early loss of teeth 11, positional interchange of the developing tooth bud 12, space deficiency 13 and genetic factors 3,4,10. Genetic aetiology has been confirmed by unilateral left-sided occurrence 1, hypodontia 7,11, retained deciduous teeth 11, peg-shaped lateral incisor 1. For these reasons genetic factors have been suggested to be the fundamental aetiology of dental transposition 1.
To our knowledge there have been few studies which reported various types of transposition and the associated dental anomalies beside reporting family pedigree looking for a family history of this dental anomaly. The aim of the present study was to investigate the clinical features of maxillary canine-premolar transposition and report the family pedigree to determine the mode of inheritance.

**Methods**

A total of 39 patients demonstrating maxillary canine and premolar transposition consisted of 10 males and 29 females (Table 1) with age range of 13-18 years at the time of diagnosis (mean age 13.7 years). No history of craniofacial anomalies or trauma was noted for all the participants. 112 family members were clinically examined looking for canine transposition and ectopic tooth position. The study population were collected from several private clinics in Baghdad city and the Orthodontic Department at the College of Dentistry/Baghdad University. The study was approved by a local committee in the Orthodontic Department at the College of Dentistry (Baghdad University).

The study focused on patients with maxillary canine-premolar transposition (unilateral or bilateral) who have not received any orthodontic treatment. The patients were clinically and radiographically examined using panoramic dental radiograph.

The following variables were reported:

1) The location of transposition, bilateral or unilateral.

2) Age at diagnosis.

3) The presence of missing teeth (hypodontia).

4) The presence of diminutive (peg-shaped) lateral incisor.

5) Family pedigree was recorded for each patients looking for a family history of transposition of teeth or ectopically erupted maxillary tooth.

Panoramic dental radiographs were available for all the patients at the time of diagnosis. They were used to confirm the presence of canine-premolar transposition, missing teeth excluding the third molar and peg-shaped lateral incisor. A lateral incisor was considered peg-shaped when the mesiodistal width at the cervical region was greater than the incisal edge. Descriptive statistics were used to define the characteristics of the study variables through the form of counts and percentages.

**Results**

A total of 39 patients with maxillary canine-premolar transposition (Figure 1) was examined both clinically and radiographically looking for the location and side of transposition and the presence of hypodontia or diminutive maxillary lateral incisor. The results revealed that unilateral transposition (n=35, 89.7%) was by far more common than bilateral transposition (n=4, 10.2%). In unilateral transposition left-sided occurrence (n=25, 64.1%) was more prevalent than right-sided (n=14, 35.9%). Unilateral occurrence was more common in females (n=25, 71.4%) than males (n=10, 28.6%). Similarly, left side occurrence was more common in females (n=17, 68%). Five of the 39 patients had congenitally missing teeth (12.8%) excluding the third molar. The lower second premolar was most frequently missing (three cases) followed by the maxillary lateral incisor. Peg-shaped maxillary lateral incisor was observed in three cases (7.7%), in some instances reduced sized lateral incisors were not recorded, since these small-sized teeth were not severe to fit the definition of peg-shaped teeth.

The family pedigree was also reported for other family members and first and second generation of the proband. The results revealed a family history of transposition or ectopically positioned maxillary canine was found in six families (15.3%). Two confirmed a similar condition in siblings while the other four mentioned an ectopically positioned tooth in a family member (Figure 2).

**Figure 1:** Intraoral photograph and panoramic radiograph showing transposition A) 12-year-old female with transposition in the maxillary left canine-premolar (encircled and arrowed). B) 16-year-old female with transposition in the maxillary left canine-premolar (encircled and arrowed).
Discussion

The present study focused on 39 patients with maxillary canine-premolar transposition who were clinically and radiographically examined. Previous studies reported that transposition most commonly occurred in the maxilla and canine-premolar teeth are most commonly involved [1,3,7,11]. Unilateral transposition was found to be more common than bilateral transposition which agree with other studies [1,3,8,11]. In bilateral cases, the same teeth were affected by the transposition which agrees with Al-Shawaf [8,15]. Left-sided occurrence was 64.1% which was comparable to what was reported by Peck et al [1].

Females were affected more by transposition when compared to males which was reported by most previous studies [1,8]. This phenomenon is not explained however, some reports of other anomalies such as cleft lip and palate found a left-side occurrence to be more common than right-side [16] and is dependent on the diagnostic procedure used. In this study we determined the prevalence of associated anomalies in patients with a cleft lip and/or palate, with a specific focus on cardiac anomalies. Materials and Methods: In this cross-sectional study, 526 patients with a cleft lip and/or palate admitted to the children’s referral hospital between 2006 and 2011 were evaluated. All associated anomalies were detected and recorded. Patient information collected included age, gender, type and side of cleft, craniofacial anomalies and presence of other anomalies, including cardiac anomalies. Data were analyzed using SPSS version 16. Results: Of the 526 patients enrolled in the study, 58% (305) Previous studies suggested the occurrence of maxillary canine-premolar transposition in girls more than boys [17]. Nevertheless, research has reported that most orthodontic practice patients are females [18]. For this reason, higher prevalence of females with transposition cannot be accounted for in comparison to males.

Figure 2: Family pedigree of a patients showing other affected family members. Empty circle=female, empty square=male, filled circle=affected female and arrow=proband.
The prevalence of hypodontia excluding the third molar is 12.8% and in the present study was twice as common as in the general population. Similarly, peg-shaped lateral prevalence was 7.7% twice as common as in patients with no teeth transposition. Most of previous studies reported higher prevalence of dental anomalies including hypodontia and peg-shaped maxillary lateral incisors when compared to the figures found in the present study which could be attributed to the sample size and ethnicity.

Interestingly, the present study reported the family pedigree for each patient, 15.3% confirmed the presence of ectopically positioned tooth or transposition. This finding could support the genetic aetiology of transposition together with the presence of dental anomalies. The pedigree suggested an autosomal dominant inheritance of the trait. Ely et al. reported that transposition is caused by both genetic and environmental factors based on the findings of their study. They supported their point by the fact that there was no previous study which reported a mutation in patients with transposition. Moreover, transposition may arise from developmental disturbances in the developing tooth dental follicle or genes that are involved in the development of dentition.

The limitations of the present study include no inferential statistics being performed due to the sample size. One of the strongest points in the present study is that the study focused on one type of transposition rather than different types of this anomaly which was seldom in previous studies.

Conclusions

The result of the present study suggested that genetics might play a role in the aetiology of maxillary canine-premolar transposition. This finding could be helpful to clinicians and can be supported by the utilization of recent technology including next-generation sequencing. Further large-scale studies are needed including larger sample and different types of transposition.

Source(s) of support: The study was self-funded.

Conflicting Interest: The authors declare no conflict of interest.

This study was approved by a local ethics committee in the Department of Orthodontics, College of Dentistry, University of Baghdad.

Abstract

The aim of this study was to verify the phagocytosis activity which displayed in CD11b and B220 markers and also the markers of erythroid 2 nuclear factor related factor 2 (Nrf2) as a key regulatory transcription factor on various antioxidant gene expressions and Superoxide dismutase (SOD) as an antioxidant marker that related with protein. Nrf2 plays an important role to inhibit the ROS accumulation and eliminate free radicals. The active compound of chlorogenic acid in robusta coffee type (Coffea canephora) in Indonesian Coffee and Cocoa Research Center was used in three groups of mice in this study and it was gave different dose in each groups. The assessment samples were taken from the peritoneal fluid of mice than it was analyzed by using Flow Cytometry method to find phagocytosis function and antioxidant activity. The results of ANOVA statistical test was p <0.05 in all parameters, this mean that there was indicated that the active compound of chlorogenic acid in coffee was involved in natural immune system mechanism and it was seen in increasing of phagocytic activity and antioxidant levels.

Keywords: Coffea Canephora, chlorogenic acid, phagocytosis, antioxidant

Introduction

The natural immune system is a non-specific defence mechanism and quickly responds to antigen exposure in the body. The natural immune response is main weapon in host use to prevent or reduce pathogen replication in early stages of infection (1). The natural immune system as first body defence against infection (non-self) or tissue injury (damaged-self) with involves many cell and molecular components. Antibodies and complement was plays in Identification molecule solvent and cellular components plays in phagocytic cells (macrophages), antigen presenting cells (dendrite cells) and killer cells (NK cells). Another addition molecular is T and B lymphocyte cells who involve in natural immunity (2).

Phagocytosis process is one of an important aspect in natural immune response because it plays a role to inhibit an adaptive immune response (3), a highly-conserved mechanism occurs in first increasing before the development of other multicellular (4), the efficiency processes is eliminates pathogens attack and help in homeostasis repair process (5).

Macrophages and neutrophils are one of the key regulators in inflammatory process because it can produce reactive oxygen species (ROS) as a defence system to clean the microorganism components. ROS has two different ways. First, in high level as a as effector molecules against intracellular pathogens and second, in low level as a signalling messengers to inflammatory expression (6). The role of B lymphocytes as phagocytic cells is to produces ROS, and it happen

because of the results of mitochondrial respiration due to high production of immunoglobulin or activation of NADPH oxidase complex (NOS)\(^7\).

The popularity of coffee drinks related with health effects and it was done in many studies on coffee and this provided some evidence such as coffee was reduced risk of cancer, improved neurological conditions, body metabolism and liver\(^8\). The phenolic compounds in coffee produced secondary metabolism which it have sentinel activity against free radicals and a role as antioxidants in body. The main phenolic compounds are phenolic acids, flavonoids and tannins. The phenolic acid family are include hydroxynamide and chlorogenic acids\(^9\). Based on this case, the researchers will assessed the phagocytosis activity by the description of CD11b and B220 also markers of nuclear factor erythroid 2 related factor 2 (Nrf2) as key transcription factor on various antioxidant gene expressions and Superoxide dismutase (SOD) as an antioxidant marker that was closely related with Nrf2 protein and it plays an important role to inhibit the accumulation of ROS and eliminating free radicals.

**Selection of coffee beans**

Four types of coffee beans were taken from several cities in East Java, Indonesia. Two types of arabica (Coffee arabica) and robusta (Coffee canephora) coffee beans were taken from one of the coffee bean suppliers on the Ijen Mount, and one of types of robusta coffee beans was taken from coffee plantations in Jember and one type of robusta coffee bean was from coffee planter in Sumber Asin Malang area.

**Measurement of chlorogenic acid levels**

The HPLC-LC-MS / MS test used to measured the levels of chlorogenic acid and it was applied on four different types of coffee beans, and the highest concentration of chlorogenic acid used in research process. Analyzes process used Thermo Surveyor HPLC LC-MS / MS system. A 2ul sample injected into LC at 16 °C, the column controlled at 30 °C, and the autosampler compartment was set in 16 °C. Columns used are Hypersil Gold specifications (50mm x 2.1mm x 1.9µm). UHPLC brand of ACCELLA type 1250 made by Thermo Scientific which consists of a vacuum degasser, quartener pump, thermostatic autosampler controlled by Personal computer through the x-calibur 2.1 program. Solvent A = 0.1% formic acid in Water and B = 0.1% formic acid in Acetonitrile. A mobile phase gradient with a speed of 300 µl / minute at a setting of 0.0-0.6.00 minutes 5% B, 0.6-3.0 minutes 75% B, 3.0-3.5 minutes 75% B, 4.0-5.5 minutes 5% B. The quantification compared with chlorogenic acid standard at 325nm of wavelength with ranged of 5-750 ng.

**Flow Cytometry analysis**

**Experimental animals**

The research subjects were male BALB / c mice aged 10-12 weeks with an average weight 20-25 grams, white skin color, active conditions and normal behavior, no visible anatomic. 24 mice were selected by using random method than they were divided into 4 groups and 6 mice in each group. Namely each group were: group 1 (healthy mice without coffee intervention), group 2 with coffee intervention per sonde of 0.5g / kgBW / day, group 3 with coffee intervention per sonde of 1.5g / kgBW / day and group 4 with coffee intervention per sonde of 2.5g / kgBW / day. The coffee intervention with different doses were carried out for 14 days, then the peritoneal fluid was taken in all mice and than it analyzed by using the Flow Cytometry method of phagocytosis function and antioxidant levels.

**Macrophages Isolation process**

The mice were dislocated on the neck, put on a sterile surgical board. The all part of mice body soaked with 70% EtOH and gave sterile injection of 10 ml PBS in an intraperitoneal. The ventral part (stomach) was tapped, then slowly taken peritoneal fluid by using a syringe and than the peritoneal fluid was put in a sterile 15ml propylene tube, than it centrifuged at 2500 rpm for 5 minutes at 10°C. The pellets were resuspended on 3 ml RPMI completed and homogenized, so in the final got macrophages.

**E. coli bacterial coloring and phagocytosis**

The 10\(^8\) cells / ml E. coli culture on sterile PZ media was transferred to a sterile 15ml propylene tube as much as 10ml than it was centrifugated 8000 rpm for 5 second at 4°C, than the supernatant was discarded, the pellets were resuspended with 0.5 ml sterile PBS and homogenized. The suspension heated on 80°C for 5 minutes. At normal temperature, the suspension add
5μl coloring solvent of carboxyfluorescein succinimydil ester (CFSE). Incubation process was did for 20 minutes at 4°C in the dark room. The stained bacterial suspension added to the macrophage cells that had been prepared before, than put in a 30mm petri dish, and cultured macrophage cells at 37°C CO₂ 5%.

**Flow Cytometry interpretation**

Macrophage cell culture carried out for 4 hours, than the suspension transferred to 15 ml propylene tube (avoided from direct exposure to light). After that, it was centrifuged in 2500 rpm for 5 second at 10°C. The supernatant removed, the pellets resuspended with 50μl working solution of specific antibodies (PE conjugated anti-CD11b, anti-B220, anti-superoxide dismustase (SOD) 1 antibody EP1727Y, and anti-Nrf2 antibody ab89443). Incubation process at 4°C for 20 minutes in dark room, then added 0.5 ml of PBS and homogenized. Then the suspension transferred to the FCM cuvette (polystyrene tube 12x75 mm) and read on a Flow Cytometry tool.

**Data Analysis**

Data analyzed by using SPSS with version 17 and the sample analyzed by using ANOVA and the significance data were continued test with Tukey’s test.

**Results and Discussion**

Note: * significant at α = 0.05, the ab superscript showed that there was no differences in each groups (ANOVA). n = number of samples, SOD = Superoxide dismutase, NRF2 = nuclear factor erythroid 2 – related factor 2, N = mice without treatment, T1 = mice with treatment 1 (0.5 mg coffee powder), T2 = mice with treatment 2 (1.5 mg coffee powder), T3 = mice with treatment 3 (2.5 mg of coffee powder).
The results of this study showed that there were significant differences in the amount (%) of CD11b, B220, SOD, NRF2 with ANOVA test. In T1 group (mice with treatment 1 (0.5 mg of coffee powder), the percentage of CD11b was higher than normal group. T2 and T3 groups were significantly different from the normal group. The highest percentage of B220 was in T3 group of mice with treatment 3 (2.5 mg of coffee powder). The highest percentage of SOD was in T1 group and the highest percentage of NRF2 was in T3 group and Tukey’s test results found that there were significant different of each groups with normal group.

Nuclear factor-Erythroid-related factor 2 (Nrf2) is a transcription of the basic leucine zipper redox-sensitive factor, namely pleiotropic proteins of regulate basal and induce basal expression of antioxidants and various other genes related to cell protection through binding of sequence enhancers (enhancers) and known as elements response of antioxidants. In normal condition, the Nrf2 level will be at low level but in stressful conditions such as oxidative stimuli, the Nrf2 will increases the transcription activation in targets that undergo protective conversion against various stress-inducing environments (10).

There was no differences of the Nrf2 level in each group, it mean that there was no environmental stress, but the active compound of Chlorogenic acid gave a different responses in each intervention group and described a response toward antioxidant function of Chlorogenic acid in coffee.

In this study, different doses were gave in each group of mice. There were differences of SOD enzyme in normal group and intervention group, there was higher antioxidant activity in low dose group compared with other groups. SOD as an endogenous antioxidant enzyme is a protein that acts as a first line of defense against ROS which clean superoxide radicals. The formation of ROS can find in a removing the potential of oxidants to become relatively stable compounds (11).

Figure 3. Phagocytosis by using Flow Cytometry method a). Untreated mice expressed that CD11b and B220 b molecules). Mice with treatment 1 (0.5 mg of coffee powder) express CD11b and B220 c molecules). Mice with treatment 2 (1.5 mg of coffee powder) expressed CD11b and B220 d molecules). Mice with treatment 2 (2.5 mg of coffee powder) expressed CD11b and B220 molecules.
CD11b is an integrin component that mediates monocytes, macrophages and granular cells to attach by using iC3b Opsonization which leads to phagocytosis, neutrophil aggregation and Chemotaxis. The expression of markers is related with T cell activation. Chlorogenic acid compounds as part of polyphenols which are present in large concentrations in coffee beans and it was proved in various clinical studies to reduce the risk of various diseases (12). In this study, the increasing of CD11b expressed that medium doses and high doses can be seen as a response to active compounds, especially Chlorogenic acid in coffee.

B220 is a CD45 isoform and it expressed in all mice B lymphocyte cells and as a subset of B lymphocyte cells in human, as a protein tyrosine kinase with various isoforms that regulate activation through a range of T and B lymphocyte cell surface receptors, as well as at cytokine receptors. CD45 known as B220, Ly-5 and T200, this mean that it is a member of the tyrosine phosphatase (PTP) protein family with a molecular weight of 220kDa. The PTP family has a function as a signaling molecule in regulatory process on cell differentiation, cell division and development. CD45R is the most common form of protein and it obtained by excess glycosylation when it expressed on B lymphocytes. NK cells (BioRad). In general, this study found that in intervention group (medium and high doses) were significantly different with normal group. Active compounds, especially Chlorogenic acid in coffee, are able to induce the activity of B lymphocytes as part of the natural immune system related with the ability of cells to internalize the phagocytosis process (13).

**Conclusion**

This study proved that the active compound of Chlorogenic Acid in Robusta coffee beans (Coffea canephora) which taken from Sumber Asin Malang area was the higher levels and it gave an effect in every component of natural immune system including phagocytosis mechanisms. The increasing levels of antioxidant was related to the neutralization mechanism of reactive oxygen species (ROS).

Call for Papers / Article Submission

Indian Journal of Forensic Medicine & Toxicology has commenced publication since 2007. IJFMT will be published twice a year.

**Purpose & Scope:** Indian Journal of Forensic Medicine & Toxicology is a peer reviewed six monthly Journal. It deals with Forensic Medicine, Forensic Science, Toxicology, DNA fingerprinting, sexual medicine and environmental medicine. It has been assigned International standard serial No. p-0973-9122 and e-0973-9130 **website:** [www.ijfmt.com](http://www.ijfmt.com). This journal is also indexed with Index Copernicus (Poland).

The journal encourages research from theoretical perspectives, research reports of evidence based practice as well as praxis research work that focuses on the interface between theory and practice and how each can support the other. In addition, the journal strongly encourages reports of research carried out within or involving countries in the Asia-Pacific region.

**Invitation to submit papers:**
A general invitation is extended to authors to submit journal papers for publication in IJFMT.

**The following guidelines should be noted:**
1. The article must be send by E-mail in word only as attachment. Hard copy need not be send.
2. The article should be accompanied by a declaration from all authors that it is an original work and has not been sent to any other journal for publication.
3. References should be in Vancouver style.
4. As a policy matter, journal encourages articles regarding new concepts and new information.

**Please submit paper in following format as far as applicable**
1. Title
2. Names of authors
3. Your Affiliation (designations with college address), email id
4. Corresponding author- name, designations, address, email id
5. Abstract with key words
6. Introduction or background
7. Material and Methods
8. Findings
9. Discussion / Conclusion
10. Conflict of Interest
11. Source of Support
12. Ethical Clearance
13. References in Vancouver style.
14. Word limit 2500-3000 words, MSWORD Format, single file
